any house near the spot, which occasioned a great
loss of time in going and coming; but when a man
should live upon the spot, then he could be ready to
seize every opportunity. 2. The moss was an unces-
taneous waste. To let it to tenants would increase the popu-
lation of the estate, and afford to a number of indus-
trious people the means of making to themselves a
comfortable livelihood.

In the mean time it was determined, till as many
tenants should be got as could occupy the whole wa-
ter, to carry on the work by means of undertakers.
But before proceeding farther, it will be necessary to
describe the manner of applying water to the purpose
of floating the moss.

A stream of water sufficient to turn a common corn-
mill will carry off as much moss as 20 men can throw
into it, provided they be stationed at the distance of
100 yards from each other. The first step is to make
in the clay, along-side of the moss, a drain to convey
the water; and for this operation the carse-clay below
the moss is peculiarly favourable, being perfectly free
from stones and all other extraneous substances, and at
the same time, when moil, slippery as soap; so that not
only is it easily dug, but its lubricity greatly facilitates
the progress of the water when loaded with moss.
The dimensions proper for the drain are found to be
two feet for the breadth, and the same for the depth.
If smaller, it could not conveniently receive the spade-
fuls of moss; if larger, the water would escape, lea-
ving the moss behind. The drain has an inclination
of one foot in 100 yards; the more regularly this in-
nclination is observed throughout, the less will the moss
be liable to obstructions in its progress with the water.
The drain being formed, the operator marks off to a
convenient extent, along-side of it a portion of moss
to feet broad; the greatest distance from which he
may heave his spadeful into the drain. This be-
repeatedly does till the entire moss be removed down to
the clay. He then digs a new drain at the foot of
the
As before, leaving the mofs-bank, turns the water into it, and proceeds as before, leaving the mofs to pursue its course into the river Forth, a receptacle equally convenient and capacious; upon the fortunate situation of which, happily forming for several miles the southern boundary of the estate, without the interposition of any neighbouring proprietor, depended the very existence of the whole operations. When the mofs is entirely removed, the clay is found to be encompassed with the roots of different kinds of trees standing in it as they grew, often very large; their trunks also are frequently found lying beside them. All these the tenants remove often with great labour. In the course of their operations they over, when the dryness admits, with a plough, and, where too soft, with a spade. A month's exposure to the sun, or an inch of rain, is sufficient to turn the crop of oats and pulse into powder fitting it for the feed in March and April. A crop of oats separated at first, with the crop of pulse, which often falls of being plentiful, yielding from eight to ten bolls after one.

In the year 1769 an agreement was made with one tenant for a portion of the Low Mofs. This, as being the first step towards the intended plan, was viewed as a considerable acquisition. The same terms agreed upon with this tenant have ever since been observed with all the rest. They are as follow:

The tenant holds eight acres of mofs by a tack of 38 years; he is allowed a proper quantity of timber, and two bolls of oatmeal to support him while employed in rearing a house; the first seven years he pays no rent; the eighth year he pays one merk Scots; the ninth year two merks; and so on with the addition of one merk yearly till the end of the first 19 years; during the last five years of which he also pays a hen yearly. Upon the commencement of the second 19 years, he begins to pay a yearly rent of 12s. for each acre of land cleared from mofs, and 2s. 6d. for each acre not cleared, also two hens yearly; a low rent indeed for so fine a soil; but no more than a proper reward for his laborious exertions in acquiring it.

In the year 1768 another tenant was settled. These two were tradesmen; to whom the preference was always given, as having this great advantage to recommend them, that even when deprived of water they need never want employment. The motives that induced these people to become settlers were, 1st, the prospect of an independent establishment for a number of years. 2dly, The mofs afforded them a great abundance of excellent fuel; to which was added the comfortable consideration, that, whilst busied in providing that necessary article, they had the double advantage of promoting, at the same time, the principal object of their settlement.

Notwithstanding these inducements, still settlers offered slowly; to which two circumstances chiefly contributed; 1st, The whole farmers surrounding the mofs threw every possible obstruction in their way. 2dly, By people of all denominations the scheme was viewed as a chimærical project, and became a common topic of ridicule. The plan however supported itself; and in the year 1769 five more tenants agreed for eight acres each; and thus 56 acres of Low Mofs were disposed of. From the progress made by the first settlers, and the addition of thefe, the obloquy of becoming a mofs-tenant gradually became less regarded; so that in the year 1772 two more were added; in 1773, three; and in 1774, one; in all 13; which disposed of 104 acres; all the Low Mofs to which water could then be conveyed. As water is the main spring of the operation, every tenant, beside the attention necessary to his share of the principal stream, collected water by every possible means, making ditches round his portion of the mofs, and a reservoir therein to retain it till wanted.

The tenants in the Lower Mofs having now begun to raise good crops, in the year 1774 several persons offered to take possessions in the High Mofs, upon condition that access to it should be rendered practicable. The High Mofs wanted many advantages that the Low possessed. To the Low Mofs, lying contiguous to the surrounding arable lands, the access was tolerably good; but from the arable lands the High Mofs was separated by 300 or 400 yards of the Low, which, even to a man, affords but indifferent footing, and to horses is altogether impracticable. The Low Mofs is in general only three feet deep; the High Mofs is from six to twelve feet in depth.

It will appear at first sight, that without a road of communication the High Mofs must for ever have proved unconquerable. Without delay, therefore, a road was opened to the breadth of twelve feet, for several hundred yards in length, by floating off the mofs down to the clay.

This being effected, and at the same time an opening given to admit water, in the year 1775 twelve tenants agreed for eight acres of High Mofs each. In consideration of the greater depth of this part of the mofs, it was agreed, that during the first 19 years they should pay no rent; but for the second 19 years the terms of agreement were the same as those made with the tenants in the Low Mofs. To the above-mentioned tenants every degree of encouragement was given; as upon their success depended, in a great measure, the disposal of the great quantity of mofs still remaining. But their success, however problematical, was such, that next year,

1776, 6 more took 8 acres each,
1777, 1
1778, 4
1779, 3
1780, 1
1781, 1
1782, 1

In all, including those upon the Low Mofs, 42 tenants, occupying 366 acres.

Though for some time the disposal of the High Mofs went but slowly on, it was not for want of tenants; but the number of operators was already sufficient for the quantity of water; to have added more would evidently have been imprudent.

In the year 1783 Mr Drummond entered into possession of the estate of Blair Drummond, and went fully into the plan adopted by his predecessor for subduing the mofs. At this time there still remained undisposed of about 1000 acres of High Mofs. As water was the great defideratum, it was determined, that
MOS [393] MOS

te to obtain that necessary article neither pains nor expense should be wanting. Steps were accordingly taken to ascertain in what manner it might be procured to most advantage.

Meanwhile, to prepare for new tenants a second road parallel to the former, at the distance of half a mile, was immediately begun and cut with what water could be got, down to the clay, 12 feet broad and 2570 yards long, quite across the moss. This opening was previously necessary, that operators might get a drain formed in the clay to direct the water; and it was to remain as a road that was absolutely necessary, and which relieved settlers from an expense they were unable to support. These preparations, the progress of the former tenants, and the prospect of a farther supply of water, induced 10 more to take possession in the year 1783; in the year 1784, 18 more took possessions; and in 1785 no fewer than 27—in all, 55 tenants in three years, which disposed of 440 acres more of the High Mosses.

As the introduction of an additional stream to the moss was to be a work both of nicety and expense, it was necessary to proceed with caution. For this reason several engineers were employed to make surveys and plans of the different modes by which it might be procured. In one point they all agreed, that the proper source for furnishing that supply was the river Teith; a large and copious stream that paffes within a mile of the moss: but various modes were proposed for effecting that purpose.

To carry a stream from the river by a cut or canal into the mosses was found to be impracticable; and Mr Whitworth (a) gave in a plan of a pumping machine, which he was of opinion would answer the purpose extremely well.

Soon after this Mr George Meikle of Alloa, a very skilful and ingenious mill-wright, gave in a model of a wheel for raising water entirely of a new construction, of his own and his father's invention jointly. This machine is so exceedingly simple, and acts in a manner so easy, natural, and uniform, that a common observer is apt to undervalue the invention: But persons skilful in mechanics view machinery with a very different eye; for to them simplicity is the first recommendation a machine can possess. Accordingly, upon seeing the model set to work, Mr Whitworth, with that candour and liberality of mind that generally accompany genius and knowledge, not only gave it the greatest praise, but declared that, for the purpose required, it was superior to the machine recommended by himself, and advised it to be adopted without hesitation.

The better, to explain this machine, two sketches are annexed, to the first of which the following letters refer. The explanation of the second will be found upon the sketch.

Plate CCCCXVI.

a. Sluice through which is admitted the water that moves the wheel.

b, b. Two sluices through which is admitted the water raised by the wheel.

Vol. XII.

(a) This gentleman is superintendent of the London water-works, and an engineer of great reputation in England. He was several years employed in Scotland in completing the great canal.
somewhat more complex, and would also increase the friction, he thought it more advisable to keep it in its present state. At the same time he fully observed, that as the stream by which the wheel is moved is at all times copious and powerful, the small loss of power occasioned by the above circumstances was of little or no avail.

This stream is detached from the Teith at the place where that river approaches nearest to the moss. The surface of the latter is about 15 feet higher than that of the former; the cistern is therefore placed 17 feet above the surface of the stream, so as to leave a declivity sufficient to deliver the water upon the surface of the moss.

The pipes through which the water descends from the cistern are composed of wooden barrels, hooped with iron 4 feet long and 18 inches in diameter within. In these pipes, having been conveyed under ground for 354 yards from the cistern, the water at once emerges into an open aqueduct. This aqueduct, which was formed according to a plan by Mr Whitworth, is constructed wholly of earth or clay; and in order to keep the water on a level with the surface of the moss, it is for nearly two thirds of its course elevated from 8 to 10 feet above the level of the adjacent grounds; the base being 40 feet broad, the summit 18 feet, and the water-course 10 feet broad. It commences at the termination of the pipes; from whence extending above 1400 yards, it discharges the water into a canal formed for its reception on the surface of the moss.

For raising the water to this height there were two reasons. 1st. That not only where it was delivered on the mosses, but even after being conveyed to the moss, diffusing currents, it might still retain sufficient power to transport the mosses to the river Forth. 2dly. That reservoirs of a sufficient height might be formed in the moss to retain the water delivered during night.

In consequence of Mr Whitworth's advice, a contract was entered into with Mr Meikle in spring 1787; and by the end of October in that year, the wheel, pipes, and aqueduct, were all completely finished, and what in fo complex and extensive an undertaking, is by no means common, the different branches of the work were so completely executed, and so happily adjusted to each other, that upon trial the effect answer'd the most sanguine expectations. The total expense exceeded L 1500 Sterling.

To induce the proprietor to embark in this undertaking, the mosses tenants laid of their own accord previously come under a formal engagement to pay the interest of any sum that might be expended in procuring a supply of water. But he was determined they should not enjoy by halves the sweets of this long-wished for acquisition. With a view therefore, not only to reward their past industry, but to render them future exertions, he at once set them free from their engagement; nor has any interest ever been demanded.

This new supply was a most acceptable boon to the mosses tenants—in order to make an equitable distribution, the water raised through the day was allotted to one division of operators; that raised during the night to another. To retain the latter, a canal was formed, extending almost three miles through the centre of the moss. From place to place along the sides are inflected sluices to admit water to the reservoirs of the potholders; each sluice having an aperture proportioned to the number of operators to be supplied from the reservoir which it fills. For the water raised through the day no reservoirs are necessary; as it is immediately used by the division to which it is allotted.

This additional stream, though highly beneficial, yet is not more than sufficient to keep 40 men at constant work. But such a quantity as would give constant work is not necessary; the operators must be often employed in making and repairing their drains, grubbing up roots of trees, &c.: so that a quantity sufficient to give five or six hours work per day to the whole inhabitants is as much as would be wanted. But as the quantity procured was still insufficient for this purpose, a small stream that descended from the higher grounds was diverted from its course and brought into the mosses. From want of level this stream could not be delivered to the greatest advantage; namely, upon the surface of the mosses. Yet by making, at a considerable expense, a drain half a mile long, and a reservoir for the night-water, it was rendered of much importance. And during the whole winter months, as well as in summer, after every fall of rain, it keeps 15 persons fully employed.

In the year 1787 two more tenants agreed for eight acres each; in 1788, four; in 1789, eight; in 1790, four tenants, all agreed for the same number of acres.

The whole moss was now disposed of, except that part called Flow-moss, which comprehended about 400 acres. Here it is twice the usual breadth, so fluid that a pole may be thrust with one hand to the bottom; and the interior part, for near a mile broad, is three feet above the level of all the rest of the mosses. Neither to the many and various difficulties that presented themselves had been overcome by perseverance and expense. But here the extraordinary elevation of the mosses, joined to its great fluidity, seemed to exclude all possibility of admitting a stream of water; and it was the general opinion that the moss operations had now arrived to the ne plus ultra, and that this moss would remain a nuisance for ages to come.

But the proprietor had now advanced so far that he could not submit to retreat; and he considered himself, as, in some measure, pledged to the country for the completion of this undertaking. To detail the various methods adopted to introduce a stream of water into that mosses, would prove tedious. It is sufficient to say, that after a thousand unsuccessful efforts, attended with much trouble and considerable expense, the point at last was gained, and a stream of water was brought in, and carried fairly and at the centre of the mosses.

The greatest obstacle was now indeed overcome; but still another remained of no small moment, namely, the discouragement given to settlers from the total impossibility of erecting habitations upon the surface of this mosses. To find a remedy for this evil was difficult. Happily a resource at last occurred. This was to bargain with a certain number of the old tenants who inhabited were nearest, to take lessees of portions of the mosses. But as some additional aid was here necessary, it was agreed that L 1200 Sterling should be gradually advanced to each tenant till he should accomplish the clearing of an acre, for which he or his successor is bound to pay 12s. of yearly rent, equal

equal to five per cent. upon the sum advanced. When
this point shall be gained, they are bound to dispose,
and adjust agreeable to themselves, either of their old or
of their new possession; for which, when once an acre
is cleared, purchasers will not be wanting.

In consequence of the above arrangement, during
the year 1791, no fewer than 35 of the old tenants
agreed, upon the foreseen conditions, for eight acres
each of the Flow-mosses. Thus 1200 acres are now
dispersed of to 115 tenants. But when these 35 tenants
shall each have cleared their acre, then, according to
agreement, 35 additional tenants will speedily be ac-
quired; and the mosses will then contain in all 150
families.

To the leaves already granted to the tenants in the
High Mosses, it is now determined to add a further
period of 19 years (making in all 37 years), during
which they are to pay one guinea per acre; a rent
not greater than the land is worth even at present, but
greatly below its probable value as that distant period.
This, it is hoped, will prove to the tenants a fufficient
inducement to continue their operations till their pos-
sessions are completely cleared from mofs.

Having now gone through, in detail, the whole pro-
gress of the colony since its first settlement in the
year 1767, it still remains to take a general view of
the results produced by that establishment.

For several years, at first, the water was used chiefly
to carry off mosses, in the forming of new roads, and
preparing reservoirs; which considerably retarded the
principal object of gaining land. Nevertheless there
have been cleared full 500 acres of excellent land pro-
ducing wheat, barley, oats, and clover, yielding from
fix to twelve bolls after one.

From the nature of the undertaking, there is good
reason to suppose that the operations will yearly ad-
vance with greater rapidity; especially as the greater
number of the settlers have only of late begun to
operate. Many, besides maintaining their families
otherwise by occasional employments, have in the
High Moss cleared in a year one rood of land; some
have cleared two, some three roods, and in the Low
Moss an acre.

It was a remark often made, even by persons of some
observation, that by collecting together such a number
of people, Kincardine would be overstocked; and the
consequence would be their becoming a burden on the
parish: for as the bulk of them were labourers not bred
to any trade, and polled of little stock, it was foreseen
that, for some time, they could not afford to con-
fine themselves solely to the mosses, from which the
return must be slow, but believed, for immediate
subsistence, to work for daily hire. Happily these pre-
dictions have proved entirely groundless; for fish is
the growing demand for hands in this country, that not
only do the whole of these people find employment
whenever they choose to look for it, but their wages
have been yearly increasing from the time of their
first establishment. In short, they have proved to the
corner where they are set down a most useful nursery
of labourers; and those very farmers who, at first, so
strongly opposed their settlement, now fly to them as
a sure resource for every purpose of agriculture. Still
they consider the moss-operatives as their principal
business; none pay them so well; and when they do
leave it to earn a little money, they return with cheer-
fulness to their proper employment. Many of them
already rile from 10 to 60 bolls of grain, and have no
occasion to go off to other work, which will soon be
the cafe with the whole. Their original stock, indeed,
did not often exceed L. 25, and some had not even
L. 10; but what was wanting in stock is compensated
by industry.

Of the whole inhabitants full nine-tenths are High-
landers, from the neighbouring parishes of Callender,
Balquhidder, &c.: a sober, frugal, and industrious
people, who, insured to hardships in their own country,
are peculiarly qualified to encounter so arduous an un-
taking. From this circumstance, too, arises a very
happy consequence; that wearing a different garb and
speaking a different language from the people amongst
whom they are settled, they consider themselves in a
manner as one family, and not as inhabitants of a foreign
province. And hence upon all occasions of difficulty, they fly
with alacrity to each others relief. Neither ought it
to be forgotten, that, from their first settlement to the
present day, not a single instance has occurred amongst
them of theft, bad neighbourhood, or of any other mil-
demeanor, that required the interposition of the civil
magistrate. Nor, however poor in circumstances, has
any one of them ever stooped to solicit assistance
from the funds of the parih appropriated to that purpose.

Though few of the tenants entered with a large
stock, one only has been obliged to leave the mosses
from incapacity to proceed. Many indeed have spent
their small stocks, and even run a little in debt: but
in this case they have been permitted to sell their tacks
upon the following conditions: 1/4, That the purchaser
shall be a good man; 1/4, That the feller shall take
another possession. By this manoeuvre a new inhabi-
tant is gained; while the old one, relieved from debt,
and aided by palt experience, recommences his opera-
tions with double spirit upon a new possession. The
monied man, again, has at once a house and a piece of
ground; the want of which, chiefly, startled new be-
ginners.

Some have even made a kind of trade of selling: in-
fomuch, that from the year 1774 to the present year
1792, no fewer than fifty sales have taken place, pro-
ducing in all the sum of L. 849 Sterling. This proved
from time to time a most fashionable recruit to the
colony, and gave new vigour and spirits to the whole.

The number of the settlers is productive of an ex-
cellent effect; and although some are generally absent,
and the others remain to occupy the water saltantly.
In a favourable day there may be seen hundreds, men,
women, and children, labouring with the utmost affi-

duity. The women declare they can make more by
working at the mosses than at their wheel; and fuch is
the general attachment to that employment, that they
have frequently been discovered working by moon-
light.

Another happy consequence arising from their num-
bers is the great quantity of moss they consume for
fuel. There are in all 115 families. Each family
requires at an average 10 dargues (a) of peats yearly.

\[S\] 2

(a) A dargue (or darg) of peats, is the quantity that one man can calf and two can wheel in a day to the
field where they are spread out to dry.
Each darg uncovers a space equal to 10 square yards of clay; so that by castingpeats, the mof tenants gain yearly about 6 roods of land.

The advantage, too, of providing their fuel with so little trouble, is very great. They require yearly 1150 dargs of peats; which, as each darg when dried and stacked is valued at five shillings, are worth 287 l. 10s. sterling; a sum which otherwise must have been expended on the prime coat and carriage of coals. Many of them call peats for sale; and L. 100 worth are yearly disposed of in the town of Sterling, the village of Down, &c.

Though mof-work be laborious, it is at the same time amusing. The operator moves the mofs five feet only at a medium; and the water, like carts in other cafes, carrying it off as fast as it is thrown in, excites him to activity. Still he must submit to be wet from morning to night. But habit reconciles him to this inconvenience; while his house and arable land fill his eye and cheer his mind. Nor is it found that the health of the inhabitants is in the smallest degree injured either by the nature of the work or the vicinity of the mofs.

The quantity of mofs that one man can move in a day is surprising; when he meets with no interruption, seldom less than 48 cubic yards, each weighing 90 flones. The weight, then, of mofs moved per day is no less than 4320 flones. A cubic yard is moved into the water, and of course carried into the river Forth for one farthing. It follows, that the expense of moving 48 cubic yards is one shilling. But the same quantity moved to the same distance by carts would cost 24 shillings. Hence the advantage derived from the possibility of floating mofs in water, and the great importance of having water for that purpose.

The mofs, when contrived with the rich lands surrounding, appeared, especially before the improvements, a very dreary spot; one wide unvaried wild, totally unproductive, unfit even to furnish sustenance to any animal, except here and there a few wretched straggling sheep. Besides, it entirely cut off all connection between the farms on either side; amongst which no intercourse was practicable but by a circuit of several miles.

The scene is already greatly changed. The following are the numbers of the inhabitants now residing in the mofs; also of their cows and horses, and of the acres gained by them from the mofs, together with their produce.

The produce in bolls cannot be exactly ascertained; but, considering the goodness of the soil, may be fairly stated at 8 bolls per acre, inde 2400 bolls.

As oats are the staple commodity, the calculation shall be confined to that grain. According to the tariffs of Stirlingshire, crop 1790 (the last crop for which they have been struck), carfe oats are valued at 14s. per boll.

An excellent gravelled road 20 feet wide and a mile and a half long, is now carried quite across the mofs. By this means, in the first place, a short and easy intercourse is established between two considerable parts of the estate, formerly as little connected as if separated by a lake or an arm of the sea. Secondly, the inhabitants of the Mofs, to whom, hitherto, all paffage with carts or horses was impracticable for at least one half of the year, have now obtained the essential advantage of being able, with ease, to transport all their different commodities at every season of the year. This road was entirely formed by the hands of the mofs-tenants, and gravelled by their own carts and horses; a work which, it will not be doubted, they performed with much alacrity; when it is considered that, to the prospect of procuring a lafting and material benefit to themselves, there was joined the additional inducement of receiving an immediate supply of money, the whole being done at the proprietor's expense.

The possessons are laid off in the manner best fitted for the operations; and are divided by lanes running in straight lines parallel to each other. Parallel to these again the drains are carried; and this straight direction greatly facilitates the progress of the water with its load of mofs. Upon the bank of mofs fronting the lanes, the operation of floating is begun; and twenty or thirty people are sometimes seen heaving mofs into the same drain. That the water may be the more conveniently applied, the lanes include between them the breadth of two possessons only. The new houses are erected upon each side of these lanes at the distance of 100 yards from each other.

Before the formation of lanes and roads, and while yet no ground was cleared, the first settlers were obliged to erect their houses upon the surface of the mofs. Its softness denied all access to flones; which, at any rate, are at such a distance as would render them too expensive. Settlers, therefore, were obliged to construct their houses of other materials. Upon the Low Mofs there is found for this purpose great plenty of sod or turf, which accordingly the tenants use for the walls of their houses. For the rudeness of the fabric nature in some measure compensates, by overtopping the outside with a luxuriant coating of heath and other moorish plants, which has a very picturesque appearance.

But upon the High Mofs there is no sod to be found. There the tenant must go differently to work. Having chosen a proper situation for his house, he first digs four trenches down to the clay, so as to separate from the rest of the mofs a solid mafs, containing an oblong, rectangular area, sufficiently large for his intended house. This being done, he then scoops out the middle of the mafs, leaving on all sides the thickness of three feet for walls; over which he throws a
offered.

Upon the foottart parts of the moss, even these walls cannot be obtained. In such places the houfes are built with peat dug out of the moss, and closely compressed together while in a humid state. It is necessary even to lay upon the surface a platform of boards to prevent the walls from sinking; which they have frequently done when that precaution was neglected. After all, to flamp with the foot will make the whole fabric as well as the moss for fifty yards around. This, at first, startled the people a good deal; but custom soon rendered it familiar.

The colonists have now made considerable advancement in rearing better habitations for their comfort and convenience. Their huts of turf are but temporary lodgings. As soon as they have cleared a little ground, they build houses of brick; when the proprietor a second time furnishes them with timber gratis. It has also been found necessary to remove them entirely from the payment of the burdensome tax upon bricks; a tax which surely was never intended to fall on such poor industrious adventurers; and which, without this allowance, would have proved a most effectual bar to the employment of these materials.

There are now erected in the moss 69 brick-houses, substantially built with lime. The total expense amounted to £33. Sterling. And it is a very comfortable circumstance, that the money expended upon these houses is wholly kept in circulation among the inhabitants themselves: for as a number of them have learned not only to manufacture but also to build bricks, and as others who have hores and carts furnish the carriage of lime and coals, they thus interchange services with each other.

With a view to excite the exertion of the colonists, the following premiums have lately been offered: 1. To the person who shall in the space of one year remove the greatest quantity of moss down to the clay, a plough of the best construction. 2. To the person who shall remove the next greatest quantity, a pair of harrows of the best kind. 3. For the next greatest quantity, a spade of the best kind, and 10 lb. of red clover-feed. But as these premiums, if contested for by the whole inhabitants, could reach but a very few of the number, they have therefore been divided into six districts according to their situation, and the above premiums have been offered to each district.

The establishment of this colony has no doubt been attended with a very considerable share of expense and difficulty; for the undertaking was altogether new, and there were many prejudices against it, which it was necessary to overcome. At the same time it was noble and interesting; it was to make a valuable addition to private property; it was to increase the population of the country, and to give bread to a number of people; many of whom having been turned out of their farms and cottaries in the Highlands, might otherwise, by emigration, have been lost to their country; and that too at a time when, owing to the great enlargement of farms, depopulation prevails but too much even in the low countries. And it was to add to the arable lands of the kingdom, making many thousand bolls of grain to grow where none ever grew before.

These considerations have hitherto preponderated with the proprietors against the various obstacles that present themselves to the execution of so extensive an undertaking. Should their example tend in any degree to stimulate others, who both in Scotland and in England possess much ground equally useless to the country, to commence similar improvements, it would be a most grateful consideration, superadded to the pleasure already arising from the progress of the infant colony.

Most-Troopers, a rebellious sort of people in the north of England, that lived by robbery and rapine, not unlike the tories in Ireland, the Buccaneers in Jamaica, or banditti of Italy. The counties of Northumberland and Cumberland were charged with an yearly sum, and a command of men to be appointed by justices of the peace, to apprehend and suppress them.

Mostroha, in the Italian music, a mark at the end of a line or space, to show that the first note of the next line is in that place: and if this note be accompanied with a sharp or flat, it is proper to place their characters along with the moltra.

MOSUL, or Moussul. See Mousul.

MOTACILLA, in ornithology, the Wagtail and Yellow Wagtail. A genus of birds of the order of passerous; distinguished by a straight or bill of a fubulated figure, a tongue lacerated at the end, and very slender legs.

1. The alba, or white wagtail, frequents the sides of ponds and small streams, and feeds on insects and worms. The head, back, and upper and lower side of the neck, as far as the breast, are black; in some the chin is white, and the throat marked with a black crescent: the breast and belly are white; the quill feathers are dusky; the covert black, tippet and edged with white. The tail is very long, and always in motion. Mr. Willoughby observes, that this species shifts its quarters in the winter; moving from the north to the south of England during that season. In spring and autumn it is a constant attendant on the plough, for the sake of the worms thrown up by that instrument. These birds make their nest on the ground, composed of dry grafts, fine fibres of roots, and moss lined within with hair or feathers. The eggs are five in number, white, spotted with brown; and for the most part there is only one brood in a year.

2. The flava, or yellow wagtail, migrates in the north of England, but in Hampshire continues the whole year. The male is a bird of great beauty; the breast, belly, thighs, and vent feathers, being of a most vivid and lovely yellow: the throat is marked with some large black spots; above the eye is a bright yellow
yellow line: beneath that, from the bill, crook the eye, is another of a dusky hue; and beneath the eye is a third of the same colour: the head and upper part of the body is of an olive-green, which brightens in the coverts of the tail; the quill-feathers are dusky; the coverts of the wings olive-coloured; but the lower rows dusky, tipped with yellowish white; the two outmost feathers of the tail half white; the others black, as in the former. The colours of the female are far more obscure than those of the male: it wants also those black spots on the throat. It makes its nest on the ground, in corn-fields: the outside is composed of decayed stems of plants, and small fibrous roots; the inside is lined with hair: it lays five eggs.

3. The regulus, or gold-crested wren, is a native of Europe, and of the correspondent latitudes of Asia and America. It is the least of all the European birds, weighing only a single dram. Its length is about four inches and an half; and the wings, when spread out, measure little more than six inches. On the top of its head is a beautiful orange-coloured spot called its crest, which it can hide at pleasure; the margins of the crest are yellow, and it ends in a pretty broad black line; the sides of the neck are of a beautiful yellowish green; the eyes surrounded with a white circle: the neck and back of a dark green mixed with yellow; the breast of a dirty white; the tail composed of 12 feathers of a brown colour, an inch and a half long, but not forked. In America it associates with the titmice, running up and down the bark of lofty oaks with them; and collecting its food in the company as if they were all of one brood. It feeds on insects lodged in their winter dormitories in a torpid state. It is said to sing very melodiously.

4. The sialis, or blue-bird, is a native of most parts of North America; and is about the bigness of a sparrow. The eyes are large; the head and upper part of the body, tail, and wings, are of a bright blue, excepting that the ends of the feathers are brown. The throat and breast are of a dirty white: so that the hawk generally pursues it in vain. It makes its nest in holes of trees; resembles the robin-red breast in its song. They are not found in America, though several of their birds improperly bear that name; and it is uncertain whether they are found in Africa. This bird visits Britain in the beginning of April, and leaves it in August; and during its continuance there, its range is confined to but a part of the island: it is not found in Scotland, Ireland, or North Wales, nor in any of the northern counties except Yorkshire; and it does not migrate so far to the west as Devonshire and Cornwall. They are solitary birds, never uniting into even small flocks; and in respect to the nests, it is very seldom that two are found near each other. The female builds in some low bush or quickset hedge well covered with foliage, for such only this bird frequents; and lays four or five eggs of a greenish brown. The nest is composed of dry leaves on the outside, mixed with grass and fibres, lined with hair or down within, though not always alike. The female alone sits on and hatches the eggs, while the male not far off regales her with his delightful song; but as soon as the young are hatched, he commonly leaves off singing, and joins with the female in the task of providing for and feeding them. After the young can provide for themselves, the old female provides for a second brood, and the song of the male recommences. They have been known to have three broods in a year, and in the hot countries even four. These birds are often brought up from the nest for the sake of their song. They are likewise caught at their first coming over; and though old birds, yet by management can be made to bear confinement, and to sing equally with those brought up from the nest. None but the wildest epicure, as Mr. Latham remarks, would think of eating these charming songsters; yet, we are told that their flesh is equal to that of the ortolan, and they are fattened in Gascony for the table. Every school-boy must have read of Helioagabalus eating of nightingales tongues; and that famed dith of the Roman tragedian Æsop, which was composed of those of every singing or talking bird, and is said to have cost about £. 6843 of our money.

7. The hippophaeis, or pettychaps, is somewhat less than a linnet. The bill is short; the upper mandible black, the under bluish: above and below the eye there is a yellowish line: the head, neck, and upper parts are of a greenish ash-colour; the quills and tail of a mouse-colour, with greenish edges and black shafts; and the under wing-coverts are yellow: the belly is of a clear white; the breast darker, and tinged with yellow: the legs are bluish or lead-coloured. This species is frequent in several parts of England, and makes a nest.
8. The atricapilla, or blackcap, is smaller than the pittychaps. The bill is brown; the top of the head is black; and the upper parts of the body are of a greenish ash-colour; the sides of the head and under parts are grey, changing to very light grey, or almost white, towards the vent; the quills and tail are cinereous brown, margined with the same colour as the upper parts; the legs are lead-coloured, and the claws black. This bird is pretty common in England, and elsewhere in Europe, as far as Italy; in all which places it is known to breed; coming in spring, and retiring in September. In Italy it builds twice in the year; in England only once. The nest, which is generally placed in some low bush not far from the ground, is composed of dried flalks, mixed with a little wool and green moss round the verge; the inside lined with the fibres of roots, thinly covered with black horse-hair. The eggs are five in number; of a pale reddish brown, mottled with a deeper colour, and sprinkled with a few dark spots. The male and female sit by turns during incubation; and the young very early leap out of the nest, especially if any one approaches it, and forake it for ever. The food is chiefly insects; but in defect of these they will eat the fruits of spurge laurel, service, and ivy; and seem to be even fond of the moss; nightingale. It is migratory; coming hither in spring, and departing in autumn about October. It is not so shy as many birds in respect to itself; for it approaches habitations, and frequently makes its nest in some hole of a wall where numbers of people pass by frequently; yet it is content, if no one meddles with the nest; for the least derangement of the eggs, or almost looking at them, especially if the female is disturbed thereby, causes her to forake the nest altogether. It frequently builds also in some hole of a tree. The nest is composed chiefly of moss, lined with hair and feathers. The eggs are blue, and four or five in number. This bird frequently wags its tail; but does it sideways like a dog when he is pleased, and not up and down like the wagtail. It is with difficulty that these birds are kept in a cage; nor will they submit to it by any means if caught old. Their song has no great strength; yet it is agreeable enough; and they will, if taught young, imitate the note of other birds, and sing by night frequently as well as in the day time.

11. The falcicaria, or sedge-bird, is about the size of the blackcap, but more slender. The head is brown, marked with dusky streaks: the cheeks are brown; with a white line over each eye, and above that a black one: the upper parts of the neck and back are of a reddish brown; and the wing-coverts and quills dusky; the under parts are white; but the breast and belly have a yellow tinge; the tail is brown, and much rounded; and the legs are dusky. This bird is common in England, and frequents places where reeds and fedges grow; among which it is said to make the nest, though it has been known to do this on the lowest branches of trees. The nest is composed of straw and dried fibres of plants, lined with hair; and the eggs five in number, of a dirty white, marbled with brown. It is observed to imitate the note of the swallow, sky-lark, bunting, and other birds, in a pleasing but hurrying manner, and sings all night.

12. The ficedula, or epicurean warbler, is in length five inches; the upper parts are grey brown; the under parts greyish white, with a tinge of brown on the breast; and the legs are blackish. This bird is much esteemed on the continent for the delicate flavour of its flesh. Their chief food is insects; except in autumn, when they make great havoc among the figs and grapes; whence it is supposed their great delicacy in some measure arises. It is not found in England, but met with in most of the intermediate parts between Sweden and Greece; where, however, it is only a summer inhabitant, probably retiring still more south at the approach of winter. In the isle of Cyprus and Candia they abound greatly, infomuch as to be an article of commerce. They transport them in vessels filled with vinegar and sweet herbs: the isle of Cyprus alone collects 1200 or 1200 of these pots every year.

13. The rubecula, or red-breast, is universally known; the upper parts are of a greenish ash-colour; the forehead, throat, neck, and breast, a rufous orange; the belly and vent whitish; the bill, legs, and sides of the body, dusky. It is a constant inhabitant of Britain, as well as of the whole European continent from Sweden to Italy. It abounds in Burgundy and Lorraine, where numbers are taken for the table, and thought...
thought excellent. It builds not far from the ground if in a bush; though it sometimes fixes on an out-house, or retired part of some old building. The nest is composed of dried leaves, mixed with hair and moss, and lined with feathers. The eggs are of a dull white, marked with irregular reddish spots; and are from five to seven in number. The young, when full feathered, may be taken for a different bird, being spotted all over. The first rudiments of the red break forth on the breast about the end of August; but it is quite the end of September before they come to the full colour. Infants are their general food; but in defect of these they will eat many other things. No bird is so tame and familiar as this; closely attending the heels of the gardener when he is using his spade, for the sake of worms; and frequently in winter entering houses where windows are open, when they will pick up the crumbs from the table while the family is at dinner. Its familiarity has caused a petty name to be given it in several countries. The people about Bornholm call it tommer-liden; in Norway, Peter Ronmad; the Germans, Thomas Gierdet; and we, the Robin Red-breast.

14. The rubicola, or stone-chatter, is in length about four inches and three quarters. The male has the upper parts of the body mixed blackish and pale rufous; on each side the neck there is a transverse streak of white; the breast is of a reddish yellow; the belly paler; and the legs are black. The female has the colours much less vivid. This bird inhabits dry places, such as heaths and commons; living on insects of all kinds. It makes its nest early, at the foot of some low bush, or under a stone; and lays five or six eggs of a bluish green, sparingly marked with faint rufous spots. It is so very crafty as not to betray the place of the nest, never alighting but at some distance, and creeping on the ground to it by the greatest stealth. It is a nestless bird, incessantly flying from bush to bush; and seems to have received its English name from its notes, resembling the clicking of two stones together.

15. The rubetra, or whin-chat, is somewhat bigger than the stone-chatter. The upper parts are blackish, edged with rufous: from the bill arises a streak of white, which passes over the eye on each side, almost to the hind head: beneath this the cheeks are blackish; the chin is white; the rest of the under parts rufous white: on the wing, near the shoulder, is a transverse white mark, and another smaller near the baffard wing, on the outer edge: the legs are black. The female differs in being paler, and the spots on the wings and the white trace over the eye being far less conspicuous. This is not uncommon in Britain, and is seen along with the stone-chatter on the heaths during the summer months; where it breeds, making the nest much after the manner of that bird. It lays five dirty white eggs, dotted with black. This species is common also on the continent of Europe, in France, Italy, Germany, and the more temperate parts of Russia; but is said to be less common than the stone-chatter there, as it is also in England. Its food is chiefly insects; and is said to be as good as the ortolan, when fat and in good condition.

16. The cananthrus, or wheat ear, is in length five inches and a half. The top of the head, hind part of the neck, and back, are of a bluish grey; and over the eye a streak of white; the under parts of the body are dull yellow, changing to pure white at the vent: the breast is tinged with red; and the legs are black. This bird is met with in most parts of Europe, even as far as Greenland; and specimens have also been received from the East Indies. It visits England annually in the middle of March, and leaves it in September. It chiefly frequents heaths. The nest is usually placed under shelter of some turf, clod, stone, or the like; always on the ground, and not unfrequently in some deserted rabbit-burrow. It is composed of dry grass or moss, mixed with wool, fur of the rabbit, &c. or lined with hair and feathers. The eggs are from five to eight in number, of a light blue, with a deeper blue circle at the large end. The young hatch in the middle of May. In some parts of England these birds are in vast plenty. About East-bourn in Sussex they are taken in snares made of horse-hair placed beneath a long turf: Being very timid birds, the motion of a cloud, or the appearance of a hawk will drive them for shelter into these traps, and so they are taken. The numbers annually ensnared in that district alone amount to about 1840 dozen, which usually fall at sixpence per dozen. Quantities of these are eaten on the spot by the neighbouring inhabitants; others are picked, and sent up to the London poulterers and many are posted, being as much esteemed in England as the ortolan on the continent. Their food is insects only; though in rainy summers they feed much on earth-worms, whence they are fated in such feasons.

17. The cyanea, or superb warbler, a most beautiful species, is five inches and a half long. The bill is black: the feathers of the head are long, and stand erect like a full crest; from the forehead to the crown they are of a bright blue; from thence to the nape, black like velvet; through the eyes from the bill there runs a line of black; and beneath the eye springs a tuft of the same blue feathers; beneath which, and on the chin, it is of a deep blue almost black, and feeling like velvet; on the ears is another patch of blue, and across the back part of the head a band of the same: the whole giving the head a greater appearance of bulk than is natural: the hind part of the neck, and upper parts of the body and tail, are of a deep blue black; the under parts, purplish blue: the wings are dusky; the shafts of the quills chestnut: the legs are dusky brown; the claws black. It inhabits Van Diemen's Land, the most southern part of New Holland. The female of this species, of which a figure is given in Phillips's Voyage to Botany Bay, is discovered to be entirely destitute of all the fine blue colours, both pale and dark, by which the male is adorned, except that there is a very narrow circle of azure round each eye, apparently on the skin only: all the upper feathers composed of shades of brown, and the whole throat and belly is pure white. Except from the shape and size, this bird would not be suspected at first sight to belong to the same species as the male: the epithet of superb applies very ill to the female.

18. The troglodytes, or wren, is a very small species, in length only three inches three quarters; though some have measured four inches. The bill is very slender, and of a dusky brown colour: the head, neck, and back, are of a reddish brown; and over each eye a pale
MOT [ 401 ]

"There is no small advantage (says Bayle) to be made of reading this writer: and we have no French author that approaches nearer to Plutarch than he. We find beautiful thoughts, and solid arguments interwoven and dispersed through all he wrote; wit and learning go hand in hand. His style concerning the education of the young, and that of pagan philosophy, are the best which he hath written."

MOTHER, a term of relation, denoting a woman who hath born a child.

Mother of Pearl. See Mytilus.

MOTION is now generally considered incapable of definition, being a simple idea or notion received by the senses. The ancients, however, thought differently. Some of them defined it to be a passage out of one state into another; which conveys no idea to him who is ignorant of the nature of motion.—The peripatetic definition has been mentioned elsewhere, and shown to be wholly unintelligible, as well as their celebrated division of motion into some classes belonging to the three categories, quality, quantity, and relation: (see Metaphysics, B 185, 186, 190.) The several definitions of motion as presented by the ancients, too, among the moderns, pretend to define motion by calling it a change of one part of matter, out of the neighbourhood of those parts to which it is immediately contiguous, into the neighbourhood of others. Borelli defines motion to be the successive passage of a body from place to place. Others say that it is the application of a body to different parts of infinite and immovable space; and a lacemaker of uncommon acuteness has given as a definition of motion — change of place.

We have elsewhere offered our opinion of every possible attempt to define motion; but as the author of the last quoted definition has endeavoured to obviate such objections as ours, candour requires that he be heard for himself. "It is said (he observes) by some, that change implies motion, and therefore cannot be a part of its definition being the very thing defined. To this I answer, We are speaking of the sensible idea of motion, as it appears to our faculties: now changes do appear to our view, and to all our senses, which give us no idea of motion. Changes in heat or cold: in colour, smell, scent, hardness, softness, pain, pleasure: in these, and many other ideas, changes do not produce ideas like that produced by a ball rolling or a stone falling. We may perhaps, ultimately trace them to motion, but to inensible motions; to motions which arise only in reflection, and conflute no part of the actual idea of change. We can, therefore, conceive of change without conceiving at the same time of motion.—Change is a generic idea, including many species; motion, as a sensible idea, is a species of that genus. Change is therefore a necessary part of the definition of motion; it marks the genus of the thing defined. Motion is a change; but as there are many species of change, which of those species is motion? The answer is, It is a change of place. This marks the species; and differentiates it from change of colour, of temper, and figure."

This is the ablest defence of an attempt to define motion that we have ever seen; and at first view the definition itself appears to be perfect. Aristotle, the prince of definers, "confiders a definition 3 as a sketch of speech Man.

Note 1. See Dr Reid's account of Aristotle's logic, in Lord Kames's 3 E.
The definition under consideration seems to consist of the genus, signified by the word change; and of the specific difference, denoted by the words of place. But does the speech change of place really declare what motion is? We cannot admit that it does; as, in our apprehension, a change of place is the effect of motion, and not motion itself. Suppose a lover of dialectic undertaking to define the stroke by which he saw his neighbour wounded with a bludgeon: what should we think of his art were he to call it a contusion on the head? He might say that contusion is a general term, as contusions may be produced on the arms, on the legs, and on various parts of the body; and as there are many species of contusion, if he were asked which of those species was the stroke to be defined, he might answer, "a contusion on the head. Here would be apparently the genus and specific difference; the former denoted by contusion and the latter by the words on the head. But would this be a definition of a stroke? No, surely: a contusion on the head may be the effect of a stroke; but it can no more be the stroke itself, than a blow can be a bludgeon, or a flesh-wound the point of a sword. Equally evident it is, that a change of place cannot be motion; because every body must have been actually moved before we can discern, or even conceive, a change of its place. The effect of changing place would perhaps come nearer to a definition of motion; but so far would it be from "a speech declaring what motion is," that we are confident a man who had never by any of his senses perceived a body in actual motion, would acquire no ideas whatever from the words "act of changing place." He might have experienced changes in heat, cold, smell, and sound; but he could not possibly combine the ideas of such changes with the signification of the word place, were he even capable of understanding that word, which to us appears to be more than doubtful. (See Metaphysics, § 40, 41.)

The distinctions of motion into different kinds have been no less various, and no less insignificant, than the several definitions of it. The moderns who reject the peripatetic division of motion into four classes, yet consider it themselves as either absolute or relative. Thus we are told, that "absolute motion" is the change of absolute place, and that its celerity must be measured by the quantity of absolute space which the moving body runs through in a given time." "Relative motion, on the other hand, is a mutation of the relative or vulgar place of the moving body, and has its celerity estimated by the quantity of relative space run through." Now it is obvious, that this distinction conveys no ideas with a farther explanation of the terms by which it is expressed: but that explanation is impossible to be given. Thus, before we can understand what absolute motion is, we must understand what is meant by absolute place. But absolute place is a contradiction: for all place is relative and consists in the positions of different bodies with regard to one another. Were a globe in the regions of empty space to be put in motion by Almighty Power, and all the rest of the corporeal worlds to be flown afterwards annihilated, the motion would undoubtedly continue unchanged; and yet, according to this definition, it would be at first relative and afterwards absolute. That the beginning of such a motion would be peregrine, and the remainder of it imperceptible, is readily granted; but on this account to consider it as of two kinds, is as absurd as to suppute the motion of the minute-hand of a clock to be affected by our looking at it.

Leaving therefore these unintelligible distinctions, we now come to consider a question full of a very strutting nature, but much agitated among philosophers: viz. What is the original source of motion in the creation? Is it natural to matter? or are we to ascribe it to the immediate and continual agency of some immaterial being? The former has been strenuously argued by the Cartesians, and the latter by the Newtonians. The arguments of the former, founded upon the chimerical hypothesis of vortices and the original momentum of matter, were evidently inconclusive; and the hypothesis of Sir Isaac Newton, who asserted that it was naturally incapable of motion, appeared more probable. To account for the quantity of motion in the universe, therefore, it became necessary to have recourse either to the Deity, or to some subordinative spiritual agent; and this became the more necessary, as the doctrine of an absolute vacuum in the celestial spaces, that is, throughout the incomparably greatest part of the creation, was one of the fundamental maxims of the system. As it was absolutely denied that matter existed in those spaces, and it was plain that the celestial bodies affected one another at immense distances, the powers of attraction and repulsion were naturally called in as the sources of motion by their impulses upon inert and sluggish matter. Those being admitted, a speculation ensued concerning their nature. By natural it was confessed, they were: but whether they were to be accounted the immediate action of the divine Spirit himself, or of some subordinate and inferior spirit, was a matter of no little dispute. Sir Isaac Newton, towards the latter part of his life, began to relax somewhat of the rigidity of his former doctrine; and allowed that a very subtle medium, which he called ether, A subtle ether the probable cause of attraction and repulsion, and thus of the whole phenomena of nature. Since his time the multitude of discoveries in electricity, the similarity of that fluid to fire and light, with the vast influence it has on every part of the creation with which we are acquainted, have rendered it very probable that the other mentioned by Sir Isaac is no other than the element of fire, "the most subtle" and clas.

Siris, duce of all bodies, which seems to pervade and expand itself throughout the whole universe. Electrical experiments show that this mighty agent is everywhere present, ready to break forth into action if not restrained and governed with the greatest wisdom. Being always relives and in motion, it actuates and vivifies the whole visible mass; is equally fitted to produce and to destroy; distingishes the various phases of nature, and keeps up the perpetual round of generations and corruptions, pregnant with forms which
Motion. The animal spirit in man is the instrument both of sense and motion. To supply the senses in the corporeal world would be gross and unwarranted; but local motive faculties are evident in all its parts. The Pythagoreans, Platonists, and Stoics, held the world to be an animal; though some of them have chosen to confider it as a vegetable. However, the phenomena do plainly show, that there is a spirit that moves, and a mind or providence that presides. This providence, Plutarch faith, was thought to be in regard to the world what the soul is in regard to man. The order and course of things, and the experiments we daily make, show that there is a mind which governs and actuates this mundane sytem as the proper and real agent and cause; and that the inferior instrumenal cause is pure ether, fire, or the substance of light, which is applied and determined by an infinite mind in the macrocosm or universe, with unlimited power, and according to fitated rules, as it is in the microcosm with limited power and skill by the human mind. We have no proof either from experiment or reason of any other agent or efficient cause than the mind or spirit. When, therefore, we speak of corporeal agents, or corporeal causes, this is to be understood in a different, subordinate, and improper sense; and such an agent we know light or elementary fire to be.

That this elementary fire, absorbed and fixed in all bodies, may be the cause of the universal principle of gravity, is made sufficiently evident by number of experiments. Homburg having calcined in the focus of a burning-glass some regulus of antimony, found that it had gained one tenth in weight, though the regulus, during the whole time of the operation, fent up a thick fumoke, and thereby lost a considerable part of its own substance. It is vain to alledge that any heterogeneous matter floating in the air, or that the air itself, may have been hurried into the mafs by the action of the fire. And that by this additional matter the weight was increased: for it is known experimentally, that if a quantity of metal be even hermetically fecured within a vessel of glass to keep the air and all foreign matter, and the vessel be placed for some time in a strong fire, it will exhibit the fame effect. "I have seen the operation performed (says Mr Jones,) on two ounces of pewter-filings, hermetically sealed up in a Florence flate, which in two hours gained 15 grains, that is nearly one 17th. Had it remained longer in the fire, it might probably have gained something more; as, in one of Mr Boyle's experiments, flite-filings were found to have gained a fourth.

"Of accounting for thefe effects there are but two possible ways: 1. If the quantity of matter be the fame, or, in the cafe of calcination, be somewhat lefs, after being exposed to the action of the fire, while the gravity of the whole is become greater; then does it follow that gross and heavy matter, to the quantity of matter, and of course is not one of its properties. 2. If there be an increafe of the mass, it can be imputed to nothing but the matter of light or fire entangled in its passage through the substance, and so fixed in its parts, or combined with its solid parts, as to gravitate together with it. Yet it is certain, from the phenomenon of light darting from the sun, that this elementary fire does not gravitate till it is fixed in metal, or some other solid substance.

Here then we have a fluid which gravitates, if it gravitate at all, in some cases and not in others. So that which way ever the experiment be interpreted, we are forced to conclude that elementary or solar fire may be the cause of the law of gravitation.

That it is likewise in many cafes the caufe of repulsion, is known to every one who has seen it fuse metals, and convert water and mercurial into elastic vapour. But there is a fæt recorded by Mr Jones, which feems to evalue that the fame fluid, which as it issues from the fun exhibits itself in the form of light and heat, is in other circumftances converted into a very fine air, or cold æther, which rushes very forcibly towards the body of that luminary. "As a sequel to what has been observed (fays he) concerning the impregnation of solid substances with the particles of fire, give me leave to subjoin an experiment of M. de Stair. He tells us, that upon heating red lead in a glafs whence the air was exhausted by the rays of the sun collected in a burning-glafs, the veffel in which the folid red lead was contained burst in pieces with a great noise. Now, as all explosions in general must be ascribed either to an admiufion of the fire into a rarefied space, or to what is called the generation of it; and as air was not admitted upon this occasion, it must have been generated from the calx within the veffel; and certainly was so, because Dr Hales has made it appear that this subfance, like crude tartar and many others, will yield a confiderable quantity of air in diftillation. What went into the metal therefore as fire, came out of it again as air; which in a manner forces upon us conclusions of ineffable value in natural philosophy, and such as may carry us very far into the most sublime part of it."

One of the conclusions which the ingenious author thinks thus forced upon us, is, that the motion of the planets round the fun, as well as round their own axis, is to be attributed to the continual agency of this fluid, under its two forms of elementary fire and pure air. As fire and light, we know that it rushes with inconceivable rapidity from the body of the fun, and penetrates every corporeal subfance, exerting itself sometimes with such a force as nothing with which we are acquainted is able to refist. If it be indeed a fæt, that this elementary fire, or principle of light and heat, afterwards cools, and becomes pure air, there cannot be a doubt, but that under fuch a form it will return with great force, though furely in a somewhat different direction, towards the fun, forming a vortex, in which the planets are included, and by which they muft of course be carried round the centre. Mr Jones does not fuppofe that the air into which the principle of light and heat is converted, is of fo gross a nature as our atmosphere. He rather confiders it as cool æther, gravitate at all, his æther, in its aerial form though not fit for human respiration, is a better pumulo of fire than the air which we breathe.

This theory is exceedingly plausible; and the au-

thor
indeed, convinced us that the folar light is inverted or convertible into pure air; but he has, by just reasoning from undoubted facts, proved that the whole expanse of heaven, as far as comets wander, is filled not only with light, which is indeed obvious to the senses, but also with a fluid, which, whatever it may be called, supplies the place of air in feeding the fire of these ignited bodies.

That the motion of the heavenly bodies should result from the perpetual agency of such a medium, appears to us a much more rational hypothesis, than that which makes them act upon each other at immense distances through empty space. But the hypothesis is by no means to complete a solution of the phenomena as some of its fond admirers pretend to think it. This fluid, whether called ether, heat, light, or air, is still material; and the question returns upon him who imagines that it is sufficient to account for gravitation, repulsion, magnetism, and cohesion, &c. "What moves the fluid itself, or makes the parts of which it is composed cohere together?" However widely it may be extended, it is incapable of positive infinity; and therefore may be divided into parts separated from each other; so that it must be held together by a foreign force, as well as a ball of lead, or a piece of wax. As matter is not essentially active, the motion of this ether, under both its forms, must likewise be considered as an effect, for which we do not think that any propelling power, in the body of the sun can be admitted as a sufficient cause. For how comes the sun to pofefs that power, and what makes the fluid return to the sun? We have no notion of power, in the proper sense of the word, but as intelligence and volition; and by the pious and excellent author of the Essay on the First principles of Natural Philosophy, we are certain that the sun was never suppossed to be intelligent.

Bishop Berkeley, who admits of light or aether as the instrumental cause of all corporeal motion, gets rid of this difficulty, by supposing, with the ancients, that this powerful agent is animated. "According to the Pythagoreans and Platonists (says his Lordship), there is a life infused throughout all things; the air, water, fire, an intellectual and artificial fire, an inward principle, animal spirit, or natural life, producing and forming within, as art does without; regulating, moderating, and reconciling the various motions, qualities, and parts of this mundane system. By virtue of this life, the great masses are held together in their ordinary courses, as well as the minutest particles governed in their natural motions, according to the several laws of attraction, gravity, electricity, magnetism, and the rest. It is this gives infinites, teaches the spider her web, and the bee her honey. This it is that directs the roots of plants to draw forth juices from the earth, and the leaves and cortical vessels to separate and attract such particles of air and elementary fire as suit their respective natures." This life or animal spirit seems to be the same thing which Cudworth calls plastic nature, and which has been considered elsewhere. (See Metaphysics, p. 200 and Plastic Nature.) We shall therefore dismiss it at present, with just admitting the truth of the Bishop's position, "that if nature be suppossed the life of the world, animated by one soul, composed into one frame, and directed or governed in all its parts by one supreme and distinct intelligence, this system cannot be accused of atheism, though perhaps it may of mistake or impropriety."

A theory of motion somewhat similar to that of Berkeley, though in several respects different from it, was not many years ago flattered with great clearness, supported with much ingenuity, in an Essay on the Powers and Mechanism of Nature, intended to improve, and more firmly establish, the grand superstructure of the Newtonian system. Mr Young, the author of the essay, admits, with most other philosophers of the present age, that body is composed of atoms which are impenetrable to each other, and may be denominated fluid. These atoms, however, he does not consider as primary and simple elements, incapable of resolution into principles; but thinks that they are formed by certain motions of the parts of a substance immaterial and essentially active.

As this notion is uncommon, and the offspring of a vigorous mind, we shall consider it more attentively under the article Plastic Nature. It is mentioned at present as being insufficient to form a necessary introduction to the author's theory of a principle of motion, of which he attributes both the origin and the vesture to the agency of this elementary substance universal, pervading the most solid atoms of the densest bodies. Of every body and every atom he holds the constituent principles to be essentially active; but their principles act in such a manner as to counterbalance each other; so that the atom or body considered as a whole is inert, unless in so far as it refits the compulsion or separation of its parts. No body or atom can of itself begin to move, or continue in motion for a single instant; but being pervious to the active substance, and composing with it, that substance, when it enters any body, carries it along with it, till, meeting some other body in the way, either the whole of the active substance lodged in the former body remains in the obstacle, in which case the impelling body instantly ceases to move; or else part of that substance passes into the obstacle, and part remains in the impelling body; and in this case both bodies are moved with a velocity in proportion to the quantity of matter which each contains, combined with the quantity of active substance by which they are respectively penetrated.

Proof of the existence of one uniform active substance, he observes, that "change being an essential constituent part of motion, and change implying action, it follows that all motion implies action, and depends on an active cause. Every motion (he continues) has a beginning, a middle, and an end. The beginning is a change from rest to motion; the middle is a continuance in motion; the end is a change from motion to rest." He then proceeds to show, that the beginning of motion is by an action begun; the continuance of motion by an action continued; and the end of motion by a cessation of action.

The drift of these positions is admitted by every body. That the continuance of motion is by an action continued, will be proved, if it shall be shown that the continuance of a motion is nothing different from its beginning, in regard to any point of time allumed in the continued motion. Now the beginning of motion (he says) consists in the beginning of change of place,
place. But if any given portions of time and of space are assumed, a body beginning to move in the commencement of that time, and in the first portion of the space assumed, then and there begins that particular motion: and whether the body began to move in that space it was moving in other spaces and times, has no relation to the motion in question; for this being in a space and time altogether different, is a distinct motion from any which might have preceded it immediately, as much as from a motion which preceded it a thousand years before. It is therefore a new motion begun: and so it may be said of every assumable point in the continued motion. The term *continua* serves only to connect any two distinct motions, the end of one with the beginning of the other; but does not destroy their distinctness.

He then proceeds to combat, which he does very successfully, the arguments by which the more rigid Newtonians endeavour to prove that a body in motion will continue to be moved by its own inertia, till stopped by some opposite force. Having done this, he establishes the contrary conclusion by the following syllogisms:

"I. Whatever requires an active force to stop its motion, is disposed to move.

   Every body in motion requires an active force to stop its motion:

   Therefore every body in motion is disposed to move.

II. Whatever is disposed to motion is possessed of action.

   But a body in motion is disposed to continue in motion.

   Therefore a body in motion is possessed of action.

Thus it appears, that the middle part of any motion is action equally with the beginning.

"The last part of motion is its termination. It is admitted that all motion is terminated by an action contrary to the direction of the motion. It is admitted, too, that the moving body *ails* at the time its motion is destroyed. Thus the beginning and the end of any uniform motion are confessed to be actions; but all the intermediate actions which connect the beginning with the end is denied to be action. What can be more unaccountable than this denial? Is it not more consonant to reason and analogy, to ascribe to the whole continued motion one uninterrupted action? Such a conclusion true philosophy, we think, requires us to make.

"To move or act, is an attribute which cannot be conceived to exist without a substance. The action of a body in motion is indeed the attribute of the body, and the body relatively to its own motion is truly a substance, having the attribute or quality of motion. But the body being a name signifying a combination of certain ideas, which ideas are found to arise from action (see PLATO *Nature*), that action which is productive of those ideas whose combination we denominate body, is of the nature of an attribute. In other terms, body is to be considered as an attribute so long as it is considered as constituted of action.—To this attribute we must necessarily ascribe its substance. The actions which constitute body must be actions of something, or there must be something which acts. What then is this active something from whose agency we get the idea of body, or whose actions constitute body? Is it not sufficient that it is something active? A name might be surely given it, but a name would not render the idea more clear. Its description may be found in every sensation; it is colour to the eye, flavour to the palate, odour to the nose, sound to the ear, and feeling to the touch; for all our sensations are but so many ways in which this active something is manifested to us. A substratum of solidity philosophers have imagined to exist, and have vainly sought to find. Our active substance is the substratum for long sought for, and with so little success. We give it a quality by which it may be perceived; it acts. One modification of action produces matter, another generates motion. These modifications of action are modes of the active substance, whose presence is action: matter and motion constitute the whole of nature. There is therefore throughout nature an active substance, the constituent essence of matter, and immediate natural agent in all effects."

By an argument which we do not think very conclusive, our author determines this active substance to be unintelligent. "In our sensations individuality, not discovering (says he) the traces, not seeing the characters of intelligence, but finding only action present and necessary, our inferences go no farther than our observations warrant us to do; and we conclude in all these things an action only, and that action unintelligent." Having given our opinion of real agency elsewhere (see METAPHYSICS, No. 118), we shall not here stop to examine this reasoning. We may, however, ask, Whether all our sensations individually be not excited for a certain end? If they be, according to our author's mode of arguing in another place, the excitable agent must be an intelligent being. By this we are far from meaning to deny the reality of a secondary or instrumental cause of sensation which is distinct of intelligence. We are strongly inclined to think that there is such a cause, though our persuasion results not from this argument of our author. In our opinion, he reasons better when he says, "that a subordinate agent constructed as the master of creation, invested with perpetual laws, and producing agreeably to those laws all the forms of being, through the varieties of which inferior intelligences can, by progressive steps, arrive ultimately at the supreme contriver, is more agreeable to our ideas of dignity, and tends to impress us with more exalted sentiments, than viewing the Deity directly in all the individual impressions we receive, divided in the infinity of particular events, and unwary, by his continual presence in operations to view insignificant and mean."

This active substance, or secondary cause, our author concludes to be neither matter nor mind. "Matter, matter (says he) is a being, as a whole quiescent and inactive, but constituted of active parts, which reftitute separation, or cohere, giving what is usually denominated vitality to the mass. Mind is a subtle one which thinks. A being which should answer to neither of these definitions, would be neither matter nor mind; but an immanent, and, if I may so say, an immaterial substance." Such is the active substance of Mr. Young, which,
The man ingenio motion. The

active substance must be considered as a being naturally either active or motive. But it cannot be

natural: if it were, there would be no such thing as a tendency to motion, cannot originate in a tendency to rest. Therefore the active substance is by nature motive, that is, tending to motion. The active substance is not solid, and does not resist penetration. It is therefore incapable of impelling or of sustaining impulse. Whence it follows, that as it tends to move, and is incapable of having its motion impeded by impulse, it must actually and continually move: in other words, motion is essential to the active substance.

In order that this substance may act, some other thing upon which it may produce a change is necessary; for whatever suffers an action, receives some change. The active substance, in acting on some other thing, must impart and unite itself thereto; for its action is communicating its activity. But it cannot communicate its activity without imparting its substance; because it is the substance alone which possesses activity, and the quality cannot be separated from the substance. Therefore the active substance acts by uniting itself with the substance on which it acts. The union of this substance with bodies, is not to be conceived of as a junction of small particles intimately blended together, and attached at their surfaces; but as an entire diffusion and incorporation of one substance with another in perfect coalescence. As bodies are not naturally active, whenever they become so, as they always do in motion, it must be by the accession of some part of the active substance. The active substance being imparted to a body, penetrates the most solid or resisting parts, and does not reside in the pores without, and at the surfaces of the solid parts. For the activity is imparted to the body itself; and not to its pores, which are no parts of the body: therefore, if the active substance remained within the pores, the cause would not be present with its effect; but the cause would be in one place and the effect in another, which is impossible.

Bodies by their impulse on others lose their activity in proportion to the impulse. This is matter of observation. Bodies which suffer impulse acquire activity in proportion to the impulse. This also is matter of observation. In impulse, therefore, the active substance paves out of the impelling body into the body impelled. For since bodies in motion are active, and activity consists in the presence of the active substance, and by impulse bodies lose their activity, therefore they lose their active substance, and the loss is proportional to the impulse. Bodies impelled acquire activity; therefore acquire active substance, and the acquisition is proportioned to the impulse. But the active substance left by the impelling body ought to be concluded to be that found in the other; because there is no other receptacle than the impelled body to which the substance parted from can be traced, nor any other source than the active body whence that which is found can be derived. Therefore, in impulse, the active substance ought to be concluded to pass from the impelling body to the body impelled. The flowing of such a substance is a sufficient cause of the communication of activity, and no other rational cause can be assigned.

The continued motion of a body depends not upon its inertia, but upon the continuance of the active substance within the body. The motion of a body is produced by the motion of the active substance in union with the body. It being evident, that since the active substance itself does always move, whatever it is united to will be moved along with it, if no obstacle prevent. In mere motion, the body moved is the patient, and the active substance the agent. In impulse, the body in motion may be considered as an agent, as it is made active by its active substance.

While the active substance is flowing out of the active body into the obstacle or impelled body, the active body will press or impel the obstacle. For while the active substance is yet within the body, although flowing through it, it does not cease to impart to the body its own nature, nor can the body cease to be active, because not yet deprived of the active substance. Therefore, during its sloughing out of the body, such portion of the active substance as is yet within, is urging and dispersing the body to move, in like manner as if the active substance were continuing in the body; and the body being thus urged to move, but impeded from moving, presses or impels the obstacle.

The question which has been so long agitated, and cause of the phenomenon, is given by Mr. Young.
Motions complex; the more motions simple and in all things first in order, and out of the more simple the more complex arises in order posterior. The most simple motion is rectilinear; therefore a rectilinear motion is to be considered as that which is the original and natural state of things and consequently that to which all things tend. It will follow from hence, that when any portion of active substance in which the law of union operates, has in the manner above explained been compelled to assume a revolving motion, that is, a motion in some curve; a tendency to a rectilinear motion will continually exist in every part of the revolving portion, and in every point of the curve which it describes during its revolution. And this rectilinear tendency will be a tendency to recede from the centre in every point of the revolving orbit, and to proceed in a tangent to the orbit of each point. These two tendencies, if not originally equal, must necessarily in all cases arrive at an equality. For the tendency towards the centre, called the centripetal tendency, that is the law of union, operating first, if we suppose the motion approaches the centre, the tendency to recede from it called the centrifugal tendency, will have its proportion to the centripetal continually increased as the orbit of revolution grows less, so as ultimately to equal the centripetal tendency, and restrain the motion from its central course, at which point it will no longer seek the centre but revolve round it."

As our author holds that every atom of matter is formed by the motion of parts of the active substance, and every body formed by the motion of atoms; so he maintains, not only that the sun, moon, earth, planets and stars, are penetrated by the same substance, but that each is the centre of a vortex of that substance and that of these vortices some are included within others. "The subtle revolving fluid, the centre of whose vortex the earth occupies, not only surrounds but pervades the earth, and other vortices their earths, to their centres; and the earth and planets are by its revolutions carried around on their own axes. The earth is an inactive mass, and all its component masses are severally as well as collectively inactive; but the earth and all its parts have various collective and separate movements, imparted from the fluid which surrounds, pervades, and constitutes it. Being immersed together with its proper surrounding sphere or vortex, in the larger sphere or vortex of the sun, it is carried thereby in a larger orbit about the sun, at the same time that by the revolution of its proper sphere it rotates on its own axis."

Such is the most complete view which our limits will permit us to give of Mr Young's theory of motion. To the philosopher who considers experiment theory, as the only test of truth, and who in all his inquiries employs his hands more than his head, we are fully aware that it will appear in no better light than as "the baleful fabric of a vixion." Even to the intellectual philosopher who is not frightened at the word metaphysics, we are afraid than such an active substance as the author contends for, as I appear as adequate to the production of the phenomena of gravitation and repulsion as the material ether of Mr Jones and his followers. A being void of intelligence, whether it be material or immaterial, quiescent or motive, cannot
be the subject of law, in the proper sense of the word. The laws of which Mr. Young speaks as necessary to regulate the motions of the active substance, must be more free, applied by some extrinsic and superior power. And since "motion, as it is effective to the active substance, is power without direction, agency without order, activity to no end; since it is of such a nature, that from its unguided agitations there could result neither connection, order, nor harmony;" it follows that those extrinsic forces must be perpetually applied, because what is effective to any substance can never be destroyed or changed so long as the substance itself remains.

Forces producing order out of confusion, can be applied only by a being possessed of intelligence; and if the immediate and perpetual agency of an intelligent being is necessary to regulate the motions of the active substance, that substance itself may be thought superfluous, and its very existence be denied. "Et a non sunt muti licentia ab fine nostris," is a rule of philosophy which every man of science acknowledges to be just. And it will hardly be denied, that the immediate and perpetual agency of an intelligent being upon Mr. Jones's ethereal fluid, or even upon the matter of solid bodies themselves, would be capable of producing every kind of motion with that instrumentality of a substance which is neither mind nor matter.

Such we conceive, are the objections which our metaphysical readers may make to this theory. Part of their force, however, will perhaps be removed by the ingenious manner in which our author analyzes matter into an inmaterial principle. But so much of it remains, that the writer of this article is inclined to believe that no mechanical account can be given of the motions of the heavenly bodies, the growth of plants, and various other phenomena which are usually solved by attraction and repulsion. In the present age, philosophers in general are strangely averse from admitting on any occasion the agency of mind; yet as every effect must have a cause, it is surely not irrational to attribute such effects as mechanism cannot produce to the operation either of intelligence or infirmity. To suppose the Deity the immediate agent in the great motions of the universe, has been deemed impious; and it must be confessed that very ingenious conclusions have been deduced from that principle. But there is surely no impropriety in supposing, with the excellent bishop of Cloyne, that the fluid which is known to pervade the solar system, and to operate with irresistible force, may be animated by a powerful mind, which acts intuitively for ends of which itself knows nothing. For the existence of such a mind, no other evidence, indeed, can be brought than what is afforded by a very ancient and very general tradition, and by the impossibility of accounting for the phenomena upon principles of mere mechanism. Perhaps some of our more pious readers may be inclined to think that the Supreme Being has committed the immediate government of the various planetary systems to powerful intelligences, or angels, who as his ministers, direct their motions with wisdom and forethought. Such an opinion is certainly not absurd in itself; and it seems to be countenanced by an ancient writer who, though not known by the name of a philosopher, knew as much of the matter as any founder of the most celebrated school.

To object to either of these hypotheses, as has been sometimes done, that it represents the government of the world as a perpetual miracle, betrays the grossest ignorance; for we might as well call the movements of the bodies of men and brutes, which are certainly produced by minds, miraculous. We do not affirm that either hypothesis is certainly true; but they are both as probable and as satisfactory as the hypothesis which attributes agency to attraction and repulsion, to a subtile ether, or to a substance which is neither a mind nor matter. Were the immediate agency of intellect to be admitted there would be no room for many of those disputes which have been agitated among philosophers, about the increase or diminution of motions in the universe; because an intelligent agent, which could begin motion as well as carry it on, might increase or diminish it as he should judge proper. If infinite agency, or something similar to it, shall be adopted, there is the same room for investigation as upon the principles of mechanism; because infinite works blindly according to steady laws imposed by a superior mind, which may be discovered by observation of their effect. As we consider this as by much the most probable hypothesis of the two, we find ourselves involved in the following question: "If a certain quantity of motion was originally communicated to the matter of the universe, how comes it to pass that the original quantity still remains? Considering the many opposite and contradictory motions which since the creation have taken place in the universe, and which have undoubtedly destroyed a great part of the original quantity, by what means has that quantity been restored?"

If this question can be solved by natural means, it must be upon the principles of Newton; for "in every case where quantities and relations of quantities are required, it is the province of mathematics to supply the information sought," and all philosophers agree that Sir Isaac's doctrine of the composition and resolution of motion, though in what respects the heavenly bodies may have no physical reality, is so mathematically just, as to be the only principle from which the quantity of motion, or the force of powers, can in any case be computed. If we choose to answer the question, by saying that the motion left is restored by the interpolation of the Deity, then we might as well have had recourse to him at first, and say that he alone is the true principle of motion throughout the creation.

Before, we are reduced to this dilemma, however, it is necessary, in the first place, to inquire whether there is or can be any real diminution of the quantity of motion throughout the universe? In this question the Cartesians take the negative side, and maintain that the Creator at the beginning impressed a certain quantity of motion on bodies, and that under such laws as that no part of it should be lost, but the same portion of motion should be constantly preferred in matter: and hence they conclude, that if any moving body strike on any other body, the former loses no more of its motion than it communicates to the latter. Sir Isaac Newton takes the contrary side, and argues in the following manner: "From the various compositions of two motions, it is manifest there is not al-
wanes the same quantity of motion in the world: for if two balls, joined together by a slender wire, revolve with an uniform motion about their common centre of gravity, and at the same time that centre be carried uniformly in a right line drawn in the plane of their circular motion, the sum of the motions of the two balls, as often as they are in a right line, drawn from their common centre of gravity, will be greater than the sum of their motions when they are in a line perpendicular to that other. Whence it appears, that motion may be both generated and lost. But, by reason of the tenacity of fluid bodies, and the friction of their parts, with the weakness of the elastic power in solid bodies, nature seems to incline much rather to the diminution than the production of motion; and in reality, motion becomes continually less and less. For bodies which are either so perfectly hard or so soft as to have no elastic power, will not rebound from each other; their impermeability will only stop their motion. And if two such bodies equal to one another be carried with equal but opposite motions, so as to meet in a void space, by the laws of motion they must rebound with equal and opposite forces. But if the obstacle is removed, they melt themselves in their primitive vigour, without the least symptom of abatement or decay.

Under the article Mechanics, it has been shown, that when motion is compounded of two powers acting obliquely upon one another, more motion is lost than the two powers taken together could spare. Thus, if the two powers $AB$ and $AC$ move a body through the diagonal of the square $AD$; supposing each of these powers to be $= 5$, the diagonal through which they pass will be $= 7$ (A) but from an inspection of the figure, it is manifest, that by the separation of the two powers, a quantity of motion $BC$, equal to the length of the other diagonal, is lost: for as far as the two acts oppose to each other, they must destroy motion. The quantity of motion produced therefore being $7$, and the quantity lost the same, the whole quantity originally existing in the two powers $AB$ and $BC$ ought to have been $= 14$, when it is only $10$. To make up for the deficiency therefore, we must search for the origin of the two powers $AB$ and $BC$, and this we shall find in the lines $Aa$, $Ac$, and $Ad$; each of which is $= 3$, altogether making $14$; whence deducting $7$ the motion lost, we have $7$ remaining for the motion produced. Let us now find out the origins of these powers, and we shall find those of $Aa$ in the lines $As$ and $Af$; the origins of $Ac$ in $Af$ and $Ag$. The sources of $Ad$ we find in the lines $Ag$ and $Ab$. Thus we have now eight fountains of the four powers which generated the two first ones; and thus we find that the power $AD = 7$, requires two of $5$ each $= 10$ for its generation; these two require four of $3\frac{1}{2}$ each for their production; and these again require eight of $2.45$ each for their production. Hence, in order to generate the two original powers $AB$ and $AC$, we see that there is required at a very few steps no less than $20$; and in like manner, to generate these eight powers, we must have recourse to $16$ others; so that the ultimate fountaine of motion increases beyond all calculation.

Whether, therefore, we reckon the ultimate source of motion to be spiritual or material, it is plain that it must be to our conceptions infinite; neither will the
Motion.

Plenchemas of nature allow us to give any other explanation than we have done: for no power whatever can lose more than its own quantity; and it seems absurd to think that the Deity would create the world in such a manner that it would ultimately become insubstantial, and that it should be necessary to unknown principle to remedy the supposed defect. On the principle we have just now laid down, however, the matter becomes exceedingly plain and obvious. The Creator at first formed two opposite powers, the action of which is varied according to the circumstances of the bodies upon which they act; and these circumstances are again varied by the action of the powers themselves in innumerable ways upon one another, and the approach of one body to another, or their receding to a greater distance. Where these powers happen to oppose each other directly, the body on which they act is at rest; when they act obliquely, it moves in the diagonal; or if the force acting upon one side is by any means increased, the body, certainly must move towards that side, as is evident from the case of the atmosphere, the prefigure of which, when removed from one side of a body, will make it move very violently towards that side; and if we could continually keep off the prefigure in this manner, the motion would assuredly be perpetual. We must not imagine that motion is destroyed because it is counteracted: for it is impossible to destroy motion by any means but by removing the cause; counteracting the effect is only a temporary obstacle, and must cease whenever the obstacle is removed. Nature, therefore, having in itself an infinite quantity of motion, produces greater or lesser motions, according to the various actions of the moving powers upon different bodies or upon one another, without a possibility of the general stock being either augmented or diminished, unless one of the moving powers was to be withdrawn by the Creator; in which case, the other would destroy the whole system in an instant. As to the nature of these great original powers, we must confess ourselves totally ignorant; nor do we perceive any data from which the nature of them can be investigated. The elements of light, air, &c. are the agents; but in what manner they act, or in what manner they received their action, can be known only to the Creator.

Perpetual Motion, in mechanics, a motion which is supplied and renewed from itself, without the intervention of any external cause; or it is an uninterrupted communication of the same degree of motion from one part of matter to another, in a circle or other curve returning into itself, so that the same momentum still returns undiminished upon the first mover.

The celebrated problem of a perpetual motion conflicts in the inventing a machine, which has the principle of its motion within itself. M. de la Hire has demonstrated the impossibility of any such machine, and finds that it amounts to this: viz. to find a body which is both heavier and lighter at the same time, or to find a body which is heavier than itself.

To find a perpetual motion or to construct an engine, &c. which shall have such a motion, is a famous problem that has employed the mathematicians of 2000 years; though none perhaps have prosecuted it with attention and earnestness equal to those of the present age.

Infinite are the schemes, designs, plans, engines, wheels, &c. to which this longed-for perpetual motion has given birth; it were as endles as impertinent to give a detail of them all.

In effect, there seems but little in nature to counterbalance all this affluence and expectation; among all the laws of matter and motion, we know of none yet which seems to furnish any principle or foundation for such an effect.

Animal Motion, that which is performed by animals at the command of the mind or will.

Though all the motions of animals, whether voluntary or involuntary, are performed by means of the muscles and nerves, yet neither these nor the subtile fluid which resides in them are to be accounted the ultimate sources of animal motion. They depend entirely upon the mind for those motions which are properly to be accounted animal. All the involuntary motions, such as those of the blood, the heart, muscles, organs sublervient to respiration and digestion, &c. are to be classed with those of vegetables; for though no vegetable have them in such perfection as animals, there are yet traces of them to be found evidently among vegetables, and that so remarkably, that some have imagined the animal and vegetable kingdoms to approach each other so nearly that they could scarce be distinguished by a philosophic eye.

Muscles.

Though the motions of animals however, depend on the action of the mind or of the will, external objects seem originally to have the command of the mind itself; for unless an animal perceive something, it will not be inclined to act. By means of the ideas once received, indeed, and retained in the memory, it acquires a self-moving power, independent of any object present at the time, which is not the case with vegetables; for however they may act from a present impulse, their motions never appear to be derived from any source which may not be accounted strictly mechanical.

According to some, motion is the cause of sensation itself; and indeed it seems very probable that the motions of that subtile fluid, called light or electricity, in our bodies always accompany our sensation; but whether this be the cause, or only the medium of sense, cannot be discovered.

Though all animals are endowed with a power of voluntary motion, yet there is a very great variety in the degrees of that power; to determine which no certain rules can be assigned; neither can we, from the situation and manner of life of animals, derive any probable reason why the motion of one should differ so very much from that of another. This difference does not arise from their size, their ferocity, their timidity, nor any other property that we can imagine. The elephant though the strongest land animal, is by no means the slowest in its motions; the horse is much swifter than the bull, though there is not much difference in their size; a greyhound much swifter than a cat, though the former be much larger, and though both live in the same manner, viz. by hunting. Among insects the same unaccountable diversity is observable. The louse and flea are both vermin, are both nearly of the same size, and both feed on the bodies of animals; yet there is no comparison between the swiftness of their motions: while the bug which is much larger than either, seems to...
MOT [ 411 ] MOT

Motion.

This very remarkable circumstance seems not even to depend on the range which animals are obliged to take in order to procure food for themselves: the motion of a shell is slower than that of an earth-worm; while that of many caterpillars is much quicker than either; though we can scarcely determine which of the three has the greatest or the least extensive range for its food.

Of all animals the shell-fish move the slowest, inasmuch that some have supposed them to be entirely destitute of loco-motive powers; and muscles particularly are said to have any faculty of this kind. Every one knows that these animals can open and shut their shells at pleasure; and it cannot escape observation, that in every muscle there is a feelyy protuberance of a much redder colour than the rest. This has been thought to be a tongue or proboscis, by which the animal takes in its food; but is in reality the instrument of its motion from place to place. This protuberance is divided into two lobes, which perform the office of feet. When the river mud is inclined to remove from its flatness, it opens its shell, thrusts out this protuberance, and digs a furrow in the sand; and into this furrow, by the action of the same protuberance, the shell is made to sink in a vertical position. It is recovered out of this into the former horizontal one, by pulling back the sand with the same tentacula, lengthens the furrow, and then the animal continues its journey by a continual turning topsy-turvy. — Marine muscles perform their motions in the same manner, and by similar instruments. In general they are firmly attached to rocks or small stones by threads about two inches long, which are spun from a glutinous substance in the protuberances already mentioned; these are called, in Scotland, the beards of muscles, and are thought to be the cause of the fatal disorders which sometimes attend the eating of muscles. See MYTTLUS.

Other animals which dwell in bivalved shells, perform their motions by a kind of leg or foot; which, however, they can alter into almost any figure they please. By means of this leg they can not only sink into the mud, or rise out of it at pleasure, but can even leap up from the place where they are; and this can be done by the limpet, which people are apt to imagine one of the most sluggish animals in nature. — When this creature is about to make a spring, it tests its shell on edge, as if to diminish friction; then, stretching out the leg as far as possible, it makes it embrace a portion of the shell, and by a sudden movement, similar to that of a spring let loose, it strikes the earth with its leg, and actually leaps to a considerable distance.

The pout, or razor-fish, is said to be incapable of moving forward horizontally on the surface; but it digs a hole sometimes two feet deep in the sand, in which it can ascend or descend at pleasure. The leg, by which it performs all its movements, is fleshy, cylindrical, and pretty long; and the animal can at pleasure make it assume the form of a ball. When lying on the surface of the sand, and about to sink into it, the leg is extended from the inferior end of the shell, and makes the extremity of it take on the form of a shovel, sharp on each side, and terminating in a point. With this instrument the animal makes a hole in the sand; after which it advances the leg still farther into it, makes it assume the form of a book, and with this, as a feather, it drives the shell to descend into the hole. This operation is continued until the whole shell be covered; and when the animal wishes to regain the surface, it makes the extremity of the leg to assume the form of a ball, and makes an effort to extend its body; ball, however, prevents any farther descent, and the re-action of the muscular effort rises up the hole, which operation is continued until it reaches the surface; and it is surprising what facility these motions are accomplished by an animal seemingly so little qualified to move at all. Another particularity in this fish is, that though it lives among salt water, it abhors salt so much that when a little is thrown into its hole it instantly leaves it. But it is still more remarkable, that if you once take hold of the pout fish, and then allow it to retire into its hole, it cannot then be driven out by salt; though unless it be taken off by the hand, this will make it come to the surface as often as you please. See SOLLEN.

All other shell-fish, even those apparently the most sluggish and destitute of any apparatus for motion, are found to be furnished with such instruments as enable them to perform all these movements for which they have any occasion. Thus the scallop, a well-known animal inhabiting a bivalved shell, can both swim upon the surface of water and move upon land. When it happens to be deflected by the tide, it opens its shell to the full extent, and shutting it again with a sudden jerk, the reaction of the ground gives such an impulse to the whole, that it sometimes springs five or six inches from the ground; and by a continued repetition of this action, it gradually tumbles forward until it regains the water. Its method of failing is still more curious. Having attained the surface of the water by means unknown to us, it opens the shell, and puts one half above water, the other with the body of the animal in it, remaining below. Great numbers of them are thus frequently seen failing in company with their shells sticking up above water when the weather is fine, and the wind acting upon them as fails; but on the least alarm they instantly shut their shells, and all sink to the bottom together. See PECTEN.

The oyster has generally been supposed one of the most sluggish animals in nature, and totally incapable of voluntary motion; but from the researches of the Abbe Dicquemarre, this opinion seems to be erroneous. The oyster, like many other bivalved shell-fish, has a power of squirting water out from its body; and this property may easily be observed by putting some of them into a plate with as much sea-water as will cover them. The water is ejected with so much force, as not only to repel the approach of ordinary enemies, but to move the whole animal backwards or sideways, in a direction contrary to that in which the water was ejected. It has been also supposed, that oysters are destitute of sensation; but M. Dicquemarre has shown, that they not only possess sensation, but that they are capable of deriving knowledge from experience. When removed from such places as are entirely covered with the sea, when destitute of experience, they open their shells and die in a few days; but if they happen to escape this danger, and the water covers them again, they will not open their shells again,
The motions of the sea-urchin are perhaps more curious and complicated than those of any other animal. It inhabits a beautiful multivalved shell, divided into triangular compartments, and covered with great numbers of prickles; from which last circumstance it receives the name of sea-urchin or sea hedge-hog. The triangles are separated from one another by regular belts, and perforated by a great number of holes, from every one of which issues a fleshy horn similar to that of a snail, and capable of moving in a similar manner. The principal use of these horns seems to be to fix the animal to rocks or stones, though it likewise makes use of them in its progressive motion. By means of these horns and prickles, it is enabled to walk either on its back or its belly; but it most commonly makes use of those which are near the mouth. Occasionally it has a progressive motion by turning round like a wheel. Thus, says Mr Smellie, 4 the sea-urchin furnishes an example of an animal employing many thousand limbs in its various movements. The reader may try to conceive the number of muscles, fibres, and other apparatus which are requisite to the progressive motion of this little animal.

Those animals called sea-nastles or medusas, though extremely slow in their motions, are nevertheless evidently capable of moving at pleasure from place to place. The variety of their figure is such, that it is difficult to assign them any determinate figure whatever. In general, however, they resemble a truncated cone, the base of which is applied to the rock to which they adhere. Their colours are various, white, brown, red, or greenish: the mouth is very large; and when opened appears surrounded with feathers or other apparatus which are requisite to the progressive motion of this little animal.

Vegetable Motion. Though vegetables have not the power of moving from one place to another like animals, they are nevertheless capable of moving their different parts in such a manner as would lead us to suspect that they are actuated by a force of infiniteness. Hence many have been induced to suppose, that the animal and vegetable kingdoms are in a manner indistinguishable from one another; and that the highest degree of vegetable life can hardly be known from the lowest degree of animal life. The essential and inexpressible distinction, however, between the two, is the faculty of sensation, and locomotion in consequence of it. Were it not, indeed, for the manifestation of sense by moving from one place to another, we should not be able to tell whether vegetables were possessed of sensation or not; but whatever motions they may be possessed of, it is certain that no vegetable has the faculty of moving from one place to another. Some have endeavoured to distinguish the two kingdoms by the digestion of food; alleging that plants have no proper organs, such as a stomach, &c. for taking in and digesting their aliment. But to this it has been replied, that the whole body of a vegetable is a stomach, and absorbs its food at every pore. This, however, seems not to be a sufficient answer. All animals take in their food at intervals, and there is not a single instance of one which eats perpetually. The food is also taken into the body of the animal, and application of the parts made by means of the internal organization of the fucus; but in vegetables, their whole bodies are immersed in their food, and absorb it by the surface, as animal bodies will sometimes absorb liquids when put into them. The roots of a tree indeed will change their direction when they meet with a stone, and will turn from barren into fertile ground; but this is evidently mere mechanism, without any proof of will or sensation; for the nourishment of the root comes not from the stone, but from the earth around it: and the increase in size is not owing to any expansion of the matter which the root already contains,
Motion contains, but to the acquisition of new matter; whence the increase of size must always take place in the direction from whence the nourishment proceeds. On this principle alone we may explain the reason why the roots of a tree, after having arrived at the edge of a ditch instead of shooting out into the air, will creep down the one side, along the bottom, and up the other.

In their other movements the vegetables discover nothing like sensation or design. They will, indeed, uniformly bend towards light, or towards water; but in the one case we must attribute the phenomena to the action of the elements of light and air upon them; and in the latter the property seems to be the same with what in other cases we call attraction. Thus, if a root be uncovered, and a wet sponge placed near it in a direction different from that in which the root was proceeding, it will soon alter its position, and turn towards the sponge; and thus we may vary the direction of the root as often as we please. The effects of a plant to turn from darkness or shade into sunshine are very remarkable, as, in order to accomplish this, not only the leaves will be inclined, but even the flowers and branches themselves. When a wet sponge or vegetable is held under the leaves of a tree, they bend down in order to touch it. If a vessel of water be put within six inches of a growing cucumber, in less than 24 hours the latter will alter its direction; the branches will bend towards the water, and never alter their course until they come in contact with it. The most remarkable instance of this kind of motion, however, is, that when a pole is brought near a vine, the latter will turn towards it, and never cease extending its branches till it lays hold of the support.

The motions of the sensitive plant, and others of the same kind, have been considered as very wonderful; but it is doubtful if any of them be really more so than that of the vine just mentioned. None of these show any kind of propensity to move without an actual touch. A very slight one indeed, makes the sensitive plant contract, and the whole branch, together with the leaves, bend down towards the earth. This is so similar to some phenomena of electricity, that very few will hesitate at ascribing both to the same cause. Even the motions of the hedyraum gynus, which at first sight seem so much more surprising than those of the sensitive plant, may be explained upon the same principle. There is a specimen of this plant in the botanic garden of Edinburgh. It is a native of the East Indies, and its motions are occasioned by the fun-beams. The leaves are the only moveable parts. They are supported by long foot-stalks; and when the sun shines upon them they move briskly in every direction. Their most usual motion is upward and downward; but not unfrequently they turn almost quite round, and then the foot-stalks are evidently twisted. These motions continue only while the light and heat of the sun continues, ceasing when at night, or when the weather becomes cloudy and cold. The American plant called Dionaea muscipula, or Venus's fly-trap, is another example of very wonderful mechanism in vegetables, though even this does not argue any degree of sensation in this plant more than in others. The leaves of the dionaea are jointed, and furnished with two rows of prickles. A number of small glands upon the surface secrete a sweet juice, which entices flies to come and settle upon it; but the moment these insects touch the folic spot, the leaves fold up, and squeeze them to death between the prickles. The leaves fold up in the same manner when the plant is touched with a straw or pin.

The folding up of the leaves of certain plants in the absence of the sun's light, called their sleep, affords another very curious instance of vegetable motion. Almost all vegetables, indeed, undergo such a remarkable change in the night, that it is difficult to know exactly how many kinds do really sleep. They fold up their leaves in many different ways; but all agree in disposing of them in such a manner as to afford the best protection to the young items, flower buds, or fruit. The leaves of the tamarind-tree contract round the young fruit, in order to protect it from nocturnal cold; and those of fenna, glycinia, and many other papilionaceous plants, disposed of their leaves in the same manner. The leaves of the chickweed,克莱, acris, &c. are disposed in opposite pairs. In the nighttime they rise perpendicularly, and join so close at the top that the flowers are concealed by them. In like manner do those of the fida, or albus theophra, the ayecia, and ammohira, the folanum, and the Egyptian weath. All these are erected during the night; but those of the white lupine, in time of sleep, hang down.

The flowers of plants also have motions peculiar to themselves. Many of them during the night are closed in their calyxes. Some, particularly those of the German spurge, geranium stiratum, and common Whitlow grass, when asleep bend towards the earth; by which means the noxious effects of rain or dew are prevented. All these motions have been commonly ascribed to the sun's rays; and Mr Smellie informs us, that in some of the examples above mentioned the effects were evidently to be ascribed to heat; but plants kept in an hot-house, where the temperature of the day and night are alike, contract their leaves, and sleep in the same manner as if they were exposed to the open air; "whence it appears (says he), that the sleep of plants is owing rather to a peculiar law, than to a quicker or slower motion of the juices." He suspects, therefore, that as the sleep of plants is not owing to the mere absence of heat, it may be occasioned by the want of light; and to ascertain this he proposes an experiment of throwing upon them a strong artificial light. "If, notwithstanding this light (says he), the plants are not roused, but continue to sleep as usual, then it may be presumed that their organs, like those of animals, are not only irritable, but require the preservation of some invigorating influence which they have lost while awake, by the agitations of the air and of the sun's rays, by the act of growing, or by some other latent cause." On this, however, we must remark, that the throwing of artificial light upon plants cannot be attended with the same consequences as that of the light of the sun, unless the former were as strong as the latter, which is impossible; and even granting that we could procure an artificial light as strong as that of the sun, a difference might be occasioned by the different directions of the rays, those of the sun being very nearly parallel, while the rays of all artificial light diverge very greatly. If, therefore,
we are to make an experiment of this kind, the rays
should be rendered parallel by means of a burning
mirror. Here again we would be involved in a diffi-
culty: for the rays of the sun, act in one di-
rection; but as of necessity we must employ differ-
ent mirrors in our experiment, the light must fall upon
the plant in different directions, so that we could not rea-
sonably expect the same results as when the plants are
directly exposed to the rays of the sun.

The motion of plants, not being deducible from
sensation, as in animals, must be ascribed to that pro-
property called irritability: and this property is pos-
sessed insensibly by the parts of animals in a greater
degree than even by the most irritable vegetable. The mu-
cular fibres will contract on the application of any fi-
mulating substance, even after they are detached from
the body, to which they belonged. The heart of a frog
will continue to beat when pricked with a pin for
several hours after it is taken out of the body. The
heart of a viper, or of a turtle, beats distinctly from
20 to 30 hours after the death of these animals. When
the intestines of a dog, or any other quadruped, are
suddenly cut into different portions, all of them crawl
about like worms, and contract upon the slightest touch.
The heart, intestines, and diaphragm, are the most
irritable parts of animal bodies; and to discover whe-
ther this quality resides in all plants, experiments should
be made chiefly on leaves, flowers, buds, and the ten-
der fibres of the roots.

The motions of plants are universally ascribed by
our author to irritability, to which also we have ascri-
bced them under the article Animal. The term,
however, requires an explanation; and to give this
in an intelligible manner requires some attention. The
most obvious comparison is that of an electrified thread;
which, on the approach of any unelectrified fibres,
shows a variety of motions, equally surprising with those
of the parts of plants or the muscular fibres cut out
of the body. Could we suppose that the electricity of a
thread might be perceived after it was cut off from
the electrifying fibres, it would show as much irrita-
bility as even the muscular fibres, or portions of the
intestines of animals. We know, from the history of
the torpedo, electrical eel, &c., that there are animals
in which the electric fluid acts in such a manner as to
produce a much more powerful effect than that of gi-
ving motion to the leaves of plants. The readiness,
therefore, with which this fluid is thrown into agita-
tions when any substance in which it acts is touched, is
without doubt the irritability in question; but we have
from thence no more reason to ascribe sensation to
these irritable bodies, than to an electrified bottle when
it discharges itself, or makes a cork-ball play round it.

In a paper read before the Academy of Sciences at
Paris, by M. Brouffonet, the author inclines to con-
found irritability and sensibility together. "The dif-
ferent parts of plants (says he) enjoy the faculty of
motion; but the motions of a vegetable are very dif-
derent in their nature from those of an animal: the most
sensible, those that are produced with most rapidity in
plants, are always influenced by some stimulating cause.
Irritability, which is nothing but sensibility made ma-
nifest by motion, is a general law to which nature has
subjected all living beings; and it is this that con-

ually watches over their preservation. Being more
powerful in animals than in plants, it may be often
confounded in these with phenomena that depend
on a quite different cause. In the vegetable it is only
the organ which is exposed to the action of the stimu-
lating power that moves. Irritation in particular pla-
ces never produces that prompt combination of sen-
factions which we observe in animals; in consequence
of which certain parts are put in motion without being
directly affected, and which otherwise might have been
passive.

"The more perfect the organization in the dif-
drent parts of animals is, the more apparent are the
signs of irritability. The parts that come nearest to
those of vegetables, and in which of consequence the
organization is most imperfect, are the least irritable.
The same law holds with regard to plants; but the
result is opposite: the signs of irritability are most sen-
sible in proportion to the analogy of the parts with
those of animals; and they are imperceptible in those
that are dissimilar. This assertion is proved by what
we observe in the organs defined in vegetables to per-
petuate the species. Those parts alone seem sensible
to stimuli; the bark, leaves, stalks, and roots showing
no signs of irritability.

"The vital motions in plants are slow, and entirely
determined by circumstances, which are always re-
peated and equally diffused over all the parts. In ani-
mals, on the contrary, almost all the vital motions are
very sensible; such as the pulsations of the heart and
arteries, the dilation of the thorax, &c.; these being
absolutely necessary to the preservation of the in-
dividual, are always reproduced in a similar manner
in those of the same species, and in the same direc-
tion; and this takes place in like manner in plants. The
twining plants, for instance such as the hop, follow
continually, as they twine themselves round a pole, the
direction of the south towards the west. If vegetables
are obstructed in exercising these motions, they soon
perish; if, for example, we untwist a twining plant
which had taken its direction round a branch from the
right to the left, and place it in a contrary direction,
it withers in a short time; especially if it has not vi-
going enough to regain its natural situation. We bring
death in the same manner on an animal, if we inter-
rupt any of its vital motions. The law by which
plants are forced to move in a particular manner is
very powerful. When two twining plants, one of which
is weaker than the other, for example two plants of
woodbine, happen to encounter, they twine round each
other, the one directing itself to the right and the
other to the left: this last is always the weakest; it
is forced to take a direction contrary to that which it
would have done if it had not met with the other;
but if by any accident, these two twigs of woodbine
should come afterwards to be separated, they both re-
fuse their natural direction, that is from right to left.

"The motions essentially vital, which have in plants
the greatest affinity with those of animals, are the course
of the sap, the passage of the air in the trachea, the
different positions which the flowers of certain plants
take at certain hours of the day &c. But if we attend
to the manner in which all these motions in plants are
performed, we will find that they present a greater
number
number of modifications than the analogous motions that take place in animals. The temperature of the atmosphere, its agitation, light, &c. have great influence on the motion of plants, by accelerating or retarding the course of their fluids; and, as they cannot change their place, these variations produce in them changes more obvious and more uniform than in animals.

Our author now proceeds to inform us, that some of the motions of plants are occasioned by the rarity of the juices in plants, and others by their abundance. Of the former kind are those by which the capules of some plants suddenly burst with a spring, and throw their seeds to some distance. Of the other kind are the action of the stamina in the parietaria, the infection of the peduncles of flowers, and of the ptililla. "These motions (says he) which are particularly observed in the organs defined to the reproduction of the individual, not appearing except in circumstances that render them absolutely necessary, seem in some measure to be the effect of a particular combination: they are, however, merely mechanical; for they are always produced in the same way and in the same circumstances. Thus the rose of Jericho, and the dry fruit of several species of mossambiantum, do not open but when their veftiles are full of water.

"The sudden disengagement of fluids produces a kind of motion. To this cause we must attribute a great number of phenomena observable in the leaves of several plants, and which do not depend on irritability. The small glands in each leaf of the diosna are no sooner punctured by an insect than it instantly folds up and seizes the animal; the puncture seems to operate a disengagement of the fluid which kept the leaf expanded by filling its veftiles. This explanation is the more probable, that in the early state of the vegetation of this plant, when the small glands are hardly evolved, and when probably the juices do not run in sufficient abundance, the leaves are folded up exactly as they appear when punctured by an insect at a more advanced period. We observe a phenomenon similar to this in both species of the drosera (lentew). The mechanism here is very easily observable: the leaves are at first folded up; the juices are not yet propelled into the fine hairs with which they are covered; but after they are expanded, the presence of the fluid is manifest by a drop seen at the extremity of each hair; it is by absorbing this fluid that an insect emptyes the veftiles of the leaf, which then folds up, and refumes its first state: the promptitude of the action is proportioned to the number of hairs touched by the insect. This motion in some degree resembles that which takes place in the limb of an animal kept, in a state of flexion by a tumour in the joint; when the matter which obstructed the motion is discharged, the limb instantly refumes its former position. The phenomena that depend on the abundance of fluids are particularly evident in plants which grow in wet soils; the drosera and diosna are of this kind; and it is known by the experiments of Mefc. Du Fay and Du Hamel, that sensitive plants are particularly sensible when the sun is obscured by clouds and the air warm and moist. The influence of external causes sometimes modifies the vital motion in plants, that we would be tempted to ascribe them to volution, like those that depend entirely on that faculty in animals. If we set a pole in the ground near a twining plant, it always lays hold of the pole for support. in whatever place we put it. The same thing occurs in the tendrils of the vine; which always attach themselves to the support presented to them on whatever side it may be placed, provided they can reach it; but these motions are entirely vital: the twining plants and the tendrils direct themselves to every quarter, and consequently cannot fail of meeting with the bodies within their reach. These motions are performed as long as the parts continue to grow; but when they cease to elongate, if they have not been able to reach any body on which they can fix, they bend back upon themselves. This and other observations show how far the vital motions in plants may be modified by external causes, and how essentially they differ from those that are the effect of volution in animals.

"Some plants appear endowed with no sort of motion; some have leaves that can move in different directions; but none appear so eminently poftificd of this quality as the beecheryngspray of Linnæus.——No part of this plant shows any sign of irritability upon application of the hand: and the motion of its foliaceous leaves when the leaves are agitated by the wind.—When the sun is warm, the little leaves of the bedy-sarum are also immoveable; but when the weather is warm and moist, or when it rains, they move very freely. This motion seems indispensably necessary to the plant; for it begins as soon as the first leaves unfold, and continues even during the night; but in time it grows weaker. In our stoves it is most considerable during the first year; in the second it is not very sensible: in its native place all the leaves have a motion never observed here. The moving leaflets are most agitated while the plants are in full flower, and the process of fructification goes on. The oscillatory motion is so natural to it, that it not only remains for three or four days in the leaves of a branch that has been cut off and put in water, but is even continued though the branch be extended to the air. The leaves seem to perform the office of the heart in vegetables. When a plant is stripped of its leaves, the progress of vegetation is arrested; and such vegetables resemble those animals which have a periodic sleep, induced by a diminution of the action of the heart. Many plants hardly show any signs of motion; many seem also wholly cataleptic; which is rarely ever found in animals. The footstalks of the flowers of dracocephalum, a Virginian plant, preserve themselves in whatever position they are placed.

Muscular Motion. See Muscle.

MOTIVE, is sometimes applied to that faculty of the human mind, by which we pursue good and avoid evil. Thus Hobbes distinguishes the faculties of the mind into two forts, the cognitive and motive.

MOTTE (Anthony Houdart de la), an ingenious Frenchman, greatly distinguished by his writings in prose and verse, and by his literary comedy, very eminent for his talents, was born at Paris in 1672. He wrote with very different success; no man having been more praised or more criticized than he was: his literary para-

doses,
doxes, his singular system, in all branches of polite learning, and above all his judgment upon the ancients, which, like those of Perrault, were thought disreputable and detracting, raised him up formidable adversaries. Racine Boileau, Roufeau, and Madame Dacier, were among the number of those who made it their business to avenge antiquity on a man who, with more wit than genius or learning, afforded a kind of dictatorial authority in the province of belles letters. He became blind in the latter years of his life, and died in 1731. He wrote a great deal in epic poetry, tragedy, comedy, lyric, pastoral, and fables; besides a vast variety of discourses, critical and academical, in prose. A complete edition of all his works was published in 1754; though, as has been said of our Swift, his reputation had been better consulted by reducing them to three or four.

MOTOUALIS, a small nation of Syria, inhabiting the eait of the country of the Druzes, in the valley which separates their mountains from those of Damascus; of which the following account is given by Mr. Volney in his Travels, vol. ii. p. 48.

The characteristic division between them and the other inhabitants of Syria (says our author) is, that they, like the Persians, are of the sect of Ali, while all the Turks follow that of Omar, or Moaouia. This division, occasioned by the schism which in the 36th year of the Hejira arose among the Arabs, respecting the sufeceffors of Mahomet, is the cause of an irreconcilable hatred between the two parties. The sectaries of Omar, who consider themselves as the only orthodox, assume the title of Sunnites which has that signification, and term their adversaries Shiites, that is sectaries of Ali.” The word Motoualis has the same meaning in this dialect of Syria. The followers of Ali, dissatisfied with this name, substituted that of Adlia, which means “affairors of justice,” literally “Jufliciators;” a denomination which they have assumed in consequence of a doctrinal point they advance in opposition to the Sunnite faith. A small Arabic treatife, entitled Theological Fragments concerning the Sects and Religions of the World, has the following passage:

“Those sectaries who pretend that God acts only on principles of justice, conformable to human reason, are called Adlia or Jufliciators. God cannot (say they) command an impracticable worship, nor ordain impossible actions, nor enjoin men to perform what is beyond their ability; but wherever he requires obedience, will bellow the powers to obey. He removes the cause of evil, he allows us to reason, and imposes only what is easy, not what is difficult; he makes no man responsible for the actions of another, nor punishes him for that in which he has no part: he imputes not as a crime what himself has created in man; nor does he require him to avoid what deftiny has decreed. This would be injustice and tyranny, of which God is incapable from the perfection of his being.”

To this doctrine, which diametrically opposes the system of the Sunnites, the Motoualis add certain ceremonies which increase their mutual aversion. They curse Omar and Moaouia as rebels and usurpers; and celebrate Ali and Hophin as saints and martyrs. They begin their ablutions at the elbow, instead of the end of the finger, as is customary with the Turks; they think themselves defiled by the touch of strangers; and, contrary to the general practice of the East, neither eat nor drink out of a vessel which has been used by a person not of their sect, nor will they even fit with such at the same table.

These doctrines and customs, by separating the Motoualis from their neighbours have rendered them a distinct society. It is said they have long existed as a nation in this country, though their name has never been mentioned by any European writer before the present century; it is not even to be found in the maps of Donville: La Roque, who left their country not a hundred years ago, gives them the name of Me'ladies. Be this as it may, in latter times their wars, robberies, succeffes, and various changes of fortune, have rendered them of confidence in Syria. till about the middle of this century, they only possessed Balbek their capital, and a few places in the valley, and Anti-Lebanon, which seems to have been their original country. At that period we find them under a like government with the Druzes, that is to say, under a number of Shaiks, with one principal chief of the family of Harfouih. After the year 1750 they established themselves among the heights of Bekaa, and got footing in Lebanon, where they obtained lands belonging to the Maronites, almost as far as Baehraal. They even encompassed them so much by their ravages, as to oblige the Emir Youfuf to attack them with open force and expel them; but on the other fide, they advanced along the river even to the neighbourhood or Sour, (Tyre). In this situation, Shaik Daher had the address, in 1760, to attach them to his party. The pachas of Saide and Damascus claimed tributes, which they have neglected paying, and complained of several robberies committed on their people by the Motoualis; they were delirious of chastifying them; but this vengeance was neither certain nor easy. Daher interposed; and by becoming security for the tribute; and promising to prevent any depredations, acquired allies who were able, as it is said, to arm 10,000 horfemen, all reftored and formidable troops. Shortly after they took thofe of Sour, and made this village the principal fea-port. In 1771 they were of great service of Ali Bey and Daher againft the Ottomans. But Emir Youfuf having in their abfence armed the Druzes, and ravaged their country. He was besieging the castle of Djezin when the Motoualis, returning from Damascus, received intelligence of this invasion. At the relation of the barbarites committed by the Druzes, an advanced corps, of only 500 men, were fo enraged, that they immediately rushed forward against the enemy, determined to perifh in taking vengeance. But the fpirit and confufion they occasioned, and the difcord which reigned between the two factions of Mofaour and Youfuf so much favoured this desperate attack, that the whole army, confifting of 25,000 men, was completely overthrown.

In the following year, the affairs of Daher taking a favourable turn, the zeal of the Motoualis cooled towards him, and they finally abandoned him in the catastrophe in which he loft his life. But they have suffered for their imprudence under the administration of the pachas who succeeded him. Since the year 1777, Djezzar, mafter of Acre and Saide has incessantly
A top of the spring arbor is or barrel, which stops it in motteux gently laboured to possess it. But the
profiteers were able to heritable
sold it. At this period not more than 500 families of the Motoualis remained, who took refuge in Anti-
Lebanon, and the Lebanon of the Maronites; and
driven, as they now are from their native soil, it is probable
they will be totally annihilated, and even their
very name become extinct.

Motteux (Peter), a French gentleman, born
and educated at Rouen in Normandy. Coming over
to England on account of the persecution of the
Protestants, he became a considerable trader in London,
kept an East-India warehouse in Leadenhall-street,
and had a genteel place in the general post-office,
relating to foreign letters, being master of several
languages. He was a man of wit and humour; and
acquired so perfect a mastery of the English language,
that he not only was qualified to oblige the world with
a very good translation of Don Quixote, but also
wrote several songs, prologues, epilogues, &c. and
what was still more extraordinary, became a very eminent
commercial writer in a language to which he was
not a native. He was at last, in the year 1718, found
dead in a disorderly way, and he completed his 58th year.

Motto, in armature, a short sentence or phrase,
carried in a scroll, generally under, but sometimes over,
the arms; sometimes alluding to the bearing, sometimes
to the name of the bearer, and sometimes containing
whatever pleases the fancy of the deviser.

Moucho Motteux. See Agaricus.

Moveable, in general, denotes any thing capable
of being moved.

Moveable Feasts, are such as are not always held
on the same day of the year or month; though they
are on the same day of the week. See Feasts.

Thus, Easter is a moveable feast, being always held
on the Sunday which falls upon or next after the first
full moon following the 21st of March.

All the other moveable feasts follow Easter, i.e. they
keep their distance from it; so that they are fixed with
respect thereto.

Such are Septuagesima, Sexagesima, Ash-Wednesday,
Ascension-day, Pentecost, Trinity-Sunday, &c.
which are under their proper articles, Septuagesima,
&c.

Moveable Subject, in law, any thing that moves itself,
or can be moved; in contradistinction to immovable
or heritable subjects, as lands, houses, &c.

Movement, motion, a term frequently used in
the same sense with automaton.

The most usual movements for keeping time are
watches and clocks: the first are such as show the parts
time, and are portable in the pocket; the second,
such as publish it by sounds, and are fixed as furniture.

Movement, in its popular use among us, signifies
all the inner work of a watch, clock, or other engine,
which move, and by that motion carry on the design
of the instrument.

The movement of a clock or watch is the inside,
or that part which measures the time, strikes, &c.
exclusive of the frame, dial, plate, &c.

The parts common to both of these movements are,
the main spring, with its appended wheel, lying in the
spring-box, and in the middle thereof lying about the
spring-arbor, to which one end of it is fastened.
A top of the spring arbor is the endless screw and its
wheel; but in spring-clocks, this is a ratchet-wheel with
its click, that stops it. That which the main spring
draws, and round which the chain or firing is wrapped,
is called the fuse; this is ordinarily taper; in large
works, going with weights, it is cylindrical, and called
the barrel.

The small teeth at the bottom of the fuse or barrel, which flap it in winding up, is called the
ratchet; and that which flaps it when wound up,
and is for that end driven up by the spring, the
garde-vent. The wheels are various: the parts of a wheel are, the
hoop or rim; the teeth, the cogs, and the collet or
piece of brass folded on the arbor or spindle whereon
the wheel is rivetted. The little wheels playing in
the teeth of the larger are called pinions; and their teeth,
which are 4, 5, 6, 8, &c. are called foars; the ends of
the pinicle are called pinion, and the guttered wheel,
with iron spikes at bottom, wherein the line of ordinary
clocks runs, the pulley. We need not say anything
of the hand, screws, wedges, flaps, &c. See Wheel,
Fuse, &c.

Perpetual Movement. Many have attempted to
find a perpetual movement, but without success;
and there is reason to think, from the principles of
mechanics, that such a movement is impossible: for though,
in many cases of bodies acting upon one another,
there is a gain of absolute motion, yet the gain is
always equal in opposite directions; so that the quantity
of direct motion is never increased.

To make a perpetual movement, it appears necessary
that a certain system of bodies, of a determined
number and quantity, should move in a certain space
for ever, and in a certain way and manner; and for this
there must be a series of actions returning in a
circle, otherwise the movement will not be perpetual;
so that any action by which the absolute quantity of
force is increased, of which there are several forms,
must have its corresponding counter-action, by which
the gain is destroyed, and the quantity of force re-
turned to its first state.

Thus by these actions there will never be any gain
of direct force to overcome the friction and resistance
of the medium; so that every motion being diminished
by their resistances, they must at length languish and cease.

Moufet (Thomas), a celebrated English physician,
was born at London, and practised medicine with
great reputation. Towards the latter end of his
life he retired to the country, and died about the year
1600. This physician is known by a work which was
begun by Edward Wotton, and printed at London in
Vol. XII.
1634, folio, with the title of Theatrum Iudiciorum. A translation of it into English was published at London in 1638, folio. Martin Lister gives a very unfavourable opinion of this book: "As Moutet (says he) made use of Wotton, Gesner, &c. an excellent work might have been expected from him; and yet his Theatrum is full of confusion, and he has made as very bad use of the materials with which these authors have furnished him. He is ignorant of the subject of which he treats, and his manner of expression is altogether barbarous. Besides this, he is extremely arrogant, to say no worse; for though he has copied Aldrovandus in innumerable places, he never once mentions his name." But Ray thinks that Lister, by expressing himself in this manner, has not done justice to Moutet; and he maintains that the latter has rendered an essential service to the republic of letters.

MOUG-DEH, or CHEN-YANG; a city of Chinese Tartary, and capital of the country of the Mantchews or eastern Tartars. These people have been at great pains to ornament it with several public edifices, and to provide it with magazines of arms and storehouses. They consider it as the principal place of their nation; and since China has been under their dominion, they have embellished the same tribunals here as at Peking, excepting that called Lii-pou; these tribunals are composed of Tartars only; their determination is final; and in all their acts they use the Tartar characters and language. The city is built on an eminence: a number of rivers add much to the fertility of the surrounding country. It may be considered as a double city, of which one is inclosed within the other: the interior contains the emperor's palace, hotels of the principal mandarins, foreign courts, and the different tribunals; the exterior is inhabited by the common people, tradesmen, and all those who by their employments or professions are not obliged to lodge in the interior. The latter is almost a league in circumference; and the walls which inclose both are more than three leagues round: these walls were entirely rebuilt in 1631, and repaired several times under the reign of Kang-hi. Near the gates are two magnificent tombs of the first emperors of the reigning family, built in the Chinese manner, and surrounded by a thick wall furnished with battlements; the care of them is entrusted to several Mantchew mandarins, who at stated times are obliged to perform certain usual ceremonies; a duty which they acquit themselves of with the same marks of respect and veneration as if their masters were still living.

MOVING PLANTS. See Hedysarum, Tremella, and Mimosa.

MOULD, or MOLD, in the mechanic arts, &c. a cavity artfully cut, with design to give its form or impression to some softer matter applied therein. Moulds are implements of great use in sculpture, foundry, &c. The workmen employed in melting the mineral or metallic glebe dug out of mines, have each several moulds to receive the melted metal as it comes out of the furnace; but these are different according to the diversity of metals and works. In gold mines, they have moulds for ingots; in silver mines, for bars; in copper and lead mines, for pigs or lamons; in tin mines, for pigs and ingots; and in iron mines, for fows, chimney-backs, anvils, caldrons, pots, and other large utensils and merchandizes of iron, which are here cast, as it were, at first hand.

Moulds of founders of large works, as statues, bells, guns, and other brazen works, are of wax, supported within-side by what we call a core, and covered without-side with a cap or case. It is in the space which the wax took up, which is afterwards melted away to leave it free, that the liquid metal runs, and the work is formed; being carried thither through a great number of little canals, which cover the whole mould. See Foundery.

Moulds of moneyers are frames full of sand, wherein the plates of metal are cast that are to serve for the striking of species of gold and silver. See COINING.

A sort of concave moulds made of clay, having within them the figures and inscriptions of ancient Roman coins, are found in many parts of England, and supposed to have been used for the striking of money. Mr Baker having been favoured with a light of some of these moulds found in Shropshire, bearing the same types and inscriptions with some of the Roman coins, gave an account of them to the Royal Society. They were found in digging of sand, at a place called Ryton in Shropshire, about a mile from the Roman street road. They are all of the size of the Roman denarius, and of little more than the thickness of our halfpenny. They are made of a smooth pot or brick clay, which seems to have been first well cleaned from dirt and sand, and well beat or kneaded, to render it fit for taking a fair impression. There were a great many of them found together, and there are of them not unfrequently found in Yorkshire; but they do not seem to have been met with in any other kingdom, except that some have been said to be once found at Lyons. They have been sometimes found in great numbers joined together side by side, on one flat piece of clay, as if intended for the striking of a great number of coins at once; and both these, and all the others that have been found, seem to have been of the emperor Severus. They are sometimes found impressed on both sides, and some have the head of Severus on one side and some well known reverse of his on the other. They seem plainly to have been intended for the coinage of money, though it is not easy to say in what manner they can have been employed to that purpose, especially those which have impressions on both sides, unless it may be supposed that they coined two pieces at the same time by the help of three moulds, of which this was to be the middle one. If by disposeing these into some sort of iron frame or case, as our letter-founders do the brass moulds for casting their types, the melted metal could be easily poured into them, it would certainly be a very easy method of coining, as such moulds require little time or expense to make, and therefore might be supplied with new ones as often as they happen to break.

Thes moulds seem to have been burnt or baked sufficiently to make them hard; but not so as to render them porous like our bricks, whereby they would have lost their smooth and even surface, which in these is plainly to close, that whatever metal should be formed in them would have no appearance like the sand-holes.
Moulds of founders of small works are like the frames of coiners; it is in these frames, which are likewise filled with sand, that their several works are fashioned; into which, when the two frames, whereof the mould is composed, are rejoined, the melted brass is run. Moulds of letter-founders, are partly of steel and partly wood. The wood, properly fashioned into which, when the two frames, whereof the mould is composed, are rejoined, the melted brass is tenoned. Moulds, in the manufacture of paper, are little frames composed of several brass or iron wires, fastened together by another wire still finer. Each mould is of the bigness of the sheet of paper to be made, and has a rim or ledge of wood to which the wires are fastened. These moulds are more usually called frames or forms. See Paper-Making.

Moulds, with furnace and crucible makers, are made of wood, of the same form with the crucibles; that is, in form of a truncated cone: they have handles of wood to hold and turn them with, when being covered with the earth, the workman has a mind to round or flatten his vessel. Moulds for leaden bullets are little iron pincers, each of whose branches terminates in a hemispherical concave, which when shut form an entire sphere. In the lips or sides where the branches meet, is a little jet or hole, through which the melted lead is conveyed. Laterns, Moulds, are made of wood, for filling and driving all sorts of rockets and cartridges, &c. Glaziers' Moulds. The glaziers have two kinds of moulds, both serving to cast their lead: in the one they cast the lead into long rods or canes fit to be drawn through the vice, and the grooves formed therein; this, they sometimes call ingot-mould. In the other, they mould those little pieces of lead a line thick and two lines broad, fastened to the iron bars. These may also cast in the vice. Goldsmiths' Moulds. The goldsmiths use the bones of the cuttle-fish to make moulds for their small works; which they do by pressing the pattern between two bones, and leaving a jet or hole to convey the silver through, after the pattern has been taken out. Moulds, among masons, is a piece of hard wood or iron, hollowed within side, answerable to the contours of the mouldings or cornices, &c. to be formed. This is likewise called caliver. Moulds, among plumbers, are the tables whereon they cast their sheets of lead. These they sometimes call simply tabler. Besides which they have other real moulds, wherewith they cast pipes without folding. See each described under Plombery. Moulds, among glaziers-grinders, are wooden frames, whereon they make the tubes wherewith they fit their spectacles, telescopes, and other optical machines. These moulds are cylinders, of a length and diameter according to the use they are to be applied to, but always thicker at one end than the other, to facilitate the sliding. The tubes made on these moulds are of two kinds; the one simply of plateboard and paper; the other of thin leaves of wood joined to the plateboard. To make these tubes to draw out, only the last or innermost is formed on the mould; each tube made afterwards serving as a mould to that which is to go over it, but without taking out the mould from the first. See Grinding.

Moulds used in basket-making are very simple, consisting ordinarily of a willow or osier turned or bent into an oval circle, square, or other figure, according to the baskets, panniers, hampers, and other utensils intended. On these moulds they make, or more properly measure, all their work; and accordingly they have them of all sizes, shapes, &c. Mould, in ship-building, a thin flexible piece of timber, used by shipwrights as a pattern whereby to form the different curves of the timbers, and other compalling pieces in a ship's frame. There are two sorts of these, viz. the bend-mould and hollow-mould; the former of these determines the convexity of the timbers, and the latter their concavity on the outside, where they approach the heel, particularly towards the extremities of the vessel. The figure given to the timbers by this pattern is called their bevelling. Moulds, among tallow-chandlers, are of two kinds: the first for the common dipped candles, being the vessel wherein the melted tallow is dispofed, and the wick dipped. This is of wood, of a triangular form, and supported on one of its angles; so that it has an opening of near a foot at top: the other, used in the fabric of mould candles, is of brass, pewter, or tin. Here each candle has its several mould. See Candel. Moulds, among gold-beaters, a certain number of leaves of vellum or pieces of guts cut square, of a certain size, and laid over one another, between which they put the leaves of gold and silver which they beat on the marble with the hammer. See Gold-Leaf.

They have four kinds of moulds; two whereof are of vellum and two of gut: the smallest of those vellum consists of 40 or 50 leaves; the largest contains 100: for the others, each contain 500 leaves. The moulds have all their several casts, consisting of two pieces of parchment, confifting of the mould in their place, and prevent their being disordered in beating. Mould, in agriculture, a general name for the soft earthy substance with which the dry land is generally covered, and in which all kinds of vegetables take root and grow. It is, however, far from being an homogeneous substance; being compounded of decayed animal and vegetable matters, calcareous, argillaceous, and siliaceous earths, all mixed together in various proportions, and with the different degrees of moisture, constituting all the varieties of soil throughout the world. All kinds of mould contain some inflammable substance, which remains in them from the decayed animals and vegetables; and they are more or less black in proportion to the quantity of phlogiston they contain. The black mould yields by distillation a volatile alkali and oil. MOULDINESS, a term applied to bodies which corrupt in the air, from some hidden principle of humidity therein; and whose corruption shows itself by a certain white down or lanugo on their surface, which viewed through a microscope appears like a kind of meadow, out of which unripe herbs and flowers, some only in the bud, others full-blown, and others decayed; each having its root, stalk, and other parts. See Mucor.
MOULDING, any thing cast in a mould, or that seems to have been so, though in reality it were cut with a chisel or the axe.

Mouldings in architecture, projections beyond the naked wall, column, window, &c. the assemblage of which forms cornices, door-cases, and other decorations of Architecture. See that article.

Moulin (Charles du), a celebrated civilian, and one of the most learned men of the 16th century, was born of a considerable family at Paris in 1500, and acquired great reputation by his skill in the law. He published many works, which have been collected together, and printed in five volumes folio; and are justly considered as the most excellent works that France has produced on the subject of civil law. He died at Paris in 1566.

Moulin (Peter du), a Protestant divine, believed to be of the same family with the former, was born in 1568. He taught philosophy at Leyden; and afterwards became chaplain to the princes of Navarre. At the king of England's desire he came to England in 1615, and prepared a plan for the union of the Protestant churches. The university of Leyden offered him a professorship of divinity in 1619; but he refused it, and prefided at the synod held by the Calvinists at Alais in 1620. Some time after, being informed by Mr Drelincourt that the French king resolved to have him thrown into prison, he retired to Sedan, where the duke de Bouillon made him professor of divinity, and minister in ordinary. He was employed by the Calvinists in the most important affairs; and died at Sedan in 1628. His principal works are, 1. The anatomy of Arminianism. 2. A treatise on repentance, and the keys of the church. 3. The capuchine, or the history of those monks. 4. The buttler of faith, or a defence of the reformed churches. 5. The judge of controversies and traditions. 6. The anatomy of the mafs. 7. The novelty of Popery.

Peter du Moulin, his eldest son was chaplain to Charles II. of England, and prebendary of Canterbury, where he died in 1684, aged 84. He wrote, 1. The peace of the soul, in French. 2. Clamor regii fanginiis; which Milton, by mistake, attributed to Alexander Morus. 3. A defence of the Protestant religion, in English.

Moulins, a town of France, and capital of Bourbonnais. The houses of the Chartreux, and that of the Visitation, are magnificent. It carries on a considerable trade in cutlery ware, and is seated on the river Allier, in a pleasant fertile plain, almost in the middle of France, 30 miles south of Nevers, and 55 miles south of Clermont.

Moulton (North), a town of Devonshire on the river Moul, and the north side of South Moulton, Moulting of whose hundred it is a member, and anciently gave name to it, as the latter does now. It has two fairs, on Tuesday after May 11, and on Nov. 12.

Moulton (South) on the same stream, 182 miles from London. This, as well as the former, was anciently a royal demeane. This corporation, which once sent members to parliament in the reign of Edward I., consists of a mayor, 18 capital burgesses, a recorder, town-clerk, and 2 serjeants at law. Here is a market on Saturdays; and fairs are held the first Tuesday after May 11, and Nov. 12. Their chief manufactures are serge, shawls, and felts; and great quantities of wool brought from the country are bought up here every Saturday. In the year 1684, a merchant of London, a native of this town, built and endowed a free-school here; besides which, here is a charity-school.

Mouling, or Moulting, the falling off or change of hair, feathers, skins, horns, or other parts of animals, happening in some annually, in others only at certain stages of their life.

The generality of animals moult in the spring. The mouling of a hawk is called mewing. The mouling of a deer is the quitting of his horns in February or March. The mouling of a serpent is the putting off his skin. See EXUVIAE.

Mound, a term used for a bank or rampart, or other fence, particularly that of earth.

Mounb, in heraldry, a ball or globe with a cross upon it, such as the British kings are usually drawn with, holding it in their left hand, as they do the sceptre in the right.

Mount, an elevation of earth, called also mountain. See Mountain.

Mount Edgecumbe, a prodigious high peak, at the entrance of Cook's strait, in New Zealand, on the west side. Its height is supposed not to be much inferior to that of the peak of Teneriffe.

Mount-Sorrel, a town in Leicestershire, so named from a high mount or solid rock adjoining to the town, of a dusky red or forre-coloured stone, extremely hard. Of rough stones hewn out of this rock the town is built. It has a market on Mondays. It was noted formerly for its cattle, and is seated on the river Stour, over which there is a bridge. It is 20 miles south west of Derby, and 105 north west of North London. W. Long. 1. 9. N. Lat. 52. 45.

Mount of Piety, certain funds or establishments in Italy, where money is lent out on some small security. There were also mounds of Piety in England, raised by contribution for the benefit of people ruined by the extortions of the Jews.

Mountain (Moun), a considerable eminence of land, elevated above every thing adjoining to it, and commanding all the surrounding places: It is commonly full of inequalities, cavities more or less exposed, and strata half laid open.

This name is likewise given to a chain of mountains; as when we speak of Mount Atlas in Africa; Mount Caucasus, which begins above Colchis and ends at the Caipian sea; the Pyrenean mountains, which separate France from Italy; and the Appenine mountains, which run through the whole of Italy.

Those who have surveyed the earth in general, and studied.

Mountain.
this kind is connected with the land, and advances farther into the sea than the adjoining country, it is then termed a Cape, Head, or Promontory, such as the Cape of Good Hope at the southern extremity of Africa. Mountains of the second rank are commonly more easy of access. Dr. Haller observes, that the angle formed between their base and their declivity is larger; that they have fewer springs; and that their plants are different from those of the Alps. The peasants in Switzerland, he tells us, are acquainted with the difference between these two kinds of mountains.

Those mountains, whether arranged in a group or not, the earth or stone of which is disposed in strata more or less regular, and consisting of one or more colours and substances, are produced by the substructions deposited flowly and gradually by the waters, or by soil gained at the time of great floods. We daily see little hills formed in this manner, which are always of a small height compared with those of the first order, and round in the top, or covered with soil, frequently forming a pretty flat and extensive surface. We there find earth and heaps of round pebbles like such as are known by the waters. The internal part of these mountains consists of a heap of strata almost horizontal, and containing a prodigious quantity of shells, marine bodies, and fish-bones. Although these mountains formed by strata sometimes degenerate into little hills, and even become almost flat, they always consist of an immense collection of fossils of different kinds, in great perfection, and which are pretty easily obtained from their surface. Dr. Haller observes, that there are many places in the Alps and in mountains, where two chains are prolonged contrary to the axis of the valley, and join so as to leave as much space as is necessary for the discharge of the water. In other places the mountain is continued, in a single line, to the north, and discontinued to the south, where it opens into a valley. In others, the two chains retire and form a bend on each side, the concavity of which fronts the axis; hence arise valleys almost round and completely united.

It is likewise worthy of observation, that primitive mountains which form great chains are commonly connected together; that they succeed one another for a space of several hundred leagues; and cover with their principal branches, and their various collateral ramifications, the surface of continents. Father Kircher and many others have observed, that the principal chain generally runs from south to north, and from east to west. The Cordilleras in the New world, Dr. Haller observes, extend from north to south; the Pyrenees have nearly the same direction; the Alps run from east to west; and there must be a chain of this kind in Africa, for the great rivers in that quarter of the world run to the east on the one side and to the west on the other. The chain of Thibet appears to be parallel to the Alps; and, from the great length of the road through the snows, it may be inferred that the mountains of Thibet have a very great elevation. Those mountains which, strictly speaking, are the principal roots, and the capital point of elevation and division, present very considerable mazes, both with regard to their height and size or extent; they commonly occupy and traverse the centre of continents.

Those
Mountains. Those which have a smaller elevation arise from the principal chains; they gradually diminish in proportion to their distance from their root, and at length wholly disappear either on the equator or in the plains. Others are continued along the shores of the sea; their chain is interrupted only to make room for the waters of the ocean, under the bed of which the base of these mountains extends, and it again occurs in islands, which, however, their continuation till the whole chain re-appears. The highest mountains and the greatest number of islands are generally found between or near the tropics, and in the middle of the temperate zones; while the lowest are adjacent to the poles; though this does not always hold good without exception.

M. Buache, a member of the Academy of Sciences at Paris, has laid down a system of physical geography concerning the structure of the terrestrial globe, considered with respect to the great chains of mountains which cross the continents and seas from pole to pole, and from east to west. According to this system, there is an uninterrupted series of mountains and high grounds which divide the earth into four quadrants, from which the rivers descend. These chains of mountains are continued from one continent to another under the ocean; and the islands which are observed in it, are as it were the umbrellas of the mountains. M. Buache's work is entitled Tables et Cartes de la Geographie physique. But that this system, with regard to the islands, must be erroneous, will appear evident from our article Earth.

In the Journal de Physique for May 1779, we are informed, that Dr Pallas, who has travelled through Siberia, and almost all the Russian empire in the north of Asia, thinks he has discovered the insufficiency of the principal systems hitherto proposed to account for the formation of mountains. This accurate observer has prosecuted the study of mountains by traversing immense regions, and visiting as it were the secret work shops of nature in almost the fourth part of our hemisphere. He has not truiled to the vague reports of others, but from observations which he himself had occasion to make for the space of ten years; he has, in a work entitled Observations on Mountains, explained both the direction of the northern chains, and the particular composition of each. He is thence led to make an ingenious conjecture concerning the formation of the principal groups of mountains, and concerning the irregular distribution and the figure of the whole continent. Under the article Earth an account is given of the different systems which have been formed concerning the formation and configuration of our globe. To establish a general system, it would perhaps be necessary to have travelled over the whole earth; and to have studied all the chains of mountains, their direction, and particular composition, for a long series of years. Thus very little attention is required to perceive, in the different systems mentioned under the article Earth, the influence of climate and local situation. Burnet, Whiston, and Woodward, who were acquainted only with England, where very few great chains of mountains are to be seen, where they are almost all isolated or detached, and where the soil of extensive plains is formed by horizontal and regular strata, naturally thought that these general and concentric strata were to be found all around the globe; and considered mountains as nothing but the wrecks of the great chain of these strata, either raised or swallowed up by the violence of the waters. Scheuchzer, who studied among the steep mountains of Switzerland, and rocks of granite, porphyry, Jasper, and hard stones, and who found nothing on the most elevated plains of the Alps but strata of similar substances, held recourse to the power of the Almighty, who brake these strata, and elevated their splinters into the form of mountains. Ray, Moro, and Cetone, who saw nothing all around them but burning mountains and traces of volcanic productions—derived by the constitution of the hills of Italy, which are almost all formed of lava, pizzolana, and basaltic substances, and by the origin of the Monte Nuovo, which rose up almost before their eyes, have considered great mountains as formed by a cause which undoubtedly has a secondary, but to which they have ascribed a primary and principal, influence. M. de Buffon, who delineated nature at the foot of the utmost extremity of the French Alps, and who perceived them gradually attain a greater elevation as they advanced towards the southern parts of France and towards Savoy, concluded from his theory, and in support of the same theory, that the highest mountains were near the equator; that they became lower towards the poles; and that, being produced by the flux and reflux of the sea, they were formed of the subflantity which is deposited.

We shall now lay before our readers the geographical description of the directions of the principal mountains, and of that kind of connection which subsists between them. This description differs from that of M Buache, and may be read with a map of the world before us.

M. Buache places the most elevated points of the great chain of mountains under the equatorial line; but according to the author whom we follow in this place, the fullest and most continuous lands, and perhaps likewise the most elevated, are to be found at a distance from the equator, and towards the temperate zones. If, in fact, we survey the globe's surface, we will not be able to perceive that chain of mountains, which running from east to west, and dividing the earth into two portions, ought again to meet. On the contrary, extensive plains seem to accompany the line through almost its whole extent. In Africa, the deserts of Nigritia, and those of Upper Ethiopia, are on the one side of the line; and on the other are the sandy plains of Nicoco, Caffaria, Monemugi, and Zanguebar. From the eastern shores of Africa to the Sunda islands, is a space of 1500 leagues of sea with almost no islands, except the Laccadive and Maldive islands; most part of which have little elevation, and which run from north to south. From the Molucca islands and New Guinea, to the western borders of America, the sea occupies a space of 3000 leagues. Though Chimbororco and Pichincha in America, the two highest mountains which have been measured, are near and even under the line, yet from this no conclusion can be drawn, because on one side these mountains run in a direction not parallel to the equator; the Andes or Cordilleras attain a greater elevation as they remove from the equator towards the poles; and a vast plain is found exactly under the line, between the Oroonooko and the river of the Amazons. Besides, the latter river, which
Mountain, which takes its rise in the province of Lima about the 11th degree of south latitude, after crossing the whole of South America from west to east, falls into the ocean exactly under the equator. This shows that there is a defect for the space of 72 degrees or 300 leagues. From the mouth of the river of the Amazon, to the western shores of Africa, the sea forms another plain of more than 50 degrees.

From the few certain facts and accurate observations which we have received from well informed travellers, we might almost affirm that the most elevated land on our globe is situated without the tropics in the northern and southern hemispheres. By examining the course of the great rivers, we in fact find that they are in general discharged into three great reservoirs, the one under the line, and the other two towards the poles. This, however, we do not mean to lay down as a thing universally true, for it is allowed, that, besides the two elevated belts, the whole surface of the earth is covered with innumerable mountains, either detached from one another or in a continued chain. In America, the Amazon and the river of the Amazonas run towards the line, while the river St Lawrence runs towards the 50th degree of north latitude, and the river de la Plata towards the 40th degree of south latitude. We are still too little acquainted with Africa, which is almost all contained within the tropics, to form any accurate conclusions concerning this subject. Europe and Asia, which form only one great mass, appear to be divided by a more elevated belt, which extends from the most westerly shores of France to the most easterly of China, and to the island of Sakalen or Anga-hata, following pretty nearly the 50th degree of north latitude. In the new continent, therefore, we may consider that chain where the Mifissipii, the river St Lawrence, the Ohio, and the river de los Eftrechos, take their rise, as the most elevated situation in North America; whence the Mifissipii flows towards the equator, the river St Lawrence towards the north-east, and the rest towards the north-west. In the old continent, the belt formerly mentioned, and to which we may assign about 10 degrees in breadth, may be reckoned from the 45th to the 55th degree of north latitude; for in Europe the Tagns, the Danube, the Dnieper, the Don, and the Volga, and in Asia the Indus, the Ganges, the Meran, the Mecon, the Hoang-ho, and the Yangt-tse-Kiang, descending as it were from this elevation, fall into the great reservoir between the tropics; whilst towards the north the Rhine, the Elbe, the Oder, the Vltula, the Obi, the Jenifei, the Lena, the Indigirka, and the Kowyma, are discharged into the northern reservoir.

Judging from these mountains the height of which has been calculated, and from the immense chains with which we are acquainted, we may infer that the highest mountains are to be found in this elevated belt. The Alps of Switzerland and Savoy extend through the 45th, the 46th, and the 47th degrees. Among them we find St Gothard, Furca, Bruning, Rifs, Whiggis, Scheidek, Guggels, Galanda, and lastly that branch of the Swis Alps which reaches Tirol by the name of Arlenberg and Arula. In Savoy, we meet with Mount Blanc, the Peak of Argentiere, Cornero, Great and little St Bernard, Great and Little Cenis, Coupline, Servin, and that branch of the Savoyard Alps which proceeds towards Italy through the duchy of Aosta and Montferrat. In this vast heap of elevated peaks, Mont Blanc and St Gothard are particularly distinguished. The Alps, leaving Switzerland and Savoy, and passing through Tirol and Carniola, traverse Saltzbourg, Stria, and Austria, and extend their branches through Moravia and Bohemia, as far as Poland and Prussia. Between the 47th and 48th degrees, we meet with Grimming the highest mountain of Stria, and Priel which is the highest in Austria. Between the 46th and 47th degrees, the der Bachar and the der Reinchnicken, form two remarkable chains. The upper one, which traverses the counties of Trenchin, Arrava, Scipua, and the Kreyna, separates Upper Hungary from Silefia, Little Poland, and Red Russia; the inferior one traverses Upper Croatia, Bosnia, Servia, and Transylvania, separates Upper Hungary from Turkey in Europe, and meets the upper chain behind Moldavia, on the confines of Little Tartary. In these mountains are situated the rich mines of Schrémnitz.

To form a general idea of the great height of this Alpine belt, it is necessary only to remark, that the greatest depth of the wells at Schrémnitz is 200 toises; and yet it appears from the barometrical calculations of the learned M. Noda, that the greatest depth of these mines is 286 toises higher than the city of Vienna. The granito-argillous mountains of Schrémnitz, and of the whole of this metallic district, are inferior, however, to the Carpathian mountains. Mount Kri-vany in the county of Arrava, and the Carpathian mountains between Red Russia and the Kreyna, appear by their great elevation to rule over the whole of the upper Alpine chain. In the inferior chain we likewise meet with mountains of an extraordinary height; among others, Mount Medednik, which gives its name to a chain extending far into Bosnia; and Mount Hemus, celebrated even among the ancients. In short, this extensive chain reaches into Asia, and is there crowned with another chain no less famous, which, following exactly the 50th degree of latitude, runs through the whole of Asia. This chain of mountains is described by Dr Pallas in the work abovementioned; and we shall now trace its course in company with this intelligent observer.

This author places the head of the mountains of Oural, between the sources of the Taik and the Bie-laia, about the 53d degree of latitude, and the 47th of longitude. Here the European Alps, after having traversed Europe and sent of various branches which we shall afterwards examine, lose their name, which is changed into that of the Uralic or Uralian mountains, and begin their course in Asia. This lofty chain, which separates Great Bulgaria from the deserts of Ichimika, proceeds through the country of the Eleuths, follows the course of the river Iriss, approaches the lake Telekaia, and afterwards forms a part of the same system of mountains with the Altai chain. There they give rise to the Oby, the Irris, and the Jenifei, which begin their course about the 50th degree of north latitude, and fall into the Frozen Ocean.

The Altai chain, after having embraced and united all the rivers which supply the Jenifei, is continued under
Mountain, under the name of Sainoy, without the smallest interruption, as far as the Baikal lake. The extension of the chain to the south forms that immense and elevated plain which is lost in Chinefe Turquie, which may be compared with the only plain in Quito, and which is called Gali or Chamo. The Altai afterwards interposing between the source of the Tchalkei and of the rivers which supply the Amur or Sagalene, rises towards the Lena, approaches the city Jaluck beyond the 60th degree of latitude, runs from that to the sea of Kamtschatka, turns round the Ochockoi and Penfink gulphs, joins the great marine chain of the Kurile islands near Japan, and forms the deep shores of Kamtschatka, between the 55th and 60th degrees of latitude. Such is the direct course of the high mountains confuting the belt which, we imagine, is to be found in the northern hemisphere, and which, after becoming lower, passing under the sea, and forming by means of its elevated peaks that archipelago which derives its name from its fortunate situation. Bhering, again rife and enter North America, on the western side, about the Straits of Anian. After running in the same parallel, and giving rife to the Ohio, the Riviere-Longue, the river St Lawrence, and the Mississipi, they are loft in Canada. From the eastern shores of America to the western shores of Europe, we find a vast interruption. Perhaps the chain was at first continued completely round the globe; but extraordinary revolutions, by separating the old and new continents, may have occasioned this division, and left nothing but the Axores and some detached points as a monument of what formerly existed, till we come to the British isles.

Before we proceed to inquire whether a belt of a similar elevation exists in the southern hemisphere, we may remark those branches and ramifications which the great northern Alpine belt sends forth both towards the equator and the antarctic pole. Those new chains, which gradually become lower as they approach the boundary towards which they tend, appear a sufficient proof that the equator is not the most elevated part of the earth.

The European Alps produce three principal chains, which run towards the equator, and some smaller ones running towards the pole. The first southern chain is sent out through Dauphine; traverses Viva-rais, Lyonnois, Auvergne, Cevennes, and Languedoc; and, after joining the Pyrenees, enters Spain. There it divides into two or three ramifications, one of which runs through Navarre, Bifcay, Arragon, Cañilfe, Marche, and Sierra Morena and extends into Portugal. The other, after traversing Andalusia and the kingdom of Grenada, and then forming a number of serras, again makes its appearance, beyond the Straits of Gibraltar, in Africa, and coasts along its northern shores under the name of Mount Atlas.—The second principal chain of the Alps passes out through Savoy and Piedmont; spreads its roughnesses over the flates of Genoa and Parma; forms the belt of the Apennines; and after frequently changing its name, and dividing Italy into two parts, terminates in the kingdom of Naples and in Sicily, producing volcanoes in every part of its course. The third chain is sent off from Hungary, and forms innumerable mountains over all Turkey in Europe, as far as the Morea and the Archipelago at the bottom of the Mediterranean sea. The northern branches, though smaller at first, are no less clearly defined; and some of them even extend their ramifications as far as the Frozen Ocean. An Alpine branch, issueing from Savoy thro' the country of Gex, proceeds through Franche-Comte, Sunegow, Alfece, the Palatinate, and Veterania.—Another issue from the territory of Salzburg, passes along Bohemia, enters Poland, and sends off a ramifications into Prufia towards the deserts of Waldow, and after having passed through Russia is lost in the government of Archangel.

The Asiatic Alps send forth in like manner several branches both to the south and north. The Ouralic mountains, between the sources of the Bielaia and the Jaik, produce three principal branches; the first of which, including the Caspian Sea in one of its divisions, enters Circellia through the government of Atracan, and, passing through Georgia under the name of Cancofu, sends a vast number of ramifications to the Caspian Sea and the mountains Tschilder, Ararat, Taurus, Argès, and many others in the three Arabias; while the other division, passing between the Caspian Sea and the lake Aral, penetrates through Chorafan into Persia. The second branch, taking a more easterly direction, leaves the country of the Eleuths; reaches Little Bucharia; and forms the ramparts of Gog and Magog, and the celebrated mountains formerly known by the name of Caf, which M. Bailly has made the seat of the war between the Dives and the Peris*. It traverses the kingdoms of Casgar and Turkistan, enters through that of Lahor into the Mogul territory, and, after giving rife to the elevated defert of Chamoo forms the western peninsula of India. While these two branches run towards the south, the third branch of the Ouralic chain rife towards the north, following almost the 70th degree of longitude, and forms a natural boundary between Europe and Asia; without, however, bounding the immense empire of Russia. This chain, after coming opposite to Nova Zembia, divides into two considerable branches. The one, running to the north-east, passes along the Arctic shores; the other, proceeding towards the north-west, meets the northern European chain, traverses Scandinavia in the shape of a horse-shoe, covers the low-lands of Finland with rocks; and, as is observed by Dr Pallas, appears to be continued from the North Cape of Norway through the marine chain of Spitzbergen, flattering islands and shelves perhaps throughout the northern ocean, that, passing through the pole, it may join the northern and eastern points of Asia and North America.

The Ouralic, which in the country of the Mongols becomes the Altai chain, proceeds towards the equator. After forming the mountains and caverns wherein, as we are told, the ashes of the Mongol emperors of the race of Ghengis-Kan are deposited, together with the vast plain of Chamo, confliting of arid sands, and the frightful rocks and precipices of Thibet, which form the mysterious and defert retreats of the Grand Lama, it crosses the rivers Ava and Menan; contains in its subdivisions the kingdoms of Ava, Pegu, Laos, Tonquin, Cochinchina, and Siam; supports the peninsula of Malacca; and overflows the Indian ocean with the isles of Sonda, the Moluccas, and the Philippines. From the borders of the Baikal lake and of the province of Selin-

MOU [428] MOU

Mountain, highest mountain which has been measured either in Europe, Asia, or Africa. The altitude of the Alps of Switzerland has been ascertained by the following philosophers; We shall content ourselves with mentioning the most remarkable of the mountains covered with snow, which in Switzerland are called Gletschers or Glaciers. St Gotthard, according to Scheuchzer, is 1850 toises; and Lignon, near the lake of Como, north east, is, according to Pini, 1486 toises in height. M. Pafumot, engineer to the king of the French, justly observes, that the heights assigned by Mikhaili to the mountains of Switzerland appear rather to be ideal computations than founded on observations. An opinion of them may be formed from the following: According to this author, Mount Pilate or Frankmont, in the district of Lucerne, is 1403 toises in height; Mount Cenis, 1445; Rauhhsok, 1760; the Nolle ridge of Tüilsberg, 2001; Ghemi, 2421; Grimselberg, is the canton of Berne, 2550; Comera, part of Loukmanier, 2654; Fourke, 2699; Schrekhorn, 2724; and St Gothard, at its moat elevated point, 2750. Mikhaili likewise reckons 20 other mountains, the height of which excess 2000 toises. The reader may consult the Table comparative des hauteurs des principaux montagnes, by M. Pafumot (Journal de Physique, September 1783.)

Throughout the globe we will perhaps meet with higher mountains than those of Peru, which go by the name of Cordilleras or las Andes. According to the observations of the academicians sent to South America in 1735 by the Spanish and French courts to measure a degree of the meridian and to ascertain the true figure of the earth, the principal summits of these extraordinary mountains, which are situated near Quito, and which are constantly covered with snow though they lie under the equator, have the following geometrical elevations above the level of the sea; Quito-Capilcate, 1707 toises; El-Corafon, 2470 (c); Cota-catche, 2570; Ek-Atlas, 2730; and Noyambre-ocru, under the line, 3030. All the other mountains have been or still are, volcanoes. The following is an enumeration of them, together with their several heights: Pichincha 2430; Cargaviejo, 2450; Sinchonilagon or Sinchonilagon, 2570; Sangra, 2680; Illimika 2717; Cotopazi, 2950; Antifana, 3020; Cogambeorcon, situated under the line, 3030; Chimborazo or Chimboraco, 3220. The last mentioned mountain, which forms part of the Cordilleras in Peru, is one of the largest and probably the highest in the world. It is seen at sea from the gulf of Guayaquil, which is more than 60 leagues distant.

Other very elevated mountains are Mount Sinai in Japan; Mount Capeanus in Asia; the southern peak of the Pyrenees; the peak of Tenerife in one of the Canary islands, which according to M. Bouguer is 2100 toises (according to later observations, made by M. M. de Verduin, de Borda, and Pingre, French academicians, in 1754, the peak of Tyde; more commonly known by the name of the peak of Teneriffe, is only 1904 toises perpendicular height above the level of the sea.) Mount Gibeil or Etna in Sicily is 1672 toises; St George's peak in the Azores; Adam's peak in Ceylon; the mountains of the Moon; Mount Athos, Olympus, Taurus, and Emaus: Mount Cenis in the Alps on the road from France to Italy, is 1460 toises; the Great and Little Atlas, and many others, on the top of which we feel, even in the middle of summer, a more piercing cold than that of the feverish frosts of our climates. After this, it cannot appear wonderful that the vapours which reach to great heights are there congealed; and that the summits of these mountains, even in the warmest climates, are constantly covered with snow, while the inhabitants of the plain enjoy a temperate atmosphere, or are subject to extreme heat. The height of those mountains, added to their being placed on the most elevated parts of the globe, is the chief cause of the phenomena peculiar to them. In that part of Asia which is separated by the chain of mountains called the Ghawr, there are two very different states at one and the same time. While it is winter on the Malabar coast, for instance, the Coromandel coast, which has the same degree of elevation, and in some places is only 20 leagues distant, enjoys an agreeable spring or the temperature of autumn.

The traveller in the Alps generally experiences, even in summer, the four seasons at the same time. In the Andes we meet with a change of temperature so less curious; for as we descend from their summits to their bases, we experience all the varieties of heat and cold which are felt in every climate of the earth, at whatever season (p). There are many other mountainous countries in which we pass at once from a serene sky to dreadful weather.
Mountains have a great influence on the climate of the countries to which they belong, by modifying the course of certain winds, by forming barriers to the clouds, by reflecting the sun’s rays, and by serving as elevated conductors to the electricity of the atmosphere. It was formerly said by travellers, that on the peak of Teneriffe they found that brandy lost its strength; that spirit of wine became almost infipid; that pepper, ginger, and salt, had little or no taste when applied to the tongue; but, it was alleged, that Canary wines still retained their flavor on that mountain. These stories appeared too marvellous not to require new experiments; and M. de Lamanon and Monges, who visited this peak in 1785, tell us, that the flavor and taste of liquors appeared to have sustained no loss at that height: (See the experiments made on the Pic du Midi in the Pyrenees by M. Darce, in the Journal de Physique for November 1776; and a journey to the peak of Teneriffe, in the fame Journal for August 1785.) At the foot, and sometimes at the middle, of those lofty mountains, the tops of which are always covered with snow, we frequently find springs which begin to run in May and dry up in September. When the sun approaches near enough to the tropic to warm the summits of these mountains, the snow with which they are covered melts, filtrates through their interior part, and issues forth at their base. The only trees which grow on mountains of this kind are firs, pines, and other resinous trees; and the grass becomes shorter towards their summit.

Mountains were not formed to be an useless load upon the earth, but evidently answer very important purposes; and we cannot enough admire their form and that kind of harmony which is discernible in their arrangement. Some of them, vomiting out fire or smoke, lava, and sulphur, indicate that they in some measure answer the purpose of a chimney to something within the earth, which, if confined, would burst it in pieces: (See Volcano.) Of this kind are Mount Hecla in Iceland, Mount Etna in Sicily, Mount Vesuvius in the kingdom of Naples, Pichincha and Cotopaxi in America, &c. Others, the summits of which reach into the clouds, attract and absorb the vapours of the sea, &c. which float in the air. It is observed by M. l’Abbé Palafion, that storms are most frequent at the foot of those high mountains which form extensive chains. Their enormous masses, which seem to support the heavens on their shoulders, arrest and fix the different meteoras as they are formed. The clouds, in like manner, driven by the winds from different points of the horizon, meet with impenetrable barriers, are there accumulated in great quantity, and remain suspended on these bulwarks of the globe’s surface, till the agitation of the atmosphere succeeding the calm, produces storms, which are so much the more terrible that they cannot expand and be dispersed but with great difficulty. They are commonly repelled from the mountains; and are then observed to spread over whole countries, to diffuse with peals of thunder, and to fall down in destructive hail-showers fatal to the harvest and to the whole produce of the fields. This scourge is peculiarly dreadful during the feasons of spring and summer, when a sufficient quantity of snow remains on the mountains to cool the atmosphere.

Some chains of mountains have openings; in others they are wanting: of the former kind are the straits of Thermopylae, the Cufip ane straits, the pas of the Cordilleras, &c.

The spaces which separate the tops of mountains are so many basons defined for the reception of the condensed mists, and of the clouds precipitated into rain. The bowels of mountains appear to be great and inexhaustible reservoirs, and to contain subterraneous canals and lateral openings formed by the hand of nature, that the several species of animals may be supplied with drink, that the earth may be fertilized, and that nourishment may be afforded for the growth of vegetables. The streams and rivers descend from the ridges of mountains, the declivities of which form so many inclined plains: Thus we find the Alps give rise to the Rhine, the Danube, the Rhone, and the Po. With regard to the wonderful structure, by means of which so many advantages are obtained, see the articles Earth, Springs, &c.

Mountains of the first order form vast solitudes and horrid deserts, where the habitations of men are not to be seen, and their footsteps are seldom to be traced. By their grandeur, their elevation, the variety of their postitions, the sublime and awful exhibition of wonders which they contain, they elevate the mind and fire the imagination of the observer. But these majestic eminences have other advantages which deserve our attention. They form the common retreat of a multitude of wild beasts, which are subservient to our use; there the bear, the lynx, the ermine, the martain, the fox, and many other animals, the skins of which we employ for furs, take up their abode; and thither the eagle and the vulture resort in safety. Mountains likewise afford nourishment to rein-deer, buffaloes, fallow-deer, roe-deer, and chamois; and they are visited by birds of passage which, under the guidance of instinct, follow the shortest road to the place of their destination. They produce medicinal plants, which almost never grow elsewhere. In Switzerland they are also covered with deep forests, which, by the great height of the trees, announce their antiquity. They afford both timber and fuel, and supply the inhabitants with abundance of excellent pasture for their beastial during the whole summer. The most precious stones, both for brilliancy and hardness, acquire their forms and colours in the fissures of the rocks: the internal rents of mountains are filled and in a manner cemented by different metallic substances; while the grottos are furnished with numerous congeulations, shining

we reach the summits of the mountains, which present to our view all the horrors of winter as they are felt in the polar regions. But below this height, as the density of the air becomes greater in consequence of being constantly pressed upon by a great superincumbent weight, the sun’s heat increases, so that those who inhabit the plains at the foot of the mountain are exposed to all the inconveniences of the torrid zone.
Mountains. shining crystals, and substances of an extraordinary nature and figure. In short, every thing conspires to shew, that the existence of mountains is absolutely necessary; and that in order to acquire a proper knowledge of them, they must be considered in many different points of view. Their position, their elevation, the extent of their base, their figure, their various external windings, their internal structure; in a word, every thing relating to the theory of the globe, and to the different temperatures of the atmosphere, must engage the observer's attention; and by studying and carefully examining the general constitution of mountains, the particular facts which they present to our view, their influence, their action on the atmosphere, the different substances of which they are composed, together with the arrangement and mixture of these substances, we may at length discover the true mechanism of the earth. The reader may consult the "Essai Sur l'étude des Montagnes; Journal de M. l'Abbé kosier, November 1773.

The difficulty and danger of ascending to the tops of mountains proceeds not from the thinnest of the air, as has been commonly reported; but the reason is, that they rise with such a rugged and precipitate ascent, that they are utterly inaccessible. In some places they appear like a great wall of 600 or 700 feet high; in others, there stick out enormous rocks, that hang upon the brow of the steep, and every moment threaten destruction to the traveller below.

In this manner almost all the tops of the highest mountains are bare and pointed; and this naturally proceeds from their being continually assailed by thunders and tempests. All the earthy substances with which they might have been once covered, have for ages been washed away from their summits; and nothing is left remaining but immense rocks, which no tempest has hitherto been able to destroy.

Nevertheless, time is every day and every hour making depredations; and huge fragments are seen tumbling down the precipice, either loosened from the summit by the frost or rains, or struck down by lightning. Nothing can exhibit a more terrible picture than one of these enormous rocks, commonly larger than an house, falling from its height with a noise louder than thunder, and rolling down the side of the mountain. Dr Plot tells us of one in particular, which being loosened from its bed, tumbled down the precipice, and was partly shattered into a thousand pieces. Notwithstanding, one of the largest fragments of the same, still preserved its motion, travelled over the plain below, crossed a rivulet in the middle, and at last stopped on the other side of the bank! These fragments, as was said, are often struck off by lightning and sometimes undermined by rains; but the most usual manner in which they are disintegrated from the mountain is by frost: the rains infusing between the interstices of the mountain, continue there until there comes a frost; and then, when converted into ice, the water swells with an irresistible force, and produces the same effect as gun-powder, splitting the most solid rocks, and thus shattering the summits of the mountain.

But not rocks alone, but whole mountains are, by various causes, disintegrated from each other. We see, in many parts of the Alps, amazing clouds, the fides of which so exactly correspond with the opposite, that no doubt can be entertained of their having been once joined together: At Cajeta in Italy, a mountain was split in this manner by an earthquake; and there is a passage opened through it, that appears as if elaborately done by the industry of man. In the Andes these breaches are frequently seen. That at Thermopylae in Greece has been long famous. The mountain of the Troglodytes in Arabia has thus a passage through it; and that in Savoy, which nature began and which Victor Amadeus completed, is an instance of the same kind.

We have accounts of some of these disruptions immediately after their happening. "In the month of June, in the year 1714, a part of the mountain of Diableret, in the district of Valais in France, suddenly fell down, between two and three o'clock in the afternoon, the weather being very calm and serene. It was of a conical figure, and destroyed 55 cottages in the fall. Fifteen persons, together with about 100 beasts, were also crushed beneath its ruins, which covered an extent of a good league square. The dust it occasioned instantly covered all the neighbourhood in darkness. The heaps of rubbish were more than 300 feet high. They stopped the current of a river that ran along the plain, which now is formed into several new and deep lakes. There appeared, through the whole of this rubbish, none of those substances that seemed to indicate that this disruption had been made by means of subterraneous fires. Most probably, the base of this rocky mountain was rotted and decayed; and thus fell, without any extraneous violence." In the same manner, in the year 1618, the town of Pleurs in Savoy was buried beneath a rocky mountain, at the foot of which it was situated.

These accidents, and many more that might be enumerated of the same kind, have been produced by various causes: by earthquakes, as in the mountains of Cajeta; or by being decayed at the bottom, as at Diableret. But the most general way is, by the foundation of one part of the mountain being hollowed by waters, and, thus wanting a support, breaking from the other. Thus it generally has been found in the great chains in the Alps, and thus it almost always is known in those disruptions of hills which are known by the name of landslips. These are nothing more than the sliding down of an higher piece of ground, disintegrated from its situation by subterraneous inundations, and settling itself upon the plain below.

There is not an appearance in all nature that so much astonishes our ancestors as these landslips. In fact, to behold a large upland, with its houses, its corn, and cattle, at once loosened from its place, and floating as it were upon the subjacent water; to behold it quitting its ancient situation, and travelling forward like a ship, in quest of new adventures; this is certainly one of the most extraordinary appearances that can be imagined; and, to a people ignorant of the powers of nature, might well be considered as a prodigy. Accordingly, we find all our old historians mentioning it as an omen of approaching calamities. In this more enlightened age, however, its cause is very well known; and, instead of exciting ominous apprehensions in the populace, it only gives rise to
some very ridiculous law-suits among them, about whose the property shall be; whether the land which has thus flipt, shall belong to the original possessor or to him upon whose grounds it has encroached and settled. What has been the determination of the judges is not so well known; but the circumstances of the flips themselves have been minutely enough and exactly described.

In the lands of Slatberg in the kingdom of Ireland, there flipt a declivity gradually ascending for near half a mile. In the year 1719, and on the roth of March, the inhabitants perceived a crack on its side, somewhat like a furrow made with a plough, which they imputed to the effects of lightning, as there had been thunder the night before. However, on the evening of the same day, they were surprized to hear a hideous confused noise issuing all round from the side of the hill; and their curiosity being raised, they returned to the place. There, to their amazement, they found the earth, for near five acres all in gentle motion, and sliding down the hill upon the subjacent plain. This motion continued the remaining part of the day and the whole night; nor did the noise cease during the whole time; proceeding probably from the attrition of the ground beneath. The day following, however, this strange journey down the hill ceased entirely; and above an acre of the meadow below was found covered with what before composed a part of the declivity.

However, these slips, when a whole mountain's side seems to defend, happen but very rarely. There are some of another kind, however, much more common; and, as they are always sudden, much more dangerous. These are snow-slips, well known, and greatly dreaded by travellers. It often happens, when snow has long been accumulated on the tops and on the sides of mountains, it is borne down the precipice either by means of tempest or its own melting. At first, when loosened, the volume in motion is but small; but it gathers as it continues to roll; and by the time it has reached the habitable parts of the mountain, it is generally grown of enormous bulk. Wherever it rolls, it levels all things in its way, or buries them in unavoidable destruction. Instead of rolling, it sometimes is found to slide along from the top; yet even thus it is generally as fatal as before. Nevertheless, we have had an instance or two slips, of a small family in Germany that lived for above a fortnight beneath one of these snow-slips. Although they were buried during that whole time in utter darkness, and under a bed of some hundred feet deep, yet they were luckily taken out alive, the weight of the snow being supported by a beam that kept up the roof, and nourishment supplied them by the milk of a fhe-goat that was buried under the same ruin.

Attraction of Mountains. This is a late discovery, and a very considerable confirmation of Sir Isaac Newton's theory of universal gravity. According to the Newtonian system, an attractive power is not only exerted between those large masses of matter which constitute the sun and planets, but likewise between all comparatively smaller bodies, and even between the smallest particles of which they are composed. Agreeably to this hypothesis, a heavy body, which ought to gravitate or tend toward the centre of the earth, in a direction perpendicular to its surface, supposing the said surface to be perfectly even and spherical, ought likewise, though in a less degree, to be attracted and tend toward a mountain placed on the earth's surface; so that a plumb line, for instance, of a quadrant hanging in the neighbourhood of such a mountain, ought to be drawn from a perpendicular situation, in consequence of the attractive power of the quantity of matter of which it is composed acting in a direction different from that exerted by the whole mass of matter in the earth, and with a proportionably inferior degree of force.

Though Sir Isaac Newton had long ago hinted at an experiment of this kind, and had remarked, that "a mountain of an hemispherical figure, three miles high and six broad, would not, by its attraction, draw the plumb-line two minutes out of the perpendicular (f); yet no attempt to ascertain this matter by actual experiment was made till about the year 1738; when the French academicians, particularly Messrs. Bouger and Condamine, who were sent to Peru to measure a degree under the equator, attempted to discover the attractive power of Chimbora<;o, a mountain in the province of Quito. According to their observations, which were however made under circumstances by no means favourable to an accurate solution of so nice and difficult a problem, the mountain Chimbora<;o, exerted an attraction equal to eight seconds. Though this experiment was not perhaps sufficient to prove satisfactorily even the reality of an attraction, much less the precise quantity of it; yet it does not appear that any steps had been since taken to repeat it.

Through the munificence of his Britannic majesty, the royal society were enabled to undertake the execution of this delicate and important experiment: the astronomer-royal was chosen to conduct it. After various inquiries, the mountain Schehallien, situated nearly in the centre of Scotland, was pitched upon as the most proper for the purpose that could be found in Britain. The observations were made by taking the meridian zenith distances of different fixed stars, near the zenith, by means of a zenith sector of ten feet radius; first on the south, and afterwards on the north side of the hill, the greatest length of which extended in a east and west direction.

It is evident, that if the mass of matter in the hill exerted any sensible attraction, it would cause the plumb-line of the sector, through which an observer viewed a star in the meridian, to deviate from its perpendicular situation, and would attract it contrarywise at the two stations, thereby doubling the effect. On the south side the plummet would be drawn to the northward, by the attractive power of the hill placed to the northward of it: and on the north side a contrary and equal deflection of the plumb-line would take

(f) By a very easy calculation it is found that such a mountain would attract the plumb-line 1' 18" from the perpendicular.
take place, in consequence of the attraction of the hill, now to the southward of it. The apparent zenith distances of the stars would be affected contrarywise; those being increased at the one station which were diminished at the other; and the correspondent quantities of the deflection of the plumb-line would give the observer the sum of the contrary attractions of the hill, acting on the plummets at the two stations; the half of which will of course indicate the attractive power of the hill.

The various operations requisite for this experiment lasted about four months; and from them it appears, that the sum of the two contrary attractions of the mountain Schehallien, in the two temporary observations which were successively fixed half-way up the hill (where the effect of its attraction would be greatest), was equal to 11. From a rough computation, founded on the known law of gravitation, and on an assumption that the density of the hill is equal to the mean density of the earth, it appears that the attraction of the hill should amount to about the double of this quantity. From hence it was inferred, that the density of the hill is only about half the mean density of the earth. It does not appear, however, that the mountain Schehallien has ever been a volcano, or is hollow; as it is extremely solid and dense, and seemingly composed of an entire rock.

The inference drawn from these experiments may be reduced to the following:

1. It appears, that the mountain Schehallien exerts a sensible attraction; therefore, from the rules of philosophizing, we are to conclude, that every mountain, and indeed every particle of the earth, is endowed with the same property, in proportion to its quantity of matter.

2. The law of the variation of this force, in the inverse ratio of the squares of the distances, as laid down by Sir Isaac Newton, is also confirmed by this experiment. For if the force of attraction of the hill had been only that of the earth as the matter in the hill to that of the earth, and had not been greatly increased by the near approach to its centre, the attraction thereof must have been wholly insensible. But now, by only supposing the mean density of the earth to be double to that of the hill, which seems very probable from other considerations, the attraction of the hill will be reconciled to the general law of the variation of attraction in the inverse duplicate ratio of the distances, as deduced by Sir Isaac Newton from the comparison of the motion of the heavenly bodies with the force of gravity at the surface of the earth; and the analogy of nature will be preserved.

3. We may now, therefore, be allowed to admit this law, and to acknowledge, that the mean density of the earth is at least double of that at the surface; and consequently that the density of the internal parts of the earth is much greater than near the surface. Hence also, the whole quantity of matter in the earth will be at least as great again as if it had been all composed of matter of the same density with that at the surface; or will be about four or five times as great as if it were all composed of water. This conclusion, Mr. Maikelyre adds, is totally contrary to the hypothesis of some naturalists, who suppose the earth to be only a great hollow shell of matter; supporting itself from the property of an arch, with an immense vacancy in the midst of it. But, were that the case, the attraction of mountains, and even smaller inequalities in the earth's surface, would be very great, contrary to experiment, and would affect the measures of the degree of the meridian much more than we find they do; and the variation of gravity, in different latitudes, in going from the equator to the poles, as found by pendulums, would not be nearly so regular as it has been found by experiment to be.

4. As mountains are by these experiments found capable of producing sensible deflections of the plumb-lines of astronomical instruments; it becomes a matter of great importance, in the mensuration of degrees in the meridian, either to choose places where the irregular attractions of the elevated parts may be small; or where, by their situation, they may compendiate or counteract the effects of each other.

For measuring the heights of mountains, see the article Barometer.

Burning Mountains. See ETNA, HECLA, VESUVIUS, and Volcano.

Marble Mountains. Of these there are great numbers in Egypt, from which, though immense quantities have been carried off for the multitude of great works erected by the ancient Egyptians; yet, in the opinion of Mr. Bruce who passed by them in his journey to Abyssinia, there is still such an abundant supply, that it would be sufficient to build Rome, Athens, Corinth, Syracuse, Memphis, Alexandria, and a dozen more of such cities.

The first mountain of this kind mentioned by Mr. Bruce is one opposite to Ternowey, consisting partly of green marble, partly of granite, with a red bluish up on a grey ground, and square oblong spots. Here he saw a monitory obelisk of marble, very nearly square, broken at the end, and nearly 30 feet long and 19 feet in the face. Throughout the plain there were scattered small pieces of jasper, with green, white, and red spots, called in Italy diaspro fanguiii; and all the mountains upon that side seemed to consist of the same materials. Here also were quantities of small pieces of granite of various kinds, as also porphyry, which had been carried down by a torrent, probably from the ancient quarries. These pieces were white mixed with black spots, and red with green veins and black spots. All the other mountains on the right hand were of red marble, but no great beauty; those on the opposite side being green marble, probably of the serpentine kind. This, he says, was one of the most extraordinary sights he ever saw. The former mountains were of a considerable height, without a tree, shrub, or blade of grass upon them; and this looked exactly as if it had been covered over with Havanannah and Brazil snuff. Proceeding farther on, he entered another defile with mountains of green marble on every side. The highest he saw appeared to be composed of serpentine marble; having a large vein of green jasper spotted with red running through about one-third of its thickness. It was extremely hard; so that it did not yield to the blows of a hammer, though it was evident that it had formerly been quarried; and there were channels for bringing water, which terminated
of Mount. Mountain.

nated in this quarry of jasper; "a proof (says Mr. Bruce) that water was one of the means used in cutting those hard stones,"

On these mountains, our author observes, that "the porphyry shows itself by a fine purple fand without any gleam upon it, though the colour is very agreeable to the eye. It is mixed with the white fand and fixed marble of the plains. Green and unvariegated marble is also found in the same mountain with the porphyry. The marble is brittle for some inches where the two veins meet; but the porphyry is as hard as in other places. The granite appears like a dirty brown fone covered with sand; but this is only the change made upon it by the fun and weather; for on breaking it, the colour appears to be green with black spots, and a reddish fand on the surface. The reddish colour appears to be impaired by exposure to the atmosphere; but is recovered upon polishing it anew. It is in greater quantity than the porphyry, and nearer to the Red Sea. The granite is next to the porphyry, but never made of red marble with white veins, which our author has seen at Rome and likewise in Britain. The common green, called ferpenite, looks as if it were covered with Brazil fult. Along with this green he saw two samples of the beautiful kind called Jasella; one of them with the yellowish cast of Quaker-colour; the other of that bluish cast called dove colour; and these two seemed to divide the mountains with the ferpenite. Here also he saw the vein of Jasper; but had not time to determine whether it was the fame with that called bloody-Jasper or blood-ftone or not.

The marble of greatest value, however, is that called Verde Antico, which is of a dark-green colour with white spots. It is found, like the Jasper, in the mountains of the plain green ferpenite, and is not disoverable by the duff or any particular colour upon it. "First (says Mr. Bruce) there is a blue fak's flone exceedingly even and smooth in the grain, folid, and without fparks and colour. When broken it is fomething lighter than a flate, and more beautiful than most kinds of marble; it is like the lava of volcanoes when polished. After lifting this we come to the beds of verde antico; and here the quarrying is very obvious; for it has been uncovered in patches not above 20 feet fquare. Then, in another part the green flone has been removed and another pit wroght." In other places of the plain he faw pieces of African marble, but no rocks or mountains, of it. He fuppofe it to be found in the heart of fome other coloured marble, and in firata like the Jasper and verde antico; and, as he fuppofe, in the mountains of Labella marble, efpially of the yelloweft fand. This vaf flone of marble is placed on a ridge, whence there is a defcent to the cafl and weft, fo that it could be conveyed either to the Nile or the Red Sea. The level ground and hard fixed gravel are proper for the heaviest carriages; fo that any weight whatever might eafily be conveyed to the place of embarkation. In the more diftant mountains also he observed the fame care taken to facilitate the carriage: for the defiles between those mountains he fuppofes not to be natural but artifi-
of any consequence. "They seem (says he) to have been executed at idle hours by travellers, who were satisfied with cutting the unpollished rock with any pointed instrument, adding to their names and the date of their journeys some rude figures, which bespeak the hand of a people but little skilled in the arts. When such inscriptions are executed with the design of transmitting to posterity the memory of such events as might afford instructive lessons, greater care is generally taken in the preparation of the stones, and the inscriptions are engraved with more regularity."

When M. Niebuhr arrived at last at the mountain to which the sheik had promised to conduct him, he did not find there any inscriptions; but, on climbing up to the top, he found nothing there but an Egyptian cemetery, the stones of which were covered with hieroglyphics. The tomb stones are from five to seven feet in length, some standing on end and others lying flat; and "the more carefully they are examined (says he), the more certainly do they appear to be sepulchral stones, having epitaphs inscribed on them. In the middle of the stones is a building of which only the walls now remain; and within it, likewise, a great many of the sepulchral stones. At one end of the building seems to have been a small chamber, of which the roof still remains. It is supported upon square pillars; and these, as well as the walls of the chamber, are covered with hieroglyphic inscriptions. Thro' the whole building are various bulws executed in the manner of the ancient Egyptians. The sepulchral stones and the bulls are of hard and fine-grained sand-stone." M. Niebuhr is of opinion that this cemetery was not the work of the Egyptians themselves, but of some colony which came from Egypt, and had adopted the manners and customs of the people. He supposes that it might have been built by the Arabs who had conquered Egypt under the shepherd kings and adopted the Egyptian manners during their residence there. As it must have belonged to an opulent city, however, he owns that there is a great difficulty in accounting for the existence of such a city in the midst of a desert.

The translator of Volney's travels abridges these inscriptions to the pilgrims which visit Mount Sinai. But to this, as well as to every other conjecture, there is this objection, that whether the inscriptions be well executed or not, whether they contain matters of importance or not, they ought to have been written in a language which somebody could understand; but from the copies that have been taken of them by Dr. Porro, and others, it does not appear that they could be explained either by him or any other person.

When Dr. Clayton, bishop of Clogher, visited this part of the world about the year 1723, he expressed the greatest desire to have the matter concerning this written mountain or mountains ascertained, and even made an offer of L. 500 Sterling to any literary person who would undertake the journey and endeavour to decipher the inscriptions; but no such person has appeared, and the existence of the mountains is testified only by the superior of a convent at Cairo, who gave that mentioned in the beginning of this article. Until that part of the world, therefore, become more accessible to travellers, there is but little hope that we can come to any certainty in the matter. M. Niebuhr plainly, from his own account, had not influence enough with the Arabs to show him anything as they refused to conduct him even to the summit of Mount Sinai.

White Mountains. See New Hampshire.

Mountains of the Moon, a chain of mountains in Africa, extending themselves between Abysinia and Monomotapa, and receiving the above denomination from their great height. They were styled by the ancients the mountains of God, on account of their being greatly subject to thunder and lightning. Mountains of Forty-days; a mountain of Judia, situated in the plain of Jericho to the north of that city. According to the Abbe Marisi's description, the summit of it is covered neither with shrubs, turf, nor earth: it consists of a solid mass of white marble, the surface of which is become yellow by the injuries of the air. "The path by which you ascend to it (says our author) fills one with terror, as it runs through a winding course between two abysses, which the eye dures fearfully behold. This path is at first pretty broad, but as length becomes so confined, that one can with difficulty place both feet upon it at the same time. When we had ascended a little higher, we found an Arab stretched out on the path, who made us pay a certain toll for our passage. Here the traveller requires courage. One of the parapets of the path being broke, we clung to the part which remained until we had reached a small grotto, situated very commodiously as it gave us an opportunity of recovering our breath. When we had rested ourselves a little, we pursued our course, which became still more dangerous. Suspended almost from the rock, and having before our eyes all the horror of the precipice, we could advance only by dragging one foot after the other; so that had the smallest fragment given way under us, we should have been hurried to the bottom of this frightful abyss.

"Proceeding a little farther, we found a second grotto, the entrance of which was about nine feet in breadth. It would be of considerable size were not about two-thirds of it filled up by part of the roof, which had tumbled down. This grotto conduits to another, which we had the curiosity to enter, but we were almost stifled by the great number of bats which were fluttering up and down in it. Being desirous of retreating almost as soon as we had entered they flew in such numbers around us that they in a manner covered our whole bodies; but they luckily made a pottage for themselves, and suffered us to breathe with freedom. By the glistening light which reached this grotto, we perceived that the bottom of it was covered to the height of a hand-breadth with the excrements of these animals; and we remarked some niches in the sides of it, which gave us reason to conclude, that it had once served as a sepulchre to the ancient anchoresses. This is the more probable, as the other grotto appears by the remains of an altar and of some Greek paintings to have been formerly a church. In the right corner there is a large cistern, the plaster of which retains its original solidity, though broken
MOURNING, among the ancients, was expressed various ways.

Amongst the Jews, on the death of their relations or intimate friends, grief or mourning was signified by weeping, tearing their clothes, figthing, their breasts, or tearing them with their nails, pulling or cutting off their hair and beards, walking softly, i.e. barefoot, lying upon the ground, falling, or casting upon the ground. They kept themselves close shut up in their houses, covered their faces, and abstained from all work, even reading the law, and saying their usual prayers. They neither dressed themselves nor made their beds, nor shaved themselves, nor cut their nails, nor went into the bath, nor saluted any body: so that fullness seems to have been an indication of sorrow; and diriments, of diriments. The time of mourning among the Jews was generally seven days: tho' this was lengthened or shortened according to circumstances; but 30 days were thought sufficient upon the feverest occasions. The different periods of the time of mourning required different degrees of grief, and different tokens of it.

The Greeks, on no other death of friends, showed their sorrow by excluding themselves from all gaiety, entertainments, games, public solemnities, the enjoyment of wine, and the delights of music. They sat in gloomy and solitary places, stripped themselves of all external ornaments, put on a coarse black stuff by way of mourning, tore their hair, shaved their heads, rolled themselves in the dust and mire, sprinkled ashes on their heads, smote their breasts with their palms, tore their faces, and frequently cried out with a lamentable voice and dwelling tone, reiterating the interjection, &c.; hence funeral lamentations were called Elegies. If they appeared in public during the time of mourning, they had a veil thrown over their faces and heads. During the funeral procession, certain persons called Scyphists marched before, and sang melancholy strains called Epitaphium. These vocal mourners sung thrice during the procession round the pile and round the grave. Flutes were also used to heighten the solemnity. At the funerals of soldiery, their fellow-soldiers who attended, as a testimony of their affliction, held their shields, their spears, and the rest of their armour, inverted.

As to the tokens of private grief among the Romans, they were the same as those already observed as customary amongst the Greeks. Black or dark-brown were the colour of the mourning habits worn by the men; they were also common to the women. The mourning of the emperors at first was black. In the time of Augustus, the women wore white veils, and the rest of their dress black. From the time of Domitian they wore nothing but white habits, without any ornaments of gold, jewels, or pearls. The men let their hair and beards grow, and wore no wreaths of flowers on their heads while the days of mourning continued. The longest time of mourning was ten months; this was Numa's establishment, and took in his whole year. For a widow to marry during this time was infamous. Mourning was not used for children who died under three years of age. From this age to ten they mourned as many months as the child was years old. A remarkable victory or other happy event, occasioned the shortening of the time of mourning.
MOUSE

MOUSE, in zoology. See Mus.

MOUSE-EAR, in botany. See Hieracium.

MOUSE-TAIL, See Myoxus.

Dor-Mous. See Myoxus.

Shre'u-Mous., See Sorex.

MOUSEL, the name of an East Indian tree, with white tubular flowers, which fall off every day in great plenty. They are of a sweet agreeable smell and the Gentoos are very fond of wearing them, flinging and hanging them about their necks and arms. The fruit is a pale red-cherry, of the shape and size of our white heart-cherry, but the fruit-stalk is not quite so long. This fruit has a f hone in it containing a bitter oily kernel. The Indians rub with this oil any part that is infested by a scorpion or bitten by a centipede, which it soon cures. The crows are very fond of the fruit.

MOUSEL, or Moule, a large city of Turkey in Asia, and capital of a Beglerbeye, stands on the west banks of the Tigris, in the latitude, according to Mr. Ives's observation, of 36°. It is surrounded with stone-walls, but has many of its streets lying walled. Taverniers speak of it as a ruined place, with only two blind markets and two night-fires.
MOUTH, in anatomy, a part of the face, containing the lips, the gums, the inside of the cheeks, the palate, the salivary glands, the os hyoides, the uvula, and the tonsils, which see under the article Anatomy.

Mr Derham observes, that the mouth in the several species of animals is nicely adapted to the uses of such a part, and well fixed and shaped for the formation of speech, the gathering and receiving of food, the catching of prey, &c. In some creatures it is wide and large, in others little and narrow; in some it is formed with a deep incisure into the head, for the better catching and holding of prey, and more easy comminution of hard, large, and troublesome food; and in others with a shorter incisure, for the gathering and holding of herbaceous food. In birds it is mostly shaped for piercing the air: hard and horny, to supply the want of teeth; hooked, in the rapacious kind, to catch and hold their prey; long and flender in those that have their food to grope for in moorish places; and broad and long in those that search for it in the mud. Nor is the mouth itself remarkable in insects; in some it is foreparted, to catch, hold, and tear the prey; in others aculeated, to pierce and wound animals, and suck their blood; in others, strongly rigid, with jaws and teeth, to gnaw and scrape out their food, carry burdens, perforate the earth, nail the hard-est wood, and even flome themselves, for houfes and nets for their young.

MOUVANS (Paul Richard), surnamed the Brave, a Protestant officer, was born at Caffelain: in Provence, of a respectable family, and made a considerable figure in the civil wars of France during the 16th century. His brother, who was likewise a Protestant, having been killed in a popular tumult excited by the Romish party at Draguignan, took up arms to avenge his death; and, having assembled 2000 men, committed great devastations in Provence. Being pursued by the Count de Tende at the head of 6000 men, and finding himself too weak to keep the field, he took post in a convent strongly fortified by nature, and there resolved to defend himself to the last extremity. That the war might be terminated amicably, the Count de Tende proposed an interview; to which Mouvans agreed, on condition that his brother's murderers should be punished, and that those who had taken up arms with him should not be molested. These terms being accepted, he dismissed his troops, referring only a guard of 50 men for the security of his person. This precaution was not unnecessary; for the parliament of Aix had received orders from court to punish him capitally for being concerned in the conspiracy of Amboise. The baron de la Garde made an attempt to apprehend him, but he was worshiped and repulsed with considerable loss. Mouvans at length resolved to retire to Geneva, where his life would not be in danger; and there he lived for some time in tranquility, nobly rejecting the splendid offers made him by the duke of Guise if he would join the Catholic party. He returned to France at the recommencement of the troubles, in consequence of the warfare of Vaffy in 1568, and continued to distinguish himself in the Protestant armies. His conduct at Siferon, where he commanded together with Captain Senas when that city was besieged by the Count de Sommerive, is particularly deserving of admiration. After sustaining an assault of seven hours, in which the besiegers were repelled with considerable loss, Mouvans, perceiving that he was too weak to wait a second, determined to abandon the city, and left it during the night with his troops and those of the inhabitants who chose to accompany him, by a path which the enemy had neglected to guard. The number of the inhabitants amounted to 4000 of every age and sex, men, women, children, and mothers with their infants at their breast. This body, in which there was not 1000 men fit to bear arms, directed their course towards Grenoble. Musketeers were placed in the front and rear, while the defenceless and unarmed occupied the centre. To add to the difficulty of the march, they were frequently obliged to go out of the way, and to cross steep and rugged
MOY [438] MUC

rugged mountains, in order to avoid the ambuscades which the enemy had laid for them on the road.

They stopped some days to refresh themselves in the valleys of Angrone and Pragclas, where they were cordially received and supplied with provisions by the Vaudois. After a march of 21 or 22 days, and being exposed to the greatest fatigue and famine, the wretched fugitives at length arrived at Grenoble. The baron des Adrets sent them under an escort to Lyons, where they remained till the treaty of pacification. In 1568 Mouvans was defeated at Mignane in Perigord, and lost his life in the engagement. Upon this occasion he commanded, together with Peter Gourde, the advanced guard of the Protestant army. It is alleged, that in despair he dashed out his brains against a tree.

MOWEE, one of the Sandwich islands discovered by Captain Cook, is 162 miles in circumference. A low, illusiss divides it into two circular peninsulas, of which the eastern is double the size of the western. The mountains in both rise to an exceeding great height, and may be seen at the distance of more than 30 leagues. The northern shores, like those of Owyhee, afford no foundings, and the country presents the same appearance of verdure and fertility. Near the well point of the smaller peninsula is a spacious bay, with a sandy beach shaded with cocoa-nut trees. The country behind has a west:

MUCK [ 439 ]

M. "prifoner."

intoxicated with opium, and then has prevailed time immemorial in Batavia. To run the mixture is entirely mucus. If the matter cannot be ration, we have also reason to believe that it is a certain precipitation in neither, it is a certain a muck, in the original sense of the word, is to get line lixivium; and let him add pure water to both.

The addition of water to either of these compounds decomposes it. The mucus thus separated either twines in the mixture or forms large flocculi in it; whereas the pus falls to the bottom, and forms, on agitation, an uniform turbid mixture.

1. Pus and mucus are both soluble in the vitriolic acid, though in very different proportions, pus being by far least soluble.

2. The addition of water to either of these compounds decomposes it. The mucus thus separated either twines in the mixture or forms large flocculi in it; whereas the pus falls to the bottom, and forms, on agitation, an uniform turbid mixture.

3. Pus is diffusible through a diluted vitriolic acid, though mucus is not. The same also occurs with water, or with a solution of feu-faut.

4. Nitrous acid dissolves both pus and mucus. Water added to the solution of pus produces a precipitate, and the fluid above becomes clear and green, while water and the solution of mucus form a turbid dirty-coloured fluid.

5. Alkaline lixivium dissolves, though sometimes with difficulty, mucus, and generally pus.

6. Water precipitates pus from such a mixture, but does not mucus.

7. Where alkaline lixivium does not dissolve pus, it still distinguishes it from mucus, as it then prevents its diffusion through water.

8. Coagulable lymph is neither soluble in concentrated nor diluted vitriolic acid.

9. Water produces no change on a solution of furm in alkaline lixivium, until after long standing, and then only a very slight sediment appears.

10. Corrosive sublimate coagulates mucus, but does not pus.

From the above experiments it appears, that strong vitriolic acid and water, diluted vitriolic acid, and caustic alkaline lixivium and water, will serve to distinguish pus from mucus; that the vitriolic acid can separate it from coagulable lymph, and alkaline lixivium from ferum.

Hence, when a person has any expectorated matter, the decomposition of which he wishes to ascertain, let him dissolve it in vitriolic acid, and in caustic alkaline lixivium; and let him add pure water to both solutions. If there be a fair precipitation in each, he may be assured that some pus is present. But if there be a precipitation in neither, it is a certain test that the mixture is entirely mucus. If the matter cannot be made to diffuse in alkaline lixivium by time and trial, we have also reason to believe that it is pus.

MUCK, or RUNNING A MUCK, is a practice that has prevailed time immemorial in Batavia. To run a muck, in the original sense of the word, is to get intoxicated with opium, and then rush through the streets with a drawn weapon, and kill any one that comes in the way, till the party is himself either killed or taken prisoner. If the officer takes one of these amokki or muharuki (as they have been called by an easy corrup-

MUDIGANA. See MURENA.

MUFFEL, in chemistry, a vessel much used in some metallurgic operations. In figure it represents an oblong arch or vault, the hinder part of which is cloven by a semicircular plane, and the lower part or floor of which is a rectangular plane. It is a little oven that is placed horizontally in a fayy and enameling furnaces, so that its open side corresponds with the door of the fire-place of the furnace. Under this arched oven small cups or crucibles are placed; and the substances contained are thus exposed to heat without contact of fuel, smoke, or ashes.

MUFTI, the chief of the ecclesiastical order, or priate of the muftiulame religion. The authority of the mufti is very great in the Ottoman empire; for even the sultan himself, if he would preserve any appearance of religion, cannot, without hearing his opinion, put any person to death, or to much as inflict any corporal punishment. In all actions, especially criminal ones, his opinion is required, by giving him a writing in which the case is stated under feigned names; which he subscribes with the words, fie [sall, or Shall not be, punished. Such outward honor is paid to the mufti, that the grand signior himself rises up to him, and advances seven steps to meet him when he comes into his presence. He alone has the honour of killing the sultan's left shoulder, whilst the prime vicer kills only the hem of his garment. When the grand signior addresses any writing to the mufti, he gives him the following titles: To the edal, the editt of the wise, instructed in all knowledge, the most excellent of excellent, abounding from things unlawful, the spring of virtue and of true science, heir of the prophetic doctrines, refuser of the problems of faith, reveler of the orthodox articles, stay of the treasures of truth, the light to the doubtful allegories, strengthened with the grace of the supreme legislator of mankind, may the Most High God perpetuate thy virtues! The election of the mufti is solely in the grand signior, who presents him with a seat of rich fables, &c. If he is convicted of treason, or any great crime, he is put into a mortar kept for that purpose in the Seven Towers at Constantinople, and pounded to death.

MUGGLETONIANS, a religious sect which arose in England about the year 1657; fo denounced from their leader Ludowick Muggleton, a journeyman tailor, who, with his associate Reeves, set up for great prophets, pretending, as it is said, to have an absolute power of saving and damning whom they pleased; and giving out that they were the two last witnesses of God that should appear before the end of the world.

MUGIL, the mullet; in ichthyology, a genus of fishes belonging to the order of abdominales. The lips are membranaceous, the inferior one being curved inwards; they have no teeth; the branchiosteg membrane has seven crooked rays; the opercula smooth and round; and the body is of a whitish colour. There are two species, distinguished by the number of rays in the back-fin.

The mullet is joyfully ranked by Aristotle among the fishes littorae; or those that prefer the shores to the
full sea; they are found in great plenty on several of the sandy coasts of Britain, and haunt in particular those small bays that have influxes of fresh water. They come in great shoals, and keep rooting like hogs in the sand or mud, leaving their traces in form of large round holes. They are very cunning; and when surrounded with a net, the whole shoal frequently escapes by leaping over it; for when one takes the lead, the others are sure to follow. This circumstance is observed by Oppian; who also informs us, that if these fishes fail to get over at the first leap, they never attempt a second, but lie without motion as if they refrained themselves to their fate. Mr Pennant says he is uncertain whether this last observation holds good or not; however, Oppian had good opportunity of examining those fishes, as they sometimes swarm on the coasts of the Mediterranean. Near Martegues, in the south of France, abundance of mullets are taken in weares made of reeds placed in the shallows. Of the males, which are there called alciants, and of the roes of females, which are called botaris, is made botargo. The materials are taken out entire, covered with salt for four or five hours, then pressed a little between two boards or flones, washed, and at last dried in the sun for 13 or 14 days.

This fish was sometimes made the instrument of a horrible punishment for unfortunate gallants. It was used both at Athens and Rome; but it is very doubtful whether it was a legal punishment or not. By Horace it is mentioned in the following lines:

Diffinita tunica fugiendum est, ac pede nude.
Nec numinum perante, aut Putea, aut dennece fanna.

Sat. l. lib. l. 133.

The mullet is an excellent fish for the table, but at present not a fashionable one. The albuia * is caught in great quantities about the Bahamas islands at the time they go in shoals to spawn; and is there esteemed very good eating.

MUGWORT, in botany; a species of Artemisia. An infusion of this plant in white wine, or a bath made of it, has been always esteemed an emmenagogue, and useful in difficult parturition. The leaves, when young and tender, are frequently made use of by the Highlanders of Scotland as a pot herb. The country people in Sweden drink a decoction of them for the ague.

MUID, a large measure in use among the French, for things dry. The mid is no real vessel used as a measure, but an estimation of several other measures; as the septier, mille, minot, buffel, &c.

Muid, is also one of the nine caiks, or regular vessels used in France, to put wine and other liquors in. The mid of wine is divided into two demi-muids, four quarter muids, and eight half quarter muids containing 367 pinte.

MULATTO, a name given to those who are begotten by a negro man on a white woman, or by a white man on a negro woman.

MULBERRY, in botany. See Morus.

Mulbe or Cyder, a name given by the people of Devonshire, and some other parts of England, to a sort of Cyder rendered very palatable by an admixture of mulberry juice in the making: they choose for the purpose the ripest and blackest mulberries, and pressing out their juice and mixing it with a full-bodied cyder at the time of the grinding and pressing, give just so much of it as adds a perceptible flavour. It is very worthy the attention of people who live in other countries, where strong and good cyder is made, that this renders it a sort of wine much more agreeable than any other English liquor, and might be brought into general use, to the great advantage of the dealer. The colour of this liquor resembles that of the bright red wine, and the flavour of the mulberry never goes off. Phil. Trans. No 133.

MULCT, a fine of money laid upon a man who has committed some fault or misdemeanour.

MULE, in zoology, a mongrel kind of quadruped, usually generated between an as and a mare, and sometimes between a horse and a she-as; but the signification of the word is commonly extended to every kind of animal produced by a mixture of two different species. There are two kinds of these animals; one from the he-as and mare, the other from the horse and the she-as. We call them indifferently mules, but the Romans distinguished them by proper appellations. The first kind are the best and most esteemed: as being larger, stronger, and having less flesh than the as in their disposition. The largest and stoutest ases, and the fairest and finest mares, are chosen in those countries where these creatures are most in use; as in Spain, Italy, and Flanders. In the last especially, they succeed in having very fatly mules from the size of their mares, some of them 16 and some 17 hands high, which are very serviceable as fummer-mules in the army. But since the Low Countries are no longer under the dominion of Spain, they breed fewer mules. These creatures are very much commended for their being stronger, fairer footed, going easier, being more cheaply maintained, and lasting longer than horses. They are commonly of a black-brown, or quite black, with that shining lift along the back and crest the shoulders which distinguishes ases. In former times they were much more common in Britain than at present; being often brought over in the days of Popery by the Italian prelates. They continued longest in the service of millers; and are yet in use among them in some places, on account of the great loads they carry on their back. As they are capable of being trained for riding, bearing burdens, and for draught, there is no doubt that they might be usefully employed in many different services. But they are commonly found to be vicious, stubborn, and obdurate to a proverb; which whether it occurs or is produced by the ill usage they meet with, is a point not easily settled. Whatever may be the case of ases, it is allowed that mules are larger, fatter, and more serviceable in mild than in warm climates. In the British American colonies, both on the continent and in the islands, but especially in the latter, they are much used and esteemed; so that they are frequently sent to them from England, suffer less in the passage, and die much felder than horses, and commonly yield, when they arrive, no incon siderable profit.

It has commonly been asserted, that animals produced by the mixture of two heterogeneous species are incapable of generating, and thus perpetuating the monstrous breed; but this, we are informed by M. Buffon, is now discovered to be a mistake. Aristotle, says he, tells us, that the mule engenders with the mare, and that the junction produces an animal which the Greeks call binus, or ginosus. He likewise...
MULES.

Mule. 

wife remarks, that the filly mule easily conceives, but seldom brings the fetus to perfection. But the most remarkable and well attested instance of this fact, is mentioned in a latter read by M. d'Alembert before the academy of sciences, which informed him, that a mule in the island of St Domingo had brought forth a foal. The fact was attested by persons of the most unquestionable veracity; and other instances, though not so well authenticated, are adduced by our author. We may therefore, continue M. Buffon, consider it as an established fact, that the mule can generate and the foal produce. Like other animals, they have a female liquor, and all the organs necessary to generation. But mongrel animals are always less fertile and more tardy than those of a pure species. Besides, mules have never produced in cold climates, seldom in warm regions, and still more seldom in temperate countries. Hence their barrenness, without being absolute, may be regarded as positive; since their productions are so rare, that a few examples can be only collected.

The translator of Buffon's works, in a note on the passage above quoted, has given a remarkable and well authenticated instance of the prolific powers of a female mule in the north of Scotland. Having heard that a mule belonging to Mr David Tullo farmer in Auchtertyre, in the county of Forfar, had some years ago brought forth a foal, he transmitted a few queries to be put to Mr Tullo; and requested that his answers might be legally attested before a magistrate. This request was cheerfully complied with; and the following is an exact copy of the queries, answers, and attestations.

Interrogatories to be put to Mr Tullo tenant in Auchtertyre, parish of Newtyle, and county of Forfar, with his answers thereto.

1st. Had you ever a filly mule? At what period? Is it true that the mule had a foal? and what time was she covered; and when did she foal?—Answered by Mr Tullo; that he bought a filly mule about 20 years ago; that she was constantly in season for a horse; that, about some years thereafter, he gave her a horse; and that she thereafter gave him a foal, about the 10th of June. The mule's price was L. 45. 5s. Sterling.

2nd. What was the colour of the foal? Was there anything particular in its figure?—Answer: The foal was exactly the colour of its mother, inclined to black, with a very large head, big ears, and small tail; and the declarant thinks, had its head been weighed when foaled, it would have weighed nearly as much as its body.

3rd. How long was the animal allowed to live?—Answer: The next day after the foal foaled, it was sent, with its mother, to the Loch of Lunde, in order to let the foal die, as the declarant could not want the mule's work, and the mother feemed not fond of the foal! That it was accordingly left, and the next day came to Auchtertyre, about two miles distance, over a hill, with the cattle of Auchtertyre, that had been grazing near to that place, and was drowned in a ditch the day following.

4th. Was its skin preferred, or the head, or any other bones of the skeleton? Could any part thereof be still found? Answered: Neither the skin nor any part of the skeleton was preserved, nor can be now had; though the declarant has often regretted the not preserving the foal, as its mother always performed any work that a horse of 15l. value could do.

5th. Was the mother still alive? What was her age?—Answer: The mother died about eight years ago, of an epidemic cold that was raging among the horses in this country: the mule had little or no milk after foaling, and the foal got some cows milk: And this is all that he remembers of the matter. DAVID TULLO.

Auchtertyre. 4th Feb. 1780. We James Small tenant in Burmouth, and Robert Ramsay tenant in Newtyle, hereby certify, that we have often seen the mule above described; and we know that the mule, as is narrated by David Tullo.

JAMES SMALL. ROB. RAMSAY.

Ballantyne-bougie, 4th Feb. 1780. The within interrogatories were put to David Tullo tenant in Auchtertyre, about the mule he had, and the foal he produced; to which he gave the answers subjoined to each query, and signed them; as did James Small and Robert Ramsay, attesting the truth thereof, in presence of GEORGE WATSON, J.P.

The original attestation is in the possession of the translator; and he lately transmitted notarial or authenticated copies of it to the count de Buffon, and to Thomas Pennant, Esq; of Downing, in Flintshire.

Mules, among gardeners, denote a sort of vegetable monsters produced by putting the farina sedum of one species of plant into the pistil or utricle of another.

The carnation and sweet-william being somewhat alike in their parts, particularly their flowers, the farina of the one will impregnate the other, and the seed so enlivened will produce a plant differing from either. An instance of this we first had in Mr Fairchild's garden at Hoxton; where a plant is seen neither sweet-william nor carnation, but resembling both equally; this was raised, not by seed, but by a carnation that had been impregnated by the farina of the sweet-william. Thee couplings being not unlike those of the mare with the ass, which produce the mule, the same name is given them; and they are, like the others, incapable of multiplying their species.

This furnishes a hint for altering the property and taste of any fruit, by impregnating one tree with the farina of another of the same class; e.g. a codlin with a pear-main, which will occasion the codlin so impregnated to laft a longer time than usual, and to be of a sharper taste. Or if the winter-fruits be fecundated with the dust of the summer kinds, they will ripen before their usual time. And from this accidental coupling of the farina of one with another, it may possibly be, that an orchard where there is variety of apples, even the fruit gathered from the same tree differ in their flavour, and in the season of maturity. It is also from the same accidental coupling that the numberless varieties of fruits and flowers raised every day from seed proceed.

Wild or Foul Mules. See Equus, p. 712.

MULHAUSEN, an imperial and Hanseatic town of Germany in Upper Saxony, and in Thuringia, under the protection of the elector of Saxony; seated in

VOL. XII.
MULHAUSEN, a considerable town of Germany, in Alsatia, and capital of a republic in alliance with the Swiss. It is populous, well built, and adorned with handsome public structures; seated in a pleasant fertile country, on an island formed by the river Ill, 15 miles north west of Bale, and 20 east of Belfort. E. Long. 7. 24. N. Lat. 47. 48.

MULLER, in law, signifies the lawful issue born in wedlock, though begotten before. The mulier is preferred to an elder brother born out of wedlock, though begotten before. The mulier is preferenced by a woman, if after that he marries her, the issue is mulier, son, or concave in a sphere or oval, or concave in a sphere or oval.

MULLER, one of the Western Islands of Scotland, about 25 miles long, and as much in breadth. It is in general rocky and barren, not producing a sufficient quantity of corn for the inhabitants; but a great number of cattle are annually exported, which with the fishings and a considerable quantity of kelp are the principal articles of commerce. It is deeply indented with bays and creeks, forming in several parts good natural harbours. There are no villages except Tobermory, near the northern point of the island, where a fishing station has been lately erected. The island was originally part of the dominions of the Lords of the Isles; but in after-times it became part of the possessions of the ancient and valiant family of Macleans, who still retain one-half. The other is the litigated property of the duke of Argyle, whose ancestor policed himself of it in 1674, on account of a debt: but after the courts of law had made an adjudication in his favour, he was obliged to support their decree by force of arms. The ruins of several ancient castles are seen on this island.

Mull of Cintyre. See CANTYRE.

Mull of Galloway. See GALLOWAY.

MULLEIN. See VERBASCUM.

MULLER or REGIAMONTANUS (John), a celebrated astronomer of the 15th century, was born at Koningshoven in Franconia in 1436, and acquired great reputation by publishing an abridgment of Ptolemy's Almagest, which had been begun by Purbach. He went to Rome to perfect himself in the Greek tongue, and to see the Cardinal Baffaron; but finding some faults in the Latin translations of George de Trebizond, that translator's son affiliated him in a second journey he made to Rome in 1476, where Pope Sextus IV. had provided for him the archbishopric of Ratisbon, and had sent for him to reform the calendar. Others say he died of the plague.

Muller (John) a noted engraver, who flourished about the year 1600, and had been bred under Henry Goltzius, whose style he closely imitated. The facility with which he handled the graver (for he worked with that instrument only) cannot be sufficiently expressed; his works must be seen, to convey a proper idea of it to the mind. His engravings are valuable, as productions of a very extraordinary nature; exclusive of which they have a prodigious share of merit. Among his most estimable performances may be mentioned, 1. The hand writing on the wall, a middling sized plate lengthwise, from his own composition. 2. The adoration of the wise men, the frame, from the same. Fine impressions of both these prints are very rare. 3. The resurrection of Lazarus, a large plate lengthwise, from Abraham Bloemart. He engraved also several much esteemed portraits.

Muller, or Mullar, denotes a plane flat and even at bottom, but round at top; used for grinding of matters on a marble. The apothecaries use mullers to prepare many of their tinctuous powders; and painters for their colours, either dry or in oil.

Muller is an instrument used by the glass-grinders; being a piece of wood, to one end whereof is cemented the glass to be ground, whether convex in a base or concave in a sphere or bowl. The muller is ordinarily about six inches long, turned round; the cement they use is composed of ashes and pitch. See GRINDING.

MULLERAS, a town of Germany, in the circle of Upper Saxony, and marquisate of Brandenburg, seated 38 miles south of Berlin, upon a canal which joins the Oder and the Spree. This canal is 15 miles in length, 10 yards in breadth, and seven feet in depth. It was eight years in making, and since that time the cities of Hamburg and Breslau have carried on great trade by water. E. Long. 14. 50. N. Lat. 52. 21.

MULLET, in ichthology. See MUGIL.

Muller, or Mullet, in heraldry, a bearing in form of the rowel of a spear, which it originally represented.

MULLINGAR, a borough or manor in the county of Westmeath, and province of Leinster, in Ireland, 30 miles from Dublin. It is the shire town of that county, and has a barracks for two troops of horse. It returns two members to parliament; patron the earl of Granard. This is a port town. N. Lat. 53. 50. W. Long. 7. 50. Within a few miles of it are the ruins of a church, and also thore of a castle. It is situated on the river Feyle. It holds a great wool fair, and is a place of good trade. In 1227, the priory of St Mary, formerly known by the name of The House of God of Mullingar, was founded here by Ralph de Petit bishop of Meath, for regular canons of the order of St Augustin. A Dominican friary was also founded here in 1237 by the family of Nugent; some ruins of which still remain. In 1622, the friars of Multifarnham began to erect a house here for friars of the order of St Francis, but it was never completed. Fairs are held here 6th April, 4th and 5th July, 29th August, and 11th November.

MULLUS, in Ichthyology, a genus of fishes belonging to the order of Thoracisci. See Plate CCCXV. This fish was highly esteemed by the Romans, and bore an exceedingly high price. The capricious epicures of Horace's days valued it in proportion to its size; not that the larger were more delicious, but that they were more difficult to be got. The price that was given for one in the time of Juvenal...
MULTUS, in Scots law, a certain stipulated quantity of meal given as payment to the proprietor or tackerman of a mill for grinding the corn; and all corn ground on farms thirled to the mill is obliged to pay multure whether the corn be ground at that mill or elsewhere.

MULTUS, a river of Barbary in Africa, which rises in the mountains of Atlas, and divides the empire of Morocco from that of Algiers, and then falls into the Mediterranean, to the westward of Martinique.

MUM, a kind of malt-liquor much drank in Germany, and chiefly brought from Brunswick, which is the place of most note for making it. The process of brewing mum, as recorded in the town-house of that city, is as follows. Take 63 gallons of water that has been boiled till one-third part is consumed, and brew it with seven bushels of wheaten malt, one bushel of oat-meal, and one bushel of ground beans. When it is tanned, the hoghead must not be filled too full at first; as soon as it begins to work, put into it three pounds of the inner rind of the tops of fir and beech, three handfuls of carduus benedictus, a handful or two of the flower of rofa folis: and burnet, betony, marjoram, avens, pensyroyal, and wild thyme, of each an handful and an half; of elder flower, two handfuls or more; seeds of cardamum bruised, 30 ounces; barberries bruised, one ounce: when the liquor has worked a while, put the herbs and seeds into the vessel; and, after they are added, let it work over as little as possible; then fill it up: lastly, when it is flopped, put into the hoghead ten new-laid eggs unbroken; flop it up close, and use it at two years end. The English brewers, instead of the inner rind of fir, use cardamum, ginger, and salafra; and also add clocampane, madder, and red sanders.

MUMIA. See PISABAULTUM.

MUMMIUS (L.), a Roman consul sent against the Achaeans, whom he conquered B. C. 147. He destroyed Corinth, Thebes, and Chalcis, by order of the senate, and obtained the surname of Achaeicus from his victories. He did not enrich himself with the spoils of the enemy, but returned home without any increase of fortune. He was consequently distinguished by the value of the paintings and works of the most celebrated artists of Greece which were found in the plunder of Corinth, that he said to those who conveyed them to Rome, that if they left them or injured them, they should make others in their stead.

MUMMY, a body embalmed or dried, in the manner used by the ancient Egyptians; or the composition with which it is embalmed. There are two kinds of bodies denominated mummiis. The first are only carcasses dried by the heat of the sun, and by that means kept from putrefaction: these are frequently found in the sands of Libya. Some imagine, that these are the bodies of deceived people buried there on purpose to keep them entire without embalming: others think they are the carcasses of travellers who have been overwhelmed by the clouds of sand raised by the hurricanes frequent in those deserts. The second kind of mummies are bodies taken out of the catacombs near Cairo, in which the Egyptians deposited their dead after embalming. See EMBAULMING.
We have two different substances preferred for medicinal use under the name of *mummy,* though both in some degree of the same origin. The one is the dried and preferred flesh of human bodies, embalmed with myrrh and spices; the other is the liquor running from such mummies, when nearly prepared, or when affected by great heat or damp. The latter is sometimes in a liquid, sometimes of a solid form, as it is preferred in vials well stopped, or suffered to dry and harden in the air. The first kind of mummy is brought to us in large pieces, to the smell agreeable; while the other is so cheap, that it will yield a scent of myrrh and aromatic virtues, or human bodies preserved without the use of Granada. seated on the declivity of a hill, at the bottom of which runs a river. *W. Long.* 4. 13. N. Lat. 48. 15.

This city was anciently famous for a victory gained by Caesar over the two sons of Pompey, who had collected an army in Spain after the defeat of their father at Pharsalia. See [History of] Rome.

The Pompeys posted their army advantageously on a rising ground, where one side was defended by the city of Munda, and the other by a small river which watered the plain, and by a marsh; so that the enemy could not attack them but in front. Caesar likewise drew up his troops with great art, and having advanced a little way from his camp, ordered them to halt, expecting the enemy would abandon the advantageous post, and come to meet him. But as they did not stir, Caesar made as if he intended to fortify himself in that post; which induced the young general, who looked upon this as a sign of fear, to advance into the plain, and attack the enemy before they could secure themselves with any works. Pompey’s army was by far the most numerous; for it consisted of 13 legions, 6000 horse, and an incredible number of auxiliaries, among whom were all the forces of Bocchus king of Mauritania, commanded by his two sons, both youths of great valour and bravery. Caesar had 80 cohorts, three legions, to wit, the third, the fifth, and the tenth, and a body of 8000 horse. As the enemy drew near, Caesar betrayed a great deal of uneasiness and concern, as if he were doubtful of the success, knowing he was to engage men no way inferior in valour and experience to his own, and commanded by officers who had on many occasions given signal proofs of their bravery and conduct. Cneius, the elder of the two brothers, was generally looked upon as an able commander; and Labienus, who had revolted, esteemed scarce inferior to himself.

However, the dictator, desirous to put an end to the civil war, either by his own death or that of his rivals, gave the signal for the battle, and fell upon the enemy with his usual vigour and resolution. At the first onset, which was dreadful, the auxiliaries on both sides betook themselves to flight, leaving the Romans to decide their quarrel by themselves. Then the legionaries engaged with a fury hardly to be expressed; Caesar’s men being encouraged by the hopes of putting an end to all their labours by this battle, and those of Pompey exerting themselves out of necessity and despair, since most of them expected no quarter, as having been formerly pardoned. Never was victory more obstinately disputed. Caesar’s men, who had been always used to conquer, found themselves so vigorously charged by the enemy’s legionaries, that they began to give ground; and though they did not turn their backs, yet it was manifest that shame alone kept them in their posts. All authors agree, that Caesar had never been in so great danger; and he himself, when he came back to his camp, told his friends, that he had often fought for victory, but this was the first time he had ever fought for life. Thinking himself abandon-
ed by fortune, which had hitherto favoured him, he had some thoughts of flaying himself with his own sword, and by a voluntary death preventing the disgrace of a defeat; but returning to himself, and concluding it would be more to his reputation to fall by the enemy's hand at the head of his troops, than, in a fit of despair, by his own, he dismounted from his horse, and matching a buckler from one of his legionaries, he threw himself like a man in despair into the midst of the enemy; crying out to his men, Are you not ashamed to deliver your general into the hands of boys? At these words, the soldiers of the tenth legion, animated by the example of their general, fell upon the enemy with fresh vigour, and made a dreadful havoc of them. But in spite of their utmost efforts, Pompey's men still kept their ground, and though greatly fatigued, returned to the charge with equal vigour. Then the Cœlarians began to despair of victory; and the dictator, running through the ranks of his disheartened legionaries, had much ado to keep them together. The battle had already lasted from the rising to the setting of the sun, without any considerable advantage on either side.

At length a mere accident decided the dispute in favour of the dictator. Bogud, a petty, king of Mauritania, had joined Cæsar soon after his arrival in Spain, with some squadrons of Numidian horse; but, in the very beginning of the battle, being terrified at the shouting of the soldiers, intermingled with groans, and the clashing of their arms, he had abandoned his post, and retired with the auxiliaries under his command to a rising ground at a small distance from the enemy's camp. There he continued the whole day an idle spectator of the battle that was fought in the plain. But towards the evening, partly out of compassion for his friend Cæsar, he resolved to fall upon Pompey's camp; and accordingly flew thither with all the forces he had with him. Labienus, apprised of his design, hastened after him to the defence of the camp; which Cæsar observing, cried to his legionaries, Courage, fellow-soldiers! the victory at length is ours; Labienus lives. This artifice had the desired effect: Cæsar's men, believing that Labienus was truly fled, made a loud effort, and charged the wing he commanded so briskly, that after a short and obstinate dispute they put them to flight.

Though the enemy's left wing was thus entirely defeated, the right wing, where the elder Pompey commanded, still kept their ground for some time. Pompey dismounting from his horse fought on foot like a private man in the first line, till most of his legionaries being killed, he was forced to save himself by flight from falling into the enemy's hands. Part of his troops fled back to their camp, and part took shelter in the city of Munda. The camp was immediately attacked, and taken sword in hand; and as for the city, Cæsar, without loss of time, drew a line of circumvallation round it. This victory was gained on the 16th of the kalends of April, i.e. according to our way of counting, on the 17th day of March, when the Dionysian festival, or the Liberalia, were celebrated at Rome; the very day, as Plutarch observes, in which Pompey the Great, four years before, had set out for the war. In this action Pompey lost 30,000 men; among whom were the famous Labienus, Attius Varus, and 3000 Roman knights. Seventeen officers of distinction were taken, and all the enemy's eagles and ensigns, together with Pompey's standards, which he had assumed as governor of Spain. On Cæsar's side only 1000 men were killed and 500 wounded.

MUNDIC, of Marcus. See Marcus.

MUNDINGOES, the name of a people who live on the sides of the river Gambia in Africa, and who are of a jet black colour, strong, and well made. They have a priest set over every year from one of the Cape de Verde islands to christen and marry.

MUNDUS PATES, the open world. In Roman antiquity, a solemnity performed in a small temple, of a round form like the world, dedicated to Divus and the rest of the infernal gods. This temple was opened but three times in the year, viz. the 24th of August, the 4th of October, and the 7th of November. During these days, the Romans believed hell was open; on those days therefore they never offered battle, killed soldiers, put out to sea, or married.

MUNICH, a town of Germany, capital of the whole duchy of Bavaria, and the residence of the elector. It stands on the Iper, 70 miles south of Ratibon and 214 miles west of Vienna, being one of the most pleasant and populous cities of Germany for its bigness. The number of the inhabitants is said to be about 40,000. Having been built at first on a spot of ground belonging to a convent, it had from thence in German the name of Munchen, i.e. Münchstäd, and a monk for its arms. The elector's palace here is a very grand structure, consisting of several courts, furnished and adorned in the most magnificent manner, with tapestry, gilding, sculpture, statues, and paintings. It contains an amazing collection of jewels, antiquities, and curiosities. The great hall is 118 feet long and 52 broad; and the stair-case leading to it, from top to bottom, of Marble and gold. In the hall of antiquities are 354 busts and statues of Jasper and porphyry, brats and marble. In this palace also is a library, containing a vast collection of books, and many valuable manuscripts, in most languages, ancient and modern; and a chamber of rarities, among which is the picture of a brave or affidim, who is said to have committed 345 murders with his own hand, and to have been accomplice in or privy to 400 more. The treasury in the chapel contains also a vast number of pictures, precious stones, medals, vessels of gold and silver, &c. Among other curiosities, here is a cherry-stone with 140 heads distinctly engraved upon it. The gardens of the palace are also very fine, and it is said a secret passage leads from it to all the churches and convents in the town. There is a great number of other fine buildings in this city, public and private, particularly the riding-house, town-house, opera-room, the Jesuits' college, the large edifice for tournaments, the churches, convents, &c. Its manufactures are those of silk, particularly velvet, wooden cloths, and tapestry; and it has two annual fairs, at which great quantities of salt, wine, &c. are sold. The streets are broad and regular; and most of the houses well built, and painted on the outside. The market place is extremely beautiful. Not far from Munich are four other palaces, with fine gardens, belonging to the elector, e.g. those of Stuhlheim, Nymphenburg, Dachau, and Starnberg. The first and last
MUNICH (Count de), was the favourite of the Czarina Anna, and was concerned in all the events of her reign. Being appointed general of her armies, he gained great advantages over the Crim Tartars, beat the Turks, A.D. 1739, in an engagement near Chocim, and took that city together with Jaffi the capital of Moldavia. He was afterwards prime minister to the Czar Ivan VI., but in a short time after he was accused of employing the power which his office conferred on him to gratify his own ambition and private resentment. The Empress Elisabeth brought him to trial, and he was condemned to lose his life A.D. 1742. This sentence was mitigated to banishment into Siberia, whither many of the victims of his power had been exiled. He was recalled by Peter III. A.D. 1762, and declared field-marshall. Upon the death of this prince, the Empress Catharine II. appointed him director-general of the ports of the Baltic. He died on the 8th of October 1767, at the age of 84.

MUNICIPAL, in the Roman civil law, an epithet which signified invested with the rights and privileges of Roman citizens. See MUNICIPIUM.

Municipal, among us, is applied to the laws that obtain in any particular city or province. And those are called municipal officers who are elected to defend the interests of cities, to maintain their rights and privileges, and to preserve order and harmony among the citizens; such as mayors, sheriffs, consuls, &c.

MUNICIPES, an appellation given by the Romans to the inhabitants of the municipal cities. See MUNICIPIUM.

MUNICIPIUM, in Roman antiquity, a corporation, a body of freemen, or enfranchised city or town, where the inhabitants enjoyed their own laws and customs, and at the same time were honoured with the privileges of Roman citizens; but then this privilege generally reached no farther than the bare title. Some indeed, by particular merit, obtained the liberty of votes, which occasioned that distinction of munici pium sine suffragio, and munici pium cum suffragio — The inhabitants of the municipium sine suffragio were called simply Romans, but those of the municipium cum suffragio were called ci vites Romanis.

The difference between proper citizens of Rome and the inhabitants of the municipia may be thus expressed. The proper citizens of Rome were, 1. Registered in the census; 2. Had the right of suffrage and of bearing honours; 3. Were assembled in the people; 4. Served in the legions; 5. Used the Roman laws and religion; 6. Were called Quiris et populus Romanus. Whereas the municipals enjoyed the three first of these privileges but were denied the last. MUNITION, the provisions with which a place is furnished in order for defence, or which follows a camp for its subsistence.

Munsters, are those that have store on board in order to supply a fleet of men of war at sea. In an engagement, all the munition-ships and victuallers attending the fleet take their station in the rear of all the rest, they are not to engage in the fight, but to attend to such directions as are sent them by the admiral.

MUNSTER (Sebastion), a learned writer, was born at Ingleheim, and became a Cordelier; but having embraced Luther's sentiments, he quitted that order in 1529, and retired to Heidelberg, and afterwards to Basle, where he taught with reputation. He was a man of great candour, and void of ambition; and was so well skilful in geography, the mathematics, and the Hebrew tongue, that he was furnished the Ezras and the Strabo of Germany. His Latin translation of the bible is esteemed. He was the first who wrote a Chaldee grammar and lexicon; he also published a treatise on chorography, and several other works. He died of the plague at Basle in 1552, aged 63.

MUNSTER, in Latin Munomia, and in Irish Mun, the most easterly province of Ireland; bounded on the north by Leinster and Connaught, and on the east, west, and south by the ocean. It contains the counties Cork, Clare, Kerry, Limerick, Tipperary, and Waterford; and 3,289,932 Irish plantation acres, 740 parishes, 66 baronies, and 26 boroughs. It is about 125 miles long, and 120 broad: and its principal town is Cork. Its ancient name was Munibhan; and in latter ages it was divided into Desmond or south Munster, Ormond or east Munster, and Thomond or north Munster. It lies between 51. 15. and 53. 0. N. Lat. and 7. 10. to 10. 30. W. Long.

MUNSTER, a territory of Germany, in the circle of Westphalia; bounded on the north by Emden and Oldenburg, on the fourth by the counties of Mark and duchy of Weftphalia, on the west by the county of Bentheim and the United provinces, and on the east by the bishoprics of Osnaburg and Paderborn together with the county of Ravensberg. It is the largest of all the Westphalian bishoprics, being in length about 80 miles, and in breadth from 20 to 60. It is divided into 13 bailiwicks; and though in general but a barren country, has some fruitful plains, with woods, and quarries of stone. The inhabitants, excepting a few of the nobility and gentry, are all Roman Catholics; though Lutheranism had once a considerable footing here. The bishop, who is generally also elector of Cologne, has a revenue from hence of about 70,000 pounds, and can maintain 8000 men. In consequence of an unjust eulom, unknown in the rest of the empire, he is heir to all strangers who die in the country without children. In the matricula he is rated at 50 foot and 118 horse; or 832 florins monthly in lieu of them. His chapter consists of 40 canons, who are all noble.

MUNSTER, a city of Germany, capital of a bishopric of the same name and of all Westphalia, stands at the conflux of the river Aa with the Em, in E. Long. 7. 49. N. Lat. 52. 0. It is of a circular form, large, and well fortified both by nature and art. It has a fine citadel called the Brille, erected by a bishop named Berraud van Galen in order to awe the burghers. The dean and chapter now elect the bishop; but till the beginning of the 15th century he was nominated by the emperor. This city has been rendered famous by three remarkable transactions. 1. By the peace concluded here 1648, which put an end to a war of 30 years, occasioned by the perfecting spirit of bigotry and papists, who chose rather to plunge their country into all the calamities of war than allow liberty of conscience to the Protestants. By this peace, however,
Manychia ever, they contended, much against their inclination to grant them a toleration. 2. By the disorders and disturbances occasioned here in 1553, by a parcel of enthusiasts, headed by a tailor called John of Leyden from the place of his birth, who turned out the magistrates, and took possession of the city, where they perpetrated the most horrid villanies and cruelties. 3. For the noble, though unsuccessful, efforts it made in defence of its liberties against the tyranny and usurpation of the above-mentioned turbulent and bloody-minded bishop, Bernard van Galen. In this city are a great number of convents and other religious houses, many of them lately piles, and surrounded with beautiful gardens.

MUNYCHIA, or Manychus Porus (anc. geog.), a village and port of Athens, nearer to the city, than, and fortified in the same manner with the Piraeus, to the east of which it lay, or between it and the promontory Sunium, at the mouth of the Ilissus. Strabo says it was an eminence in form of a peninsular, at the foot of which stood three harbours, anciently encompassed with a wall, taking within its extent the Piraeus and other harbours, full of docks, with the temple of Diana, Manychion; taking its name from Manychus, the founder of the temple. Manychus, an anniversary solemnity observed at Athens in honour of Diana, on the 16th of the month Manychion. Cakes were offered on the occasion called MUNYCHION.

MUNYCHION, the tenth month of the Athenian year, containing 29 days, and answering to the latter part of our March and the beginning of April. It was so called from the festival Manychion, which was observed in this month. See Month and MUNYCHIA.

MUPHTGI. See MUFF。

MURÆNA, or Eel, in ichthyology; a genus of fishes, belonging to the order of apodes. The head is smooth; there are ten rays in the membrane of the gills; the eyes are covered with a common skin: and the body is cylindrical and slimy. There are seven species, distinguished by their fins, tails, &c. The most remarkable are,

1. The anguilla, or common eel, is very frequent in most fresh waters, ponds, ditches, and rivers: according to Mr Pennant, it is the most universal of fish; yet is scarce ever found in the Danube, though very common in the lakes and rivers of Upper Austria.

The eel is very singular in many things relating to its natural history, and in some respects borders on the nature of the reptile tribe. It is known to quit its element, and during night to wander along the meadows, not only in order to change its habitation but also for the sake of prey, feeding on fish, as it passes along. During winter it beds itself deep in the mud, and continues in a hibernation, during which it is known to quit the mud, and continues in a hibernation, during which it is known to quit the mud, and continues in a hibernation, during which it is known to quit the mud, and continues in a hibernation, during which it is known to quit

Eels are extremely voracious, and destructive to the fry of others. No fish lives so long out of water as the eel; and it is so extremely tenacious of life, that its parts will move a considerable time after they are flayed and cut to pieces. They vary much in their colour, from a fomber brown to a light olive green; and those which are called pilchard eels have their bellies white, and a remarkable clearness throughout. Besides these, there is a variety of this fish known in the river Thames by the name of grigs, and about Oxford by that of grigs or golt. These are scarce ever seen near Oxford in the winter; but appear in spring, and bite readily at the hook, which common eels in that neighbourhood will not. They have a larger head, a blunter nose, thicker skin, and fewer, than the common eel; neither are they so much esteemed, nor do they often exceed three or four pounds in weight.—Common eels grow to a large size, sometimes weighing 15 or 20 pounds; but that is extremely rare. Mr Dale indeed, in the Phi opological Transactions, and some others, bring instances of eels much exceeding that size; but Mr Pennant suspects them to have been congers, since the enormous fish they describe have all been taken at the mouths of the Thames or Medway. The Romans believed eels cheap, probably on account of their likeness to snakes. On the contrary, the luxurious Sybarites were so fond of these fish, as to exempt from tribute of every kind persons who sold them.

There is scarce any animal the generation of which has puzzled the learned more than this. Ariosto first broached an opinion that eels were of no sex, nor did propagate their species like other animals, but were unequivocally gendered of the mud; and as wild and aburd a system as this is, there have not been wanting many, even in these latter and more enlightened times, who have given into it. But there is now no room to doubt that all animals are produced by the copulation of parents like themselves; and the several sexes may be discovered on a comparison of the parts, and of the young. Dr Plot, and many others, have given accounts of whole droves of them leaving one ditch or pond to go to another.

Though the learned world at this time generally allows that eels are produced like other animals' by parents of their own kind, yet there remain many doubts about the manner in which the generation is performed. Some allow the eels to be, like the generality of other animals, of different sexes in the different individual's; and others affirm that they are all hermaphrodites, each having the parts of generation of both sexes. Rondeletius affirms that they are of both sexes; and Mr Allen, who has given a very curious paper concerning them in the Philosophical Transactions, is of the same opinion; and both say, that the parts of the sexes may be discovered on a careful inspection; and some are found to be males, and others females; but those parts are, in both sexes they say, buried in a large quantity of fat; and they are of opinion, that hence proceeded the mistake of Ariosto and his followers, who, not being able to find those parts, concluded that they did not exist at all. Among those who allow the eel to be produced, like other animals, from animal-parents which have the sexes, some are of opinion that they are viviparous, and;
and others that they are oripitous; but Mr. Chart-Teed seems to have determined this controversy by observing, that if the aperture under the belly of the eel, which looks red in the month of May, be cut open at that time, the young eels will be seen to come forth alive after the operation. Mr. Lewen-hore, says, that he found an uterus in every eel he examined; and therefore concludes that they are hermaphrodites; and he supposes that they have no male parts of generation like those of other animals; but that the office of these is performed by a liquor analogous to the male seed of animals, which is contained in certain glands, situated in the inside of the uterus itself.

Eels have sometimes been met with in recent ponds, made at such a distance from any other water that we cannot reasonably suppose them to have migrated thither over land. But in these cases there is reason to believe, that the ponds have been supplied with them by the aquatic fowls of prey, in the same manner as vegetation is spread by many of the land-birds, either by being dropped, as they carry them, to feed on their young, or by passing quick through their bodies, as is the case with herons.

2. The conger, or conger-eel, grows to a vast size. Dr. Borrach informs us, that they are sometimes taken near Mount’s bay of 100 lb. weight; and Mr. Pennant affures us, that he has heard of some taken near Scarborough that were 10 feet and a half long, and 18 inches in circumference in the thickest part. They differ from the common eel in the following particulars: 1. Their colour in general is more dark. 2. Their eyes much larger in proportion. 3. The irides of a bright silvery colour. 4. The lower jaw is rather shorter than the upper. 5. The infide-line is broad, whitish, and marked with a row of small spots. 6. The edges of the dorsal and anal fins are black. 7. They have more bones than the common eel, especially along the back quite to the head. 8. They grow to a much larger size.

Congers are extremely voracious, preying on other fish, and on crabs at the time they have lost their shell, and are in a soft state. They and eels in general are also particularly fond of carcasses of any kind, being frequently found lodged in such as are accidentally taken up.

The conger eels probably generate like the fresh-water species. Innumerable quantities of what are supposed to be their fry come up the Severn about the month of April, preceding the shads, which it is conjectured migrate into that river to feed on them; they are called eelers. They swarm during their season, and are taken in a kind of sieve made of hair-cloth fixed to a long pole; the fisherman standing on the edge of the water during the tide, puts in his net as far as he can reach, and drawing it out again, takes multitudes at every sweep, and will take as many during one tide as will fill a bannel. They are dried, and reckoned very delicate.

These fish are an article of commerce in Cornwall; numbers are taken on that coast, and exported to Spain and Portugal, particularly to Barcelona. Some are taken by a single hook and line, but (because that way is tedious, and does not answer the expense of time and labour) they are chiefly caught by baits, which are strong lines 500 feet long, with 60 hooks, each eight feet distance, baited with pick-licks or mud-balls; the baits are fixed to the ground by a stone fastened to them: sometimes such a number of these are tied together as to reach a mile. The fishermen are very fearful of a large conger, lest it should endanger their legs by clinging round them: they therefore kill them as soon as possible by striking them on the navel. They are afterwards cured in this manner: They are flit, and hung on a frame till they dry, having a considerable quantity of salt, which it is necessary should exude before they are fit for use. It is remarkable that a conger of 100 weight will walk by drying to 24 lb.; the people therefore prefer the smallest, possibly because they are soonest cured. During the proceeds there is a considerable fetch; and it is said that in the fishing villages the poultry are fed with the maggots that drop from the fish. The Portuguese and Spaniards use those dried eels after they have been ground into a powder, to thicken and give a relish to their soups. They are sold for about 40 brilliantings the quintal, which weighs 125 lb. A fishery of congers, says Mr. Pennant, would be of great advantage to the inhabitants of the Hebrides. Perhaps they would at first undertake it with repugnancy, from their abhorred aversion to the eel kind.

3. The firen, or mud niguana, a singular animal, first observed by Dr. Garden of Charlestown, and afterwards described by Mr. Ellis in the Philosophical Transactions for 1766. It has gills, fins, and two feet; and is in length from 31 to 40 inches. It is an inhabitant of South Carolina, where it is found in swampy and muddy places, by the sides of pools, and under the trunks of old trees that hang over the water, and feeds on serpents. The feet appear like little arms and hands, each furnished with four fingers, and each finger with a claw. "The head is something like an eel, but more compressed; the eyes are small and placed as those of the eel are. This smallness of the eye befits suits an animal that lives so much in mud. The nostrils are very plainly to be distinguished: these, with the gills, and remarkable length of the lungs, show it to be a true amphibious animal." The mouth is small in proportion to the length of the body, but its palate and infide of the lower jaw are well provided with many rows of pointed teeth; with this provision of nature, added to the sharp exterior bony edges of both the upper and under jaw, the animal seems capable of biting and grinding the hardest kind of food. The skin, which is black and full of small scales, resembles shagreen. These scales are of different sizes and shapes, according to their situation; but all appear sunk into its gelatinous surface; those along the back and belly are of an oblong oval form, and close set together; in the other parts they are round, and more distinct. Both the parts are mottled with small white spots, and have two distinct lines composed of small white streaks continued along from the feet to the tail. The fin of the tail has no rays, and is no more than an adipose membrane like that of the eel.

Dr. Garden, in a letter to Mr. Ellis, mentions a remarkable property of this animal, which is, that his servant endeavouring to kill one of them by dashing it
it against the stones, it broke into three or four pieces. Linnaeus, from the descriptions sent him, made it a new genus named Syren, of a new order Meantes, of the class amphibia. But from this class both the order Meantes and that of Montier have been lately expunged; and Gmelin has reduced the syren to a species of the present genus. Its place here, however, seems still of doubtful propriety; as Gmelin himself acknowledges in the Preface to his edition of the Systema Nature. For Camper, having lately had an opportunity to dissect the syren, has discovered, that on each side of the head it is furnished with three true gills, separated from each other by membranes having tooth-like appendages; that the mouth is armed with strong and firmly planted teeth; that the heart has only one ventricle; and that the abdomen is filled with very long and capacious intestines. From all these circumstances, he concludes, that this animal ought to be considered as a fith of the order Branchiopodei—while in other respects it is more nearly allied to the genus Murana, of the order Apodes; although it differs materially from the other species of that genus, by having only three notched bones in the gills, and from the pectoral fins being each divided into four finger-like appendages.

Mural, something belonging to a wall; which the Latins call murus, Mural-Crown, among the ancient Romans. See Crown.

Mural-Arch, is a wall, or walled arch, placed exactly in the plane of the meridian, i.e., upon the meridian line, for the fixing of a large quadrant, sextant, or other instrument, to observe the meridian altitudes, &c. of the heavenly bodies.

Tycho Brahe was the first who used a mural arch in his observations; after him Hevelius, Mr Flamsteed, De la Hire, &c. used the same means. See Astronomy.

Muralt (N—de), a native of Switzerland, travelled through a great part of Europe with the views of a philosopher. He published a collection of Lettres sur les Franños et sur les Anglais, 12mo, 2 vols. 1726, which met with great success, though they are written in a vague and superficial manner. Some other works which he published are below mediocrity. He died about the year 1750.

Murent (Emanuel), a much admired landscape painter, was born at Amsterdam in 1622. He had the happiness to be a disciple of Philip van Wouwermans, from whom he acquired that warmth and brilliancy of colouring, and that exquisite pencil, which have rendered him deservedly eminent. His subjects were views in Holland, villages, towns, cities, ruins of houses, and decayed castles; all of them exactly sketched after nature, and so exquisitely finished, that every minute part of a building was perfectly decipherable, and even every particular stone or brick might be counted by the assistance of a convex glass. But this demanded so much patience and time; that it was impossible for him to paint many pictures, and on that account they are exceedingly scarce, and sold for high prices as much place them out of the reach of all ordinary purchasers. He died in 1705.

Vol. XII. labria Citra, at the springs of the Sybaris, midway between the Sinus Tarentinus to the east, and the Tau-

can sea to the west. Supposed to have arisen from the ruins of Syphium, a town of the Bruttii mentioned by Livy.

Muratori (Lewis Anthony), a learned and celebrated Italian writer, born at Vignoles, in the territory of Bologna, in 1672. He early discovered an extreme fondness for the learned languages and sciences; and this was seconded by an excellent education. After having completed his first studies, he embraced the state of an ecclesiastic; and applied himself to polite literature, philosophy, theology, civil law, antiquities, and other sciences; by which means he became in a manner universally learned. He was scarcely 22 years of age when he was made librarian of the Ambrosian library at Milan. In 1700 the duke of Modena, his sovereign recalled him, and made him his librarian, and keeper of the archives of his duchy. Muratori discharged this double employment during the rest of his life, and had no other benefit than the provostship of Santa Maria del Pomposa. He acquired the esteem of the learned throughout Europe, who had recourse to him for the lights they wanted. He became an associate to the Academies of the Arcades of Rome, Della Crusca, and Colombaia of Florence, the Academy of Etruria at Corona, the Royal Society of London, and of the Imperial Academy of Olmutz; and died in 1750. He wrote a great number of learned works; the principal of which are—

Murcita, the pagan goddess of idyls. The name is taken from murus or murculus, an oblong word, signifying a dull, slothful, or lazy person. The statues of this goddess were always covered with dust and moss, to express her idleness and negligence. She had a temple in Rome at the foot of the Aventine mount.

Murcia, a kingdom in Spain, bounded on the north by the Castile, on the east by the kingdom of Valencia, on the west by Andalusia and Granada, and on the south by the Mediterranean Sea. It is about 62 miles in length, and 58 in breadth; and its principal river is Segura. The soil is dry, because it seldom rains, and therefore it produces little corn or wine; but there is plenty of oranges, citrons, lemons, olives, almonds, mulberries, rice, pulses, and sugar. It has also a great deal of silk. It was taken from the Moors in 1265. The air is very healthful.

Murcia, a large handomme, and populous town of Spain, capital of a kingdom of the same name. It is a bishop's see, and contains six parishes. The cathedral is a most superb edifice, with the turrets of the steeples so contrived that a man may ride up to the top,
MURDER, or MURDER, the act of killing another with violence and injustice. The word comes from the Saxon mordran “death,” which some will have to signify a violent death; whence the barbarous Latin mordrum and mordrum.

Among the number of popular errors, is the notion which has obtained, that the dead body would bleed in the presence or upon the touch of the murderer.

The crime of murder is punished with death in almost all nations.

Murder, or Murder, in law, is thus defined or rather described, by Sir Edward Coke: “When a person, of sound memory or discretion, unlawfully killeth any reasonable creature in being, and under the king’s peace, with malware aforethought, either express or implied.” The best way of examining the nature of this crime will be by considering the several branches of this definition.

1. It must be committed by a person of sound memory and discretion; for lunatics or infants are incapable of committing any crime; unless in such cases where they throw a conciousness of doing wrong, and of course a discretion or discernment between good and evil.

2. Next, it happens when a person of such sound discretion unlawfully killeth. The unlawfulness arises from the killing without warrant or excuse; and there must also be an actual killing to constitute murder; for a bare assault, with intent to kill, is only a great misdemeanor, though formerly it was held to be murder. The killing may be by poisoning, striking, starving, drowning, and a thousand other forms of death, by which human nature may be overcome. Of these the most detestable is all poison; because it can of all others be the least prevented, either by manhood or forethought. And therefore, by the stat. 2 Hen. VIII. c. 9., it was made treason, and a more grievous and lingering kind of death was inflicted on it than the common law allowed; namely, boiling to death; but this act did not live long, being repelled by Edw. VI. c. 12.

3. There was also by the ancient common law, one species of killing held to be murder, which may be dubious at this day, as there hath not been an instance wherein it hath been held to be murder for many ages past, viz. bearing false witness against another, with an express premeditated design to take away his life, so as the innocent person be condemned and executed. The Gothic laws punished in this case both the judge, the witnese, and the protactor; and, among the Romans, the lex Cornelia de faccaris, punished the false witnese with death, as being guilty of a species of affasination. And there is no doubt but this is equally murder in foro consciente as killing with a sword; though the modern law (to avoid the danger of deterring witnesses from giving evidence upon capital prosecutions, if it must be at the peril of their own lives) has not yet punished it as such. If a man, however, does such an act, of which the probable consequence may be and eventually is, death; such killing may be murder, although no stroke be struck by himself, and no killing may be primarily intended: as was the case of the unnatural son who exposed his sick father to the air against his will, by reason whereof he died; and of the harlot, who laid her child under leaves in an orchard, where a kite struck it and killed it. So too, if a man hath a beast that is tamed to do mischief; and he, knowing it, suffers it to go abroad, and it kills a man; even this is manslaughter in the owner; but if he had purposely turned it loose, though barely to frighten people and make what is called sport, it is with us (as in the Jewish law) as much murder as if he had incited a bear or a dog to worry them.

If a physician or surgeon gives his patient a potion or platter to cure him, which, contrary to expectation kills him, this is neither murder nor manslaughter, but misadventure; and he shall not be punished criminally, however liable he might formerly have been to a civil action for neglect or ignorance; but it hath been held, that if it be not a regular physician or surgeon who administers the medicine, or performs the operation, it is manslaughter at the least. Yet Sir Matthew Hale very justly questions the law of this determination; since physic and salves were in use before licensed physicians and surgeons; wherefore he treats this doctrine as apocryphal, and fitted only to gratify and flatter licentiates and doctors in physic; though it may be of use to make people cautious and wary how they meddle too much in so dangerous an employment. In order also to make the killing murder, it is requisite that the party die within a year and a day after the stroke received, or cause of death administered; in the computation of which the whole day upon which the hurt was done shall be reckoned the first.

3. Farther: The person killed must be “a reasonable creature in being, and under the king’s peace,” at the time of the killing. Therefore to kill an alien, a Jew, or an outlaw, who are all under the king’s peace or protection, is as much murder as to kill the most regular-born Englishman; except he be an alien enemy, in time of war. To kill a child in its mother’s womb, is now no murder, but a great misprision: but if the child be born alive, and dieth by reason of the potion or bruises it received in the womb, it seems, by the better opinion, to be murder in such as administered or gave them. As to the murder of bastard children, see Bastard.

4. Lastly, the killing must be committed “with male cereafothught,” to make it the crime of murder. This is the grand criterion which now distinguishes murder from other killing; and this malice prepara maliitia praecognitata, is not so properly fithe or malevolence to the deceased in particular, as any evil design in general; the dictate of a wicked, depraved, and malignant heart; un disposition a faire un mal choie; and it may be either express, or implied, in law. Express malice is when one, with a sedate deliberate mind and formed design, doth kill another: which formed design is evidenced by external circumstances discovering that inward intention; as lying in wait, antecedent menaces, former grudges, and concerted schemes to do him some bodily-harm. This takes in the case of deliberate dueling, where both parties meet avowedly with an intend to murder: thinking it their duty, as gentlemen, and claiming it as their right, to wanton with
Murder, with their own lives and those of their fellow-creatures; without any warrant or authority from any power either divine or human, but in direct contradiction to the laws both of God and man: and therefore the law has justly fixed the crime and punishment of murder on them, and on their seconds also. Yet it requires such a degree of pugilistic valour to combat the dread of even unmerited contempt, arising from the false notions of honour too generally received in Europe, that the strongest prohibitions and penalties of the law will never be entirely effectual to eradicate this unhappy custom, till a method be found out of compelling the original aggressor to make some other satisfaction to the affronted party, which the world shall esteem equally reputable as that which is now given at the hazard of the life and fortune, as well of the person insulted, as of him who hath given the insult. Also, if ever upon a sudden provoked one beats another, in a cruel and unusual manner, so that he dies, though he did not intend his death, yet he is guilty of murder by express malice; i.e. by an express evil design, the genuine sine of malitia. As when a park-keeper tied a boy that was feeding wood to a horse's tail, and dragged him along the park; when a jailer corrected his tenant with an iron bar, and a schoolmaster dashed on his scholar's belly, so that each of the sufferers died; these were justly held to be murders, because the correction being excessive, and such as could not proceed but from a bad heart, it was equivalent to a deliberate act of slaughter. Neither shall he be guilty of a lefs crime who kills another in consequence of such a wilful act as shows him to be an enemy to all mankind in general; as going deliberately, and with an intent to do mischief, upon a horse used to strike, or coolly discharging a gun among a multitude of people. So if a man resolves to kill the next man he meets, and does kill him, it is murder, although he knew him not; for this is universal malice. And if two or more come together to do an unlawful act against the king's peace, of which the probable consequence might be bloodshed; as to beat a man, to commit a riot, or to rob a park, and one of them kills a man; it is murder in them all, because of the unlawful act, the malitia praecognitae, or evil intended beforehand.

Also in many cases where no malice is expressed, the law will imply it: as, where a man wilfully poisons another, in such a deliberate act the law presumes malice, though no particular enmity can be proved. And if a man kills another suddenly, without any or without a considerable provocation, the law implies malice; for no person, unless of an abandoned heart, would be guilty of such an act upon a flight or no apparent cause. No assault before, by words of gaffes only, is a sufficient provocation, so as to excuse or extenuate such acts of violence as manifestly endanger the life of another. But if the person so provoked had unfortunately killed the other, by beating him in such a manner as showed only an intent to chastise and not to kill him, the law so far considers the provocation of contumelious behaviour, as to adjudge it ony manslaughter, and not murder. In like manner, if one kills an officer of justice, either civil or criminal, in the execution of his duty, or any of his auxiliaries endeavouring to preserve the peace, or any private person foreseeing to suppress an affray or apprehend a felon, knowing his authority or the intention with which he interposes, the law will imply malice, and the killer shall be guilty of murder. And if one intends to do another felony, and undesignedly kills a man, this is also murder. Thus if one shoots at A, and misses him, but kills B, this is murder; because of the previous felonious intent, which the law transfers from one to the other. The same is the case, where one lays poison for A, and B, against whom the prisoner had no malicious intent, takes it, and it kills him, this is likewise murder. So also if one gives a woman with child a medicine to procure abortion, and it operates so violently as to kill the woman, this is murder in the person who gave it. It were endless to go through all the cases of homicide, which have been adjudged, either expressly or impliedly, malicious; these therefore may suffice as a specimen; and we may take it for a general rule, that all homicide is malicious, and of course amounts to murder, unless where justified by the command or permission of the law; excused on a principle of accident or self-prevention; or alleviated into manslaughter, by being either the involuntary consequence of some act, not strictly lawful, or (if voluntary) occasioned by some sudden and sufficiently violent provocation. And all these circumstances of justification, excuse, or alleviation, it is incumbent upon the prisoner to make out, to the satisfaction of the court and jury: the latter of whom are to decide whether the circumstances alleged are proved to have actually existed; the former, how far they extend to take away or mitigate the guilt. For all homicide is presumed to be malicious, until the contrary appeareth upon evidence.

The punishment of murder, and that of manslaughter, were formerly one and the same; both having the benefit of clergy: so that none but unlearned persons, who knew the guilt of it, were put to death for this enormous crime. But now, by several statutes, the benefit of clergy is taken away from murderers through malice prelence, their abettors, procurers, and connivers. In atrocious cases it was frequently usual for the court to direct the murderer, after execution, to be hung upon a gibbet in chains near the place where the fact was committed; but this was no part of the legal judgment; and the like is still sometimes practised in the case of notorious thieves. This, being quite contrary to the express command of the Mosaic law, seems to have been borrowed from the civil law; which, besides the terror of the example, gives also another reason for this practice, viz. that it is a comfortable sight to the relations and friends of the deceased. But now, in England, it is enacted by statute 25 Geo. II. c. 37, that the judge, before whom any person is found guilty of wilful murder, shall pronounce sentence immediately after conviction, unless he gives cause to postpon it; and shall in passimg sentence direct him to be executed on the next day but one (unless the same shall be Sunday, and then on the Monday following), and that his body be delivered to the surgeons to be dissected and anatomized; and that the judge may direct his body to be afterwards hung in chains, but in nowife to be buried without diffension. And, during the short but awful interval between sentence and execution, the prisoner...
MUR [ 452 ]

MURDERERS shall be kept alone, and furnished with only bread and water. But a power is allowed to the judge, upon good and sufficient cause, to reprieve the execution, and relax the other restraints of this act. See farther, PARADIGM, and PETI TEAON.

MURDERERS, or Murdering Piers, in a ship, are small pieces of ordinance, either of brass or iron, which have chambers put in at their breeches. They are used at the bulk-heads of the fore-castle, half-deck, or steerage, in order to clear the deck, on the ship's being boarded by an enemy.

MURENA. See MUREN.

MURENGERS, two officers of great antiquity in the city of Chelten, annually chosen out of the aldermen, to see that the walls are kept in repair, and to receive a certain toll and custom for the maintenance thereof.

MURET (Mark Anthony Francis), in Latin Muretus, was born at Muret, near Limoges, in 1526. He acquired a perfect knowledge of the Greek and Latin tongues without any instructor, and became one of the most learned men of his time. After having taught some time in Provence, he was made a professor at Paris in the same college with Turrebus and Buchanan. In 1554 he went into Italy; and in 1563 was professor of law, philosophy, and history, at Rome, where he died in 1585. His principal works are, 1. Excellent notes on Terence, Horace, Catullus, Tacitus, Cicero, Sallut, Arifotle, Xemophon, &c. 2. Orations. 3. Varie, Lebon, Poemata, Hymni Sacri. 4. Difputationes in Lib. I. Pendiculorum, de Origine Juris, &c. 5. Epitole, Juvenilia Carmina, &c. Most of Muret's works have been printed in the Venice edition of 1737, in 5 vols 8vo.

MUREX, in zoology, a genus of infects belonging to the order of vermns thactaca. This animal is of the shell-kind: the shell consists of one spiral valve, rough, with membraneous furrows; and the aperture terminates in an entire canal, either straight, or somewhat aequiformal. There are 60 species, particularly distinguished by peculiarities in their shells, &c.

From a species of murex was obtained the famous Tyrian dye so much valued by the ancients. This, however, has long been superseded by the use of the cochineal. One of the shells producing the dye was a kind of buccinum; but the finest, or Tyrian purple, was got from the murex. These species of shells are found in various parts of the Mediterranean. Immense heaps of them are to be seen about Tarentum to this day, evincing one place where this precious liquor was extracted. See Plate CCCXXI.

In the accounts of a Spanish philosopher it is mentioned, that on the coasts of Guayaquil and Gaitalina in Peru the murex is also found. The shell which contains it adheres to the rocks that are washed by the sea: it is of the size of a large walnut. The liquor may be extracted two ways; some kill the animal after they have drawn it out of the shell; then perf it with a knife from head to tail; separate from the body the part where the liquor is collected, and throw away the rest. When this operation, after being repeated on several snails, has afforded a certain quantity of fluid, the thread intended to be dyed is dipped in it, and the process is finished. The colour, which is at first of the whiteness of milk, becomes afterwards green, and is not purple till the thread is dry.

Those who disapprove of this method, draw the fish partly out of the shell, and, squeezing it, make it yield a fluid which serves for dying: they repeat this operation four times at different intervals, but always with less success. If they continue it, the fish dies. No colour at present known, says the Abbé Raynal, can be compared to this, either as to lustre, liveliness, or duration. It succeeds better on cotton than wool, linen, or silk.

Murex, a caltrar or iron instrument, with sharp points projecting in every direction, used by the Romans as a defence against the enemy's horse. It was so called, probably, because the points bore some resemblance to the spines and tubercles with which the shell of the fish murex is surronded.

MURG, or Murgis (anc. geog.), the last town of Bética, next the Tarraconensis: the Urce of Ptolem. Now Murcia, a port-town of Granada, on the Mediterranean. W. Long. 1° 50'. N. Lat. 37° 6'.

MURIA, a very early inclination to painting. He was instructed by his uncle John de Calillo, an artist of some note, whose subjects were fairs and markets; in which style Murillo painted several pictures while he continued with that matter; but his principal knowledge in the art was derived from Velasquez, who directed his studies, and frequently retouched his designs. Many writers affirm, that he studied at Rome, and improved himself excessively in that city. But Velasquez, a Spanish author, affirms that he never was in Italy; but arrived at the excellence he possessed by copying the works of Titian, Rubens, and--Vandyck, which were at Madrid, and the Eucida; and also by studying after the antique statues, which are in the Royal collections. However, he became an excellent painter, and was employed by the king of Spain to execute several historial pictures, which raised his reputation through every province of his own country. Those paintings being afterwards sent to Rome as a present to the pope, the Italians were so much pleased with his performances, that they called him a second Paul Vero-ne. In Spain he desinged and finished several grand altar-pieces, for the churches and convents at Madrid, Seville, Cordova, Cadiz, and Granada; and some of his compositions are in the churches of Flanders. But notwithstanding his genius, taste, and abilities, qualified him to execute subjects of history with general applause; yet his favourite subjects were beggar-boys, as large as life, in different actions and amusements; which he usually designed after nature, and gave them a strong and good expression. His original pictures of those subjects have true merit, and are much esteemed, many of them being admired into the most capital collections of the English nobility; but of these, there are abundance of copies, which, to the dishonour of the artift, are sold as originals to indig:entious purchasers. He died in 1685.

MURREN, or Garle, a contagious disea: among cattle. The symptoms are, a hanging down and
MURAY, a county of Scotland, extending by the coast from the river Spey on the east to Beaula on the west, which is the boundary of the province of Ross. It sends two members to parliament, and is an earldom in a branch of the Stuart family.

According to the account of the reverend Mr Shaw minister of Elgin, in answer to some queries of Mr Pennant, the country produces wheat, barley, oats, rye, peas, and beans. Of these, in plentiful years, upwards of 20,000 bolls are exported, beside serving the county itself and some of the Highland counties. Some hemp is also cultivated, and a great deal of flax; of which linen is made, not only for home-consumption, but a considerable quantity of large-yarn is exported. Great quantities of potatoes are also cultivated. Several hundreds of black cattle are also exported from the Highlands of Murray, but few or none from the Low-lands.—Peculiar to this province is a kind of wood, called red fcaugb, or fallow; which is no less beautiful than mahogany. It is much more firm and tough than mahogany, and resembles the lighter-coloured kind of that wood. It receives a fine polish, but is very scarce, growing on rocks. But there are great forefts of firs and birches, which our author thinks are the remains of the Sylva Caledonia. Here also is found a remarkable root, called by the natives carmelie; it grows in heaths and birch-woods to the bigness of a large nut; and sometimes there are four or five roots joined together by fibres. It has a green stalk and small red flowers. Dido speaking of the Caledonians, says, Curtum cibi genus parent ad omnem, quem si cepantis quantum est unus, habe magnitudinem, minimum e fiere aut forte felimet. Caesar also tells us of a root called chara, which his soldiers mixed with milk and made into bread when in want of provision, which greatly relieved them. This root, Mr Shaw thinks, is the same with the carmelie or sweet root of Murray. He informs us, that he hath often seen it dried, and kept for journeys through hills where no provision was to be had: he has likewise seen it pounded and infused; the liquor makes a more agreeable and wholesome liquor than mead. It grows in such plenty, that a cart-load of it can easily be gathered.

Murray is intersected by the rivers Spey, Loffey, Findern, Nairn, Nefs, and Beaula. The river of Spey, rising on the borders of Lochaber, is more than 60 Scots, or 100 English miles long; but too rapid to be navigable. Upon this river great floats of fir and birch-wood are carried down to the Frith; the float is guided by a man sitting on a corvach. This vesse1 is of an oval shape, about four feet long and three feet broad; a small keel from head to stern; a few ribs cross the keel, and a ring of pliable wood round the lip of it; the whole covered with the rough hide of an ox or horse. The rower sits on a transverse seat in the middle, and holds in his hand a rope, the end of which is tied to the float, and with the other hand he manages a paddle, keeps the float in deep water, and brings it to shore when he pleases. In this province also is Loch Nefs, remarkable for its never freezing. There are many other lakes in this country, of which one called Dundelkock is remarkable in that it is never covered with ice before the month of January; but after that time one night’s strong fruit covers it all over. On the east side of Loch Nefs, a large lake above the loch, is the water-fall of Foher, where the river Feeb-len falls over a steep rock about 80 feet high; and a thick fog rises from the place where it falls, occasioned by the violent dashing of the water. There is a considerable salmon-fishery on the rivers Spey, Findern, Nefs, and Beaula, which serves the towns and country, besides exporting to the value of 12,000 annually.

There are many natural caves in the hills of this country, which formerly were the receptacles of thieves and robbers and now afford shelter to hunters and shepherds in stormy weather. The most remarkable mountain is Carneg.in Strathfarr. In its loft is found a particular kind of bones well known to the lapidaries. They are of blue, green, yellow, and amber colours; some so large as to make snuff-boxes, or small cups; some of hexagonal or pentagonal figures, and tapering to a point at each end. The mountain of Benalar, in Badenoch, is by Mr Shaw reckoned to be the highest land in Scotland, as waters flowing from it fall into the sea at Dundee, Inverlochy, and Garmoch in Murray.

MURHINE, or Murrinh, Murrin, in antiquity an appellation given to a delicate sort of ware brought from the east, whereof cups and vases were made, which added not a little to the splendour of the Roman banquets.

Critics are divided concerning the matter of the potula, or vaia murrhina, murrina, or murrea. Some will have it to have been the same ware with the British porcelain or china-ware.

The generality hold them to have been made of some precious kind of stone, which was found chiefly, as Pliny tells us, in Parthia, but more especially in Carmania. Arrian tells us, that there was a great quantity of them made at Diospolis in Egypt. This he calls another sort of murrhina work; and it is evident, from all accounts that the murrhina of Diospolis was a sort of glafs-ware made in imitation of the porcelain or murrhine of India. There is some difference in the accounts given by Pliny and Martial of the murrhina vaia. The first author says, that they would not bear hot liquors, but that only cold ones were drank out of them. The latter, on the other hand, tells us, that they bore hot liquors very well. If we credit Pliny’s account, their porcelain was much inferior to the Britih in this particular. Some conjecture them to have been of agate, others of onyx, others of coral. Baromius, doubtefully, was farthest out of the way, when he took them to be made of myrrh, congealed and hardened. Some have supposed these vessels to be made of crystal; but this is contrary to the account of all the ancients. The Greeks had the words spelaees for crystal, and eijuses for myrrh, very common among them; and therefore, if these vessels had been made of either...
of these substances, they would in some places have called them smyrna or crystallina. On the contrary, the most correct among them call them murrhina or morrha. The cups made of crystal; which were also in use at these times, were called crystallina, and these murrhina or murrha, by way of keeping up the distinction; and Martial tells us, that the stones were made of was spotted or variegated, calling them pocula maculata murrha. And Statius mentions the crystalline and murrhine cups in the same sentence, but as different things, not the same. Arrian mentions also the stape papyraceus, which his interpreters confuse as an error of the copies, and would alter into myrrha, the name of the gum myrrh.

Pompey is recorded as the first who brought these murrhine vessels out of the east, which he exhibited in his triumph, and dedicated to Jupiter Capitolinus. But private persons were not long without them. So fond, in fact, did the Roman gentry grow of them, that a cup which held three festaries was sold for 70 talents. T. Petronius, before his death, to spite Nero (or as Pliny expressly states, ut menam ejus uncheeret, to disinherit his table), broke a bason, trulla murrhina, valued at 300 talents, on which that emperor had set his heart.

MUS, in zoology: A genus of quadrupeds belonging to the order of Gliridae; the characters of which are these: The upper foreteeth are wedge-shaped; there are three grinders, sometimes, (though rarely) only two, on each side of the jaws; and the clavicles or collar-bones are complete. In the new edition of the Systema Naturae, by Dr. Gmelin, the numerous species of this genus have been distributed into different groups or divisions, distinguished by some particular character common to the individuals of each. —

The first division consists of:

I. Myocastores, or Beaver-rats, the individuals of which have the tail flattened laterally at the end.

1. The cyopus, or webbed beaver-rat, has a thick hairy tail of a moderate length, and the hind feet webbed. It is an inhabitant of Chili, where it frequents the water. It has a strong resemblance, both in colour and shape, to the otter; but is allied to the murine tribes by the number and arrangement of its teeth.

2. The zibethicus, or musk cat, with a long sharp-pointed tail, and the feet not webbed. This has been already described under the article Castor, of which it was ranked as a species in the former editions of Linnaeus. In fact, it does resemble the beaver in the form of the body and flat scaly tail, as well as in its manners and economy. In size, however, and length of tail, it comes nearer to the brown rat; but in its general appearance, and in the short hairy ears, it resembles the water-rat.

II. Murus, or Rats and Mice; having round tails, some naked and some hairy.

1. The piloris, or musk cavy, with a naked tail blunt at the end, and covered with scales. There are two varieties: one with the body of an uniform whitish colour; the other with the upper parts tawny, and the under parts white. The former inhabits Ceylon, and the latter the West Indies. They are nearly of the size of a rabbit: they both burrow in the ground; sometimes infest houses like the rat; and have a strong flavour of musk.

2. The curaco has a naked tail, long, scaly, and somewhat blunt; the body is of a brown grey colour, and the hind feet are very slightly webbed. It inhabits the eastern parts of Siberia, and probably China. —

Tartary and the northern provinces of China; surrouning like the rabbit, near the banks of rivers. — It swims remarkably well, and even infests houses. The body and head are six inches in length, and the tail four and a half.

3. The americanus, or American rat, has a long naked, and scaly tail; the head is long-shaped with a narrow pointed nose, the upper jaw being much longer than the lower; the ears are large and naked. It is larger than the black, and smaller than the brown rat; its colour is of a deep brown, inclining to ash on the belly, and the fur is coarse and harsh. It is probably this species which is said (Kalm's Trav. ii. 48,) to live among the fomes and clefts of rocks, in the blue mountains of Virginia, at a distance from the peopled part of the country, which comes out only at night, and makes a terrible noise.

4. The decumanus, or brown rat, has a long, naked, scaly tail; the upper parts of the body are of a light brown, mixed with a tawny and ash colour, the lower parts dirty white. The head and body measure about nine inches; and the length of the tail, which consists of 200 rings, is seven and a half. The whiskers are larger than the head; and the eyes are large, black, and prominent. The fore-feet have four toes, with a small claw in place of the fifth or thumb. It inhabits India and Persia, and has only been known in Europe in the present century. They dwell in burrows which they dig in the banks of rivers; and frequent towns, aqueducts, drains, and houses, stables, barns, gardens, fields, and houses. They swim and dive with great dexterity; feed on vegetables, grain, fruits, and even destroy poultry; and are hunted eagerly by cats, dogs, and ferrets. They lay up stores of acorns, beech-mast, and other provisions in their holes; in which the males remain during winter, except in fine weather, without hibernating; but the females and their young live mottly in barns and out-houses in that season. They often emigrate from one place to another in great companies. The female produces three times in the year, having 12 or 15, even 18 or 19, at a litter. The bite of this creature is not only fever but dangerous, the wound being immediately attended with great swelling, and is a long time in healing. These animals are so bold as to turn upon those who pursue them, and fasten on the flank or hand of such as offer to strike them. This species is supposed to be the mus caficus of Aelian, which he says was nearly as large as the ichneumon and made periodic visits in vast multitudes to the countries which border on the Caspian, swimming boldly over the rivers, holding by each others tails.

5. The rattus, black or common rat, has an almost naked scaly tail, which is very small, has 350 distinct rings, and is eight inches long. The head and body measure seven inches in length: the upper parts are a deep black grey, and the under parts ash-coloured. There are four toes, and a small claw in place of the fifth, on each fore foot, and five on the hind feet. This species inhabits India, Persia, and Europe except its most northern parts; from hence it has been carried to
of the lever or jaw, they have not much force. But the weasel bites cruelly with the whole jaw; and instead of letting go its hold, sucks the blood from the wounded part, so that the rat is always killed.

The rat was first introduced into America by the Europeans in 1544, and is now the pest of all that continent. In the neighbourhood of the lower parts of the river Volga, there is a small variety of this species found in the deserts, which does not weigh above five or seven drams.

6. The musculus, or common mouse, has a very long, feithy, and almost naked tail; the fore feet have each four toes; the hind feet five, the fifth or thumb having no claw; the hand and body measure three inches and a half in length; the upper parts are tawny, and the lower parts whitish or ash-coloured. This little animal, which inhabits all parts of the world, lives almost entirely in hovves, and follows mankind for the sake of their provisions. It feeds on almost everything, such as grain, bread, cheese, butter, oil, and every kind of food used by mankind, and drinks little; it is of mild and gentle manners, exceedingly timid, and very quick in all its motions. The mouse never issues from his hole but in quest of food, and runs in again upon the least alarm. It does not, like the rat, from house to house, unless forced, and is not near so destructive. It is capable also of being tamed to a certain degree, though not so perfectly as other animals. It has many enemies, from whom it can escape only by its agility and minuteness. Owls, birds of prey, cats, weasels, hedge-hogs, and even rats make war upon the mice, so that they are destroyed by millions; yet the species still subsists by its amazing fecundity. They bring forth at all seasons, and several times in the year; the litter generally consists of five or six; and in less than 15 days the young disperse, and are able to provide for themselves. Aristotle tells us, that having shut up a pregnant mouse in a vessel, along with plenty of grain, he found in a short time after 120 mice, all sprung from the same mother.

Several varieties of mice as to colour are found, some being altogether black, some yellowish, some spotted with white, some of a white colour with ash-coloured spots, and the most beautiful of all, and the least common, are entirely white, with red eyes; but as these agree in every other circumstance, it is unnecessary to describe them more at large.

7. The sylvaticus, or long-tailed field-mouse, is Fig. 6 larger than the common mouse, measuring from the end of the nose to the seting on of the tail four inches and an half, the tail four inches; the upper parts of the body are of a yellowish brown; the breast is yellow, and the belly white: the tail is covered with short hair. The fore feet have four toes each: the hind feet five. These animals are found in fields, gardens, and shrubberies. In some places they are called bean-mice, from the havoc they make among beans when first sown. They feed also on nuts, acorns, and grain, of which they amass quantities, not proportioned to their wants, but to the capacity of the place where it is deposited, insomuch that a single animal will collect more than a bushel. Thus they provide for other animals as well as themselves: the hog comes in for a share, and the great damage done
The fields by these creatures, in rooting up the ground, is chiefly owing to their search after the concealed hoards of the field-mice. M. Buffon informs us, that he has often seen great damage done to the plantations by the field-mice. They carry off the new fawn acorns; by following the fursow of the plough, they dig up one after another, not leaving a single feed. This happens chiefly in those seasons when the acorns are scarce; not finding a sufficient quantity in the woods, they come in quest of them in the cultivated fields, and often carry off such quantities that they corrupt in their magazines. These creatures according to the same author, do more mischief in a nursery of trees than all the birds and other animals put together. The only way to prevent this damage is to lay traps at ten paces asunder, through the extent of the town field. No other apparatus is necessary than a roasted wall-nut placed under a flat stone, supported by a fick. The animals come to eat the wal-nut which they prefer to acorns; and as it is fixed to the fick, whenever they touch it, the stone falls down and crushes them to death. The same expedient M. Buffon also made use of with success against the short-tailed field-mouse, which also destroys acorns. In this way he found that upwards of 100 were taken each day, from a piece of ground confining only of about 40 French appents. From the 15th of November to the 4th of December, above 2000 were caught in this manner. Their numbers gradually diminished till the frost became severe, which is the time they retire into their holes to feed on their magazines. In autumn they are more numerous; for if provisions fail during the winter they devour one another. The long-tailed mice eat also the short-tailed species, and even thrushes, blackbirds, &c. which they find entangled in snares. They first eat the brain, and then the rest of the body. M. Buffon once kept a dozen of these mice in a cage, and furnished them with food every morning at eight o'clock. One day they were neglected for about a quarter of an hour, when one of their number was eaten up by the rest; next day another suffered the same fate; and in a few days only one remained; all the others had been killed, and partly devoured; and even the survivor himself had his feet and tail mutilated. These animals are very prolific, producing more than once a year, and being nine or ten at a birth. They generally make the nest for their young very near the surface and often in a thick tuft of grass. During winter they frequent barns, stables, and outhouses.

8. The mefforius, harvest mouse, or less long-tailed field-mouse, is a very small species, or perhaps rather a variety of the former; and inhabits Hampshire, where it is very numerous, particularly during harvest. They form their nest above the ground, between the straw of the standing corn, and sometimes in thistles; it is of a round shape, and composed of the blades of corn. They bring about eight young ones at a time. These never enter houses; but are often carried, in the sheaves of corn, into ricks; and 100 of them have frequently been found in a single rick on pulling it down to be hove. Thote that are not thus carried away in the sheaves, shelter themselves during winter under ground and burrow deep, forming a warm bed for themselves of dead grass. They are the smallest of the British quadrupeds; the length from nose to tail is only two inches and a half; the tail two inches, and the weight one sixtieth of an ounce. They are more slender than the other long-tailed field-mouse; and their back of a fuller red, inclining to the colour of a dormouse.

9. The agrarius, or rufius mouse, is about three inches long, and scarcely weighs half an ounce; the tail is only about half the length of the body and head; the upper part of the body is of a yellowish colour, with a dark line along the back; the belly and the legs are white; the head is oblong, with a sharp nose, and small ears lined with fur; the hind legs have each a dusky circle just above the foot. It inhabits Russia, and is found in Siberia, rarely in Germany. This species is migratory; and wanders about often in vast multitudes, doing immense injury to the corn: It burrows in the ground, forming a long gallery just below the surface, and a little elevated, leading to a larger chamber, in which considerable quantities of grain and seeds are stored up for winter provision.

10. The minutus, or minute mouse, has the upper parts of the body of a deep tawny or ferruginous colour, and the under parts whitish. It is about half the size of the common mouse, the tail being scarcely two inches long; the female is smaller than the male, and less elegant in her colours; the nose is somewhat sharper; the face is dusky, with some whitiness at the corners of the mouth; the ears are small, and almost laid in the fur; the feet are grey. This species inhabits Russia; where it is found in the corn-fields and in barns, and is plentiful in birch-woods; it seems to wander about without any fixed places for its nest; and much greater numbers of males are found than of females.

11. The vagus, or wandering mouse, is between two and three inches long; the colour of the upper parts of the body is a pale ash, waved with black, and having a black line along the middle of the back; the ears are large, oval, naked, and plaited. The legs are very slender, and the whitish, having some toes and a conical excrecence before; and five behind. All armed with long claws: the tail is longer than the body, very slender, prehensile at the end, of an ash colour above and whitish below; the head is oblong with a blunt nose reddish at the tip, having yellow fore-teeth, and only two grinders on each side in the upper-jaw. The female has eight teats. This species inhabits the deserts of Tartary and Siberia, as high as the Ural, Irtish, Obij, and Jenish. It is frequent in the birch woods, and lives in fissures of rocks, under stones, and in hollows of trees; feeding chiefly on seeds, and likewise on small animals of the same genus. It wanders about in great flocks, migrating from one place to another in the night; hibernates during winter, and is of a very chilly nature, so as even to become torpid and fall asleep, in a round form in the cold nights of the month of June. It has carnivorous inclinations.

12. The betulius, or beech-mouse has a conical resemblance to the wandering mouse, but is somewhat smaller. The upper parts of the body are tawny, with a black line along the back, the under parts whitish or pale ash-colour, the nose is sharper;
with a red tip; the ears are small, oval, plaited, brown, and bril-ly at the ends; the limbs are very slender, with long and very separable toes; the tail is slender and much longer than the body. This species inhabits the birch woods in the defect plains of Ithim and Baraba, and between the Oby and Jen-nei. It lives solitary, frequenting the hollows of decayed trees. It runs up trees readily, and falls on their branches with its tail; and by means of its slender fingers or toes, it can clamber even to a very smooth surface. It is a very tender animal, soon growing torpid in cold weather; and its voice is very weak.

13. The pumilio, or dwarf-mouse, is of a brownish ash colour, with the forehead and nape of the neck more than four inches, and having four black lines along the back meeting at the tail. It is scarcely two inches long, the tail is about two-thirds of the length of the body, and the whole animal, even when steeped many months in spirits, hardly weighs four scruples. The body is somewhat flattened; the regions of the eyes, the ears, and the nose, are of a paler colour than the rest of the body; all the feet have five toes, the thumb or inner toe of the fore foot being very small, but diffusely furnished with a claw; the legs and feet are strongly made; the tail is almost naked, and of a pale ash-colour. This species, which was first described by Dr. Sparrman, inhabits the forests of Stittcamma near Lagen river, 200 hours journey from the Cape of Good Hope.

14. The faxatilis, or rock mouse, is about four inches long, and weighs nearly nine grains; the tail is hairy, an inch and a half in length, of a brown colour above, and white beneath; the head is oblong, with a longish nose, and oval downy ears, brown at the edges; the limbs are strong; and the tail is thinly covered with hair; the upper parts of the body are of a brown colour, slightly mixed with yellowish or grey; the sides are rather inclined to the latter colour; the belly is of a light ash or whitish; the feet and legs are blackish; the snout is dusky, and surrounded with a slender white ring. This species is a very abundant of the eastern parts of Siberia beyond lake Baikal, and of the defects of Mongol Tartary.—It burrows in the fissures of rocks, forming a winding oblique passage, which afterwards branches out into several others pointing downwards, and ending in a chamber, in which is a bed or nest of soft herbs. It feeds chiefly on the seeds of the alfahgras.

15. The amphibious, or water-rat, with a long tail; the upper parts of the body being covered with black hair mixed with yellowish, and the under parts ash-coloured; the ears scarcely appear above the fur; the feet have three toes on each, and the rudiments of a fourth. This species of which there are several varieties, differing in the toes and in the colour, inhabits the whole of Europe, the northern parts of Asia as far as the icy sea, and North America.—They dwell chiefly near waters, forming burrows in their shallow banks; about ponds and wet ditches; likewise in marshy places, meadows, and gardens; feeding on roots, herbs, and shrubs; and on frogs, craw-fish, insects, small fish, and the fry of larger ones. They swim and dive with great facility, and live much in the water. They are very fierce, and bite bitterly. The flesh of these animals is reckoned very delicate by some of the more savage inhabitants of the Russian empire; and is eaten by the French along with that of the otter during lent. The female is smaller than the male, and has a greater yellowness of colour; the has eight teats, four of which are placed on the breast and four on the belly. They procreate about the end of winter, at which time they smell strongly of musk, and produce as far as eight young ones in the month of April.

16. The alliarius, or garlic mouse, has a short tail; the ears rather large, and somewhat hairy; the body ash-coloured on its upper parts, and whitish underneath. The head and body measure somewhat more than four inches, the tail scarcely an inch and a half. This species inhabits Siberia, about the rivers Jenisei, Kan, Lena, and Angara; and feeds on the roots of garlic, of which it lays up large stores in subterranean burrows.

17. The rutilus, or red mouse, has a short tail; the ears are longer than the fur, which is tawny red on the back, light grey and yellow on the sides, and whitish on the belly. The head and body measure about four inches, and the tail one.—This species inhabits Siberia, from the Oby as far as Kamtschatka, and within the Arctic circle. It lives in holes and in hollows of trees; feeding on grain, and sometimes on animals of the same genus. It comes often into houses and barns, eating almost of every thing which comes in its way, but it is particularly fond of flesh. It is very lively, and runs about even on the snow the whole winter.

18. The arvalis, or meadow-mouse, is from three to six inches long, the female being much longer than the male, and the tail is little more than an inch: the head is large, with a blunt nose, short ears almost hid in the fur, and prominent eyes; the upper parts of the body are of a mixed ferruginous and black colour; the belly is deep ash, and the legs and feet dusky; the tail is terminated by a small tuft of hair. There is a variety which is almost black.—This species inhabits all Europe, Siberia, Hircania, and Newfoundland; dwelling in bushy places, corn-fields, meadows, and gardens, chiefly near waters; living on grain, nuts, acorns, and walnuts, which it collects into subterranean burrows: but it appears to prefer corn to every other food. When the grain is ripe, they assemble from all quarters, and often do great damage by cutting the stalks of corn in order to come at the ears. They follow the reapers, and eat up all the fallen and neglected grain. When the gleanings are devoured, they flock to the new-sown fields, and destroy the crop of the ensuing year. In winter most of them retire into the woods, where they feed upon filberts, acorns, and the seeds of trees. In particular years they appear in numbers so immense, that they would destroy every thing if they continued long; but they always kill and eat one another during a scarcity of provisions. They besides are devoured by the long-tailed fieldmice, by foxes, wild cats, and weasels. These creatures are often carried home in the feather of corn, and 100 of them have been found in hounding a rich. In such cases it is been observed, that the dogs devoured all the mice of this sort they could find, rejecting the common kind; and, on the contrary, the cats would touch none but the last. The female produces a number of young ones in the month of April.
several times a year, and brings from eight to twelve
young at a birth: it has a strong affection for them;
one was seduced into a wire-trap by placing its
broad in it, was so intent on fostering them, that it
appeared quite regardless of its captivity. In New-
foundland, these mice are very destructive to gar-
dens; but seldom do much damage in this way in
Britain.

19. The socialis, or social mouse, with a very short
tender tail, and naked, rounded, and very short ears;
the fore-feet have each three toes and the rudiments of
a fourth; the upper parts of the body are light-grey;
the sides, shoulders, and belly, are white. The head
and body are somewhat more than three inches long,
the tail half an inch. This species inhabits the sandy
shores between the Volga and Ural, near the Caspian
sea, and in the mountains of Hircania.—They live, in
pairs, or in families, confining of a male and a female
with their young ones; and of these families vast
numbers live together, the whole country being covered
with little hills of earth thrown out of their burrows.
They feed mostly on tulip roots; and are preyed on
by weasels, polecats, crows, and otters. They swarm
chiefly in springs, and rarely appear in autumn, at
which season it is supposed they migrate, or take shel-
fing among the bushes.

20. The ecominos, or economic mice, in its
general form, resembles the meadow-mouse; but the
body is rather longer and the belly larger. The ears
are naked and hid in the fur; the colour is tawny;
and the fore-feet have each three toes with the rud-
iments of a fourth. The head and body measure four
inches and a quarter, the tail somewhat more than an
inch. This species inhabits Siberia, from the river
Ural, southwards, in Kamtschatka, and under the
Arctic circle. They are called by Dr Pallas 'mures
ecomini,' from their curious way of living. They
dwell mostly in damp soils, forming burrows, with
many chambers and numerous entrances, immediately
under the turf. In these they lay up magazines of
various vegetable food, chiefly bulbous roots; which
they spread out in funny days to dry, and never touch
them but in winter, living all summer on berries and
other vegetables. The Kamtschatkans hold these ani-
mals in great regard, and never destroy their hoards;
they take away only part, and leave some caviare or
other substanee to support them in its stead. This
species sometimes emigrates in vast multitudes, keep-
ing a straight course, like the lemmus, even over ri-
vew; and are much infested on their march by birds,
fish, wild hogs, foxes, and other wild beasts. They
begin their March from about the river Pengin in
spring, and about the middle of July reach Ochet-
flka and Judomia, at a vast distance; and return in Oc-
tober. The Kamtschatkans are much alarmed at
their migrations which portend rainy weather and a
bad change; and when they find them lying weak and
spent with fatigue after crossing a river, give them
every affittance in their power. The Tichetik are
not so much attached to this animal, and make use
both of their winter stores and of their carcasses as food.

21. The gregarius, or gregarious mouse, has a short
tail; the ears are longer than the fur; the fore-feet
have each three toes and the rudiments of a fourth;
the fur is dark ash-coloured on the upper parts, and
whitish below. This species is left than the economic
mouse, and longer than the social; the female being
five inches long and the male four. It inhabits the
eastern parts of Siberia, where it dwells in arid places,
forming burrows with numerous openings directly un-
der the sod; these lead to chambers in which it lays
up large stores of roots, especially those of the Lilium
pompomii and garlic. It eats fitting up.

22. The laniger, or woolly mouse, with woolly fur
of an ash-colour, inhabits Peru and the north parts of
Chili. It burrows in the earth, is very docile and
cleanly, and is easily tamed; it lives on bulbous roots,
especially onions; the female breeds twice a year,
and brings five or six young ones at each litter. It is
about six inches long, with a short nose, and small
sharpl-pointed ears; the fur is very long and exceed-
ingly fine, almost like the threads of a spider's 
web, and was formerly employed as the very finest species
of wool by the Peruvians.

23. The lagurus or rambling mouse, has hardly any
tail; the ears are shorter than the fur; the fore-feet
have each three toes, and the rudiments of a fourth;
the upper parts of the body are ash-coloured mixed
with dusky, and having a black line along the back.
The head is long, with rough and swelling lips; the
limbs are short and slender; and the length of the body
and head is between three and four inches. This
species inhabits the deserts between the Volga and
K Jens; but do much damage in this way in up large
number of regions; and is called by them 'Kengin,' or
having a black line across the back.

24. The lagurus, or ruticola, has a short
fore-feet, and a round black tail, with a tuft of
short hairs at the lower end. It is very
active, and feeds chiefly on bulbous roots, and
on dried roots; it makes a hole in the ground,
and hides its provisions. It was first described
by Dr Pallas in his 'Systema Naturae,' vol. ii.

25. The Lemmus, or lemming, has a very short
tail; the ears are shorter than the fur; the fore-feet
have each five toes; the fur is furrinous,
varied with grey, yellow, and dusky, having a whitish
collar round the neck, and a dark line along the back.
The head and body are somewhat more than three
inches long, the tail scarcely one inch. It inhabits
the northern parts of the Urallian mountains, and
the marshes near the frozen ocean; feeding chiefly on the
lichen rangiferinus, lichen nivalis, and polygonus vi-
ipurus; these articles of food are stored up in bur-
rows, having numerous passages, which it digs under
the turfy soil. This species is migratory, and refem-
bles the lemmus in its manners.

26. The lemmus, or lemming, has a very short tail:
The head is pointed, having very long whiskers, fix
of the hairs on each side being longer and stronger
than the rest; the mouth is small, having only two very
long fore-teeth in each jaw, and the upper lip is di-
vided; the eyes are small and black; the ears are
shorter than the fur, rounded, and reclined backwards;
the fore-legs are very short, having four slender hairy
The males are about ten inches long, and the tail about three, but the females are fearfully more than half so large; the former weigh from 12 to 16 ounces; while the latter seldom exceed from four to six ounces.

The head is thick, with a blunt nose, and numerous whiskers, large full black eyes, and large rounded open ears; usually the head and back are of a reddish brown colour, with red cheeks; the sides are paler, with three white spots; the breast, upper part of the fore-legs and belly, are black; the feet are large and white, having four toes, and a claw instead of a fifth toe on the fore-feet, and five toes on each hind foot: The colour varies; sometimes though rarely, they are found entirely white or yellowish, or white with black spots on the back; sometimes the front is white, and the forehead ash-coloured, or the lower jaw of a white colour. There is a variety (the black German hamster) which is entirely black, excepting the tip of the nose, edge of the ears, and the feet, which are white. This species inhabits Siberia to the north of Russia, Poland, Scalinavia, Hungary, Silesia, Bohemia, and Germany beyond the Rhine, especially in Thuringia.—Each individual forms a subterraneous burrow, consisting of several chambers, with two holes or entrances leading from the surface; one of these is perpendicular and the other, in which the excrements are lodged, is oblique; the holes of the females have several perpendicular openings, and each young one of her family is lodged in a separate chamber: The chambers which are set apart for the lodging of themselves and young are lined with straw or grass; the rest are larger, and are appropriated for containing magazines of grain, beans, peas, linseed, vetches, and other such foods, each in a separate cell. The chambers of the older animals are dug several feet deep, while those of the younger ones seldom exceed a foot under the surface. The hamster sleeps during the winter like the marmots; when in a torpid state, neither respiration nor any kind of breathing can be perceived. The heart, however, beats 15 times in a minute, which has been discovered by opening the chest. The blood continues to be fluid, but the intestines are not irritable; even an electrical shock does not awaken him; but in the open air he never becomes torpid. When dug up in his state of torpifity, the hamster is found with his head bent under his belly between the two fore-legs, and those behind rest upon his muzzle. The eyes are shut; and when the eye-lids are forced open, they instantly close again. The members are stiff, like those of a dead animal, and the whole body feels as cold as ice. When defeptl during this state, he seems to feel very little; sometimes indeed he opens his mouth as if he wanted to respire; but his lethargy is too strong to admit of his awakening entirely. This lethargy hath been ascribed to a certain degree of cold which indeed may be true with regard to dormice, bats, &c. But experience shows, that, in order to render the hamster torpid, he must also be excluded from all communication with the external air; for when he is shut up in a cage filled with earth and straw, and exposed in winter to a degree of cold sufficient to freeze the water, he never becomes torpid; but when the cage is sunk four or five feet underground, and well secured against the access of the air, at the end of eight or ten days he is equally torpid as.

The hammerers copulate about the end of April; when the males enter the apartments of the females, where they remain only a few days. If two males happen to meet in the same hole, a furious combat ensues, which generally terminates in the death of the weakest. The conqueror takes possession of the female; and both, though at every other period they persecute and kill each other, lay aside their natural ferocity during the few days their amours continue. They even mutually defend each other against aggressors; and if a hole is opened about this time, the female defends her husband with the utmost fury. The females bring forth twice or thrice every year. Their litter is never fewer than six, and more frequently from 16 to 18. Their growth is very rapid. At the age of 15 days they begin to dig the earth; and soon after, the mother banishes them from her habitation: so that at the age of about three weeks they are abandoned to their own management. The mother in general discovers little affection for her offspring; and when her hole is opened, flies in the most dastardly manner, leaving her young ones to perish. Her only solicitude at that time is to provide for her own defence. With this view she digs deeper into the earth, which she performs with amazing quickness. The young would willingly follow her; but she is deaf to their cries, and even shuts the hole which she has made.

The hammerers feed upon all kinds of herbs, roots, and grains, which the different seasons produce, and even eat the flesh of such animals as they can conquer. They are particularly fond of places where liquorice grows, and feed much on its seeds. Their pace is very slow, and they do not climb; but they dig with vast quickness, and will gnaw through piece of wood an inch and a half thick in a very short time. As they are not adapted for long journeys, their magazines are first flocked with the provisions which are nearest their abode. This is the reason why some of the chambers are frequently filled with one kind of grain only. When the harvest is reaped, they go to a greater distance in quest of provisions and carry every article they can find, without distinction to their granary. To facilitate the transportation of their food, nature has furnished them with two pouches in the inside of each cheek. On the outside, these pouches are membranous, smooth, and shining; and in the inside there are a great many glands, which secrete a certain fluid, to preserve the flexibility of the parts, and to enable them to reftit any accidents which may be occasioned by the roughness or sharpness of particular grains. Each of these receptacles is capable of containing an ounce and an half of grain, which, on his return to his lodgings, the animal empties, by pressing his two fore-feet against his cheeks. When we meet a hammerer having his cheeks filled with provisions, it is easy to seize him with the hand, without the risk of being bitten; because in this condition he has not the free motion of his jaws. But if he is allowed a little time, he soon empties his pouches, and stands upon his defence. The quantity of provisions found in the holes depends on the age and sex of the inhabitant. The old hammerers frequently amass 100 pounds of grain; but the young and the females content themselves with a quantity much smaller. Their object...
object in laying up provisions, is not to nourish them during winter, which they pass in sleep, and without eating but to support them after they awake in the spring, and previous to their falling into a torpid state, which resembles a profound sleep. At the approach of winter, the hamsters retire into their subterraneous abodes; the entrance to which they shut up with great address. Here the animal reposes, in the situation already described, upon a bed of straw, and in this state he is commonly dug up. They are preyed on by polecats, weasels, cats, dogs, foxes, and birds of prey; and are procured by man, on account of their devotions. In winter the peafants generally go a hammer-hunting as they call it; the retreat is known by a small eminence of earth raised near the oblique passage formerly described. The peafants dig down till they discover the hoard, and are generally well paid for their trouble; as they often find two bushels of corn, besides the skins of the animals, which are valuable for market; and it is remarkable, that the hairs sticks fast to the skin, that it cannot be plucked off without the utmost difficulty. In some species the hamsters are fo numerous, that they occasion a dearth of corn. In one year about 11,000 skins, in a second year 54,000, and in a third year 110,000 skins, were brought to the head, back, and sides are pure white. It inhabits the sandy or muddy places; and in a third year, the whole body is already like that of rabbits; and digs about four inches deep, and in the mountains of the north of Persia; where it is about three inches long, and the tail near one. This species inhabits Dauria, Siberia in the dept of Barabia, towards the Oby, between the Onon and Argum, and in the Chinfe empire near lake Dalai; living chiefly on the seeds of the asparagus and ariphex; but its manners are unknown.

IV. Myotalpe †, or Mole-rat. These have no external ears, very small eyes, and a very short tail or none. They live entirely under ground like the moles.

1. The talpina, or Russian mole-rat, is of a dusky colour; has a very short tail, appearing beyond the fur; and no external ears; the fore-teeth are long, extended from the mouth, wedge-shaped; the eyes are very small, and hid in the fur; the fore feet are very strong, flat, and formed for digging. It is about four inches long, and in the general form resembles the water rat. As to colour the head, back, and sides are dusky, and the belly and limbs white. There is a variety (the nigra), which is entirely black. This species inhabits the plains of Russia and Western Siberia, fearfully extending beyond the Itil, and never beyond the Oby. It is fond of a turfy soil, avoiding sandy or muddy places; and digs holes like those of the hamster, which it lines with soft grass, and fills with bulbous roots, throwing up hillocks of earth all along the tracks; each individual has its separate burrow: it works only in the night, and seldom comes out except in the season of love. Its fight is very weak in the day-time. It feeds chiefly on the roots of tulips, tuberol lathyrus, and tuberol philomus. It procreates about the beginning of April, at which time it shakes strongly of musk; and the females produce three or four young; and when five toes, the fore feet are very strong, flat, and formed for digging.

2. The capensis, or Cape mole-rat, is of a dark brown colour tinged with yellowish, with the fore-part of the face, orbits, and regions of the ears, white. It has a very short tail, and no external ears; and is about five inches and a half long. It inhabits the Cape of Good Hope, where it inhabits the gardens.

3. The maritima, or African mole-rat, is of a pale brownish ash colour mixed with yellowish on the upper parts, the sides and under parts paler; the tail is very short, and there are no external ears. It inhabits the sand hills adjacent to the sea at the Cape of Good Hope; and resembles the former species, but is much larger, measuring 12 or 13 inches long, and the head is more lengthened. It forms burrows in the sand like those of rabbits; and digs with surprising velocity. It runs slowly; but is very fierce, and bites severely. It feeds chiefly on the roots of xise, antholyza, gladiolis, and irides; and is reckoned good eating.

4. The sphaerol, or Daumian mole-rat, is of a dirty yellow ash-colour on the upper parts, and white ash on the lower: it has a very short tail, and no external ears; the eyes are very small, and deep seated; the feet have each five toes, the claws of the fore feet being very long. This species inhabits Dauria, and Sibe in beyond the Itil, between the Aile and Tsilurich rivers.
The Marmot, Agouti, Guinea-pig, Cavy, Jerboa, Dormouse, &c., which were formerly comprehended under the present genus in the Linnaean arrangement, have, in consequence of more accurate investigation, been lately disjoined, and distributed under four new genera, Myoxus, Arctonyx, Dipus, and Cavia*. But as we are not in the alphabetical order in which the three last of these genera should have been introduced, we must still describe these animals (excepting the first) in this place; observing, however, to distinguish them according to their new generic arrangement.

I. Myoxus, or Dormouse. See Myoxus, the Marmot.

II. Arctonyx, the Marmot; the characters of which genus are: There are two wedge-like cutting teeth in each jaw; the grinders are five above, and four below, on each side; and there are perfect clavicles or collar-bones.

1. The marmotto, or common marmot, has short round ears; gibbous cheeks; a short hairy tail; the upper parts of the body of a dusky brown colour, and the lower parts reddish. The body and head measure 8.5 inches, the tail 8 inches. This species inhabits the upper parts of the black turfy soil or firm sand, throwing up numerous hillocks, which extend over a considerable surface; it works both with its feet and nose, and sometimes with its teeth. It feeds chiefly on the roots of bulbous plants.

This species varies in size, those of Dauria being near nine inches long, while those farther east are scarcely fix.

5. The typhus, or blind mole-rat, is of a reddish ash colour; and has no tail, external ears, or appendent eyes, but has each five sharp teeth, and the four front teeth are broad. The body and head measure between seven and eight inches: the mouth is continually gaping, with short wrinkled nose-tooth above, and very long ones below, likewise furrowed or wrinkled, none of them being hid by the lips: the body is covered with short, soft, and close fur, which is of a dusky colour at the bottom, with the ends of a rusty brown mixed with ash-colour; the legs are very short, having five toes on each foot armed with short claws, and slightly connected by a short membrane at their bases.

This species inhabits the southern parts of Russia, from Poland to the Volga. Each individual forms burrows under the turfy soil of very considerable extent, with many lateral passages, and throws out the earth at different distances, in large hillocks sometimes two yards in circumference, and proportionally high. It works with its snout, feet, rump, and even with its teeth; and digs with great celerity, especially when frightened, in which case it digs directly downwards. When irritated, it thrusts its head in a menacing posture, and bites with great ferocity. It feeds on roots, especially those of the bulbous chamomile. It is entirely blind, though it has the rudiments of very small eyes, which are covered over with a continuation of the skin; but it possesses the sense of touch and hearing in a very eminent degree, to make up for the loss of sight. It breeds in spring and summer; and the female, which has two teats, brings from two to four young ones at a birth.

The Marmot, Agouti, Guinea-pig, Cavy, Jerboa, Dormouse, &c., which were formerly comprehended under the present genus in the Linnaean arrangement, have, in consequence of more accurate investigation, been lately disjoined, and distributed under four new genera, Myoxus, Arctonyx, Dipus, and Cavia*. But as we are not in the alphabetical order in which the three last of these genera should have been introduced, we must still describe these animals (excepting the first) in this place; observing, however, to distinguish them according to their new generic arrangement.

I. Myoxus, or Dormouse. See Myoxus, the Marmot.

II. Arctonyx, the Marmot; the characters of which genus are: There are two wedge-like cutting teeth in each jaw; the grinders are five above, and four below, on each side; and there are perfect clavicles or collar-bones.

1. The marmotto, or common marmot, has short round ears; gibbous cheeks; a short hairy tail; the upper parts of the body of a dusky brown colour, and the lower parts reddish. The body and head measure 8.5 inches, the tail 8 inches. This species inhabits the upper parts of the black turfy soil or firm sand, throwing up numerous hillocks, which extend over a considerable surface; it works both with its feet and nose, and sometimes with its teeth. It feeds chiefly on the roots of bulbous plants.

This species varies in size, those of Dauria being near nine inches long, while those farther east are scarcely fix.

5. The typhus, or blind mole-rat, is of a reddish ash colour; and has no tail, external ears, or appendent eyes, but has each five sharp teeth, and the four front teeth are broad. The body and head measure between seven and eight inches: the mouth is continually gaping, with short wrinkled nose-tooth above, and very long ones below, likewise furrowed or wrinkled, none of them being hid by the lips: the body is covered with short, soft, and close fur, which is of a dusky colour at the bottom, with the ends of a rusty brown mixed with ash-colour; the legs are very short, having five toes on each foot armed with short claws, and slightly connected by a short membrane at their bases.

This species inhabits the southern parts of Russia, from Poland to the Volga. Each individual forms burrows under the turfy soil of very considerable extent, with many lateral passages, and throws out the earth at different distances, in large hillocks sometimes two yards in circumference, and proportionally high. It works with its snout, feet, rump, and even with its teeth; and digs with great celerity, especially when frightened, in which case it digs directly downwards. When irritated, it thrusts its head in a menacing posture, and bites with great ferocity. It feeds on roots, especially those of the bulbous chamomile. It is entirely blind, though it has the rudiments of very small eyes, which are covered over with a continuation of the skin; but it possesses the sense of touch and hearing in a very eminent degree, to make up for the loss of sight. It breeds in spring and summer; and the female, which has two teats, brings from two to four young ones at a birth.

The Marmot, Agouti, Guinea-pig, Cavy, Jerboa, Dormouse, &c., which were formerly comprehended under the present genus in the Linnaean arrangement, have, in consequence of more accurate investigation, been lately disjoined, and distributed under four new genera, Myoxus, Arctonyx, Dipus, and Cavia*. But as we are not in the alphabetical order in which the three last of these genera should have been introduced, we must still describe these animals (excepting the first) in this place; observing, however, to distinguish them according to their new generic arrangement.

I. Myoxus, or Dormouse. See Myoxus, the Marmot.

II. Arctonyx, the Marmot; the characters of which genus are: There are two wedge-like cutting teeth in each jaw; the grinders are five above, and four below, on each side; and there are perfect clavicles or collar-bones.
that he is protected by his mawer, he attacks and bites dogs of the most formidable kind. Though not so large as a hare, he is fouter, and his strength is aided by a peculiar suppleness and dexterity. With his fore-teeth, which are pretty long, he bites not cruelly: he attacks not, however, other dogs or men unless previously irritated. If not prevented, he gnaws furniture and fluids; and when confined, piers even through wood. His voice resembles the murmuring of a young dog when carewitted or in a sporting humor; but when irritated or frightened, he makes a whistling noise, so loud and piercing, that it tears the ear. The marmots eat every thing presented to them: as flesh, bread, fruit, roots, pot herbs, may bugs, grasshoppers, &c. but milk and butter they prefer to every other aliment. Though lefs inclined to theft than the cat, they endeavour to slip into the dairy, where they drink great quantities of milk, making, like the cat, a murmuring noise expressive of pleasure. Milk is also the only liquor that is agreeable to them; for they rarely drink water, and they refuse wine. They procreate but once a year; and the female, after three or four weeks, produces two, three, or four young. The growth of their young is very quick; they live only nine or ten years, and the species is neither numerous nor much diffused. They are easily caught when on plain ground, but with difficulty in their holes, as they dig deeper when in danger of being taken, except in winter when torpid; at which time they are caught in great numbers. They are searched for partly on account of their flesh, which is tender and delicate; partly for their skins: and partly for their fat which is esteemed medicinal by the inhabitants of the Alps: but they are chiefly taken by the Savoyards for the purpose of being exposed as hawks through various parts of Europe. The marmot would make very good eating, if it had not always a disagreeable flavour, which cannot be concealed but by strong seasonings.

Plate CCCXVII, figs. 1 & 4

2. The monax, or American marmot, is about the size of a rabbit. It has short rounded ears: the nose and cheeks are bluish; the body is of a deep brown colour; the tail is longish, and very hairy. This species inhabits the warmer states of North America and the Bahamas. It forms holes in the crests of rocks and under the roots of trees, in which it passes the winter in a torpid state; though it is uncertain if those of the Bahamas hibernate, as the climate of those islands is very mild. It feeds on vegetables; and its flesh is very good, resembling that of a pig.

3. The bobac, or Polish marmot, is of a greyish colour, mixed with long dusky hairs on the upper parts of the body, the under parts yellowish; It has small oval ears, small eyes, a hairy straight tail, and the fore-feet have each a claw in place of the thumb or fifth toe. The head and body measure sixteen inches, the tail four and a half. This species inhabits the dry and sandy places of the mountains, from the Borithenes through the temperate climates of Asia as far as China and Kamtschat. It forms very deep burrows, in which societies of 20 or more live together, each individual having a particular nest at the bottom of the common gallery, which is often three or four yards deep, and from which numerous galleries or passages branch off to the several apartments. They go about in search of food in the morning and middle of the day, placing a sentinel to give warning of approaching danger. The bobac is a timid animal, and feeds only on vegetables, chieflyleracious plants. It fits up on the hams, and carries its food with the fore paws to its mouth, and defends itself in the same posture. It may be easily tamed even when old; it then eats cabbages or bread, and laps milk; but refuses to drink water. In summer it feeds on worms; but in winter it gnaws torpid all winter when kept in very warm places; and even then it eats very little; and escapes if possible, that it may get to some place proper for hibernating; but returns to its marmot in spring. The flesh resembles that of a hare, though rank; the fat is used for dressing leather and furs; and the skins are employed for clothing by the Russians. The female has eight teats; and probably brings forth early, as by the month of June the young ones are half grown.

4. The citillus, or earless marmot, is of a variable colour, has a convex head, no external ears, and a short hairy tail. This species inhabits the southern parts of Russia as far as Kamtschatka, and the islands between Asia and America; is found in Persia and China; but is now rarely met with in the west of Europe. They dwell in open, high, dry, and uncultivated places, preferring turfy and loamy soils, near the high roads, and never frequent bogs or woods. Each individual has its separate burrow, in which, for provision in the beginning and end of winter, it lays up vegetables, fruit, and berries; sometimes though rare, the carcasses of mice and small birds are added. In the middle of winter these animals lie torpid during the greatest severity of the frost. From the very beginning of spring, as soon as the weather becomes mild, they go out in the day time in quest of food, which they eat fitting on their haunches, carrying it in their fore paws to the mouth. The male is very easily tamed; but the female is fiercer, more given to bite, and is less easily made tame; she goes between there and four weeks with young, and brings forth from three to eight young ones about the beginning of May. The fur is very good in the spring; and the flesh is reckoned tolerable. They are preyed on by polecats, weasels, hawks, carrion crows, and cranes.

This animal varies considerably both in size and colour, being sometimes as large as the common marmot, and sometimes not larger than the water-rat. In general the colour is of a yellowish ash on the upper parts, and dirty white on the belly, (the head of Buffon;) sometimes it is variegated either with waves or small spots of white, (the fouslik of the same author.) Some are white on the upper parts, and waved with tawny or yellow, being pale yellow on the yellow parts of the body, and having a longish tail, with shied hair like that of a squirrel; others are of a grey colour on the upper parts of the body, spotted with white; the under parts being of a yellowish white, with white orbits, and the face, between the eyes and the nose, of a brownish yellow, with a short tail.

5. The empetra, or Canadian marmot, is of a mixed grey colour on the upper parts of the body; the lower parts orange; having short rounded ears, and a hairy tail. It is rather larger than a rabbit, and the tail is about two inches and a half long; the head is round, with a blunt nose, and short rounded ears; the cheeks
are full, and of a grey colour: the face is dusky, with a black nose: the hair on the back is grey at the roots, black in the middle, and whitish at the tips; the belly and legs are of an orange colour; the feet are black and naked, having four long, slender, divided toes, and the rudiments of a thumb on each fore foot, and five similar on each behind, all armed with pretty strong claws. This animal was described by Mr. Pennant from a living specimen in possession of Mr. Brooks, which was very tame, and made a hissing noise. It inhabits Canada, Hudson's Bay, and the other northern parts of America.

Five or six other species of arctomys, some of them suspected to be only varieties, are described by Kerr.

III. Dirus, or Jerboa. There are two fore-teeth in each jaw: the tail is long, and tufted at the end: but the most striking characteristic of this genus is the enormous length of the hind feet and extreme shortness of the fore-paws. From this conformation, instead of walking or running on all fours, they hop like the hare on the hind-feet like birds, making prodigious bounds, and only use the fore paws for burrowing, or for carrying their food to the mouth like squirrels. From this peculiarity of conformation, the kangaroo, genus is the enormous length of the hind leg; the contortion, the faphon is gregarious, and builds its nest always to dig under the roots of some bushy plant or shrub. It particularly delights in those places which are frequented by the cerastes or horned viper, though it would appear that the serpent sometimes preyed upon it; for Mr. Bruce tells us that he once saw a jerboa taken out of the belly of a female viper big with young, and almost consumed by the digestive powers of the animal. It is a very cleanly creature, and keeps its hair always in excellent order. It jumps about with great agility, in which it is assisted by its long tail, which we should suppose would rather be a hinderance to it. The Arabs of the kingdom of Tripoli in Africa teach their greyhounds to hunt the antelope, by learning them first to catch jerboas; and so agile are the latter, that Mr. Bruce has often seen, in a large court-yard or inclosure, the greyhound employed a quarter of an hour before he could kill his diminutive adversary; and had he not been well trained, so that he made use of his feet as well as his teeth, he might have killed two antelopes in the time he could have killed one jerboa. This animal is very fat, and the flesh well coloured: the buttocks, thighs, and part of the back, are roasted and eaten by the Arabs, as already mentioned, and taste almost exactly like a young rabbit, but without the strong smell of the latter. It is said, that the flesh dried in the air is very nourishing, and prevents coughs; so that it seems endowed also with medical qualities. The animal is found in most parts of Arabia and Syria, and in all parts of the southern desert of Africa, but nowhere in fuch plenty as in the Cyrenaicum or Pentapolis. In his journey thither, Mr. Bruce employed several Arabs, together with his own servants, to kill these animals with sticks, that their skins might not be hurt with their teeth. Having got them dressed in Syria in Greece, and fewed together, making use of the tail, in as ermine, for the lining of a cloak, he found they had a very good effect, making a finer and glossier appearance the longer they were worn.

Bochart thinks this animal is the saphe of holy writ, and displays a vast deal of learning on the subject. But this opinion is refuted by Mr. Bruce, who observes, that the faphon is gregarious, and builds its nest often seen, in a sandy place, with the word is expressly translated jerboa. See the article Saphe.

2. The figutta, or Arabian jerboa, has three toes on the hind feet, and no thumb or fifth toe on the fore-paws. It is only about six inches long, and the tail rather shorter than the body; the soles of the hind feet and bottom of the toes are covered with a very thick coat of hair; the head is more rounded than that of the preceding animal, and the ears are much longer than the head. It inhabits Arabia, and near the Irish in Siberia, where it frequents the sandy plains.

The two following are distinguished as different species by Mr. Pennant, though Dr. Gmelin seems not to have considered them as distinct from the preceding.

A. The
A. The aegyptius, or Egyptian Jerboa, has three toes only on the hind feet; and four toes with a scarcely apparent thumb or fifth toe, furnished with a claw on the fore-paws.

This animal Mr Pennant supposes to be the mus bi-fer of the ancients, mus fogitis of Pallas, jerbo of Buffon, and daman Ifrael of the Arabs. He says: that it inhabits Egypt, Barbary, Palestin, the deserts between Bafora and Aleppo, the sandy tracks between the Don and Volga, and the hills south of the Iridh.

Fig. 17.

B. The fibricius, or Siberian jerboa, with three toes on the hind feet, and two flat toes some way up the legs; five toes on the fore feet, the thumb or fifth toe having no nail. Of this species Mr Pennant distinguishes four varieties, the major, medius, minor, and pumilio; differing in size, colour, &c. But they all (he says) agree in manners. They burrow is hard ground, clay, or indurated mud; not only in high and dry spots, but even in low and flat places. They dig their holes with great celerity, not only with their fore-paws but with their teeth, and flinging the earth back with their hind feet so as to form a heap at the entrance. The burrows are many yards long, but not above half a yard deep. These run obliquely; and end in a large space or nest, the receptacle of the finest herbs. They have usually but one entrance; yet by a wonderful sagacity they work from their nest another passage to within a very small space of the surface, which in case of necessity they can burst through, and so escape.

They sleep rolled up with their head between their thighs: at sun-fet they come out of their holes, clear them of the filth, and keep its hole exceedingly clean, to which it returns on the return of cold.

The Meridianus, Caspian jerboa, has five toes behind and three before, with the rudiments of a thumb or inner toe. It is five inches long, and the tail three. This species inhabits the sandy deserts between the Ural and Volga, near the Cape of Good Hope, is larger than any of the foregoing, being 14 inches long, the tail 15, the ears three. It is called aerdiuannius, or little earth man, and fpringen baas, or leaping hare, by the Dutch at the Cape. It has a grunting voice; is very strong, and leaps 20 or 30 feet at one bound. It burrows with its fore-feet; and leaps sitting on its hind legs, with the knees separated, the head between, and holding its ears with the fore-paws over its eyes. It is eaten by the natives; and is caught by pouring water into its hole, which forces it to come out.

Fig. 6.

The Meridianus, Caspian jerboa, or long-legged mouse, has five toes behind and three before, with the rudiments of a thumb or inner toe. It is five inches long, and the tail three. This species inhabits the sandy deserts between the Ural and Volga, near the Caspian. It forms burrows, with three entrances, about a yard in depth; and feeds chiefly on the seeds of the pterococci and aftragali.

The Meridianus, Caspian jerboa, or long-legged mouse, has five toes behind and three before, with the rudiments of a thumb or inner toe. It is five inches long, and the tail three. This species inhabits the sandy deserts between the Ural and Volga, near the Caspian. It forms burrows, with three entrances, about a yard in depth; and feeds chiefly on the seeds of the pterococci and aftragali.

The tamaricinus, or marib jerboa, has five toes. Fig. 19. behind and three before, with the rudiments of a fourth; the tail is obscurely annulated. The body and head measure about five inches and a half in length; the tail is about the same length. This species inhabits the salt marshes near the Caspian sea; and is supposed to feed on the fruit of the tamarix and nitrium, which grow in these marshes. Under the roots of these trees it forms very deep burrows, which have two entrances. It is a very elegant little animal. There are two or three other species of this genus.

IV. The Cavia, or Coy, a genus which seems to hold a middle place between the murine and the leporine quadrupeds. The characters are: there are two wedge-like cutting teeth in each jaw, and eight grinders in both jaws; the fore-feet are furnished with four or five toes: the hind feet have three, four, or five each; the tail is either very short or entirely wanting: there are no clavicles or collar-bones.

1. The paca, or spotted coy, has five toes on all the feet; and the sides are marked with rows of grey cccxv, or pale yellow spots. The body and head measure about two feet in length; the tail is like a small button, and so extremely short as to be hardly apparent; the mouth is very small, and the upper lip is divided; the nostrils are very large, and the muzzle is garnished with long whiskers; the ears are short and rounded; the eyes are large, prominent, and brownish; the two cutting teeth in each jaw are very long and of great strength; the hind legs are longer than the fore.—This species inhabits Brazil, Guyana, and probably all the warmer parts of America. It lives in fenny places near rivers, burrowing in the ground, and keeping its hole exceedingly clean, to which it has always three distinct outlets: It grows very fat, and is esteemed a great delicacy. The female has

MUS

[ 466 ]

Two sorts of pigs are found in England; both are very voracious, and when fat, their flesh is white like that of a rabbit, but dry. What food they cannot immediately consume they hoard in their retreats, and eat at their leisure. Their pace is hopping like that of a hare or rabbit; they beat the ground like them with their feet, when angry; they flop and listen to the sound of music; and they take shelter when pursued, in their holes, or in hollow trees.—They are hunted with dogs. When one of them is forced among the cut sugar canes, he is soon taken; because these grounds being generally covered a foot thick with straw and leaves, at each leap he finks in this litter, so that a man may overtake and slay him with a baton. He commonly runs very nimbly before the dogs; and when he gains his retreat, he lies quiet, and remains obstinately in his concealment. The hunters are obliged to chase him out by filling his hole with smoke. The animal, half suffocated, utters mournful cries; but never issues forth unless when pushed to the last extremity. His cry, which he often repeats when disturbed or irritated, resembles that of a small hog. If taken young he is easily tamed, and goes out and returns of his own accord.

3. The cobaya or reflexive cavy, has four toes on the fore, three on the hind-feet, with no tail: it is about seven inches in length; and the whole body is white, usually variegated with irregular orange and black blotches. This species inhabits Brazil; but its manners in a wild state are not mentioned by authors. In a domestic state, as they appear in Europe, they are very refractory and make a continual noise.—They feed on all kinds of herbs; but especially on parsley, which they prefer to grain or bread; and they are likewise fond of apples and other fruits. They eat precipitately like the rabbit, little at a time, but very often. Buffon says they never drink; but Gmelin, that they drink water. Their voice is commonly a kind of grunt like a young pig; when engaged in their amours, it resembles the chirp of a bird; and when hurt, they emit a sharp cry. They are of a tame and gentle, but stupid disposition. The female breeds at two months old, bringing from four or five to ten or twelve young ones at a birth, though she has only two teats; and breeds very often during the year, as she goes but three weeks with young, and takes the male 12 or 15 days after littering. As they breed so fast their multitudes would be innumerable, if there were not so many enemies which destroy them. They cannot resist either cold or moisture; when cold, they assemble and crowd close together; in which case they often all perish together. They are also devour in great numbers by cats, and many are killed by the males. Rats are said to avoid their haunts. They are called in England Guinea-pigs, from their being supposed to come from that country.

4. The magellanica, or Patagonian cavy, has hardly Fig. 12. any tail; the fides of the nose are garnished with tufts of curly hair and long numerous whiskers. This species inhabits the country about Port Defire in Patagonia, and is of considerable size, sometimes weighing 26 pounds. It has the same manners with the rest of the genus; it fits on its hind legs, burrows in the ground, and feeds on vegetables. The flesh is very white, and has an excellent flavour.

5. The
Plate CCCCXIX

Mus
5. The capybara, or thick nosed tapir, has no tail; the hind feet have each three webbed toes. The length of the animal, when full grown, is above two feet and a half; the head and nose are very large and thick; having small, erect, rounded, naked ears, and large black eyes: and the nose is garnished with numerous black whiskers: in each jaw are two large strong fore-teeth, and eight grinders; the legs are short, having the toes connected by a web, and their extremities are guarded with a kind of hoofs instead of claws; the neck is short and thick; the hair is short, rough and harsh, like bristles, being longer on the back, and mottled of them are yellowish in the middle and black at both ends.—This species inhabits the eastern side of South America, from the illims of Darien to Brazil and Paraguay; living in fenny woods near the large rivers, such as the Amazons, Oroonoko, and Plata. They swim and dive remarkably well, and keep for a long time under water. They catch fish at night with great dexterity, and bring them on shore to eat them; which they do sitting on the hind legs, and holding the food in the fore-paws like the apes. They likewise live on fruits and vegetables, especially the sugar cane, and feed only in the night. They keep together in large herds, making a great noise like the braying of asses, and do not micturite in gardens. They grow very fat; and the flesh is eating, tender, but has an oily and fishy flavour. In the breeding season, one male and one female live together, and the female only produces a single one at a birth. These animals are easily rendered tame, and become very familiar.

6. The acufchry, or olive cavy, has a short tail; the upper parts of the body are of an olive colour, the under parts whith. This species inhabits Guiana, Cayenne, and Brazil.—It is about the size of an half-grown rabbit, is easily tamed, and is reckoned very delicate food. The female brings one, sometimes two at a litter. This animal resembles the agouti, but is uniformly smaller, has a tail of some length, and is of a different colour. It inhabits the woods, living on fruits; abhors water; and sometimes, though rarely, makes a cry like that of the reitfeus cavy.

There are five or six other species described by authors as belonging to the cavy genus. Two of them, however, have been lately marked by Dr Gmelin under a new genus Hyrax; while, as there was not an opportunity of introducing it in the order of the alphabet, we shall here subjoin together with the descriptions of the species as given by Mr Kerr.

V. Hyrax, or afhoko. There are two broad and distant fore-teeth above; four contiguous, broad, flat, notched fore-teeth below; and four large grinders on each side in both jaws. The fore feet have four toes, the hind feet only three. There is no tail; and the clavicles are wanting.

1. The capenisch, or cape afhoko, “has flat nails on all the toes, except one toe of each hind-foot which is armed with a sharp pointed claw. It inhabits the Cape of Good Hope.—This animal is about the size of a rabbit, being about 15 inches long; the head is short, with the back part very thick, and the snout very short and blunt; the eyes are small; the ears are oval and open, brown, woolly, and half hid in the fur; the legs are very short, the upper joints of both being concealed beneath the skin; the hind legs are rather longer than the fore; the feet are large, black, and naked; the body is short, thick, and contracted, with a prominent belly, and is covered with a soft woolly fur of a yellowish brown or greyish colour, hoary at the roots; the sides are of a dirty whitish grey; and along the back is a brownish stripe; this fur is intermixed with longer and coarser black hairs; and a few very coarse long bristles. The fore-feet have four short, scarce divided, thick toes, furnished with flat nails; the two outer toes of the hind-feet are similar, but the inner toe is longer, and has a sharp claw. This animal has a sharp voice, and acute sense of hearing; its gait is very wavering and unsteady, owing to the shortness of its thighs and unequal length of the hind and fore legs; notwithstanding of which it is very active and moves by leaps; it is very cleanly living entirely on vegetable food, drinks little, is fond of heat and burrows in the ground. In manners and general appearance, this animal resembles the marmot and cavy; in the conformation of its toes it has some analogy with the muscovado; but from the circumstances of the teeth it cannot be ranked with the last; and the peculiarity of the feet has caused Dr Gmelin to separate it from both of the former.”

2. The syriacus, or Syrian afhoko, (Bruce, Schreber), has soft tender nails on all the toes. It inhabits Syria and Ethiopia.—The body of this is more lengthened than that of the former, and the foot more oblong. The fur is of a reddish grey colour like that of the wild rabbit, the throat, breast, and belly, being white; all over the body a number of long, strong and polished hairs are scattered among the fur. The body and head of the individual described by Mr Bruce measured 17 inches. The ears are broad, open, and rounded; each side of the mouth is garnished with long whiskers. In walking, which is performed creeping low with the belly almost touching the ground, the hind feet are used as far as the heel. All the toes have short, broad, weak, flat nails, except the inner toe of the hind foot, which is provided with a flat crooked nail somewhat longer than the rest; the soles of the feet are formed of fleshy naked protuberances, divided by furrows. It lives mostly about the mouths of caves or clefts in rocks; is gregarious; feeds entirely on vegetables; is mild, feeble, timid, and unctuous. Opposite to the bristles, or rickets, it has no voice or cry. Mr Bruce is of opinion, that this animal is the ganim or Daman Lizard of the Arabs, and the fipham of sacred scripture, which has erroneously been translated the reitfeus.—Its flesh is very white, but is not eaten by the Abyssinians or Mahometans. The fame celebrated traveller is of opinion that it ruminates or chews the cud.”

MUSA, the Plantain-tree: A genus of the monacca order, belonging to the polyantra clas of plants; and in the natural method ranking under the eighth order, Scitamnia. The calyx of the male hermaphrodite is a spathe or flat; the corolla is tepalous; the one petal erect and quinquedentate; the other nectariferous, conca, and shorter; there are fix filaments; five of which are perfect; one style; the stamens inferior and abortive. The female hermaphrodite has the calyx, corolla, filaments, and pistil of the male hermaphrodite, with only one filament perfect; the berry is oblong, and three-angled below. The
most remarkable species are, 1. The paradisiaca, or plantain; 2. The maja sapientum, or banana-tree. See Plate CCCXX.

The first is cultivated in all the islands of the West Indies, where the fruit serves the Indians for bread; and some of the white people also prefer it to most other things, especially to the yams and caffada bread. The plant rises with a soft stalk 15 or 20 feet high; the lower part of the stalk is often as large as a man's thigh, diminishing gradually to the top, where the leaves come out on every side; these are often eight feet long, and from two to three feet broad, with a strong fleshy midrib, and a great number of transverse veins running from the midrib to the borders. The leaves are thin and tender, so that where they are exposed to the open air, they are generally torn by the wind: for as they are large, the wind has great power against them: these leaves come out from the centre of the stalk, and are rolled up at their first appearance; but when they are advanced above the stalk, they expand and turn backward. As these leaves come up rolled in the manner before-mentioned, their advance upward is so quick that their growth may almost be discerned by the naked eye; and if a fine line is drawn across level with the top of the leaf, in an hour's time the leaf will be near an inch above it. When the plant is grown to its full height, the spikes of flowers will appear in the centre, which is often near four feet in length, and nod on one side. The flowers come out in bunches: these in the lower part of the spike being the largest; the others diminish in their size upward. Each of these bunches is covered with a sheath or sheath of a fine purple colour, which drops off when the flowers open. The upper part of the spike is made up of male or barren flowers, which are not succeeded by fruit, but fall off with their covers. The fruit or plantains are about a foot long, and an inch and a half or two inches diameter: it is at first green, but when ripe of a pale-yellow colour. The skin is tough; and when it is a soft pulp of a juicy sweet flavour. The spikes of fruit are often so large as to weigh upwards of 40 lb. The fruit of this sort is generally cut before it is ripe. The green skin is pulled off, and the heart is roasted in a clear fire for a few minutes; and frequently turned: it is then scraped, and served up as Bread. Boiled plantains are not so palatable. This tree is cultivated on a very extensive scale in Jamaica; without the fruit of which, Dr Wright says, the island would scarce be habitable, as no species of provision could supply their place. Even flour or bread itself would be less agreeable, and less able to support the laborious fatigue, so as to enable him to do his business or to keep in health. Plantains also fatten horses, cattle, swine, dogs, fowls, and other domestic animals.

The leaves being smooth and soft are employed as duplings after blisters. The water from the soft trunk is affreignant, and employed by some to check diarrhoeas. Every other part of the tree is useful in different parts of rural economy. The leaves are used for napkins and table cloths, and are food for hogs.

The second sort differs from the first, in having its stalks marked with dark purple stripes and spots. The fruit is shorter, straighter, and rounder; the pulp is softer, and of a more luscious taste. It is never eaten green; but when ripe it is very agreeable, either eaten raw or fried in slices as fridies; and is relished by all ranks of people in the West Indies.

Both of these plants were carried to the West Indies from the Canary islands; whether, it is believed, they had been brought from Guinea, where they grow naturally. They are also cultivated in Egypt, and in most other hot countries, where they grow to perfection in about 10 months from their first planting to the ripening of their fruit. When their stalks are cut down, there will several suckers come up from the root, which in six or eight months will produce fruit: so that by cutting down the stalks at different times, there is a conflant succession of fruit all the year.

In Europe there are some of these plants preferred in the gardens of curious persons, who have hot-houses capacious enough for their reception, in many of whom they have ripened their fruit very well; but as they grow very tall and their leaves are large they require more room in the stove than most people care to allow them. They are propagated by suckers, which come from the roots of these plants which have fruited; and many times the younger plants, when they are fruited in growth, will also put out suckers.

The fruit of the banana-tree is four or five inches long, of the size and shape of a middling cucumber, and of a high, grateful flavour: the leaves are two yards long, and a foot broad in the middle; they join to the top of the body of the tree, and frequently contain in their cavities a great quantity of water which runs out, upon a small incision being made into the tree, at the junction of the leaves. Bananas grow in great bunches, that weigh a dozen pounds and upward. The body of the tree is so porous as not to merit the name of wood; the tree is only perennial by its roots, and dies down to the ground every autumn.

When the natives of the West Indies (says Labat) undertake a voyage, they make provision of a palte of banana; which, in case of need, serves them for nourishment and drink: for this purpose they take ripe bananas; and having squeezed them through a fine sieve, form the solid fruit into small leaves, which are dried in the sun or in hot ashes, after being previously wrapped up in the leaves of Indian flowering-reed. When they would make use of this pulse they dissolve it in water, which is very easily done; and the liquor, thereby rendered thick, has an agreeable acid taste imparted to it, which makes it both refreshing and nourishing.

The banana is greatly esteemed, and even venerated, by the natives of Madeira, who term it the forbidden fruit, and reckon it a crime almost inexpiable to cut it with a knife; because, after digestion, it exhibits, as they pretend, a similitude of our Saviour's crucifixion: and to cut the fruit open with a knife is, in their apprehension, to wound his sacred image.

Some authors have imagined, that the banana-tree was that of the leaves of which our first parents made themselves aprons in Paradise. The sacred text, indeed, calls the leaves employed for that purpose fifth leaves: and Milton, in a most beautiful but erroneous description, affirms the bearded or Bengal fig to have been the tree alluded to. But besides that the fruit of the banana is often by the most ancient authors called...
called a fig, its leaves, by reason of their great size and solidity, were much more proper for a veil or covering than those of the Bengal fig, which are seldom above six or eight inches long and three broad. On the other hand, the banana leaves being three, four, and five feet long, and proportionally broad, could not fail to be pitched upon in preference to all others; especially as they might be easily joined, or sewed together, with the numerous thread-like filaments that may, with the utmost facility, be peeled from the body of this tree.

Some have supposed the Abyssinian plant ensete to be a species of musa. It is said to be a native of the province of Narea, where it grows in the great marshes and swamps for which that province is remarkable, owing to the many rivers which originate in that country, and have but a small declivity to the ocean.

This plant, as well as the coffee-tree, is said to have been unknown in Abyssinia before the arrival of the Galla, who imported them both along with them. It comes to great perfection about Gondar; but the principal plantations of it are in that part of Maitha and Gouth, to the west of the Nile, where it is almost the sole food of the Galla who inhabit that country. Maitha is almost entirely on a dead level; so that the rains flagitate and prevent the sowing of grain.

Were it not for the enete, therefore, the Galla would have scarce any vegetable food. Mr Bruce thinks that the enete may have been cultivated in some of the gardens of Egypt about Rosetta, but that it was not a native of the country. He strongly controverts the opinion that this plant is a species of musa. It is true, (says he), the leaf of the banana resembles that of the enete; it bears figs, and has an excrecence from its trunk, which is terminated by a conical figure, and this is the part which is eaten. This fig is sweet, though mealy, and of a taste highly agreeable. It is supposed to have no seeds, though in fact there are four small black seeds belonging to every fig. But the figs of the enete are not eatable: they are of a soft tender substance: watery, tasteless, and in colour and consistence resembling a rotten apricot: they are of a conical form, crooked a little at the lower end; about an inch in length, and an inch in breadth where thickened. In the inside of the leaf is a large thin white, long, the shape of a bean or cashewnut, of a dark-brown colour; and this contains a small seed, which is fedom hardened into fruit, but confists only of skin.

The long stalk that bears the figs of the enete springs from the centre of the plant, or rather is the body or solid part of the plant itself. Upon this, where it begins to bend, are a parcel of loose leaves; then grows the fig upon the body of the plant without any stalk; after which the top of the stalk is thickened with small leaves, in the midst of which terminates the flower in the form of an artichoke; whereas in the banana, the flower in form of the artichoke grows at the end of that shoot or stalk, which proceeds from the middle of the plant, the upper part of which bears the row of figs. The leaves of the enete are of a web of longitudinal fibres closely set together; the leaves grow from the bottom without stalks; whereas the banana is in form like a tree, and has been mistaken for such. One half of it is divided into a stem, the other is a head formed with leaves; and in place of the stem that grows out of the enete, a number of leaves, rolled round together like a truncheon, shoot out of the heart of the banana, and renew the upper as the under leaves fall off; but all the leaves of the banana have a long stalk; this fixes them to the trunk, which they do not embrace by a broad base or involucre as the enete does.

"But the greatest differences are still remaining.—The banana has by some been mistaken for a tree of the palmaceous kind, for no other reason but a kind of familiarity in producing the fruit on an excrecence or stalk growing from the heart of the plant: but all the musa is neither woody nor perennial; it bears the fruit but once; and in all these respects it differs from trees of the palmaceous kind, and indeed from all sorts of trees whatever. The enete, on the contrary, has no naked stem; no part of it is woody: the body of it, for several feet high, is succulent; but no part of the banana plant can be eaten. As soon as the stalk of the enete appears perfect and full of leaves, the body of the plant turns hard and fibrous, and is no longer fit to be eaten: before, it is the best of all vegetables. When boiled, it has the taste of the best new wheat bread not perfectly baked. When you make use of the enete for eating, you cut it immediately above the small detached roots, and perhaps a foot or two higher, as the plant is of age. The green musa is stripped from the upper part till it becomes white: when soft, like a turnip well boiled, if eat with milk or butter, it is the best of all food, wholesome, nourishing; and easily digested."

Our author now proceeds to consider an hieroglyphic sometimes met with in Egypt, viz. "the figure of Isis sitting between some branches of the banana tree, as is supposed, and some handfuls of ears of wheat. You see likewise the hippopotamus ravaging a quantity of the banana tree. Yet the banana is merely adventitious in Egypt; it is a native of Syria; it does not even exist in the low hot country of Arabia Felix; but chooses some elevation in the mountains where the air is temperate; and is not found in Syria farther to the southward than Lat. 34°.

For these reasons Mr Bruce thinks, that the banana, not being a plant of the country, "could never have entered into the list of their hieroglyphics; for this reason it could not figure any thing regular or permanent in the history of Egypt or its climate. I therefore imagine (adds he), that this hieroglyphic was wholly Ethiopian; and that the supposed banana, which, as an adventitious plant, signifies nothing in Egypt, was only a representation of the enete; and that the record in the hieroglyphic of Isis and the enete-tree was something that happened between harvest, which was about August, and the time that the enete-tree came in ū, which was in October.—The hippopotamus is generally thought to represent a Nile that has been so abundant as to be destructive. When, therefore, we see upon the obelisks the hippopotamus destroying the banana, we may suppose it meant, that the extraordinary inundation had gone so far as not only to destroy the wheat, but also to retard or hurt the growth of the enete, which was to supply its place."
MUSÆUS, an ancient Greek poet, was, according to Plato and Diodorus Siculus, an Athenian, the son of Orpheus, and chief of the Eleusinian mysteries initiated at Athens in honour of Ceres: or, according to others, he was the only disciple of Orpheus: but from the great resemblance which there was between his character and talents and those of his master, by giving a stronger outline to the figure he was called his son, as those are styled the children of Apollo who cultivated the arts of which he was the tutelar god.

Museus is allowed to have been one of the first poets who verified the oracles. He is placed in the Arundelian marbles, epoch 15. 1426 B. C. at which time his hymns are said to have been received in the celebration of the Eleusinian mysteries. Laerterius tells us, that Museus not only composed a theogony, but formed a sphere for the use of his companions; yet as this honour is generally given to Chiron, it is more natural to suppose, with Sir Isaac Newton, that he enlarged it with the addition of several oracles after the conquest of the golden fleece. The sphere itself shows that it was delineated after the Argonautic expedition, which is described in the after-times, together with several other ancient histories of the Greeks, and without anything later; for the ship Argo was the first long vessel which they had built: hitherto they had used round ships of burthen, and kept within sight of the shore; but now, by the dictates of the oracle, and consent of the princes of Greece, the flower of that country sail rapidly through the deep, and guide their ship by the stars.

Museus is celebrated by Virgil in the character of hierophant, or priest of Ceres, at the head of the most illustrious mortals who have merited a place in Elysium. Here he made the conductor of Æneas to the recess where he meets the shade of his father Anchises.

A hill near the citadel of Athens was called MUSEUM, according to Pausanias, from Museus, who used to retire thither to meditate and compose his religious hymns; at which place he was afterwards buried. The works which went under his name, like those of Orpheus, were by many attributed to Oronomacritus. Nothing remains of this poet now, nor were any of his writings extant in the time of Pausanias, except a hymn to Ceres, which he made for the Lycomides.

And as these hymns were likewise set to music, and sung in the mysteries by Museus himself in the character of priest, he thence perhaps acquired from future times the title of musician as well as of poet; the performance of sacred music being probably at first confined to the priesthood in these celebrations, as it had been before in Egypt, whence they originated. However, he is not enumerated among ancient musicians by Plutarch; nor does it appear that he merited the title of son and successor to Orpheus for his musical abilities, so much as for his poetry, piety, and profound knowledge in religious mysteries.

MUSCA, the Fly, in zoology; a genus of insects belonging to the order of diptera. The mouth is furnished with a feathery proboscis, and two lateral lips; but it has no palp. This genus is divided into two different sections: 1. Those with simple antennae. 2. Those which are furnished with a lateral hair or feather. Those have downy bodies, though scarce perceptibly so; and have either a lateral plume or feather on the antennae, or a simple hair on the side of the antenna. The pilose have a few hairs scattered upon their bodies, principally upon the thorax; they have either a lateral feather or a lateral hair. Under these divisions are comprehended about 400 different species, as enumerated in Dr. Gmelin's edition of the Systema Naturae. "Variety (as Mr. Barbut observes) runs through their forms, their structure, their organization, their metamorphosis, their manner of living, propagating their species, and providing for their posterity. Every species is furnished with implements adapted to its exigencies. What exquisiteness in what proportion in the several parts that compose the body of a fly! What precision, what mechanism in the springs and motion! Some are oviparous, others viviparous; which latter have but two young ones at a time, whereas the propagation of the former is by hundreds. Flies are lascivious troublesome insects, that put up with every kind of food. When storms impend, they have most activity, and fly with greatest force. They multiply most in hot moist climates; and go great was formerly their numbers in Spain, that there were fly-hunters commissioned to give them chase. The vapour of sulphur or arsenie destroys them; and their numbers may be reduced by taking them in phials of honeyed water, or between boards done over with honey." There are 129 species, principally distinguished by the peculiarities in their feelers.

Museus, a name given to such persons among the Romans as officially thrust themselves into the company of their superiors and those who defied them, by finding means of getting admission to entertainments without invitation, and without a welcome: so that mutsa were the same as parasites, who were frequently by the Greeks termed museus. See Parasite.

MUSCADINE, a rich wine, of the growth of Provence, Languedoc, Cividal, &c. —The word, as well as the liquor, is French: Some fetch its origin from the mutsa; the wine being suppos'd to have a little of the smell of that perfume; others from mutsa, a fly," because the flies are extremely fond of its grapes; as the Latins had their vinum apianum, so called ab aphis, from the bees which fed on it.

The way of making muscadine at Frontignac is as follows: They let the muscadine grapes grow half dry on the vine; as soon as they are gathered, they tread and press them immediately, and run up the liquor, without letting it stand and work in the fat; the lees occasioning its goodness.

MUSCHENBROECK. (Peter de), a very distinguished natural philosopher and mathematician, was born at Utrecht a little before 1700. He was first professor of theology in his own university, and afterwards invited to the chair at Leyden, where he died full of reputation and honours in 1761. He was a member of several academies; particularly the Academy of Sciences at Paris. He was the author of several works in Latin, all of which show the greatest penetration and exactness in this way. He was also very eminent in the knowledge of law.

MUSCI, Mosaii, one of the seven families or classes into which all vegetables are divided by Linnaeus in the Philosophia Botanica. The ancients took the moss of trees to be the effect of a disorder or decomposition of the texture of the bark; or at most a kind of little filaments arising from the bark; but the moderns find by several observations, that mosses are all
all real distinguid plants, whose feed, being extremely
small, is inoculated in little capfule: which bursting of
themselves, the feed is carried off by the winds; till,
falling into the inequalities of the bark of trees, it is
there stopped, takes root, and feeds at the expense of
the tree, as mouldines does on bread, &c.

What the botanical writers freely understand by
the word moss, is a class of plants appearing of an
inferior rank to the common vegetables; the
fruit of flower or feed, or any thing analogous to ei.
fifty parts; the semblance of those parts which ferve other plants for
Goll their appropriated organs
of parts, and carry fomething that looks analo
gous to vegetation in the common way, having a re
semblance of thofe parts which ferve other plants for
their fructification. The more perfect genera of the
mofes not only confit of different parts, but have alto
their appropriated organs containing a pulpy matter,
which finally becomes dry, and affumes the form of a
fine and fubtile powder, compofed of granules, each of
which is either a feed or a granule of farina, ferve
for the propagation of the species.
The more imperfect mofes are diftinguifhed
from the others by their appearance to the naked eye; they
are either in form of a fine lanugo or down covering
the surface of different bodies; or else they appear as
fleender filaments, or foliaceous bodies, floating about
in the water; or as filaments of a tougher texture,
hanging down from the branches of old trees; or as
little frubs, or fingle horns, growing creft on the
parched earth of mountains and heathy places; or
finally, as broad and foliaceous bodies reading
over the dry barks of trees or rocks, without
any pedicle or other fupport.
The more perfect kinds of mofes are found in the
shape of small but regular plants, divided into feveral
branches, and clothed with leaves: these are of vari
ous forms and ftructures; fome being broad and thin,
others flenfer as hairs; fome pelhucd, others opake;
fome smooth, others hairy. From the fide of thefe
leaves in fome kinds, and from the fummit of the
flalk; in others, there arife heads or capfules of va
rious form and ftructure, but all peculiar to mofes; fome
of these are naked, and others covered with a calyptra
or hood; fome fland on long pedicles, and others
are placed clofe to the flalks. Thofe heads are ufual
ly called capfules, which contain their feeds or farina,
and their pedicles fata, in the moss, hypna, brya, and
polyptrichas, &c.

Thefe capfules in fome are covered with a calyptra
or hood; in others they are naked. Of the first kind
are the fphacium, polyptrichum, meium, bryum, hypna,
fostinulus, and buxbaumia; and of the latter for, the
lycophorium, porrela, fphagnum, and phalcaum.
The fublinance with which the heads or capfules of
all the mofes are filled, resembies either feeds, or the
small globules of the farina of flowers, which all re
femblce feeds of particular figures in miniature. The
fructifications of thofe minute plants feem to be either
from these, as feeds falling to the earth; or, according
to the opinion of fome, they feem to contain only fa
rina in the capfules, which impregnating certain bulbs
or nodules in the ale of the leaves, caufe them to grow
and vegetate, as is seen in fome of the larger plants;
as in the bulbs produced in the ale of the leaves of the
dentaria, and of the libes, and fome others. The for
mer opinion, of the powder in the heads or capfules
being actually perfect feeds, is the more probable, as
the bulbs in the ale of the leaves are found only in
fome of the hypna, and others of a few other genera;
whereas the propagation is as quick and certain in
thofe which have none of them as in thofe which
have; and the want of female parts of fructification,
which makes fo many defiderata in the Linnean fytem
of botany, is easily made up, and the whole explain
ed according to the ufual courfe of nature in other
vegetables, by allowing the powder in the capfules to
be real feeds, and the small globules on the points;
surrounding the aperture of the capfule, the farina.
The opinion of the mofes growing from thofe no
dules in the ale of the leaves, or from the impregnated
ends of the branches which had received the pow
der from the capfules, was originally founded on the
observing that the trailing or branched hypna an
nually grew out in length, from the extremities of all
their branches, and annuallv loft as much of the old
flalk at the root as they gained of the new at the fum
mit; but it appears from farther obfervations, that
they are real feeds which are contained in form of
powder in the capfules; fince the brya, and many
others, are found growing from small points or spot
which are afsemblages of their minute leaves, propa
gated on the ground, under the old ones juft where
the powder of the capfules has fallen; and though it
be allowed that the hypna and other trailing mofes do
grow from the ends of the branches, yet they may
also be produced in form of new plants, from regular
and perfect feeds fed from the capfules. It is cer
tain that the brya are by this means propagated and
spread into large tufts, and the other genera may alto
be fo propagated, though they have bene a property
of increasing by growth of the flalk; which feems no
other than the property of many of the large plants
to creep at the root, and fhoot out in length greatly
from the extremities of their horizontal branches, ly
ing on or under the ground, as thofe spreading parts
may more properly be fo called than roots, the fibres
propagated out from them peculiarly adhering to the
earth being properly the roots; and it is well known that
thofe plants, though they propagate themselves thus
by the root, they produce feed alto like others, by
which they may be equally propagated: and this ana
logy is to be carried yet farther; for as thofe plants
which creep by the roots produce fewer feeds than thofe which are propagated only by feeds; fo the hyp
na, which are the genus of mofes in which this
growth by the flalk is principally observed, are very
thinly befet with capfules of feed, and many of them
produce but very few in a feafon; whereas the brya,
and other mofes which have not this advantage of
growing from the ends of the flalks, are found every
year profusely covered with capfules from every tuft;
and, there is scarce any branch which does not pro
duce its capfule. Now, if thofe capfules contained only
a farina capable of impregnating the nodules or the
ends of the branches, it is obvious there would be as
much of it required for the hypna as for any other
kinds of mofes; but if they are real and perfect feeds,
it is no wonder that nature has given them profu
to such kinds as are to be propagated only by seeds, and more sparingly to those which are propagated also by the increase of the branches.

To this it may finally be added, that the ferns and other epiphylophorperous plants approach most of all others to the nature of the mosses; and though it has been suspected by many that the fine powder at the back of their leaves was not seeds, but only a farina, yet it is now well known that it is true and perfect feed; since, under many species of them, there are constantly found new and self-torn plants arising in their first rudiments of leaves and figure, which have plainly grown from the dust or powder fallen from the old plants; and as this is now found to be the case in regard to the ferns, probably it will also appear the same in regard to mosses, when they have been yet farther examined than at present. But whether these grains of powder have the lobes and radicles by which the seeds of larger plants propagate themselves, or whether they grow into plants like the parent ones, in the manner of the lichens, by mere expansion, is a thing that requires farther observation to determine.

Some of the mosses, it is evident, approach to the nature of the plants which have their male and female parts in the same flower, and others to those which have them in different ones.

After all, this tribe of plants, as well as the mushrooms, ferns, and sea-weed, is still imperfectly known. Dillenius, professor of botany at Oxford, was the first who attempted an arrangement of them. In his Catalogus Plantarum circa Cifam, published at Francfort in 1719, and afterwards in his Historia Musorum, published at Oxford in 1744, he divides the mosses into 16 genera. This arrangement, however, includes the lichens, some of the fungi, and other plants which belong to very different families. The work in question is, notwithstanding, valuable, in having introduced the knowledge of upwards of 200 plants, which were unknown before Dillenius; it is, besides, of all his works of this kind, the best executed, both for the descriptions and figures, and should serve as a model to such authors as intend to publish in detail the history of any particular family of plants.

Micheli, in a work intitled Nova Plantarum Genera, published at Florence in folio in 1629, divides the mosses into two sections, from the figure and situation of their flowers. These sections comprehend together 16 genera, among which are improperly arranged, like those of Dillenius, several of the lichens and other sea-weeds.

The discovery of the seeds of the mosses, though made by Dillenius in 1719, is arrogated by Linnaeus to himself, who did not begin to write till 1735.

In Ray’s method, the mosses form the third class: in Tournefort’s, they continue a single genus, by the name of muscos, in the first section of the 17th class, which comprehends the mosses, mushrooms, and some of the algae or sea-weed, and is distinguished by the name of alperna, or plants without feed; the feeds of the mosses not having been detected by Tournefort.

The characteristics of these plants, according to the fourth section, are: 1. Top without filaments or threads. 2. The male flower, constituted by the presence of the anthere or tops, placed apart from the female, either on the same or distinct roots. 3. The female flowers deprived of the pilillum or pointal. 4. The feeds devoid of both lobes (castiglileus) and proper coverings; so that they exhibit the naked embryo.

In the sameylum, these plants constitute the second order of the class cryptogama, which contains all the plants in which the parts of the flower and fruit are wanting, or not conspicuous. This order is subdivided into 13 genera, from the presence or absence of the calyx, which in these plants is a veil or cover like a monk’s cowl, that is placed over the male organs or tops of the flamina, and is denominated calyptra, from the fexes of the plants, which bear male and female flowers, sometimes on the same, sometimes on distinct roots; and from the manner of growth of the female flowers, which are sometimes produced fingly, sometimes in bunches or cones. These distinctions are mostly borrowed from Dillenius, whose excellence in developing this part of the vegetable kingdom Linnaeus very readily acknowledges.

The manner of feeding of mosses in general may be more clearly understood from the description of that genus of them which has been traced through all its stages, and to which most of the others, though every genus has its distinct fructification in some respects, yet bear a very great general analogy.

The genus already observed, is that called by Dr Dillenius the hypnum. The species of this are very numerous and common; but that particular one which was the subject of these observations, is the short branched silky kind, common on old walls; and called by that author in his history hypnum vulgare, sericum, recurvum, capulis ereticis sustitutus.

The head of this moss appears to the naked eye a small, smooth, brownish-yellow, oblong body, of about a ninth of an inch long; this is covered at its upper end with a membranaceous calyptra or hood, in shape resembling an extinguiher or a funnel inverted. When this calyptra is taken off, and the head viewed with a microscope, the surface of it is seen to be ridged with longitudinal frits. The base of the head is of a deep orange colour, and more opaque than the rest; and the top is bounded by an orange-coloured ring, dwelling out something beyond the surface of the contiguous parts of the head. The whole glass show that in this head there are not wanting the parts effectual to the fructification of what are usually called the more perfect plants. This ring is truly a monophyllous undulated calyx, within which arise sixteen pyramidal fringed flamina; these are of a pale greenish colour, and are loaded with a whitish oval farina. The flamina all bend toward each other from their bases, and almost meet at a point in the tops. This is their appearance when the head is nearly ripe; and immediately under the arch formed by these flamina is a cylindric hollow pilillum, through which the farina makes its way, and is dispersed among the feeds in the head; the fruit is a large capsule, filling every part of the membrane which shows itself on the outside of the head, and in most places is contiguous to it; this capsule is filled with perfect and very beautiful seeds; they are round, transparent when unripe, but afterwards opaque, and of a very beautiful green, which colour they retain even when dried.

When this head is first produced from the plant, the flamina are very slender, and stand erect; the head
is scarce any thicker than the stalk, and the calyx
covers it all over, to shield the tender substance of the
farina from external injury. As the farina afterwards
swells in the stamina, the seeds in the head increase
also in bulk, and by their increase the head is more ex-
tended in thickness; and the stamina are by this means
separated farther and farther from each other at their
bales, but bend inwards toward their points, so as to
form a kind of arched covering over the stigma of the
pilifillum, which is single; and from hence the far-
ina falls as it ripens into the head, and impregnates
the seeds.

The principal genera are as follow: Lycopodium,
polytricum, bryum, folgens, ufnce, minutum, bryf, sphag-
num, hypna, conserves, and fontinalis. These are found
growing on the barks of trees as well as on the
ground. See Plates CCCXI and CCCXII.

Mothes, by the inconsiderate mind, are generally
debuted an ufeless or in{ignificant part of the creation.
That they are not, is evident from hence; that He who
made them has made nothing in vain, but on the con-
trary, has pronounced all his works to be very good.
Many of their ues we know; that they have many
more which we know not, is unquestionable, since
there is probably no one thing in the universe of which
we dare to assert that we know all their ues. Thus
much we are certain of with respect to mothes, that as
they flourish moft in winter, and at that time cover
the ground with a beautiful green carpet, in many
places which would be otherwise naked, and when
little verdure is elsewhere to be seen; fo at the fame
time they shelter and preserve the seeds, roots, gems,
and embryo plants of many vegetables, which would
otherwise perish; they furnish materials for birds to
build their nests with; they afford a warm winter's
retreat for some quadrupeds, fuch as bears, dormice,
and the like, and for numberlefs insects, which are the
food of birds and flies, and these again the food or
delight of man. Many of them grow on rocks and
barren places, and roting away, afford the
materials for birds to
build their nests with; they afford a warm winter's
retreat for some quadrupeds, fuch as bears, dormice,
and the like, and for numberlefs insects, which are the
food of birds and flies, and these again the food or
delight of man. Many of them grow on rocks and
barren places, and roting away, afford the

1. The grifola, or spotted fly-catcher, is about five Mucicapa.
inches and three quarters long. The head is large of
a brownhine hue spotted obscurely with black; the back
is of a moule-colour: the wings and tail are difky:
the breast and belly white; the throat and fides under
the wings darted with red: the legs and feet are short
and black. It is a bird of palette; appears in England
in the spring, breeds there, and departs in September.
It builds its nest again any part of a tree that will
support it; often in the hollow caufed by the decay
of some large limb, hole in a wall, &c. on old
pofts and beams of barns; and is found to return to the
fame place inear after foearon. It lays four or
five pale eggs marked with reddifh. It feeds on in-
sects, and collects them on the wing. When the young
can fly, the old ones withdraw with them into thick
woods, where they frolic among the top branches;
dropping from the boughs frequently quite perpendi-
cularly on the flies that sport beneath, and rising again
in the fame direction. It will also take its stand on
the top of fome flake or poft, from whence it fprings
forth on its prey, returning till to the fame ftand, for
many times together. They feed alfo on fherries, of
which they ftew very fond.

2. The pondiceriana, Pondicherry or Coromandel
fly-catcher, is rather bigger than a sparrow. The
general colour of the upper parts is a cinereous grey:
the throat, breast, belly, white: the legs black. It
inhabits the coaft of Coromandel; where, from the
agreeableness of its fong, it is called the Indian night-
ingale.

3. The flabellifera or fan-tailed fly-catcher, is in
length six inches and a half; the head is black, which
colour descends on the back part lower than the nape,
whence it passes forward in a narrow collar to the
throat; the chin, throat and fides of the neck, except
where this collar paffes, are white; and over the eye
is a white ftrâk like an eye-brow: the upper parts of
the body are olive-brown; the under parts yellowish
ruft, growing whitifh towards the vent: the tail is
longer than the body; the two middle feathers black,
the others white: the legs are dusky. This species
inhabitsthe fouth ifle of New Zealand; where it is
cenefantly hunting after insects, and flies always
with its tail in fhape of a fan. It is easily tamed;
will then fit on any person's shoulder, and pick off the
flies. It has a chirping kind of note; and is called by
the natives Diago-wagh-wagh. There is a beautiful fi-
gure of this bird in Mr Latham's Synophis, plate
xlí.

4. The caribonenfis, or cat-bird, is somewhat bigger
than a lark: length eight inches. Bill black: the
upper parts of the body and wings are of a deep
brown; the under ash-coloured; the crown of the
head is black; the tail is blackish, and the legs are
brown. This species is found in Virginia in the sum-
mer-seaon: where it frequents shrubs rather than tall
trees; and feeds on insects; its cry resembles that of a
cat, whence the English name given it by Catesby.
See Plate CCCXX, fig. 1.

5. The crinita, or crested fly-catcher, is about the
size of a lark: the head is crested, and of a dull green:
the hind part of the neck and back are of the fame
colour; the under parts from the chin to the break
of an ashy-colour, and from thence to the vent yellow: the legs are black. This inhabits Carolina and Virginia in summer; builds there, and departs in autumn.

6. The rubricollus, purple throated fly-catcher, is about the size of a black bird; the whole plumage is black; except the chin, throat, and fore part of the neck, on which is a large bed of beautiful crimmon, including to purple; the legs are black.—These birds inhabit Cayenne and other parts of South America; where they are found in flocks, and precede in general the toucans in their movements. They feed on fruits and insects; and are lively birds, always in action. They for the most part frequent the woods, like the toucans; and where the first are found the others are seldom far off.

7. The rubra, or summer red-bird of Catesby, is a most beautiful species, somewhat bigger than a sparrow: the bill is yellowish; the eyes are black; the legs dusky; the male is wholly of a scarlet colour, except the tips of the quill-feathers, which are of a dusky red; the colour of the female is brown tinged with yellow. It inhabits Carolina and Virginia in the summer.

This is a very numerous genus: there being about 90 other species described by authors. In the Syll. Nat. (Gmelin), the whole number is 92; in Mr Latham's Index Ornithologicus, 62 are enumerated.

MUSCLE, in anatomy. See Anatomy, Part II. Fac, ii.

The motion of the muscles of animals has been thought a matter of such curiosity and importance, that an annual lecture upon it was founded by Dr Croone, one of the original members of the Royal Society at London. In consequence of this the investigation of the subject has exercised the pens of a great number of very learned and ingenious men; notwithstanding which it still remains involved in almost as much obscurity as ever. Many curious observations, however, have been made; and as far as the laws of dead mechanism can be applied to a living machine, the investigators have been successful; but still there has been a ne plus ultra, a certain barrier by which their investigations have been limited, which no person has hitherto been able to pass, and which it is very improbable ever will be passed. To give an account of all the different theories which have appeared on this subject is impossible; but in the year 1788 a lecture on the subject was delivered by Dr Blanc, F. R. S., of which, as it seems to contain the substance of all that can be said upon the subject, we shall here give the following abridgment.

The doctor considers as muscles not only those large masses of flesh which compose so great a part of the bulk of the body, but likewise all the minute organs subervient to circulation, nutrition and secretion; since not only the heart itself, but the whole vascular system and the intestines, owe their action to certain powers of irritability and contrariety peculiar to muscular fibres.

The first and most obvious considerations with respect to the muscles is the regular organization of their fibres in a parallel direction. In this they are distinguished from every other matter of a fibrous structure, whether vegetable or mineral, by a certain degree of moisture, tenacity, and elasticity, entirely peculiar to themselves.

The fibres of the muscles visible to the naked eye are composed of others discoverable by glasses, and these others of fibres still smaller; neither hath any per son been able to discover the ultimately fine fibres of a muscle, which are not composed of others. Some have indeed imagined that they have been able to do this, but their observations have been fallacious, and it is now universally allowed that the fibres are divisible beyond what the best assisted sight can trace, and that they are to all appearance uniform. In this regular and fibrous organization they resemble the crystals of salts, many of which are found composed of fibres more and more fine, and which, like those of the muscles, can never be ultimately traced.

The doctor next touches a little upon the vis inertia of matter; and, contrary to the generally received opinion of modern philosophers, considers matter as an active substance. What is called the vis inertia, he thinks, is not a resistance of change from rest to motion, or from motion to rest, but a resistance to acceleration or retardation, or to change of direction. The activity of matter is further proved by the attractions and repulsions which take place universally among its parts; and every influence of motion within the cognition of our senses, may be referred, either in itself or its cause, to some mode of attraction or repulsion. These may both be considered as one principle, being both expressive of that state of activity originally inherent in matter; and because any two particles, having affinity with each other, must either attract or repel, according to their distance, their common temperature, and other circumstances; and it is so universal an agent in nature, that some modern philosophers have made it absorb, as it were, every other power and property in matter. It is evident, however, whether this hypothesis be just or not, that the cause of muscular motion cannot be referred to mechanism, which is itself only a secondary principle. Some have had recourse to a fluid conveyed into the fibres of muscles, by which they were swelled, and thereby shortened. One of the most plausible of these hypotheses supposes this fluid to be the blood; but this is plainly a petitio principii: for in order to set the blood in motion, muscular motion is necessary. Other fluids have been supposed to have this effect; but even the existence of these has not been proved, and indeed the most solid objections might be brought against all the theories that have hitherto been invented.

Our author having now established it as a maxim, that the primary properties of matter, are attraction and repulsion, and that mechanism is only a secondary property, he next considers muscular motion as referable to an original law of animated matter, whereby its particles are endowed with an attractive power, for which no cause can be assigned any more than for gravitation, cohesion, or chemical affinity. If the shortening of a muscular fibre depends on this increased power of attraction between its particles, the effect will be to add to the power of cohesion in the fibre; and to determine this the doctor made the following experiment: Having taken the flexor muscle of the thumb of a man newly dead while yet warm and flexible,
MUS

MUS

Muscles, he appended a weight to it, continually augmenting it until the muscle broke; and this he found was done when 26 pounds had been added: yet a living man of the same apparent strength and age could with ease lift a weight of 38 pounds by the exertions of the same muscle. "It is farther in proof of this fact (adds he), that in the case of a violent strain from muscular contraction in the living body, it is the tendon that gives way; whereas we have seen that in the dead body the muscle is the weaker of the two. It is also well known, that in cases of our exertion the muscular fibres themselves do not give way, though the strongest tendons, such as the tendon Achilles, and even bones, such as the knee-pan, are broken by their living force, which in such instances must be many times greater than the strength of the dead fibres. There is a case related in the Philosophical Transactions by Mr Amyand, wherein the os humeri was broken by an exertion of the muscles. Every one has heard of fractures happening from very slight accidents. These occur most probably from a jerk of the muscles concurring with the external violence. The sensible increase of the length of a muscle, when in a state of contraction, may also be considered as a proof of an increased attraction of its particles to each other at that time."

The Doctor next considers whether or not a muscle, when in a state of contraction, undergoes any change of density. "Every homogeneous body (says he) possesses a certain degree of density, determined by the dismance of its integrant particles. The most common means in nature by which the density of such bodies is altered, are heat and cold; the one universally producing expansion, the other condensation. Whether mechanical force has the same effects, is a point in natural philosophy not so well acertained; for though tension and collision produce in solid elastic bodies a change of figure, which they immediately resume when the force is withdrawn, it has not been ascertained whether in such cases a change of density takes place while the body is in a state of elongation or compression. Two elastic balls in the act of collision undergo a momentary change of figure, so that there must be an approximation of particles in the direction in which they are flattened; and in the elongation of an elastic cord by tension there must be an increased distance of the particles in one direction: but while these changes take place in one dimension of the respective bodies, they may be compensated by contrary changes in the other dimensions, so that the several bodies may preserve, upon the whole, the same solid contents. In order to ascertain this in the case of tension, which is the only case bearing analogy to muscular motion, I made the following experiment: I took a piece of the elastic gum, or caoutchouc, three inches square, and about the eighth of an inch in thickness; I procured a piece of sheet tin three inches broad and about six inches long, cut into sharp teeth at each end. The gum was first weighed in air, and found to be 380.25 grains. It was then weighed in water along with the tin, to which it was loosely attached, and the weight of both was then 758.75 grains. The gum was then stretched upon the tin by means of the teeth at each end to a surface of about five inches square, the tin being bent so as to leave a free space between it and the gum; in order that when immersed in water no air-bubbles might be entangled. In this situation, the weight of both in water was found to be 746.75 grains. Here was a difference of 12 grains, which could be owing only to a diminution of specific gravity; and in order to be sure that there was no fallacy nor inaccuracy in the experiment, the gum was immediately disengaged from one end of the tin so as to allow it to shrink; and being again weighed in this state in the water, it was found to have recovered exactly its former weight."

From this very remarkable experiment, the Doctor argues to what may probably happen in the contraction of the muscles. "This point (he says) cannot be decided but by an experimental examination. It might be determined whether a muscle occupies most space when relaxed or when contracted, by finding its specific gravity in each of those states by means of the hydrostatical balance. But this would be found extremely difficult; for the state of contraction is very transitory, and the motion itself would produce such a disturbance as would render the result unsatisfactory. As there is this obstacle to an experiment on a living muscle, it occurred to me that it might be performed on the muscles of a fish which had undergone the operation of cramping, as it is called; for in consequence of dividing the muscles, by cutting them when alive, they undergo a contraction which continues after death; and upon comparing by the hydrostatical balance, portions of muscle which had been crimped with those of the opposite side of the same fish which had on purpose been faved from this operation, it did not appear that there was any difference in the specific gravity. Two trials were made; one with the maeifter muscles of a skate, the other with the sides of a large trout."

To determine whether the contraction or relaxation of a living muscle made any alteration in its density, our author took one half of a living eel, and put it into a glass flask, of which the mouth was afterwards futed by a blow-pipe, and drawn out like the stem of a thermometer. The flask and tube being then filled with water, our author observed, with great attention, whether the convulsive agonies of the creature would make the fluid rise or fall; but it did neither. The tail part of the eel was made use of in this experiment, that there might be no deception from the other, which contained the organs of respiration and the air-bladder. In one of his trials, the tail portions of two eels were introduced into the flask; but though they were frequently both in convulsion at once, not the leaft motion of the fluid in the tube could be perceived. On this account also the Doctor made some experiments to decide the question, whether the mere circumstance of life made any alteration in the gravity of bodies? His first trials were with animals of warm blood, included in oil-skin and close tin vessels: but not being satisfied with the accuracy of these, from the difficulty of cutting off all communication with the external air, he included live eels in flasks; and having sealed them hermetically, he found that the weight of them when alive and dead was the very same.

The result of all our author's experiments is, that the contraction of a muscle produces no change in its density, and that animal life differs from inanimate matter in this respect, as well as in most of its other properties and laws. One purpose in nature for muscles always
always preferring the same density may be, that as
some of them act in confined cavities, inconveniences
might arise from their occupying more space at one
time than at another. In the extremities of crufi.
cacious animals, for instance, which are filled with
muscles, a change of density would be apt to burst them.

Another circumstance in which the contractions
of muscles differ from simple elasticity is, that the
former, however frequent and violent, does not pro-
duce any heat, as collision and tension are known to
do. This may admit of some cavil with regard to
animals of warm blood; for one of the theories with
regard to animal heat is, that it arises from the perpe-
tual vibration of muscular fibres, particularly those
of the vascular system; but this will not hold with re-
spect to animals of cold blood, in which the actions
of life are equally vigorous. The principal pheno-
mena, therefore, of muscular motion are, the shorten-
ing of the fibres, the lateral swell, the increase of
cohesion and hardness, and the unchanged density and
temperature. It would appear from the two last cir-
stances, that the intimate motions of the particles in
relation to one another must be different from what
take place in the several infancies of contraction and ex-
pansion of dead bodies. In the expansion arising from
the action of heat and the contraction from cold, the
change of density flows, that in the one case the ul-
timate particles must recede from each other, and in
the other they must approach. The same may be said
of elasticity. But as there is no alteration in the den-
fity of a muscle in passing from relaxation to contrac-
tion, this change cannot consist in the approximation
of the integral parts of the fibres, but must depend
on some other circumstances in the intimate dispositions
of the particles. In attempting to conceive in what
this consists, the following explanation may be offered.
It is probable that the regular structure of solid bodies
depends on the polarity and shape of their integrant
parts. Now all bodies, except such as are spherical,
must have a long and a short axis; and let us imagine
the fibres of muscles to be composed of spheroidal
particles, we may then conceive relaxation to consist
in their being disposed within their long axis in the line
of their fibres and contraction to consist in their short
axis being disposed more or less in that direc-
tion. This will not only account for the decurrent
and uniform density, but for the lateral swell, and
also for the increased hardness and cohesion; for
though the particles do not approach or recede, as
in bodies simply elastic, yet their power of attraction
will be increased by their centres being brought near-
er, and by being applied to each other by more ob-
late surfaces. This hypothesis accords with what has
been before proved concerning the unchangeable
density, for what is lost in one dimension is gained in
another; and the cause for there being no increase in
temperature depends probably on the same circum-
stance by which the density is preferred unaltered.”

Muscles always preferring the same density may be, that as
some of them act in confined cavities, inconveniences
might arise from their occupying more space at one
time than at another. In the extremities of crural-
cacious animals, for instance, which are filled with
muscles, a change of density would be apt to burst them.

Another circumstance in which the contractions
of muscles differ from simple elasticity is, that the
former, however frequent and violent, does not pro-
duce any heat, as collision and tension are known to
do. This may admit of some cavil with regard to
animals of warm blood; for one of the theories with
regard to animal heat is, that it arises from the perpe-
tual vibration of muscular fibres, particularly those
of the vascular system; but this will not hold with re-
spect to animals of cold blood, in which the actions
of life are equally vigorous. The principal pheno-
mena, therefore, of muscular motion are, the shorten-
ing of the fibres, the lateral swell, the increase of
cohesion and hardness, and the unchanged density and
temperature. It would appear from the two last cir-
stances, that the intimate motions of the particles in
relation to one another must be different from what
take place in the several infancies of contraction and ex-
pansion of dead bodies. In the expansion arising from
the action of heat and the contraction from cold, the
change of density flows, that in the one case the ul-
timate particles must recede from each other, and in
the other they must approach. The same may be said
of elasticity. But as there is no alteration in the den-
fity of a muscle in passing from relaxation to contrac-
tion, this change cannot consist in the approximation
of the integral parts of the fibres, but must depend
on some other circumstances in the intimate dispositions
of the particles. In attempting to conceive in what
this consists, the following explanation may be offered.
It is probable that the regular structure of solid bodies
depends on the polarity and shape of their integrant
parts. Now all bodies, except such as are spherical,
must have a long and a short axis; and let us imagine
the fibres of muscles to be composed of spheroidal
particles, we may then conceive relaxation to consist
in their being disposed within their long axis in the line
of their fibres and contraction to consist in their short
axis being disposed more or less in that direction.
This will not only account for the decuration and uniform density, but for the lateral swell, and
also for the increased hardness and cohesion; for
though the particles do not approach or recede, as
in bodies simply elastic, yet their power of attraction
will be increased by their centres being brought nearer,
and by being applied to each other by more ob-
late surfaces. This hypothesis accords with what has
been before proved concerning the unchangeable
density, for what is lost in one dimension is gained in
another; and the cause for there being no increase in
temperature depends probably on the same circum-
stance by which the density is preferred unaltered.”

Thus far the Doctor has proceeded upon a plan,
which may become plausible by means of an hypothe-
sis at least; but in the prosecution of his subject he is
involved in the same difficulty which has proved too
hard for every other person, and which he, indeed,
does not attempt to solve. This is the action of stim-
uli, by which the muscles are exerted to contraction,
and upon which all the phenomena of life depends,
and which indeed is the thing that particularly ought
to be explained; but of this our author is forced to
confess his entire ignorance, and to content himself
with enumerating the stimuli of which he cannot ex-
plain the action. Stimuli then, according to him, are
divided into internal and external. An example of the
former kind is the circulation of the blood, which is
kept up by an exciting influence of the blood upon
the heart and vessels which contain and impel it. The
earliest perceivable instance of muscular motion is the
beating of the heart, as it is seen in the frst
rudiments of the embryo in an egg, and called the pudeum falens.
There seems to be established by nature a certain habi-
tude of action between the vessels and their fluids; for
if a fluid even more mild than the blood, such as milk, be injected into the circulation, it will produce great
disturbance; and if the blood, by being deprived of
the influence of respirable air, becomes destitute of a
certain property which it would naturally acquire in
the act of respiration, it does not prove a stimulus to
the heart.

In like manner, all the containing parts are accom-
modated to the nature of their respective contents.—
The intestines are so calculated as to have proper mo-
tions excited in them by the aliment and the secre-
tions which are mixed with it; and there are bodies
which, though perfectly mild, such as alimentary sub-
stances of difficult digestion, yet excite more violent
commotions in the stomach than other substances which
are very apericinous. The various effects of poisons
in different parts of the body may also be mentioned
as an illustration of the peculiar susceptibility of the
several organs of the body. The poison of a viper, for
instance, is perfectly innocent, not only in the re-
ceptacles of the animal which produces it, but may be
taken into the stomach of any animal without the least
bad effect, and only exerts its deleterious power when
brought in contact with a wounded part. Some ve-
getable poisons, on the contrary, such as that of lau-
vel water, prove deadly when taken into the mouth, or
applied to any part of the alimentary canal, but are
innocent when injected into the veins. It may be re-
marked also, that the receptacles of the several se-
crated fluids, such as the gall-bladder and bladder of
urine, are so adapted to their natural contents, by a
due measure of irritability, as to bear their accumu-
lation to a certain degree, and then to expel them.
We have here also a proof that irritability is not in pro-
portion to senibility; for both these receptacles are
extremely sensitive to pain and irritation from extra-
aneous acrmony, though so moderately sensitive to the
acrimony of their natural contents. This disposition
in the several organs to perform their natural functions,
in consequence of the stimulus of the respective fluids
they contain, has aply enough been called the natural
perception of these organs.

Our author now considering that the internal or-
gans are calculated to perform their functions in conseque-
ence of certain stimuli, concludes the application of che-
ical and mechanical stimuli is not a mode of expe-
iment likely to produce useful knowledge; and hence,
he thinks, we may fuggelt the most likely means of
reftoring lost irritability and action to the vital func-
tions, when suspended by suffocation, strangulation,
or immersion. In these cases, he says, that all other
means are far inferior to that of inhaling the lungs
with
muscles with atmospheric air, and stroking and pressing the ribs in such a manner as to imitate natural respiration. The only other thing which he supposes to be any way useful, is the application of heat to such as have been immersed in cold water; but of cool air to those who have suffered from mephitic vapours.

The Doctor having thus considered some other points of the animal economy, enters into an investigation of the analogy between motion and sensation. This analogy (says he) is the more exact, that the nerves seem to be the instruments of both; for not only the organs of sensation and voluntary motion, but those of involuntary motion, are supplied with nerves, and dependent upon them; for if the influence of the nerves leading to the heart or intestines be interrupted by cutting, ligation, or paralysis, the function of these parts, is thereby destroyed. Thus, as there is a peculiar sensibility belonging to the several senses, so there is a peculiar irritability belonging to the several organs of motion. The intention of nature, therefore, in distributing nerves to every muscular organ, was probably in order to constitute those peculiar perceptions on which the various vital and natural functions depend. But I give this view only as a conjecture, and though the nervous influence may thus modify irritability, there is reason to think that it does not flow it.

Our author controverts the principle which has been held by some very able physiologists, that all muscular irritability depends upon a sentient principle. There have been several influences (says he) in support of this opinion is, the existence of animals without brain or nerves. That there are such, was, I believe, first observed by Haller, and has been confirmed by Mr. Hunter, who maintains farther, that the stomach is a centre or seat of life more essential to it than the brain. That the stomach should be an organ of so much consequence, from natural enough from the importance of its function, which is that of assimilation; and life can be more immediately and completely extinguished by an injury to it, such as a blow, than by the flame violence to any other part of the body. It is also well known, that the muscular fibres of animals endowed with a nervous system, will retain their irritability for some time after their separation from the brain and nerves. It is evident likewise, from the phenomena of vegetation, that irritability may exist in nature without sensation, consciousness, or any fulpicion of the existence of a nervous system. In favour of this opinion, it is farther observable, that those animals which are defective of brain and nerves are of the class of nematous, the most simple in nature, having only one function, viz. that of assimilation; and therefore not requiring that variety of action, and those perceptions which are peculiar to more complex animals. Lastly, the state of an egg before incubation, and the condition of those animals which become torpid from cold, and afterwards revive, affords facts which favour this opinion; as they show that there is a certain principle of self-preservation, independent not only of the operation of the nervous system, but even of the circulation; for in this quiescent state, those portions of animal matter are preferred for a great length of time from that corruption to which they would otherwise be liable, and their fluids are prevented from freezing in a degree of cold which would congeal them, were they deficient of every principle of life.

In the course of his reasoning, our author considers the nervous system not only as a mere appendage to life, but as tending to impede its operation, and shorten its existence. "Simple life (adds he) will not only survive sensation, but will survive it longer, if the animal is killed by destroying the nervous system, than if it had been destroyed by hemorrhagy, suffocation, or other violence. If a fish, immediately upon being taken out of the water, is stunned by a violent blow on the head, or by having the head crushed, the irritability and sweetness of the muscles will be preserved much longer then if it had been allowed to die with the organs of sense entire. This is so well known to fishermen, that they put it in practice in order to make them longer susceptible of the operation called crimping. A salmon is one of the fishes least tenacious of life, inasmuch that it will lose all signs of life in less than half an hour after it is taken out of the water, if suffered to die without any farther injury; but if immediately after being caught, it receives a violent blow on the head, the muscles will show visible irritability for more than 12 hours afterwards."

To the same purpose, our author observes, that in warm-blooded animals an excessive exertion of voluntary motion immediately before death, prevents the muscles from being rigid when cold, and renders them more prone to putrefaction. Thus, if an ox is killed immediately after being overdrove, the carcass will not become stiff when it grows cold, nor is it capable of being preserved by means of salt. In confirmation of the same hypothesis also, our author observes, that in some disorders of the brain, such as hydrocephalus, and apoplectic palsy, in which the functions of the brain are suspended, the office of digestion is sometimes better performed than in health.

From all this our author concludes, along with Mr. Hunter, that the exercise of sensation is inimical to life, and that a sort of fatigue is induced by this as well as by voluntary motion; so that all that intercourse carried on through the nerves, whether towards the brain in the case of sensation, or from the brain in acts of volition, tends to wear out the animal powers. And, as intense and long continued thought, thought not terminating in any outward action, tends also to produce an inability for farther exertions, it would appear that the brain or fenestrum is more particularly the organ which is subject to that species of sufferance called fatigue. From these facts we perceive the necessity of sleep, which consists in a temporary suspension of sensation, volition, and thought, and is a resource of nature, whereby the powers of life recover themselves after satiety and fatigue, which are provided as guards to warn us when nature is in danger of being strained, either by repose or over-exertion; and it is evident that such barriers were absolutely necessary, in order to set bounds to operations which are only occasionally requisite, and which would otherwise depend on the caprice of the will. The exercise of sensation and voluntary motion in a moderate degree is conformable to the intention of nature, and therefore salutary; and it is only when they are excessive
efficaciously that they tend to wear out the powers of life, and more especially if there are not duly recruited by sleep. It follows, from the same principle, that when life is threatened by certain diseases, of which the chief symptom is irritation, any means by which sensation, whether natural or morbid, and muscular motion, whether voluntary, or involuntary, convulsive or spasmodic, can be foothered or suspended, will prove salutary, by allowing the powers of life to rally as it were, and to recover themselves. In this consists the operation of narcotic medicines, such as opium; which, in complaints both of a general and local nature, proves useful, not merely as a palliative by the time being then in the case of the removal of temporary pain or spasm, or by procuring sleep, but as a principal instrument of recovery, by allowing the powers of life to exert their natural action, in consequence of the removal of irritation."

In treating this subject, the Doctor considers the effects of opium as affecting simple or sensitive life; and to determine this, he made the following experiments: Having made a solution of opium in water he put into one portion of it some found living eels, and other portion he treated bruised; and in a number of trials it was found that the found eels generally died much sooner than the bruised ones. This, however was the case only when the solution was of a certain degree of strength, such as half a grain of opium at least to an ounce of water; for when only about half this strength, the found eels lived much longer, the time being then protracted to that in which the bruised eels would have died merely in consequence of their injury; but it must be observed, that even the wounded eels died considerably sooner than when put into plain water.

From all this, our author concludes, that "the great muscles of muscle in the trunk and extremities of the body are the instruments of the mind in acting upon external bodies; and we may therefore rank in the list of stimuli the nervous power by which the will and the passions excite external motions. This is a function sufficiently important for the nerves, without admitting as the principle on which irritability depends."

Having disclaimed all inquiry into the connection between muscular motion and volition, the Doctor proceeds to consider the effects of the different passions upon the muscles. Though these are distinct from the motions directly produced by the will, yet he considers them among those arising from consciousness; "for there are emotions of the mind which have visible and powerful effects upon the heart and vasaular system, which are organs entirely out of the reach of the will. Not to mention the well-known effects of grief, fear, and joy, which affect the whole circulation, there are certain passions and sentiments which produce partial and local effects. These are established by nature, either to answer some important purpose in nature, as in the case of the conjuction of the fluids in the parts of generation in consequence of the venereal appetite, to serve as natural expressions, as in the case of blushing or weeping. One of the most striking effects of the passions upon muscular action, is the influence they have upon the strength or mechanical force of the voluntary muscles. Fear produces debility almost amounting to palsy. Courage and ardour of mind, on the contrary, add to the natural strength. When the mind is agitated by some interesting object, and calls upon the body for an extraordinary exertion to effect its end, the muscles are thereby enabled, as it were by magic, to perform acts of strength of which they would be entirely incapable in cold-blood. In circumstances of danger, for instance, where life or honour are at stake, exertions are made for overcoming mechanical resistance which seem incredible, and would be impossible, were not the mind in a fort of frenzy; and it is truly admirable in the economy of nature, that an idea in the mind should thus in a moment augment the powers of motion and inspire additional resources of strength adequate to the occasional calls of life. The great increase of strength in maniacs is also referable to the passions of the mind. These considerations would almost lead us to doubt whether or not the accounts we have of the great feats of strength ascribed to individuals in the heroic ages be fabulous or not. It is also worthy of remark, that, in great and lafting exertions of strength to which men are impelled by active and generous affections, fatigue is not induced in the same proportion by the same degrees as by the same quantity of muscular action in the cool and deliberate actions of common life."

Having thus discussed the subject of internal stimuli, our author next proceeds to take notice of the second class, viz. such as are external. These are either immediate or remote, viz. such as are excited by mechanical means, or by acronymly directly and artificially applied to a muscular fibre; or such as occur in the instances of sympathy, and in the case of those instincts which have instituted for the purpose of self-preservation in brutes, and in the early part of human life. "There are certain habits (says he) between outward stimuli and the moving powers whereby natural propensities are constituted equally necessary to the support of life as the internal functions. Thus, in new born animal, the first contact of the external air excites the act of respiration, and the contact of the nipple excites the act of sucking; both of which actions are absolutely necessary to the maintenance of life, and require the nice co-operation of a great number of muscles prior to all experience. Actions of this kind are called instinctive; but though different from those of voluntary motion, they nevertheless run into one another; so that what was at first merely instinctive, may afterwards become a matter of deliberate choice. The same muscles are the instruments of both; and they differ from the muscles obeying the internal stimuli, such as the heart, as being liable to fatigue, and thereby concurring with the exercise of sensation and of thought, in rendering sleep necessary. There are no muscles except those of respiration, of which the constant action is necessary to life, and which are void of consciousness in their ordinary exercise, but which are yet in some measure under the control of the will. The principal and answered by this power of the will over the muscles of respiration in man, is to form and regulate the voice. But though instinctive motions are in some cases convertible into those which are voluntary, they ought by no means to be confounded together; for even those animals which are destitute of brain and nerves, are capable of actions evidently of the instinctive kind."
Besides these observations on the inferior animals, our author brings some experiments to shew, that instinctive actions, even in animals furnished with a brain and nerves, do not depend on sensibility. Having divided the spinal marrow of a live kitten a few days old, he irritated the hind-paws by touching them with a hot wire. By this the muscles of the posterior extremities were thrown into contractions, so as to produce the motion of shrinking from the injury; and the same effects were observed in another kitten of which the head was entirely separated from the body. In repeating this experiment he found, that when the spinal marrow was cut through between the lumbar vertebrae and os ilium, the posterior extremities lost their irritability, but the tail returned it. Even the head retained its irritability after it was cut off; as appeared by touching the ears with a hot wire, or by prickling them: “and (says our author) as the extremities are also irritable, it will not be said that consciousness and sensation exist in two separated portions of the body.”

The effects of habit are then considered; and the conclusion from the doctor’s reasoning upon this subject is, that “there is a co-ordination, or pre-establish ed harmony, as it were, between the faculties of animals and the laws of external matter, which is the foundation of all the instinctive habits of animals, as well as the rational conduct of man.”

To the law of habit have been referred the effects of certain contagions, such as that of the small-pox, which do not produce their effect more than once in life. With respect to this he observes, “that upon whatever principle this property of the animal economy depends, it is an undoubted fact, that these morbid poisons, after exciting a certain degree of disturbance, and a certain series of diseased actions, no longer make any impression on the powers of life, otherwise there could be no such thing as recovery; for at the time in which a person begins to recover from the small-pox, the poison actually present in the circulating fluid is multiplied infinitely beyond what it was when it excited the disease. The constitution has therefore at that time, with respect to this acrimony, acquired an insensibility, or rather want of irritability; and this it preserves ever afterwards. This, however, holds only with regard to those morbid poisons which excite febrile affections, and seems to be a necessary provision of nature to guard against such noxious principles as are generated within the body itself.”

Having lastly considered the effects of irritation upon the human body, the Doctor goes on to consider a very remarkable property of living muscles, viz. that of their being in a constant state of tension, more or less, independent of any temporary stimulus. This is evident from what happens when any muscle is cut; for then there is an immediate retardation of the separated parts; and that this is their natural state is farther proved by the spontaneous motion which takes place in consequence of the relaxation of an antagonist muscle, as when the mouth is drawn to one side in consequence of hemiplegia. Some degree of tension indeed is necessary for the performance of the natural motions of the muscles, whether voluntary or involuntary; and the vigour with which the several actions are performed depends on the due degree of this tone.

This tone of muscles is every where maintained by a certain counteracting mechanical power; the great muscles are kept on the stretch by the bones, the heart and vessels by the mass of fluids, and the intestines by the aliment taken in, and their other contents. Difficulties of various kinds may arise from the different degrees of this tension, and the vacuular system is more apt to be affected by different degrees of tension than any other part of the body; and our author considers what is called a nervous habit as one of the effects of want of tension. He likewise attributes to the different degrees of tension, more than to any thing else, the great difference of constitutions observable among mankind. He observes also that the tension of the muscles is greatly affected by sympathy. “This, says he) is particularly observed in the blood-veins and intestines; for a relaxation in those will produce a like affection in every other part of the animal system. With regard to the intestines, it may be mentioned among other proofs, that it is common for persons in a state of great weakness to be affected by syncope, and even instantaneous death in the act of evacuating the bowels. It seems to be from a like cause that a temporary lowness is produced by an abscess being opened.

The Doctor concludes his subject with considering the muscles as mechanical powers. “As they constitute the strength of animals, it may be proper to consider the relation of their strength to their bulk, and the relation of the bulk and strength of the body to the density and cohesion of its own materials; and to the bulk, density, and cohesion of the external inanimate bodies with which it is conterminous.”

“According to the observations of Galileo, that in familiar unequal bodies, of a cylindrical or prismatic shape, such as the limbs of animals nearly are, the ratio of their efforts to break by their own weight is in the quadruplicate ratio of their lengths; but that the resistance they make to the same force is only in the triple ratio of their lengths. It follows from this, that in order to endow the limbs of animals with the same relative force, it is not only necessary that the bones should possess an increased proportion of thickness, in order to give an adequate increase of what may be called the dead strength; but a similar increase of living strength is necessary, by a suitable addition of muscular power, in order to keep pace with the increased size of the bones. Now we observe, in fact, that in the large-sized animals, such as the bull and the elephant, the thickness of their bones and muscles becomes greater in proportion to the length of their limbs than in the smaller animals, and they are therefore of a less elegant form. But nature has not carried this so far as to compensate for the disadvantage arising from the increase of size; for the greater animals have not the same proportional strength, in relation to their bulk, that the smaller animals have. It has been computed that a flea can draw from 70
to 80 times its own weight, whereas a horse cannot
with ease draw more than three times his own weight.
This disproportion between size and strength is very
obvious in different individuals of the human species;
and great men are not muscular, even in the simple
proportion of their stature."

Our author now proceeds to assign some reasons why
the stature of mankind in general is not larger than we
see it. Some observations upon this subject are made
under the article Giant, where it is attempted to show,
that by increasing the proportional strength of the
materials, the size of the human body might have
been augmented in any proportion. To this, however,
the Doctor replies, that "had the bones been
harder, they would not have been calculated for the
common duration of life, the effect of which being to
increase their hardneß and dryness, they must be
endowed originally with a certain degree of softness
and succulence; and, with regard to muscles, a degree of
hardness much greater than they possess would have been
incompatible with their contractility." But the reason
that does not seem to be conclusive. The bones of
a lion are said to be much harder than those of any
other animal; yet we do not find that these creatures
are liable to any kind of disease in consequence of this
superior hardneß. Neither is any inconvenient degree
of hardneß in the muscles a necessary consequence of
their increased strength; for silk, though equally soft
and flexible, may much more so than hemp or flax, is
nevertheless much stronger; and we cannot by any
means doubt, that if men had formerly been of a larger
stature than they are at present, the materials of
their bones and muscles might have been proportiona-
ably stronger, without the least injury or impediment to
any of the operations of life.

When we consider the manner in which the muscles
act upon the bones into which they are inserted, we
may be apt to think that nature has been very prodi-
gal of mechanical power; for considering the bones
as levers, the muscles act upon them at a very great
disadvantage, being always inserted much nearer
the fulcrum than the weight to be raised. Thus the two
muscles of the arm, named biceps and brachialis internus,
in order to support in the hand a weight of one pound
with the forearm at right angles to the humerus, must
exert a power equal to ten pounds. Another circum-
cance also which tends to waste the power is, the ob-
liquity with which they are inserted into their bones;
so that the greater part of the force is expended in
pressing one bone against another at the articulation,
and only a small part of it in making the flexures
and extensions. These disadvantages, however, are
compensated by a number of conveniences which could
not have been obtained on any other plan. We must
think, that the musculous fibres of the arm are so con-
structed that they are inserted at an angle to the long
axis of the bone, so that, making the momentum of
this last depend on velocity, it is evident that there must
be a great advantage from the insertion of the tendons
in the centre of rotation, as greater velocity with less
expense of contraction will thus be communicated to the extremity. The
muscles, for instance, which are attached to the olecu-
navus, in performing those actions with the hand which
require rubbing, act with a disadvantage exactly pro-
portional to the inequality of the distance from their
insertion to the joint of the elbow, and that from the
same joint to the hand. This is an act of pleasure.
But in the case of percussion, as in the action of using
a hammer, there is an evident advantage resulting from
the velocity communicated to the extremity; for in
order to have produced the same velocity, with the in-
sertion at a greater distance from the centre of motion,
a much greater degree of contraction would have been
necessary; and our author shows that fatigue principally
depends on a contraction of the muscles. "If any
one (says he) will take the trouble of comparing
the fatigue of the biceps muscle, in bearing a weight in
the hand with the elbow-joint bent to a right angle
with that of bearing the same weight for the same
length of time with the joint at an acute angle, he
will be sensible how much the degree of fatigue de-
pends on the extent of contraction; and, by attend-
ing to the relative situation of muscular fibres, it will
appear, that Nature, in distributing the fibres of
muscles obliquely, has had it in view not only to in-
crease their number, but to save contraction."

In considering the actions of the various muscles in
producing the different actions of the body, we find
several one produced that can be called direct. In
some instances, we find two muscles, or two sets of
muscles, co-operating, so that the motion effected by
them shall be in the diagonal of their direction. This
is the case of the oblique muscles of the abdomen in
some of their actions, and of the intercostal muscles in
all theirs. Sometimes different portions of the fame
muscles combine in like manner to produce a similar
effect; and in all the long muscles, however simple
their origin and insertion may be, there is an internal
obliquity of their fibres with regard to one another;
for these do not run from end to end, but there are
parts of the tendon running into the belly of the
muscle, so as to divide it into penniform and rhomboidal
portions. This distribution of the fibres takes off
from the length; but as it takes place in those cases
where the origin and insertion are at a considerable
distance, this can be afforded: and this, as well as the
waste of power, in consequence of oblique action, is
more than compensated by the increased strength from
the fibres being multiplied; for, in consequence of
this structure, there is an extent of tendon afforded
sufficient for the insertion of a greater number of fleth
fibres.

The Doctor illustrates this principle in the mecha-
nism of muscular action from the example of fish;
a species of animals which exert greater muscular
powers than any others. "The muscles of most fish
(says he) consist of regular series of oblique short
fibres, forming those frata which every one must have
observed in their muscular substance. Their motions
are more simple and limited than those of land-animals,
but much more vigorous; for a fish in the sea has to
make its way through a medium about 1000 times
more dense than air, and with more rapidity than
those which inhabit the land. Nature, therefore, in
stead of giving them muscles whose fibres would run
straight from one end of their body to the other, has
multiplied their numbers, by distributing them into
short and oblique portions. I have seen the sword of
a swordfish striking in a plank, which it had
penetrated from side to side: and when it is considered
that
that the animal was then moving through so dense a medium, and in the same direction with the ship, we must form a high conception of its muscular power.

Lastly, our author gives a mathematical demonstration, that by the obliquity of the muscles a very considerable quantity of contraction is saved, and consequently a proportional degree of fatigue prevented.—

"Let the line AB (says he) in the annexed diagram, represent a moveable bone, and the line CD a fixed bone parallel to it. Let FE, perpendicular to these lines, represent a muscle acting in its own direction, and the lines GE, HE, represent two muscles acting obliquely, and producing by a diagonal action the same effect as the other. If the bone AB be brought to the situation a b by the action of the muscle FE, the muscle will then be in the situation FK. If the bone is brought in the same situation by the action of the muscles GE, HE, these muscles will then be in the situation GK, HK.

"The proposition to be demonstrated is, that the line GK bears a greater proportion to the line GE, than the line FK does to line FE; for FK is to GE as GL is to GE (Eucl. Elem. B. vi. Prop. 2.) and the angle ELK being less than a right angle, the angle GLK, which is adjacent to it, must be greater than a right angle; and the angle GKL being in the same triangle with GLK, must be less than a right angle. The line GK, therefore, which subduals the greater angle, is greater than the line GL, subtending the lesser, and therefore bears a greater proportion to GE. But the line GL is to GE as FK is to FE; and therefore GK bears a greater proportion to GE than FK does to FE; that is, the fibres of the muscles acting obliquely, suffer a less proportional decrature than those of the muscle acting directly.

"It is farther obvious, that the more oblique the action becomes, the greater saving there will be of contraction; for in moving the line a b towards CD, the line FK diminishes in a swifter ratio than the line GK; and when the former has vanished, the latter is in the situation GF."

Besides these advantages in point of diminishing fatigue, there are others relating to the shape of the members. Thus, if the insertions of the muscles had been at a great distance from the joints, they must upon every occasion have paffed like bow-strings from one bone to the other, and the limbs must have been exceedingly clumsy and unwieldy; all the motions must also have been extremely slow: and notwithstanding the superior strength which people would then have enjoyed, it is very plain that they would scarce have been fit for any of the offices of life which they now perform.

MUSCLE, in zoology. See Myotus.
MUSCOVY. See Russia.
Muscovy-Glass, or Glimmer. See Mica.
MUSCULUS, a military machine, made use of by the Romans to cover and protect the soldiers while they approached and undermined the walls of besieged places, or filled the ditches. It seems to have resembled the teitudo in form, but was smaller in size. See Testudo.

MUSEA, were Grecian festivals in honour of the Muses, celebrated with games every fifth year, particularly by the Thesprians. The Macedonians also observed a festival of the same name in honour of Jupiter and the Muses, which lasted for nine days, and was celebrated with stage plays, songs, and poetical compositions.

MUSES, certain fabulous deities among the Pagan, supposed to preside over the arts and sciences; for this reason it is usual for the poets, at the beginning of a poem, to invoke these goddesses to their aid.

The Muses were originally only singers and musicians in the service of Orpheus, or the great Egyptian Bacchus, under the instruction and guidance of his son Orus; but in succeeding times they were called the daughters of Jupiter and Mnemosyne or Memory.

These are the only pagan divinities whose worship has been continued through all succeeding changes in the religion and sentiments of mankind. Protectors of every liberal art in all the countries of Europe still revere them; particularly the poets, who seldom undertake the slightest work without invoking their aid.

Sir Isaac Newton tells us, that the singing women of Oliris were celebrated in Thrace by the name of the Muses; and that the daughters of Pierus, a Thracian, imitating them, were celebrated by the same name.

Diodorus Siculus informs us, that Alcman of Melfene, a lyric poet who flourished in the 27th Olympiad, 670 years B.C. makes them the daughters of Uranus and Terra. It has been asserted by some ancient writers, that at first they were only three in number, but Homer, Hesiod, and other profound mythologists, admit of nine (a).

In his hymn to Apollo, Homer says,

—By turns the nine delight to sing.
And Hesiod, in his theogony, names them all.—
They are said severally to preside over some art or science, as music, poetry, dancing, astronomy. By some they are called virgins, because the virtues of education appear unalterable; they are called musae from a Greek word which signifies to explain mysteries, because they have taught things the most curious 

(a) It has been said, that when the citizens of Sicyn directed three skillful flatuaries to make each of them statues of the three Muses, they were all so well executed, that they did not know which to choose, but erected all the nine, and that Hesiod and Homer only gave them names.
and important to know, and which are above the comprehension of vulgar minds. Each of their names is said to include some particular allegory; Cloe, for instance, has been thus called, because those who are praised in verse acquire immortal fame; Euterpe, on account of the pleasure accruing to those who hear learned poetry; Thalia implies for ever flourishing; Melpomene, that her melody infinuates itself into the immortal recettes of the soul; Terpsichore marks the pleasure which those receive who are versed in the liberal arts; Erato seems to indicate, that the learned command the elate and friendship of all mankind; Polyhymnia, that many poets are become immortal by the number of hymns which they have addressed to the gods; Urania, that those whom the intrusts elevate their contemplations and celebrity to the heavens and the stars; and lastly, the exquisite voice of Calliope has acquired her that appellation, as the inventress and guardian of eloquence and rhetoric.

An epigram of Callimachus gives the attributes of the muses in as many lines.

Calliope the deeds of heroes sings;
Great Cloe sweeps to history the strings;
Euterpe teaches mimes their silent flow;
Melpomene prefides o'er scenes of woe;
Terpsichore the flute's soft pow'r displays;
And Erato gives hymns to the gods to praise;
Polyhymnia's skill inspires melodious strains;
Urania, the harry course explains;
And gay Thalia's glas points out where folly reigns.

This epigram does not however, exactly correspond with the ideas of other poets, or of the ancient painters, in characterizing the attributes of the muses. The ancients had numberless ingenious and fanciful ideas concerning the muses, which we have not room to recite." It seems (says the Abbe Barthelme*) as if the first poets, enchanted with the beauties of nature, occasionally were led to invoke the nymphs of the woods, hills, and fountains; and that yielding to the prevailing taste for allegory, they gave them names relative to the influence they might be supposed to have over the productions of the mind. At first three muses only were admitted, Melete, Mneme, and Aecia: that is to say, the meditation or reflection necessary to study; memory which records illustrious deeds; and song which accompanies their recital. In proportion as improvement was made in the art of verification, its characters and effects were perfonified, the number of the muses increased, and the names they now received referred to the charms of poetry, its celestial origin, the beauty of its language, the pleasure and gaiety it inspires, the song and dance which add to its new charms, and the glory with which it is crowned. Afterwards were associated with them the Graces, whose employment it is to embellish poetry, and Love who is so frequent in its object. These ideas took birth in a barbarous country, in Thrace, where Orphics, Linus, and their disciples, suddenly appeared in the midst of ignorance. The muses were honoured there on the Pierian mount, and extending their dominion, successively to k their illustrious on Pindus, Parnassus, Helicon, and all those solitary places where the painters of nature, surrounded by the most pleasing images, experience the divine glow of inspiration."

Pythagoras, and afterwards Plato, make the muses the soul of the planets in our sytem; from whence the imaginary music of the spheres.

MUSEUM, a name which originally signified a part of the palace of Alexandria, which took up at least one-fourth of the city. This quarter was called the museum, on account of its being set apart for the muses and the study of the sciences. Here were lodged and entertained the men of learning; who were divided into many companies or colleges, according to the sciences of which they were the professors; and to each of these houses or colleges was allotted a handsome revenue. The foundation of this establishment is attributed to Ptolemy Philadelpbus, who here placed his library. Hence the word museum is now applied to any place set apart as a repository for things that have an immediate relation to the arts.

The museum at Oxford, called the Ashmolean museum, is a noble pile of building, created at the expense of the university, at the west end of the theatre, at which tide it has a magnificent portal, sustained by pillars of the Corinthian order. The front, which is to the street, extends about 60 feet, where there is inscribed over the entrance in gilt characters, Museum Ashmoleanum, schola naturalis historiae, officina othyica. It was begun in 1679, and finished in 1683, when a valuable collection of curiosities was presented to the university by Elias Ashmole, Esq: which were the same day repofited there; several acquisitions have been since made to the museum; among which are hieroglyphics, and other Egyptian antiquities, an entire mummy, Roman antiquities, altars, medals, lamps, &c. and a variety of natural curiosities.

The British museum in London is a large, beautiful, and magnificent building, the noblest cabinet of curiosities in the world. See the article London, no 155.

MUSGRAVE (Dr William), a learned physician and antiquary, was born at Charlton-Musgrave in Somcrshire, about the year 1657; and studied at New-college, Oxford. Having distinguished himself by his knowledge in his profession, and his skill in natural philosophy, he was elected fellow of the Royal Society; and being made secretary in 1684, he continued the Philosophical Transactions from no 167 to no 178 inclusive. After having taken his degrees in physic, and being admitted a fellow of the college of physicians, he went and settled at Exeter, where he practiced physic with great reputation and success.

Being a man of extensive learning, he composed, at his leisure hours, several curious and valuable works, as, 1. De arborescere anomala seu interna differentia. 2. De arborescere symptomatica differentia. 3. Full. Visulii epistilium, cum commentario. 4. De legiones epilola. 5. De aquila Romanæ epilola. 6. Inscriptio Terrae-venenatis, cum commentario. 7. Geta Britannicus, &c.—8. Belgium Britannicum. This learned physician died in 1721.

MUSHROOM, in botany. See Agaricus and Lycopus.

To try the quality of mushrooms:—Take an onion, and stripe the outer skin, and boil it with your mushrooms: if the onion become blue or black, there are certainly dangerous ones among them; if it remain white, they are good.
THE art of combining sounds in a manner agreeable to the ear. This combination may be either simultaneous or succesive; in the first case, it constitutes harmony; in the last melody. But though the same sounds, or intervals of sound, which give pleasure when heard in succession, will not always produce the same effect in harmony; yet the principles which constitute the simpler and more perfect kinds of harmony, are almost, if not entirely the same with those of melody. By perfect harmony, we do not here mean that plenitude, those complex modifications of harmonic sound, which are admired in practice; but that harmony which results from the coalescence of simultaneous sounds produced by vibrations in the proportions of thirds, sixths, and octaves, or their duplicates.

The principles upon which these various combinations of sound are founded, and by which they are regulated, constitute a science, which is not only extensive but profound; when we would investigate the principles from whence these happy modifications of sound result, and by which they are determined; or when we would explore the sensations, whether mental or corporeal, with which they affect us. The ancient definitions of music are not proportioned in their extent to our present ideas of that art; but M. Roufeau betrays a temerity highly inconsistent with the philosophical character, from whence he infers, that their ideas were vague and undetermined. Every soul susceptible of refinement and delicacy in taste or of which sounds are susceptible: relations which, comprehending all the possible combinations of music and sounds, seem likewise to comprehend all the causes of the impressions which their succession can make upon the ear and upon the soul.

Practical music is the art of applying and reducing to practice those principles which result from the theory of agreeable sounds, whether simultaneous or succesive; or, in other words, to conduct and arrange sounds according to the proportions resulting from them, from duration and succession, in such a manner as to produce upon the ear the effect which the composer intends. This is the art which we call composition. With respect to the actual production of sounds by voices or instruments, which is called execution, this department is merely mechanical and operative; which, only presupposing the powers of sounding the intervals true, of exactly proportioning their degrees of duration, of elevating or depressing sounds according to those gradations which are prescribed by the voice, and to the value required by the time, demands no other knowledge but a familiar acquaintance with the characters used in music, and a habit of expressing them with promptitude and facility.

Speculative music is likewise divided into two departments; viz. the knowledge of the proportions of sounds or their intervals, and that of their relative durations; that is to say, of measure and of time.

The first is what among the ancients seem to have been called harmonical music. It flows in what the nature of air or melody consists; and discovers what is consonant or discordant, agreeable or disagreeable, in the modulation. It discovers, in a word, the effects which sounds produce on the ear by their nature, by their force, and by their intervals; which is equally applicable to their consonance and their succession.

The second has been called rhythmic, because it treats of sounds with regard to their time and quantity. It contains the explication of their continuance, of their proportions, of their measures whether long or short.
short, quick or slow, of the different modes of time and
the parts into which they are divided, that to these
the succession of sounds may be configured.

Practical music is likewise divided into two depart-
ments, which correspond to the two proceeding.
That which answers to harmonical music, and which
the ancients called melopée, teaches the rules for com-
bining and varying the intervals, whether consonant or
dissonant, in an agreeable and harmonious manner.
The second, which answers to the rhythmical music,
and which they called rythmogetes, contains the rules
for applying the different modes of time, for under-
standing the feet by which verses or phrases were scanned,
and the diversities of measure; in a word, for the practice of
the rhythmus.

Music is at present divided more simply into melody
and harmony; for since the introduction of harmony the
proportion between the length and shortness of sounds,
or even between that of returning cadences, are of less consequence amongst us. For it often
happens in modern languages, that the very affumee their measure from the musical air and almost
together lose the small share of proportion and quantity
which in themselves they possess. By melody the successions of sound are regulated in
such a manner as to produce pleasing airs. See Melo-
dy.

Harmony consists in uniting to each of the sounds,
in a regular succession, two or more different sounds,
which simultaneously striking the ear sound by their
concurrency. See Harmony.

Music, according to Rousseau, may be, and perhaps
likewise ought to be, divided into the physical and the
initiative. The first is limited to the mere mechanism of
sounds, and reaches no farther than the external senses.
without carrying its impression to the heart, and can
produce nothing but corporeal sensations more or less
agreeable. Such is the music of songs, of hymns, of
all the airs which only consist in combinations of mel-
lodious sounds, and in general all music which is
merely harmonious.

It may, however be questioned, whether every sound,
even to the most simple, is not either by nature or by
early and confirmed association, initiative. If we may
trust our own feelings, there is no such thing in nature as
music which gives mechanical pleasure alone. For
if it, must give such pleasure as we receive from
tastes, from odours, or from other grateful titillations;
but we absolutely deny that there are any musical sen-
sations or pleasures in the smallest degree analogous to
these. Let any piece of music be resolved into its ele-
mental parts and their proportions, it will then easily
appear from this analysis that sense is no more than
the vehicle of such perceptions, and that mind alone
can be susceptible of them. It may indeed happen
from the number of the performers and the complica-
tion of the harmony, that meaning and sentiment may be
lost in the multiplicity of sounds; but this, though
it may be harmony, loses the name of music.

The second department of this division, by lively and
accentuated inlections, and by sounds which may be
said to speak, expresses all the passions, paints every
possible picture, reflects every object, subjects the
whole of nature to its skilful imitations, and impres-
ses even on the heart and soul of man sentiments
proper to affect them in the most sensible manner.
This continues he, which is the genuine lyric and
theatrical music, was what gave double charms and
energy to ancient poetry; this is what, in our days,
we exert ourselves in applying to the drama, and what
our fingers execute on the stage. It is in this music
alone, and not in harmonics or the refection of na-
ture, that we must expect to find accounts of those
prodigious effects which it formerly produced.

But, with M. Rousseau's permission, all music which
is not in some degree characterized by these pathetic
and imitative powers, deserves no better name than that
of a musical jargon, and can only be effectuated by such
a complication and intricacy of harmony, as may con-
found, but cannot entertain the audience. This cha-
acter therefore, ought to be added as essential to the
definition of music; and it must be attributed to our
neglect of this alone, whilst our whole attention is be-
lowed on harmony and execution, that the best per-
fomances of our artists and composers are heard with
little or indifference and omission, nor even can con-
vince any admirers, but such as are induced, by pedan-
try and affectation, to pretend what they do not feel.
For may the curfe of indifference and want of pur-
pose and bareness the fons of every composer or per-
former, who pretends to regale our ears with this mu-
cical legedemain, till the grin of scorn, or the hiss of
infamy, teach them to correct this depravity of taste,
and entertain us with the voice of nature!

Whilst moral effects are fought in the natural effects
of sound alone, the scrutiny will be vain, and disputes
will be maintained without being understood; but founds, as representatives of objects, whether by nature
or association, introduce new scenes to the fancy and
new feelings to the heart; not from their mechanical
powers, but from the connection established by the au-
thor of our frame between sounds and the objects
which either by natural resemblance or unavoidable
association they are made to represent.

It would seem that music was one of those arts
which were first discovered, and that the vocal was prior
to instrumental music, if in the earliest ages there
was any music which could be said to be purely intru-
mental. For it is more than probable, that music was
originally formed to be the vehicle of poetry; and of
consequence, though the voice might be supported and
accompanied by instruments, yet music was never in-
tended for instruments alone.

We are told by ancient authors, that all the laws,
whether human or divine, exhortations to virtue, the
knowledge of the characters and actions of gods and
heroes, the lives and achievements of illustrious men
were written in verse, and sung publicly by a quire to
the sound of instruments; and it appears from the
Scriptures, that such from the earliest times was the
custom among the Israelites. Nor was it possible to
find means more efficacious for impressing on the mind
of man the principles of morals, and inspiring the
love of virtue. Perhaps, however, this was not the
result of a premeditated plan; but inspired by sublime
sentiments and elevation of thought, which in accents
that were suited and proportioned to their celestial
nature endeavored to find a language worthy of themselves and expressive of their grandeur.

It merits attention, that the ancients were duly sen-
fible
Music.

Of the value and importance of this divine art, not only as a symbol of that universal order and symmetry which prevails through the whole frame of material and intelligent nature, but as productive of the most momentous effects both in moral and political life. Plato and Aristotle, who disagreed almost in every other maxim of politics, are unanimous in their approbation of music, as an efficacious instrument in the formation of the public character and in conducting the state; and it was the general opinion, that whilst the gymnastic exercises rendered the constitution robust and hardy, music humanized the character, and softened those habits of roughness and ferocity by which men might otherwise have degenerated into savages. The gradations by which voices were exerted and tuned, by which the invention of one instrument succeeded to another, or by which the principles of music were collected and methodized in such a manner as to give it the form of an art and the dignity of a science, are topics so fruitful of conjecture and so void of certainty, that we must leave them to employ minds more speculative and invention more prolific than ours, or transfer them to the History of Music as a more proper place for such dilusions. For the amelioration of the curious, Routian in his Musical Dictionary, Plates C and N, has transferred some fragments of Greek, Persian, American, Chinese, and Swiss music, with which performers may entertain themselves at leisure. When they have tried the pieces, it is imagined they will be less fancifully fond than that author of ascribing the power of music to its affinity with the national accents where it is composed. This may doubtless have its influence; but there are other causes more permanent and less arbitrary to which it owes its most powerful and universal charms.

The music now most generally celebrated and practiced is that of the Italians, or their successful imitators. The English, from the invasion of the Saxons, to that more late though lucid era in which they imbibed the art and copied the manner of the Italians, had a music which neither pleased the soul nor charmed the ear. The primitive muse of the French deserves no higher panegyric. Of all the barbarous nations, the Scots and Irish seem to have possesed the most affecting original music. The first consists of a melody characterized by tenderness: It melts the soul to a pleasing pensive languor. The other is the native expression of grief and melancholy. Tartini informs us, that in his time a prince from Scotland had imported into Italy a lamentable kind of music from his own country; and that he himself had composed pieces in the same spirit. From this expressive though laconic description, we learn, that the character of our natural music was even then established: yet so gross is our ignorance and credulity, that we ascribe the best and most impassioned airs which are past among us to David Rizzie; as if an Italian Lutanist, who had lived but a time in Scotland, could at once, as it were by inspiration, have imbued a spirit and composed in a manner different from his own. It is yet more surprising that Gemmisati should have entertained and published the same prejudice, upon the miserable authority of popular tradition alone; for the fact is authenticated by no better credentials. The primitive music of the Scots may be divided into the martial, the pastoral, and the idyllic. The first consists either in marches, which were played before the chieftains, in imitation of the battles which they fought, or in lamentations for the catastrophes of war and the extinction of families. These wild effusions of natural melody preserve several of the rules prescribed for composition. The strains, though rude and untutored, are frequently terrible or mournful in a very high degree. The port or march is sometimes in common, sometimes in treble time; regular in its measures, and exact in the distance between its returning cadences; most frequently, though not always, loud and brisk. The pastoral, or imitation of battles, is wild, and abrupt in its transitions from interval to interval and from key to key; various and defultory in its movements: frequent irregular in the return of its cadences; and in short, through the whole, seems inspired with such fury and enthusiasm, that the hearer is irresistibly infected with all the rage of precipitate courage, notwithstanding the rudeness of the accents by which it is kindled. To this the pastoral forms a striking contrast. Its cadences are plaintive, yet soothing; its harmony generally flat; its modulations natural and agreeable; its rhythm simple and regular; its returning cadences at equal distance; its transitions from one conciseful interval to another, at least for the most part; its movements slow, and may be either in common or treble time. It scarcely admits of any other harmony than that of a simple bass. A greater number of parts would cover the air and destroy the melody. To this we shall add what has been said upon the fame subject by Dr Franklin. Writing to Lord K——, he proceeds thus:

"Give me leave, on this occasion, to extend a little the sense of your position, 'That melody and harmony are separately agreeable, and in union delightful;' and to give it as my opinion, that the reason why the Scotch tunes have lived so long, and will probably live for ever (if they escape being filched in modern affected ornament), is merely this, that they are really compositions of melody and harmony united, or rather that their melody is harmony. I mean, the simple tunes sung by a single voice. As this will appear paradoxical, I must explain my meaning. In common acceptation, indeed, only an agreeable succession of sounds is called melody; and only the concurrence of agreeable sounds, harmony. But since the memory is capable of retaining for some moments a perfect idea of the pitch of a past sound, so as to compare it with the pitch of a succeeding sound, and judge truly of their agreement or disagreement, there may and does arise from thence a sense of harmony between the present and past sounds, equally pleasing with that between two present sounds. Now the construction of the old Scotch tunes is this, that almost every succeeding emphatic note is a third, a fifth, an octave, or in short some note that is in concord with the preceding note. Thrice are chiefly used, which are very pleasing concords. I use the word emphatic, to distinguish those notes which have a freis laid on them in singing the tune, from the lighter connecting notes that serve merely, like grammar articles in common speech, to tack the whole together."

That we have a most perfect idea of a sound just past, I might appeal to all acquainted with music,
MUSIC is capable of a variety so infinite, so greatly does the most simple differ from the most complex, and so multiplied are the degrees between these two extremes, that in no age could the incidents respecting that fascinating art have been few or uninteresting. But, that accounts of these incidents should have been handed down to us, scanty and imperfect, is no matter of surprise; when we recollect that the history of music is the history only of sounds, of which writing is a very inadequate medium; and that men would long employ themselves in the pleasing exercise of cultivating music before they possessed either the ability or the inclination to record their exertions.

No accurate traces, therefore, of the actual state of music in the earlier ages of the world, can be discerned. Our ideas on the subject have no foundation firmer than conjecture and analogy. It is probable, that among all barbarous nations some degree of similarity is discernible in the style of
History.

Musical instruments, Neithor will much difference appear during the first dawnings of civilization. But in the more advanced periods of society, when the powers of the human mind are permitted without obstacle to exert their native activity and tendency to invention, and are at the same time affected by the infinite variety of circumstances and situations which before had no existence, and which in one case accelerate, and in another retard; then that similarity, once so distinguishable, gives place to the endless diversity of which the subject is capable.

The practice of music being universal in all ages and all nations, it would be absurd to attribute the intelligence and the favourite residence of genius to any one man. It must have suffered a regular progression, through infancy, childhood, and youth, before it could arrive at maturity. The first attempts must have been rude and artless; perhaps the first flute was a reed of the lake.

No nation has been able to produce proofs of antiquity so indisputable as the Egyptians; it would be vain, therefore, to attempt tracing music higher than the history of Egypt.

By comparing the accounts of Diodorus Siculus and of Plato, there is reason to suppose, that in very ancient times the study of music in Egypt was confined to the priesthood, who used it only on religious and solemn occasions; that, as well as sculpture, it was sanctified by law; that it was esteemed a sacred and forbidden to be employed on light or common occasions; and that innovation in it was prohibited before the siege of Troy. These were by the Pharaohs, the Egyptians fell, divided into two pillars, which during the sacking of the city of Heliopolis, about 400 years before the siege of Troy. These were by the order of Augustus brought to Rome after the conquest of Egypt. One of them called juglia rotta, or the broken pillar, which during theacking of the city in 1527 was thrown down and broken, still lies in the Campus Martius. On it is seen the figure of a musical instrument of two strings, and with a neck. It resembles much the cithar of the kingdom of Naples.

This curious relic of antiquity is mentioned, because it affords better evidence than, on the subject of ancient music, is usually to be met with, that the Egyptians, at so early a period of their history, had advanced to a considerable degree of excellence in the cultivation of the arts. By means of its neck, this instrument was capable, with only two strings, of producing a great number of notes. These two strings, if tuned fourths to each other, would form that series of sounds called by the ancients septachord, which consists of a conjunct tetra chord as B, C, D, E, F, G, A; if tuned fifths, they would produce an octave or two disjunct tetra chords. The cithara is tuned in this last manner. The annals of no nation other than Egypt, for many ages after the period of the obelisk at Heliopolis, exhibit the vogue of any contrivance to shorten strings during performance by a neck or finger-board. Father Montfaucon observes, that after examining 500 ancient lyres, harps, and citharas, he could discover no such thing.

Egypt indeed seems to have been the source of human intelligence, and the favourite residence of genius and invention. From that celebrated country did the Greeks derive their knowledge of the first elements of those arts and sciences in which they afterwards so eminently excelled. From Greece again did the Romans borrow their attainments in the same pursuits. And from the records of these different nations have the moderns been enabled to accomplish an improvement so wonderful in literature.

The Hermes or Mercury of the Egyptians, Sir. The Egyptian named Tefyngtus, or threc illustrious, who was, according to Sir Isaac Newton, the secretary of Otho, is celebrated as the inventor of music. It has already been observed, that no one person ought chiefly to be called the inventor of an art which seems to be natural to, and coeval with, the human species; but the Egyptian Mercury is without doubt intended to be the prototype of having made striking improvements in music, as well as of having advanced in various respects the civilization of the people, who; government was chiefly committed to his charge. The account given by Apollodorus of the manner in which he accidentally invented the lyre, is at once entertaining and probable. "The Nile (says Apollodorus), after having overflowed the whole country of Egypt, when it returned within its natural bounds, left on the shore a great number of dead animals of various kinds, and among the rest a tortoise; the flesh of which being dried and salted by the sun, nothing remained within the shell but nerves and cartilages, and these being braced and contracted by the drying heat became concave. Mercury, walking along the shores of the Nile, happened to strike his foot against this shell; and was so pleased with the sound produced, that the idea of a lyre started into his imagination. He contrived the instrument in the form of a tortoise, and strung it with the dried sinews of dead animals."

How beautiful to conceive the energetic powers of the human mind in the early ages of the world, exploring the yet undiscovered capabilities of nature, and directing to the inexhaustible store by the finger of God, in the form of accident!

The monaulon, or single flute, called by the Egyptians, the single flute of the Egyptians, was probably one of the most ancient instruments used either by them or any other nation. From various remains of ancient sculpture, it appears to have been flaped like a bull's horn, and was at first, it may be supposed, no other than the horn itself. Before the invention of flutes, as no other instrument except those of percussion were known, music must have been little more than metrical. When the art of refining and lengthening sounds was first discovered, the
the power of music over mankind, from the agreeable surpise occasioned by soft and extended notes, was probably irresistible. At a time when all the rest of the world was involved in savage ignorance, the Egyptians were possessed of musical instruments capable of much variety and expression. Of this the astonishment remains of the city Thebes still testifying afford ample evidence. In a letter from Mr Bruce, ingrossed in Dr Buraey's History of Music, there is given a particular description of the Theban harp, an instrument of extensive compass, and exquisite elegance of form. It is accompanied with a drawing taken from the ruins of an ancient sanctuary at Thebes, supposed by Mr Bruce to be that of the father of Seolfris.

On the subject of this harp, Mr Bruce makes the following striking observation. "It overturns all the accounts of the earliest state of ancient music and instruments in Egypt, and is altogether, in its form, ornaments, and compass, an incontrovertible proof, stronger than a thousand Greek quotations, that geometry, drawing, mechanics, and music, were at the greatest perfection when this harp was made; and that what we think in Egypt was the invention of arts was only the beginning of the era of their restoration."

Indeed, when the beauty and powers of this harp, along with the very great antiquity of the painting which represents it, are considered, such an opinion as that which Mr Bruce limits at, does not seem to be devoid of probability. It cannot be doubted that during the reigns of the Ptolemies, who were voluptuous princes, music must have been much cultivated and encouraged. The father of Cleopatra, who was the least of that race of kings, derived his title of auletes, or flute-player, from his excessive attachment to the flute. Like Nero himself used to array himself in the dress of a tibicen, and exhibit his performance in the public musical contests.

Some authors, particularly Am. Marcellinus and M. Pau, refuse to the Egyptians, at any period of their history, any musical genius, or any excellence in the art; but the arguments used to support this opinion seem to be inconclusive, and the evidences of the opposite conclusion appear to be incontrovertible.

The sacred Scriptures afford almost the only materials from which any knowledge of Hebrew music can be drawn. In the rapid sketch, therefore, of an ancient music which we mean to exhibit, a few very few observations are all which can properly be given to that department of our subject.

Moses, who led the Israelites out of Egypt, was educated by Pharaoh's daughter in all the literature and elegant arts cultivated in that country. It is probable, therefore, that the taste and style of Egyptian music would be infused in some degree into that of the Hebrews. Music appears to have been interwoven through the whole tiffue of religious ceremony in Palestine. The priesthood seem to have been musicians hereditarily and by office. The prophets appear to have accompanied their inspired effusions with music; and every prophet, like the present improvisator of Italy, seems to have been accompanied by a musical instrument.

Music, vocal and instrumental, constituted a great part of the funeral ceremonies of the Jews. The pomp and expense used on these occasions advanced by degrees to an excursive extent. The number of flute-players in the processions amounted sometimes to several hundreds, and the attendance of the guests continued frequently for 30 days.

The Hebrew language abounds with confonants, and has few vowels, that in the original alphabet they had no characters. It must, therefore, have been harsh and unfavourable to music. Their instruments of music were chiefly those of percussion; so that both on account of the language and the instruments, the music must have been coarse and noisy. The vast numbers of performers too, whom it was the taste of the Hebrews to collect together, could with such language and such instruments produce nothing but clamour and jargon. According to Josephus, there were 200,000 musicians at the dedication of Solomon's temple. Such are the circumstances from which only an idea of Hebrew music can be formed; for the Jews neither ancient nor modern have ever had any characters peculiar to music; and the melodies used in their religious ceremonies have at all times been entirely traditional.

Cadmus, with the Phoenician colony which he led Grecian into Greece, imported at the same time various arts music. into that country. By the assistance of his Phoenician artificers, that chief discovered gold in Thrace and copper at Thebes. At Thebes that metal is still termed cadium. Of these materials, and of iron, they formed to themselves armour and instruments of war. Thus they struck against each other during their dances at sacrifices, by which they first obtained the idea of music. Such is the account given of the origin of that species of music in Greece produced by instruments of percussion. The invention of wind instruments in Greece is attributed to Minerva; and to the Grecian Mercury is assigned, by the poets and historians of that country, the honour of many discoveries probably due to the Egyptian Hermes, particularly the invention of stringed instruments. The lyre of the Egyptian Mercury had only three strings; that of the Grecian Venus: the last was perhaps no more than an improvement on the other. When the Greeks defied a prince or hero of their own country, they usually adorned him an Egyptian name, and with the name beheaded on their new divinity all the actions, attributes, and rites of the original.

The Grecian lyre, although said to have been invented by Mercury, was cultivated principally by Apollo, who first played upon it with method, and accompanied it with the voice. The celebrated contest between him and Marsyas is mentioned by various authors; in which, by conjoining the voice with his lyre (a combination never before attempted), his music was declared superior to the flute of Marsyas. The progress of the lyre, according to Diodorus Siculus, is the following. "The muses added to the Grecian lyre the string called mode; Linus that of Echoes, and Orpheus and Thamyris those strings which are named hypate and parhypate." It has been already mentioned, that the lyre invented by the Egyptian Mercury had but three strings; by putting these circumstances together, we may perhaps acquire some knowledge of the progress of music, or at least of the extension of its scale in the highest antiquity. Mode, in the Greek music, is the fourth sound of the second tetradchord.
I-lify.

Greece, and of Iceland and Scandinavia. They fung their poems of five sounds. The two tetrachords of the great system of the ancients, the hypate and parhypate, corresponding with our B and C in the base, completed the heptachord or seven sounds b, c, d, e, f, g, a; a compass which received no addition till after the days of Pindar.

It might perhaps be expected, that in a history of Greek music something ought to be said concerning the Muses Apollo, Bacchus, and the other gods and demi-gods, who in the mythology of that country appear to have promoted and improved the art. But such a discussion would be too diftructive, and involve too much foreign matter for the plan we have chosen to adopt. We cannot avoid, however, making a few observations on the poems of Homer, in so far as connected with our subject. It has been imagined, with much appearance of probability, that the occupation of the first poets and musicians of Greece resembled that of the Celtic and German bards and the scalds of Iceland and Scandinavia. They sung their poems in the streets of cities and in the palaces of princes. They were treated with high respect, and regarded as inspired persons. Such was the employment of Homer. His poems, so justly celebrated, exhibit the most authentic picture that can be found in the annals of antiquity, although perhaps somewhat highly coloured, of the times of which he wrote and in which he lived. Music is always named throughout the Iliad and Odyssey with rapture; but as in these poems no mention is made of instrumental music unaccompanied with poetry and singing, a considerable share no doubt of the poet's praise is to be attributed to the poetry. The instruments most frequently named are the lyre, the flute, and the syrinx. The trumpet appears not to have been known at the siege of Troy, although it had come to be in use in the days of Homer himself. From the time of Homer till that of Sappho, there is almost a total blank in literature. Only a few fragments remain of the works of those poets and musicians whose names are preferred as having flourished between those periods (†). During the century which elapsed between the days of Sappho and those of Anacreon, no literary productions are preferred entire.—From Anacreon to Pindar there is another chasm of near a century. Subsequent to this time, the works fill extant of the three great tragic poets, Aeschylus, Sophocles, and Euripides, together with those of Plato, Aristotle, Arifloquenous, Euclid, Theocritus, Callimachus, Polybius, and many others, produced all within a space less than 300 years, distinguish this illustrious and uncommon period as that in which the whole powers of genius seem to have been exerted to illuminate and instruct mankind in future ages. Then it was that eloquence, poetry, music, architecture, history, painting, sculpture, like the spontaneous blossoms of nature, flourished without the appearance of labour or of art.

The poets, as well epic as lyric and elegiac, were all likewise musicians; so closely connected were music and poetry for many ages. It would afford amusement to collect the biographical anecdotes of these favourites of genius, and to assign to each the respective improvements made by him in music and poetry; but our limits do not admit of so extensive a disquisition; for which, therefore, reference must be made to the editors and commentators of these authors, and to the voluminous histories of music lately published.

The invention of notation and musical characters marked a distinguished era in the progress of music. There are a diversity of accounts respecting the period to whom the honour of that invention is due; but the evidences seem to preponderate in favour of Terpander, a celebrated poet and musician, to whose genius music is much indebted. He flourished about the 27th Olympiad, or 671 years before Christ.

Before that valuable discovery, music being entirely traditional, must have depended much on the memory and taste of the performer.

There is an incident mentioned in the accounts handed down to us of the Olympic games, which may serve in some degree to mark the character of music at the time in which it happened. Lucian relates that a young flute-player named Harmonides, at his first public appearance in these games, began a solo with so violent a blast, on purpose to surprise and elevate the audience, that he breathed his last breath into his flute, and died on the spot. When to this anecdote, wonderful to us, and almost incredible, is added the circumstance, that the trumpet-players at these public exhibitions expended an excess of joy when they found their exertions had not rent their cheeks nor burst their blood-vessels, some idea may be formed of the noisy and vociferous style of music which then pleased; and from such facts only can any opinion be obtained of the actual style of ancient music.

In whatever manner the flute was played on, there is no doubt that it was long in Greece an instrument of high favour, and that the flute-players were held in much estimation. The flute used by Iphicrates, a celebrated Theban musician, cadd at Corinth three talents, or L.381. 55. If, says Xenophon, a bad flute-player would pass for a good one, he must, like the great flute-players, expend large sums on rich furniture, and appear in public with a great retinue of attendants.

The ancients, it appears, were not less extravagant in gaiifying the minstrels of their pleasures than our selves. 

†) He anon lived so near to Homer, that it has been disputed which of them is the most ancient. It is now, we believe, universally admitted, that the palm of antiquity is due to Homer; but we consider them as having both flourished in the same era.

History.

selves. Amalbeus, a harper, was paid an Attic talent, or L. 193, 15s. per day for his performance (1).

It is proper to add, that the celebrated musicians of Greece who performed in public were of both sexes; and that the beautiful Lamia, who was taken captive by Demetrius, in the sea engagement in which he vanquished Polemy Soter, and who herself captivated her conqueror, as well as many other elevated female spirits, are recorded by ancient authors in terms of admiration, and of whom, did our limits here admit of biography, we would treat with pleasure. The philosophers of Greece, whose capacious minds grasped every other object of human intelligence, were not inattentive to the theory of music, or the philosophy of sound. This department of science became the source of various fepts, and of much diversity of opinion. The founders of the most distinguished sects were Pythagoras and Arifloctenus. Of their theories, mention is made in the Appendix to this article.

Like every other people, the Romans, from their first origin as a nation, were possessed of a species of music which might be distinguished as their own. It appears to have been rude and coarse, and probably was a variation of the music in use among the Etruscans and other tribes around them in Italy; but as soon as they began to open a communication with Greece, from that country, with their arts and philosophy, they borrowed also their music and musical instruments. No account, therefore, of Roman music is to be expected that would not be a repetition of what has been said on the subject of the music of Greece.

The excessive vanity of Nero with respect to music, displayed in his public contents for superiority with the most celebrated professors of the art in Greece and Rome, is known to every one conversant in the history of Rome. The solicitude with which that detestable tyrant attended to his voice is curious, and will throw some light on the practices of fingers in ancient times. He was in ufe to lie on his back, with a thin plate of lead on his breast; and after his return from Greece established an officer (Phonaecus) to regulate his tones in speaking.

Most nations have conformed in introducing music into their religious ceremonies. That art was early admitted into the rites of the Egyptians and Hebrews; and that it constituted a considerable part of the Grecian and Roman religious service, appears from the writings of many ancient authors. The fame pleasing art soon obtained an introduction into the Christian church, as the Acts of the Apostles discover in many passages. There remain no specimens of the music employed in the worship of the primitive Christians; but probably it was at first the same with that used in the Pagan rites of the Greeks and Romans. The practice of chanting the psalms was introduced into the western churches by St. Ambrose, about 350 years after Christ. In the year 600, the method of chanting was improved by St. Gregory the Great. The Ambrosian chant contained four modes. In the Gregorian the number was doubled. So early as the age of Constan
tine the Great, prior to either of the periods last mentioned, when the Christian religion first obtained the countenance of power, instrumental music came to be introduced into the service of the church. In England, according to bishop Stillingfleet, music was introduced in the church service, first by St. August
tine, and afterwards much improved by St. Dunstan, who was himself an eminent musician, and who is said to have first furnished the English churches and convents with the organ. The organ, the most majestic of all instruments, seems to have been an improvement of the hydraulic or water organ of the Greeks. The first organ seen in France was sent from Constantinople in 757, as a present to king Pepin from the emperor Constantine Copromyus VI. In Italy, Germany, and England, that instrument became frequent during the 10th century.

During the dark ages no work of genius or taste in any department of science seems to have been produced in any part of Europe; and except in Italy, where the cultivation of music was rather more the object of attention, that art was neglected equally with all others. There has always been observed a correspondence in every country between the progress of music and the cultivation of other arts and sciences.

In the middle ages, therefore, when the most fertile provinces of Europe were occupied by the Goths, Huns, Vandals, and other barbarous tribes, whose language was as harsh as their manners were savage, little perfection and no improvement of music is to be looked for. Literature, arts, and refinements, were encouraged more early at the courts of the Roman pontiffs than in any other country; and owing to that circumstance it is, that the scale, the counterimprovements in music had point, the beat melodies, the dramatic religions and fe-
ticular, the chief graces and elegancies of modern mu-

Ancient music. The great point, the beat melodies, the dramatic religions and fe-

In modern times, Italy has been to the rest of Europe what ancient Greece was to Rome. The Italians have sided the civilization of their conquerors, and enlightened the minds of those whose superior powers had enslaved them.

Having mentioned counterpoint, it would be improper not to make one or two observations on an invention which is supposed to have been the source of great innovation in the practice of music. Counterpoint, or music in parts, seems to be an invention purely modern. The term harmony meant in the language of antiquity what is now understood by melody. Guido, a monk of Arezzo in Tuscany, is, in Counterpoint, the general opinion, supposed to have entertained the first idea of counterpoint about the year 1022: an art which, since his time, has experienced gradual and imperceptible improvements, far exceeding the powers or comprehension of any one individual. The term counterpoint, or contra punctum, denotes its own etymology and import. Musical notation was at one time performed by small points; and the present mode is only

(1) Roscius gained 500 sesteria, or L. 4956:9:2 d. Sterling per annum.

(2)...
only an improvement of that practice. Counterpoint, therefore, denotes the notation of harmony or music in parts, by points opposite to each other. The improvements of this important acquisition to the art of music kept pace at first with those of the organ; an instrument admirably adapted to harmony: And both the one and the other were till the 15th century employed chiefly in sacred music. It was at this period that secular music began to be cultivated.

Before the invention of characters for time, music in parts must have confined entirely of simple counterpoint, or note against note, as it is practised in psalmody. But the happy discovery of a time-table extended infinitely the powers of combined sounds. The ancients had no other resource to denote time and movement in music except two characters (— —), equivalent to a long and a short syllable. But time is of such importance in music, that it can impart meaning and energy to the repetition of the same sound; without it variety of tunes has no effect with respect to gravity and accentus. The invention of the time-table is attributed by almost all the writers on music of the last and present century to John de Muris, who flourished about the year 1330. But in a manuscript of John de Muris himself, bequeathed to the Vatican library by the Queen of Sweden, that honour seems to be yielded to Magister Frane, who appears to have been alive as late as at 1383. John de Muris, however, who there is some cause to believe was an Englishman, though not the inventor of the cantus denaturabili, did certainly by his numerous writings greatly improve it. His treatise on the Art of Counterpoint is the most clear and useful essay on the subject of which those times can boast.

In the 11th century, during the first crusade, Europe began to emerge from the barbarous simplicity and ignorance which had long overwhelmed it. While its inhabitants were exercising in Asia every species of rapine and pious cruelty, art, ingenuity, and reason, indefitibly civilized and softened their minds. Then it was that the poets and fongs, known by the name of Troubadours, who first appeared in Provence, instituted a new profession; which obtained the patronage of the count of Poitou, and many other princes and barons who had themselves cultivated music and poetry with success. At the courts of their munificent patrons the troubadours were treated with respect. The ladies, whose charms they celebrated, gave them the most generous and flattering reception. The successes of some inspired others with hopes, and excited exertions in the exercise of their art; impelling them towards perfection with a rapidity which the united force alone of emulation and emulation could occasion. These founders of modern verification, conftructing their songs on plans of their own, classical authority, either through ignorance or design, was entirely disregarded. It does not appear, however, during the cultivation and favour of Provencal literature, that any one troubadour far outfripped the rest as to become a model of imitation. The progress of taste must ever be impeded by the ignorance and caprice of those who cultivate an art without science or principles.

During almost two centuries after the arrangement of the scale attributed to Guido, and the invention of the time-table ascribed to Franco, no remains of secular music can be discovered, except those of the troubadours or Provencal poets. In the simple tunes of these bard no time indeed is marked, but little variety of notation appears; it is not difficult, however, to discover in them the germs of the future melodies, as well as the poetry of France and Italy. Had the poetry and music of the troubadours been treated of in an agreeable manner by the writers who have chosen that subject, it would have been discovered to be worthy of attention; the poetry, as interesting to literature; the melody to which it was sung, as curious to the musical historian. Almost every species of Italian poetry is derived from the Provencals. Air, the most captivating part of secular vocal music, seems to have had the same origin. The most ancient strains that have been spared by time, are such as were set to the songs of the troubadours. The Provencal language began to be in favour with poets about the end of the 10th century. In the 11th it became the general vehicle, not only of poetry, but of prose, to all who were ignorant of Latin. And these were not the laity only. At this period violars, or performers on the vielle or violin, jugglars or flute-players, musars or players on other instruments, and comedians, abounded all over Europe. This swarm of poet-musicians, who were formerly comprehended in France under the general titles of jugglars, travelled from province to province singing their verses at the courts of princes. They were rewarded with clothes, horses, arms, and money. Jougleurs or musicians were employed often to sing the verses of troubadours, who themselves happened to be deficient in voice or ignorant of music. The term troubadour, therefore, implies poetry as well as music. The jouglers, menetriers, trélliers, or minstrels, were frequently musicians, without any pretensions to poetry. These last have been common at all times, but the troubadour or bard has distinguished a particular profession, either in ancient or modern times, only during the early dawning of literature.

In the 13th century the songs were on various subjects, moral, merry, amorous: and at that time melody seems to have been little more than plain song or chanting. The notes were square, and written on four lines only like those of the Romish church in the E flat, and without any marks for time. The movements and embellishments of the air depended on the abilities of the finger. Since that time, by the cultivation of the voice modern music has been much extended, for it was not till towards the end of St. Lewis's reign that the fifth line began to be added to the flat. The finger always accompanied himself with an instrument in unison.

As the lyre is the favourite instrument in Grecian poetry, so the harp held the same place in the embellishment of the poets who flourished in the period of which we are at present speak. A poet of the 14th century, Macca, wrote a poem on the subject of the harp alone, in which he assigns to each of its 25 strings an allegorical name; calling one liberality, another wealth, &c.

The instrument which frequently accompanied, and the violin indeed disputed the pre-eminence with the harp, was the viol. Till the 16th century this instrument was furnished with frets; after that period it was reduced
to four strings; and still under the denomination of violin holds the first place among treble instruments. The violin was played with a bow, and differed entirely from the vielle, the tones of which were produced by the friction of a wheel; the wheel performed the part of a bow.

British harpers were famous long before the conquest. The bounty of William of Normandy to his joculator or bard is recorded in the doomsday book. The harp seems to have been the favourite instrument in Britain for many ages, under the Britsh, Saxons, Danes, and Norman kings. The fiddles, however, is mentioned so early as 1200 in the legendary life of St Christopher. The ancient privileges of the minstrels at the fairs of Chester are well known in the history of England.

The extirpation of the bards of Wales by Edward I. is likewise too familiar an incident to be mentioned here. His perfecuting spirit, however seems to have been limited to that principality; for we learn, that at the ceremony of knighting his sons, a multitude of minstrels attended.

In 1345, during the reign of Edward II. such extensive privileges were claimed by the minstrels, and so many disolute persons assumed that character, that it became necessary to restrain them by express laws. The father of our genuine poetry, who in the 14th century enlarged our vocabulary, polished our numbers, and with acquisitions from France and Italy augmented our store of knowledge (Chaucer), entitles one of his poems The History of St. Cecilia; and the celebrated patronesses of music must no doubt be mentioned in a history of the art. Neither in Chaucer, however, nor in any of the histories or legendary accounts of this Saint, does any thing appear to authorize the religious veneration paid to her by the votaries of music; nor is it easy to discover whence it has arisen. As an incident relative to the period of which we speak, it may be mentioned, that, according to Spelmann, the appellation of Doctor was not among the degrees granted to graduates in England sooner than the reign of King John, about 1207; although, in Wood's history of Oxford, that degree is said to have been conferred, even in music, in the reign of Henry II. It is known that the title was created on the continent in the 12th century; and as, during the middle ages, music was always ranked among the seven liberal arts, it is likely that the degree was extended to it.

After the invention of printing, an art which has tended to disseminate knowledge with wonderful rapidity among mankind, music, and particularly counterpoint, became an object of high importance. The names of the most eminent composers who flourished in England, from that time to the Reformation, were, Fairfax, William of Newark, Sheringham, Turges, Banister, Tudor, Taverner, Tye, Johnson, Parfons; to whom may be added John Marbeck, who set the whole English cathedral service to music.

Before this period Scottish music had advanced to a high degree of perfection. James I. was a great composer of airs to his own verses; and may be considered as the father of that plaintive melody which in Scotch tunes is so pleasing to a taste not vitiated by modern affectation. Besides the testimony of Morison and Major, who may be suspected of being under the influence of national prejudice, we have that of Alessandro Tescani, to the musical skill of that accomplished prince. "Among us moderns (says this foreigner) we may reckon James king of Scotland, who not only composed many sacred pieces of vocal music, but also of himself invented a new kind of music, plaintive and melancholy, different from all others; in which he has been imitated by Carlo Gesuello prince of Venosa, who in our age has improved music with new and admirable inventions."

Under such a genius in poetry and music as king James I. it cannot be doubted that the national music must have been greatly improved. We have seen that he composed several anthems, or vocal pieces of sacred music, which shows that his knowledge of the science must have been very considerable. It is likewise known, that organs were by him introduced into the cathedrals and abbeys of Scotland, and choir-service brought to such a degree of perfection, as to fall little short of that established in any country of Europe.

By an able antiquary of the present age, the great era of music as of poetry, in Scotland, is supposed to have been from the beginning of the reign of James I. down to the end of the reign of James V. During that period flourished Gavin Douglas bishop of Dun­keld, Ballenden archdeacon of Murray, Dunbar, Hen­ryfon, Scott, Montgomery, Sir David Lindsay, and many others, whose fine poems have been preferred in Ba­natyne's Collection, and of which several have been published by Allan Ramsay in his evergreen.

Before the Reformation, as there was but one religion, there was but one kind of sacred music in Eu­rope, plain chape, and the defcant built upon it. Both of these were used by Luther; and in the reform­ation on the Scotch he adopted the Cantus Firmus, and applied it to the composition of his psalms. The most eminent composers of sacred music were not inferior to any others of the same character, nor in any other period of the history of this country. Sacred music was the principal object of study all over Europe.

In the 16th century music was an indispensible part of polite education. The composers of the 16th century were instructed in that art. There is a collection preserved in manuscript called Queen Elizabeth's Virginal Book. If her majesty was able to execute any of the fable part pieces in that book, the music must have been of a great degree of difficulty; a month's practice would not be sufficient for them. If the music were any matter now in Europe to enable him to play one of them to the end. Tallis, singularly profound in musical composition, and Bird his admirable scholar, were two of the authors of this famous collection.

During the reign of Elizabeth, the genius and learning of the British musicians were not inferior to any on the continent; an observation scarcely applicable at any other period of the history of this country. Sacred music was the principal object of study all over Europe.

The most eminent musical theorists of Italy, who flourished in the 16th century, were, Franchinus Gae­rius, or Gaffioro of Lodi, Pietro Aaron of Flo­rence,
Vittorio, deferve likewise to be mentioned; and to mention them is all we can attempt; the purpose of which is, to excite more minute inquiry by those who may choose to investigate the subject particularly.

The Netherlands, likewise, during the period of The Netherlands, which we have been speaking, produced many eminent composers; of whom we may mention Verletot, Gombert, Arkadelt, Berchem, Richafort or Ricciafort, Crequilon Le Cock or Le Coq, Canis, Jacob Clemens Non Papa, Pierre Manchicourt, Balzou, Kerl, Rore, Orlando di Lasso, and his sons Ferdinand and Rodolph.

In the 17th century, the musical writers and composers who acquired fame in England, were, Dr Nathaniel Giles, Thomas Tomkins, and his son of the same name; Elw; Bevin, Orlando Gibbons, Dr William Child, Adrian Batten, Martin Pierson, William Lawes, Henry Lawes, Dr John Willon, John Hilton, John Playford, Captain Henry Cook, Pelham Humprey, John Blow, William Turner, Dr Christopher Gibbons, Benjamin Rogers, and Henry Purcell. Of thefe, Orlando Gibbons, Pelham Humprey, and Henry Purcell, far excelled the rest.

About the end of the reign of James I., a music-lecture or professorship was founded in the university of Oxford by Dr William Hyacin.

In the reign of Charles I., a charter was granted to the musicians of Weftminster, incorporating them, as the king's musicians, into a body politic, with powers to prosecute and fine all who, except themselves, should attempt to make any benefit or advantage of music in England or Wales; powers which in the subsequent reign were put in execution.

About the end of the reign of Charles II. a passion seems to have been excited in England for the violin, and for pieces expressly composed for it, in the Italian manner (*). Prior to 1600, there was little other music except masses and madrigals, the two principal divisions of sacred and secular music; but from that time to the present, dramatic music becomes the chief object of attention. The music of the church and of the chamber continued indeed to be preferred, even in sacred music, by the success of dramatic composition, consisting of recitation and melodies for a fingle voice. Such melodies began now to be preferred to music of many parts; in which canons, fugues, and full harmony, had been the productions which chiefly employed the master's study and the hearer's attention.

So late as the beginning of the present century, according to Riccoboni, the performers in the opera of Germany, particularly at Hamburg, were all tradesmen or handcrafts; your shoemaker (says he) was often the first performer on the stage; and you might have bought fruit and sweetmeats of the same girl.

(*) The most celebrated violin players of Italy, from the 16th century to the present time, have been Farina, M. Angelo Roffi, Baffani the violin-master of Corelli, the admirable Angelico Corelli himself, Terelli, Alberti, Albenoni, Testarini, Vivaldi, Geminiani one of the most distinguished of Corelli's scholars. Tartini, Veracini, Barcella, Locatelli, Ferrari, Martini, Poccherini, and Giardini.
Music. History.

Girls, whom the night before you had seen in the characters of Armida or Semiramis. Soon, however, the German opera profited to a more reprehensible situation; and even during the 17th century many eminent composers flourished in that country.

The life of great musicians which France produced during the early part of the same century is not numerous. Music seems to have been but little cultivated in that country, till the operas of Lulli, under the powerful patronage of Louis XIV. excited public attention.

The favourite finging-master and composer of France, about the middle of the 17th century, was Michael Lambert. John Baptist Lulli, soon after this time, rose from the rank of a menial servant to fame, opulence, and nobility, by his skill in musical compositions. The celebrated singer La Rochois was taught singing and acting by Lulli.

La Maupin, the successor of La Rochois, on account of her extraordinary character and romantic adventures, deserves to be mentioned. She was equally fond of both sexes, fought and loved like a man, resided and felt like a woman. She eloped from her husband with a fencing-master, of whom she learnt the small sword; she became an excellent fencer. At Marseilles she became enamoured of a young lady, whom she seduced; on account of this whimsical affection the lady was by her friends confined in a convent. La Maupin obtained admittance into the same convent as a novice: she set fire to the convent, and in the confusion carried off her favourite. At Paris, when she appeared on the stage in 1655, Dumenil a singer having affronted her, she put on mens clothes, and infcribed on his drawing his sword and fighting her: when he refused, she came at him, and took from him his sword and flax-box as trophies of victory. At a ball given by Monfieur brother of Louis XIV. she again put on mens clothes; and having behaved impertinently to a lady, three of the lady's friends, supposing La Maupin to be a man, called her out: she killed them all, and returning coolly to the ball, told the story to Monfieur, who obtained her pardon. She became afterwards mistress to the elector of Bavaria. This prince quitting her for the countess of Arco, sent her by the count, husband of that lady, a purse of 40,000 livres: she threw it at the count's head, telling him, it was a recompense worthy of such a fcountred and cuckold as himself. At last, feized with a fit of devotion, she recalled her husband, and spent the remainder of her life in piety. She died in 1677 at the age only of 34.

The English musician whom we last mentioned was the celebrated Purcell; after his time the chief composers for the church were Clarke, Dr Holden, Dr Creyghton, Tucker, Aldrich, Goswin, Weldon, Dr Crofts, Dr Green, Boyce, and Nares; to whom may be added John Stanley, who attained high proficiency in music, although from two years old totally deprived of sight.

The annals of modern music have hitherto furnished no event so important to the progres of the art as the invention of recitative or dramatic melody; a style of music which resembles the manner of the ancient rhetoricians.

The Orfeo of Politian was the first attempt at musical drama. It was afterwards perfected by Metastasio. No musical dramas similar to those afterwards, first musical opera, became so popular. The names of opera and oratorio had existed in Italy before the beginning of the 17th century. It was above the 1660, or a little before that time, that enuchs were first employed for singing in Italy.

There seems to have been no singing enuchs in an earlier time, unless the galli or archigalli, priests of Cybele, were such. Calification has, however, at all times been practised in eastern countries, for the purpose of furnishing to tyrannical jealous guards of female chastity; but never, so far as modern writers on the subject have discovered, merely to preserve the voice, till about the end of the 16th century.

At Rome, the first public theatre opened for the exhibition of musical dramas, in modern times, was il Torre de Nona, where in 1671 Giafone was performed. In 1679, the opera of Don' Amore, set by the famous organist Bernardo Faguan, was represented at Nella Sala de Signori Capranica; a theatre which still subsists. In the year 1680, L'Orfisa nell'Amore was exhibited; the first dramatic composition of the elegant, profound, and original Alessandro Scarlatti.

The inhabitants of Venice have cultivated and encouraged the musical drama with more zeal and dilgence than the rest of Italy, during the end of the 17th and beginning of the present century; yet the opera was not established in Venice before the year 1637; in that year the first regular drama was performed: it was Andromeda.

In 1680 the opera of Berenice was exhibited at Opera de Padua with such astonishing splendour as to merit the notice. There were choruses of 100 virgins, 100 soldiers, 100 horsemen in iron armour, 40 cornets of horse, 6 trumpeters on horseback, 6 drummers, 6 en spoilers, 6 fackluts, 6 great flutes, 6 minstrels playing on Turkish instruments, 6 others on oclave flutes, 6 pages, 3 sergeant's, 6 cymbalists. There were 12 trumpeters, 12 grooms, 12 coachmen for the triumph, 6 others for the procession, 2 lions led by two Turks, 2 elephants by two others; Berenice's triumphal car drawn by 4 horses, 6 other cars with prisoners and spoils drawn by 12 horses, 6 coaches. Among the scenes and representations in the first act were, a vast plain with two triumphal arches, another plain with pavilions and tents, and a foret for the chase: in act third, the royal dressing-room completely furnished, stables with 100 live horses, portico adorned with tapestry, and a stupendous palace in perspective. At the end of the first act were representations of every kind of chase, wild bear, flag, deer, bears. At the end of the third act, an enormous globe, defended as from the sky, divided itself into other globes suspended in the air, and ornamented with emblematical figures of time, fame, honour, &c.

Early in the last century, machinery and decoration usurped the importance due to poetry and music in such exhibitions.

Few instances occur of musical dramas at Naples till the beginning of the present century. Before the time of the elder Scarlatti, it seems as if Naples had been less fertile in great contrapuntists, and less diligent in the cultivation of dramatic music, than any other state of Italy. Since that time all the rest of
Europe has been furnished with composers and performers from that city. The word opera seems to have been familiar to English poets from the beginning of the 16th century. Stilo recitativo, a recent innovation even in Italy, is mentioned by Ben Johnson to early as 1617. From this time it was used in masques, occasionally in plays, and in cantatas before a regular drama wholly set to music was attempted. By the united abilities of Quinault and Lulli, the opera in France had arisen to high favour. This circumstance afforded encouragement to several attempts at dramatic music in England by Sir William D'Avenant and others, before the music, language, or performers of Italy were employed on our stage. Pieces, styled dramatic operas, preceded the Italian opera on the stage of England. These were written in English, and exhibited with a profuse decoration of scenery and habits, and with the best singers and dancers that could be procured: Piffche and Circe, are entertainments of this kind: the Temple and Macbeth were acted with the same accompaniments.

During the 17th century, whatever attempts were made in musical drama, the language sung was always English. About the end of that century, however, Italian singing began to be encouraged, and vocal as well as instrumental musicians from that country began to appear in Britain. The first musical drama, performed wholly after the Italian manner in recitative for the dialogue or narrative parts, and measured melody for the airs, was Arfinoe queen of Cyprus, translated from an Italian opera of the same name, written by Stanzani of Bologna. The English version of this opera was set to music by Thomas Clayton, one of the royal band, in the reign of William and Mary. The singers were all English, Mr. Hughes, Leveredge, and Cook; Mrs Tofts, Mrs Crofs, and Mrs Lyndsey. The translation of Artinoe, and the music to which it is set, are execrable; yet such is the charm of novelty, that this miserable performance, deferving neither the name of a drama by its poetry, nor of an opera by its music, furnished 24 representations, and the second year 11.

Operas, notwithstanding their deficiencies in poetry, music, and performance (no foreign composer or eminent finger having yet arrived), became so formidable to our actors at the theatres, that it appears from the Daily Courant, 14th January 1707, a subcription was opened "for the encouragement of the comedians ad in the Haymarket, and to enable them to keep the diversions of plays under a separate interest from operas."

Mr Addison's opera of Rosamond appeared about this time; but the music set by Clayton is so contemptible, that the merit of the poetry, however great, could not of itself long support the piece. The choice of so mean a composer as Clayton, and Mr Addison's partiality to his abilities, betray a want of musical taste in that elegant author. The first truly great singer who appeared on the stage of Britain was Cavaliier Niclino Grimaldi, commonly known by the name of Nicolini. He was a Neapolitan; and though a beautiful finger indeed, was still more eminent as an actor. In the Tatler, \textit{n}° 115, the elegance and propriety of his action are particularly described. Recently before his appearance, Valentinii Urbani and a female finger called Spedtator, The Barronets, arrived. Margarita de l'Epin, who afterwards married Dr Pepusch, had been in this country some time before.

The first opera performed wholly in Italian, and by Italian fingers was Aiman. As at present, so at that time, operas were generally performed twice a-week.

The year 1710 is distinguished in the annals of music by the arrival in Britain of George Frederick Handel. Handel had been in the service of the elector of Hanover, and came first to England on a visit of curiosity. The fame of this great musician had penetrated into this country before he himself arrived in it: and Aaron Hill, then in the direction of the Haymarket theatre, infantly applied to him to compose an opera. It was Rinaldo; the admirable music of which he produced entirely in a fortnight. Soon after this period appeared, for the first time as an opera finger, the celebrated Mrs Anaflasia Robinson. Mrs Robinson, who was the daughter of a portrait painter, made her first public exhibitions in the concerts in York buildings; and acquired so much the public favour, that her father was encouraged to take a house in Golden Square, for the purpose of establishing weekly concerts and assemblies, in the manner of Conservatorio, which became the resort of the most polite audiences.

Soon after Mrs Robinson accepted of an engagement at the Opera, where her salary is said to have been L. 1000, and her other emoluments equal to that sum. She quit the stage in consequence of her marriage with the gallant earl of Peterborough, the friend of Pope and Swift. The eminent virtues and accomplishments of this lady, who died a few years ago at the age of 88, entitled her to be mentioned even in a compend too short for biography. The conduct of the opera having been found to be more expensive than profitable, it was entirely suspended from 1717 till 1720, when a fund of L. 50,000 for supporting and carrying it on was subscribed by the first perfomans of the kingdom. The subscribers, of whom king George I. was one, for L. 1000, were formed into a society, and named The Royal Academy of Music. Handel was commissioned to engage the most eminent performers; for that purpose he went to Dresden, were Italian operas were at that time performed in the most splendid manner at the court of Augustus elector of Saxony, then king of Poland. Here Handel engaged Seneino-Berendi, Bocchi, and the Duranianti.

In the year 1723, the celebrated Francesca Cuzzoni appeared as a first-rate finger; and two years afterwards arrived her distinguished rival Signora Paulina Bordoni.

In a cantabile air, though the notes Cuzzoni added were few, she never lost an opportunity of enriching the cantilena with the most beautiful embellishments. Her shake was perfect. She possessed a creative fancy, and she enjoyed the power of occasionally accelerating and retarding the measure in the most artificial and able manner, by what is in Italy called tempo rubato. Her high notes were unrivalled in clearness and sweetness. Her intonations were so just and so fixed, that
it seemed as if she had not the power to sing out of tune.

Paulina Bordoni, wife of the celebrated Saxon composer Handel, invented a new kind of singing, by running divisions, with a neatness and velocity which astonished all who heard her. By taking her breath imperceptibly, she had the art of attaining a note apparently longer than any other finger. Her beats and trills were strong and rapid; her intonation perfect. Her professional perfections were enhanced by a beautiful face, fine symmetry of figure, and a countenance and gesture on the stage which indicated an entire intelligence and possession of the several parts allotted to her.

These two angelic performers excited so signal the attention of the public, that a party spirit between the abettors of the one and of the other was formed, as violent and as invertebrate almost as any of those that had ever occurred relative to matters either theological or political; yet so distinct were their styles of singing, so different their talents, that the praise of the one was no reproach to the other.

In less than seven years, the whole L. 50,000 subscribed by the Royal Academy, besides the produce of subscription to non-subscribers, was expended, and the governors and directors of the society relinquished the idea of continuing their engagements; consequently, at the close of the season 1727, the whole band of singers dispersed. The next year we find Senefino, Paulina, Balde, Cuzzoni, Nicollini, Farinelli, and Bofchis, at Venice.

Handel, however, at his own risk, after a suspension of about a twelvemonth, determined to recommence the opera; and accordingly engaged a band of performers entirely new. These were Signor Bernacchi, Signora Merighi, Signora Strada, Signor Anibale Pio Fabri, his wife, Signora Bertoldi, and, John Godfried Reimoldner.

The sacred musical drama, or oratorio, was invented early in the 14th century. Every nation in Europe seems first to have had recourse to religious subjects for dramatic exhibitions. The oratorios had been common in Italy during the last century; they had never been publicly introduced in England till Handel, stimulated by the rivalry of other adventurers, exhibited in 1732 his oratorios of Ethelred, and of Acis and Galatea, the last of which he had composed 12 years before for the duke of Chandos's chapel at Cannons. The most formidable opposition which Handel met with in his conduct of the Italian opera was a new theatre for exhibiting these operas, opened by subscription in Lincoln's Inn Fields, under the conduct of Nicola Porpora, a reputed composer. A difference having occurred between Handel and Senefino, Senefino had for some time deserted the Haymarket, where Handel managed, and was now engaged at the rival theatre of Lincoln's Inn Fields. To supply the place of Senefino, Handel brought over Giovanni Carellini, a singer of the most extensive powers. His voice was at first a powerful and clear soprano; afterwards it changed into the full, fine, deep, counter-tenor that has perhaps ever been heard. Carellini's person was tall, beautiful, and majestic. He rendered every thing he sung interesting by energy, taste, and judicious embellishment. In the execution of difficult divisions from the chief, his manner was articulate and admirable. It was the opinion of Handel, as well as other eminent professors, that whoever had not heard Carellini, was unacquainted with the most perfect style of singing. The opera under the direction of Porpora was removed to the Haymarket, which Handel had left. Handel occupied the theatre of Lincoln's Inn Fields; but his rivals now acquired a vast advantage of attraction, by the accession of Carlo Brodchi, della Farinelli to their party, who at this time arrived. This renowned singer seems to have transcended the limits of all anterior vocal excellence. No vocal performer of the present century has been so unanimously allowed to possess an uncommon power, sweetness, extent, and agility of voice, as Farinelli. Nicollini, Senefino, and Carellini, gratified the eye as much by the dignity, grace, and propriety of their action and deportment, as the ear, by the judicious use of a few notes within the limits of a small compass of voice; but Farinelli, without the abundance of significant gestures or graceful attitudes, enchanted and astonished his hearers, by the force, extent, and mellifluous tones of the mere organ, which he had nothing to execute, articulate, or express. Though during the time of singing he was as motionless as a statue, his voice was so active that no intervals were too close, too wide, or too rapid, for his execution.

Handel having lost a great part of his fortune by the opera, was under the necessity of trying the public gratitude in a benefit, which was not disgraced by the event; the theatre, for the honour of the nation, was so crowded, that he is said to have cleared L. 800. After a fruitless attempt by Heidggeir, the co-operative in Handel the conduct of the opera, and patrician of the King's Theatre in Haymarket, to procure a subscription for continuing it, it was found necessary to give up the undertaking.

It was about this time that the statue of Handel was erected in Vauxhall, at the expense of Mr Tyers, proprietor of those gardens.

The next year (1739), Handel carried on oratorios at the Haymarket, as the opera there was suspended. The earl of Middlesex now undertook the troublesome office of impresario of the Italian opera. He engaged the King's theatre, with a band of singers from the continent almost entirely new. Caluppi was his composer. Handel, almost ruined, retired at this time to Ireland, where he remained a considerable time. In 1744, he again attempted oratorios at the King's theatre, which was then, and till 1746, unoccupied by the opera, on account of the rebellion.

The arrival of Giardini in London this year forms a memorable era in the instrumental music of England. His powers on the violin were unequalled. The fame year Dr Croza, then manager of the opera, eloped, leaving the performers, and innumerable trades-people his creditors. This incident put an end to operas of all kinds for some time.

This year a comic opera, called Il Filippo di Campagna, composed by Caluppi, was exhibited, which surpassed in musical merit all the comic operas performed in England till the Bizona Figliula. Signora Paganini acquired such fame by the airs allotted to her in that piece, that the crowds at her benefit were beyond example. Caps were lost, gowns torn in pieces,
History.

At this period the arrival of Giovanni Manzoli marked a splendid era in the annals of musical drama, by conferring on serious opera a degree of importance to which it had hitherto yet arisen since its establishment in England. Manzoli's voice was the most powerful and voluminous soprano that had been heard since the time of Farinelli; his manner of singing was grand, and full of taste and dignity.

At this time Tenducci, who had been in England some time before, and was now returned much improved, performed in the flation of second tenor to Manzoli.

Gaetano Guadagni made a great figure at this time. He had been in this country early in life (1748), as serious-man in a burletta troop of singers. His voice was then a full and well-toned counter-tenor; but he sung wildly and carelessly. The excellence of his voice, however, attracted the notice of Handel, who assigned him the parts in his oratorios Messiah and Samson, which had been originally composed for Mrs Cibber. He quitted London for the first time about 1753.

The highest expectations of his abilities were raised by fame before his second arrival, at the time of which we treat. As an actor he seems to have had no equal on any stage in Europe. His figure was uncommonly elegant and noble; his countenance replete with beauty, intelligence, and dignity; his attitudes were full of grace and propriety. Those who remembered his voice when formerly in England were now disappointed: it was comparatively thin and feeble; he had now changed it to a soprano, and extended its compass from six or seven notes to fourteen or fifteen. The music he sung was the most simple imaginable: a few notes with frequent pauses, and opportunities of being librated from the composer and the band, were all he required. In these effusions, seemingly extemporaneous, he displayed the native power of melody unaided by harmony or even by unisonous accompaniment; the pleasure he communicated proceeded principally from his artful manner of diminishing the tones of his voice, like the dying notes of the Eolian harp. Most other fingers affect a swell, or mezza voce; but Guadagni, after much practice, now with force, attempted it so delicately that itpossessed all the effect of extreme distance. During the season 1770 and 1771, Tenducci was the immediate successor of Guadagni. This performer, who appeared in England first only as a singer of the second or third clas, was during his residence in Scotland and Ireland so much improved that it was well received as first man, not only on the stage of London but in all the great theatres of Italy. It was during this period that dancing seemed first to gain the ascendant over music by the superior talents of Mademoiselle Heimel, whose grace and execution were so perfect as to eclipse all other excellence.

In the first opera performed this season (Lucio Flora) appeared Miss Cecilia Davies, known in Italy by the name of L'Inglesina. Miss Davies had the honour of being the first English woman who had ever been thought worthy of singing on any stage in Italy. She even performed with celat the principal female characters on many of the great theatres of that country. Gabrielli only on the Continent was said to surpass her. Her voice, though not of great volume, was clear and perfectly in tune; her shake was open and distinct, without the sluggishness of the French cadence. The flexibility of her throat rendered her execution equal to the most rapid divisions.

Next season introduced Venanzio Ravygini, a beautiful and animated young man; a composer as well as a singer.—His voice was sweet, clear, flexible; in compass much wider than most of his age.

The season 1775 and 1776 was rendered memorable by the arrival of the celebrated Caterina Gabrielli, styled early in life La Cochetina, being the daughter of a cardinals cook at Rome. She had, however, in her countenance and deportment no indications of low birth. Her manner and appearance depicted dignity and grace. So great was her reputation before her arrival in England for singing and for caprice, that the public expecting perhaps in both too much, were unwilling to allow her due praise for her performance, and were apt to ascribe every thing she did to pride and insolence. Her voice, though exquisite, was not very powerful. Her chief excellence having been the neatness and rapidity of her execution, the surplice of the public must have been much diminished on hearing her after Miss Davies, who sung many of the same songs in the same style, and with a neatness so nearly equal, that common hearers could distinguish no difference. The discriminating critic, however, might have discovered a superior sweetness in the natural tone of the Gabrielli's voice, an elegance in the finishing of her musical periods or paffages, an accent and precision in her divisions, superior not only to Miss Davies, but to every other singer of her time. In slow movements her pathetic powers, like those in general of performers most renowned for agility, were not exquisitely touching. She now resides at Bologna.

About the time of which we have been treating, the Aguiari at the proprietors of the Pantheon ventured to engage the Aguiari at the enormous salary of L.100 per night, for singing two songs only! Lucresia Aguiari was a truly wonderful performer. The lower part of her voice was full, round, and of excellent quality; its compass more than a twelfth. She had two octaves of fair natural voice, from A on the fifth line in the bass to A on the fifth line in the treble, and beyond that in alto she had in early youth more than another octave. She has been heard to ascend to B in alitissimo. Her shake was open and perfect; her intonation true; her execution marked and rapid; the style of her singing, in the natural compass of her voice, grand and majestic.

In 1776 arrived Anna Pozzi, as successor to the Anna Pozzi. She possessed a voice clear, sweet, and powerful; but her inexperience, both as an actress and as a singer, produced a contrast very unfavourable to her when compared with so celebrated a performer as Gabrielli. Since that time, however, Pozzi, with more study and knowledge, has become one of the best and most admired female singers in Italy.

After the departure of Aguiari for the second and last time, the managers of the Pantheon engaged the Georgi as her successor. Her voice was exquisitely fine, Georgi.
but totally uncultivated. She is now employed as the first woman in the operas of the principal cities of Italy.

During the feasons 1777 and 1778, the principal fingers at the opera in London were Frandefco Roncaologia and Franfesca Danze, afterwards Madame Le Brun.

Roncaologia possessed a sweet-toned voice; but of the three great requites of a complete flage-finger, pathos, grace, and execution, which the Italians call cantabile, graziofa, and bravura, he could lay claim only to the second. His voice, a voci de camera, when confined to the graziofa in a room, leaves nothing to wish for.

Danzc had a voice well in tune, a good shake, great execution, prodigious compass, with great knowledge of music; yet the pleasure her performance imparted was not equal to these accomplishments: but her object was not so much pathos and grace, as to surpise by the imitation of the tone and difficulties of instruments.

This year Gaffaro Pacchierotti appeared in London, whither his high reputation had penetrated long before. The natural tone of his voice is interfing, sweet, and pathetic. His compass downwards is great, with an ascent up to B♭, and sometimes to C in all. He possesses an unbounded fancy, and the power not only of executing the most difficult and refined passages, but of inventing embellishments entirely new. Ferdinando Bertoni, a well-known composer, came along with Pacchierotti to Britain.

During the last ten years, dancing has become an important branch of the amusements of the opera-house. Made'moielle Heinel, M. Veltris le Jeune, Mademoiselle Baccell, had, during some years, delighted the audience at the opera; but on the arrival of M. Veltris l'Aine, pleasure was exchanged for ecstasy. In the year 1781, Pacchierotti had by this time been so frequently heard that his singing was no impediment to conversation; but while the elder Veltris was on the stage, not a breathing was to be heard. Those lovers of music who talked the loudest while Pacchierotti sung, were in agonies of terror lest the graceful movements of Veltris, le dieu de la danse, should be disturbed by audible approbation. Since that time, the most mute and respectful attention has been paid to the manly grace of Le Picq, and the light, fantastic toe of the younger Veltris; to the Roffis, the Theodores, the Coulon, the Hillingburgs; while the lighted fingers have been disturbed, not by the violence of applause, but the clamour of inattention.

The year 1784 was rendered a memorable era in the annals of music by the splendid and magnificent manner in which the birth and genius of Handel were celebrated in Westminster Abbey and the Pantheon, by five performances of pieces selected from his own works, and executed by a band of more than 500 voices and instruments, in the presence and under the immediate auspices of their majesties and the first personages of the kingdom. The commemoration of Handel has been since established as an annual musical festival for charitable purposes; in which the number of performers and the perfection of the performances have continued to increase. In 1785 the band, vocal and instrumental, amounted to 616; in 1786 to 741; in 1787 to 806.

Dr Burney published An Account of the Musical Performances in Commemoration of Handel, for the benefit of the Musical Fund. The members and guardians of that fund are now incorporated under the title of Royal Society of Musicians. See Handel.

This year Pacchierotti and his friend Bertoni left England. About the same time our country was deprived of the eminent composer Sacchini, and Giardini the greatest performer on the violin then in Europe.

As a compensation for these losses, this memorable Excellence year is distinguished by the arrival of Madam Mara, of Madam Mara, whose performance in the commemoration of Handel in Westminster Abbey inspired an audience of 3000 of the first people of the kingdom, not only with pleasure but with ecstasy and rapture.

In 1786 arrived Giovanni Rubinielli. His voice is a Rubinielli, true and full contralto from C in the middle of the scale to the octave above. His style is grand; his execution neat and distinct; his taste and embellishments new, fedt, and masterly.

In 1788 a new dance, composed by the celebrated M. Noverre, called Capit and Pfyche, was exhibited along with the opera Locandiera, which produced an effect so uncommon as to deserve notice. So great was the pleasure it afforded to the spectators, that Noverre was unanimously brought on the stage and crowned with laurel by the principal performers. This, though common in France, was a new mark of approbation in England.

This year arrived Signor Luigi Marchesi, a finger Marchesi, whose talents have been the subject of praise and admiration on every great theatre of Europe. Marchesi's style of singing is not only elegant and refined in an uncommon degree, but often grand and full of dignity, particularly in his recitative and occasional low notes. His variety of embellishment and facility of running extempore divisions are wonderful. Many of his graces are elegant, and of his own invention.

The three greatest Italian fingers of the present time are certainly Pacchierotti, Rubinielli, and Marchesi. In discriminating the several excellencies of these great performers, a very respectful judge, Dr Burney, has particularly praised the sweet and touching voice of Pacchierotti; his fine shake, his exquisiterattle, his great fancy, and his divine expression in pathetic songs: Of Rubinielli's voice, the fulness, steadiness, and majesty; the accuracy of his intonations, his judicious graces; Of Marchesi's voice, the elegance and flexibility, his grandeur in recitative, and his boundless fancy and embellishments.—Having mentioned Dr Burney, we are in justice bound to acknowledge the aid we have derived from his history; a work which we greatly prefer to every other modern production on the subject. During the latter part of the present century many eminent composers have flourished on the continent: such as Jomelli, the family of the Bachs, Gluck, Haydn, and many others, whose different styles and excellencies would well deserve to be particularized, would our limits permit. With the same regard to brevity, we can do no more than just mention the late king of Prufia, the late elector of Bavaria, and prince Lobkowitz, as eminent dilettanti of modern times.

Besides the opera-fingers whom we have mentioned, our
our theatres and public gardens have exhibited fingers of considerable merit. In 1730, Mrs Rafter, afterwards the celebrated Mrs Clive, first appeared on the stage at Drury-lane as a singer. The same year introduced Miss Cecilia Young, afterwards the wife of Dr Arne. Her style of singing was infinitely superior to that of any other English woman of her time.

Our favourite musicians at this time were, Dubourg, Clegg, Clarke, and Pelling, on the violin; Kyte, on the hautboy; Jack Fielding on the German flute; Ballon on the common flute; Kerbi on the basoon; Valentine Snow on the trumpet; and on the organ, Rolle, gravé, Green, Robinson, Magnus, Jack James, and the blind Stanley, who seems to have been preferred. The favourite playhouse singer was Salway; and at concerts Mountier of Chichester.

As composers for our national theatre, Pepusch and Galliard feem to have been unrivalled till 1732; when two competitors appeared, who were long in possession of the public favour: We allude to John Frederick Lampe and Thomas Augustus Arne.

In 1736 Mrs Cibber, who had captivated every hearer of sensibility by her native sweetness of voice and powers of expression as a finger, made her first attempt as a tragic actress. The same year Beard became a favourite singer at Covent-garden. At this time Miss Young, afterwards Mrs Arne, and her two sisters Labella and Ethelred, were the favourite English female singers.

In 1738 was instituted the fund for the support of decayed musicians and their families.

It was in 1745 that Mr Tyers, proprietor of Vauxhall gardens, first added vocal music to the other entertainments of that place. A short time before Relagh had become a place of public amusement. In 1749 arrived Giardini, whose great taste, hand, and style in playing on the violin, procured him universal admiration. A few years after his arrival he formed a morning académie or concert at his house, composed chiefly of his scholars.

About this time San Martini and Charles Avilon were eminent composers.

Of near 150 musical pieces brought on our national theatres within these 40 years, 30 of them at least were set by Arne. The style of this composer, if analyfed, would perhaps appear to be neither Italian nor English; but an agreeable mixture of both and of Scotch.

The earl of Kelly.

The late earl of Kelly, who died but a few years ago, deferves particular notice, as posseffed of a very eminent degree of musical science, far superior to other dilettanti, and perhaps not inferior to any professor of his time. There was no part of theoretical or practical music in which he was not thoroughly versed: He posseffed a strength of hand on the violin, and a genius for composition, with which few professors are gifted.

Charles Frederic Abel was an admirable musician. His performance on the violin da gamba was in every particular complete and perfect. He had a hand which no difficulties could embarrass; a taste the most refined and delicate; a judgment so correct and certain as never to permit a single note to escape him without meaning. His compositions were easy and elegantly simple. In writing and playing an adagio he was superior to all praise: the most pleasing yet learned modulation, the richest harmony, the most elegant and polished melody, were all expressed with the most exquisite feeling, taste, and science. His manner of playing an adagio soon became the model of imitation for all our young performers on bowed instruments. Bartholomew, Cervetto, Cramer, and Credulì, may in this respect be ranked as of his school. All lovers of music must have lamented that Abel in youth had not attached himself to an instrument more worthy of his genius, talents, and learning, than the viol da gamba, that remnant of the old chert of viols which during the last century was a necessary appendage of a nobleman's or gentleman's family throughout Europe, previous to the admission of violins, tenors, and basses, in private houses or public concerts. Since the death of the late elector of Bavaria, who was next to Abel (the best performer on the viol da gamba in Europe), the instrument seems quite laid aside. It was used longer in Germany than elsewhere; but the place of gambill seems now as much superseded in the chapels of German princes as that of lutins. The celebrated performer on the violin, Lolle, came to England in 1785. Such was his caprice, that he was seldom heard; and for eccentricity was his style and composition, that by many he was regarded as a madman.

He was, however, during his lucid intervals a very great and expressive performer in the serious style.

Mrs Billington, after distinguishing herself in childhood as a neat and expressive performer on the piatto-forte, appeared all at once in 1786 as a sweet and captivating finger. In emulation of the Mara and other great bravura fingers, she at first too frequently attempted passages of difficulty; now, however, she greatly has the improved, that no long seems too high or too rapid for her execution. The natural tone of her voice is so exquisitely sweet, her knowledge of music so considerable, her shake so true, her claire and embellishments fo various, her expressions fo grateful, that envy only or apathy could hear her without delight. The present composers, and performers of the first class, are so well known to the lovers of the art, that it would be needless and improper to mention them particularly; and to describe the distinctive powers of Bartholomew, Cramer, Piel-tain, Raimonde, and Salomon, would be too delicate a task for us to undertake.

The Catch-club at the Thatched House, instituted in 1762 by the late earl of Eglinton, the present duke of club and Queensberry, and others; and the concert of ancient music, founded by the earl of Sandwich in 1776, have had a beneficial effect in improving the art. We have been somewhat particular in our account of musical affairs in our own country during the present century, as what would be most interesting to general readers, and of which a well-informed gentleman would not wish to be ignorant. The protector and connoisseur is not to be expected to content himself with disquisitions much more minute than those of which our limits can be supposed to admit.
Preliminary Discourse.

Music may be considered, either as an art, which has for its object one of the greatest pleasures of which our senses (†) are susceptible; or as a science, by which that art is reduced to principles. This is the double view in which we mean to treat of music in this work.

It has been the case with music as with all the other arts invented by men: some facts were at first discovered by accident; soon afterwards reflection and observation investigated others; and from these facts, properly disposed and united, philosophers were not slow in forming a body of science, which afterwards increased by degrees.

The first theories of music were perhaps as ancient as the earliest age which we know to have been distinguished by philosophy, even as the age of Pythagoras; nor does history leave us any room to doubt, that from the period when that philosopher taught, the ancients cultivated music, both as an art and as a science, with great agility. But there remains to us much uncertainty concerning the degree of perfection to which they brought it. Almost every question which has been propounded with respect to the music of the ancients has divided the learned; and may probably still continue to divide them, for want of monuments sufficient in theil number, and discoveries to unite and diffuse in the fame work the moft probable opinions established or propounded by the learned upon a subject so difficult and curious. This philosophical history of a nobly embellished the literature of our times.

In the mean time, till an author can be found sufficiently instructed in the arts and in history to undertake such a labour with success, we shall content ourselves with considering the present state of music, and limit our endeavours to the explanation of those acceptions which have already been communicated to the theory of music in these latter times.

There are two departments in music, melody and harmony. Melody is the art of arranging several sounds in succession one to another in a manner agreeable to the ear; harmony is the art of pleasing that organ by the union of several sounds which are heard at one and the same time. Melody has been known and felt through all ages; perhaps the same cannot be affirmed of harmony (§); we know not whether the ancients made any use of it or not, nor at what period it began to be practised.

Not but that the ancients certainly employed in their music
music, those chords which were most perfect and simple; such as the octave, the fifth, and the third; but it seems doubtful whether they knew any of the other consonances or not, or even whether in practice they could deduce the same advantages from the simple chords which were known to them, that have afterwards accrued from experience and combinations.

If that harmony which we now practise owes its origin to the experience and reflection of the moderns, there is the highest probability that the first essays of this art, as of all the others, were feeble, and the progress of its efforts almost imperceptible; and that, in the course of time, improving by small gradations, the successive labours of several generations have elevated it to that degree of perfection in which at present we find it.

The first inventor of harmony escapes our investigation, from the same causes which leave us ignorant of those who first invented each particular science; because the original inventors could only advance one step, a succeeding discoverer afterwards made a more sensible improvement, and the first imperfect essays in every kind were lost in the more extensive and striking views to which they led. Thus the arts which we now enjoy, are for the most part far from being due to any particular man, or to any nation exclusively: they are produced by the united and successive endeavours of mankind; they are the results of such continued and united reflections, as have been formed by all men at all periods and in all nations.

It might, however, be wished, that after having ascertained, with as much accuracy as possible, the state of ancient music by the small number of Greek authors which remain to us, the same application might be extended to the investigation of the inconstant traces of harmony which appear in the succeeding ages, and to pursue those traces from period to period. The productions of those researches would doubtless be very imperfect, because the books and monuments of the middle ages are by far too few to enlighten any principles of harmony, and the causes of the perfection which we receive from it. His principle of music were produced by it: he reduced all the consonances to a small number of simple and fundamental chords, of which the others are only combinations or various arrangements. He has, in short, been able to discover, and render sensible to others, the mutual dependence between melody and harmony.

Though these different topics may be contained in the writings of this celebrated artist, and in these writings for writing for musicans as were not philosophers, and such philosophers as were not musicians, have long desired to see these objects brought more within the reach of their capacity: such is the intention of the treatise I now present to the public. I had formerly composed it for the use of some friends. As the work appeared to them clear and methodical, they have engaged me to publish it, perfused (though perhaps with too much credulity) that it might be useful to facilitate the progress of initiates in the study of harmony.

This was the only motive which could have determined me to publish a book of which I might without hesitation assume the honour, if its materials had been the fruits of my own invention, but in which I can now boast no other merit than that of having developed, elucidated, and perhaps in some respects improved, the ideas of another (c).

The first edition of this essay, published 1752, has been favourably received by the world, and copies of it have not been found in the hands of booksellers, I have endeavoured to render this more perfect. The detail which I mean to give of my labour, will present the reader with a general idea of the principle of M. general. Rameau, of the consequences deduced from it, of the manner in which I have disposed this principle and its consequences; in short, of what is still a-wanting, and might be advantageous to the theory of this amiable art; of what is still remains for the learned to contribute towards the perfection of this theory; of the rocks and quickfands which they ought to avoid in this research, and which could serve no other purpose than to retard their progress.

Every honourable body, besides its principal found, Rameau’s likewise exhibits to the ear the 12th and 17th major origin of that found. This multiplicity of different yet connected harmonies, cordant founds, known for a considerable time, constitutes

---

they were in possession of what we denominate counterpoint. Without supposing this, there are some passages in the Greek authors which can admit of no satisfactory interpretation. See the Origin and Progress of Language, Vol. II. Besides, we, can discover some vestiges of harmony, however rude and imperfect, in the history of the Gothic ages, and amongst the most barbarous people. This they could not have derived from more cultivated countries, because it appears to be incorporated with their national music. The most rational account, therefore, which can be given, seems to be, that it was conveyed in a mechanical or traditionary manner through the Roman provinces from a more remote period of antiquity.

One end which we have proposed in this treatise, was not only to place the discoveries of M. Rameau in their most conspicuous and advantageous light, but even in particular respects to render them more simple.

—For instance, besides the fundamental experiment which we have mentioned above, that celebrated musician, to render the explication of some particular phenomena in music more accessible, had recourse to another experiment; I mean that which shows that a nonorous body struck and put in vibration, forces its
tone to a particular kind of diatonics, and the multiplied sounds which arise from it, are a sufficient foundation for the whole harmonic system.

But though this work is intended to explain the theory of music, and to reduce it to a system both complete and more luminous than has hitherto been done, we ought to caution those who shall read this treatise, that they may be careful not to deceive themselves, either by misapprehending the nature of our object, or the end which our endeavours pursue.

We must not here look for that striking evidence which is peculiar to geometrical discoveries alone, and which can be so rarely obtained in these mixed diquisitions, where natural philosophy is likewise concerned: into the theory of musical phenomena there must always enter a particular kind of metaphysics, which these phenomena implicitly take for granted, and which brings along with it its natural obscurity. In this subject, therefore, it would be absurd to expect what is called demonstration: it is an achievement of no small importance, to have reduced the principal facts to a system consistent with itself, and firmly connected in its parts; to have deduced them from one simple experiment; and to have established upon this foundation the most common and essential rules of the musical art. But in another view, if here it be improper to require that intimate and unalterable conviction which can only be produced by the strongest evidence, we remain in the mean time doubtful whether it is possible to elucidate this subject more strongly.

After this declaration, one should not be astonished, that, amongst the facts which are deduced from our fundamental experiment, there should be some which appear immediately to depend upon that experiment, and others which are deduced from it in a way more remote and less direct. In dilquisitions of natural philosophy, where we are scarcely allowed to use any other arguments, except such as arise from analogy or congruity, it is natural that the analogy should be sometimes more sometimes less sensible: and we will venture to assert, that such a mind must be very improper for philosophy, which cannot recognize and distinguish this gradation and the different circumstances on which it proceeds. It is not even surprising, that in a subject where analogy alone can take place, this conduct may drive us all at once in our attempts to account for certain phenomena. This likewise happens in the subject which we now treat; nor do we conceal the fact, however mortifying, that there are certain points (though their number be but small) which appear still in some degree accountable from our principles. Such, for instance, is the procedure of the diatonics scale in descending; the formation of the chord commonly termed the first redundant or superfluous, and some other facts of less importance, for which as redundant we are yet we can scarcely offer any satisfactory account except from the experience alone.

Thus, though the greatest number of the phenomena in the art of music appear to be deducible in a simple and easy manner from the protracted tone of nonorous bodies, one ought not with perhaps too much temerity to affirm as yet, that this mixed and protracted tone is demonstratively the only original principle of nor any law; though they should be incommensurable one with another; the protracted tone of a nonorous body, and the multiplied sounds which result from it, are a sufficient foundation for the whole harmonic system.
of harmony (n). But in the mean time it would not be less unjust to reject this principle, because certain phenomena appear to be deduced from it with less success than others. It is only necessary to conclude from this, either that by future scrutinies means may be found for reducing these phenomena to this principle; or that harmony has perhaps some other unknown principle, more general than that which results from the projected and compounded tone of famous bodies, and of which this is only a branch; or, lastly, that we ought not perhaps to attempt the reduction of the whole science of music to one and the fame principle; which, however, is the natural effect of an impatience fo frequent even among philosophers themselves, which induces them to take a part for the whole, and to judge of objects in their full extent by the greatest number of their appearances.

In those sciences which were called physico-mathematical (and amongst this number perhaps the science of sounds may be placed), there are some phenomena which depend only upon one single principle and one single experiment: there are others which necessarily suppose a greater number both of experiments and principles, whose combination is indispensable in forming an exact and complete system; and music perhaps is in this last case. It is for this reason, that, whilst we bellow on M. Rameau all due praise, we should not at the same time neglect to stimulate the learned in their endeavors to carry them still to higher degrees of perfection, by adding, if it is possible, such improvements as may be wanting to confummate the science.

Whatever the result of their efforts may be, the reputation of this intelligent artist has nothing to fear; he will still have the advantage of being the first who rendered music a science worthy of philosophical attention; to have made its practice more simple and easy; and to have taught musicians to employ in this subject the light of reason and analogy.

We would the more willingly persuade those who are skilled in theory and eminent in practice to extend and improve the views of him who before them pursued and pointed out the career, because many amongst them have already made laudable attempts, and have even been in some measure successful in diffusing new light through the theory of this enchanting art. It Tartini's was with this view that the celebrated Tartini has presented us in 1754 with a treatise of harmony, founded on a principle different from that of M. Rameau. This principle is the result of a most beautiful experiment (†). If at once two different sounds are produced from two instruments of the same kind, these two

---

(n) The demonstration of the principles of harmony by M. Rameau was not thus intimated in the exposition which he presented in the year 1749 to the Academy of Sciences, and which that Society besides approved with all the eulogiums which the author deserved; the title, as inserted in the register of the academy, was, "A memorial, in which are explained the foundations of a system of music theoretical and practical." It is likewise under this title that it was announced and approved of by the Commissioners, who in their printed report, which the public may read along with M. Rameau's memorial, have never dignified his theory with any other name than that of a system, the only name in reality which is expressive of its nature. M. Rameau, who after the approbation of the Academy, has thought himself at liberty to adorn his system with the name of demonstration, did not certainly recollect what the Academy has frequently declared; that, in approving any work, it was by no means implied, that the principles of that work appeared to them demonstrated. In short, M. Rameau himself, in some writings posterior to what he calls his demonstration, acknowledges, that upon particular points in the theory of the musical art, he is under a necessity of having recourse to analogy and supposition; this excludes every idea of demonstration, and refounds the theory of the musical art exhibited by M. Rameau to the classes in which it can only be ranked with probability, I mean the classes of probabilities.

(†) Had the utility of the preliminary discourse in which we are now engaged been less important and obvious than it really is, we should not have given ourselves the trouble of translating, nor our readers that of perusing it. But it must be evident to every one, that the caution here given and the advice offered, are no less applicable to students than to authors. The first question here decided is, Whether pure mathematics can be successfully applied to the theory of music? The author is jutly of a contrary opinion. It may certainly be doubted with great justice, whether the solid contents of famous bodies and their degrees of cohesion or elasticity, can be ascertained with sufficient accuracy to render them the subjects of musical speculation, and to determine their effects with such precision as may render the conclusions deduced from them geometrically true. It is admitted, that found is a secondary quality of matter, and that secondary qualities have no obvious connection which we can trace with the sensations produced by them. Experience therefore, and not speculation, is the grand criterion of musical phenomena. For the effects of geometry in illustrating the theory of music (if any will fill be so credulous as to pay them much attention), the English reader may consult Smith's Harmonics, Malcolm's Difcertation on Music, and Pleydel's Treatise on the same subject insert in a former edition of this work. Our author next treats of the famous discovery made by Sig. Tartini, of which the reader may accept the following compendious account.

If two sounds be produced at the same time properly tuned and with due force, from their conjunction a third sound is generated, so much more distinctly to be perceived by delicate ears as the relation between the generating sounds is more simple; yet from this rule we must except the union and octave. From the fifth is produced a sound union with its lowest generator; from the fourth, one which is an octave lower than the highest of its generators; from the third major, one which is an octave lower than its lowest; and from the fifth
MUSIC.

They have inserted in the Encyclopedia, under the article Fundamental, a detail of this experiment according to M. Tartini; and we owe to the public an information of which in composing this article we were ignorant; M. Rameau, a member of the Royal Society at Montpellier, had presented to that society in the year 1753, before the work of M. Tartini had appeared, a memorial printed the same year, and where may be found the same experiment displayed at full length. In relating this fact, which, it was necessary for us to do, it is by no means our intention to detract in any degree from the reputation of M. Tartini; we are persuaded that he owes this discovery to his own researches alone: but we think ourselves obliged in honour to give public testimony in favour of him who was the first in exhibiting this discovery.

But whatever be the case, it is in this experiment that M. Tartini attempts to find the origin of harmony: his book, however, is written in a manner so obscure, that it is impossible for us to form any judgment of it; and we are told that others distinguished for their knowledge of the science are of the same opinion. It were to be wished, that the author would engage some man of letters, equally practised in music and skilful in the art of writing, to unfold these ideas which he has not discovered with sufficient perspicuity, and from whence the art might perhaps derive considerable advantage if they were placed in a proper light. Of this I am so much the more persuaded, that even though this experiment should not be regarded by others in the same view with M. Tartini as the foundation of the musical art, it is nevertheless extremely probable that one might use it with the greatest advantage to enlighten and facilitate the practice of harmony.

In exhorting philosophers and artists to make new attempts for the advancement of the theory of music, we ought at the same time to let them know the danger of mistaking what is the real end of their researches. Experience is the only foundation upon which they can proceed; it is alone by the observation of facts, by bringing them together in one view, by showing their dependency upon one, if possible, or at least upon a very small number of primary facts, that they can reach the end to which they so ardently aspire, the important end of establishing an exact theory of music, where nothing is wanting, nothing obscure, but every thing discovered in its full extent, and in its proper light. The philosopher who is properly enlightened, will not give himself the trouble to explain such facts as are less essential to his art, because he can discern those on which he ought to expatiate for its proper illustration. If one would entire them according to their proper value, he will only find it necessary to cast his eyes upon the attempts of natural philosophers who have discovered the greatest skill in their science; to explain, for instance, the multiplicity of sounds produced by the bodies. These fages, after having remarked (what is by no means difficult to conclude) that the universal vibration of a musical string is a mixture of several partial vibrations, from thence infer, that a sonorous body ought to produce a multiplicity of tones, as it really does. But why should this multiplied sound only appear to contain three, and why these three preferable to others? Some pretend that there are particles in the air, which, by their different degrees of magnitude and texture, being naturally susceptible of different oscillations, produce the multiplicity of found in question. But what do we know of all this hypothetical doctrine? And though it should be granted, that there is such a diversity of tension in these aereal particles, how should this diversity prevent them from being all of them confounded in their vibrations by the motions of a sonorous body? What then should be the result, when the vibrations arrive at our ears, but a confused and inappreciable noise, where one could not distinguish any particular sound?

If philosophical musicians ought not to lose their time in searching for mechanical explications of the phenomena in music, explications which will always be found vague and unsatisfactory; much less is it their province to exhaust their powers in vain attempts to rife above their sphere into a region still more remote from the prospect of their faculties, and to lose themselves in a labyrinth of metaphysical speculations upon the causes of that pleasure which we feel from harmony. In vain would they accumulate hypothesis on hypothesis, to find a reason why some chords should please us.

Sixth minor (whose highest note forms an octave with the lowest in the third formerly mentioned) will be produced a found lower by a double octave than the highest of the lesser sixth; from the third minor, one which is double the distance of a greater third from its lowest; but from the sixth major (whose highest note makes an octave to the lowest in the third minor) will be produced a found only lower by double the quantity of a greater third than the highest; from the second major, a found lower by a double octave from the lowest; from a second minor, a found lower by triple the quantity of a third major than the highest; from the interval of a diatonic or greater femitone, a found lower by a triple octave than the highest; from that of a minor or chromatic semitone, a found lower by the quantity of a fifth four times multiplied than the lowest, &c. &c.

But that these musical phenomena may be tried by experiments proper to ascertain them, two hautboys tuned with scrupulous exactness must be procured, whilst the musicians are placed at the distance of some paces one from the other, and the hearers in the middle. The violin will likewise give the same chords, but they will be left distinctly perceived, and the experiment more fallacious, because the vibrations of other strings may be supposed to enter into it.

If our English reader should be curious to examine these experiments and the conclusions made from them in the theory of music, he will find them clearly explained and illustrated in a treatise called Principles and Power of Harmony, printed at London 1771.
Elements.

Music.

Let us in sincerity confess our ignorance concerning the genuine causes of these effects (+). The metaphysical considerations concerning the acoustical organs are probably in the same predicament with those which are formed concerning the organs of vision, if one may speak so, in which philosophers have even till now made such incon siderable progress, and in all likelihood will not be surpassed by their successors.

Since the theory of music, even to those who confine themselves within its limits, implies questions from which every wise musician will abstain, with much greater reason should they avoid idle excursions beyond the boundaries of that theory, and endeavours to investigate between music and the other sciences chimerical relations which have no foundation in nature. The singular opinions advanced upon this subject by some even of the most celebrated musicians, deserve not to be rescued from oblivion, nor refuted; and ought only to be regarded as a new proof how far men of genius may deviate from truth and taste, when they engage in subjects of which they are ignorant.

The rules which we have attempted to establish concerning the track which every one ought to pursue in the theory of the musical art, may suffice to show our readers the end which we have proposed, and which we have endeavoured to attain in this Work. We have nothing to do here (for it is proper that we repeat it), we have nothing to do with the mechanical principles of protracted and harmonic tones produced by sonorous bodies; principles which till now have been explored in vain, and which perhaps may be long explored with the same success; we have still

3 S

less

(+). We have as great an aversion as our author to the explication of musical phenomena from mechanical principles; yet we fear the following observations, deduced from irrefutable and universal experience, evidently show that the latter necessarily depend on the former. It is, for instance, universally allowed, that dissonances grate and concords please a musical ear; it is likewise no less unanimously agreed, that in proportion as a chord is perfect, the pleasure is increased; now the perfection of a chord consists in the regularity and frequency of coincident oscillations between two sonorous bodies impelled to vibrate; thus the third is a chord less perfect than the fifth, and the fifth than the octave. Of all these consonances, therefore, the octave is most pleasing to the ear; the fifth next, and the third last. In absolute discord, the vibrations are never coincident, and of consequence a perpetual pulsation or jarring is recognized between the protracted sounds, which exceedingly hurts the ear; but in proportion as the vibrations coincide, those pulsations are superceded, and a kindred formed betwixt the two continued sounds, which delights even the corporeal senses: that relation, therefore, without recognizing the aptitudes which produce it, must be the obvious cause of the pleasure which chords give to the ear. What we mean by coincident vibrations is, that while one sonorous body performs a given number of vibrations, another performs a different number in the same time; so that the vibrations of the quickest must sometimes be simultaneous with those of the slowest, as will plainly appear from the following demonstration: Between the extremes of a third, the vibrations of the highest are as 5 to 4 of the lowest; those of the fifth as 3 to 2; those of the octave as 2 to 1. Thus it is obvious, that in proportion to the frequent coincidence of periodic vibrations, the compound sensation is more agreeable to the ear. Now, to inquire why that organ should be rather pleased with these than with the pulsation and tremulous motion of encountering vibrations which can never coincide, would be to ask why the touch is rather pleased with polished than rough surfaces? or, why the eye is rather pleased with the waving line of Hogarth than with sharp angles and abrupt or irregular prominences? No alteration of which any chord is susceptible will hurt the ear unless it should violate or destroy the regular and periodical coincidence of vibrations. When alterations can be made without this disagreeable effect, they form a pleasing diversity; but still this fact corroborates our argument, that in proportion as any chord is perfect, it is impatient of the smallest alteration; for this reason, even in temperament, the octave endures no alteration at all, and the fifth as little as possible.
lefs to do with the metaphysical causes of those plea-
ing sensations which are impressed on the mind by
harmony; causes which are still less discovered, and
which, according to all appearances, will remain latent
in perpetual obscurity. We are alone concerned to
show how the chief and most essential laws of harmony
may be deduced from one single experiment; and for
which, if we may speak so, preceding artists have been
under a necessity of groping in the dark.

With an intention to render this work as generally
useful as possible, I have endeavored to adapt it to
the capacity even of those who are absolutely unin-
structed in music. To accomplish this design, it ap-
ppeared necessary to pursue the following plan.

To begin with a short introduction, in which are
defined the technical terms most frequently used in this
art; such as chord, harmony, key, third, fifth, octave, &c.

Afterwards to enter into the theory of harmony,
which is explained according to M. Rameau, with all
possible perspicuity. This is the subject of the First
Part; which, as well as the introduction, presupposes
no other knowledge of music than that of the names
and powers of the syllables, ut, re, mi, fa, sol, la, ti, or
C, D, E, F, G, A, B, which all the world knows (†).

The theory of harmony requires some arithmetical
calculations, which are necessary for comparing founds
one with another. These calculations are very short,
extremely simple, and conducted in such a manner as
not to be feebly comprehended by every one; they de-
mand no operation but what is clearly explained,
and which every school boy with the greatest simplic-
ity, and other calculations not transferable to fenil
objects but that of the third major as 4 to 5, &c. are not perhaps
transferred to fémil

Thefe calculations I have not endeavoured to mul-
triply; I could even have wished to suppress them, if it
had been possible: so much did it appear to me to be
apprehended that my readers might be miffed upon
this subject, and might either believe themselves, or
at least suspect me of believing, all this arithmetic
necessary to form an artif. Calculations may indeed
facilitate the understanding of certain points in the
theory, as of the relations between the different notes
in the gamut and of the temperament; but the cal-
culations necessary for treating of these points are fo
simple, and, to speak more properly, of too little im-
portance, that nothing can require a lefs minute or

Oftentations display. Do not let us imitate those mu-
icians who, believing themselves geometers, or those
gemeaters who, believing themselves musicians, fill
their writings with fures upon figures; imagining,
perhaps, that this apparatus is necessary to the art.
The propensity of adorning their works with a false
air of science, can only impose upon credulity and
ignorance, and serve no other purpose but to render
their treatises more obscure and less instructive. In
the character of a geometer, I think I have some right
to protest here (if I may be permitted to express myself
in this manner) against fuch ridiculous abuse of geo-
metry in music.

This I may do with so much more reason, that in
this subject the foundations of those calculations are
in some manner hypothetical, and can never arrive to
a degree of certainty above hypothesis. The relation
of the octave as 1 to 2, of that in the fifth and third,
may be fpared to fuch as are not disposed to take it,
whether the genuine relations established in nature; but only
relations which approach them, and such as experience
can discover. For are the refults of experience any
thing more but mere approaches to truth?

But happily these approximated relations are suf-
cient, though they should not be exactly agreeable
to truth, for giving a satisfactory account of those phe-
omena which depend on the relations of found; as
in the difference between the notes in the gamut, of
the alterations necessary in the fifth and third, of
the different manner in which instruments are tuned,
and other facts of the fame kind. If the relations
of the octave, of the fifth, and of the third, are not

The secound part contains the most esential rules of
composition *; or in other words the practice of * See Com-
harmony. These rules are founded on the principles position.
laid down in the first part; yet those who wish to
understand no more than is necessary for practice,
without exploring the reasons why such practical
rules are necessary, may limit the objects of their
study to the introduction and the secound part. They
who have read the first part, will find at every rule
contained in the second, a reference to that passage in

(†) The names of the seven notes used by the French are here retained, and will indeed be continued
through the whole ensuing work; as we imagine, that, if properly associated with the founds which they de-
nominate, they will tend to impress these sounds more distinctly on the memory of the scholar than the letters
C, D, E, F, G, A, B, from which characters, except in syllables, the notes in the diatonic series are gene-

92. Some rules on the part of rules and observations which are left to the reader to establish and practice, without the necessity of reading the whole; and beginning with the fundamental principles, I have not the remotest claim. The whole part which I proposed was to be useful; to teach the reader to succeed one in another, do not seek to find my endeavours unsatisfactory.

DEFINITIONS OF SEVERAL TECHNICAL TERMS.

1. What is meant by Melody, by Chord, by Harmony, by Interval.

2. That which arises from the mixture of several sounds heard at the same time; and harmony is properly a series of chords which in their succession one to another delights the ear. A single chord is like the sometimes called harmony, to signify the coalescence of sounds which that chord creates, and the satisfaction produced in the ear by that coalescence. We shall occasionally use the words harmony in this last sense, but in such a manner as never to leave our meaning ambiguous.

3. In melody and harmony, the distance between one sound and another is called an interval; and this is increased and diminished as the sounds between which it intervenes are higher or lower than the other.

4. That we may learn to distinguish the intervals, and the manner of perceiving them, let us take the ordinary scale ut, re, mi, fa, sol, la, ti, ut, C, D, E, F, G, A, B, C, every person whose ear or voice is not extremely false, naturally modulates. These are the observations which will occur to us in singing this gamut.

The sound re is higher or sharper than the sound ut, and the found mi higher than the found re, the found fa the simple sound higher than the found mi, &c. and so through the whole series of intervals, ut, re, mi, fa, sol, la, ti, ut, C, D, E, F, G, A, B, C, every person whose ear or voice is not extremely false, naturally modulates. These are the observations which will occur to us in singing this gamut.

5. In general, the interval between two sounds is proportionally greater, as one of these sounds is higher or lower with relation to the other: but it is between necessary to observe, that two sounds may be of equal and high or low, though unequal in their force. The string of a violin touched with a bow produces always a sound equally high, whether strongly or faintly struck; the sound will only have a greater or lesser degree of strength. It is the same with vocal modulation.

(1) From my general recommendation of this code, I except the reflections on the principles of sound which are at the end, and which I think not advisable any one to read.

(x) Printed at Paris by Lambert in the year 1754.

(1) That criticism and my answers may be seen in the Journeaux Economiques of 1752.
9. As interval composed of a tone and a semitone, as from mi to fa, from la to ut, or from re to fa, is called a third minor.

An interval composed of two full tones as from ut mi, from fa to la, or from fol to fi, is called a third major.

An interval consisting of two tones and a semitone, as from ut to fa, or from fol to ut is called a fourth. Triton, what.

An interval consisting of three full tones, as from fi to fi, is called a triton or fourth redundant.

An interval composed of three tones and a semitone, as from ut to fol, from fa to ut, from re to la, or from mi to fi, &c. is called a fifth.

An interval composed of three tones and two semitones, as from mi to ut, is called a sixth minor.

An interval composed of four tones and a semitone, as from ut la, is called a sixth major.

An interval consisting of four tones and two semitones, as from re to ut is called a seventh minor.

An interval composed of five tones and a semitone, as from ut to fi, is called a seventh major.

And

(a) This experiment may be easily tried. Let any one sing the scale of ut, re, mi, fa, fol, la, fi, ut, it will be immediately observed without difficulty, that the last four notes of the octave are quite similar to the first ut, re, mi, fa; inasmuch, that if, after having sung this scale, one would chose to repeat it beginning with ut in the same tone which was occupied by fol in the former scale, the note re of the last scale would have the same found with the note la in the first, the mi with the fi, and the fa with the ut.

From whence it follows, that the interval between ut and re is the same as between fol and la; between re and mi, as between la and fi; and mi and fa, as between fi and ut.

It will likewise be found, that from re to mi, from fa to fol, there is the same interval as from ut to re. To be convinced of this, we need only sing the scale once more; then sing it again, beginning with ut, in this last scale, in the same tone which was given to re in the first; and it will be perceived, that the re in the second scale will have the same found, at least as far as the ear can discover, with the mi in the former scale; from whence it follows, that the difference between re and mi is, at least as far as the ear can perceive, equal to that between ut and re.

It will also be found, that the interval between fa and fol is, so far as our senses can determine, the same with that between ut and re.

This experiment may perhaps be tried with some difficulty by those who are not inured to form the notes and change the key; but such may very easily perform it by the assistance of a harpsichord, by means of which the performer will be favorably the trouble of retaining the sounds in one intonation whilst he performs another. In touching upon this harpsichord the keys fol, la, fi, ut, and in performing with the voice at the same time ut, re, mi, fa, in such a manner that the same sound may be given to ut in the voice with that of the key fol in the harpsichord, it will be found that re in the vocal intonation shall be the same with la upon the harpsichord, &c.

It will be found likewise by the same harpsichord, that if one should sing the scale beginning with ut in the same tone with mi on the instrument, the re which ought to have followed ut, will be higher by an extremely perceptible degree than the fa which follows mi: thus it may be concluded, that the interval between mi and fa is less than between ut and re; and if one would rise from fa to another found which is at the same distance from fa as fa from mi, he would find in the same manner, that the interval from mi to this new found is almost the same as that between ut and re. The interval then from mi to fa is nearly half of that between ut and re.

Since then, in the scale thus divided ut, re, mi, fa, fol, la, fi, ut, the first division is perfectly like the last; and since the intervals between ut and re, between re and mi, and between fa and fol, are equal; it follows, that the intervals between fol and la, and between la and fi, are likewise equal to every one of the three intervals between ut and re, between re and mi, and between fa and sol; and that the intervals between mi and fa and between fi and ut are also equal, but that they only constitute one half of the others.
Elements.

Definitions.

1. 1st. An interval consisting of five tones and two semitones, as from ut to UT, is called an octave. A great many of the intervals which have now been mentioned, are still signified by other names, as may be seen in the beginning of the second part; but those which we have now given are the most common, and the only terms which our present purpose demands.

10. Two sounds equally high, or equally low, however unequal in their force, are said to be in unison one with the other.

11. If two sounds form between them any interval, whatever it be, we say, that the highest when ascending is in that interval with relation to the lowest; and when descending, we pronounce the lowest in the same interval with relation to the highest. Thus in the third minor, mi, sol, where mi is the lowest and sol the highest; sol is a third minor from mi ascending, and mi is third minor from sol in descending.

12. In the same manner, if speaking of two sonorous bodies, we should say, that the one is a fifth above the other in ascending; this infers that the sound given by the one is at the distance of a fifth ascending from the sound given by the other.

III. Of Intervals greater than the Octave.

13. If, after having sung the scale ut, re, mi, fa, sol, la, si, UT, one would carry this scale still farther in ascent, it would be discovered without difficulty, that a new scale would be formed, UT, RE, MI, FA, &c. entirely similar to the former, and of which the sounds will be an octave ascending, each to its correspondent note in the former scale; thus RE, the second note of the second scale, will be an octave in ascent to the re of the first scale: in the same manner MI shall be the octave to mi, &c. and so of the rest.

14. As there are nine notes from the first ut to the second RE, the interval between these two sounds is called a ninth, and this ninth is composed of six full fifths, tones and two semitones. For the same reason the interval from ut to FA is called an eleventh, and the interval between ut and SOL, a twelfth, &c.

It is plain that the ninth is the octave of the seventh, eleventh the fourteenth of the fourth, and the twelfth of the fifteenth.

The octave above the octave of any sound is called a double octave; the octave of the double octave is called a triple octave, and so of the rest.

The double octave is likewise called a fifteenth; and for the same reason the double octave of the third is called a seventeenth, the double octave of the fifth a ninetieth, &c. (b).

IV. What is meant by Sharps and Flats.

15. It is plain that one may imagine the five tones Sharps and Flats, what enter into the scale, as divided each into two semitones; thus one may advance from ut to re, forming in his progress an intermediate sound, which shall be higher by a semitone than ut, and lower in the same degree than re. A sound in the scale is called flat, when it is raised by a semitone; and it is marked with this character: thus ut flat signifies ut, that is to say, ut raised by a semitone above its pitch in the natural scale. A sound in the scale depressed by a semitone is called flat, and is marked thus, b; thus la b signifies la flat, or la depressed by a semitone.

V. What is meant by Consonances and Dissonances.

16. A chord composed of sounds whose union or consonance pleases the ear is called a consonance; and one, the sounds which form this chord are said to be consonant.

(a) Let us suppose two vocal strings formed of the same matter, of the same thickness, and equal in their tension, but unequal in their length, it will be found by experience.

1/6. That the shortest is equal to half the longest, the found which it will produce must be an octave above the found produced by the longest.

2d/o, That if the shortest constitutes a third part of the longest, the found which it produces must be a twelfth above the found produced by the longest.

3d/o, That if it constitutes the fifth part, its found will be a seventeenth above.

Besides, it is a truth demonstrated and generally admitted, that in proportion as one musical string is less than another, the vibrations of the leaf will be more frequent (that is to say, its departures and returns through the same space) in the same time; for instance, in an hour, a minute, a second, &c. in such a manner that one string which constitutes a third part of another, forms three vibrations, whilst the largest has only accomplished one. In the same manner, a string which is one half less than another, performs two vibrations, whilst the other only completes one; and a string which is only the fifth part of another, will perform five vibrations in the same time which is occupied by the other in one.

From thence it follows, that the sound of a string is proportionally higher or lower, as the number of its vibrations is greater or smaller in a given time; for instance, in a second.

It is for that reason, that if we represent any sound whatever by 1, one may represent the octave above by 2, that is to say, by the number of vibrations formed by the string which produces the octave, whilst the longest string only vibrates once; in the same manner we may represent the twelfth above the found 1 by 3, the seventeenth major above 5, &c. But it is very necessary to remark, that by these numerical expressions, we do not pretend to compare sounds as such; for sounds in themselves are nothing but mere sensations, and it cannot be said of any sensation that it is double or triple to another: thus the expressions 1, 2, 3, &c. employed to denominate a sound, its octave above, its twelfth above, &c. signify only, that if a string performs a certain number of vibrations, for instance, in a second, the string which is in the octave above shall double the number in the same time, the string which is in the twelfth above shall triple it, &c.

Thus to compare sounds among themselves is nothing else than to compare among themselves the numbers of vibrations which are formed in a given time by the strings that produce those sounds,
MUSIC

Definitions.

17. The octave of a found is the most perfect of confronances of which that found is susceptible; then the fifth, afterwards the third, &c. This is a fact founded on experiment.

18. A number of founds simultaneously produced whose union is displeasing to the ear is called a diffusion, and the founds which form it are said to be dissonant one with relation to the other. The second, the triton, and the seventh of a found, are diffonants see Diffusion, with relation to it. Thus the founds ut re, ut fi, or cord. fa, fi, &c. simultaneously heard, form a diffusion.

The reason which renders diffusion disagreeable, is, that the founds which compose it, seem by no means coalescent to the ear, and are heard each of them by itself as distinct founds, though produced at the same time.

PART I. THEORY OF HARMONY.

CHAPTER I. Preliminary and Fundamental Experiments.

Experiment I.

When a sonorous body is struck until it gives a found, the ear, besides the principal found and its octave, perceives two other founds very high, of which one is the twelfth above the principal found, that is to say, the octave to the fifth of that found; and the other is the seventeenth major above the same found, that is to say, the double octave of its third major.

20. This experiment is peculiarly sensible upon the thick strings of the violoncello, of which the found being extremely low, gives to an ear, though not very much practised, an opportunity of distinguishing with sufficient ease and clearness the twelfth and seventeenth now in question (c).

21. The principal found is called the generator*; * See Ge- and resonor.

---

(c) Since the octave above the found 1 is 2, the octave below that same found shall be 1; that is to say, that the striking which produces this octave shall have performed half its vibration, whilst the striking which produces the found 1 shall have completed one. To obtain therefore the octave above any found, the operator must multiply the quantity which expresses the found by 2; and to obtain the octave below, he must on the contrary divide the same quantity by 2.

It is for that reason that if any found whatever, for instance ut, is denominated

| Its octave above will be | - | - | - | - | 1 |
| Its double octave above | - | - | - | - | 2 |
| Its triple octave above | - | - | - | - | 4 |
| In the same manner its octave below will be | - | - | - | - | 1 |
| Its double octave below | - | - | - | - | 2 |
| Its triple octave below | - | - | - | - | 4 |

And so of the rest.

Its twelfth above | - | - | - | - | 3 |
Its twelfth below | - | - | - | - | 3 |
Its 17th major above | - | - | - | - | 5 |
Its 17th major below | - | - | - | - | 5 |

The fifth then above the found 1, being the octave beneath the twelfth, shall be, as we have immediately observed, 1; which signifies that this striking performs 1 vibrations; that is to say, one vibration and a half during a single vibration of the string which gives the found 1.

To obtain the found above the found 1, we must take the twelfth below that found, and the double octave above that twelfth. In effect, the twelfth below 1, for instance, is fa, of which the double octave fa is the fourth above ut. Since then the twelfth below 1 is 1, it follows that the double octave above this twelfth, that is to say, the fourth from the found 1 in ascending, will be multiplied by 4, or 2.

In short, the third major being nothing else but the double octave beneath the seventeenth, it follows, that the third major above the found 1 will be 5 divided by 4, or in other words 5.

The third major of a found, for instance the third major mi, from the found ut, and its fifth sol, form between them a third minor mi, sol; now mi is 5, and sol 5, by what has been immediately demonstrated; from whence it follows, that the third minor, or the interval between mi and sol, shall be expressed by the relation of the fraction 5 to the fraction 1.

To determine this relation, it is necessary to remark, that 5 is the same thing with 5, and that 5 are the same thing with 5: so that 5 shall be to 5 in the same relation as 5 to 5; that is to say, in the same relation as 10 to 12, or as 5 to 6. If, then, two founds form between them a third minor, and that the first is represented by 5, the second shall be expressed by 6; or, what is the same thing, if the first is represented by 1, the second shall be expressed by 5.
22. There is no person insensible of the resemblance which subsists between any found and its octave, whether above or below. These two founds when heard together, almost entirely coalesce in the organ of sensation. We may besides be convinced (by two facts which are extremely simple) of the facility with which one of these founds may be taken for the other.

Let it be supposed that any person has an inclination to sing a tune, and having at first begun this air upon a pitch too high or too low for his voice, so that he is obliged, lest he should strain himself too much, to sing the tune in question on a key higher or lower than the first; I affirm, that without being initiated in the art of music, he will naturally take his new key in the octave below or the octave above the first; and that in order to take this key in any other interval except the octave, he will find it necessary to exert a sensible degree of attention. This is a fact of which we may easily be persuaded by experience.

Another fact. Let any person sing a tune in our presence, and let it be sung in a tone too high or too low for our voice; if we will to join in singing this air, we naturally take the octave below or above, and frequently, in taking this octave, we imagine it to be the unison (p).

23. To render our ideas still more precise and permanent, we shall call the tone produced by the for- 

24. This octave of sol then, and this double octave of mi, produce the most perfect chord which can be joined with ut, since that chord is the work and choice of nature (v).

25. For the same reason, the modulation formed by ut with the octave of sol and the double octave of mi, as well as one after the other, would likewise be the most simple and natural of all modulations which do not descend or ascend directly in the diatonic order, if our voices had sufficient compass to form intervals so great without difficulty: but the ease and freedom with which

Thus the third minor, an harmonic found which is even found on the protracted and coalescent tones of a sonorous body between the found mi and sol, an harmonic of the principal found, may be expressed by the fraction 3.

N. B. One may see by this example, that in order to compare two founds one with another which are expressed by fractions, it is necessary first to multiply the numerator of the fraction which expresses the first by the denominator of the fraction which expresses the second, which will give a primary number; as here the numerator 5 of the fraction 9, multiplied by 2 of the fraction 1, has given 10. Afterwards may be multiplied the numerator of the second fraction by the denominator of the first, which will give a secondary number, as here 12 is the product of 4 multiplied by 3; and the relation between these two numbers (which in the preceding example are 10 and 12), will express the relation between these founds, or, what is the same thing, the interval which is between the one and the other; in such a manner, that the farther the relation between these founds departs from unity, the greater the interval will be.

Such is the manner in which we may compare two founds one with another whose numerical value is known.

We shall now show the manner how the numerical expression of a found may be obtained, when the relation which it ought to have with another found is known whose numerical expression is given.

Let us suppose, for example, that the third major of the fifth is sought. That third major ought to be, by what has been shown above, the 9 of the fifth, for the third major of any found whatever is the 9 of that found.

We must then look for a fraction which expresses the 9 of 1; which is done by multiplying the numerators and denominators of both fractions one by the other, from whence results the new fraction 19. It will likewise be found that the fifth of the fifth is the 9 of 1.

Thus far we have only treated of fifths, fourths, thirds major and minor in ascending; now it is extremely easy to find by the same rules the fifths, fourths, thirds major and minor in descending. For suppose ut equal to 1, we have seen that its fifth, its fourth, its third, its major and minor in ascending, are 9, 19, 19, 19. To find its fifth, its fourth, its third, its major and minor in descending, nothing more is necessary than to reverse these fractions, which will give 1, 9, 9, 9, 9.

(p) It is not then imagined that we change the value of a found in multiplying or dividing it by 2, by 4, or by 8, &c. the number which expresses these founds, since by these operations we do nothing but take the simple, double, or triple octave, &c. of the found in question, and that a found coalesces with its octave.

(s) The chord formed with the twelfth and seventeenth major united with the principal found, being exactly conformed to that which is produced by nature, is likewise for that reason the most agreeable of all; especially when the composer can proportion the voices and instruments together in a proper manner to give this chord its full effect. M. Rameau has executed this with the greatest success in the opera of Pygmalion page 34, where Pygmalion sings with the chorus, L'amour triomphe, &c.; in this passage of the chorus, the two parts of the vocal and instrumental basses give the principal found and its octave; the first part above, or treble, and that of the counter-tenor, produce the seventeenth major, and its octave, in descending; and in short, the second part or tenor above, gives the twelfth.
which we can substitute its octave to any found, when it is more convenient for the voice, afford us the mean of representing this modulation.

26. It is on this account that, after having sung the tone ut, we naturally modulate the third mi, and the fifth fa, instead of the double octave of mi, and the octave of fol; from whence we form, by joining the modulation of the octave of the found ut, this modulation, ut, mi, fol, ut, which in effect is the simplest and easiest of them all; and which likewise has its origin even in the protracted and compounded tones produced by a sonorous body.

27. The modulation ut, mi, fol, ut, in which the chord ut, mi, is a third major, constitutes that kind of harmony or melody which we call the mode major; from whence it follows, that this mode results from the immediate operation of nature.

28. In the modulation ut, mi, fol, of which we have now been treating, the founds mi and fol are so proportioned one to the other, that the principal found ut (art. 19.) causes both of them to sound; but the second tone mi does not cause fol to sound, which only forms the interval of a third minor.

29. Let us then imagine, that, instead of this found mi, one should substitute between the founds ut and fol another note which (as well as the founds ut) has the power of causing fa to sound, and which is, however, different from the found ut; the found which we explore ought to be fah, by art. 19. that it may have for its 17th major fol, or one of the octaves of fol; of consequence the found which we seek ought to be a 17th major below fol, or, what is the same thing, a third major below the found fol. Now the found mi being a third minor below fol, and the third major being (art. g.) greater by a semitone than the third minor, it follows, that the found of which we are in search shall be a semitone beneath the natural mi, and of consequence mi,.

30. This new arrangement, ut, mi, fol, in which the founds ut and mi have both the power of causing fol to sound, though ut does not cause mi to sound, is not indeed equally perfect with the first arrangement ut, mi, fol; because in this the two founds ut and fol are both the one and the other generated by the principle found ut; whereas, in the other, the found mi is not generated by the found ut; but this arrangement ut, mi, fol, is likewise dictated by nature (art. 19.), though less immediately than the former; and accordingly experience evinces that the ear accommodates itself almost as well to the latter as to the former.

31. In this modulation or chord ut, mi, fol, ut, Origin of it is evident that the third from ut to mi, is minor; mode mi and such is the origin of that mode which we call minor (heading).

32. The most perfect chords then are, 1. All chords related one to another, as ut, mi, fol, ut, consisting of any found of its third major, of its fifth, and of its Perfect octave. 2. All chords related one to another, as ut, mi, fol, ut, consisting of any found of its third minor, of its fifth, and of its octave. In effect, these two kinds of chords are exhibited by nature: but the first more immediately than the second. The first are called perfect chords major, the second perfect chords minor.

CHAP. III. Of the Series which the Fifth requires, and of the Lows which it observes.

33. Since the found ut causes the found fol to be Fundamental, and is itself heard in the found fa, which founds fol and fa are its two-twelfths, we may imagine a modulation composed of that found ut and its two-twelfths, or, which is the same thing (art. 22.), of its two-fifths, fa and fa, the one below, the other above; which gives the modulation or series of fifths fa, ut, fol, which I call the fundamental basis of ut by fifths.

We shall find in the sequel (Chap. XVIII.), that there may be some fundamental bases by thirds, deduced from the two seventeenth, in which the one is an attendant of the principal found, and of which the other includes that found. But we must advance step by step, and satisfy ourselves at present to consider immediately the fundamental bases by fifths.

34. Thus, from the found ut, one may make a transition indirectly to the found fol, or to the found fa.

35. One may for the same reason, continue this kind of fifths in ascending and in descending, from ut, in this manner:

fa, fol, ut, mi, fol, fa, ut, sa, etc.

And from this series of fifths one may pass to any found which immediately precedes or follows it.

36. But it is not allowed in the same manner to pass

The origin which we have here given of the mode minor, is the most simple and natural that can possibly be given. In the first edition of this treatise, I had followed M. Rameau in deducing it from the following experiment.—If you put in vibration a musical string AB, and if there are at the same time contiguous to the two other strings CF, LM, of which the first shall be a twelfth below the string AB, and the second a seventeenth major below the same AB, the strings CF, LM, will vibrate without being struck as soon as the string AB shall give a found, and divide themselves by a kind of undulation, the first into three, the last into five equal parts; in such a manner, that in the vibration of the string CF, you may easily distinguish two points at rest D, E, and in the tremulous motion of the string LM four sequent points N, O, P, Q, all placed at equal distances from each other, and dividing the strings into three or five equal parts. In this experiment, says M. Rameau, if we represent by ut the tone of the string AB, the two other strings will represent the founds fa and la, and from thence M. Rameau deduces the modulation fa, la, ut, and of consequence the mode minor. The origin which we have assigned to the minor mode, in this new edition, appears to me more direct and more simple, because it presupposes no other experiment than that of art 19, and because also the found equal found ut is still retained in both the modes, without being obliged, as M. Rameau found himself, to change it into fa.
Chapter IV. Of Modes in general.

38. A mode, in music, is nothing else but the order of sounds prescribed, as well in harmony as melody, by the series of fifths. Thus the three sounds fa, ut, sol, and the harmonics of each of these three sounds, that is to say, their thirds major and their fifths, compose all the major modes which are proper to ut.

39. The series of fifths then, or the fundamental series fa, ut, sol, of which ut holds the middle space, may be regarded as representing the mode of ut. One may likewise take the series of fifths, or fundamental series, ut, sol, re, as representing the mode of fa; in the same manner, fa, ut, will represent the mode of fa.

By this we may see, that the mode of fa, or rather the fundamental series of that mode, has two sounds in common with the fundamental series of the mode of ut. It is the same with the fundamental series of the mode of fa.

40. The mode of ut (fa, ut, sol) is called the principal mode with respect to the modes of these two fifths, which are called its two adjunctors.

41. It is then, in form, measure, indifferent to the ear whether a transition be made to the one or to the other of these adjunctors, since each of them has equally two sounds in common with the principal mode.

Yet the mode of fa seems a little more eligible: for fa is heard amongst the harmonics of ut, and of consequence is implied and signified by ut, whereas ut does not cause fa to be heard, though ut is included in the same sound. It is hence that the ear, affected by the mode of ut, is a little more prepossessed for the mode of fa than for that of fa. Nothing likewise is more frequent, nor more natural, than to pass from the mode of ut to that of fa.

42. It is for this reason, as well as to distinguish the two fifths one from the other, that we call fa the fifth above the generator the dominant found, and the satellite fa beneath the generator the subdominant.

43. It remains to add, as we have seen in the preceding chapter, that, in the series of fifths, we may indifferently pass from one found to that which is contiguous: In the same manner, and for the same reason, one may pass from the mode of fa to the mode of ut, after having made a transition from the mode of ut to the mode of fa, as from the mode of fa to the mode of f. But it is necessary, however, to observe, that the ear which has been immediately affected with the principal mode feels always a strong propensity to return to it. Thus the further the mode to which we make a transition is removed from the principal mode, the less time we ought to dwell upon it; or rather, to speak in the terms of the art, the less ought the phrase (1aa) of that mode to be protracted.

Chapter V. Of the Formation of the Diatonic Scale at ut.f by the Greeks.

44. From this rule, that two sounds which are contiguous may be placed in immediate succession in the series of fifths, fa, ut, sol, it follows, that one may form this modulation, or this fundamental bafs, by fifths, sol, fa, ut, sol, fa, ut.

45. Each of the sounds which forms this modulation brings necessarily along with itself its third major, its fifth, and its octave; infomuch that he who, for the formation of the Greek diatonic scale, raises the note sol, may be reckoned to sing at the same time the notes sol, fa, re, sol; in the same manner the found ut in the fundamental bafs brings along with it this modulation, ut, mis sol, ut; and, in the fundamental bafs, the same sound fa brings along with it fa, la, baf, ut, fa.

This modulation then, or this fundamental bafs, sol, fa, ut, sol, fa, ut, fa, gives the following diatonic series, fa, ut, re, mis sol, sol, la, which is precisely the diatonic scale of the Greeks. We see that are ignorant upon what principles they had formed this scale; but it may be discerned perceived, that that series arises from the bafs sol, ut, sol, ut, ut, fa, ut; and of consequence this bafs is justly called fundamental, as being the real primitive modulation, which

Vol. XII.

(g) I say especially if they are major; for in the major chord re, fa, la, re, besides that the sounds ut and re have no common harmonic relation, and are even different between themselves (Art. 18.), it will likewise be found, that fae forms a dissonance with ut. The minor chord, re, fa, la, re, would be more tolerable, because the natural fa which occurs in this chord carries along with it its fifth ut, or rather the octave of that fifth. It has likewise been sometimes the practice of composers, though rather by a licence indulged them than freely agreeable to their art, to place a minor in diatonic succession to a major chord.

(1aa) As the more English reader, unacquainted with the technical phraseology of music, may be surprised at the use of the word phrase when transferred from language to that art, we have thought proper to infer the definition of Rouelle.

A phrase, according to him, is in melody a series of modulations, or in harmony a succession of chords, which form without interruption a feint more or less complete, and which terminate in a repose by a cadence more or less perfect.
concludes the ear, and which it feels to be implied in the diatonic modulation, \( f_5, ut, re, mi, fa, fol, la \) (\( n \)).

We shall be still more convinced of this truth by the following remarks.

In the modulation \( f_5, ut, re, mi, fa, fol, la \), the sounds \( re \) and \( fa \) form between themselves a third minor, which is not so perfectly true as that between \( mi \) and \( fol \) (1). Nevertheless, this alteration in the third minor between \( re \) and \( fa \) gives the ear no pain, because that \( re \) and that \( fa \), which do not form between themselves a true third minor, form, each in particular, consonances perfectly just with the sounds in the fundamental bases which correspond with them: for \( re \) in the scale is the true fifth of \( fol \), which answers to it in the fundamental bases; and \( fa \) in the scale is the true octave of \( fa \), which answers to it in the same bases.

If, therefore, these sounds in the scale form consonances perfectly true with the notes which correspond to them in the fundamental bases, the ear gives itself little trouble to investigate the alterations which there may be in the intervals which these sounds in the scale form between themselves. This is a new proof that the fundamental bases is the genuine guide of the ear, and the true origin of the diatonic scale.

Moreover, this diatonic scale includes only seven sounds, and goes no higher than \( f_5 \), which would be the octave of the first: a new singularity, for which a reason may be given by the principles above established. In reality, in order that the sound \( f_5 \), may succeed immediately in the scale to the sound \( la \), it is necessary that the note \( fol \), which is the only one from whence \( f_5 \) as a harmonic may be deduced, should immediately succeed to the sound \( fa \) in the fundamental bases, which is the only one from whence \( la \) can be harmonically deduced. Now, the diatonic succession from \( fa \) to \( fol \) cannot be admitted in the fundamental bases, according to what we have remarked (art. 36.) The sounds \( fa \) and \( f_5 \), then, cannot immediately succeed one another in the scale: we shall see in the sequel why this is not the case in the series \( ut, re, mi, fa, fol, la \), \( f_5, UT \), which begins upon \( ut \); whereas the scale in question here begins upon \( f_5 \).

The Greeks likewise, to form an entire octave, completed added before the first \( f_5 \) the note \( la \), which they distinguished and separated from the rest of the scale, and which for that reason they called \( proflamabonamen \) (= not subject to division). See Pro. Rameau, when he published, in 1726, his New theoretical and practical System of Music, had not as yet found the true reason of the alteration in the consonances which is between \( re \) and \( fa \), and of the little attention which the ear pays to it. For he pretends, in the work now quoted, that there are two thirds minor, one in the proportion of \( 5 \) to \( 6 \), the other in the proportion of \( 27 \) to \( 32 \). But the opinion which he has afterwards adopted, seems much preferable. In reality, the genuine third minor, is that which is produced by nature between \( mi \) and \( fol \), in the continued tone of these honorous bodies of which \( mi \) and \( fol \) are the two harmonies; and that third minor, which is in the proportion of \( 5 \) to \( 6 \), is likewise that which takes place in the minor mode, and not that third minor which is false and different, being in the proportion of \( 27 \) to \( 32 \).
Part I. Theory of Harmony.

137. Intervals in both tetrachords equal.

51. Moreover, the intervals between any two sounds, taken in each tetrachord in particular, are precisely true: thus, in the first tetrachord, the intervals of ut, re, mi, fa; fol, la, ut are thirds, the one major and the other minor, exactly true, as well as the fourth. The same thing is true with the tetrachord mi, fa, sol, la, since this tetrachord is exactly like the former.

52. But the case is not the same when we compare two sounds taken each from a different tetrachord; for we have already seen, that the note re is the second tetrachord with the note fa in the second a third minor, which is not true. In like manner it will be found, that the fifth from re to la is not exactly true, which is evident; for the third major from fa to la is true, and the third minor from re to fa is not so; nor, in order to form a true fifth, a third major and a third minor, which are both exactly true, are necessary.

53. From thence it follows, that every consonance is absolutely perfect in each tetrachord taken by itself; but that there is some alteration in passing from one tetrachord to the other. This is a new reason for distinguishing the scale into these two tetrachords.

54. It may be ascertained by calculation, that in the tetrachord fa, ut, re, mi, the interval, or the tone from re to mi, is a little less than the interval or tone from ut to re (a). In the same manner, in the second tetrachord mi, fa, sol, la, which is, as we have proved, perfectly similar to the first, the note from sol to la is a little less than the note from fa to fol. It is for this reason that they distinguish two kinds of tones; the greater tone*, as from ut to re, from fa to fol, &c.; and the lesser †, as from re to mi, from fol to ut. See la, &c.

Chap. VI. The Formation of the Diatonic Scale among the Moderns, or the Ordinary Gamut.

144. We have just shown in the preceding chapter, how the scale of the Greeks is formed, fi, ut, re, mi, fa, fol, la by means of a fundamental bass composed of three sounds only, fe, ut, fol: but to form the scale ut, re, mi, fa, fol, la, ut, UT, which we use at present, we must necessarily add to the fundamental bass the note re, and, with these four sounds fa, ut, fol, re, the following fundamental basses: ut, fol, ut, fa, fol, re, fol, ut;

from whence we deduce the modulation or scale ut, fa, re, ut, mi, fa, sol, la, ut, UT.

In effect (o), ut in the scale belongs to the harmony of ut which corresponds with it in the bass; re, which is the second note in the gamut, is included in the harmony of fol; the second note of the bass; mi, the third note of the gammut, is a natural harmonic of ut, which is the third found in the bass, &c.

From thence it follows, that the diatonic scale of the Greeks is, at least in some respects, more simple than ours; since the scale of the Greeks (chap. v.) may be formed alone from the mode proper to ut; whereas ours, and theirs is originally and primitively formed, not only from the mode of ut (fa, ut, fol), but likewise from the mode of fol (ut, fol, re).

It will likewise appear, that this last scale consists of two parts; of which the one, ut, re, mi, fa, fol, is

\[ \text{3T2} \]

(a) The proportion of fi to ut is as \( \frac{1}{2} \) to 1, that is to say as 15 to 16; that between mi and fa is as \( \frac{3}{4} \) to \( \frac{3}{4} \), that is to say (note c), as 5 times 3 to 4 times 4, or as 15 to 16; these two proportions then are equal. In the same manner, the proportion of ut to re is as 1 to \( \frac{3}{2} \), or as 8 to 9; that between fa and fol is as \( \frac{1}{2} \) to \( \frac{3}{4} \); that is to say (note c), as 8 to 9. The proportion of mi to ut is as \( \frac{3}{4} \) to 1, or as 5 to 4; that between fa and la is as \( \frac{3}{4} \) to \( \frac{3}{4} \), or as 5 to 4: the proportions here then are likewise equal.

(m) The proportion of mi to ut is as \( \frac{3}{4} \) to 1, or as 5 to 4, which is a true third major; that from re to fi is as \( \frac{3}{4} \) to \( \frac{3}{4} \), that is to say, as 9 times 16 to 15 times 8, or as 9 times 2 to 15, or as 6 to 5. In like manner, we shall find, that the proportion of mi to fi is as \( \frac{3}{4} \) to \( \frac{3}{4} \); that is to say, as 5 times 16 to 15 times 4, or as 4 to 3, which is a true fourth.

(u) The proportion of re to ut is as \( \frac{3}{4} \) to 1, or as 9 to 8; that of mi to re is as \( \frac{3}{4} \) to \( \frac{3}{4} \), that is to say, as 40 to 36, or as 10 to 9: now \( \frac{3}{4} \) is less removed from unity than \( \frac{3}{4} \); the interval then from re to mi is a little less than that from ut to re.

If any one would wish to know the proportion which \( \frac{3}{4} \) bear to \( \frac{3}{4} \), he will find (note c) that it is as 8 times 10 to 9 times 9, that is to say, as 80 to 81. Thus the proportion of a lesser to a greater tone is as 80 to 81; this difference between the greater and lesser tone is what the Greeks called a comma.

We may remark, that this difference of a comma is found between the third minor when true and harmonical, and the same chord when it suffers alteration re, fa, of which we have taken notice in the scale (note 1); for we have seen, that this third minor thus altered is in the proportion of 80 to 81 with the true third minor.

(o) The values or estimates of the notes shall be the same in this as in the former scale, excepting only the tone la; for re being represented by \( \frac{3}{4} \), its fifth will be expressed by \( \frac{3}{4} \); so that the scale will be numerically signified thus:

\[ \text{Ut, Re, Mi, Fa, Sol, La, Fi, UT}. \]

Where you may see, that the note la of this scale is different from that in the scale of the Greeks; and that the la in the modern series stands in proportion to that of the Greeks as \( \frac{3}{4} \) to \( \frac{3}{4} \), that is to say, as 81 to 80; these two lates then likewise differ by a comma.
...the mode of ut; and the other sol, la, si, ut, in that of sol.

57. It is for this reason that the note sol is found to be twice repeated in immediate succession in this scale; once as the fifth of ut, which corresponds with it in the fundamental bafil; and again, as the octave of sol, which immediately follows ut in the same bafil. As to what remains, these two consecutive sols are otherwise in perfect union. It is for this reason that we are satisfied with finging only one of them when one modulates the scale ut, re, mi, fa, sol, la, fa, UT; but this does not prevent us from employing a pause or repose, expressed or understood, after the sound fa. There is no person who does not perceive this whilst he himself sings the scale.

58. The scale of the moderns, then, may be considered as consisting of two tetrachords, disjunctive indeed, but perfectly similar one to the other, ut, re, mi, fa, and sol, la, si, ut, one in the mode of ut, the other in that of sol. For what remains, we shall see in the sequel by what artifice one may cause the scale ut, re, mi, fa, sol, la, si, UT, to be regarded as belonging to the mode of ut alone. For this purpose it is necessary to make some changes in the fundamental basils, which we have already assigned: but this shall be explained at large in chap. xiii.

59. The introduction of the mode proper to sol in the fundamental bafil has this happy effect, that the notes fa, sol, la, si, may immediately succeed each other in ascending the scale, which cannot take place (art. 48.) in the diatonic series of the Greeks, because that series is formed from the mode of ut alone. From whence it follows:

1. That we change the scale at every time when we modulate three notes in succession.

2. That if these three notes are sung in succession in the scale ut, re, mi, fa, sol, la, si, UT, this cannot be done but by the allusion of a pause expressed or understood after the note fa, so much, that the three tones fa, sol, la, si, (three only because the note sol which is repeated is not enumerated) are supposed to belong to two different tetrachords.

60. It ought not then any longer to surprise us, that we feel some difficulty whilst we ascend the scale in singin three tones in succession, because this is impracticable without changing the mode; and if one pauses in the same mode, the fourth found above the first note will never be higher than a semitone above that which immediately precedes it; as may be seen by ut, re, mi, fa, and by sol, la, si, ut, where there is no more than a semitone between mi and fa, and between si and ut.

61. We may likewise observe in the scale ut, re, mi, fa, that the third minor from re to fa is not true, for the reasons which have been already given (art. 49.)—though altered, it is the same scale with the third minor from la to ut, and with the third major from fa to la: but each of these, themselves, founds form otherwise consonances perfectly true, with their correspondent founds in the fundamental basils.

62. The thirds la ut, fa la, which were true in the former scale, are false in this; because in the former scale la was the third of fa, and here it is the fifth of re, which corresponds with it in the fundamental basil.

63. Thus it appears, that the scale of the Greeks contains fewer consonances that are altered than consonances in the fundamental scale than in ours.

We see likewise that the value of la in the diatonic scale, a value which authors have been divided in ascertaining, solely depends upon the fundamental bafil, and that it must be different according as the note la has fa or re for its bafil. See the note (o).

CHAP. VII. Of Temperament.

64. The alterations which we have observed in the Temperament intervals between particular sounds of the diatonic scale, naturally lead us to speak of temperament. To give a clear idea of this, and to render the necessity of it palpable, let us suppose that we have before us an instrument with keys, a harpsichord, for instance, consisting of several octaves or scales, of which each includes its twelve semitones.

(r) In the scale of the Greeks, the note la being a third from fa, there is an altered fifth between la and re; but in ours, la being a fifth to re, produces two altered thirds, fa la, and la ut; and likewise a fifth altered, la mis, as we shall see in the following chapter. Thus there are in our scale two intervals more than in the scale of the Greeks which suffer alteration.

(a) But here it may be with some colour objected: The scale of the Greeks, it may be said, has a fundamental basil more simple than ours; and besides, in it there are fewer chords which will not be found exactly true; why then, notwithstanding this, does ours appear more easy to be sung than that of the Greeks? The Greeks in their scale begins with a semitone, whereas the intention prompted by nature seems to impel us to raise by a full tone at once. This objection may be thus answered. The scale of the Greeks is indeed better disposed than ours for the simplicity of the basil, but the arrangement of ours is more suitable to natural intonation. Our scale coincides by the fundamental found ut, and it is in reality from that found that we ought to begin; it is from this that all the others naturally arise, and upon this that they depend; now, if I may speak for, in this they are included: on the contrary, neither the scale of the Greeks, nor its fundamental basil, commences with ut; but it is from this ut that we must depart, in order to regulate our intonation, whether in rising or descending: now, in ascending from ut, the intonation, even of the Greek scale, gives the series ut, re, mi, fasil, la: and to true it is that the fundamental found ut is here the genuine guide of the ear, that, before we modulate the found ut, we should attempt to rise to it by that note in the scale which is most immediately contiguous, we cannot reach it but by the note fi, and by the semitone from fi to ut. Now to make a transition from fi to ut, by this semitone, the ear must of necessity be predisposed for that modulation, and consequently preoccupied with the mode of ut; if this were not the case, we should naturally rise from fi to ut, and by this operation pass into another mode.
65. What is still more, if, after having successively and alternately tuned the strings UT, SOL, &c. LA, mi, in perfect fifths and fourths one from the other, we continue to tune successively by true fifths and fourths the strings mi, fi, fa, ut, &c. we shall find, that, though fi, being a semitone higher than the natural note, should be equivalent to UT in the scale, it will by no means form a just octave to the first UT in the scale, but be considerably higher (s); yet this fi upon the harpsichord ought not to be different from the octave above UT; for every fi and every UT is the same found, since the octave or the scale only consists of twelve semitones.

66. From thence it necessarily follows, 1. That it is impossible that all the octaves and all the fifths should be just at the same time, particularly in instruments which have keys, where no intervals but a semitone or a eighth is admitted. 2. That, of consequence, it is impossible that the fifths are justly tuned, some alteration must be made in the octaves; now the sympathy or found which subsists between any note and its octave, does not permit us to make such an alteration: this perfect coalescence of found is the cause why the octave should

(r) The LA considered as the fifth of re is 1/16, and the fourth beneath this LA will constitute 1/2 of 1/16, that is to say, 1/32; &c. then shall be the value of mi, considered as a true fourth from LA in descencing: now mi considered as the third major of the found UT, is 1/3, or 1/16: these two mi's are between themselves in the proportion of 1:2 to 2:3; thus it is impossible that mi should be at the same time a perfect third major from UT, and a true fourth beneath LA.

(s) In effect, if you thus alternately tune the fifth above, and the fourth below, in the same octave, you may here see what will be the proceed of your operation.

UT, SOL a fourth; re a fourth; LA a fifth; mi a fourth; fi a fifth; fa a fourth; ut a fifth; re a fourth; LA 1/3; mi 1/2; &c. and so of the rest, till you arrive at fi, which will be found 1/3 1/3. This fraction is evidently greater than the number 2, which expresses the perfect octave ut to its correspondent UT; and the octave below fi would be one half of the same fraction, that is to say 1/3 1/3, which is evidently greater than UT represented by unity. This last fraction is composed of two numbers; the numerator of the fraction is nothing else but the number 3 multiplied 11 times in succession by itself; and the denominator is the number 2 multiplied 18 times in succession by itself. Now it is evident, that this fraction, which expresses the value of fi, is not equal to the unity which expresses the value of the found UT; though, upon the harpsichord, found and UT are identical.

This fraction rises above unity by 1/3 1/3, that is to say, by about 1/2, and this difference was called the comma of Pythagoras. It is palpable that this comma is much more considerable than that which we have already mentioned (note r), which is only 1/12.

We have already proved that the series of fifths produces an ut different from fi, the series of thirds major gives another still more different. For, let us suppose these series of thirds, fi, mi, sol, &c., &c.; we shall have mi equal to 1/2, sol to 1/4, and fi to 1/8, whose octave below is 1/3; from whence it appears, that this last fi is less than unity (that is to say, than ut); by 1/8, or by 1/8, or near it: A new comma, much greater than the preceding, and which the Greeks have called apotome major.

It may be observed, that this fi, deduced from the series of thirds, is to the fi deduced from the series of fifths, as 1/2 is to 1/8, that is to say, in multiplying by 52428/8, as 125 multiplied by 496 is to 531441, or as 51200 to 520832; that is to say, nearly as 26 is to 27. For it may be seen, that the value of fi is very considerably different from the other, and even sufficiently different to make the ear sensible of it; because the difference consists almost of a minor semitone, whose value, as will afterwards be seen (art. 129.) is 1/12.

Moreover, if, after having found the fi equal to 1/2, we then tune by fifths and by fourths, &c., &c., mi, fi, fa, ut, &c., we shall find that the fi must be 1/8 1/8; its difference, then, from unity, or, in other words, from UT, is 1/12, that is to say, about 1/12; a comma still less than any of the preceding, and which the Greeks have called apotome minor.

In a word, if, after having found mi equal to 1/4 in the progression of thirds, we then tune by fifths and fourths mi, fi, fa, ut, &c., we shall arrive at a new fi, which shall be 1/8 1/8, and which will not differ from unity but by about 1/12, which is the least and smallest of all the commas; but it must be observed, that, in this case, the thirds major from mi to sol, from sol to ut, &c. are extremely false, and greatly altered.
should serve as limits to the other intervals, and that all the notes which rise above or fall below the ordinary scale, are no more than replications, i.e. repetitions, of all that have gone before them. For this reason, if the octave were altered, there could be no longer any fixed point either in harmony or melody. It is then absolutely necessary to tune the two $ut$ or $f$ in a just octave with the first; from whence it follows, that, in the progression of fifths, or what is the same thing, in the alternate series of fifths and fourths, UT, SOL, re, LA, $mi$, $fa$, $sol$, $la$, $re$, $mi$, $fa$, $sol$, it is necessary that all the fifths should be altered, or at least some of them. Now, since there is no reason why one should either be altered than another, it follows, that we ought to alter them all equally. By these means, as the alteration is made to influence all the fifths, it will be in each of them almost imperceptible; and thus the fifth, which, after the octave, is the most perfect of all consonances, and which we are under the necessity of altering, must only be altered in the least degree possible.

67. It is true, that the thirds will be a little harsh; but as the interval of sounds which constitutes the third, produces a less perfect consonance than that of the fifth, it is neccessary, says M. Rameau, to sacrifice the justice of that chord to the perfection of the fifth; for the more perfect a chord is in its own nature, the more displeasing to the ear any alteration which can be made in it. In the octave the least alteration is insupportable.

68. This change in the intervals of instruments which have, or even which have not, keys, is that which we call temperament.

69. It results then from all that we have now said, that the theory of temperament may be reduced to this question.—The alternate succession of fifths and fourths having been given, UT, SOL, re, LA, $mi$, $fa$, $sol$, $la$, $re$, $mi$, $fa$, $sol$, or $ut$ is not the true octave of the first UT, it is proposed to alter all the fifths equally, in such a manner that the two $ut$s may be in a perfect octave the one to the other.

70. For a solution of this question, we must begin with tuning the two $ut$s in a perfect octave the one to the other; in consequence of which, we will render all the semitones which compose the octave as equal as possible. By this means ($r$) the alteration made in each fifth will be very considerable, but equal in all of them.

71. In this, then, the theory of temperament consists: but as it would be difficult in practice to tune a method of harpsichord or organ by thus rendering all the semitones equal, M. Rameau, in his "Generation Harmonique," has furnished us with the following method, to alter all the fifths as equally as possible.

72. Take any key of the harpsichord which you please; but let it be towards the middle of the instrument; for instance, UT: then tune the note SOL a fifth above it, at first with as much accuracy as possible; this you may imperceptibly diminie: tune afterwards the fifth to this with equal accuracy, and diminish it in the same manner; and thus proceed from one fifth to another (r) All the semitones being equal in the temperament proposed by M. Rameau, it follows, that the twelve semitones $ut$, $ut$$\sharp$, re, re$$\sharp$, $mi$, $mi$$\sharp$, &c. shall form a continued geometrical progression; that is to say, a series in which $ut$, shall be to $ut$$\sharp$ in the same proportion as $ut$$\sharp$ to re, as re to re$$\sharp$, &c. and so of the rest. These twelve semitones are formed by a series of thirteen sounds, of which UT and its octave $ut$ are the first and last. Thus to find by computation the value of each sound in the temperament, which is the present object of our speculations, our scrutiny is limited to the investigation of eleven other numbers between 1 and 2 which may form with the 1 and the 2 a continued geometrical progression.

However little any one is practised in calculation, he will easily find each of these numbers, or at least a number approaching to its value. These are the characters by which they may be expressed, which mathematicians will easily understand, and which others may neglect.

$$UT \quad ut\sharp \quad re \quad re\sharp \quad mi \quad fa \quad fa\sharp \quad sol \quad sol\sharp$$

$$1 \quad \sqrt{2} \quad \sqrt{2} \quad \sqrt{2} \quad \sqrt{2} \quad \sqrt{2} \quad \sqrt{2} \quad \sqrt{2} \quad \sqrt{2} \quad \sqrt{2} \quad \sqrt{2}$$

It is obvious, that in this temperament all the fifths are equally altered. One may likewise prove, that the alteration of each in particular is very inconsiderable; for it will be found, for instance, that the fifth from $ut$ to $sol$, which should be $\frac{3}{2}$, ought to be diminished by about $\sqrt{2}$ of $\frac{3}{2}$; that is to say, by $\sqrt{2}$, a quantity almost inconceivably small.

It is true, that the thirds will be a little more altered; for the third major from $ut$ to $mi$, for instance, shall be increased in its interval by about $\sqrt{2}$; but it is better, according to M. Rameau, that the alteration should fall upon the third than upon the fifth, which after the octave is the most perfect chord, and from the perfection of which we ought never to degenerate but as little as possible.

Besides, it has appeared from the series of thirds major $ut$, $mi$, $sol$, $sol\sharp$, that this last $sol\sharp$ is very different from $ut$ (note s); from whence it follows, that if we would tune this $sol\sharp$ in unison with the octave of $ut$, and alter at the same time each of the thirds major by a degree as small as possible, they must all be equally altered. This is what occurred in the temperament which we propose; and if in it the third be more altered than the fifth, it is a consequence of the difference which we find between the degrees of perfection in their intervals; a difference with which, if we may speak so, the temperament proposed conforms itself. Thus this diversity of alteration is rather advantageous than inconvenient.
Another in ascent; and as the ear does not appreciate perfectly just; it will be necessary then to try if this UT, or its octave, forms a just fifth with the last found $mi$ or $fa$ which has been already tuned. If this be the case, we may be certain that the harpichord is properly tuned. But if this last fifth be not true, in this case it will be too sharp, and it is an indication that the other fifths have been too much diminished, or at least some of them; or it will be too flat, and consequently discover that they have not been sufficiently diminished. We must then begin and proceed as formerly, till we find the last fifth in tune of itself, and without our immediate interpolation.

By

(v) All that remains, is to acknowledge, with M. Rameau, that this temperament is far remote from that which is now in practice; you may here see in what this last temperament confisits as applied to the organ or harpichord. They begin with UT in the middle of the keys, and they flatten the four first fifths $sol$, $re$, $la$, $mi$, till they form a true third major from $mi$ to $ut$; afterwards, setting out from this $mi$, they tune the fifths $fa$, $sol$, $ut$, $sol$, but flattening them still less than the former, so that $sol$ may almost form a true third major with $mi$. When they have arrived at $sol$, they flop; they resume the fifth $ut$, and tune to it the fifth $fa$ in defending, then the fifth $sol$, &c. and they heighten a little all the fifths till they have arrived at $la$, which ought to be the same with the $sol$ already tuned.

If, in the temperament commonly practised, some thirds are found to be less altered than in that prescribed by M. Rameau, in return, the fifths in the first temperament are much more faite, and many thirds are likewise so; infomuch, that upon a harpichord tuned according to the temperament in common use, there are five or six modes which the ear cannot endure, and in which it is impossible to execute any thing. On the contrary, in the temperament suggested by M. Rameau, all the modes are equally perfect; which is a new argument in its favour, since the temperament is peculiar necessary in passing from one mode to another, without shocking the ear; for instance, from the mode of $ut$ to that of $sol$, from the mode of $sol$ to that of $re$, &c. It is true, that this uniformity of modulation will to the greatest number of musicians appear a defect: for they imagine, that, by tuning the semitones of the scale unequal, they give each of the modes a peculiar character; so that, according to them, the scale of $ut$,

$$ut, re, mi, fa, sol, la, fa, UT,$$

is not perfectly similar to the gammut or diatonic scale of the mode of $mi$

$$mi, fa, sol, la, fa, ut, re, mi,$$

which, in their judgment, renders the modes of $ut$ and $mi$ proper for different manners of expression. But after all that we have said in this treatise on the formation of diatonic intervals, every one should be convinced, that, according to the intention of nature, the diatonic scale ought to be perfectly the same in all its modes; The contrary opinion, says M. Rameau, is a mere prejudice of musicians. The character of an air arises chiefly from the intermixture of the modes; from the greater or lesser degrees of vivacity in the movement; from the tones, more or less grave, or more or less acute, which are alligned to the generator of the mode; and from the chords more or less beautiful, as they are more or less deep, more or less flat, more or less sharp, which are found in it.

In short, the last advantage of this temperament is, that it will be found conformed, or at least very little different from that which they practice upon instruments without keys; as the bass-viol, the violin, in which true fifths and fourths are preferred to thirds and sixths tuned with equal accuracy; a temperament which appears incompatible with that commonly used in tuning the harpichord.

Yet we must not suffer our readers to be ignorant, that M. Rameau, in his New System of Music, printed in 1726, had adopted the ordinary temperament. In that work, (as may be seen Chap. XXIV.,) he pretends that the alteration of the fifths is much more supportable than that of the thirds major; and that the last interval can hardly suffer a greater alteration than the octave, which, as we know, cannot suffer the slightest alteration. He says, that if three strings are tuned, one by an octave, the other by a fifth, and the rest by a third major to a fourth string, and if a sound be produced from the last, the strings tuned by a fifth will vibrate, though a little less true than it ought to have been; but that the octave and the third major, if altered in the least degree, will not vibrate: and he adds, that the temperament which is now practised, is founded upon that principle. M. Rameau goes still farther; and as, in the ordinary temperament, there is a neccessity for altering the last thirds major, and to make them a little more sharp, that they may naturally return to the octave of the principal found, he pretends that this alteration is tolerable, not only because it is almost insensible, but because it is found in modulations not much in use, unless the composser should choose it on purpose to render the expression stronger. "For it is proper to remark (says he), that we receive different impressions from the intervals in proportion to their different alterations: for instance, the third major, which naturally elevated us to joy, in proportion as we feel it, heightens our feelings even to a kind of fury, when it is tuned too sharp; and the third minor, which naturally inspires us with tenderness and serenity, depresses us to melancholy when it is too flat." All this strain, as you may see, is immensely different from that which this celebrated musician afterwards
By this method all the twelve sounds which compose one of the scales shall be tuned: nothing is necessary but to tune with the greatest possible exactness their octave in the other scale, and the harpsichord shall be well tuned.

We have given this rule for temperament from M. Rameau: and it belongs only to disinterested artists to judge of it. However this question be determined, and whatever kind of temperament may be received, the alterations which it produces in harmony will be but very small, or not perceptible to the ear, whose attention is entirely engaged in attuning itself with the fundamental bafs, and which suffers, without uneasiness, these alterations, or rather takes no notice of them, because it supplies from itself what may be wanting to the truth and perfection of the intervals.

Simple and daily experiments confirm what we now advance. Listen to a voice which is accompanied, in singing, by different instruments; though the temperament of the voice, and the temper of each of the instruments, are all different one from another, yet you will not be in the least affected with the kind of cacophony which one is to feel from these diversities, because the ear supposes these intervals true of which it does not appreciate differences.

We may give another experiment. Strike upon an organ the three keys $\text{mi}$, $\text{fa}$, $\text{si}$, you will hear nothing but the minor perfect chord; though $\text{mi}$, by the constitution of that instrument, must cause $\text{fa}$ like to be heard; though $\text{fa}$ should have the same effect upon $\text{re}$, and $\text{si}$ upon $\text{fa}$ & $\text{re}$: infomuch, that the ear is at once affected with all those sounds, $\text{re}$, $\text{mi}$, $\text{fa}$, $\text{fa}$, $\text{sol}$, $\text{sol}$, $\text{si}$: how many differences perceived at the same time, and which a jarring multitude of discordant sensations, would result from thence to the ear, if the perfect chord with which it is pre-occupied had not power entirely to abstrait its attention from such sounds as might offend!

Chap. VIII. Of Repose or Cadences (+).

73. In a fundamental bafs whose procedure is by fifths, there always is, or always may be, a repose, or crisis, in which the mind acquiesces in its transition from one sound to another: but a repose may be more or less distinctly signified, and of consequence more or less perfect. If one should rise by fifths; if, for instance, we pass from $\text{ut}$ to $\text{sol}$, it is the generator which advances to one of these fifths, and this fifth was already pre-existent in its generator: but the generator exists no longer in this fifth; and the ear, as this generator is the principle of all harmony and of all melody, feels a desire to return to it. Thus the transition from a found to its fifth in ascents, is termed an imperfett repose, or imperfett cadence; but the transition from any found to its fifth in descents, is denominated a perfect cadence, or an absolute repose: it is the offpring which returns to its generator, and as it were recovers its existence once more in that generator itself, with which whenounding it resounds (chap. i).

74. Amongst absolute repoes, there are some, if Perfect cadence we may be allowed the expression, more absolute, that denote s more or less perfects, and why.

75. We may thus add, that what is commonly called cadence in melody ought not to be confounded with what we name evidence in harmony.

In the first case, the word only signifies an agreeable and rapid alteration between two contiguous sounds, called likewise a trill or flake: in the second, it signifies a repose or close. It is however true, that this shake implies, or at least frequently enough pre­ages, a repose, either present or impending, in the fundamental bafs (x).

76. Since there is a repose in passing from one found to another in the fundamental bafs, there is also a fundamental bafs necessary in the diatonic scale, which is formed from it, and which this bafs represents, and as the absolute repose $\text{sol}$ $\text{ut}$, is

- Throughout the page, the author discusses the concept of temperament in music, focusing on the influence it has on harmony and the perception of musical intervals. The text explores the idea that different temperaments can affect the way music sounds, with particular emphasis on the concept of repose or cadence.

- The author references sources such as M. Rouffeau's Musical Dictionary, and Rouffeau's Harmonie Universelle, to support the discussion on the influence of temperament on musical expression.

- The text is rich with examples and experiments to illustrate the concepts being discussed, including comparisons between the perception of music with and without temperament.

- The page contains a variety of musical terms and concepts, such as perfect and imperfect cadences, repose, and the diatonic scale, which are explained in detail.

- The author concludes by emphasizing the importance of understanding the role of temperament in music, and how it can be used to enhance the expressiveness of musical compositions.
music

of all others the most perfect in the fundamental bass, is the scale which contains the notes which answer to it in the scale, and which is likewise terminated by the generator, is for that reason the most perfect of all others in the diatonic scale ascending.

It is then a law dictated by nature itself, that if you would ascend diatonically to the generator of a mode, you can only do this by means of the third major from the fifth of that very generator. This third major, which with the generator forms a fermite, has for that reason been called the sensible note, as introducing the generator, and preparing us for the most perfect repose.

We have already proved, that the fundamental bass is the principle of melody. We shall besides make it appear in the sequel, that the effect of a repose in melody arises solely from the fundamental bass.

CHAP. IX. Of the Minor Mode and its Diatonic Series.

The diatonic series of the minor mode ascended by different examples. 78. In the second chapter, we have explained (art. 59, 60, 71, and 72.) by what means, and upon what principle, the minor chord ut, mi♭, fa, ut, may be formed, which is the characteristic chord of the minor mode. Now what we have there said, taking ut for the principal and fundamental found, we might likewise have said of any other note in the scale, affirmed in the same manner as the principal and fundamental found: but as in the minor chord ut, mi♭, fa, ut, there occurs a mi♭ which is not found in the ordinary diatonic scale, we shall immediately substitute, for greater ease and convenience, another chord, which is likewise minor and exactly similar to the former, of which all the notes are found in the scale.

The scale affords us three chords of this kind, viz. re, fa, la, re; la, ut, mi, fa; and mi, fa, re, mi. Amongst these three we shall choose la, ut, mi, la; because this chord, without including any sharp or flat, has two founds in common with the major chord ut, re, mi, fa; and besides, one of these two founds is the very same found; so that this chord appears both the most immediate, and at the same time the most simple, relation with the chord ut, mi, fa, ut. Concerning this we need only add, that this preference of the chord la, ut, mi, la, to every other minor chord, is by no means in itself necessary for what we have to say in this chapter upon the diatonic scale of the minor mode. We might in the same manner have chosen any other minor chord; and it is only, as we have said, for greater ease and convenience that we fix upon this.

60. Let us now remark, that in every mode, whether major or minor, the principal found which implies the perfect chord, whether major or minor, may be called the tonic note or key: thus ut is the key in its proper mode, la in the mode of la, &c. Having laid down this principle.

61. We have shown how the three founds fa, ut, fa, which constitute (art. 38.) the mode of ut, of which the first fa and the last fa are the two fifths of ut, one defending the other, rising, produce the scale fa, ut, re, mi, fa, ut, fa, of the major mode, by means of the fundamental bass fa, ut, fa, ut, fa, ut, fa: let us in the same manner take the three founds re, la, mi, which constitute the mode of la, for the same reason that the founds fa, ut, fa, constitute the mode of ut; and of them let us form this fundamental bass, perfectly like the preceding, mi, la, mi, la, re, la, re: let us afterward place below each of these founds one of their harmonics, as we have done (chap. v.) for the first scale of the major mode; with this difference, that we must suppose re and la as implying their third minor in the fundamental bass to characterize the minor mode; and we shall have the diatonic scale of that mode, fol, la, ut, re, mi, fa.

82. The fol, which corresponds with mi in the fundamental bass, forms a third major with that mi, though the mode be minor; for the same reason that a third from the fifth of the fundamental found ought to be major (art. 77.) when that third rises to the fundamental found la.

83. It is true, that, in causing mi to imply its third, See Sempire, &c., one might also rise to la by a diatonic progression, but that manner of rising to la would be less perfect than the preceding; for this reason (art. 76.), that the absolute repose or perfect cadence, mi, la, which is found in the fundamental bass, ought to be represented in the most perfect manner in the two notes of the diatonic scale which answer to it, especially when one of these two notes is la, the key itself upon which the repose is made. From whence it follows, that the preceding note fol ought rather to be sharp than natural; because fol, being included in mi (art. 19.), much more perfectly represents the note mi in the bass, than the natural fol could do, which is not included in mi.

84. We may remark this first difference between diversities in the scales

f, ut, re, mi, fa, fol, la,

and the scale which corresponds with it in the major mode

f, ut, re, mi, fa, fol, la,

that from mi to fa, which are the two last notes of the former scale, there is only a semitone; whereas from fol to la, which are the two last of the latter scale, there is the interval of a complete tone: but this is not the only discrimination which may be found between the scales of the two modes.

85. To investigate these differences, and to discover the reason for which they happen, we shall begin by taking these forming a new diatonic scale of the minor mode, similar to the second scale of the major mode,

ut, re, mi, fa, fol, la, fa, ut.

That last series, as we have seen, was formed by means of the fundamental basses fa, ut, fol, re, disposed in this manner,

ut, fol, fa, ut, re, fol, fa, ut.

Let us take in the same manner the fundamental basses re la mi, ut, and arrange them in the following order,

la, mi, la, re, la, mi, fa, mi, la,

and it will produce the scale immediately subjoined,

la, fa, ut, re, mi, fa, fol, la, &c.

in which ut forms a third minor with la, which in the fundamental bass corresponds with it, which denominates the minor mode: and, on the contrary, fol forms a third major with mi in the fundamental bass, because fol rises towards la, (art. 82. and 83.)
It is easily perceived, according to M. Rameau, by this fundamental base, la, re, la, re, la, mi, la, which produces
la, fa, mi, re, ut, fi, la; which may be regarded, as he says, as the real scale of the minor mode in descending; to which is added fol natural between la and fa, to preserve the diatonic order.

This answer appears the only one which can be given to the difficulty above proposed: but I know not whether it will fully satisfy the reader; whether he will not see with regret, that the fundamental base does not produce, to speak properly, the diatonic scale of the minor mode in descending, when at the same time this same base so happily produces the diatonic scale of that identical mode in ascending, and the diatonic scale of the major mode whether in rising or descending (v).

CHAP. X. Of Relative Modes.

91. Two modes which are of such a nature that we can pass from the one to the other, are called relative, or transitive, modes. Thus we have already seen, that the major mode of ut is relative to the major mode of fa and to that of fol. It may likewise appear from what goes before, how many intimate connections there are between the species (v) of the species or the minor mode of la. For, 1. The perfect chord, major ut mi fol ut, the other minor la ut mi fa, which characterizes each of those two kinds of modulation or harmony, have two foundations in common, ut or et. See Mode.

2. The diatonic scale of the minor mode of la in descending, absolutely contains the same sounds with the gamut or diatonic scale of the major mode of ut. It is for this reason that the transition is so natural and easy from the major mode of ut to the minor mode of la, or from the minor mode of la to the major mode of ut, as experience proves.

92. In the minor mode of mi, the minor perfect chord mi fol fi mi, which characterizes it, has likewise two foundations, mi, fol, in common with the perfect chord major ut mi fol ut, which characterizes the major mode of ut. But the minor mode of mi is not so closely related nor allied to the major mode of ut as to the minor mode of la; because the diatonic scale of the minor mode of mi in descending, has not, like the series of

[56x246]de-

[69x687]yet the artift does not hesitate sometimes
to pafs immediately from the one to the other.

Of this may be seen one instance (among many others) in the prologue des Amours des Dieux, at this passage Ovide si l'objet de la faire, which is in the minor mode of mi, though what immediately precedes it is in the major mode of ut.

We may see besides, that when we pafs from one mode to another by the interval of a third, whether in descending or rising, as from ut to la, or from la to ut, from ut to mi, or from mi to ut, the major mode becomes minor, or the minor mode becomes major.

There is still another minor mode, into which an immediate transition may be made in ilufing from the major mode of ut. It is the minor mode of ut itself in which the perfent minor chord ut mi b fol ut has two founds, ut and fol, in common with the perfect minor chord mi fol ut. Nor is there anything more common than a transition from the major mode of ut to the minor mode, or from the minor to the major.

Chap. IX. Of Diffonances.

94. We have already observed, that the mode of ut (fa, ut, fol), has two founds in common with the mode of fol (ut, fol, re); and two founds in common with the mode of fa (fi, fa, ut); of consequence, this procedure of the bafs ut fo may belong to the mode of ut, or to the mode of fol, as the procedure of the bafs fa ut, or ut fa, may belong to the mode of ut or the mode of fa. When any one therefore pafs from ut to fa or to fol in a fundamental bafs, he is still ignorant even to that crisis what mode he is in. It would be, however, advantageous to know it, and to be able by some means to diftinguish the generator in its founds.

95. This advantage may be obtained by uniting at the same time the founds fi and fa in the fame harmony, that is to fay by joining to the harmony fol fi re of the fifth fol the other fifth fa in this manner, fol, fi, re, fa; this fa which is added, forms a diftonance with fol (art. 18). It is for this reafon that the chord fol fi re fa, is called a diftonant chord, or a chord of the seventh. It serves to diftinguish the fifth fol from the generator ut, which always implies, without mixture or alteration, the perfent chord ut, mi, fol, ut, resulting from nature itself (art. 32.) By this we may see, that when we pafs from ut to fol, one pafs at the fame time from ut to fa, because fa is found to be comprehended in the chord of fol; and the mode of ut by these means plainly appears to be determined, because there is none but that mode to which the founds fa and fol at once belong.

96. Let us now see what may be added to the harmonic diftonance of the fifth fa, la, ut, of the fifth fa below the generator, to conftruct another kind of harmonic diftonance.

One may here remark the analogy there is observed between the harmony of the fifth fol and that of the fifth fa.

97. For this reafon, instead of fol, we shall take its Chord of fifth re, which is the found that approaches it the nearest; and we shall have, instead of the fifth fa, the chord fifh fa, la, ut, re, which is called a chord of the great fifh.

One may here remark the analogy there is observed between the harmony of the fifth fol and that of the fifth fa.

98. The fifth fa, in rising above the generator, gives a chord entirely consisting of thirds ascending from fol fi, fa, re; now the fifth fa being below the generator ut in desceniding, we shall find, as we go lower by thirds from ut towards fa, the same founds ut, la, fa, re, which form the chord fa, la, ut, re, given to the fifth fa.

99. It appears besides, that the alteration of the harmony in the two fifth fifteen only in the third minor re, fa, which was reciprocally added to the harmony of these two fifths.

Chap. XII. Of the Double Ut or Employment of Diffonances.

100. It is evident by the reformation of founds to account of their oftens, that the chord fa, la, ut, re, is in effect the double of the same as the chord re, fa, la, ut, taken inverfely, employment that the inverted of the chord ut, la, fa, re, has been ment, and that which

(2) There are likewise other minor modes, into which we may pafs in our egress from the mode major of ut; as that of fa minor, in which the perfect minor chord fa, la b, ut, includes the found ut, and whose scale in ascent fa, fol, lab, fi, ut, re, mi, fo, only includes the two founds lab, fi, fol, which do not occur in the scale of ut. We find an example of this transition from the mode major of ut to that of fa minor, in the opera of Pyramion by M. Rameau, where the farahando is in the minor mode of fa, and the rigadoon is in the mode major of ut. This kind of transition, however, is not frequent. The minor mode of re has only in its scale ascending to the scale of ut. For this reason a transition may likewise be made, without grating the ear, from the mode of ut major to the mode of re minor; but this passage is left immediate than the former, because the chords ut, mi, fol, ut, re, fa, la, re, not having a single found in common, one cannot (art. 37) pafs immediately from the one to the other.
MUSIC.

Part I.

Musick (Art. 98.) in defending by thirds from the generator ut (AA).

104. The chord re, fa, la, ut, is a chord of the seventh like the chord sol, fa, re, fa: with this only difference, that in this the third sol, is major; whereas in the second, the third re, fa, is minor. If the fa were sharp, the chord re, fa#, la, ut, would be a genuine chord of the dominant, like the chord sol, fa, re, fa; and as the dominant may defend to ut in the fundamental base, the dominant implying or carrying with it the third major fa#, might in the same manner defend to fa.

105. Now I say that if the fa# should be changed into fa natural, re, the fundamental tone of this chord re, fa, la, ut, might still defend to fa; for the change from fa# to fa natural, will have no other effect, than to prevent the impression of the mode of ut, instead of that of the mode of sol, which the fa# would have here introduced. For what remains, the note re will always preserve its character as the dominant, on account of the mode of ut, which forms a seventh. Thus in the chord of which we treat, re, fa, la, ut, re, may be considered as an imperfect dominant: I call it imperfect, because it carries with it the third minor fa, instead of the third major fa#. It is for this reason that in the sequel I shall call it simply the dominant, to distinguish it from the dominant fol, which shall be called the tonic dominant.†

106. Thus the sounds fa and fol, which cannot succeed each other (Art. 37.) in a diatonic bass, when they only carry with them the perfect chords fa, la, ut, sol, fa, re, may succeed one another if you join re to the harmony of the first, and fa to the harmony of the second; and if you invert the first chord, that is to say, if you give to the two chords this form re, fa, la, ut, sol, fa, re, fa.

107. Besides, the chord fa, la, ut, re, being allowed to succeed the perfect chord ut, mi, fol, ut, it follows for the same reasons, that the chord ut, mi, fol, ut, may be succeeded by re, fa, la, ut, which is not contradictory to what we have said before (Art. 37.), that the sounds ut and re cannot succeed one another in the fundamental bass: for in the passage quoted, we had supposed that both ut and re carried with them a perfect chord major; whereas, in the present case, re carries the third minor fa, and likewise the found ut, by which the chord re, fa, la, ut is connected with that which precedes it ut, mi, fol, ut; and in which the found ut is found. Besides, this chord, re, fa, la, ut, is properly nothing else but the chord fa, la, ut re inverted, and if we may speak so, diguited.

Chap. XIII. Concerning the Use of this Double Employment, and its Rules.

109. Thus the double employment of the fundamental bass fa, ut, fol, re, by twice repeating the word fol in that series, so that this gamut is primitive and originally composed of two similar tetradic chords, one in the mode of ut, the other in that of sol, now it is possible, by means of this double employment, to preserve the impression of the mode of ut through the whole extent of the scale, without twice repeating the note fol, or even without supposing this repetition. For this effect we have nothing to do but to follow the fundamental bass, ut, sol, ut, fol, ut, re, fol, ut; in which ut is underfoot to carry with it the perfect chord ut, mi, fol, ut; fol, the chord fol, re, fa; fa, the chord
CHAP. XIV. Of the Different Kinds of Chords of the Seventh.

112. The dissonance added to the chord of the dominant and of the sub-dominant, though in some measure intimated by nature (chap. xi.), is nevertheless a work of art; but as it produces great beauties in harmony by the variety which it introduces into it, let us discover whether in consequnce of this first advance, art may not still be carried farther.

113. We have already three different kinds of chords of the seventh, viz.

1. The chord $\text{fa} \text{si} \text{re} \text{fa}$, composed of a third major followed by two thirds minor.

2. The chord $\text{re} \text{fa} \text{la} \text{ut}$, or $\text{re} \text{fa} \text{la} \text{ut}$, composed of a third major between two minors.

3. The chord $\text{fa} \text{re} \text{fa} \text{la}$, composed of two thirds minor followed by a major.

114. There are still two other kinds of chords of the seventh which are employed in harmony; one is composed of a third minor between two thirds major, $\text{ut} \text{fa} \text{re} \text{fa}$ or $\text{fa} \text{la} \text{ut}$; the other is wholly composed of thirds minor followed by a major. These two chords, which at first appear as if they ought not to enter into harmony if we rigorously keep to the preceding rules, are nevertheless frequently practised with success in the fundamental bas.

The reason is this:

115. According to what has been said above, if we add a seventh to the chord $\text{ut} \text{mi} \text{fa}$, to make a third dominant of $\text{ut}$, one can add nothing but $\text{fa} \text{fa}$; and in this case $\text{ut} \text{mi} \text{fa} \text{fa} \text{fa}$ would be the chord of the tonic dominant in the mode of $\text{fa}$, as $\text{fa} \text{fa} \text{fa} \text{fa}$ is the chord of the tonic dominant in the mode of $\text{ut}$; but if you would prefer the impression of the mode of $\text{ut}$ in the harmony, you then change this $\text{fa} \text{fa}$ into $\text{fa}$ natural, and the chord $\text{ut} \text{mi} \text{fa} \text{fa}$ becomes $\text{ut} \text{mi} \text{fa} \text{fa}$. It is the same case with the chord $\text{fa} \text{la} \text{ut} \text{mi}$, which is nothing else but the chord $\text{fa} \text{la} \text{ut} \text{mi}$, in which one may substitute for $\text{mi} \text{fa}$, natural, to preserve the impression of the mode of $\text{ut}$, or of that of $\text{fa}$.

Besides, in such chords as $\text{ut} \text{mi} \text{fa} \text{fa} \text{la} \text{ut} \text{mi}$, the sounds $\text{fa} \text{fa}$, though they form a dissonance

Chords of the seventh continued and explained.

118. With respect to the chord of the seventh folge re fa, wholly composed of thirds minor, it may be regarded as formed from the union of the two chords of the dominant and of the sub-dominant in the minor mode. In effect, in the minor mode of la, for instance, these two chords are mi folge fi re, and re fa la fi, whose union produces mi, folge, fa re fa, la. Now, if we should suffer this chord to remain thus, it would be disagreeable to the ear, by its multiplicity of dissonances, from mi, mi, la, la folge, la fi, re folge, (art. 182); so that, to avoid this inconvenience, the generator la is immediately expunged, which (art. 19) is as it were underfoot in re, and the fifth or dominant mi whose place the sensible note folge is supposed to hold: thus there remains no more than the chord folge fi re fa, wholly composed of thirds minor, and in which the dominant mi is considered as underfoot; in such a manner that the chord folge fi re fa represents the chord of the tonic dominant mi folge fi re, to which we have joined the chord of the sub-dominant re fa la fi, but in which the dominant mi is always reckoned the principal note (as).

119. Since, then, from the chord mi folge fi re, we may pass to the perfect la ut mi la, and vice versa, we may in like manner pass from the chord folge fi re fa to the chord la ut mi la, and from this last to the chord folge fi re fa: this remark will be very useful to us in the sequel.

Chap. XV. Of the Preparation of Dissonances.

187

Dissonance.

120. In every chord of the seventh, the highest note, that is to say, the seventh above the fundamental, is called a dissonance or discord; thus fa is the dissonance of the chord fol fi re fa, ut in the chord re fa la ut, &c.

188

Manner of preparing dissonances investigated.

121. When the chord fol fi re fa follows the chord ut mi fol ut, as this may happen, and in reality often happens, it is obvious that we do not find the dissonance fa in the preceding chord ut mi fol ut. Nor ought it: indeed to be found in that chord; for this dissonance is nothing else but the sub-dominant added to the harmony of the dominant to determine the mode: now, the sub-dominant is not found in the harmony of the generator.

120. For the same reason, when the chord of the sub-dominant fa la ut re follows the chord ut mi fol ut, the note re, which forms a dissonance with ut, is not found in the preceding chord.

It is not so when the chord re fa la ut follows the chord ut mi fol ut; for ut, which forms a dissonance in the second chord, stands as a consonance in the preceding.

122. In general, dissonance being the product of dissonances, of art (chap. xi.), especially in such chords as are not only tolerable to the ear when found too heterogeneous to the chord, is, that it may be, if in process we may speak so, announced to the ear by being sung found in the preceding chord, and by that means serve chords to connect the two chords. From whence follows this rule:

123. In every chord of the seventh, which is not prepared, the tonic of the dominant, that is to say, (art. 182), which is not composed of a third major followed by two thirds minor, the dissonance which this chord forms ought to stand as a consonance in the chord which precedes it.

This is what we call a prepared dissonance. From whence it follows, that in order to prepare a dissonance, it is absolutely necessary that the fundamental basis should be formed by the interval of a second, as:

UT mi fol ut, RE fa la ut;

or defined by a third, as:

UT mi fol ut, LA ut mi fol;

or defined by a fifth, as:

UT mi fol ut, FA la ut mi:

in every other case the dissonance cannot be prepared. This is what may be easily ascertained. If, for instance, the fundamental basis rises by a third, as ut mi fol ut, mi fol fi re, the dissonance re is not found in the chord ut mi fol ut. The same might be said of ut mi fol ut, fi fol fi re, and ut mi fol ut, fi re fa la, in which the fundamental bases rises by a fifth or sixth by a second.

124. It may only be added, that when a tone, that is to say, a note which carries with it a perfect chord, is followed by a dominant in the interval of a fifth or third, this procedure may be regarded as a process from that same tone to another, which has been

(cc): On the contrary, a chord such as ut mi fol fi, in which mi would be flat, could not be admitted in harmony, because in this chord the fi is not included and under foot in mi. It is the same case with several other chords, such as fi re fa la, fi re re fa la, &c. It is true, that in the latter of these chords, la is included in fa, but it is not contained in re, and this re likewise forms with fa and with la a double dissonance, which, joined with the dissonance fi, would necessarily render this chord not very pleasing to the ear; we shall yet, however, see in the second part, that this chord is sometimes used.

(oo) We have seen (art. 109) that the chord fi re fa la, in the minor mode of la, may be regarded as the inverse of the chord re fa la fi; it would likewise seem, that, in certain cases, this chord fi re fa la may be considered as composed of the two chords fol fi re fa, la ut re, of the dominant and of the sub-dominant of the major mode of ut; which chords may be joined together, after having excluded from them, 1. The dominant fol, represented by its third major fi, which is presumed to retain its place. 2. The note ut which is under foot in fa, which will form this chord fi re fa la. The chord fi re fa la, considered in this point of view, may be understood as belonging to the major mode of ut upon certain occasions.
Moreover, we have seen (art. 119. and 120.) that a dissonance does not stand in need of preparation in the chords of the tonic dominant and of the sub-dominant; from whence it follows, that every tonic carrying with it a perfect chord, may be changed into a tonic dominant (if the perfect chord be major), or into a sub-dominant (whether the chord be major or minor) by adding the dissonance all at once.

**CHAP. XVI. Of the Rules for resolving Dissonances.**

191. Difsonances to be resolved, must be disguised and made to appear in the character of harmony, or in some measure, as much the character of a harmonic found as may be possible, it is necessary that this part of the modulation where it is found, should defend or rise dissonantly upon another note, which may be one of the consonances of the sub-frequent chord.

192. In the chord of the tonic dominant it ought rather to defend than to rise; for this reason. Let us take, for instance, the chord $f_{a} f_{r} f_{s} f_{a}$ followed by the chord $u_{t} m_{i} f_{o} l_{u}$; the part which formed the dissonance $f_{a}$ ought to defend to $m_{i}$ rather than rise to $f_{o}$, though both the founds $m_{i}$ and $f_{o}$ are found in the sub-frequent chord $u_{t} m_{i} f_{o} l_{u}$; because it is more natural and more conformed to the connection which ought to be found in every part of the music, that $f_{a}$ should be found in the same part where $f_{a}$ has already been founded, whilst the other part was founding $f_{a}$, as may be here seen (parts first and fourth.)

193. Consequences of the former rule.

194. Another consequence.

195. But it is deduced from the dissonant or simple, the note which constitutes the seventh, that is to say, the dissonance, ought dissonantly to defend upon one of the notes which form a consonance in the sub-frequent chord.

197. The tell of the perfection in cadences to be found in the fundamental bass.

198. In a fundamental bass which moves by fifths, there is always, as we have formerly observed, (chap. viii.), a repose more or less perfect from one found to another; and of consequence there must likewise be a repose more or less perfect from one found to another in the dissonant scale, which results from that bass.

199. It may be demonstrated by a very simple experiment, that the cause of a repose in melody is solely in the fundamental bass expressed or understood. Let any performer sing these three notes $r_{e} u_{t} r_{e}$, performing on the $r_{e}$ a flage, which is commonly called a cadence; the modulation will appear to him to be finished after the second $u_{t}$, in such a manner that the ear will neither expect nor any thing to follow. The same if we accompany this modulation with its natural fundamental bass $f_{o} l_{u}$; but if, instead of this bass, we should give it the following $u_{t} f_{o} l_{u}$; in this case the modulation $u_{t} r_{e}$ would not appear to be finished, and the ear would still expect and desire something more. This experiment may easily be made.

200. This passage $f_{o} l_{u}$, when the dominant $f_{o} l_{u}$, broken cadentially ascends upon the note $l_{u}$, instead of descending by a fifth upon the generator $u_{t}$, as it ought, but naturally to do, is called a broken cadence; because the perfect cadence $f_{o} l_{u}$, which the ear expected after the dominant $f_{o} l_{u}$, if we may speak so, broken and suspended by the transition from $f_{o}$ to $l_{u}$.

201. From thence it follows, that if the modulation $u_{t} r_{e}$ appeared finished when we supposèd no bass to it at all, it is because its natural fundamental bass $u_{t} f_{o} l_{u}$ is supposed to be implied; because the ear desires something to follow this modulation, as soon as it is reduced to the necessity of hearing another bass.

202. The
138. The series or fundamental bays by fifths produces the diatonic species in common use (chap. vi.).

139. If then we should form this bay ut, ut, fol, fol, and the two first founds carrying each along with their thirds major and fifths, it is evident that ut will give fol, and that mi will give fol, now the semitone which is between this fol and this sol, is an interval much less than the semitone which is found in the diatonic scale between mi and fa, or between fi and ut. This may be ascertained by calculation (xx): it is for this reason that the semitone from mi to fa is called major, and the other minor (vr).

140. If the fundamental bays should proceed by thirds minor in this manner, ut, mi, fa, a succession which is allowed when we have investigated the origin of the minor mode (chap. ix.), we shall find this modulation fol, fol, which would likewise give a minor semitone (gg.)

141. The minor semitone is hit by young practitioners in imitation with more difficulty than the semitone major. For which reason this may be ascribed: The semitone major which is found in the diatonic scale, as from mi to fa, results from a fundamental bay by fifths ut fa, that is to say, by a succession which is most natural, and for this reason the same to the ear. On the contrary, the minor semitone arises from a succession by thirds, which is still less natural than the former. Hence, that scholars may truly hit the minor semitone, the following artifice is employed. Let us suppose, for instance, that they intend to rise from sol to fol ; they rise at first from sol to la, then descend from fa to sol by the interval of a semitone major; for this sol sharp, which is a semitone below si, proves a semitone minor above sol. (See the notes (ee) and (ff).)

142. Every procedure of the fundamental bays by thirds, whether major or minor, rising or descending, gives the minor semitone. This we have already seen from the succession of thirds in ascending. The series of thirds minor in descending, ut, la, gives ut, ut &c.

2

(EE) In reality, ut being supposed 1, as we have always supposed it, mi is 2, and fol 2 3 2 : now fol being 3, fol will then shall be to sol as 5 2 to 5 ; that is to say, as 25 times 3 to 3 16 : the proportion then of fol to sol is as 25 to 2 4, an interval much less than that of 16 to 1 15, which constitutes the semitone from ut to fi, or from fa to mi (note 1.)

(FF) It may be observed, that a minor joined to a major semitone will form a minor tone; that is to say, if one rises, for instance, from mi to fa, by the interval of a semitone major, and afterwards from fa to sol by the interval of a minor semitone, the interval from mi to sol will be a minor tone. For let us suppose mi to be 1, fa will be 1 1 2, and sol will be 1 2 of 1 4; that is to say, 25 times 16 divided by 2 4 times 1 5, or 25 ; and mi then is to sol as 1 is to 1 5, the interval which constitutes the minor tone (note n.).

With respect to the tone major, it cannot be exactly formed by two semitones; for, 1. Two major semitones in immediate succession would produce more than a tone major. In effect, 1 5 multiplied by 1 3 gives 1 5 8, which is greater than 1, the interval which constitutes (note k) the major tone. A semitone minor and a semitone major would give less than a major tone, since they amount only to a true minor. 3. And, a fortiori, two minor semitones would give still less.

(oo) In effect, mi being 2, fol will be 3 of 1; that is to say, (note c) 1 3; now the proportion of 1 to 3 4 (note c) is that of 3 times 25 to 2 times 36; that is to say, as 25 to 24.

Part I.

Music

Theory of Harmony.

143. The jar, enharmonic notes, and the series of thirds major in descending, ut, fa, b, gives ut, ut, b, (ii).

The minor femitone confitutes the species called chromatic, and with the species which moves by diatonic intervals, resulting from the succession of fifths (chap. v. and vi.), it comprehends the whole of melody.

Chap. XIX. Of the Enharmonic Species.

144. The two extremes, or highest and lowest notes, ut, fa, b, give this modulation fa, b, and these two founds ut, fa, b, differ between themselves by a small interval which is called the diffuse, or enharmonic fourth of a tone (ll.), which is the difference between a femitone major and a femitone minor (mm). This quarter tone is inappreciable by the ear, and impracticable upon several of our instruments. Yet have means been found to put it in practice in the following manner, or rather to perform what will have the same effect upon the ear.

145. We have explained (art. 116.) in what manner the chord fa, b, re, fa may be introduced into the minor mode, entirely confituting of thirds minor perfectly pure, or at least fupplely such. This chord supplying the place of the chord of the dominant (art. 116.) from thence we may pass to that of the tonic or generator la (art. 117.). But we must remark,

1. That this chord fa, b, re, fa, entirely confituting of thirds minor, may be inverted or modified according to the three following arrangements, fa, re, fa, b, fa, b, fa, re, fa, b, and that in all these three

3. X nothing,

Theory of Harmony.

\[(\text{HH})\] La being \(\frac{5}{4}\), ut, b, is \(\frac{5}{4}\) of \(\frac{5}{4}\); that is to say \(\frac{5}{4}\), and ut is 1: the proportion then between ut and ut, is that of 1 to \(\frac{3}{2}\), or of 24 to 25.

\[(\text{ii})\] La, b, being the third major below ut, will be \(\frac{6}{4}\) (note c): ut, b, then, is \(\frac{6}{4}\) of \(\frac{6}{4}\); that is to say \(\frac{6}{4}\).

The proportion, then, between ut and ut, b, is \(\frac{24}{25}\) to \(\frac{25}{24}\).

\[(\text{ll})\] Sol, b, being \(\frac{24}{25}\) and fa, b, being \(\frac{24}{25}\) of \(\frac{24}{25}\), we shall have fa, b, equal (note c) to \(\frac{24}{25}\), and its octave above shall be \(\frac{24}{25}\) an interval less than unity by about \(\frac{1}{2}\) or \(\frac{1}{2}\). It is plain then from this fraction, that the \(\frac{24}{25}\) in question must be considerably lower than ut.

This interval has been called the fourth of a tone and this denomination is founded on reason. In effect, we may distinguish in music four kinds of quarter tones.

1. The fourth of a tone major: now, a tone major being \(\frac{6}{4}\), and its difference from unity being \(\frac{6}{4}\), the difference of this quarter tone from unity will be almost the fourth of \(\frac{6}{4}\); that is to say, \(\frac{6}{4}\).

2. The fourth of a tone minor: and as a tone minor, which is \(\frac{6}{4}\), differs from unity by \(\frac{6}{4}\), the fourth of a tone minor will differ from unity about \(\frac{6}{4}\).

3. One half of a tone major: and as this femitone differs from unity by \(\frac{6}{4}\), one half of it will differ from unity about \(\frac{6}{4}\).

4. Finally, one half of a femitone minor, which differs from unity by \(\frac{6}{4}\): its half then will be \(\frac{6}{4}\).

The interval, then, which forms the enharmonic fourth of a tone, as it does not differ from unity but by \(\frac{6}{4}\), may justly be called the fourth of a tone, since it is less different from unity than the largest interval of a quarter tone, and more than the least.

We shall add, that since the enharmonic fourth of a tone is the difference between a femitone major and a femitone minor; and since the tone minor in formed (note rr.) of two femitones, one major and the other minor; it follows, that two femitones major in succession form an interval larger than that of a tone by the enharmonic fourth of a tone; and that two minor femitones in succession form an interval less than a tone by the same fourth of a tone.

\[(\text{xx})\] That is to say, that if you rise from \(\text{mi}\) to \(\text{fa}\), for instance, by the interval of a femitone major, and afterwards, returning to \(\text{mi}\), you should rise by the interval of a femitone minor to another found which is not in the scale, and which I shall mark thus, \(\text{fa}+\), the two founds \(\text{fa}+\) and \(\text{fa}\) will form the enharmonic fourth of a tone: for \(\text{mi}\) being \(\frac{1}{2}\), \(\text{fa}\) will be \(\frac{1}{2}\); and \(\text{fa}+\), \(\frac{1}{2}\); the proportion then between \(\text{fa}+\) and \(\text{fa}\) is that of \(\frac{1}{2}\) to \(\frac{1}{2}\) (note c); that is to say, as \(25\) times \(15\) to \(16\) times \(24\); or otherwise, as \(25\) times \(5\) to \(16\) times \(8\); or as \(125\) to \(128\). Now this proportion is the same which is found in the beginning of the preceding note, to express the enharmonic fourth of a tone.
nothing, in common with the minor mode of la, and which are entirely foreign to it (†).

146. It must, however, be acknowledged, that a transition so abrupt, and so little expected, cannot deceive nor elude the ear; it is struck with a sensation so unlooked-for without being able to account for the passage to itself. And this account has its foundation in the enharmonic fourth of a tone; which is overlooked as nothing, because it is inappetiteble by the ear; but of which, though its value is not ascertained, the whole harshness is sufficiently perceived. The intent of surprize, however, immediately vanishes; and that astonishment is turned into admiration, when one feels himself transported as it were all at once, into a new and entirely unexpected state.

Chap. XXI. Of the Diatonic Enharmonic Species.

147. If we form a fundamental bass, which rises alternately by fifths and thirds, as fa, ut, mi, fa, this bass will give the following modulation, fa, mi, mi, re, in which the femitones from fa to mi, and from mi to re, are equal and major (N). This species of modulation or of harmony, in which all the femitones are major, is called the enharmonic diatonic species. The major femitones peculiar to this species give it the name of diatonic, because major femitones belong to the diatonic species; and the tones which are greater than major by the excess of a fourth, resulting from a succession of major femitones, give it the name of enharmonic (note 1).

Chap. XXII. Showing that Melody is the Offspring of Harmony.

153. All that we have hitherto said, as it seems to The effects of melody, is more than sufficient to convince us, that melody of harmony has its own principle in harmony; and that it is impossible that melody be formed of two sounds which are not contiguous one to the other in the series of thirds (art. 144.).

154. If this should still appear doubtful, nothing or uncertainty is more necessary than to pay due attention to the first and most surprising experiment (art. 19.), where it may be seen that the principal sound is always the lowest, and that the sharp sound which it generates is with relation to it what the treble of an air is to its bass.

155. Yet more, we have proved, in treating of broken cadence (chap. xviii.), that the diversification of basses...
Part I.

MUS I C.

Theory of Harmony.

157. From these different observations it may be main, the same with that of the
classical theory of bases and the different pairs of different names, and the different effects of a modulation, without any other alteration except that of changing its fundamental basis.

M. Rameau has shown, in his New System of Music, printed at Paris 1726, p. 44, that this modulation of a, of which it will be found susceptible of a great many, and each of these bases will give a different character to the modulation of a, though in itself it remains always the same; in such a manner that we may change the whole nature and effects of a modulation, without any other alteration except that of changing its fundamental basis.

217 Consequence deducible from this principle.

158. Composition, which is likewise called counterpoint, is not only the art of composing an agreeable air, but also that of composing a great many airs in such a manner that when heard at the same time, they may unite in producing an effect agreeable and delightful to the ear; this is what we call composing music in several parts.

The highest of these parts is called the treble, the lowest is termed the bass; the other parts, when there are any, are termed middle parts; and each in particular is figured by a different name.

Chap. I. Of the Different Names given to the same Interval.

159. In the introduction (art. 9.), which is at the front of this treatise, we have seen a detail of the most common names which are given to the different intervals. But there are particular intervals which have obtained different names, according to particular circumstances; which it is proper to explain.

160. An interval composed of a tone and a semitone, which is commonly called a third minor, is likewise sometimes called a second redundant; such is the interval from a to f which can be used in ascending, or that of a to a.

This interval is so termed, because one of the grounds which form it is always either sharp or flat, and that, if you deduce that sharp or that flat, the interval will be that of a second.

161. An interval composed of two tones and two semitones is called the false fifth, from its being composed of two tones and two semitones, as f to a, is called the false fifth.

This interval is the same as that of the triton (art. 9.), since two tones and two semitones are equivalent to three tones. There are, however, some reasons for distinguishing them, as will appear below.

162. As the interval from a to a in ascending and descending.

This interval is in the main, the same with that of the fifth minor (art. 6.): but in the fifth redundant, there is always a sharp or a flat; in some, though if this sharp or flat were deduced, the interval would become a true fifth.

163. For the same reason, an interval composed of seven semitones is also.

Three tones and three semitones, as from a to a in minished, ascending, what.

In particular, we have seen a detail of the most common names which are given to different intervals. But there are particular intervals which have obtained different names, according to particular circumstances; which is proper to explain.

160. An interval composed of a tone and a semitone, which is commonly called a third minor, is likewise sometimes called a second redundant; such is the interval from a to a in ascending, or that of a to a.

This interval is so termed, because one of the grounds which form it is always either sharp or flat, and that, if you deduce that sharp or that flat, the interval will be that of a second.

161. An interval composed of two tones and two semitones is called the false fifth, from its being composed of two tones and two semitones, as f to a, is called the false fifth.

This interval is the same as that of the triton (art. 9.), since two tones and two semitones are equivalent to three tones. There are, however, some reasons for distinguishing them, as will appear below.

162. As the interval from a to a in ascending and descending.

This interval is in the main, the same with that of the fifth minor (art. 6.): but in the fifth redundant, there is always a sharp or a flat; in some, though if this sharp or flat were deduced, the interval would become a true fifth.

163. For the same reason, an interval composed of seven semitones is also.

Three tones and three semitones, as from a to a in minished, ascending, what.

There are likewise several eminent musicians, who in their compositions, if we can depend on what has been affirmed, begin with determining and writing the bases. This method, however, appears in general, more proper to produce a learned and harmonious music, than a strain prompted by genius and animated by enthusiasm.

224 There are several eminent musicians, who in their compositions, if we can depend on what has been affirmed, begin with determining and writing the bases. This method, however, appears in general, more proper to produce a learned and harmonious music, than a strain prompted by genius and animated by enthusiasm.
afcending, is called a seventh diminished; because if 
you deduce the sharp from fa, the interval from fa to 
fa will become that of an ordinary seventh. The in-
terval of a seventh diminished is in other respects 
the fame with that of the fith major (art. 9.)
164. The major feventh is likewise sometimes called 
a seventh redundant (qq.)

**MUSIC.**

**Part II.**

**CHAP. III. Of the different Clefs: of the Value or 
Quantity; of the Ritbmus; and of Syncopation.**

170. There are three clefs* in music; the cleff of *See Cleff. 
fa F; or the cleff of fa $\begin{array}{l}
\text{the cleff of fa}
\end{array}$; and the cleff of fa 
$\begin{array}{l}
\text{the cleff of fa}
\end{array}$.
But, in Britain, the following characters are 
used: The F, or bafs-cleff $\begin{array}{l}
\text{the C, or tenor}
\end{array}$; and the G, or treble cleff $\begin{array}{l}
\text{the C, or tenor}
\end{array}$.

The cleff of fa is placed on the fourth line, or on 
the third; and the line upon which this cleff is placed 
and the line upon which this cleff is placed. And how 
gives the name of fa or F, to all the notes which are 
placed upon that line.

The cleff of ut is placed upon the fourth, the third, 
the second, or the firft line; and in these different po-
tions all the notes upon that line where the cleff is 
placed take the name of ut, or C.

Lastly, the cleff of fa is placed upon the second or 
first line; and all the notes upon that line where the 
clef is placed take the name of fa or C.

171. As the notes are placed on the lines, and in 
Names of 
the spaces between the lines, any one, when he sees notes to be 
the cleff, may easily find the name of any note what-
soever. Thus he may see, that, in the firft cleff of fa, 
the note which is placed on the lowest line ought to be 
fa; that the note which occupies the space between 
the two firft lines should be fa; and that the note 
which is on the second line is a fa, &c. (kr).

172. A

*The chief use of these different denominations is to distinguish chords: for instance, the chord of the redundant fifth and that of the diminished seventh are different from the chord of the fifth; the chord of the seventh redundant, from that of the seventh major. This will be explained in the following chapters.*
Thus far the translator has followed his original as accurately as possible; but this was by no means an easy task. Among all the writers on music which he has found in English, there is no such thing as different names for each particular part which is employed to constitute full or complete harmony. He was therefore under a necessity of substituting by analogy such names as appeared most expressive of his author's meaning. To facilitate this attempt, he examined in Rousseau's musical dictionary the terms by which the different parts were denominated in l'Alembert; but even Rousseau, with all his depth of thought and extent of erudition, instead of expounding himself with that precision which the subject required, frequently applies the same names indiscriminately to different parts, without alluding any reason for this promiscuous and licentious use of words. The English reader therefore will be best able to form an accurate idea of the different parts, by the nature and situation of the clefs with which they are marked; and if he should find any impropriety in the names which are given them, he may adopt and abbreviate others more agreeable to his ideas.

SYNCOPE. Syncope is a note which is protracted in two different times belonging partly to the one and partly to the other, or in two different bars; yet not so as entirely to occupy or fill up the two times, or the two bars. A note, for instance, which begins in the imperfect time of a bar, and which ends in the perfect time of the following, or which in the same bar begins in the imperfect part of one time and ends in the perfect part of the following, is syncopated. A note which of itself occupies one or two bars, whether the measure consists of two or three times, is not considered as syncopated: this is a consequence of the preceding definition. This note is said to be continued or protracted. In the end of the example Z, the ut of the first bar constituting three times is not syncopated, because it occupies two whole times. It is the same case with ma of the second bar, and with the ut of the fourth and fifth. These therefore are continued or protracted notes.

† Times and bars in music answer the very same end as punctuation in language. They determine the different periods of the movement, or the various degree of completion, which the sententia, expressed by that movement, has attained. Let us suppose, for instance, a composer in music intending to express grief or joy, in all its various gradations, from its first and finest shade of expression, to its acme or highest possible degree. We do not say that such a progress of any passion either has been or can be delineated in practice, yet it may serve to illustrate what we mean to explain. Upon this hypothesis, therefore, the degrees of the sententia will pass from less to more intense, as it tides to its most intense degree. The first of these gradations may be called a time, which is likewise the most convenient division of a bar or measure into its elementary or quaver parts, and may be deemed equivalent to a comma in a sentence; a bar denotes a degree still more sensible, and may be considered as having the force of a semiceloc; a strain brings the sententia to a tolerable degree of perfection, and may be reckoned equal to a colon: the full period is the end of the inititative piece. It must have been remarked by observers of measure in melody or harmony, that the notes of which a bar or measure consists, are not diversified by their different durations alone, but likewise by greater or lesser degrees of emphasis,
The most emphatic parts of a bar are called the second and third, which require the greater degree of importance. To prevent ambiguity or confusion of ideas, it is necessary to inform our readers that we have allowed the different measures by different quantities of duration. By confining both these ideas, the word "duration" is employed by Dr. Almer. The reader, therefore, will find it easy to mark the importance of a note in height. The time is employed by different degrees of duration. The notation of time is employed by different degrees of duration. The notation of time is employed by different degrees of duration. The notation of time is employed by different degrees of duration. The notation of time is employed by different degrees of duration.
Part II.

Principles of Composition.

247 Tonic and simple dominant.

In every other chord of the seventh the fundamental is called the simple dominant (art. 102.) Thus in the chord fol fi re fa, the fundamental fol is the tonic dominant, but in the other chords of the seventh, as ut mi fol fi, re fa la ut, &c., the fundamentals ut and re are simple dominants.

186. In every chord, whether perfect, or of the seventh, or of the sixth, if you have a mind that the third above the fundamental note should be major, though it is naturally minor, you must place a sharp above the fundamental note. For example, if I would mark the perfect major chord re fa la re, as the third fi above re is naturally minor, I place above re a sharp, as you may see in example IV. In the same manner the chord of the seventh re fa la ut, and the chord of the great sixth re fa la fi, is marked with a flat above re, and above the fi a 7 or a 5 (see V. and VI.)

On the contrary, when the third is naturally major, and if you should incline to render it minor, you must place above the fundamental note a fi. Thus the examples VII. VIII. IX. show the chords fol fi re fa, fol fi fi re fa, fol fi re fi re mi (TT).

CHAP. V. Of the Fundamental Bass.

189. Invent a modulation at your pleasure; and under this modulation let there be set a bass composed of different notes, of which some may carry a perfect chord, others that of the seventh, and others that of the great sixth, in such a manner that each note of the modulation which answers to each of the basses, may be one of those which enters into the chord of that note in the bass; this bass being composed according to the rules; which shall be immediately given, will be the fundamental bass of the modulation proposed. See Part I., where the nature and principles of the fundamental basses are explained.

Thus (Exam. XVIII.) you will find that this modulation, ut re mi fa fol fi la ut, has or may admit for its fundamental bass ut fol fi fa ut re fol ut.

In reality, the first note ut in the upper part is found in the chord of the first note ut in the bass, which chord is ut mi fol ut; the second note re is found in the chord fol fi re fa, which is the chord of the second note in the bass, &c., and the bass is composed only of notes which carry a perfect chord, or that of the seventh, or that of the great sixth. Moreover, it is formed according to the rules which we are now about to give.

CHAP. VI. Rules for the Fundamental Basses.

190. All the notes of the fundamental bass being only capable of carrying a perfect chord, or of the formation of this bass, the fundamental bass of the seventh, or that of the great sixth, is either tonic, or dominants, or sub-dominants; and the dominants may be either simple or tonic.

The fundamental bass ought always to begin with a tonic, as much as it is practicable. And now follow the rules for all the succeeding chords; rules which are evidently derived from the principles established in the First Part of this treatise. To be convinced of this, we shall find it only necessary to review the articles 34, 91, 122, 124, 126, 127.

RULE I.

191. In every chord of the tonic, or of the tonic dominant, it is necessary that at least one of the notes which form that chord should be found in the chord that precedes it.

RULE II.

192. In every chord of the simple dominant, it is necessary

(TT) We may only add, that there is no occasion for making these sharps or flats when they are originally placed at the clef. For instance, if the sharp be upon the clef of fa (see Exam. X.), one may satisfy himself with simply writing re, without a sharp to mark the perfect chord major of re, re fa la re. In the same manner, in the Example XI. where the flat is at the clef upon fi, one may satisfy himself with simply writing fol, to mark the perfect chord minor of fol fi re fol.

But if a case occurs where there is a sharp or a flat at the clef, if any one would wish to render the chord minor which is major, or vice versa, he must place above the fundamental note a fi or natural. Thus the Example XII. marks the minor chord re fa la re, and Example XIII. the major chord fol fi re fol. Frequently, in lieu of a natural, a flat is used to signify the minor chord, and a sharp to signify the major. Thus Example XIV. marks the minor chord re fa la re, and Example XV. the major chord fol fi re fol.

When in a chord of the great sixth, the dissonance, that is to say, the sixth, ought to be sharp, and when the sharp is not found at the clef, they write before or after the fi a fi; and if this sixth should be flat according to the clef, they write a fi.

In the same manner, if in a chord of the seventh of the tonic dominant, the dissonance, that is to say, the seventh, ought to be flat or natural, they write by the side of the seventh a fi or a fi. Many musicians, when a seventh from the simple dominant ought to be altered by a sharp or a natural, have likewise written by the side of the seventh a fi or a fi; but M. Rameau supposes these characters. The reason shall be given below, when we speak of chords by supposition.

If there be a sharp on the clef of fa, and if I should incline to mark the chord fol fi re fa, or the chord la ut mi fa, I would place before the seventh or the fi a fi or a fi.

In the same manner, if there be a flat on the clef at fi, and if I should incline to mark the chord ut mi fol fi, I would place before the seventh a fi or a fi, and so of the rest.
RULE III.

193. In every chord of the sub-dominant, at least one of its consonances must be found in the preceding chord. Thus, in the chord of the sub-dominant fe la ut re, it is necessary that fe, la, or ut, which are the consonances of the chord, should be found in the chord preceding. The distance re may either be found in it or not.

RULE IV.

194. Every simple or tonic dominant ought to descend by a fifth. In the first case, that is to say, when the dominant is simple, the note which follows can only be a dominant; in the second it may be any one you please; or, in other words, it may either be a tonic, a tonic dominant, a simple dominant, or a sub-dominant. It is necessary, however, that the conditions prescribed in the second rule should be observed, if it be a simple dominant.

This last reflection is necessary, as you will presently see. For let us assume the succession of the two chords la ut se, fol re fa la ut (see Exam. XIX.), this succession is by no means legitimate, though in it the dominant descends by a fifth; because the ut which forms the dissonance in the second chord, and which belongs to a simple dominant, is not in the preceding chord. But the succession will be admissible, if, without meddlin; with the second chord, one should take away the sharp carried by the ut in the first, or, if without meddlin; with the first chord, one should render ut or fa sharp in the second (uv); or in short, if one should simply render the re of the second chord a tonic dominant, in causing it to carry fa instead of fa natural (119. & 122.).

It is likewise by the same rule that we ought to reject the succession of the two following chords, re fa la ut, fol fi re fa re (uv); (see Exam. XX.).

RULE V.

195. Every sub-dominant ought to rise by a fifth; and the note which follows it may, at your pleasure, be either a tonic, a tonic dominant, or a sub-dominant.

Remark. Of the five fundamental rules which have now been given, instead of the three first, one may substitute the three following, which are nothing but consequences from them, and which you may pass unnoticed, if you think it proper.

RULE I.

If a note of the fundamental bass be a tonic, and rise by a fifth or a third to another note, that second note may be either a tonic (34. & 91.), see Examples XXI. and XXII. (xx); a tonic dominant (124.), see XXIII. and XXIV.; or a sub-dominant (124.), see XXV. and XXVI.; or, to express the rule more fully, that second note may be any one you please, except a dominant simple.

RULE II.

If a note of the fundamental bass be a tonic, and descend by a fifth or a third upon another note, this second note may be either a tonic (34. & 91.), see Exam. XXVII. and XXVIII.; or a tonic dominant, or a simple dominant, yet in such a manner that the rule of art. 192. may be observed (124.), see XXIX. XXX. XXXI. XXXII.; or a sub-dominant (124.), see XXXIII. and XXXIV.

The procedure of the bass ut mi b fol ut, fa la ut mi, from the tonic ut to the dominant fa (Ex. XXXV.), is excluded by art. 192.

RULE III.

If a note in the fundamental bass be a tonic, and descend by a fifth or a third upon another note, that note ought to be a dominant simple, or a simple dominant (101. & 122.). See XXXVI. and XXXVII. (yy.)

We must here advertise our readers, that the examples XXXVIII. XXXIX. XL. XLI. belong to the fourth rule above, art. 194; and the examples XLII. XLIII. XLIV. to the fifth rule above, art. 195. See the articles 34, 35, 121, 123, 124.

Remark. I.

196. The transition from a tonic dominant to a perfect and tonic is called an absolute repercussion, or a perfect cadence imperfect (73.); and the transition from a sub-dominant to a cadence, tonic is called an imperfect or irregular cadence (73.) what, and by what, and how employed.

The cadences are formed at the distance of four bars one from another, whilst the tonic then falls within the first time of the bar. See XLV. and XLVI.

Remark II.

197. We must avoid, as much as we can, syncopations in the fundamental bass; that, within the first time only of which a bar is constituted, the ear may be entertained with a harmony different from that which it is accustomed to the fundamental bass by license.
**Part II.**

**Musical Principles of Composition.**

had before perceived in the last time of the preceding task. "Never-theless, fyncopeation may be sometimes admitted in the fundamental bas, but it is by a licence (21).

**Chap. VII. Of the Rules which ought to be observed in the Treble with relation to the Fundamental Bas.**

214. Definition of treble.

198. The treble is nothing else but a modulation above the fundamental bas, and whole notes are found in the chords of that bas which corresponds with it (199). Thus in Ex. XVIII. the scale at re mi fa sol la, is a treble with respect to the fundamental bas ut sol fa ut re fol ut.

215. One note in the treble or bas may answer to several of its corresponding parts, and why.

1. It is obvious, that many notes of the treble may answer to one and the same note in the fundamental bas, when these notes belong to the chord of the same note in the fundamental bas. For example, this modulation ut re mi fa sol la may have for its fundamental bas the note ut alone, because the chord of that note comprehends the sounds ut, mi, sol, which are found in the treble.

2. In like manner, a single note in the treble may, for the same reason, answer to several notes in the bas.

**Rule I. for the Treble.**

200. If the note which forms the seventh in a chord of the simple dominant is found in the treble, the note which precedes it must be the very same. This is what we call a discord prepared (12). For instance, let us suppose that the note of the fundamental bas shall be re, bearing the chord of the simple dominant re fa la ut; and that this ut, which (art. 18. and 118.) is the dissonance, should be found in the treble; it is necessary that the note which goes before it in the treble should likewise be an ut.

201. And it is requisite to observe, that according to the rules which we have given for the fundamental bas, ut will always be found in the chord of that note in the fundamental bas which precedes the simple dominant re. See XLVIII. XLI. L. In the first example the dissonance is ut, in the second fol, and in the third mi; and these notes are already in the preceding chord (bbb).

**Rule II.**

202. If a note of the fundamental bas be a tonic dominant, or a simple dominant, and if the dissonance be found in the treble, this dissonance in the same treble ought to descend diatonically. But if the note...
of the bass be a sub-dominant, it ought to rise diatonically. This diﬀerence, which rises or descends diatonically, is what we have called a diﬀerence forced or refolved (129, 130). See L.II. L.III. L.IV.

205. One may likewise observe here, that, according to the rules for the fundamental bass which we have given, the note upon which the dissonance ought to descend or rise will always be found in the subse-
quent chord (ccc).

CHAP. VIII. Of the Continued Basses, and its Rules.

204. A continued or thorough bass, is nothing else but a fundamental bass whose chords are inverted. We invert a chord when we change the order of the notes which compose it. For example, if instead of the chord $\text{f} \text{i} \text{r} \text{e} \text{f} \text{a}$, I should say $\text{f} \text{e} \text{r} \text{i} \text{a} \text{f} \text{e} \text{r}$ or $\text{f} \text{a} \text{f} \text{e} \text{i} \text{r}$, &c. the chord is inverted. Let us see then, in the first place, all the possible ways in which a chord may be inverted.

**The ways in which a Perfect Chord may be Inverted.**

205. The perfect chord $\text{m} \text{i} \text{f} \text{a} \text{f} \text{u} \text{u}$ may be inverted in two different ways.

1. $\text{m} \text{i} \text{f} \text{a} \text{f} \text{u} \text{m}$, which we call a chord of the sixth, composed of a third, a sixth, and an octave, and in this case the note $\text{m}$ is marked with a 6. (See L.V.)

2. $\text{s} \text{i} \text{m} \text{a} \text{f} \text{u}$, which we call a chord of the sixth and fourth, composed of a fourth, a sixth, and an octave; and it is marked with a 2. (See L.VII.)

The perfect minor chord is inverted in the same manner.

**The ways in which the Chord of the Seventh may be Inverted.**

206. In the chord of the tonic dominant, as $\text{f} \text{i} \text{r} \text{e} \text{f} \text{a}$, the third major $\text{f} \text{i}$ above the fundamental note $\text{f} \text{a}$ is called a sensible note (77); and the inverted chord $\text{f} \text{i} \text{r} \text{e} \text{f} \text{a} \text{f} \text{a}$, composed of a third, a false fifth, and sixth, is called the chord of the false fifth, and is marked with an 8 or a 6 (see L.VII. and L.IX.)

The chord $\text{f} \text{i} \text{r} \text{e} \text{f} \text{a}$, composed of a third, a fourth, and a sixth, is called the chord of the senible sixth, and marked with a 6 or a $\text{f} \text{a}$. In this chord thus figured, the third is minor, and the sixth major, as it is easy to be perceived. (See L.X.)

The chord $\text{f} \text{i} \text{r} \text{e} \text{f} \text{a}$, composed of a second, a tritone, and a sixth, is called the chord of the tritone, and is marked thus $\text{f} \text{i} \text{r} \text{e} \text{f} \text{a} \text{f} \text{a}$, thus $\text{f} \text{i} \text{r} \text{e} \text{f} \text{a} \text{f} \text{a}$ or thus $\text{f} \text{i} \text{r} \text{e} \text{f} \text{a} \text{f} \text{a}$ (See L.XI.)

207. In the chord of the simple dominant $\text{f} \text{i} \text{r} \text{e} \text{f} \text{a}$, we find,

1. $\text{f} \text{i} \text{r} \text{e} \text{f} \text{a}$, a chord of the great fifth, which is composed of a third, a fifth, and a sixth, and which is figured with a $\text{f} \text{i}$. See L.XII. (fnd).

2. $\text{f} \text{i} \text{r} \text{e} \text{f} \text{a}$, a chord of the lesser sixth, which is figured with a 6. See L.XIV. (see).

3. $\text{f} \text{i} \text{r} \text{e} \text{f} \text{a} \text{f} \text{a}$, a chord of the second, composed of a second, a fourth, and a sixth, and which is marked with a 2. See L.XII. (ff).

**The ways in which the Chord of the Sub-dominant may be Inverted.**

209. The continued bass is a fundamental bass, whose chords are only inverted in order to render it more in the taste of singers, and suitable to the voice. See L.XV. in which the fundamental bass which in itself is monotonous and little suited for singing, $\text{f} \text{i} \text{r} \text{e} \text{f} \text{a}$, produces, by inverting its chords, this continued
RULE I.

210. Every note which carries the chord of the false fifth, and which of consequence must be what we have called a *false* note, ought (77) to rise diatonically upon the note which follows it. Thus in example LXV, the note $j$, carrying the chord of the false fifth marked with an 8, rises diatonically upon $u$ (HHH).

RULE II.

211. Every note carrying the chord of the tritone of the fundamental bass, should descend diatonically upon the subsequent note. Thus in the same example LXV, $j$, which carries the chord of the tritone figured with a 4, descends diatonically upon $u$ (Art. 202).

RULE III.

212. The chord of the second is commonly put in practice upon notes which are syncopated in descending, because these notes are dissonances which ought to be prepared and resolved (200, 202). See the example LXVI, where the second $n$, which is syncopated, and which descends afterwards upon $f$, carries the chord of the second (111).

CHAP.
Broken cadence, how executed. 213. The broken cadence is executed by means of a dominant which rises diatonically upon another, or upon a tonic by a licence. See, in the example LXXIV.

214. The interrupted cadence is formed by a dominant which descends by a third upon another (136). See, in the example LXXV. fol mi (LLL).

These cadences ought to be permitted but rarely and with precaution.

2. Of Supposition.

215. When a dominant is preceded by a tonic in the fundamental bass, we add sometimes, in the continued balsa to the chord of that dominant, a new note which is a third or fifth below; and the chord which results from it in this continued balsa is called a chord by supposition.

For example, let us suppose, that in the fundamental bass we have a dominant fol carrying the chord of the seventh fol f re fa; let us add to this chord the note ut, which is a third below this dominant, and we shall have the total chord ut fol f re fa, or ut re f fol f, which is called a chord by supposition (MMM).

Of the different kinds of chords by supposition.

216. It is easy to perceive, that chords by supposition are of different kinds. For instance, the chord of the tonic fol f re fa gives:

1. By adding the fifth ut, the chord ut fol f re fa, called a chord of the seventh redundant, and composed of a fifth, seventh, ninth, and eleventh. It is figured with a 5, see LXXVI. (MM). This chord is not a dominant, of the same kind as the above, pradiced but upon the tonic. They sometimes leave out the sensible note, for reasons which we shall give more fully in the note 1ooq, upon the art. 219: it is then reduced to ut fa fol re, and marked with 5 or 6.

2. By adding the third mi, we shall have the chord mi fol f re fa, called a chord of the ninth, and composed of a third, fifth, seventh, and ninth. It is figured with a 7. This chord may be added to every third of the dominant. See LXXVII. (000).

3. If to a chord of the simple dominant, as re fa la ut, we should add the fifth fol, we would have the chord fol f re fa la ut, called a chord of the eleventh, and which is figured with a 5 or 6. (See LXXVIII.)

Observe.

217. When the dominant is not a tonic dominant, occasions may arise, when they often take away some notes from the chord. For when we examine, that in the example LXXIV. (LLL), the fourth and fifth notes of the fundamental balsa are all figurred, it is necessary, to render it practicable, that the fifth below the first tonic should be found in the chord of the tonic following, as here fa, a fifth below the first tonic ut, is found in the chord re fa la re, and in the chord f re fa f (37 and note a.)

Even without having recourse to this experiment, we may remark, that the note added beneath the fundamental found, causes that very fundamental found to be heard. For instance, if added beneath the fundamental folve, it causes the fol to be found. Thus fol is found in some measure to be implied in ut.

If the third added beneath the fundamental found be minor, for example, if to the chord fol f re fa, we add the third mi, the supposition is then no longer found on the experiment, which only gives the seventeenth major, or, what is the same thing, the third major beneath the fundamental found. In the same, the addition of the third minor must be considered as an extension of the rule, which in reality has no foundation in the chords emitted by a famous body, but is authorized by the fandition of the ear and by practical experiment.

(MMM) Many musicians figure this chord with a 5, M. Rameau suppresses this 5, and merely marks it to be the seventh redundant by a 7, or 7. But it may be said, how shall we distinguish this chord from the seventh major, which, as it would seem, ought to be marked with a 7, M. Rameau answers, that there is no danger of mistake, because in the seventh major, as the seventh ought to be prepared, it is found in the preceding chord; and thus the sharp subsisting already in the preceding chord, it would be useless to repeat it.

Thus re fole, according to M. Rameau, would indicate re fole la ut, fol f re fa. If we would change fa fole, of the second chord into fa, it would then be necessary to write re fol. In notes fifth as ut, whose natural seventh is major, the figure 7 preceded or followed by a sharp will sufficiently serve to distinguish the chord of the seventh redundant ut fol f re fa, from the simple chord of the seventh ut mi fol f, which is marked with a 7 alone. All this appears just and well founded.

(000) Supposition introduces into a chord dissonances which were not in it before. For instance, if to the chord mi fol f re, we should add the note of supposition ut descending by a third, it is plain that, besides the dissonance
Part II.

M U S I C.

Principles of Composition.

219. In this state the chord is simply composed of a third, fifth, and ninth, and is marked with a $9$. See LXXIX. ([prp])

218. What is more, in the chord of the simple dominant, as re fa la $ut$, when the fifth $fa$ is added, they frequently obliterate the sounds $fa$ and $la$, that too great a number of dissonances may be avoided, which reduces the chord to $fa$ ut $re$. This last is composed only of the fourth and the fifth. It is called a chord of the fourth, and it is figured with a $4$. (See LXXX.)

219. Sometimes they only remove the note $la$, and then the chord ought to be figured with $4$ or $6$. ([qqq])

220. Finally, in the minor mode, for example, in that of $la$, where the chord of the tonic dominant (109) is $mi fol$ $fa$ $re$ $si$; if we add to this chord the third $ut$ below, we shall have $ut mi fol$ $fa$ $re$, called the chord of the fifth redundant, and composed of a third, a fifth redundant, a seventh, and a ninth. It is figured with a $5$ or $4+5$. See LXXXI. (rrr.)

§ 3. Of the Chord of the Diminished Seventh.

221. In the minor mode, for instance, in that of $la$ a third $mi$ a fifth $re$ from $la$ is the tonic dominant (109), and carries the chord $mi fol$ $fa$ $re$, in which $fa$ is the sensible note. For this chord they sometimes substitute that other $jol$ $fa$ $re$ $fa$ (116), all composed of minor thirds; and which has for its fundamental found the sensible note $jol$. This chord is called a chord of the flat, or diminished seventh, and is figured with a $7$ in the fundamental bass, (see LXXXII.): but it is always considered as representing the chord of the tonic dominant.

222. This chord in the fundamental bass produces in the continued bass the following chords:

1. The chord $fa$ $fol$ $fa$ $re$, composed of a third, a fifth, and fifth major. They call it the chord of the seventh sensible and false fifth; and it is figured thus $7$ or $7+5$. (See LXXXIII.)

2. The chord $re$ $fa$ $fol$ $fa$, composed of a third, a tritone, and a sixth, they call it the chord of the tritone and third minor; and they mark it thus $5$. (See LXXXIV.)

3. The chord $fa$ $fol$ $fa$ $re$, composed of a second redundant, a tritone, and a sixth. They call it the chord of the second redundant, and they figure it thus $5+5$, or $5+4$. See LXXXV. (ss)."
MUSI C.

Part II.

Principles of Composition.

542

To add to the chord whose effect is to be produced, the notes must be such that the effect will be obtained.

1. By adding a seventh, the chord $\text{fa} \text{fa} \text{fa}$, composed of a fifth redundant, a seventh, a ninth, and an eleventh, which is the octave of the fourth, is called the chord of the fifth redundant and fourth, and marked $\text{fa} \text{fa}$ or $\text{fa} \text{fa}$. (See LXXXVI.)

2. By adding a minor seventh, we shall have the chord $\text{fa} \text{fa} \text{fa}$, composed of a seventh redundant, a ninth, an eleventh, and a thirteenth minor, which is the octave of the sixth minor. It is called the chord of the seventh redundant and sixth minor, and marked $\text{fa} \text{fa} \text{fa}$. (See LXXVII.)

In like manner, in a continued bass, the diatonic effect which it has to be produced is obtained by raising the note upon which it ought to have descended. This licence ought to be rarely practised.

In like manner, in a continued bass, the diatonic effect which it has to be produced is obtained by raising the note upon which it ought to have descended. This licence ought to be rarely practised.

Chap. XI. Containing the Method of finding the Fundamental Basses when the Continued Bases are figured.

226. To exercise yourself with greater ease in finding the fundamental basses, and to render it more familiar to you, it is necessary to observe how eminent masters have practised their works, and above all how M. Rameau has put the rules into practice. Now, as they never place any thing but the continued basses in their works, it becomes then necessary to know how to find the fundamental basses when the continued bass is figured. This problem may be easily solved by the following rules.

227. 1. Every note which has no figure in the continued bass, ought to be the same, and without a figure in the fundamental bass; it either is a tonic, or reckoned such, (uuu). We shall distinguish these two cases below. (See LVI. red. and LXIV. and the note z z z.)

2. Every note which in the continued bass carries a $\text{fa}$, ought in the fundamental bass to give its third below, and without a figure, (uuu). Every note which has no figure in the continued bass is figured. (See LXVII.)

3. Every note carried $\text{fa}$ gives in the fundamental bass its fifth below not figured. (See LVI.

4. Every note figured with a 7 or a 5, is the same in both basses, and with the same figure. (xxx.)

5. Every note figured with a 2 gives in the fundamental bass the diatonic note above figured with a 7. (See LXII. (yyy.)

6. Every note marked with a 4 gives in the fundamental bass a 7, and that a simple dominant, carrying the diatonic note above figured with a 7. (See LXIV.)

As the chord of the diminished seventh $\text{fa} \text{fa} \text{fa}$, and the chord of the tonic dominant $\text{fa} \text{fa} \text{fa}$, only differ one from the other by the notes mi and fa; one may form a diatonic modulation of these two notes, and then the fundamental bass does nothing but pass from the tonic dominant to the fundamental note, and from that note to the tonic dominant, till it arrives at the tonic. (See XCII.)

For the same reason, as the chord of the diminished seventh $\text{fa} \text{fa} \text{fa}$, and the chord $\text{fa} \text{fa} \text{fa}$, which carries the fifth of the tonic dominant, only differs by the notes fa and la, one may sometimes, while the treble modulates $\text{fa} \text{fa} \text{fa}$, ascend in the fundamental bass, from the bass note to the third above, provided one descend at last from thence to the tonic dominant, and from thence to the tonic; (see XCIII.) As to what remains, this and the preceding examples are licences.

(yyy) A note figured with a 2, gives likewise sometimes in the fundamental bass its fourth above, figured with a 6. For example, this continued bass $\text{fa} \text{fa} \text{fa}$ gives this fundamental bass $\text{fa} \text{fa} \text{fa}$; but in this case it is necessary that the note figured with a 6 should rise by a fifth, as we see here $\text{fa}$ rise to $\text{fa}$.
Principles of Composition.

Part II.

Mental bas the diatonic note above, figured with a 7. (See LXI.)

7. Every note figured with an 8 gives its third below figured with a 7. (See LVII.)

8. Every note marked with a 6 gives the fifth below marked with a 7; (See LX.) and it is plain that the chord of the seventh, of which we treat in the three last articles, the third ought to be major, and the seventh minor, this chord the seventh being the chord of the tonic dominant. (See art. 102.)

9. Every note marked with a 9 gives its third above figured with a 7. (See LXXVII and LXXIX.)

10. Every note marked with a 2 gives the fifth above figured with a 7. (See LXXVIII.)

11. Every note marked with a + 5, or with a + 7, gives the third above figured with a 7. (See LXXXI.)

12. Every note marked with a 8 gives a fifth above figured with a 7, or with a 5. (See LXXXII.) It is the same case with the notes marked 7, 4, or 5, which shows a retrenchment, either in the complete chord of the eleventh, or in that of the seventh redundant.

13. Every note marked with a 4 gives a fifth above figured with a 7, or a 7. (See LXXX.)

14. Every note marked with a + 5 gives the third minor below, figured with a 7. (See LXXXIII.)

15. Every note marked with a + 6 gives the tritone above figured with a 7. (See LXXXIV.)

16. Every note marked with a + 2 gives the second redundant above, figured with a 7. (See LXXXV.)

17. Every note marked with a + 4 gives the fifth redundant above, figured with a 7. (See LXXXVI.)

18. Every note marked with a + 5 gives the seventh redundant above, figured with a 7. (See LXXXVII.)

Remark.

228. We have omitted two cases, which may cause some uncertainty.

The first is that where the note of the continued bass is figured with a 6. We now present the reason of the difficulty.

Suppose we should have the dominant seventh in the fundamental bass, the note which answers to it in the continued bass may be la carrying the figure 6 (See LXIV.); that is to say, the chord la re fa: now if we should have the sub-dominant fa in the fundamental bass with a 6; but it is necessary in that case that the note figured with a 6, may even here rise to a fifth. (See note xxi)

These variations in the fundamental bass, as well as the chord concerning which we now treat, as in the chord figured with a 7, and in the two others which shall afterwards be mentioned (art. 228 and 229), are caused by a deficiency in the figure proper for the chord of the sub-dominant, and for the different arrangements by which it is inverted.

M. Abbe Rouillé, to redress this deficiency, had invented a new manner of figuring the continued bass. His method is most simple for those who know the fundamental bass. It consists in expressing each chord by only signifyng the fundamental found with that letter of the scale by which it is denominated, to which is joined a 7 or 7, or a 6, in order to mark all the discords. Thus the fundamental chord of the seventh re fa la ut is expressed by a D; and the same chord, when it is inverted from that of the sub-dominant fa la ut re, is characterized by F; the chord of the second ut re fa la, inverted from the dominant re fa la ut, is likewise represented by D; and the same chord ut re fa la inverted from that of the sub-dominant fa la ut re is signified by F; the same is the same when the chords are differently inverted. By this means it would be impossible to mistake either with respect to the fundamental bass of a chord, or with respect to the note which forms its dissonance, or with respect to the nature and species of that discord.

(zzz) We may only add, that here and in the preceding articles, we suppose, that the continued bass is figured in the manner of M. Rameau. For it is proper to observe, that there are not, perhaps, two musicians who characterize their chords with the same figures; which produces a great inconvenience to the person who plays the accompaniments: but here we do not treat of accompaniments. For every reason, then, we should advise initiates to prefer the continued basses of M. Rameau to all the others, as by them they will most successfully study the fundamental bass.

It is even necessary to advert the reader, and I have already done it (note xxx), that M. Rameau only marks the letter sixth by a 5 without a line, when this letter sixth does not result from the chord of the tonic dominant; in such a manner that the 6 renders it uncertain whether in the fundamental bass we ought to choose the third or the fifth below; but it will be easy to see whether the third or the fifth is signified by that figure. This may be distinguished, 1. In observing which of the two notes is excluded by the rules of the fundamental bass. 2. If the two notes may with equal propriety be placed in the fundamental bass, the preference must be determined by the tone or mode of the treble in that particular passage. In the following chapter we shall give rules for determining the mode.

There is a chord of which we have not spoken in this enumeration, and which is called the chord of the fourth redundant. The chord is composed of a note, of its third major, of its redundant fourth or tritone, and its redundant sixth, as fa la si re. It is marked with a 6. It appears difficult to find a fundamental bass for this chord; nor is it indeed much in use amongst us. (See the note upon the art. 115.)
mental bars, this sub-dominant might produce in the
continued bars the same note $a_A$ figured with a 6.
When therefore one finds in the continued bars a note
marked with a 6, it appears at first uncertain whether
we should place in the fundamental bars the fifth
below marked with a 7, or the third below marked with
a 6.

229. The second case is that in which the con­tinued bars is figured with a $\frac{7}{2}$. For instance, if there
should be found $fa$ in the continued bars, one may be
ignorant whether he ought to infer in the fundamental
bars $fa$ marked with a 6, or $re$ figured with a 7.

230. You may easily extricate yourself from this
little difficulty, in leaving for an instant this uncertain
note in suspense, and in examining what is the suc­ceeding
note of the fundamental bars; for if that note be
in the present case a fifth above $fa$, that is to say,
if it is $ut$ in this case, and in this alone, he may place
$fa$ in the fundamental bars. It is a consequence of this
rule, that in the fundamental bars every sub-dominant
ought to rise by a fifth (193).

CHAP. XII. What is meant by being in a Mode or
Tone.

231. In the first part of this treatise (chap. vi.) we
have explained, how by the means of the note $ut$, and
of its two fifths $fol$ and $fa$, one in ascending, which
is called a tonic dominant, the scale $ut$ $re$ $mi$ $fa$ $fol$ $la$ $fi$ $ut$
may be found: the different founds which form this
scale compose what we call the major mode of $ut$,
because the third $mi$ above $ut$ is major. If therefore we
should have a modulation in the major mode of $ut$, no
other founds must enter into it than those which com­pose
this scale; in such a manner that if, for instance,
I should find $fa$ in this modulation, this $fa$ dis­covers
to me that I am not in the mode of $ut$, or at least
that, if I have been in it, I am no longer $fa$.

232. In the same manner, if I form this scale in
ascending $la$ $fi$ $ut$ $re$ $mi$ $fa$ $bol$ $la$, which is exactly
similar to the scale $ut$ $re$ $mi$ $fa$ $bol$ $la$ $fi$ $ut$ of the major
mode of $ut$, this scale, in which the third form $la$ to
$ut$ is major, shall be in the major mode of $la$; and if I
incline to be in the minor mode of $la$, I have nothing
to do but to substitute for $ut$ sharp $ut$ natural; so that
the major third $la$ $ut$ may become minor $la$ $ut$; I
shall have then

$la$ $fi$ $ut$ $re$ $mi$ $fa$ $bol$ $la$ $fi$ $ut$ $re$ $mi$ $fa$ $bol$,
which is (85) the scale of the minor mode of $la$ in ascen­ding; and the scale of the mode of $la$ in de­scending shall be (go)

$la$ $fol$ $fa$ $mi$ $ut$ $re$ $fi$ $la$,
in which the $fol$ and $fa$ are no longer sharp. For it is
a singularity peculiar to the minor mode, that its scale
is not the same in rising as in descending (89).

233. This is the reason why, when we wish to be­gin a piece in the major mode of $la$, we place three
sharps at the clef upon $fa$, $ut$, and $fol$; and on the
contrary, in the minor mode of $la$, we place none, be­cause
the minor mode of $la$, in descending, has neither
sharps nor flats.

234. As the scale contains twelve founds, each dis­tant from the other by the interval of a femitone, it
is obvious that each of these founds can produce both
in the major mode of $la$, where it is sharp a major and a minor mode, which constitute 24 modes
in the whole. Of these we shall immediately give the minor
a table, which may be very useful to discover the mode
in which we are.

A TABLE of the Different Modes.

</tbody>
</table>

(1111) The major mode of $fa$, of $re$ or $re$, and of $sol$ or $lab$, are not much practised. In the opera
of Pyramus and Thisbe, p. 267, there is a passage in the scene, of which one part is the major mode of $fa$,
and the other in the major mode of $ut$, and there are fix sharps at the clef.

When a piece begins upon $ut$, there ought to be seven sharps placed at the clef; but it is more convenient
to place five flats, and to suppose the key $reb$, which is almost the same thing with $ut$. It is for this
reason that we substitute here the mode of $reb$ for that of $ut$.

It is still much more necessary to substitute the mode of $lab$ for that of $fol$; for the scale of the major mode
of $sol$ is

$fol$, $la$, $fi$, $ut$, $re$, $mi$, $fa$, $bol$,
in which you may see that there are at the same time both a $sol$ natural and a $fol$: it would then be necessary,
even at the same time, that upon $sol$ there should and should not be a sharp at the clef; which is shocking and
inconvenient. It is true that this inconvenience may be avoided by placing a sharp upon $sol$ at the clef, and by
marking the note $sol$ with a natural through the course of the music wherever it ought to be natural; but this
would become troublesome, above all if there should be occasion to transpose. In the article 236, we shall
give an account of transposition. One might likewise in this series, instead of $sol$ natural, which is the note
immediately before the last, substitute $fa$, that is to say, $fa$ twice sharp: which, however, is not absolutely
the same found with $sol$ natural, especially upon instruments whose scales are fixed, or whose intervals are
variable. But in that case two sharps may be placed at the clef upon $fa$, which would produce another incon­venience. But by substituting $lab$ for $fol$, the trouble is eluded.

\[ \text{Music.} \]

233. These are all the modes, as well major Modes as minor. Those which are crowded with sharps and crowded flats are little practiced, as being extremely difficult in execution.

236. From thence it follows,

1. That when there are neither sharps nor flats at the clef, it is a token that the piece begins in the major mode of ut, or in the minor mode of la.

2. That when there is one single sharp, it will always be placed upon fa, and that the piece begins in the major mode of fol, or the minor of mi, in such a manner that it may be sung as if there were no sharp, by finging \( \bar{f} \) instead of \( *f \), and in finging the tune as if it had been in another clef. For instance, let there be a sharp upon fa in the clef of fol upon the first line; one may then sing the tune as if there were no sharp. And instead of the clef of fol upon the first line, let there be the clef of ut for the fa, when changed into \( \bar{f} \), will require that the clef of fol should be changed to the clef of ut, as may be easily seen.

This it what we call transposition (\( \bar{f} \)).

237. It is evident, that when \( *f \) is changed into \( \bar{f} \), fol must be changed into ut, and mi into la. Thus by transposition, the air has the same melody as if it were in the major mode of ut, or in the minor mode of la.

Chap. XIII. To find the Fundamental Bases of a given Modulation.

238. As we have reduced to a very small number the rules of the fundamental bass, and those which in the treble ought to be observed with relation to this bass, it should no longer be difficult to find the fundamental bass of a given modulation, may, frequently to find several; for every fundamental bass will be legitimate, when it is formed according to the rules which we have given (Chap. VI.), and that, besides the dissonances which the modulation may form with this first difficult, and why.

For the Sharps.
Suppose fo, re, la, mi, fi, fa, and change fa into ut if there is one sharp at the clefT, re into ut if there are two sharps, la into ut if there are three, &c.

For the Flats.
Suppose fi, re, la, mi, &c. and change fa into ut if there is only one flat at the clefT, fi into ut if there are two flats, mi into ut if there are three, &c.
Principles of Composition.

The diatonic scale, or gammus of the Greeks was la fa ut re mi fa, fol la (art. 49.) A method has likewise been invented of representing each of the sounds in this scale by a letter of the alphabet; la by A, fa by B, ut by C, &c. It is from hence that these forms of speaking proceed. Such a piece is upon A, re mi la, and its third minor; or, simply, it is upon A, re mi la, and its minor; such another piece upon C, with fol, ut, and its third major; or, simply, upon C, with fol, ut, and its major; to signify that the one is the mode of la minor, or that the other is in that of ut major; this latter manner of speaking is more concisely, and on this account it begins to become general.

They likewise call the key of ut fa F, the key of re fol G, &c. to denote the key of fa, the key of fol, &c.

They likewise take the A mi la, to give the A mi la; that is to say, to take the union of a certain note called la in the harpichord, which la is the same note that occupies the fifth line, or the highest line in the fifteenth fa. This la divides in the middle the two octaves which succeed (note n.) between the sol which occupies the first line in the key of fa upon that same line, and that sol which occupies the first line in the key of fa upon the fourth; and as it continues (if we may speak so) the middle station between the sharpest and lowest sounds, it has been chosen to be the sound with relation to which all the voices and instruments ought to be tuned in a concert (§).

Thus far our author; and though the note is no more than an illustration of the technical phraseology in his native language, we did not think it consistent with the facility of a translation to omit it. We have little reason to envious, and fill less to follow, the French in their abbreviatory forms of speech, the native energy of our tongue supercedes this necessity in a manner so effectual, that, in proportion as we endeavour to become facile, our style, without the smallest sacrifice of perspicuity, becomes more agreeable to the genius of our language; whereas, in French, acyclic definition is equally ambiguous and disagreeable. Of this we cannot give a more flagrant instance than the note upon which these observations are made, in its original. We must, however, follow the author's example, in reciting a few technical forms upon the same subject, which occur in our language, and which, if we are not mistaken, will be found equally concise, at the same time that they are more natural and intelligible. When we mean to express the fundamental key of that feries within the diatonic octave which any piece of music demands, we call that note the key. When we intend to signify its mode, whether major or minor, we denote the harmony sharp or flat. When in a concert we mean to try how instruments are in tune by that note upon which, according to the genius of each particular instrument, they may best agree in union, we declare the musicans who join us to found A.
Principles of Composition.

M U S I C.

Part II.

The major mode of UT.

Major mode of UT. ut mi fa re fa.

Tonic dominant.

Minor mode of LA. mi fol ut re.

Sub-dominant.

Major mode of UT. fa la ut re.

Minor mode of LA. re fa la fi.

The three sounds, the tonic, the tonic dominant, and the sub-dominant, contain in their chords all the notes which enter into the scale of the mode; so that when a melody is given, it may almost always be found which of these three sounds should be placed in the fundamental bafs, under any particular note of the upper part. Yet it sometimes happens that not one of these notes can be used. For example, let it be supposed that we are in the mode of UT, and that we find in the melody these two notes la fi in succession; if we confine ourselves to place in the fundamental bafs one of the three sounds ut fol fa, we shall find nothing for the sounds la and fi but this fundamental bafs fa fol; now such a succession as fa to fol is prohibited by the fifth rule for the fundamental bafs, according to which every sub-dominant, a fa, should rise by a fifth; so that fa can only be followed by ut in the fundamental bafs, and not by fol.

To remedy this, the chord of the sub-dominant fa la ut re must be inverted into a fundamental chord of the seventh, in this manner, re fa la ut, which has been called the double employment (art. 105.) because it is a secondary manner of employing the chord of the sub-

(EEE) It is certain that the minor mode of mi has an extremely natural connection with the mode of ut, as has been proven (art. 92.) both by arguments and by examples. It has likewise appeared in the note upon the art. 93. that the minor mode of re may be joined to the major mode of ut; and thus in a particular sense, this mode may be considered as relative to the mode of ut, but it is still less so than the major modes of fol and fa, or than those of la and mi minor, because we cannot immediately, and without licence, pass in a fundamental bafs from the perfect minor chord of ut to the perfect minor chord of re; and if you pass immediately from the major mode of ut to the minor mode of re in a fundamental bafs, it is by passing, for instance, from the tonic ut, or from mi fol ut, to the tonic dominant of re, carrying the chord la ut re mi fol, in which there are two sounds, mi fol, which are found in the preceding chord; or otherwise from ut mi fol ut to fol fi re mi, a chord of the sub-dominant in the minor mode of re, which chord has likewise two sounds, fol and mi, in common with that which went immediately before it.

(FFF) All these different manners of distinguish the modes ought, if we may speak so, to give mutual light and assistance one to the other. But it often happens, that one of these signs alone is not sufficient to determine the mode, and may even lead to error. For example, if a piece of music begins with these three notes, ut mi fol, we must not with too much precipitation conclude from thence that we are in the major mode of ut; although these three sounds, mi fol, be the principal and characteristic sounds in the mode of ut: we may be in the minor mode of mi, especially if the note mi should be long. You may see an example in the fourth act of Zoroaster, where the first air sung by the priests of Arianes begins thus with two times fol mi fol, each of these notes being a crotchet. The air is in the minor mode of fol, and not in the major mode of mi fol, as one would at first be tempted to believe. Now we may be sensible that it is in fol minor, by the relative modes which follow, and by the notes where the cadences fall.
Principles of Composition.

Part II.

MUSIC.

Principles of Composition.

By these means we give to the modulation la, this fundamental bass re sol, which procedure is agreeable to rules.

Here then are four chords, ut mi sol ut, sol fa re fa, fa la ut re, re fa la ut, which may be employed in the major mode of ut. We shall find in like manner, for the minor mode of la, four chords;

la ut mi la, mi sol si re, re la fa la.

And in this mode we sometimes change the last of these chords into re fa re la, substituting the fa for re. For instance, if we have this melody in the minor mode of la mi fa sol la, we would caufe the first note mi to carry the perfect chord la ut mi la, the second note fa to carry the chord of the seventh, re fa la, the third note sol to carry the chord of the tonic dominant mi sol si re, and in short, the last the perfect chord la ut mi la.

On the contrary, if this melody is given always in the minor mode la la sol la, the second la being syncopated, it might have the same bass as the modulation mi fa sol la, with this difference alone, that fa might be substituted for sol in the chord re fa la, the better to mark out the minor mode.

Besides these chords which we have just mentioned, and which may be regarded as the principal chords of the mode, there are a great many others; for example, the series of dominants,

ut la re sol ut fa mi la si re sol ut

which are terminated equally in the tonic ut, either entirely belong, or at least may be reckoned as belonging (gogo) to the mode of ut; because none of these dominants are tonic dominants, except sol, which is the tonic dominant of the mode of ut; and besides, because the chord of each of these dominants forms no other sounds than such as belong to the scale of ut.

But if I were to form this fundamental bass,

7 7 7 7 b

ut la re sol ut,

considering the last ut as a tonic dominant in this manner ut mi sol fa; the mode would then be changed at the second ut, and we should enter into the mode of fa, because the chord ut mi sol fa indicates the tonic dominant of the mode of fa; besides, it is evident that the mode is changed, because fa b does not belong to the scale of ut.

In the same manner, were I to form this fundamental bass

7 7 6

ut la re sol ut,

considering the last ut as a tonic dominant in this manner, ut mi sol la; this last ut would indicate the mode of sol, of which ut is the sub-dominant.

In like manner, still, if in the first series of dominants, I caused the first re to carry the third major, in this manner re fa la ut; this re having become a tonic dominant, would signify to me the major mode of sol, and the sol which should follow it, carrying the chord re fa, would relapse into the mode of ut, from whence we had departed.

Finally, in the same manner, if in this series of dominants, one should cause fa to carry fa for this manner, fa re fa la, this fa would show that we had departed from the mode ut, to enter into that of sol.

From hence it is easy to form this rule for discovering the changes of mode in the fundamental basses.

1. When we find a tonic in the fundamental bass, a rule for discovering the changes of mode.

2. When we find a sub-dominant, we are in the mode of that tonic; and the mode is major or minor, according as the perfect chord is major or minor.

3. When we find a tonic dominant, we are in the mode of the fifth below that tonic dominant. As the tonic dominant carries always the third major, one cannot be secure by the affiduosity of this dominant alone, whether the mode be major or minor; but it is only necessary for the composer to cast his eye upon the following note, which must be the tonic of the mode in which he is; by the third of this tonic he will discover whether the mode be major or minor.

243. Every change of the mode supposes a cadence; and when the mode changes in the fundamental bass, it is almost always either after the tonic of the mode in which we have been, or after the tonic dominant of that mode, considered then as a tonic by favour of a close which ought necessarily to be found in that place: Whence it happens that cadences in a melody for the most part preface a change of mode which ought to follow them.

244. All these rules, joined with the table of modes which we have given (art. 234.), will serve to discover in what mode we are in the middle of a piece, especially in the most effentiel passages, as cadences (mnmn).

I here subjoin the folioquy of Aranda, with the continued and fundamental basses. The changes of the mode will be easily distinguished in the fundamental basses.

(gogo) I have said, that they may be reckoned as belonging to this mode, for two reasons: 1. Because, properly speaking, there are only three chords which essentially and primitively belong to the mode of ut, viz. ut carrying the perfect chord, fa carrying the sub-dominant, and sol that of the tonic dominant, to which we may join the chord of the seventh, re fa la ut (art. 105.) but we here regard as extended the series of dominants in question, as belonging to the mode of ut, because it preserves in the ear the impression of that mode.

2. In a series of dominants, there are a great many of them which likewise belong to other modes; for instance, the simple dominant fa belongs naturally to the mode of sol, the simple dominant si to that of la, &c. Thus it is only improperly, and by way of extension, as I have already said, that we regard here these dominants as belonging to the mode of ut.

(mnmm) Two modes are so much more intimately relative as they contain a greater number of sounds common to both; for example, the minor mode of ut and the major mode of sol, or the major mode of ut and the minor of
Musical principles of composition.

550 Principles of Composition.

247. When the air is chromatic in ascending, one may form a fundamental bass by a series of tonics and of tonic dominants, which succeed one another alternately by the interval of a third in descending, and of a fourth in ascending. (See LXXXIX.)

248. With respect to the enharmonic, it is very rarely put in practice; and we have explained its formation in the first book, to which we refer our readers. We shall content ourselves with saying, that,

in the beautiful foliloquy of the fourth act of Dardanus, at the words

la re mel &c. "fatal places, &c." we find an example of the enharmonic; an example of the diatonic enharmonic in the trio of the Fatal Sisters, in Hippolitus and Arietta, at the words, Ou couru tu mat爿ements, "Whither, unhappy, dost thou run?" and that there are no examples of the chromatic enharmonic, at least in our French operas.

M. Rameau had imitated an earthquake by this species of music, in the second act of the Gallant Indians; but he informs us, that in 1735 he could not cause it to be executed by the band. The trio of the Fatal Sisters in Hippolitus has never been sung in the opera as it is composed. M. Rameau afferts, (and we have heard it elsewhere by people of taste, before whom the piece was performed), and the trial had succeeded when made by able hands that were not mercenary, and that its effect was astonishing.

249. In music, the name of design, or subject, is generally given to a particular air or melody, which the what composer intends should prevail through the piece; whether it is intended to express the meaning of words to which it may be set, or merely inspired by the impulse of taste and fancy. In this last case, design is distinguished into imitation and fugue.

250. Imitation consists in causing to be repeated the See Imi-melody of one or of several bars in one single part, or tation, in the whole harmony, and in any of the various modes in what, of la: on the contrary, two modes are left intimately relative as the number of sounds which they contain as common to both is smaller; for instance, the major mode of ut and the minor of fi, &c.

When you find yourself led away by the current of the modulation, that is to say, by the manner in which the fundamental bass is constituted, into a mode remote from that in which the piece was begun, you must continue in it but for a short time, because the ear is always impatient to return to the former mode.

(LLL) It is extremely proper to remark, that we have given the fundamental, the continued bass, and in general the modulation of this foliloquy, merely as a lesson in composition extremely suitable to beginners; not that we recommend the foliloquy in itself as a model of expression. Upon this last object what we have said may be seen in what we have written concerning the liberties to be taken in music, Vol. IV. p. 435, of our Literary Miscellany. It is precisely because this foliloquy is a proper lesson for initiates, that it would be a bad one for the mature and ingenious artist. The novice should learn tenaciously to observe his rules; the man of art and genius ought to know on what occasions and in what manner they may be violated when this expedient becomes necessary.

(LLLL) We may likewise give a chromatic melody in descending, a fundamental bass, into which may enter chords of the seventh and of the diminished seventh, which may succeed one another by the intervals of a fall fifth and a fifth redundant: thus in the Example XC, where the continued bass descends chromatically, it may easily be seen that the fundamental bass carries successively the chords of the seventh and of the seventh diminished, and that in this bass there is a fall fifth from re to sol &c, and a fifth redundant from sol &c to ut.

The reason of this licence is, as it appears to us, because the chord of the diminished seventh may be considered as representing (art. 221.) the chord of the tonic dominant; in such a manner that this fundamental bass

\[
\begin{align*}
7 & 7 & 7 & 7 & 7 & 7 \\
la & re & fol & ut & fa & fi & mi & la
\end{align*}
\]

(see Example XCI.) may be considered as representing (art. 116.) that which is written below,

\[
\begin{align*}
7 & 7 & 7 & 7 & 7 & 7 \\
la & re & mi & ut & fa & fi & mi & la
\end{align*}
\]

Now this last fundamental bass is formed according to the common rules, unless that there is a broken ca-
dence from re to mi, and an interrupted cadence from mi to ut, which are license (art. 213 and 214.)
Part II.

Principles of Composition.

• See Air, Canon, Fugue.

293. Principal rules for composing in several parts.

251. Imitation and fugue are sometimes conducted by rules merely deducible from tafte, which may be seen in the 332d and following pages of M. Rameau's Treatise on Harmony; where will likewise be found a detail of the rules for composition in several parts. The chief rules for composition in several parts are, that the discords should be found, as much as possible, prepared and resolved in the same part; that a discord should not be heard at the same time in several parts, because its harshness would disturb the ear; and that in no particular part there should be found two octaves or two fifths in succession (mmm) with respect to the bass. Musicians, however, do not hesitate sometimes to violate this precept, when taste or occasion require. In music, as in all the other fine arts, it is the business of the artist to assign and to observe rules; the province of men who are adorned with taste and genius is to find the exceptions.

Chap. XVI. Definitions of the Different Airs.

252. We shall finish this treatise by giving in a few words the characteristic distinctions of the different airs to which names have been given, as chacon, minuet, rigadoon, &c.

The minuet is a long piece of music, containing three times in each bar, of which the movement is regular, and the bars sensibly distinguished. It consists of several couplets which are varied as much as possible. Formerly the bass of the chacon was a confined bass, or regulated by a rhythmus terminating in 4 bars, and proceeding again by the same number; at present composers of this species no longer confine themselves to that practice. The chacon begins, for the most part, not with the perfect time, which is struck by the hand or foot, but with the imperfect, which passes while the hand or foot is elevated.

The villanelle is a chacon a little more lively, with its movement somewhat more brisk than the ordinary chacon.

The piafaccaille only differs from a chacon as it is more flow, more tender, and beginning for ordinary with a perfect time.

The minuet is an air in triple time, whose movement is regular, and neither extremely brisk nor flow, consisting of two parts or strains, which are each of them repeated; and for which reason they are called by the French reprise: each strain of the minuet begins with a time which is struck, and ought to consist of 4, of 8, or of 12 bars; so that the cadences may be easily distinguished, and recur at the end of each 4 bars.

The farabando is properly a flow minuet; and the courant a very flow farabando: this last is no longer in use. The piafaccaille is properly a very brisk minuet, which does not begin like the common minuet, with a stroke of the foot or hand; but in which each strain begins in the last of the three times of which the bar consists.

The loure is an air whose movement is flow, whose time is marked with \( \frac{4}{4} \), and where two of the times in which the bar consists are beaten; it generally begins with that in which the foot is raised. For ordinary the note in the middle of each time is shortened, and the first note of the same time pointed.

The jig is properly nothing else but a loure very brisk, and whose movement is extremely quick.

The forlana is a moderate movement, and in a mediocrity between the loure and the jig.

The rigadoon has two times in a bar, is composed of two strains, each to be repeated, and each consisting of 4, of 8, or of 12 bars: its movement is lively; each strain begins, not with a stroke of the foot, but at the last note of the second time.

The bourée is almost the same thing with the rigadoon.

The gavotte has two times in each bar, is composed of two strains, each to be repeated, and each consisting of 4, of 8, or of 12 bars: the movement is sometimes flow, sometimes brisk; but never extremely quick, nor very flow.

The tarentella has two times in each bar, is made of two strains, each to be repeated, and each consisting of 4, of 8, or of 12 bars, &c. Two of the times that make up each bar are beaten, and are very lively; and each strain generally begins in the second time.

The musette consists of two or three times in each bar; its movement is neither very quick nor very slow; and for its base it has often no more than a single note, which may be continued through the whole piece.

Appendix.

The treatise of D’Alembert, of which we have given a translation, is well entitled to the merit of accuracy; but perhaps a person who has not particularly studied the subject, may find difficulty in following the scientific deductions of that author. We subjoin, therefore, a few general observations on the philosophy of musical found, commonly called harmonic, which may perhaps convey the full portion of knowledge of the theory of music, with which one in search only of general information, and not a professed student of this particular science, would choose to rest satisfied.

The theory of musical found, which only in the beginning of the present century was ultimately established by mathematical demonstration, is no other than that which distinguished the ancient musical sect who

\( \text{mmm} \) Yet there may be two fifths in succession, provided the parts move in contrary directions, or, in other words, if the progress of one part be ascending, and the other descending; but in this case they are not properly two fifths, they are a fifth and a twelfth; for example, if one of the parts in descending should found fa re, and the other ut la in rising, ut is the fifth of fa, and la the twelfth of re.
Music

Musical Proportions

Pythagoras supposed the air to be the vehicle of sound, and the agitation of that element, occasioned by a similar agitation in the parts of the founting body, to be the cause of it. The vibrations of a string, or other rotund body, being communicated to the air, affected the auditory nerves with the sensation of sound, and this sound, he argued, was acute or grave in proportion as the vibrations were quick or slow.

He discovered by experiment, that of two strings equal in every thing but length, the shorter made the quicker vibrations, and emitted the acuter sound:—in other words, that the number of vibrations made in the same time, by two strings of different lengths, was inversely as those lengths; that is, the greater the length the smaller the number of vibrations in any given time. Thus found, considered in the vibrations that cause it, and the dimensions of the vibrating body, came to be reduced to quantity, and as such was the subject of calculation, and expressible by numbers.

For instance, the two sounds that form an octave could be expressed by the numbers 1 and 2, which would represent either the number of vibrations in a given time, or the length of the strings; and would mean, that the acuter sound vibrates twice, while the graver vibrates once; or that the string producing the lower sound is twice the length of that which gives the higher. If the vibrations were considered, the higher sound was as 2, the lower as 1; the reverse, if the length was allowed to. In the same manner, in the same fene, the 5th would be expressed by the ratio of 2 to 3, and the 4th by that of 3 to 2.

Aristoxenus, in opposition to the calculations of Pythagoras, held the ear to be the sole standard of musical proportions. That sense he accounted sufficiently accurate for musical, though not for mathematical, purposes; and it was in his opinion absurd to aim at an artificial accuracy in gratifying the ear beyond its own power of distinction. He therefore rejected the velocities, vibrations, and proportions of Pythagoras as foreign to the subject, so far as they subtitled artificial cause in the room of experience, and made music the object of intellect rather than of sense.

Music

Musical Proportions

MUSIMON, in natural history, the name of an animal esteemed a species of sheep, described by the ancients as common in Corfica, Sardinia, Barbary, and the north-east parts of Asia. It has been doubted whether the animal described under this name is now anywhere to be found in the world; and whether it was not, probably, a furred breed between two animals of different species, perhaps the sheep and goat.

Music

Musical Proportions

Of late, however, as has been already mentioned, the opinions of Pythagoras have been confirmed by absolute demonstration; and the following propositions, in relation to musical sound, have passed from conjecture to certainty.

Sound is generated by the vibrations of elastic bodies, which communicate the like vibrations to the air; and these again to our organs of hearing. This is evident, because sounding bodies communicate tremors to other bodies at a distance from them. The vibrating motion, for instance, of a musical string, excites motion in others, whose tension and quantity of matter displace their vibrations to keep time with the undulations of air propagated from it (the string first in motion.)

If the vibrations be isochronous, and the found musical, continuing at the same pitch, it is said to be acuter, sharper, or higher, than any other found whose vibrations are slower; and graver, flatter, or lower, than any other whose vibrations are quicker.

For while a musical string vibrates, its vibrations become quicker by increasing its tension or diminishing its length; its found at the same time will be more acuter: and, on the contrary, by diminishing its tension or increasing its length, the vibrations will become slower and the found graver.

The like alteration of the pitch of the sound will follow, by applying, by means of a weight, an equal degree of tension to a thicker or heavier and to a smaller or lighter string, both of the same length, as in the smaller string the mass of matter to be moved by the same force is less.

If several strings, however, different in length, density, and tension, vibrate altogether in equal times, their sounds will have all one and the same pitch, however they may differ in loudness or other quality. They are called unisons. The vibrations of unisons are isochronous.

The vibrations of a musical string, whether wider or narrower, are nearly isochronous. Otherwise, while the vibrations decrease in breadth till they cease, the pitch of the sound could not continue the same (which we perceive by experience it does), unless where the first vibrations are made very violently; in which case, the sound is a little acuter at the beginning than afterwards.

Lastly, the word vibration is understood to mean the time which passes between the departure of the vibrating body from any assigned place and its return to the same.

Translation. Intended to give such Readers as do not understand French, an idea of the Song.

At length the victim in my power I see,
This fatal year resigns him to my rage;
Subdued by sleep he lies, and leaves me free,
With chastening hand my fury to assuage.
That mighty heart invincible and fierce,
Which all my captives free'd from servile chains;
My rage inventive wanton in his pains.
Ha! in my soul what perturbation reigns!
What? would compassion in his favour plead?
Strike, hand. O heaven! what charm thy force restrains?
Obey my wrath. I sigh; yet let it bleed.
And is it thus my just revenge improves
The fair occasion to cajole my foe?
As I approach, a softer passion moves,
And all my boating fury melts in wo.
Trembling, relax'd, and faithless to my hate,
The dreadful task this coward arm declines.

How cruel thus to urge his infant fate,
Depriv'd of life amid his great designs!
In youth how blooming! what a heavenly grace,
Thro' all his form, refittles power displays!
How sweet the smile that dwells upon his face,
Relentless rage disarming whilst I gaze!
Thou' to the prowes of his conquering arms
Earth stood with all her hosts oppos'd in vain;
Yet is he form'd to spread more mild alarms,
And bind all nature in a softer chain.
Can then his blood, his precious blood alone
Extinguish all the vengeance in my heart?
Thou' till surviving, might he not atone.
For all the wrongs, I feel, by gentler smart?
Since all my charms, unfeeling, he defies,
Let Magic force his stubborn soul subdue;
Whilst I, inflexible to tears and sighs,
With hate (if I can hate) his peace pursue.
and so capacious, that young foxes often shelter themselves in the hollow of such as by accident fall off in the defects. See Ovis.

MUSIS (Agostino de), a noted engraver, better known by the name of Agostina Venetina, or in England by that of "Augustin the Venetian," but Mu-

fis was his proper family name. He was a native of Venice, and scholar of Marc Antonio Raimondi. It is not certain at what period he began his studies under

different masters, but the first dated print by Agostino appeared A. D. 1509, at which time, it is probable, his tutor still resided at Venice. After the death of Raphael, which happened in 1520, Agostino de Musis, and Marc de Ravenna, his fellow-
disciple, who had conjointly assisted each other, separated, and worked entirely upon their own account. It is uncertain at what time Agostino died; but his prints are not dated later than 1536. So that it may be reasonably supposed that he did not long survive that period. Agostino de Musis imitated the style of his master with great attention, and was, upon the whole, the most successful of all his scholars. In me-
nanical and mechanical execution with the graver, he has often excelled if not sometimes excelled him; but in point of taste, and in the purity and correctness of outline, he certainly fell greatly short of him. Ago-
sino's drawing had more of manner and stiffness; the heads of his figures are not so accurately marked; nor the other extremities expressed with equal truth.

MUSIVUM AURUM. See CHEMISTRY, n° 1224.

MUSK, a very strong-scented substance found under the belly of an East Indian animal. See MOSCHUS.

According to Tavernier, the best and greatest quantities of musk come from the kingdom of Bontan, from whence it is carried for sale to Patna, the chief town of Bengal. After killing the animal, the peafants cut off the bag, which is about the size of an egg, and is situated nearer the organs of generation than the navel. They next take out the musk, which has then the appearance of clotted blood. When they want to adulterate it, they put a mufh of the animal's blood and liver into the place of the musk they had extracted. In two or three years this mixture produces certain small animals which eat the good musk; so that, when opened, a great consumption is perceived. Others, after extracting a portion of the musk, put in small pieces of lead to augmen-
t the weight. The merchants who transport the musk to foreign countries are less averse to this trick than the farmers; because in this case none of the animals above-mentioned are produced. But the deceit is full worse to discover, when, on the skin taken from the belly of a young animal, they make little bags, which they few fo dexterously with threads of the same skin, that they resemble genuine bags. Those they fill with what they take out of the genuine bags, and some fraudulent mixture, which is extremely difficult for the merchants to detect. When the bags are sewed immediately on their being cut, without allowing any part of the odour to diSipate in the air, after they have abstracted as much of the musk as they think proper, if a person applies one of these bags to his nose, blood will be drawn by the mere force of the odour, which musk necessarily be weakened or diluted in order to render it agreeable without injuring the brain. Our author brought one of the animals with him to Paris, the odour of which was so strong, that it was impossible for him to keep it in his chamber. It made every head in the house giddy; and he was obliged to put it in a barn, where the servants at last cut away the bag: the skin, notwithstanding, always retained a portion of the odour. The largest musk-

bag seldom exceeds the size of a hen's egg, and cannot furnish above half an ounce of musk; three or four of them are sometimes necessary to afford a single ounce. In one of his voyages to Patna, Tavernier purchased 1663 bags, which weighed 1557 ounces and a half; and the musk, when taken out of the bags, weighed 452 ounces.

Musk affords the strongest of all known odours. A small bit of it perfumes a large quantity of matter. The odour of a small particle extends through a confider-

dable space. It is likewise so fixed and permanent, that at the end of several years it seems to have lost no part of its activity. When it comes to us, it is dry, with a kind of unctuousness, of a dark reddish brown or rusty blackish colour, in small round grains, with very few hard black cots, and perfectly free from any sandy or other visible foreign matter. If chewed, and rubbed with a knife on paper, it looks smooth, bright, yellowish, and free from bitterness. Laid on a red hot iron, it catches flame, and burns almost entirely away, leaving only an exceeding small quantity of light greyish ashes: if any earthly substances have been mixed with the musk, the quantity of the residuum will readily discover them.

Musk has a bitterish subacid taste; a fragrant smell, agreeable at a distance, but when smelt near to, so strong as to be disagreeable unless weakened by the admixture of other substances. If a small quantity be infused in spirit of wine in the cold for a few days, it imparts a deep, but not red tincture; this, though it discovers no great smell of the musk, is nevertheless strongly impregnated with its virtues; a single drop of it communicates to a whole quart of wine a rich musky flavour. The degree of flavour which a tincture drawn from a known quantity of musk communicates to vinous liquors, is perhaps one of the best criteria for judging the goodness of this commodity. Neumann informs us, that spirit of wine dissolves 10 parts out of 30 of musk, and that water takes up 12; that water elevates its smell in distillation, whilst pure spirit brings over nothing.

Musk is a medicine of great esteem in the eastern countries; among us, it has been for some time pretty much out of use, even as a perfume, on a supposition of its occaSioning vapours, &c. In weak females and persons of a sialent life, it appears, however, from late experience, to be, when properly managed, a remedy of good service even against those disorders which it has been fuppofed to produce. Dr Wall has communicated (in the Philosopb. Tranf. n° 474,) an account of some extraordinary effects of musk in convulsive and other diseases, which have too often baffled the force of medicine. The doctor observes, that the smell of perfumes is often of different, where the substance, taken inwardly and in considerable quantity produces the happiest effects; that two persons, labouring under a fubflitus tendicos, extreme anxiety, and wants of sleep, from the bite of a mad dog,
dog, by taking two doses of musk, each of which was 16 grains, were perfectly relieved from their complaints. He likewise observes, that convulsive hiccups, attended with the worst symptoms, were removed by about one or two of 10 grains, and that in some cases, where this medicine could not, on account of strong convulsions, be administered to the patient by the mouth, it proved of service when injected as a glibter. He likewise adds, that under the quantity of six grains, he never found much effect from it; but that, taken to 10 grains and upwards, it never fails to produce a mild diaphoreis, without all heating or giving any uneasiness: that, on the contrary, it eases pain, rafties the spirits; and that, after the sweat breaks out, the patient usually falls into a refreshing sleep: that he never met with any hysterical person, how averse foever to perfumes, but could take it, in the form of a bolus, without inconvenience. To this paper is annexed an account of some farther extraordinary effects of musk, observed by another gentleman. Repeated experience has since confirmed its efficacy in these disorders. The dose has sometimes been increased, particularly in convulsive disorders, to the quantity of half a dram every three or four hours, with two or three spoonfuls of musk julep between. The julep is the only official preparation of it. It is combined with opium in tetanus, and with mercury in rabies canina.

Musk-Animal. See Moschus.
Musk-Ox. See Bos.
Musk-Rat, in zoology. See Castor.

MUSKET, or MUSQUET, properly a fire-arms borne on the shoulder, and used in war; to be fired by the application of a lighted match.

The length of the barrel is fixed to three feet eight inches from the muzzle to the touch-pan, and its bore is to be such as may receive a bullet of 14 in a pound, and its diameter differs not above one 50th part from that of the bullet.

Muskets were anciently borne in the field by the infantry; and were used in England so lately as the beginning of the civil wars. At present they are little used except in the defence of places, fences or firelocks having taken their place and name.

MUSKETOON, a kind of short thick musket, whose bore is the 38th part of its length: it carries five ounces of iron, or seven and a half of lead, with an equal quantity of powder. This is the stoutest kind of blunderbusses.

MUSLIN, a fine sort of cotton cloth, which bears a downy knot on its surface. There are several sorts of muslins brought from the East Indies, and more particularly from Bengal: such as doreas, betelles, malmuls, tanjebes, &c. Muslin is now manufactured in Britain, and brought to very great perfection.

MUSONIUS, (Caius Ricius), a Stoic philosopher of the second century, was banished into the island of Cyzic, under the reign of Nero, for criticizing the manners of that prince; but was recalled by the emperor Vespasian. He was the friend of Apollonius Tyaneus, and the letters that passed between them are still extant.

MUSQUETO. See Culex.

MUSULMAN, or MUSULMAN, a title by which the Mahometans distinguish themselves; signifying, in the Turkish language, “true believer, or orthodox.” Musulman See Mahometan.

In Arabic, the word is written Moslem, Moslem, or Mosliman. The appellation was first given to the Saracens, as is observed by Leunclavius. There are two kinds of Mahometans, very averse to each other; the one called Sonnites, and the other Shiites. The Sonnites follow the interpretation of the Alcoran given by Omar; the Shiites are the followers of Ali. The subjects of the king of Persia are Shiites; and those of the grand signior, Sonnites. See Sonna, and Alcoran.

Some authors will have it, that the word Musulman signifies fared, that is, predestinated; and that the Mahometans give themselves the appellation, as believing they are all predestinated to salvation—Martinius is more particular as to the origin of the name; which he derives from the Arabic χρος, μουλαμ, “faved, snatched out of danger”: the Mahometans, he observes, establishing their religion by fire and sword, massacred all those who would not embrace it, and granted life to all that did, calling them Moul­stan, q. d. erpeti & periculo: whence the word, in course of time, became the distinguishing title of all those of that sect, who have affixed to it the signification of true believers.

MUST, Mustum, sweet wine newly pressed from the grape; or the new liquor pressed from the fruit before it has worked or fermented. See Wine.

MUST of Rhenish wine. This is a liquor that, tho' drank by some, is found extremely to affect the brain; for not having passed the natural effervescence which it would have been subject to, in the making of wine, itsarts are locked up till the heat of the stomach setting them to work, they raise their effervescence there, and send up abundance of subtle vapours to the brain. The Rhenish must is of two kinds, being made either with or without boiling. That made without boiling is only put up so close in the vessel that it cannot work; this is called jumna-wine. The other boiling is thus prepared: they take strong vessels not quite filled, and putting them into a cellar, they make a fire mild at first, but increased by degrees, and afterwards they gradually leffen it again, that the boiling may cease of itself. This operation is finished in 36 or 40 hours, according to the size of the vessel; and the wine-boilers, instead of common candles, which would melt by the heat, use thin pieces of split beech-wood. These also serve for a double purpose; not only lighting them, but giving them notice of the boiling being enough; before that time, the quantity of vapours thrown up make them burn dim; but as soon as it is finifhed, the vapours ascend in less quantity, and the lights burn brisk and clear. About seven or eight days after this boiling, the must begins to work, and after this working it is called wine. They have also another kind of Rhenish must which is thus prepared: they boil the liquor to half the quantity, and put into it the medicinal ingredients they are most fond of; such as orange-peel, elecampane-root, and Juniper berries, or the like; being thus medicated, the whole works much more slowly than it otherwise would.

If the boiled must, by too violent an effervescence, cast out its lees, it will on this become rapid and dead, unless this separation is stopped by some fatty sub­stance,
MUS

MUSTARD. See SNAPE.

MUSTARD-Seed, is one of the strongest of the pungent, stimulans, diuretic medicines, that operate without exciting much heat. It is sometimes, taken unbruised, to the quantity of a spoonful at a time, in paralytic, cachectic, and febils, disorders. It is applied also as an external stimulant, to benumbed and paralytic limbs; to parts affected with fixed rheumatic pains; and to the soles of the feet, in the low rate of acute diseases, for raising the pulse; in this intention, a mixture of equal parts of the powdered seeds and crumbles of bread, with the addition of a little bruised garlic, are made into a cataplasm with a sufficient quantity of vinegar. See SNAPE.

MUSTARD-feed yields upon expression, a considerable quantity of oil, which is by some recommended externally against rheumatisms and pulleys, though it has nothing of that quality by which the seeds themselves prove useful in those disorders; the oil being mild and insipid as that of olives, and the pungency of the seed remaining entire in the cake left after expression; nor is any considerable part of the pungent matter extracted by redified spirit. The bruised seeds give out readily to water nearly the whole of their active matter; added to boiling milk they curdle it, and communicate their pungency to the whey. The powder of mustard-feed may be made into the conquest of a loch with warm water, in which a little sea salt has been dissolved. Of this a common-spoonful, sometimes two, diluted with tepid water, are given on an empty stomach; it operates as well as an emetic, and proves an excellent remedy in most nervous disorders, according to Dr Monro, in Med. Eff. Edinb. vol. ii. art. 19. p. 303. note.

MUSTELA, the OTTER and WEESEL; a genus of quadrupeds of the order of fere. There are six cutting teeth in each jaw; those of the upper jaw, crest, sharp-pointed, and distinct: of the lower jaw, blunter, huddled together, and two placed within the line of the reil: The tongue is smooth.

Plate eccxan.

1. The lutris, or sea-otter, having hairy feet and a hairy tail. The length from nose to tail is about three feet long, and the tail is about 13 inches; the body and the limbs are black, except the fore-part of the head, which is white or grey; the largest individual weighs from 70 to 80 pounds; the fur is very thick, long, black, and glossy, sometimes varying to silvery, with a soft down beneath. The sea-otter inhabits the coasts of North-west America and Eastern Asia, and the intermediate islands. It lives mostly in the sea, and swims with great facility: frequenting shallows which abound in sea-weeds, and feeding on lobsters, fish, jetie or cuttle-fish, and shell-fish. It is a harmless animal; very affectionate to its young, infomuch that it will pine to death at the loss of them, and die on the very spot where they have been taken from it.

Before the young can swim, the dams carry them in their paws, lying in the water on their backs; they swim often on their back, their sides, and even in a perpendicular posture; are very sportive; embrace, and kiss each other; they breed but once a year, and have but one young at a time, suckle it for a year, and bring it on shore. They are dull-fighted, but quick-scented; and run very swiftly on land. They are hunted for their skins, which are of great value; being sold to the Chinese for 70 to 80 rubles a-piece; each skin weighs 3/4 lib. The young are reckoned very delicate meat, scarce to be distinguished from a sucking lamb. The cry of this creature is nearly similar to a young dog; and it is sometimes interrupted by another cry similar to that of the fisk or fox-tailed monkey. It may be nourished with the flour of manioc diluted in water.

2. The lutra, or common otter, has naked feet, and the tail is about half the length of the body. It is in general about two and a half feet long, from the top of the nose to the base of the tail. The fur is of a deep brown colour, with two small white spots on each side of the nose, and one beneath the chin. This animal inhabits Europe, North America, and Asia as far south as Peridia. It frequents fresh water rivers, lakes, and fish-ponds; and preys on fish, frogs, and fresh-water crustaceous animals, being exceedingly destructive to fish-ponds. The otter procreates in February, and the female brings forth three or four young ones in May: the male calls the female by a soft musing noise. The otter shows great sagacity in forming its habitation; it burrows under ground on the banks of some river or lake: it always makes the entrance of its hole under water; working upwards to the surface of the earth and forming, before it reaches the top, several holes or lodges, that in case of high floods, it may have a retreat; for no animal affects lying drier at top: it makes a minute orifice for the admission of air. It is further observed, that this animal, the more effectually to conceal its retreat, contrives to make even this little air-hole in the middle of some thick bulk. Our author also informs us, that, the otter is capable of being tamed; that he will follow his master like a dog and even fish for him, and return with his prey. Though the otter does not caft his hair, his skin is browner, and sells dearer in winter than in summer; and makes a very fine fur. His flesh has a disagreeable sly taste. His retreats exhal a noxious odour from the remains of putrid fishes: and his own body has a bad smell. The dogs chase the otter spontaneously, and easily apprehend him when at a distance from water or from his hole. But, when feized, he defends himself, bites the dogs most cruelly, and sometimes with such force as to break their legs bones, and never quits his hold but with life. The beaver, however, who is not a very strong animal, pursues the otters, and will not allow them to live on the same banks with himself.

3. The lutreola, or small otter, has very broad hairy feet, and a white mouth: and seldom exceeds a foot in length. The body is of a tawny and dusky colour mixed together; the fur having two series of hairs, the shorter of which are yellowish and the long black. This animal inhabits Poland, Finland, Russia, and Siberia; frequenting marshy places, and preying on
MUS [ 556 ]

Muller.

It is caught with dogs and traps, and is exceedingly fomid; but its fur is very valuable, being esteemed next in beauty to that of the fable.

4. The canadenfis, or Canadian otter, is of a black colour, and the fur is smooth. It has a long taper tail, and inhabits Canada and other parts of North America.

5. The guianaenfis, or small Guiana otter, with the hind-feet webbed, the toes of the fore-feet unconnected, and a long taper naked tail inhabits Cayenne, and probably other parts of South America. It is only about seven inches long from the nose to the rump; the tail is near seven; the upper parts of the head and body are marked with large brownish black spots, exacly correponding on both fides, and the intervals are of a yellowy grey colour; all the under parts of the body and head, and the fore-parts of the fore-legs are white, and there is a white spot over each eye: the ears are large and round; and the mouth is garnished with long whifkers. Buffon informs us that there are three species of otters common in Cayenne.

6. The zibellina, or fable, has a great refemblance to the martins, from which it differs in having a longer head; longer ears, surrounded by a yellow margin: longer and more elegant fur; the feet more thickly clothed with hair; and the tail shorter than the hind-legs when extended, while that of the martins is much longer. The colour of the hair is cincrus on the bottom, and black at the tips; the chin is cincrus, sometimes white, yellowish, or spotted; the mouth is garnished with long whifkers; and the feet are large, with white claws. It inhabits the northern parts of Asia.
Kmile iflands, and formerly in Mullclla. Alia and commonly of a yellowifh colour; the male is whitifh with white fon in the fpring; and bring forth three, four, or five times they will form neifs in the trees, and skip with great agility from one to the other: they are very lively, and much in motion during the night. Gme- 
lin tells us, that after eating, they generally sleep half an hour or an hour, when they may be pulhed, flaken, and even pricked, without awaking. During the night they are excelfively active and reflelts. A tame one kept by Gmelin was acclutoned to rise up on its hind-legs on sight of a cat, in order to prepare for the combat: in the woods they are much infefled by wild cats. During summer the fables prey on eraines, weafels, and squifforels, but efpecially on hares; in winter, on birds; in autumn, on whortleberries, cranberries, and the berries of the service-tree; but during this laft feafon their skins are at the world; that diet caufing their skins to itch, and to rub off their fur againift the trees. They bring forth at the end of March or beginning of April; and have from three to five at a time, which they fuckle for four or five weeks. In spring, after shedding the coat, the male goes six weeks with young. Some of them de- 
vour their young as soon as they are brought forth, inftantly come again in feafon, and have three litters, which generally confift of five or six, and oftentimes of seven, eight, or nine. They are employed for hunting rabbits; and as in this country they are apt to degenerate, Warreners are in use to crofs the breed, procuring an intercoufe between a female ferret and a male pole, by leaving the former, when in feafon, near the haunts of the latter: The produce is of a much darker colour than the ferret, having a great remlenfence to the pole-cat. This animal is by nature a mortal enemy to the rabbit. Whenever a dead rab- 
bbit is for the firft time prefented to a young ferret, he flies upon it, and bites it with fury; but if it be alive, he eifizes it by the throat or the nofe, and fucks its blood. When let into the burrows of rabbits, he is muzzled, that he may not kill them in their holes, but only oblige them to come out, in order to be caught in the nets. If the ferret is left in without a mufle, he is in danger of being loft: for, after fuck- 
ing the blood of the rabbit, he fallsaffe; and even fmoaking the hole is not acertain method of recalling him; because the holes have often feveral entries which communicate with each other, and the ferret retires into one of thoile when incommended with the fhock. Boys likewife ufe the ferret for catching birds in the holes of walls, or of old trees. The ferret, though eafily tamed, and rendered docile, is extremely infedible; his odour is always difagreeable; but when he is irritat- 
ed, it becomes much more offenfeive. His eyes are lively, and his aspet is inflammatory; all his move- ments are nimble; and he is at the fame time fo vi- 
gorous, that he can eafily matter a rabbit, though at least four times larger than himfelf.

7. The putorous, or pole-cat, is of a dirty yellow colour, with white muzzle and ears. He inhabits moft parts of Europe, and in the temperate climates of Afticca Ruflia; and has a great remlenfence to the martifn in temperament, mufles, diftribution, and figure. Like the latter, he approaches our habitations, mounts on the roofs, takes up his abode in hay-lofts, barns, and unfrequened places, from which he ifues during the night only in queft of prey. He burrows under ground, forming a fhallow retreat about two yards in length, generally terminating under the roots of some large tree. He makes greater havoc among the poultry than the martifn, cuttng of the head of all the fowls, and then carrying them off one by one to his magazine. If, as frequently happens, he cannot carry them off entire, on account of the finallifes of the entry to his hole, he eats the brains, and takes only the hands along with him. He is likewise very fond of honey, attacks the hives in winter, and forces the bees to abandon them. The females come in feafon in the fpring; and bring forth three, four, or five at a time. In the defarts of Afticca Ruflia, pole-cats are efpecially found, efpecially in winter, of a white colour; they are likewife found beyond lake Baikali with white or yellowifh rumps, boned with black. It is exceedingly fetid, like feveral other efpecies of this genus, efpecially the martifn and fable, giving out from the anus a moft offenfive vapour when frightenfed. The male is moftly of a yellowifh tinge, having a whitifh muzzle, while the muzzle of the female is commonly of a yellowifh dirty white.

8. The fryo, or ferret, has red and fiery eyes; the colour of the whole body is of a very pale yellow; the length from nose to tail is about 14 inches, the tail five. In its wild state it inhabits Africa; from thence it was brought into Spain, in order to free that country from multitudes of rabbits with which it was overrun; and from Spain the rest of Europe has been supplied. This creature is incapable of bearing the cold, and cannot subsift even in France unless in a do- 
matic state. The ferret is not in our climates endow- ed with the fame capacity of finding his subfistence as other wild animals, but must be carefully nourifhed within doors, and cannot effit in the fields; for those who are lost in the burrows of rabbits never multiply, but probably perish during the winter. Like other domellic animals, it varies in colour. The female ferret is lefs than the male; and when in feafon, we are affured, he is fo extremely ardent, that the dies if her defires are not gratified. Ferrets are brought up in caids or boxes, where they are furnished with beds of hemp or flax. They sleep almoft continually. Whenever they awake they search eagerly for food; and bran, bread, milk, &c. are commonly given them. They produce twice every year; and the female goes fix weeks with young. Some of them de- vour their young as soon as they are brought forth, in- 
stantly come again in feafon, and have three litters, which generally confift of five or six, and oftentimes of seven, eight, or nine. They are employed for hunting rabbits; and as in this country they are apt to degenerate, Warreners are in use to crofs the breed, procuring an intercoufe between a female ferret and a male pole, by leaving the former, when in feafon, near the haunts of the latter: The produce is of a much darker colour than the ferret, having a great remlenfence to the pole-cat. This animal is by nature a mortal enemy to the rabbit. Whenever a dead rab- 
bbit is for the firft time prefented to a young ferret, he flies upon it, and bites it with fury; but if it be alive, he eifizes it by the throat or the nofe, and fucks its blood. When let into the burrows of rabbits, he is muzzled, that he may not kill them in their holes, but only oblige them to come out, in order to be caught in the nets. If the ferret is left in without a mufle, he is in danger of being loft: for, after suck- 
ing the blood of the rabbit, he fallsaffe; and even fmoaking the hole is not acertain method of recalling him; because the holes have often feveral entries which communicate with each other, and the ferret retires into one of thoile when incommended with the fhock. Boys likewise ufe the ferret for catching birds in the holes of walls, or of old trees. The ferret, though eafily tamed, and rendered docile, is extremely infedible; his odour is always difagreeable; but when he is irritat- 
ed, it becomes much more offenfeive. His eyes are lively, and his aspet is inflammatory; all his move- ments are nimble; and he is at the fame time fo vi- 
gorous, that he can eafily matter a rabbit, though at least four times larger than himfelf.

9. The carmatica, or Sarmatian weafel, is of a brownifh black colour, spotted and striped irregularly with obscure yellow, and is about 14 inches in length, exclusive of the tail, which is five inches in length. It resembles the pole cat, but has a narrower head, a more lengthened body, a long tail, and shorter hair, except on the feet and tail; inhabits Polanad, efpecially Vol- 
ynia, in the deferts of Ruflia between the Volga and Tanais, the mountains of Caucaflus, Georgia, and Bu- 
charia,
The Mus cardia. This is a most voracious animal, which feeds on marmots, rats, mice, jerboas, birds, and other small animals. It procreates in spring, and after eight weeks the female which has eight teats, brings forth from four to eight young ones. It lives in holes, sometimes of its own burrowing, but mostly in those which have been made by other animals, and is exceedingly fecund.

The vulgaris, or common weasel,found, or M. Buffon informs us, that a peasant in one of the provinces of Barbary, in the more northern parts of Russia and Sweden, particularly in Westphalia, it becomes white in winter like the ermine; but even in this state it is easily distinguishable from the latter, being a great deal smaller. The body and head not exceeding seven inches long, and the tail two inches and a half. It is very destructive to young birds, poultry, and young rabbits; and is besides a great devourer of eggs. It does not eat its prey on the place; but after killing it by one bite near the head, carries it off to its young, or to its retreat. It preys also on moles, as appears by its being sometimes caught in mole-traps.

This species is much more domestic than any of the rest, and frequents out-houses, barns, and granaries. It clears its haunts in a short time from mice and rats, being a much greater enemy to them than the cat itself. In summer, however, they retire farther from houses, especially into low grounds, about mills, along rivulets, concealing themselves among brushe wood, in order to surprise birds; and often take up their abode in old willows, where the female brings forth her young. She prepares for them a bed of straw, leaves, and other herbage, and litters in the spring, bringing from six to eight or more at a time. The young are born blind; but soon acquire sight and strength sufficient to follow their mothers. Their motion consists of unequal and precipitate leaps; and when they want to mount a tree, they make a sudden bound, by which they are at once elevated several feet high. They leap in the same manner when they attempt to seize a bird. These creatures, as well as the polecat and ferret, have a disagreeable odour, which is stronger in summer than in winter; and when purged or irritated, their smell is felt at a considerable distance. They move always with caution and silence, and never cry but when they are hurt. Their cry is sharp, rough, and very expressive of resentment. As their own odour is offensive, they seem not to be sensible of a bad smell in other bodies. M. Buffon informs us, that a peasant in his neighborhood took three new-littered weasels out of the carcase of a wolf that had been hung up on a tree by the hind-feet. The wolf was almost entirely putrid, and the female weasel had made a nest of leaves and herbage for her young in the thorax of this putrid carcase. The weasel may be perfectly tamed, and rendered as carefree and frolicksome as a dog or squirrel. The method of taming them is to stroke them often and gently over the back; and to threaten, and even to beat them when they bite. In the domestic state their odour is never offensive but when irritated. They are fed with milk, boiled flesh, and water.

The erminea, or ermine, has the tail tip with black, and has been distinguished by authors into two varieties, the float and the white ermine, though the difference seems chiefly to depend on climate and the season of the year; the float of a pale tawny brown or reddish yellow colour in summer, becoming the white ermine of winter in cold countries. They inhabit the north of Europe, Asia, and America, and as far as the northern parts of Peru and China; living in heaps of stones on the banks of rivers, in the hollows of trees, and particularly in forests, especially those of beech, preying on squirrels and lêmings. In manners and food this animal resembles the common weasel, but does not frequent houses, haunting chiefly in woods and hedges, especially such as border on brooks or rivulets. In general appearance it comes very near to the martin, but is shorter in the body, being scarcely ten inches long from nose to rump, and the tail about five and a half; the hair is likewise shorter and less fibbing than in that animal. In the northern regions, the fur of the ermine becomes entirely white during winter, except the outer half of the tail, which remains black. The skin is reckoned valuable, and sells in Siberia from two to three pounds Sterling a hundred; but in ancient times it was in much greater request than now. In summer, the upper part of the body is of a pale tawny brown colour; the edges of the ears, and ends of the toes, are yellowish white; the throat, breast, and belly are white; in winter in the more temperate regions, it is sometimes mottled with brown and white; but in more severe winters becomes entirely white; the farther north and the more rigorous the climate, the white is the purer; those of Britain generally retain a yellowish tinge. In Peru and other more southern parts, it is brown the whole year. In Siberia they burrow in the fields, and are taken in traps baited with flesh. In Norway they are either shot with blunt arrows, or taken in traps made of two flat stones, one being propped up with a stick, to which is fastened a baited string, which when the animals nibble, the stone falls down and crushes them to death. The Laplanders take them in the same manner, only instead of stones make use of two logs of wood.

There are about 12 other species of the weasel tribe described by authors.—A beautiful species of weasel, as it is called by some authors and universally considered by the Arabs, is described by Mr. Bruce in his appendix under the name of Edeenne. It is about ten inches long from the snout to the tail; the tail near five inches and a quarter, and about half an inch of it black at the tip. From the point of the fore-shouder to the point of the fore-toe it is two inches and seven eighths; from the occiput to the point of the nose, two inches and a half; and the ears are three inches and three eights in length; and about an inch and a half in breadth, with the cavities very large. They are doubled and have a plait on the outside; the border of the inside is thick and covered with white soft hair, the middle part being bare and of a rose or pink colour. The pupil of the eye

**MUS**

Eye is large and black, surrounded with a deep blue iris; the mustachios are thick and strong; the tip of the nose is very sharp, black, and polished. There are four grinders on each side of the mouth, six fore-teeth in each jaw, and the upper jaw projected beyond the lower one. The canine teeth are large, long, and very sharp pointed; the legs small and the feet broad, with four toes armed with short, black, sharp retractile claws; those on the fore-feet being sharper than those behind. The whole body of the animal is of a dirty white, approaching to cream-colour; the hair of the belly rather whiter, longer, and softer than the rest, with a number of paps upon it.

Mr Bruce obtained one of these animals for two sequins, by means of a janifary, who had it from a Turkish foot-soldier just returned from Biscara, a southern district of Mauritania Cafenariensis, now called the Province of Contflantia. According to his account, they are not uncommon in this district, though more frequently to be met with in the neighbouring date-territories of Beni Mezab and Werglab, the residence of the ancient Melano-Gestuli. In the Werglab the animals are hunted for their skins, which are sold at Mecca, and afterwards exported to India. Mr Bruce kept this one for several months at his country-house near Algiers, that he might learn its manners. Its favourite food he tells us was dates or other sweet fruit, yet it is also very fond of eggs. It devoured those of pigeons and small birds with great avidity when first brought to him; but did not seem to know how to manage hen's eggs, though when they were broken to him he ate the contents with as great avidity as the others. When hungry, he would eat bread, especially with honey or sugar. His attention was greatly engrossed by the sight of any bird flying across the room where he was, or confined in a cage near him, and could not be diverted from viewing it by placing biscuit before him; so that it seems probable, that he preys upon them in his wild state. He was extremely impatient of having his ears touched; so that it was with much difficulty that they could be measured; and, on account of this impatience, it was found impossible to count the protuberances or paps on his belly. He seemed very much frightened at the sight of a cat; and endeavoured to hide himself, though he did not appear to meditate any defence. On this occasion also he lowered his ears, which at other times he kept erect. Notwithstanding his impatience, he would suffer himself, though with difficulty, to be handled in the day-time; but in the night he was extremely refractory, always endeavouring to make his escape; and though he did not attempt the wire, yet with his sharp teeth he would soon have made his way through a wooden one, as two others which they attempted to bring along with him actually did. These animals are very swift of foot. They build their nests in trees, particularly the palms, of which they eat the fruit; feeding also on locusts and other insects, and perhaps sometimes preying upon small birds. Mr Bruce has a long criticism on Dr Sparmann for pretending that one Mr Brander was the discoverer of this animal, whereas he says that he himself gave it to Mr Brander. This is the same animal with that

---

**MUT**

Plate CXX. Its exact place in the zoological system has not yet been ascertained.

**MUSTER,** in a military sense, a review of troops under arms, to see if they be complete and in good order; to take an account of their numbers, the condition they are in, viewing their arms and accoutrements, &c.

**Muster-Muster-general, or Commiffary-general of the Musters**; one who takes account of every regiment, their number, horses, arms, &c. reviews them, sees the horses be well mounted, and all the men well armed and accoutred, &c.

**Muster-Rolls,** lists of soldiers in each company, troop, or regiment, by which they are paid, and the strength of the army is known.

**Mutability** is opposed to immutability. See **Immutability.**

**Mutation,** the act of changing, or sometimes the change itself.

**Mutation,** in the ancient music, is applied to the changes or alterations that happen in the order of the sounds which compose the melody.

**Mutationes,** among the Romans, postages, or places where the public couriers were supplied with fresh horses.—The *mutationes* were wholly designed for the use of these couriers, or messengers of State; in which respect they differ from *manifesti.*

**Mutchkin,** a liquid measure used in Scotland; it contains four gills, and is the fourth part of a Scotch pint.

**Mute,** in a general sense, signifies a person that cannot speak, or has not the use of speech.

**Mute,** in law, a person thatstands dumb or speechless, when he ought to answer, or to plead. See **Arraignment.**

**Mute,** in grammar, a letter which yields no sound without the addition of a vowel. The simple conso-nants are ordinarily distinguished into mutes and liquids, or semi-vowels. See the articles **Consonant, Liquid, &c.**

The mutes in the Greek alphabet are nine, three of which, viz. ή, ξ, ο, are termed **tenuis;** three θ, ϑ, ρ, termed **medio;** and three ι, υ, ο, termed **aspire.** See the article **Aspirate, &c.**

The mutes of the Latin alphabet are also nine, viz. B, C, D, G, H, K, P, Q, T.

**Mutilation,** the retrenching or cutting away any member of the body.

This word is also extended to statues and buildings, where any part is wanting, or the projection of any member, as a cornice or an impost, is broken off. It is sometimes also used in a more immediate manner for calibration: (See **Castration and Eunuch.**) The practice of this sort of mutilation is of various kinds: The Hottentots are said to cut away one testicle from their children, upon supposition that they are thereby made lighter and more active for running. In other countries poor people completely mutilate their boys, to prevent the misery and want which would attend their offspring. Those who have nothing in view but the improvement of a vain talent, or the formation of a voice which disfigures nature, as was the case formerly in Italy, are contented with cutting away the testicles. But in some countries of Asia, especially among the Turks and in part of Africa, those whom
jealousy inspires with distrust, would not think their wives fit in the custody of such eunuchs: They employ no slaves in their seraglio who have not been deprived of all the external parts of generation.

Amputation is not the only means of accomplishing this end. Formerly, the growth of the testicles was prevented, and their organization destroyed, by simple rubbing, while the child was put into a warm bath made of a decoction of plants. Some pretend that by this species of castration the life is in no danger. Amputation of the testicles is not attended with much danger; but complete amputation of the external parts of generation is often fatal. This operation can only be performed on children from seven to ten years of age. Eunuchs of this kind, owing to the danger attending the operation, cost in Turkey five or fix times more than others. Chardin relates, that this operation is so painful and dangerous after 15 years of age, that hardly a fourth part of those by whom it is undergone escape with life. Pietro della Valle, on the contrary, informs us, that in Persia those who suffer this cruel and dangerous operation as a punishment for rapes and other crimes of this kind, are easily cured though far advanced in life; and that nothing but ashes is applied to the wound.

There are eunuchs at Constantinople, throughout all Turkey, and in Persia, of a grey complexion; they come for the most part from the kingdom of Golconda, the peninsula on this side the Ganges, the kingdoms of Affan, Aracan, Pegu, and Malabar. Those from the gulph of Bengal are of an olive colour. There are some white eunuchs who come from Georgia and Ciscaflia, but their number is small. The black eunuchs come from Africa, and especially from Ethiopia. These, in proportion to their horrible appearance, are the more esteemed and soft dearer. It appears that a very considerable trade is carried on in this species of men; for Tavernier informs us, that when he was in the kingdom of Golconda, in the year 1657, 22,000 eunuchs were made in it. In that country they are sold at the fair.

Eunuchs, who have been deprived only of their testicles, continue to feel a titillation in what remains, and to have the external sign even more frequently than other men. But the part which remains is very small, and continues almost in the same state in which it was when the operation was performed during childhood.

If the different kinds of Eunuchs are examined with attention, it will be found almost universally, that castration and its consequences have produced greater or less changes in their shape and appearance, independent of its physical effects.

Eunuchs, says Mr. Withof, are timid, irresolute, fearful, foplicious, and unsteady: And this seems to hold generally, though not universally, or without exceptions; see the article Eunuch). The reason is, that their blood has not received all the necessary preparation in passing through the spermatic vessels. Thus being deprived of the properties of males, they participate of the dispositions of females, and their very soul is of an intermediate sex. They are not, however, without advantages: They become larger and fatter than other men; but they sometimes grow to a drolling size. Though oily substances are more abundant in eunuchs, they are likewise less subject to gout and to madness than men who have a greater quantity of blood and of splanchnic humour. The abundant circulation of oily liquor prevents roughness or inequalities in the trachea or palate. This, joined to the flexility of the epiglottis and of the other organs of the voice, makes it honourable and extensible, and at the same time so sweet, that it is almost impossible for eunuchs to pronounce distinctly the letter R. Is this factitious advantage a sufficient consolation to these unhappy men for the barbarity of those who have dared to sacrifice nature at the shrine of avarice? Is it impossible to reflect on all the motives for making eunuchs without a sigh of pity and regret: and yet it must not be supposed that this abominable cruelty is always infallibly attended with that advantage which is sometimes expected from it. Of 2000 victims to the luxury and extravagant caprices of the art, hardly three are found who unite good talents with good organs. The other languishing and inactive wretches, are outcasts from both sexes, paralytic members in the community, an useless burden upon the earth, by which they are supported and nourished. But let us pay the tribute which is due to that virtuous pontiff Pope Clement VIII. who, listening to the voice of modesty and humanity, persuaded and abolished this detestable and infamous practice. Mutiny he declared was the most abominable and disgraceful of crimes.

MUTILLA, in zoology, a genus of animals belonging to the order of insects hymenoptera. There are 10 species; the most remarkable of which is the occidentalis, or velvet ant, an inhabitant of North America. It has six legs, with short crooked antennae; the abdomen large, with a black split crossing the lower part of it, and another black spot at the joining of the thorax; excepting which, the whole body and head resembles crimson-velvet. The trunk or shell of the body is of such a strong and hard texture, that though trod upon by men and cattle they produce no harm. They have a long sting in their tails, which caufes inflammation and great pain for half an hour to those who are stinged by them; which usually happens to negroes and others that go barefooted. They are mostly seen running very nimbly on sandy roads in the hottest summer-weather; and always single. What they feed on, in what manner they breed, and where they secure themselves in winter, is unknown.

MUTINA (anc. geog.) a noble city of the Cipadan, made a Roman colony in the same year with Parma, situated between the rivers Gabellus and Scultenna, on the Via Aemilia. Here D. Brutus, being besieged by Antony, was relieved by the confuls Hirtius and Papia. The Greeks called it Mutina; except Polybius, in whom it is Mutine; and in Polyennus Mutina, after the Roman manner.—Now Modena, a city of Lombardy, and capital of a cognominal duchy. E. Long. 11. 20. N. Lat. 44. 45.

MUTINY, in a military sense, to rise against authority.—Any officer or soldier who shall presume to use traitorous or disrespectful words against the State or Executive power.

"Any officer or soldier who shall behave himself with
MUTY

with contempt or disrespect towards the general or other commander in chief of the forces, he shall speak words tending to their hurt or dishonour, is guilty of mutiny.

Any officer or soldier who shall begin, excite, cause, or join in, any mutiny or sedition, in the troops, company, or regiment, to which he belongs, or in any other troop or company in the service, or on any party, post, detachment, or guard, on any pretence whatsoever, is guilty of mutiny.

Any officer or soldier who, being present at any mutiny or sedition, does not use his utmost endeavours to suppress the same, or coming to the knowledge of any mutiny, or intended mutiny, does not without delay give information to his commanding officer, is guilty of mutiny.

Any officer or soldier who shall strike his superior officer, or draw, or offer to draw, or shall lift up any weapon, or offer any violence against him, being in the execution of his office, on any pretence whatsoever, or shall disobey any lawful command of his superior officer, is guilty of mutiny.

Mutius refus'd to continue his country; he told himfelf. Being ordered that he should have his freedom and return to his family.

Mutius obtained the furname (Caius), furnamed Godrus, and afterwards Scevola was one of the illuftrious Roman family of the Mutians, and rendered his name famous in the war between Porfenna king of Tufcany and the Romans. That prince refolving to refire the family of Tarquin the Proud, went to befiege Rome 507 B.C. Mutius refolved to fervice himself for the safety of his country; and boldly entering the enemy's camp, killed Porfenna's secretary, whom he took for Porfenna himself. Being feized and brought before Porfenna, he told him boldly, that 300 young men like himfelf had sworn to murder him; but since this hand has miffed thee, continued he, it must be punifhed; then putting his right hand on the burning coal, he let it burn with fuch a confufion as confounded the beholders. The king, amazed at the intrepidity of this young Roman, ordered that he should have his freedom and return to Rome, and foon after concluded a peace with the Romans. From this action Mutius obtained the furname of Scevola, "or left-handed," which was enjoyed by his family.

Mutius Scevola (2), furnamed the Augur, was an excellent civilian, and instructed Cioero in the laws. He was made praetor in Afta; was afterwards conful, and performed very important services for the republic.

He ought not to be confounded with Quintus Mutius Scevola, another excellent civilian, who was praetor in Afta, tribune of the people, and at length conful, 95 B.C. He governed Afta with fuch prudence and equity, that his example was propofed to the governours who were lent into the provinces. Cioero fays, "that he was the moft eloquent orator of all the ci­

MUTY

quires a very nice intermediate state, which it seems to enjoy in temperate climates; for although northern countries supply what are reckoned the best cattle, it is in the rich southern pastures that they are brought to perfection. Now the sheep can be brought almost to the fame perfection in the bleak northern regions as in the southern countries.

MUTUAL, a relative term, denoting something that is reciprocal between two or more persons.

Thus we say, mutual affiance, mutual con­

There are mutual or reciprocal duties, offices, &c. between superiors and inferiors; as the State and its Citizens the master and his servants, &c.

VAUGelas makes a distinction between mutual and reciprocal; mutual, according to him, is understood of what is between two only; and reciprocal, of what is between more than two; but this distinction is little regarded in common life.

MUTULE, in architecture, a kind of square 모­

ition set under the cornice of the Doric order.

MUTUNUS, or Mutivus (fap. hirc.); — deity among the Romans, much the fame as the Priapus of the Greeks. The Roman matrons, and particularly newly married women, disgraced themselves by the offene ceremonies which custom obliged them to observe before the statue of this impure deity.

MUZZLE of a Gun or Mortar, the extremity at which the powder and ball is put in; and hence the muzzle-ring is the metallic circle or moulding that furrounds the mouth of the piece.

MYA, the Gaper, in zoology; a genus belonging to the order of vermes tectae, the characters of which are thefe. It has a bivalve shell gaping at one end; the hinge, for the most part, furnished with a thick, strong, and broad tooth, not inferred into the opposite valve. Its animal is an Ascidia. The most remarkable species are:

1. The decilius, or sloting mya, has a brittle, half-transparent shell, with a line slightly prominent near the open, and sloping downwards. It inhabits the rivers of Europe. It is in fcnt about the Hebrides; the fifth eaten there by the gentry.

2. The mya pictorum has an oval brittle shell, with a single longitudinal tooth like a lamina in one shell, and two in the other; the breadth is a little above two inches, the length one. It inhabits rivers. The shells are used to put water-colours in, whence the name. Otters feed on this and the other fresh-water shells.

3. The margaritifera, or pearl mya, has a very thick, coarfe, opaque shell; often much decorticated; oblong, bending inward on one side, or arcuated; black on the outside; usual breadth from five to six inches, length two and a quarter. It inhabits great rivers, especially those which water the mountainous parts of Great Britain. This shell is noted for producing quantities of pearl. There have been regular fisheries for the sake of this precious article in several English rivers. Sixteen have been found within one shell. They are the disease of the fish, analogous to the stone in the human body. On being squeezed, they will eject the pearl, and oftentimes spontaneously in the hand of the swimmer. The river Conway was noted for them in the days of Cambden. A notion also prevails, that Sir Richard Wynne of Gwydir chamberlain to Catha-
raine queen to Charles II, presented her majesty with a pearl (taken in this river) which is to this day honoured with a place in the regal crown. They are called by the Welch cregen dilwir, or "deluge shells," as if left there by the flood. The 1st in Cumberland was also productive of them. The famous circumnavigator, Sir John Hawkins, had a patent for fishing in that river. He had observed pearls plentiful in the straits of Magellan, and flattered himself with being enriched by procuring them within his own island. In the last century, several of great size were got in the rivers of the counties of Tyrone and Donegal in Ireland. One that weighed 36 carats was valued at 401. but being foul, lost much of its worth. Other single pearls were sold for 41. 10s. and even for 101. The last was sold a second time to Lady Glenely, who put it into a necklace, and refused 801. for it from the duchess of Ormond. Suetonius reports, that Cæsar was induced to undertake his British expedition for the sake of their pearls; and that they were so large that it was necessa-ry to use the hand to try the weight of a single one. Mr Pennant supposes that Cæsar only heard this by report; and that the crystalline balls called mineral pearl, were mistaken for them. We believe that Cæsar was disappointed of his hope; yet we are told that he brought home a buckler made with Bri-tish pearl, which he dedicated to, and hung up in, the temple of Venus Genetrix: a proper offering to the goddess of beauty, who sprung from the sea. It may not be improper to mention, that notwithstanding the classicals honour English pearl with their notice, yet they report them to have been small and ill-coloured, an imputation that in general they are still liable to. Pliniy says, that a red small kind was found about the Thracian Bosporus, in a shell called mya; but does not give any mark to ascertain the species.

Linneas made a remarkable discovery relating to the generation of pearls in this fish.—It is a fish that will bear removal remarkably well; and it is said, that in some places they form refurvs for the purpose of keeping it, and taking out the pearl, which, in a certain period of time, will be again renewed. From observations on the growth of their shells, and the number of their annual laminæ or scales, it is supposed the fish will attain a very great age; 50 or 60 years are imagined to be a moderate computation. The discovery turned on a method which Linnaeus found, of putting these shell-fish into a state of producing pearls at his pleasure; though the final effect did not take place for several years: He says, that in five or six years after the operation, the pearl would have acquired the size of a vetch. We are unacquainted with the means by which he accomplished this extraordinary operation; but it was probably published at the time, and considered as important, since it is certain that the author was rewarded with a munificent premium from the states of the kingdom on this account. We regret that we cannot speak more fully on this head; but may observe, that it is probable, from a paper published many years afterwards in the Berlin Acts, that the method was effected in injuring the shell externally, perhaps by a perforation; as it has been observed, that these concretions in shell-fish are found on the inside, exactly opposite to perforations and injuries made from without by ferpule and other animals.

MYAGNUM, GOLo of PLEASURE, in botany; Myagrum A genus of the ficutulosa order, belonging to the te-tradynamia class of plants; and in the natural method ranking under the 39th order, Situgae. The ficutulosa is terminated by an oblong style; the cell generally monoperaous. There are five species; but the only remarkable one is the fativum, which grows naturally in corn-fields in the south of France and Italy, and also in some parts of Britain. It is an annual plant, with an upright stalk, a foot and a half high, sending out two or four side-branches, which grow erect; the flowers grow in loose spikes at the end of the branches, standing upon short foxtails an inch long; they are composed of four small yellowish petals, placed in form of a cross; these are succeeded by oval capsules, which are bordered and crowned at the top with the style of the flower, having two cells filled with red seeds—This is cultivated in Germany for the sake of the expressed oil of the seeds, which the inhabitants use for medicinal, culinary, and economical purposes. The seeds are a favourite food with geese. Horses, goats, sheep, and cows, eat the plant.

MYCALE, a city and mountain of Caria; also a promontory of Asia opposite Samos, celebrated for a battle which was fought there between the Greeks and Persians about the year of Rome 275. The Persians were about 100,000 men, who had just returned from the unsuccessful expedition of Xerxes in Greece.—They had drawn their ships to the shore, and fortified themselves strongly, as if determined to support a siege. They suffered the Greeks to disembark from their fleet without the least molestation, and were soon obliged to give way before the cool and resolute intrepidity of an inferior number of men. The Greeks obtained a complete victory, slaughtered some thousands of the enemy, burned their camp, and failed back to Samos with an immense booty, in which were 70 cheffs of money.

MYCENÆ (anc. geog.) a town of Argolis, in Peloponnesus. The kingdom of the Argives was divided into two portions by Acritus and his brother Protus. Argos and Mycenæ were their capitals.—These, as belonging to the same family, and distant only about 50 fladia or fix miles and a quarter from each other, had one tutelary deity, Juno, and were jointly proprietors of her temple, the Heraeum, which was near Mycenæ. It was here that Agamemnon reigned. He enlarged his dominions by his valour and good fortune, and possessed, besides Mycenæ, the region about Corinth and Sicyon, and that called afterwards Achaia. On his return from Troy, he was slain with his companions at a banquet. Mycenæ then declined; and under the Heraclide was made subject to Argos. (See ARGOS and ARGIA.) The Mycenæans sending 80 men, partook with the Lacedemonians in the glory acquired at Thermopylae. The jealousy of the Argives produced the destruction of their city, which was abandoned after a siege, and laid waste in the first year of the 78th Olympiad, or 466 years before Christ. Some part of the wall remained in the second century, with a gate, on which were lions, a fountain, the subterraneous edifices where Atreus and his sons had deposited their treasures, and, among other sepulchral monuments, one of Agamemnon, and one of his fellow-fighters and sufferers.

MYCETITES DISCOIDES, in natural history, a name
The bill is dusky, almost straight above, and gibbous near the fore head; the under mandible swelled beneath; and there being but one well on the island. There are a great number of churches and chapels, with some monasteries. The drefs of the women in this island is very remarkable, and as different from that of the other islands as that of those islanders is different from the drefs of the other European ladies. Their heads are adorned with lively coloured turbans; their garments are a short white shirt plaited before and behind, which reaches to their knees; they have white linen-drawers; and red, green, yellow, or blue turbans; order Mercury, because water, especially in summer, there being but one well on the island. There are a great number of churches and chapels, with some monasteries. The dres of the women in this island is very remarkable, and as different from that of the other islands as that of those islanders is different from the dres of the other European ladies. Their heads are adorned with lively coloured turbans; their garments are a short white shirt plaited before and behind, which reaches to their knees; they have white linen-drawers; and red, green, yellow, or blue turbans, with various coloured flippers. An ordinary suit for the better fort will cost 200 crowns.

MYCNE (anc. geog.) one of the islands called Cyclades, near Delos, under which the last of the Centaurs slain by Hercules are feigned to lie buried. Hence the proverb, Omnia fab unam Myconum congrere, applied to an injudicious or unnatural farrago. Myconii, people noted for baldness. Hence Myconius, a bald perfon. According to Strabo, the inhabitants became bald at the age of 20 or 25; and Pliny says that the children were always born without hair. The island was poor, and the inhabitants very avaricious; whence Archilocho reproached a certain Pericles, that he came to a feast like a Myconian, that is, without previous invitation. Now called Mycone, an island in the Archipelago. E. Long. 25° 6'. Lat. 37°.

MYCTERIA, the Jabiru, in ornithology; a genus of birds belonging to the order of Grallae. The bill is long, bending upwards, and acute; the nostrils are small and linear; there is no tongue; and the feet have four toes. There are two species: 1. The American, or American jabiru, is about the size of a turkey. The bill is long, stout, and of a black colour; the whole plumage is white, except the head, and about two thirds of the neck, which are bare of feathers and of a blackish colour; the remainder is bare, and of a fine red; on the hind-head are a few greyish feathers; the legs are strong, of a great length, and covered with black scales; wings and tail even at the end. This bird is found in all the Savannas of Cayenne, Guiana, and other parts of South America.

MYCOS (a name given by Dr. Woodward to those kinds of toadstool bodies which the generality of writers had called, after Dr Plott, porpites. These are usually small, and of a roundish, but flattened figure; they are hollowed on one side with a sort of umbilicus, and flinted on the other, they are found on the ploughed lands in Oxfordshire, and some other of the midland counties, and in other places, buried in the solid strata of stone; they are sometimes yellowish, sometimes brownish, and are from the breadth of an inch to a fourth part or less of that size; when broken, they are usually found to confift of a kind of flar, not unlike that of which the shelly coats of the echinates, or the lapides incerti, and other flines of echinidae in their toadstool flate; and in some of them the ridges and flaves are thick set with little knobs and tubercles. The bills in some of these is flat, as it is in others rising in form of a circular elevation from the umbilicus, and others have a circular groove in the same place.

MYCONE, an island on the Archipelago, situated in E. Long. 25° 51'. N. Lat. 37° 28'. It is about 36 miles in circuit, and has a town of the same name, containing about 3000 inhabitants. The people of this island are said to be the best sailors in the Archipelago, and have about 150 vessels of different sizes. The island yields a sufficient quantity of barley for the inhabitants, and produces abundance of figs, and some olives; but there is a scarcity of water, especially in summer, there being but one well on the island. There are a great number of churches and chapels, with some monasteries. The dres of the women in this island is very remarkable, and as different from that of the other islands as that of those islanders is different from the dres of the other European ladies. Their heads are adorned with lively coloured turbans; their garments are a short white shirt plaited before and behind, which reaches to their knees; they have white linen-drawers; and red, green, yellow, or blue flappers, with various coloured flippers. An ordinary suit for the better fort will cost 200 crowns.
MYOIDES, in the heathen mythology, a name sometimes given to Jupiter, but more frequently to Juno, to whom a bull was sacrificed, in order to make him protective in driving away the flies that infested the Olympic games.

MALAE (anc. geog.) a Greek city situated on an island of the same name, on the north-east side of the island. Mylae, or Myliness, once people. A town built by those of Zanci (Strabo). Mylaeus, the epithet, as MYLAUS Campus mentioned by Polybius. Now called Mylazo a port town of Sicily, in the Val di Nomentana. E. Long. 15° 5'. Lat. 38° 36'.

MULAEY, or MYLASSA, a noble city of Caria in Asia Minor, situated at the distance of about three leagues from the Sinus Carinensis. It was the capital of Hecatomnus king of Caria, and father of Mausolus. Pliny speaks of Menander king of Caria, and says that the Rhodians preferred with the greatest care his portrait painted by Appelles; but it was not in honour of this Menander that a Corinthian pillar was erected at Mylae, which still exists, and which bears the inscription:

"The people erected this pillar in honour of Menander, the son of Uliades, and grandson of Euthydemus, the benefactor of his country, and whose ancestors rendered great services also." Euthydemus, the grandfather of this Menander, lived in the time of Julius Caesar and Augustus. Caria was taken by Mithridates, and afterwards by Labienus, whose father had been one of Caesar's generals. Hybris, whose eloquence and valour defeated intimated him to a distinguished rank among his countrymen, in vain encouraged them to make a more obstinate defence while it was besieged by the latter. He himself was obliged to yield to necessity, and to take refuge at Rhodes; but rarely had the conqueror quitted the city, when Hybris returned and restored liberty to his country.

Not content with rendering this service, he also destroyed the power of a dangerous citizen, whose riches and talents rendered him a necessary evil. Euthydemus, often banished, and often recalled, always too powerful in a state the independence of which he threatened, saw his ambition checked by the zeal and activity of Hybris. The Romans left to Mylae that protection which it rendered itself so worthy, by the great efforts it made to preserve it. Pliny calls it Mylae libera. Strabo informs us, that it was one of the most magnificent cities of antiquity, and one of those the temples, porticoes, and other public monuments of which were highly admired. A quarry of white marble in the neighbourhood furnished it with abundance of materials for erecting these edifices.

The Mylaites had two temples dedicated to Jupiter, one situated in the city, which was named Olyg, and another built on a mountain, at the distance of 60 leagues. The latter was dedicated to Jupiter Stratus, Jupiter the Warrior. His statue, which was very ancient, inspired great veneration; people came from all quarters to implore his protection; and for the greater accommodation of his 

The houses are numerous, but chiefly of plaster, and mean, with trees interspersed. The air is accounted bad; and scorpions abound as formerly, entering often at the doors and windows, and lurking in the rooms. The plain is surrounded by lofty mountains, and cultivated. Round the town are ranges of broken columns, the remnants of porticoes, now with rubbish bounding the vineyards. A large portion of the plain is covered with scattered fragments, and with pieces of ordinary aqueducts; besides inscriptions, mostly ruined and illegible. Some altars dedicated to Hecatomnus have been discovered. Of all the ancient temples which formerly ornamented this city, one only escaped the power of time, the hind seal of the early Christians, and the barbarous usurpation of the Mahometans. This monument was dedicated to Augustus and the divinity of Rome. When Pisocke visited Melia to, it was perfect and entire; but at present no traces of it remain, except a few fragments, which have been employed to construct a Turkish mosque.

MYLOGLOSSUM, in anatomy. See Anatomy, Table of the Muscles.

MYOHYOIDAE. Ibid.

MYNSICHT (Hadrian), physician to the duke of Mekenburgh and several other German princes, was distinguished for his knowledge of chemistry, at the beginning of the 17th century. He published a work entitled Armentarium Medico-Chiruricum, which has undergone various editions. In this work he gives a description of several medicines, of the virtues of which he is not always to be depended upon. To him we are indebted for a knowledge of the fable de dubus or the Acanthum, which is still in use.

MYOLOGY, formed of μυς, μυς, "a muscle," and λευκος, "discoluric!"), in anatomy, a description of the muscles; or the knowledge of what relates to the muscles of the human body. See Anatomy, Table of the Muscles.

MYOMANCY, a kind of divination, or method of foretelling future events by means of mice. Some authors hold myomancy to be one of the most ancient kinds of divination; and think it is on this account that Isai. lxvii. 17. reckons mice among the abominable things of the idolators. But, besides that it is not certain that the Hebrew word יבכ used by the prophet signifies a mouse, it is evident it is not the divination by that animal, be it what it will, that is spoken of, but the eating it.

MYOPIA, SHORT-SIGHTEDNESS: a species of vision wherein objects are seen only at small distances. See Medicine, N° 361.

MYOSOTIS, SCORPION-GRASS: A genus of the monotypia order, belonging to the pentandria clas of plants; and in the natural method ranking under the 45th order, Affinisfolia. The corolla is silver-shaped, quinqueloba, and emarginated; the throat fluted by small arches. There are four species; of which the most remarkable is the scorpioides, or Venuil grass. This is a native of Britain, growing naturally in dry fields, and on the margins of springs and rills. It hath naked seeds, and the points of the leaves callous. It varies considerably in different situations. In dry places the plant and flowers are smaller; in moist ones both are larger, and sometimes hairy. The blossoms vary
MYO [565]  M Y R

**Myosurus** vary from a full blue to a very pale one, and sometimes a yellow; and appear in a long spirally twisted spike. When it grows in the water, and its taint and smell is thereby rendered less observable, fleer will sometimes eat it, but it is generally fatal to them. Cows, horses, fowes, and goats refuse it.

**Myosurus**, in botany: A genus of the polygynous order, belonging to the dianthia class of plants; and in the natural method ranking under the 16th order of *Myriacae*. The caryophyllaeus, the leaves and flower at the base; there are five fubulate nectaria reforming petals; the seeds are numerous.

**Po**. 

**Plate CCCXVIII.** The *Dormouse*, in zoology; a genus of quadrupeds belonging to the order of glires. There are two toe-teeth in each jaw; the upper ones cuneated, the under compressed; the whiskers are long, the tail is hairy and round, growing thicker towards the extremity; the fore and hind legs are of equal length, and the fore-feet have four toes.

1. The *gla*, or hoary dormouse, is of a pale ash-colour on the upper parts of the body, and whitish on the under; and is about the size of the common squirrel, but thicker in the body. It inhabits France and the south of Europe, and the south-west of Russia about the Volga of Samara. This animal, which is the *squirre* of Aristotle, *mus-tigris* of Oppian, and *gla* of Pliny, was held in great esteem by the ancient Romans as a luxurious delicacy: they were, fed in places called *gliraria*, constructed for the purpose, and they are eaten chiefly by the modern Italians. It forms a nest in the hollow of some tree, in which it sleeps all day; feeds in the night on nuts, walnuts, the feeds of rats, but has the fame disagreeable odour with the domestic rat.

2. The *nitella*, or garden dormouse, is of a tawny colour on the upper parts of the body, and whitish ash, tinged with yellow on the under; has a black circle round each eye, and a black spot behind each ear; and is five inches long, besides the tail, which measures four. It inhabits the south parts of Europe and Russia, where it lives chiefly in gardens, though it sometimes is found in houfes. They are very destructive to fruit, particularly peaches, which they seem to prefer to every other kind. They also eat peaches, apricots, and plums; and when soft fruits are not to be had, they will eat almonds, filberts, nuts, and even leguminous plants. Of these they carry off great quantities into their retreats which they dig in the earth, and particularly in well cultivated gardens; for in old orchards they are often found in hollow trees, where they make beds of herbs, mosses, and leaves. Eight or ten of them are frequently found in the same place, all benumbed, and rolled up in the midst of their provision of fruits and nuts. They copulate in spring, and bring forth in summer. The litter consists of five or six young, who grow very quickly, but are not fertile till the next year. Their flesh is not eatable but has the same disagreeable odour with the domestic rat.

3. The *mustcardim*, or common dormouse, is about the size of the domestic mouse, but of a plumper appearance; the nose is more blunt; the head, sides, belly, and tail, are of a tawny red colour, the throat white. Dormice inhabit woods, or very thick hedges; forming their nests in the hollow of some low tree, or near the bottom of a close thrush; they form little magazines of nuts, and eat in an upright posture like the squirrel. The consumption of their hoard, however, during the rigour of the feast is but small; for they sleep most of the time, retiring into their holes; at the approach of winter they roll themselves up, and become torpid. Sometimes they experience a short revival in a warm sunny day, when they take a little food, and relapse into their former state. These animals seldom appear far from their retreats, or in any open place; for which reason they seem less common in Britain than they really are. They make their nests of moss, grafts, and dead leaves; and bring usually three or four young at a time.

**Myrapalus** (Nicolas), was a physician of Alexandria, to whom we are under great obligations for the pains he took to collect into a kind of pharmacopeia, all the compound medicines which lie scattered in the works of the Greeks and Arabian writers. His work was accomplished before the beginning of the 14th century; and though written in barbarous Greek, continued for a long time to be the rule of pharmaceutical preparations in Europe. A translation of it into Latin by Leonard Fussich is entitled *De Medicamentorum, in S. Hieronymi quadriginta et octo digestum*. There are a great many editions of this work; the best is that of Hartman Beverus; Nuremberg, 1658, 8vo.

**Myriad**, a term sometimes used to denote ten thousand.

**Mykica, Gals, or Sweat-willow**, in botany: A genus of the tetrandria order, belonging to the dioecia class of plants; and in the natural method ranking under the fifth order, *Amentaceae*. The scale of the male catkin is in the form of a crescent, without any corolla. The scale of the female catkin the same: there is no corolla; but two styles, and a monoliferous berry.

1. The gale, Dutch myrtle, or sweet-willow, grows naturally upon bogs in many places both of Scotland and England. It rife about four feet high, with many shrubby stalks, which divide into several slender branches, garnished with flat pear-shaped leaves of a light yellowish green, smooth and a little sawed at their points. The female flowers or catkins are produced from the sides of the branches, growing upon separate plants from the female, which are succeeded by clusters of small berries, each having a single seed. It flowers in July, and ripens in autumn. When transplanted into shrubberies, the most left parts must be alligned to it.

The leaves, flowers, and seeds of this plant, have a strong fragrant smell, and a bitter taste. They are said to be used among the common people for destroying moths and cutaneous insects, being accounted an enemy to insects of every kind; internally, in infirmities, as a stimulant and vermifuge; and as a subltitute to hops for preserving malt liquors, which they render more inebriating, and of consequence less flatulous: it is said that this quality is destroyed by boiling.
MYRICA.  2. The cerifera, wax-bearing myrica, or candleberry myrtle, is a native of North America. It is a small tree, about ten or twelve feet high, with crooked stems branching forth near the ground irregularly. The leaves grow irregularly on them all round; sometimes by pairs, sometimes alternately but generally at unequal distances. They are of a lanceolate figure; and some are serrated at the top, while others have their edges wholly entire. They stand on very short footstalks; having their upper surface smooth, and of a shinning green colour, while their under is of a more dusky hue. The branches of the old plants shed their leaves in the autumn; but the young plants raified from seeds retain them the greatest part of the winter so as during that season to have the appearance of an evergreen. But this beauty will not be lasting, for they shed their leaves proportionally earlier as the plants get older. There are both male and female trees of this sort; the flowers are small, of a whitish colour, and make no figure; neither does the fruit that succeeds the female, which is a small, dry, blue berry, though produced in clusters, make any show. So that it is from the leaves this tree receives its beauty and value; for these being bruised as well as the bark of the young shoots emit the most refreshing and delightful fragrance, that is exceeded by no myrtle, or any other aromatic shrub.

There is a variety of this species of lower growth, with shorter but broader leaves, and of equal fragrance. This grows commonly in Carolina; where the inhabitants collect from its berries a wax of which they make candles, and which occasions its being called the candleberry tree. It delights in a moist soil.

—The wax is procured in the following manner: In November and December, when the berries are ripe, a man with his family will remove from home to some island or sand-bank near the sea, where these trees most abound, taking with them kettles to boil the berries in. He builds a hut with palmetto leaves for the shelter of himself and family during his residence there which is commonly four or five weeks. The man does the trees, while the children strip off the berries into a porridge-pot; and having put water to them, they boil them till the oil floats, which is then skimmed off into another vessel. This is repeated till no more oil appears. When cold, this hardens to a paste, and yields a grateful smell.

MYRIOPHILLUM, in botany: A genus of the polyandria order, belonging to the monoeica class of plants; and in the natural method ranking under the 15th order, Lauraceae. The male calyx is tetraphyllous; there is no corolla; the stamens are eight in number. The female calyx is tetraphyllous; the pistil four; there is no style; and four naked seeds.

MYRISTICA, the Nutmeg tree, in botany, A genus of plants belonging to the class dicotyledon, and order syngensia, in the New Genera Plantarum of Linnaeus by Sprecher; and of the natural order Lauri, in his fourth class Monocotyledones. —The male calyx is monophyllous, strong, and parted into three lacinii of an oval shape, and ending in a point, it has no corolla. In the middle of the receptacle rises a column of the height of the calyx: to the upper part of which the anthers are attached. They vary in number from three to twelve or thirteen. —The female calyx and corolla as in the male, on a different tree. The germ of the ovum is drawn, the style short, with a bifid stigma; the lacinii of which are oval and spreading —The fruit is of that sort called drupa. It is fleshy, round, sometimes unilocular, sometimes bivalved, and bursts when ripe at the side. The seed is enveloped with a fleshy and fleshy membraneous fleshy envelope, which divides into filaments (this, in one of the species is the mace of the hours). The seed or nutmeg is round or oval shaped, unilocular, and contains a small kernel variegated on the surface by the fibres running in the form of a screw.

Species. There are five species of this genus according
MYRIFICA, according to some authors, but several of those being only varieties, may be reduced to three, viz.,

1. Myrifica fatica, or wild nutmeg; this grows in Tobago, and rises to the height of an apple-tree; has oblong, lanceolated, downy leaves, and hairy fruit — the nutmeg of which is aromatic, but when given inwardly is narcotic, and occasion drunkmens, delirium, and madness, for a time. See a figure in Guerraer de Sent and Frid. T. 41. f. 3-4.

2. The myrifica, feibiera, (Pirola Sibifera Aublet, page 904. Tab. 345.) A tree frequent in Guiana, rising to 40 or even to 60 feet high; on wounding the trunk of which, a thick, acrid, red juice runs out. Aublet says nothing of the nutmegs being aromatic; he only observes, that a yellow fat is obtained from them, which serves many economical and medical purposes, and that the natives make candles of it.

3. The myrifica, mofchata, or nutmeg, attains the height of 6 to 8 feet, and produces numerous branches which rise together in storys, and covered with bark, which of the trunk is a reddish brown, but that of the young branches is of a bright green colour: the leaves are nearly elliptical, pointed, undulated, obliquely nervet, on the upper side of a bright green, on the under whitish, and flant alternately upon footstalks: the flowers are small, and hang upon slender peduncles, proceeding from the axil of the leaves: they are both male and female upon separate trees.

M. Schwartz, who has carefully examined this as well as the two first species, preferred in spirits, places them among the monodelphas.

The nutmeg has been suppos'd to be the Conacum of Theophrastus, but there seems little foundation for this opinion; nor can it with more probability be thought to be the Chryseololmum of Galen. Our first knowledge of it was evidently derived from the Arabsians; by Avicenna it was called jayfiban, or jayfband, which signifies nut of baa. Kundah. Both figures and described this tree; but the figure given by him is so imperfect, and the description so confused, that Linnaeus, who gave it the generic name myrifica, was unable to assign its proper character. Sonnerat's account of the myfcedar is still more erroneous; and the younger Linnaeus was unfortunately misled by this author, placing the myrifica in the clafs Polyandria, and describing the corolla as consisting of five petals. Thunberg who examined the flower of the nutmeg, places it in the clafs Monocla; and according to this description, the male flower has but one filament, surrounded at the upper part by the anther, and as the filaments are short and slender, and the anther united, this mistake might easily arise. M. De La Marck informs us, that he received several branches of the myrifica, both in flower and fruit, from the Isle of France, where a nutmeg-tree, which was introduced by Monsieur Poivre in 1770, is now very large, and continually producing flowers and fruit. From these branches, which were sent from Mons. Cere, director of the king's garden in that island, Mons. De La Marck has been enabled to describe and figure this and other species of the myrifica with tolerable accuracy; and that we have profited by his labours, will appear from the annexed figure, of which the following is an explanation:

Fig. a. A spur with fructification. The drups of the natural size, and bursting open. Fig. b. The full-grown fruit cut lengthways. Fig. c. Another section of the same. Fig. d. The nutmeg enveloped with its covering the mace. Fig. e. The fatty membrane or mace spread out. Fig. f. The nutmeg of its natural size. Fig. g. The same with its external tegument removed at one end. Fig. h. The mace with its outer tegument entirely removed. Fig. i. A transverse section of the nutmeg. Fig. j, k, and l. Sprigs of the Myrifica mofhata in flower, with a leaf of the natural size, and a representation of the calyx and column in the flower.

The seeds or kernels called nutmegas are well known, as they have been long used both for culinary and medical purposes. Dilluted with water, they yield a large quantity of essentail oil, ressembling in flavour the spice itself; after the distillation, an infipid fæaceous matter is found swimming on the water; the decocion infipidifies, gives an extract of anbious, very lightly bitter taste, and with little or no astringency. Rectified spirit extracts the whole virtue of nutmegs by infusion, and elevates very little of it in distillation; hence the spirituous extract possesses the flavour of the spice in an eminent degree.

Nutmegs, when heated, yield to the press a confidereable quantity of limpid yellow oil, which on cooling concretes into a fæaceous consistence. In the shops we meet with three forts of unctuous substances, called oil of mace, though really expressed from the nutmeg. The belt is brought from the East Indies in flone jars; this is of a thick consistence, of the colour of mace, and has an agreeable fragrant fmecl, the second fort, which is paler coloured, and much inferior in quality, comes from Holland in folid masses, generally flat, and of a square figure; the third, which is the worth of all, and usually called common oil of mace, is an artificial composition of fæven, palm oil, and the like, flavoured with a little genuine oil of nutmeg.

Method of gathering and preparing Nutmeg. When the fruit is ripe, the natives ascend the trees, and gather it by pulling the branches to them with long hooks. Some are employed in opening them immediately, and in taking off the green shell or frith-rind, which is laid together in a heap in the woods, where in time it putrefies. As soon as the putrefaction has taken place, there spring up a kind of mushrooms, called boleti mofchetani, of a blackifh colour, and much valued by the natives, who consider them as delicate eating. When the nuts are stripped of their frith-rind they are carried home, and the mace is carefully taken off with a fmall knife. The mace, which is of a beautiful red, but afterwards assumes a darkifh or reddish colour, is laid to dry in the fun for the space of a day, and is then removed to a place left exposed to the rays, where it remains for eight days, that it may toren a little. They afterwards moisten it with water, to prevent it from drying too much, or from losing its oil. They are careful, however, not to employ too much water, lest it should become putrid, and be devoured by the worms. It is last of all that is put into flmall bags, and squeezed very close. Mace must not be confounded with mace. See the word Mace.

The nuts, which are still covered with their ligneous shell, are for three days exposed to the sun, and afterwards...
afterwards dried before a fire till they emit a found
when they are shaken; they then beat them with
small flicks in order to remove their shell, which flies
off in pieces. These nuts are distributed into three
parcels; the first of which contains the largest and most
beautiful, which are destined to be brought to Eu-
rope; the second contains such as are reserved for the
use of the inhabitants; and the third contains the small-
est, which are irregular or unripe. These are burnt;
and part of the elk is employed for procuring oil by
preliminary. A pound of them commonly gives three
ounces of oil, which has the consistence of tallow, and
has entirely the taste of nutmeg. Both the nut and
mace, when distilled, afford an essential, transparent,
and volatile oil, of an excellent flavour.

The nutmegs which have been thus selected would
soon corrupt if they were not watered, or rather
pickled, with lime-water made from calcined shell-fish,
which dilute with salt-water till it attain the
confidence of tallow, and. has entirely the taste of nutmeg. Both the nut
and mace, when distilled, afford an essential, transparent,
and volatile oil, of an excellent flavour.

In the island of Banda, the fruit of the nutmeg-tree
is preserved entire in the following manner: When it
is almost ripe, but previous to its opening, it is boiled
in water and pierced with a needle. They next lay
it in water to soak for ten days, till it be- loit its four
and sharp taffe. They then boil it gently in a syrop
of sugar, to which, if they with it to be hard, a lime
is added. This operation is repeated for a few
times, and each time the syrup is renewed. The fruit
when thus preserved is put for the
whole of Europe, and of great part of

The medicinal qualities of nutmeg are supposed to
be aromatic, astringent, and referoxent; and
with a view to the last mentioned effects, it has been
much used in diuretics and dyuretics. To many
people the aromatic flavour of nutmeg is very agree-
able; they however should be cautious not to use it in
to large quantities, as it is apt to affect the head, and
even to manifest an hypnotic power in such a degree
as to prove extremely dangerous. Bonitus speaks of
this as a frequent occurrence in India; and Dr Cullen
relates a remarkable instance of this soporific effect
of the nutmeg, which fell under his own observation,
and hence concludes, that in apoplectic and paralytic
cases this spice may be very improper. He observes,
that a person by mistake took too drachmas or a little
more of powdered nutmeg: he felt it warm in his stom-
ach, without any uneasiness; but in about an hour
after he had taken it he was seized with a drowsiness,
which gradually increased to a complete stupor and
insensibility; and not long after he was found fallen
from his chair, lying on the floor of his chamber in
the state mentioned. Being laid a-bed he fell asleep;
but waking a little from time to time, he was quite
delicious; and he thus continued alternately sleeping
and delirious for several hours. By degrees, however,
both these symptoms diminished; so that in about six
hours from the time of taking the nutmeg he was
pretty well recovered from both. Although he still
complained of headache, and some drowsiness, he slept
naturally and quietly the following night, and next
day was quite in his ordinary health.

Remarks on the Trade of Nutmeg. Nutmeg-trees grow
in several islands in the eastern oceans. The wood-pigeon
of the Moluccas is intentionally a great planter of
these trees, and disseminates them in places where a nation,
powerful by its commerce, thinks it in its interest
that they should be rooted out and destroyed. The
Dutch, who unawares planted a forest mount of
flavors, have appropriated to themselves the
confectionary of nutmeg, as well as that of cloves and cinnamon,
growing in the island of Ternat, Ceylon, &c., either by
night of conquest or by paying subsidies to the
rulers, who find them much more profitable than
the former produce of their trees. It is nevertheless
ture, that they have prevailed upon or compelled the
inhabitants of the Moluccas to cut down and root out
all the clove-trees, which they have preserved only in
the islands of Ambon and Ternate, which are in a
great measure subject to them. We know for certain,
that the Dutch pay 18,000 rix dollars yearly to the
king of Ternate, by way of tribute or gift, in order
recompense him for the loss of his clove trees in the
other Molucca islands; and that they are moreover
bound by treaty to take at 34 d. a pound, all the
cloves brought by the natives of Ambon to their
magazines. They have likewise succeeded to
destroy the cinnamon every where except in the
island of Ceylon, which is in their possession.
The spice is the caye with white pepper, &c., so that the
trade of the whole of Europe, and of great part of
Asia in this species of commodity, passes through their
hands.
the loth of June 1760, M. Beaumare law at Amsterdam, near the Admirality, a fire, the fuel of which was valued at 8,000,000 of livres; and as much was to be burned on the day following. The feet of the spectators were bathed in the effulgent oil of their substances; but no person was allowed to gather any of it, much less to take any of the pieces which were in the fire.

Some years before, upon a similar occasion, and at the same place, a poor man who had taken up some nutmegs which had rolled out of the fire, was, as M. Beaumare was informed, seized and condemned to immediate execution. We will only add, that notwithstanding the jealousy of the Dutch, and the pain they take to preserve the files of cloves wholly to themselves, they have never been able to prevent their own officers in several parts of India from embezzeing and selling considerable quantities of them. M. de Jaucourt informs us, that in order to defraud the company, they sell them to the vecchils of other nations with which they meet at sea, and moisten the remainder with water, that they may still have the number of quinmals of which their cargo consisted. The quantity sold may amount to 10 quintals in 100 before it can be perceived by the clerks of the magazines at Batavia, where they are received.

We are informed by M. Romé de Lille, who has lately arrived from India, that the English draw a great deal of cinnamon, pepper, and cloves, from the island of Sumatra. The staple for this commodity, which gives great offence to the Dutch, is at the factory of Bengoolen. We have likewise seen a specimen of pretty good cinnamon raised at Martinico; the French, to prevent the exportation of splend for this commodity, which gi...
MYR [570]

The abdomen is of an oblong form, and consists of eight segments; the wings are diaphanous, adorned with a net-work of black fibres, charged with several blackish brown spots. The larva of this insect is very fond of ants, which it hunts after, whence its name. The larve proceed from the egg which the perfect insect had deposited in very fine dry sand, in a place sheltered from rain, either within a crevice of a wall or of the ground, or at the foot of a wall generally exposed to the south sun. There they are hatched, and make their usual abode. Their colour is grey, and their body, which is covered with small protuberances, is of an oval form. Its posterior extremity terminates in a point, and is of use to sink itself down into the sand; for it only walks retrogressively, though furnished with six feet. Before the head is placed a dentated forceps, sharp and hollow within, with which the creature catches flies and other insects, but especially ants. This forceps serves as a mouth or rostrum, as well as for an offensive weapon. The animal's retrospective march not allowing it to run after the insects on which it is fed, it uses a stragam. It dives down into the sand, and turning about in a circle, hollows out concentric furrows, gradually deeper and deeper, calling at a distance with its horns the sand it takes from that place. At length it manages to dig a hole in shape like a funnel, at the bottom of which it takes its flattening, concealed in the sand, nothing but the open extended forceps appearing above it. Mischief overtakes every insect that happens to fall into that hole. The myrmelio who is apprised of it by the Granis of sand rolling down to the bottom, overwhelms him with a shower of dust, which it ejects with its horns, then drags the insect to the bottom of the hole, where it fetizes him with its forceps and sucks its vitals. It does not even spare other myrmelions who in their motions to and fro chance to fall into it. When the larva is come to its full growth, it digs no more holes; it moves backwards and forwards tracing irregular furrows on the sand, and at length spins itself a cocoon, shaped like a ball, the outward part of which is formed of the sand in which it lived, and the inward is lined with fine white silk. Within this cocoon it turns to a chrysalis, which is curved into a semi-circle, and wherein may be distinguished all the parts of the perfect insect that is to issue from it. It is more oblong than the larva, but much shorter than the perfect insect. After a certain period the chrysalis casts off its shell, turns to a winged insect, and flies through the hole in order to take its flight. The perfect insect is very scarce, but is sometimes met with in sandy places, and near rivulets.

MYRMIDONS (MYRMIDONES), in antiquity; a people on the southern borders of Thessaly, who accompanied Achilles to the Trojan war. They received their name from Myrmidon, a son of Jupiter and Eurymedusa, who married one of the daughters of Aeolus son of Helen. His son Actor married Migea, the daughter of Aepus. He gave his name to his subjects, who dwelt near the river Peneus in Thessaly. According to some, the Myrmidons received their name from their having arisen from ants or plumes, upon a prayer put up for that purpose by king Aeolus to Jupiter, after his kingdom had been depopulated by a severe pestilence. According to Strabo, they received it from their industry, because they imitated the diligence of the ants, and like them were indefatigable, and were continually employed in cultivating the earth.

MYRMILLONES, were gladiators of a certain kind at Rome, who fought against the Retiarii. Their arms were a sword, head-piece and shield. On the top of the head-piece they wore a fillet embossed, called MARSAPES, whence their name is by some supposed to be derived. The Retiarii, in their engagements, made use of a net, in which they endeavoured to entangle their adversaries, and flung during the fight, "Non te pote, plicem pote; quid me fugis, Galile?" I aim not at thee, but I aim at thy fish; why dost thou shun me, O Gaul?" The myrmillones were called Galli, because they wore Gallic armour. They were also named Saturi. This kind of gladiators was suppressed by Caligula. See GLADIATORS, RETIARI, &c.

MYROBALANS, a kind of medicinal fruit brought from the Indies, of which there are five kinds.
1. The citrine, of a yellowish red colour, hard, oblong, and the size of an olive. 2. The black, or Indian myrobolan, of the bigness of an acorn, wrinkled, and without a stone. 3. Chebulic myrobolan, which are of the size of a date, pointed at the end, and of a yellowish brown. 4. Emblic, which are round, rough, the size of a gall, and of a dark brown. 5. Balleritic, which are hard, round, of the size of an ordinary prune, less angular than the rest, and yellow. They are all slightly purgative and astringent. The word comes from the Greek μυρο, "ointment," and βαλλειος, "acorn," as being in the form of acorns, and used in medicine.

MYRON, an excellent Grecian satyr, flourished 442 B.C. The cow he represented in brass was an admirable piece of workmanship, and was the occasion of many fine epigrams in Greek.

MYROXYLON, in botany: a genus of the monogynia order, belonging to the decandria class's of plants. The calyx is campanulate; the superior petal larger than the rest; the germ is longer than the corolla; the legumen monospermous. There is but one species, the peruifera, a native of Peru and the warmer parts of America. It is this shrub that yields the balsam of Peru, which is said to be extracted from it by coccion in water. This balsam, as brought to us is nearly of the consistence of thin honey, of a reddish brown colour inclining to black, an agreeable aromatic smell, and a very hot biting taste. Distilled with water, it yields a small quantity of a fragrant essential oil of a reddish colour, and in a flowing state, without addition, a yellowish red oil. Balsam of Peru is a very warm aromatic medicine, considerably hotter and more acrid than copaiva. Its principal effects are to warm the habit, to strengthen the nervous system, and attenuate vitilic humours. Hence its use in some kinds of aitmas, gonorrhoeas, dysenteries, suppressions of the uterine discharges, and other disorders proceeding from a debility of the solids or a sluggishness and inactivity of the juices. It is also employed externally, for cleansing and healing wounds and ulcers, and sometimes against pains and rheumatic pains.

There is another sort of balsam of Peru of a white colour,
Myrrh, or the mineral, is a gummy-refrinite concrete juice, obtained from an oriental tree of which we have as yet no certain account. It comes over to us in globes or drops, of various colours and magnitudes. The best is of a somewhat transparent, friable, in some degree undeutous to the touch, of an uniform brownish or reddish-yellow colour, often streaked internally with whitish semicircular or irregular veins; of a moderately strong, not disagreeable smell; and a lightly pungent, very bitter taste, accompanied with aromatic flavour, but not sufficient to prevent its being nauseous to the palate. There are sometimes found among it hard shining pieces, of a pale yellowish colour, resembling gum-arabic, of no taste or smell: sometimes mallees of bdellium, darker coloured, more opaque, internally softer than the myrrh, and differing from it both in smell and taste: sometimes an unction gum-refine, of a moderately strong somewhat ungrateful smell, and a bitterish very durable taste, obviously different both from those of bdellium and myrrh: sometimes likewise, as Cartheyer observes, hard compact dark coloured tears, less aromatic than myrrh, of an offensive smell; and a most ungrateful bitterness, so as, when kept for some time in the mouth, to provoke reaching, though so refined, that little of them is dissipated by the saliva. Great care is therefore requisite in the choice of this drug.

We have, as already observed, no certain information concerning the tree from which this substance flows; we are only told that the myrrh-tree, or plant, is a native of Abexim in Ethiopia, and is named bedeia by the Arabs. It is affirmed by some that the myrrh we have at present is not equal in quality to that of the ancients, and has not that exquisite smell which all authors ascribe to the latter. They aromatized their most delicious wines with it; and it was preferred as a very valuable perfume to our Lord while he lay in the manger (a). But to this it may be easily answered, that there is no disputing about perfumes any more than about tastes and colours. Men are equally changeable with regard to smells, of which we have striking examples in musk and civet (b). The ancients reckoned two kinds of myrrh: the one liqud,
The true Troglodite myrrh will be entirely lost; and the erroneous descriptions of the ancient Greeks will lead posterity, as it has done us, to form many mistaken conjectures concerning the nature of the myrrh of the ancients.

Though the Troglodite myrrh was superior to every species of Arabian myrrh, the Greeks plainly perceived that it was not all of the same quality. Pliny and Theophrastus affirm, that this difference was owing to the trees, some of which were wild, and others improved by culture: but this is a mere conjecture; for the truth is that none of them are cultivated. The quality of the drug formerly depended, and must still depend, on the age and foundness of the tree, on the way of making the incision, and on the season of the year, and the natives do not bring so great a price by the second as by the first myrrh of the first year. When the rains have ceased, that is from April to June: and the myrrh is produced in July and August. At each return of the season, the sap continues to run in the course to which it has been accustomed; but the tropical rains, which are very violent, and which last for six months, convey so much filth and water into the incision, that by the second year the tree begins to rot at that place; so that the myrrh is of a secondary quality, and at Cairo does not bring so great a price by a third as the myrrh of the first year. That which issues from incisions near the roots and in the trunks of old trees is of the second growth and quality, and sometimes worse; but it is reckoned good myrrh in the shops of Italy everywhere except Venice. It is of a red blackish colour, dirty, solid, and heavy. It loses very little of its weight by being long kept, and can scarcely be distinguished from that of Arabia Felix. The third and worst kind is that which flows from old incisions formerly made in old trees, or which not having been at first observed, has remained a whole year upon the tree. It is black, heavy, and of an earthy colour: it has little smell and bitterness, and is probably the canculus of the ancients.

Myrrh newly gathered has always a strong smell of rancid oil; and when put into water, globules of an oily substance are detached from it, which rise and swim on the surface. This oiliness does not arise from the myrrh, but from being put by the natives into goats' skins, which they anointed with butter to make them tight. It is kept in these skins, and thus carried to market: so that instead of being a fault, as some suppose, it is a proof that the myrrh is newly gathered; which is the best property that myrrh of the first kind can have. Besides, this oily covering must have retained the volatile particles of the fresh myrrh, which escape in such abundance as frequently to occasion a considerable diminution in the weight.

(c) Pliny speaks of the Sarsi as a recent or liquid myrrh: and Dioscorides, chap. 67, says nearly the same thing. Mr Bruce is of opinion (but we think he is mistaken), that the ancient Greeks and Romans, who lay at so great a distance, could never have it in that state; because he was a native of the myrrh country, and covered with the erroneous descriptions of the ancient Greeks will lead posterity, as it has done us, to form many mistaken conjectures concerning the nature of the myrrh of the ancients.

To prevent this juice from hardening, or at least in a very small degree it is sufficient to exclude it from the contrast of the air immediately after its issuing from the tree; and by these means its aromatic nature will be much better preserved. The medical effects of this aromatic bitter are to warm
warm and strengthen the vices; it frequently occasion
flows a mild diaphoretic, and promotes the fluid secre
tions in general. Hence it serves serviceable in l
guid cases, diaphoretic from a simple inactivity,
those female disorders which proceed from a cold, mu
ous, sluggish indigestion of the humours, suppress
tions of the uterine discharges, catarrhal disorders,
and where the lungs and thorax are oppressed by vi
ey fever.

Myrrh is likewise supposed in a peculiar man
er to refit putrefaction in all parts of the body; and
in this light it stands recommended in malignant, putrid,
and putrid fevers, and in the small-pox; in which
last it is said to accelerate the eruption.

The present practice does not seem to expect any
peculiar virtue from myrrh; and it is now perhaps less
employed than formerly. Some late writers, however,
and particularly Dr. Simons, in his treatise on Con
sumptions, have bestowed very high encomiums on it,
even in cases of tuberculous phthisis; and although it
can by no means be represented as a remedy much to
be depended on, yet there is reason to believe that it
has been serviceable in some cases.

Rectified spirit extracts the fine aromatic flavour and
bitterness of this drug, and does not elevate any thing
of either in evaporation; the gummy substance left by
this menstruum has a disagreeable taste, with scarcely
any of the peculiar flavour of the myrrh: this part
dilutes in water, except some impurities which re
main. In distillation with water, a considerable
quantity of a ponderous essential oil arises, resembling in
flavour the original drug. Myrrh is the balls of an
official tincture. It enters the pilulae ex aloe et myr
rha, the pilulae gummii, and pilulae floridicae, and
some other formule. But for obtaining its full effects,
it must be given in doses of half a dram or upwards; and
it is thought to be advantageously united with a pro
portion of nitre, cream of tartar, or some other refri
gerant salt.

MYRURHINE, or Murrine. See Murrine.

MYRSINE, in botany: A genus of the mono
gynia order, belonging to the pantandria class of plants;
and in the natural method ranked under the 18th order,
Bicorne. The corolla is semiquinquefid and connivent,
the stamens filling the corolla: the berry quinquefo
cular and pentamerous.

MYRTIFORM, in anatomy, an appellation giv
en to several parts, from their resembling myrtle-berries.

MYRTIS, a Greek woman who distingui
shed herself by her poetical talents. She flourished about 500
years before the Christian era, and infringed the cele
brated Corinna in the severest rules of criticism.
Pindar himself, as some report, was also one of her
pupils.

MYRTLE, in botany. See Myrtus.

MYRTOM, a part of the Augean sea, ly
ing between Eubea, Peloponnese, and Attica. It
receives this name from Myrtos a woman, or from
Myrtos a small island in the neighbourhood, or from
Myrtus the son of Mercury who was drowned there,
etc.

MYRTUS (anc. geog.), a small island near Cary
thus in Eubea, which gave name to the Mare Myrt
toun. Others, according to Paulaniers, derive the ap
pellation from Myrio; the name of a woman. Strabo
extends this sea between Crete, Argia, and Attica.

Paulaniers beginning it at Eubea, joins it at Hel-
...
Myrtus, or myrtle, hath a narrow, sharp-pointed leaves, crinkled at intervals. These are all beautiful evergreen shrubs of exceeding fragrance; exotics originally of the southern parts of Europe, and of Asia and Africa, and consequently in this country require shelter of a greenhouse in winter; all of which, though rather of the small-leaved kind, have their foliage closely placed, and remain all the year, and are very floriferous in summer; and when there is a collection of the different sorts, they afford an agreeable source of variety with each other. They therefore claim universal esteem as principal greenhouse plants, especially as they are easily raised from cuttings, and of such easy culture, as to be attainable in every garden where there is any sort of greenhouse, or garden frames furnished with glass for protecting them in winter from frost, but some of the broad-leaved sorts are so hardy as to succeed in the full ground, against a south wall and other warm exposures, all the year, by only allowing them shelter of mats occasionally in severe frosty weather; so that a few of these sorts may also be exhibited in a warm situation in the shrubbery: observing, however, all the sorts are principally to be considered greenhouse plants, and a due portion of them must always remain in pots to move to that department in winter. 

2. The pimento, pimento, Jamaica pepper, or allspice tree, grows above 50 feet in height and two in circumference; the branches near the top are much divided and thickly beset with leaves, which by their continual verdure always give the tree a beautiful appearance; the bark is very smooth externally, and of a grey colour; the leaves vary in shape and in size, but are commonly about four inches long, veined, ashy-grey and elliptical, and of a deep shining green colour: the flowers are produced in bunches or panicles, and stand upon subdividing or trichotomous stalks, which usually terminate the branches; the calyx is cut into four roundish segments; the petals are all four, white, small, reflex, oval, and placed opposite to each other between the segments of the calyx; the filaments are numerous, longer than the petals, spreading, of a greenish white colour, and rise from the calyx and upper part of the germs; the anther are roundish, and of a pale yellow colour; the style is smooth, simple and erect; the stigma is obtuse; the germs become a round succulent berry, containing two kidney-shaped fleshy seeds. This tree is a native of New Spain and the West India islands. In Jamaica it grows very plentifully; and in June, July, and August, puts forth its flowers, which with every part of the tree breathes an aromatic fragrance. The berries when ripe are of a dark purple colour, and full of a sweet pulp, which the birds devour greedily, and mashing the seeds, afterwards propagate these trees in all parts of the woods. It is thought that the seeds passing through them, in this manner undergo some fermentation, which fits them better for vegetating than those gathered immediately from the tree. 

The pimento is a most beautiful odoriferous evergreen, and exhibits a fine variety in the flowers at all seasons. It was first introduced and cultivated in England by Mr. Philip Miller in 1739. With respect to flowering, all the varieties of the myrtus communis flower there in July and August, most of which are very floriferous. The broad-leaved Roman kind in particular is often covered with flowers, which in some of the sorts are succeeded here by berries ripening in winter. The pimento also flowers in the flow with great beauty and luxuriance. The flowers of most of the sorts are small, but numerous; and are all formed each of five oval petals and many filaments. As all these plants require protection in this country, they must be kept always in pots, for moving to the proper places of shelter, according to their nature; the myrtus communis’s and varieties to the greenhouse in winter, the pimento and other delicate kinds to the flow, to remain all the year; therefore let all the sorts be potted in light rich earth; and as they advance in growth, shift them into larger pots, managing the myrtles as other green house shrubs, and the flow-kinds as other woody exotics of the flower.

Properties, &c. The leaves and flowers of common upright myrtle have an astringent quality, and are used for cleansing the skin, fixing the teeth when loosened by the scurvy, and strengthening the fibres. From the flowers and young tops is drawn a distilled water that is detereive, astringent, cosmetic, and used in gargles. A decoction of the flowers and leaves is applied in ointments. The berries have a binding detereive quality; and the chemical oil obtained from them is excellent for the hair, and used in pomatum and ointment and other external beautifiers of the face and skin. As an internal medicine, these berries have little or no merit.

In the Dictionnaire portatif d’Histoire Naturelle, a fact is related, which, if true, tends to show the strongly astringent quality of myrtle. “Myrtle. (says he) is likewise the base of a pomade called pomade de la Comtesse, and well known on account of an extraordinary historical fact. One of those gay youths who flutter about the toilets of the fair happened one day to be left alone in the flowerhouse of the graces. With eager curiosity he examined the purfumes, the smelling bottles, the perfumed powder, the essences, and the cosmetics. To give more of the vermillion and greater pliancy to his lips, and to remove some disagreeable eruption, he lightly spread with his indifferent finger the fatal pomade, looks at himself in the glass, and contemplates his beauty with admiration. The lady enters; he wishes to speak, but his lips contracted, and he could only stammer. ‘The lady looked at him with astonishment; at length calling her eyes on the toilet, she discovered by the open pot the cause of the mischief, and enjoyed a hearty laugh at the expense of her admirer, whose confusion announced his indiscretion.’

Pimento berries are chiefly imported into Britain from Jamaica; whence the name Jamaica pepper. It is also called allspice, from its taste and flavour being supposed to resemble those of many different spices mixed together. It is one of the staple articles of Jamaica; where the pimento walks are upon a large scale, some of them covering several acres of ground. When the berries arrive at their full growth, but before they begin to ripen, they are picked from the branches, and exposed to the sun for several days, till they are sufficiently dried; this operation is to be conducted with great care, observing that on the first and second day’s exposure

chief cities were Cyzicum, Lampacbus, &c. The
de of Apollo, to
extract. Pimento
ferent
or
on this account is not unfrequently employed with
active
oil of cloves, or rather a
spice,
of an
mixture
and nutmegs. To redhilt spirit it imparts, by maceration
or
digested, the whole of its virtue; in distillation it
gives over very little to this menstruum, nearly all its
active matter remaining concentrated in the impregnated
extract. Pimento can scarcely be considered as a
medicine: it is, however, an agreeable aromatic, and
on this account is not unfrequently employed with dif-
ferent drugs, requiring such a grateful adjunct. Both
the pharmacopoeias direct an aqueous and spirituous
distillation to be made from these berries, and the
Edinburgh college order also the oleum officinale piperis
farnacensis.

MYSIA, a country of Asia Minor, generally di-
vided into Major and Minor. Mylia Minor was bounded
on the north and west by the Propontis and Bi-
thynia, and Phrygia on the southern and eastern bor-
ders. Mylia Major had Asia on the south, Aegean
on the west, and Phrygia on the north and east. Its
chief cities were Cysicum, Lampsacus, &c. The
inhabitants were once very warlike; but they greatly
degenerated, and the words Mylenum ultima was em-
phatically used to signify a person of no merit. The
ancients generally hired them to attend their funerals as
mourners, because they were naturally melancholy
and inclined to shed tears. They were once governed
by monarchs. They are supposed to be descended from
the Myrians of Europe, a nation who inhabited that part of Thrace which was situated between Mount
Haemus and the Danube.

The wife of a native of Sparta, one of the seven wife
women of Greece. When Anacharsis consulted the or-
acle of Apollo, to know which was the wisest man in
Greece, he received for answer, he is now plough-
ing his fields. This was Mylon.

MYSORE, or MYSORE DOMINIONS, a kingdom
of Asia in the East Indies, consisting of the follow-
ing territories usurped or subdued by the late Hyder
Ali, and transmitted to his son Tippoo Saib the pre-
rent sultan.

1. Myfore Proper, or Seringapatam (from its cap-
it), forming the independent state of a Hindoo
rajah, for near 200 years from its dismemberment, as
a province of the Bejcanur empire, fell into the hands
of Hyder Ali Khan about the year 1763, by cutting
off the Delaway, or regent usurper of the govern-
ment, and seizing the reins of administration himself;
but without leaving even the shadow of any authority
to a nominal rajah of his own creation, excepting in
the formularies of justice or finance, and preferring
on one side of the pagoda coin the impression of two
divinities of the Hindoos, while the other
was made to bear the initial letter of his proper name
Hyder. The whole country now again reduced in-
to the form of a province dependent on the New My-
orean dominion of a Mussulman in the person of Tipp-
oo, is bounded on the west by the Balagaut hills of
Koork, and those called Anemally, bordering the whole
coast of Malabar; on the east it fronts with the
Carnatic Payengaut and its dependencies along the
Coromandel coast; and, on the north, with the pargau-
ns of Serah, Bangalore, and Cojur, belonging to
the Carnatic Balagaut-Bejapour, in a longitudinal
line little short of 20 English miles. From this lat-
ter boundary, in a form nearly triangular, it stretches
240 miles towards the north, where it terminates in a
point at the extremity of Dindigul, near the pafs of
Goodalore, through the Anemally hills, on the con-
finies of Travancore, and within 100 miles of Cape
Comorin. It partakes of the two great divisions of
country known in the Decan by the terms Balagaut
and Payengaut, or upper and lower region. The
former, comprehending the districts immediately de-
pendent on the capital, and 43 hundred forts, chiefly
on eminences, is but indifferently watered by the
everal branches of the Caveri, at 10 great distance
from its source; and much therefore, as in con-
sequence of an elevated situation, precluded from
foreign commerce, with scarcely any internal industry,
be comparatively poor, as it is productive only of the
smaller grains of joary and Bajary, or a species of
Indian corn, with the different kinds of vetches com-
mon to India; from all which, however, a nett reve-
rue, in money or kind, of seven lacks of hoon or paga-
das, being about 21 lacks of rupees, is computed to be
forth coming to the state, after defraying the ordinary
charges of collection, which here as in the reft of Hin-
dofian, confift chiefly of an establishment of village
peons or militia, reckoned 40,000 in number, for the
whole province of Myfore suppos'd to contain 15,400
square geographic miles. The latter, or Payengaut
division, making scarcely a third of this extensive
area, is better known to us under the name of Coim-
batore, including the Difticts of Caroor, Darampour,
Dongar, Namul, on both sides of the Caveri, and the
valley of Dindigul, on the south, and the great pads
of Palligautcherry towards Malabar on the west: it is
extremely fertile and well cultivated; therefore, in
proportion to its extent, more productive of revenue
than the Balagaut territory, being estimated nett at
19 lacks of rupees. The rajahs of Koork, and other
Palygars among the Gau's, from Biddenore south to
Dindigul, occupy independently a considerable tract
of country within the general description of Tippoo's
dominions; but which being inaccessible to regular
troops by hills or impervious woods, the Myorean
power hath never been able to conquer, further than
to facilitate the catching of a few elephants, yearly by
means of the natives.

2. Biddenore, or Ikeri, now Hydernagur, on the
diftolution of the Carnatic empire, of which it was a
part, became an independent state under its Naiks of
the race of Vencapatuppy, after which it fell under
the divided female government of different rannies or
queens, and so continued until conquered wholly by
Hyder between the years 1763-5. This country is
also divided into Alagaut and Payengaut; the latter
stretching
Hyderabad, stretching 140 miles along the sea-coast from Declah, or the river Cangrecora, being the northern frontier of Malabar, north to Honawar or Onore, on the confines of Soonda, in different breadths of plain territory, from 40 to 50 miles, but which may in all form an area of 3200 square miles, full retaining the ancient name of Canara, and including the ports of Mangalore, Barcolore, Onore, &c. The former or elevated division beyond the Supramany Gaults, and immediately dependent on the capital Bedenore, Hanampon, &c. is of great indefinite extent inland, on both sides of the Tumbhûdra; perhaps twice more considerable in size, though not proportionally so in value, to the maritime border. Both divisions, however, allowing for a revenue establishment of about 22,000 village peons, are assessed for seven lacks of Ikeri pagodas, which, at four rupees each, make a clear income to the exchequer of 28 lacks of rupees.

3. Soonda, in circumstances of history or final conquest, might be placed under the preceding head; as also from a similarity in its geographical description, with only the difference of being on a much smaller scale. The Payengaut, from the district of Onore to the frontiers of Goa, along a sea-coast of 60 miles, cannot comprehend above 1100 square miles of territory, in which the port of Carwar may be considered the capital; while a much larger extent must be allowed for that portion of the district beyond the Gaults to the easterly. The whole revenue, however, of both divisions, does not exceed two lacks of pagodas, or eight lacks of rupees.

4. Malabar. The country under this description, and conquered by Hyder in 1765-6, exclusive of Kook, is altogether Payengaut; stretching along the shore from Declah south to Cochín about 200 miles, and comprehending, in an area of perhaps 6000 square miles, the Samary’s territory of Calicut, with the petty states of Cartinad, Cotiotie, Cherica, or Cananore, on the north, and the tributary kingdom of Cochín on the south—the whole divided into about 16 lacks of rupees; and because the amount thus stated may comprehended be allowed for that portion of the district beyond the Gaults to the eastward. The whole revenue, however, of both divisions, does not exceed two lacks of pagodas, or eight lacks of rupees.

5. Barah Mhal, or twelve gunnaiss, was one of the earliest conquered annexations of Hyder to the Myoren dominion, though in the war of 1768 it was over-run and for a while in possession of the company’s troops. The whole circuit or district of Judgee, composed of heights and valleys on the confines of the Balangan and Payengaut Carnatics, being one of the seven dependencies of Giejee subjunct to the Mogul in 1698, was then subdivided into 17 gunnaiss, and assessed for a gross revenue of 1,757,717 rupees. Of these subdivisions, Amboor, Saiutgur, &c. remain to the Payengaut: the rest in the hands of Tippoo, may comprehend, exclusive of the poligari of Shili Naick, about 1800 square miles; but the net revenue of the same territory, after defraying the ordinary expenses of collection, does not exceed five lacks of rupees at present.

These five provinces of the Myoren empire, with the districts of Bangalore, Colar, &c. of the Carnatic-Balangan Bejapoory, formed the whole of Hyder’s dominion in the war 1768; and were calculated then to yield in all a net income of 119 lacks and a half of rupees, allowing an establishment of 115,000 village peons to enforce the collections, and maintain internal peace.

6. Petty states of Hindoo rajahs, situated on the west and north of the Hendery and Tumbhûdra rivers, to the confines of Goa, and the Merhatta territories of Toorgul, Raibaug, and Merith, forming the jager of Perferam Bow beyond the southern branch of the Kifnàh. Some of these rajahships had been entirely conquered by the Mogul; but the most considerable of them never were subdued by any Mufulman power until Hyder’s conquest of them between the years 1774-7, though different districts from each may have been dismembered for a while by the Mogul deputies of the Carnatic-Balangan Bejapoory, and therefore annexed in the accounts of the revenue of that circuit. The frontier forts, and dependencies, of Goojunder-gur, Darwar, Badamy, &c. near the southern branch of the Kifnàh towards the Merhatta dominion, composed at one time the jager of Ragenaut Row, and have frequently changed their masters. They fell ultimately to Tippoo at the peace of 1784, but he was forced to pay chout for them to the Pethwa. On the whole, all these states, of great indefinite extent and extremely poor, yield only a precarious revenue of 16 lacks of rupees to the Myoren.

7. Carnatic Balangan Bejapoory, confiding, under the Mogul, of one circuit of the same name, and of which the capital was Serah. It comprehended 51 gunnaiss, of which Bangalore, Colar, &c. on the south, were seized by Hyder, immediately when he possessed himself of Myoren; but Anantpour, Penckonda, &c. on the north, with the rest of the Merhatta state of Gooty, did not fall into his hands until the year 1776, when he overcame and made prisoner the proprietor Morarow, who had rendered signal service to the English in the preceding Myoren war. The whole circuit was rated at a jumma kaamil, or total gross revenue on the king’s books, of 43,916,396 rupees; but the accuracy of this valuation is much to be doubted: because it does not appear from the registers of the fobah of Bejapoory that the Mogul government ever ascertained the办好 or village collections of either of the Carnatics, or went into greater detail than to fix the standard allowance of the different gunnaiss; and because the amount thus stated seems too large a receipt from a country naturally so poor and destitute of commerce, probably in all its dimensions not exceeding 16,000 square miles, and which was so liable to internal disturbances or foreign invasion, that notwithstanding the number of strong holds to be found in it, every town required and has its own particular fortification. However this may be, the revenue actually forthcoming to Hyder in 1778, after defraying charges of collection and an establishment of about 30,000 village peons, was only 3,205,306 rupees.

8. Carnatic-Balangan Hydrabad, comprehending the five circars of Sidhout, Kalmam, Ganjeccottah, Gootty, and Gorrumbonda, which were subdivided into 66 gunnaiss, rated by the Moguls kaamins 4,707,506 rupees: but from this amount is to be deducted the aggregate valuation of the gunnaiss or Chittoore, &c. now annexed to the Payengaut, together with the establishment of the diamond-mines of Ganjecottah,
MYS [ 577 ]

MYSTERIES.

RELIGION, in its original form, was simple and intelligible. It was intended for the instruction and edification of all ranks of men; and of consequence its doctrines were on a level with vulgar capacities. The Jewish dispensation was openly professed: nothing was performed in secret; every article was plain, open, and accessible. The divine author of the Christian economy commanded his disciples to preach his doctrine in the most public manner: "What ye have heard in secret (says he) preach openly; and what I have taught you in private teach ye publicly, and proclaim it on the housetops." Such are the charms of truth, and such the character of that religion which came down from heaven, that they, as it were,
Mysteries.

We have already observed, that the avarice and ambition of the pagan priesthood probably gave birth to the institution of the mysteries. To this observation we may now add, that the ministers of that superstitious thing possibly imagine, that some articles of the ritual were too profound to be comprehended by the vulgar; others, too sacred to be communicated to a description of men whom the institutions of civil society had placed in a situation not only subordinate but even contemptible. It was imagined, that things sacred and venerable would have contrived a taint and pollution by an intercourse with forbid and unctored souls. These appear to us the most probable motives for making that odious and pernicious distinction between the popular religion and that contained in the sacred and mysterious ritual.

The learned Bishop Warburton is positive, that the mysteries of the Pagan religion were the invention of legislators and other great personages, whom fortune or their own merit had placed at the head of the most civil societies which were formed in the earliest ages in different parts of the world. It is with reluctance, and indeed with diffidence, that we presume to differ in our sentiments from such respectable authority. Whatever hypothesis this prelate had once adopted, so extensive was his reading, and so exuberant his intellectual resources, that he found little difficulty in defending it by an appearance of plausibility, if not of rational argumentation. The large quotations he has adduced from Plato and Cicero, do indeed prove that the sages and legislators of antiquity sometimes availed themselves of the influence derived from the doctrines of the mysteries, and from the authority they acquired by the opinion of their having been initiated in them; but that those men were the inventors and fabricators of them, is a position for which his quotations do not furnish the most slender presumption. At the same time, we think it not altogether certain, that the doctrine of a divine providence, and a future state of rewards and punishments, were revealed in the mysteries with all the clearness and cogency which is pretended by his Lordship.

But granting that the fabric was raised by the hands of sages and legislators, we imagine it would be rather difficult to discover with exactness that description of men could propose to derive from the enterprise. The institution was evidently, and indeed confessedly, devised to conceal from the vulgar the million of heterogeneous doctrines and maxims, which, had they known and embraced them, would have contributed most effectually to disperse them to submit to those wise regulations which their governors and legislators wished most ardently to establish. Experience has taught, that nothing has a more commanding influence on the minds of the vulgar, than those very dogmas, which, according to the Bishop, were communicated to the initiates. A conviction of the Unity of the Deity, of his wisdom, power, goodness, omnipresence, &c., the steady belief of the immorality of the human soul, and of a future state of rewards and punishments, have in all ages, and in all countries, proved the firmest supports of legal authority. The very same doctrines, in the dawn of Christianity, contributed to all other methods the most effectually to tame and civilize the savage.

were, "delight in the light, and lift up their voice in the streets, and cry in the chief places of concourse."

But such is the depravity of the nature of man, that the noblest institutions degenerate in his hands. Religion itself, originally pure, simple, and amiable, under his management has often been transformed into pollution, perplexity, and deformity. The ministers of religion, whose province it was to guard the sacred deposit, and to secure it from foreign and spurious intermixtures, have generally been the first innovators, and the first and most industrious agents in corrupting its integrity and tarnishing its beauty. Avarice and ambition prompted that class of men to deviate from the original plainness and simplicity of religious institutions, and to introduce articles, rites and usages, which might furnish them with opportunities of gratifying these unhallowed and incontinent passions. Hence diffinctions unknown to pure and undefiled religion were fabricated, and that heavenly institution, heretofore one, simple, indivisible, was divided into two partitions: the one popular and public: the other dark, secret, and mysterious. The latter of these we intend as the subject of this article.

The English word mystery is derived from the Greek μυστήριον; and in its modern acceptance imports some thing above human intelligence, something awfully mysterious, and more frequently by his apostles, especially St Paul. In these cases, it generally signifies those doctrines of Christianity which the Jews, prior to the advent of the Messiah, either did not or could not understand. The favourite doctrines of the Trinity in Unity, and the Unity in Trinity; the union of two natures in one and the same person, &c. were generally called mysteries, because they were thought infinitely above human comprehension. All these significations are out of the question at present. Our intention in this article is to lay before our readers the fullest and fairest account we have been able to collect, of those μυστήρια, or σωφρόνες, rites, of the pagan superstitition, which were carefully concealed from the knowledge of the vulgar, and which are universally known under the denomination of mysteries.

The word μυστήριον is evidently deduced from μυς, but the origin of this last term is not altogether so obvious. The etymologies of it exhibited by the learned are various; some of them absurd and inconsistent, others foolish and futile. Instead of fatiguing our readers with a detail of these, which would be equally unentertaining and uninterseting, we shall only produce one, which to us appears to come nearest the truth. The mysteries under consideration at present were certainly imported into Greece from the East. In those regions, then, we ought of course to look for the etymology of the word. μυστήριον, in Hebrew, signifies "any place or thing hidden or concealed." As this word implies a kind of definition of the nature of the thing intended, and as it is one of the excellencies of original languages to apply vocables with this propriety, we find ourselves strongly inclined to affign the word μυστήριον as the root of the form μυστήριον, μυθάρκη.
Mysteries.

Mysteries of Eleusis, as revealed publicly in Crete.

Of all the legislators of antiquity, the Cretan alone was prudent enough to see and adopt this rational plan. Diodorus the Sicilian informs us, that the mysteries of Eleusis, Samothrace, &c., which were elsewhere buried in profound darkness, were among the Cretans taught publicly, and communicated to all the world.

Minos, however, was a successful legislator; and his interpolations with Jupiter Idaeus extended his influence and established his authority. He was not under the necessity of calling in the mysteries to his assistance; on the contrary, it is highly probable that the universal knowledge of the doctrines of the mysteries among his countrymen contributed in a considerable degree to facilitate his labour, and ensure his success.

The divine Author of the Christian economy, viewed in the light of a human legislator, saw the propriety of this procedure. Nothing was concealed in his institutions; nothing was veiled with mystery, or buried in darkness. The success was answerable to the wisdom of the plan. The million flocked to the evangelical standard: the gospel was preached to the poor, to the illiterate and the vulgar; and the means of mankind eagerly embraced its maxims. Wherever it prevailed, it produced civilization, morality, sobriety, loyalty, and every other private and social virtue.

Upon the supposition that the mysteries had contained and inculcated the principles and practices which the prelate supposes they did, the civilizers of mankind, legislators, magistrates, and princes, ought to have combined to make them public for the sake of their own tranquillity, and the more effectual support of their authority and influence.

Upon the whole, we are inclined to believe that the mysteries were the offspring of Egyptian priestcraft. They were instituted with a view to aggravate the order of men, to extend their influence, and enlarge their revenues. To accomplish those selfish projects, they applied every engine towards befotting the multitude with superflition and enthusiasm. They taught them to believe, that themselves were the distinguished favourites of heaven; and that celestial doctrines had been revealed to them, too holy to be communicated to the profane rabble, and too sublime to be comprehended by vulgar capacities. It is, we confess, exceedingly probable, that after the mysteries were instituted, and had acquired an excited reputation in the world, legislators, magistrates, judges, and potentates, joined in the imposture, with the same views and from the same principles. Princes and legislators, who found their advantage in overawing and adopting the multitude, readily adopted a plan which they could find so artfully fabricated to answer those very purposes. They had interest enough with the face-dotal (a) myriapogues, to induce them to allow them to participate in those venerable rites which had already established the authority of that description of men in whose hands they were deposited. The views of both parties were exactly congenial. The reception, the administration, and dependence of the million, were the ultimate objects of their ambition respectively.

Priests and princes were actuated by the same spirit. The combination was advantageous, and of consequence harmonious. For these reasons we have taken the liberty of differing from his lordship of Gloucester with respect to the persons who first instituted the secret mysteries of the Pagan religion.

Another writer, of considerable reputation in the Hypothetically republic of letters, is of opinion, that the mysteries of Mithras were entirely commemorative, that they were instituted with a view to preserve the remembrance of heroes and great men, who had been deified in consideration of their martial exploits, useful inventions, public virtues, and especially in consequence of the benefits by them conferred on their contemporaries.

According to him, the (c) mysteries of Mithras were established for this very purpose. It would be no difficult matter to prove that the Persian deity of that name was the fun, and that his name and insignia jointly ascertain the truth of this assertion. The same writer extends this observation to the mysteries of the Egyptians, Phcenicians, Greeks, Hetruscan; and in a word, to all the institutions of that species throughout the world. In opposition to this singular opinion, it may be argued that with some show of reason, that the mean and inessential method of preserving the memory of great and illustrious men generally adopted, was the establishing festivals, celebrating games, offering sacrifices, singing hymns, dances, &c. We can recollect no secret mysteries instituted for that purpose at least in their original import. If any usage of the commemorative kind was introduced, it was superinduced at some period posterior to the primary institution. At the same time, upon the supposition that the orgia of Bacchus were the same with those of the Egyptian Osiris, and that the mysteries of Ceres exhibited at Eleusis were copied from those of the Egyptian Isis, and allowing that the former was the fun, and the latter the moon; it will be difficult to find out the human persons which exploits, adventures, inventions,

(a) The Germans, Russians, and Scandinavians, who were never thoroughly civilized till the gospel was preached among them.

(b) The myriapogues were the ministers who added the chief part in celebrating the mysteries.

inventions, &c. were intended to be immortalized by those institutions. Upon the whole, the mysteries were performed in secret; they were intended to be communicated only to a few; of course, had they been instituted with a view to immortalize the memory of heroes and great men, the authors would have added the most foolish and inconsistent part imaginably.—Instead of transmitting the fame of their heroes with eclat to posterity, they would by this procedure have configned it to eternal oblivion.

We must then recur to our first position. The mysteries were the offspring of bigotry and priestcraft; they originated in Egypt, the native land of idolatry. In that country the priesthood ruled preeminent. The kings were ingrained into their body before they could ascend the throne. They were professor of a third part of all the land of Egypt. The facerdotal function was confined to one tribe, and was transmitted unalienably from father to son. All the orientals, but more especially the Egyptians, delighted in mysterious and allegorical doctrines. Every maxim of morality, every tenet of theology, every dogma of philosophy, was wrapt up in a veil of allegory and mysticisms. This propensity, no doubt, confpired with ambition and avarice to diffuse them to a dark and mysterious system of religion. Besides, the Egyptians were a gloomy race of men; they delighted in dark and solitary. Their sacred rites were generally celebrated with melancholy airs, weeping, and lamentation. This gloomy and unfaithful bias of mind must have stimulated them to a congenial mode of worship. In Egypt then we are to search for the origin of the mysteries. Both the nature of the institution and the genius of the people confirm this position; and historians, both ancient and modern, are agreed in admitting the certainty of the fact.

13. The Oris of Egypt, every body knows, was the original Bacchus; as the Isis of the fame country was the Ceres of the Greeks. The rites of Oris were performed with loud shrieks and lamentations when he was put into the coffin; and with the most extravagant mirth, when he was in a manner raised from the dead, or supposed to be found again. Their hymns were upon the whole always composed in melancholy affecting strains; and conforted of lamentations for the loss of Oris, the mystic flight of Bacchus, the wandering of Isis, and the sufferings of the gods. The Canaanites, who were a kindred tribe of the Mizrains or Egyptians, imitated them in their sacred rites. At Byblis, Berytus, Sidon, and afterwards at Tyre, they used particularly mournful dirges for the death of Adonis or Tammuz, who was the fame with the Egyptian Oris, i.e., the sun. The Egyptians, then, naturally inclined to gloom and severity, instituted a mode of worship congenial with their natural disposition of mind. The recells of the sun towards the southern hemisphere, was the death of Oris; the wanderings of Isis in search of her husband and brother, allegorically imported the longings of the earth for the return of the fruitful influence of the solar heat.

When that luminary returned towards the summer solstice, and grain, trees, fruits, herbs, and flowers adorned the face of nature, another festival was celebrated of a very different complexion from that of the former. In this season all Egypt was dissolved in the most extravagant mirth and folly. During the celebration of those festivals, the priests formed allegorical representations of the sun and the earth (n). They personified the one and the other, and allegorized their motions, aspects, relations, sympathies, accedes, recedes, &c. into real adventures, peregrinations, sufferings, contests, battles, victories, defeats, and so forth. These, in process of time, were held up to the vulgar as real occurrences; and these in a few ages became the most essential articles of the popular creed. From this source were derived the conquests of Dionysus or Bacchus, so beautifully exhibited by Nonnus in his Dionysiaca; the wanderings of Isis, wonderfully adorned by Azuchus; and the labours of Hercules, afterwards usurped by the Greeks.

Whether the Egyptians deified mortal men in the earliest ages has been much controverted. Jablentians deified departed heroes. Diocletianus affures us that they paid their monarchs a kind of divine adoration, even in their lifetime. Plutarch tells us plainly that some of opinion that. Plutarch, Isis, Oris, Horus, Anubis, Typhon, were once mortal personages, who were exalted into demons after their death. The Sicilian, in his history of Isis and Oris, Pan, Hermes, &c, plainly represents them as human personages; and informs us, that the Egyptians imagined, that after their decease they transmigrated into particular stars. From these authorities, we are inclined to believe that the Egyptians, as well as the other pagans, did actually deify persons who had distinguished themselves in their days of nature by prowess, wisdom, useful arts, and inventions. This was a constant practice among the Greeks, who probably learned it from the people in question.

The exploits of these heroes had been disguised by allegorical traditions and hieroglyphical representations. They had been magnified beyond all dimensions, in order to ascribe to them and to commemorate the objects of worship. The important events in the history of these heroes had been interlarded with the most extravagant fables, in order to gratify their propensity towards the marvellous. All these stories were developed in the mysteries. The catechumens (p) were informed of every particular relating to the birth, the life, the exploits, the adventures, the misfortunes, and decease of those demi-gods, and when, and by what means, they had attained to the high rank of divinities. At the same time we think it highly probable, that those demi-gods were represented in their state of exaltation and heavenly splendour. The magicians of Egypt were abundantly qualified for exhibiting angels in machines. The sons of virtuous men, who had not been eminent enough to merit the honour of deification, were shown in all the perfection of Elyan felicity; and perhaps the

\[(n) I\text{i}s, \text{among the Egyptians, sometimes signified the moon, and sometimes the earth.}\]
\[(p) \text{Catechumens were pupils who were learning the elements of any science.}\]
Mysteries.

the souls of tyrants, and of the children of (f) Typhon, were shown in Tartarus, suffering all the extremes of infernal punishment. From these exhibitions the mystagogues might naturally enough take occasion to read their pupils suitable lectures on the happy tendency of a virtuous conduct, and the diabolous and misery consequent upon a contrary course. They might set before them immortal renown, delineation, and elyium, on the one hand, and eternal infamy and misery on the other. This will probably be deemed the chief advantage accruing from this institution.

Besides the communications above mentioned, the catechumens were taught many secrets of physiology, of the nature of the phenomena of the world. This De Nat. Deorum* every where affirms, especially in his last book towards the end. Plutarch too informs us, that many of the Greek philosophers were of opinion, that most of the Egyptian fables were allegorical details of physical operations. Eusebius acquaints us §§ that the physiology, not only of the Greeks, but likewise of the barbarians, was nothing else but a kind of science of nature, a concealed and dark theology, involved in fable and fiction, whose hidden mysteries were so veiled over with enigmas and allegories, that the ignorant million were as little capable of comprehending what was said as what was suppressed in fable. This, says he, is apparent from the poems of Orpheus and the fables of the Phrygians and Egyptians. Dionysius of Halicarnassus likewise observes ¥ that the fables of the Greeks detail the operations of nature by allegories. Proclus § makes the fable observation concerning the people in question. The Egyptians, says he, taught the latent operations of nature by fables.

These physiological secrets were no doubt expounded to the initiated; and that the Egyptian priests were deeply skilled in physiological science, can scarce be questioned, if we believe that Janes and Jambres rivalled Moses with their enchantments. The preceding detail comprehends all that was revealed to the Egyptians in the original Egyptian mysteries. What articles might have been introduced afterwards we cannot pretend to determine.

Be that as it may, one thing is certain, namely that the vulgar were excluded from all those choice secrets, which were carefully reserved for the nobility and sacerdotal tribes. To them it was given to know the mysteries of the kingdom of darkness; but to those who were without, all was mystery and parable. While the laity fed on huffs, the clergy and quality feasted on royal dainties. The priests who had deciphered these allegories understood their original import, and bequeathed it as an inestimable legacy to their children. Here then we have the primary object of the mysteries, namely, to develop to the initiated the original and rational import of those allegorical and mythical doctrines which were tendered to the uninitiated, wrapped up in impenetrable allegory and obscurity.

To the former, these were communicated and explained: The latter were obliged to stand at an awful distance, and retire as the Procul, O procul astra profani, thundered in their ears.

These allegorical traditions originated in Egypt, (see Mythology). It was the general bias of the oriental genius. The Egyptians, however, according to the most authentic accounts (c), were the greatest proficients in that science. The original subject of these institutions were, we imagine, the articles we have specified above; but in progress of time, according to the natural course of things, numerous improvements were made, and many new rites, ceremonies, usages, and even doctrines were superinduced, which were utterly unknown to the original hierophants (h). Simplicity is for the most part one of the distinguishing characters of a new institution; but succeeding architects generally imagine that something is still wanting to complete the beauty, the regularity, the uniformity, the magnificence, and perhaps the convenience of the structure. Hence, at length, it comes to be so overloaded with adventitious drapery, that its primary elegance and symmetry is altogether defaced. This was the case with the earliest Egyptian mysteries. Their subject was at first simple and easy to be comprehended; in time it became complex, intricate, and unintelligible.

In order to celebrate those mysteries with the greater secrecy, their temples were so constructed as to favour the artifice of the priests. The rites, in which they used to execute their sacred functions, and to perform the rites and ceremonies of their religion, were subterraneous apartments, contrived with such wonderful skill and dexterity, that every thing that appeared in them breathed an air of solemn secrecy. Their walls were covered with hieroglyphic paintings and sculpture, and the altar was situated in the centre of the apartment. Modern* travellers have of late years discovered some vestiges of them, and bear witness to Shaw, For- the above description of those dark abodes (i). In cock's, &c. those subterraneous mansions, which the priests of that ingenious nation had planned, with the most consummate skill, the kings, princes, and great men of the state, encountered the dangers and hardships contrived to prove their prudence, fortitude, patience, abstinence &c. Those were appointed to try their merit; and by these the hierophants were enabled to decide whether or not they were duly qualified for receiving that benefit. Upon those occasions we may believe, abundance of those magical tricks were exhibited, for which the magicians of Egypt were so much celebrated among the ancients. The strange and astonishing sights, the alternate successions of light and dark, the hideous spectres exposed to view, the frightful howlings echoing through their infernal domes, the scenes of Tartarus and

---

(f) Typhon was the evil genius, or devil of the Egyptians.

(c) As early as the age of Joseph, the Egyptians were skilled in the interpretations of dreams, divinations, &c. and in the age of Moses they were become wise men, magicians, &c.

(h) Hierophant imports a priest employed in explaining the doctrines, rites, &c. communicated to the initiates.

(i) See an excellent description of those subterraneous abodes, and of the process of probation carried on there, in a French romance, intitled The life of Setes.
and Elysium, exhibited alternately and in quick succession, must have made a deep and lasting impression on the mind of the instructed votary (x). These scenes we shall describe more fully in the sequel.

From the scenes exhibited in celebrating the Egyptian mysteries, especially those of Isis and Osiris, the Greeks seem to have copied their ideas of the infernal regions, and the subterranean mansions of departed souls. Many colonies of Egyptians settled in Greece. From these the mysteries (1), or most early bards of Greece, learned them imperfectly. Of course, we find Homer's account of the infernal regions, and of the state of departed souls, lame and incoherent. Succeeding bards obtained more full and more definite information. Euripides and Aristo-phanes seem to have paved the way for the prince of Roman poets, Plato* and some of the other philosophers have shown by their descriptions or allusions, that the whole apparatus of Tartarus and Elysium had become a hackneyed topic some centuries before Virgil was born. This incomparable poet borrowed his ideas from Homer, Aristophanes, Euripides, Plato, &c. These, under his plastic hand, in the first Aeneid, grew into a system beautiful, regular, uniform, and consistent. The materials he has employed were created to his hand; he had only to collect, polish, arrange, and connect them.—

The sentiments collected from the Platonic philosophy, and the inimitable episode copied from the annals of Rome, by the masterly skill which he has displayed in the application of them, form the chief excellencies of the piece. For the rest, he could well dispense with going to Elysium (m): every old women in Athens and Rome could repeat them.

Mysteries brought from Egypt into Persia and Greece

Egypt was then the native land of mysteries as well as of idolatry. Every god and goddess respectively had their mysteries; but as those of Isis and Osiris were the most celebrated, they of course became principal objects of pursuit as well as of imitation to the neighbouring nations. These, as is generally believed, were carried into Persia by Zoroastres, or Zorod, by whom they were consecrated to Mithras. On these we shall make some observations on the sequel.—Orpheus imported them into Thrace; Cadmus brought them into Baotia, where they were sacred to Bacchus. Inachus celebrated them at Argos in honour of Juno, the same with Isis (n); Cyneis in Cyprus, where they were dedicated to Venus. In Phrygia they were sacred to Cybele, the mother of the gods.

Our learned readers, who will probably reflect that the Egyptians were in ancient times inhospitable to strangers, will perhaps be surprised that this foolish and jealous people were so ready to communicate the secrets of their religion to foreigners. But they will please to recollect, that a great part of Greece was planted with colonies from Egypt, Phcenicia, Palatine, &c. This we could easily prove, did the bounds prescribed us admit such a digression. Orpheus, if not an Egyptian, was at least an oriental extraction. Inachus, Cadmus, and Melampus, are universally allowed to have been Egyptians. Frechthaus, in whose reign the Eleusinian mysteries were established, was an Egyptian by birth, or at least sprung from Egyptian ancestors. The Egyptians, then, in those early ages, did not view the Greeks in the light of aliens, but as a people nearly related either to themselves or the Phcenicians, who were their brethren. Upon this connection we imagine it was, that in later times most of the fages of Greece, especially Athens, found so hospitable a reception among that people. They probably viewed them in the light of propagandists; apolies and willing to disseminate their idolatrous rites. This observation, which might be supported by numberless authorities, did the nature of the present inquiry permit, will, we think, go a great way towards obviating the objection.

Although, as has been observed, every particular deity had his own peculiar mysterious sacred rites, yet of all others those of Mithras, Bacchus (o), and Ceres, were deemed the most august, and were most universally and most religiously celebrated. To these, therefore, we shall in a good measure confine ourselves upon this occasion. If our readers shall become intimately acquainted with these, they may readily dispence with the knowledge of the rest, which are, indeed, no more than echoes and emanations from these fources. We shall then, in the first place, present to our readers a brief sketch of the mysteries of Mithras.

Mithras, or according to the Perian, Mib, was one of the great gods of the Afiatics. His worship was for many ages confined to Persia. Afterwards, however, it was propagated so far and wide that some have imagined they had discovered vestiges of it even in Gaul. Mib, according to Dr Hyde*, signifies vet. Per. love, and likewise the Sun. If we might presume to faram. differ from so respectable an authority, we should conjecture that it is a cognate of the Hebrew word Mibir, "excellence, preludion." That there was an analogy between the Hebrew and old Perian, is generally admitted by the learned. Be that as it may, Mithras was the sun (r) among the Perians; and in honour of

(x) Persons who had descended into Tropthonius's vault were said to have been so terrified with shocking sights, that they never laughed during the remainder of their lives.

(1) These were tripping poets like our minstrels; who frequented the houses of the great men of Greece, and entertained the company upon public occasions with finging and tales of other times.

(o) Bishop Warburton has, with much ingenuity, and a vast profusion of reading, endeavoured to prove that Virgil borrowed the whole scenery of the first Aeneid from the sources mentioned in the text.

(n) Isis was the moon, and the original Juno was the same planet.

(p) Moehm, in his notes on Cudworth's Intellectual System, page 330, has taken much pains to prove that Mithras was a deified mortal; but we cannot agree with that learned man in this point.
of that luminary this institution was established. Mithras, according to Plutarch (q), was the middle god between Oramaz and Ariman, the two supreme divinities of Persia. But the fact is, the solar planet was the visible emblem of Oramaz, the good genius of the Persian tribes, and the same with the Osiris of the Egyptians. From these people, some have imagined that Zoroaftres (r), or Zerdust, borrowed his mysteries of Mithras. To this opinion we cannot give our assent, because the probationary trials to be undergone by the candidates among the former were much more savage and fanglinary than among the latter. — Both, however, were instituted in honour of the same deity, and probably the scenes exhibited, and the information communicated in both were analogous; a circumstance which perhaps gave birth to the opinion abovementioned.

The grand festival of Mithras was celebrated six days, in the middle of the month Mihr (s). Upon those days, it was lawful for the kings of Persia to get drunk and dance. On this festival we imagine, the candidates for initiation, having duly proved their vocation, were solemnly admitted to the participation of the mysteries.

Zoroaftres (r) worshipped Mithras, or the Sun, in a certain natural cave, which he formed into a temple, and filled up in a manner exactly mathematical. There Mithras was represented as presiding over the lower world with all the pomp of royal magnificence. In it too were seen the symbols of Mithras and of the nature, worshipped. This deity was sometimes represented as mounted on a bull, which he is breaking, and which he kills with a sword. On some bas reliefs still existing, he appears as a young man with his tiara turned upward, after the manner of the Persian kings. He is clothed with a short tunic and breeches, after the Persian fashion. Sometimes he wears a small cloak. By his sides are seen other human figures, with tiaras of the same fashion on their heads, but without cloaks. One of these figures commonly holds in his one hand a torch lifted up; in the other one turned downward. Sometimes over the cave is seen the chariots of the Sun and moon, and divers constellations, such as cancer, scorpion, &c.

In one of these caves the ceremonies of initiation were performed; but before the candidate could be admitted, he was forced to undergo a course of probationary exercises, so numerous and so rigorous that very few had courage and fortitude enough to go through them. He was obliged to live a life of virtue and abstinence for a space of seven years previous to the period of his initiation. Some months before he it was obliged to submit to a long and austere fast, which continued fifty days. He was to retire several days to a deep and dark dungeon, where he was successively exposed to all the extremes of heat and cold. Meanwhile he frequently underwent the baptismo, which the priests applied without mercy. Some say this purification continued two whole days, and was repeated no less than 15 times. In the course of these probationary exercises, the candidate was generally reduced to a skeleton; and we are told, that there have been several inferences of persons who have perished in the attempt.

Upon the eve of the initiation, the aspirant was obliged to brace his armour, in order to encounter the fiercest giants and savage monsters. In those spacious subterranean mansions a mock hunting was exhibited. The priests and all the subordinate officers of the temple, transformed into lions, tigers, leopards, bears, serpents, and other savage creatures, attacked him with loud howlings, roaring, and yelling, and every instance of fierce fury. In those mock combats, the hero was often in danger of being really worried, and always came off with bruises and wounds. Lampridius informs us, that when the emperor Commodus was initiated, he actually carried the joke too far, and butchered one of the priests, who attacked him in the figure of a wild beast. The Persians worshipped Mithras or the Sun by a perpetual fire: hence the votary was obliged to undergo a trial; that is, to pass seven times through the sacred fire, and each time to plunge himself into cold water. Some have made these probationary penances amount to 80; others have thought that they were in all only 8. As we find no good authority for either of these numbers, we think ourselves at liberty to hazard the following conjecture: The number seven was deemed sacred over all the casts. The Mythriac penances we imagine were either seven, or if they exceeded it, were regulated by seven repetitions of that number. The candidate having undergone all these torturing trials with becoming patience and fortitude, was declared a proper initiate. But before his admission he was obliged to bind himself by the most solemn oath, with horrible imprecations annexed, never to divulge any single article of all that he had learnt, nor should be communicated to him in the course of his initiation.

What inaudible or ineffable secrets were imparted to reveal the initiated, it is impossible at this distance of time to discover with any tolerable degree of certainty. We mysteries may, however, rest assured that the most authentic tradition concerning the origin of the universe; the nature, attributes, perfections, and operations, of Ormazd: the haftful influences of Ariman; and the "

---

(q) Isis and Osiris, page 369. l. 20. from the bottom. This philosopher makes Zoroaftres, according to some, 5000 years prior to the Trojan war. This date is certainly extravagant. We cannot, however, agree with some moderns, who make him contemporary with Darius Hyllapés, the immediate succour of Cambyses, because it contradicts all antiquity.

(r) M. Silowette, Differ. V. page 17. affirms that Zoroaftres was initiated among the Egyptians.

(s) The month Mihr began September 30, and ended October 30.

(t) See Dr. Hyde de Rét vet. Perc. page 16, 17. Mr Bryant's Anal. vol. i. page 232. Porphyry, de autro Nymph. page 254. This philosopher often mentions the cave of Mithras, and always attributes the institution of his rites to Zoroaftres.
nigh effects of the government of Mithras, were unfolded and incalculable. The secret phenomena of nature, as far as they had been discovered by the magi, were likewise exhibited; and the application of their effects, to astonish and delude the vulgar, were taught both in theory and practice. The exercise of public and private virtues was warmly recommended; and vice represented in the most odious and frightful colours. Both these injunctions were, we may suppose, enforced by a display of the pleasures of Elysium and the pains of Tartarus, as has been observed above in describing the mysteries of the Egyptians.

Those initiations are mentioned by Lampridius in the life of Commodus, and likewise by Justin, and Tertullian, who both flourished in the second century. The last of these two speaks of a kind of baptism, which washed from the souls of the initiated all the stains which they had contracted during the course of their lives prior to their initiation. He at the same time mentions a particular mark, which was impressed upon them (v), of an offering of bread, and an emblem of the resurrection: which particulars, however, he does not describe in detail. In that offering, which was accompanied with a certain form of prayer, a vessel of water was offered up with the bread. The same father elsewhere informs us, that there was sent to the initiated a crown suspended on the point of a sword; but that they were taught to say, Mithras is my crown. By this answer was intimated, that they looked upon the service of that deity as their chief honour and ornament.

After that the Telete (x) were finished, the pupil was brought out of the cave or temple, and with great solemnity proclaimed a lion of Mithras (y); a title which imported strength and intrepidity courage in the service of the deity. They were now consecrated to the god, and were supposed to be under his immediate protection; an idea which of course animated them to the most daring and dangerous enterprises.

The worship of Mithras was introduced into the Roman empire towards the end of the republic, where it made very rapid progress. When Christianity began to make a figure in the empire, the champions for paganism thought of proposing to men the worship of this power of benevolence, in order to counterbalance or annihilate that worship which the Christians paid to Jesus Christ the true Sun of righteousness. But this mode was soon abolished, together with the other rites of paganism. The Perian grandees often affected names compounded with Mithras; hence Mithridates, Mithrobazane, &c.: Hence too, the precious stone called Mithridat *, which by the reflection of the sun sparkled with a variety of colours. There is likewise a certain pearl of many different colours, which they call Mithras. It is found among the mountains near the Red Sea; and when exposed to the sun, it sparkles with a variety of dyes. We find likewise a king of Egypt of that name who reigned at Heliopolis; who being commanded in a dream to erect an obelisk to the solar deity, reared a most prodigious one in the neighbourhood of that city.

The votaries of Mithras pretended that he was sprung from a rock, and that therefore the place where the mysteries were communicated to the initiated was always a cave. Many different reasons have been assigned for the origin of this rock-born deity, most of which appear to be unsatisfactory. If our readers will not belive the probability of this conjecture, we should beg leave to remit them to the learned Mr Brant's Anal. sa of Mythology, where they will find this point discussed with deep research and wonderful ingenuity. Whatever may have been the origin of this opinion with relation to the birth of Mithras, it is certain that some reverence to rocks and caves was kept up a long time even after the establishment of Christianity. Hence the prohibition given to some of the proleynes to that religion that they should no more presume to offer up their prayers ad petras at the rocks (a).

We shall conclude our account of the mysteries of Mithras with a passage from Mr Anquetil, to whom are so much indebted for what knowledge we have of the Ptolemaic theology, and in which the functions of that deity are briefly and comprehensively delineated. "The peculiar functions of Mithras are to fight continually against Ahriman and the impure army of evil genii, whose constant employment is to scatter terror and desolation over the universe: to protect the frame of nature from the demons and their productions. For this purpose he is furnished with a thousand ears and a thousand eyes, and traverses the space between heaven and earth,

(v) In allusion to this practise of imprinting a sacred mark, probably on the forehead of the initiated, we find the injunction to the angel, Ezek. chap. ix. ver. 4, and the Revelation 14:1.

(x) The mysteries were called Telete, which imports, "the rites which confer perfection."

(y) Tertull. adv. mar. p. 55. The priests of Mithras were called the lions of Mithras, and his priests foci liones: some say hyenas. The other inferior ministers were called eagles, hawks, ravens, &c., and on their festivals they wore masks corresponding to their titles, after the Egyptian manner, where the priests appeared at the ceremonies with masks resembling the heads of lions, apes, dogs, &c., a circumstance which furnishes a presumption that the mysteries of Mithras were of Egyptian original.

(z) Our Saviour probably alludes to this emblem, when he talks of building his church on a rock, and adds, that the gates of hell should not prevail against it.

(a) The Caledonian druids seem to have regarded certain stones with a superstitious veneration, in which the Catholics initiated them. There are in several places of Scotland large stones, which the vulgar call leopard stones, i.e. we imagine, leper.
Mysteries.

earth his hands armed with a club or mace. Mithras gives to the earth light and fun; he traces a course for the waters; he gives to men corn, pastures, and children; to the world virtuous kings and warriors; maintains harmony, upon earth, watches over the law, &c." As the history of Mithras, and the nature of his mysteries, are not generally known, we imagined it would be agreeable to many of our readers to have the most important articles relating to that subject laid before them as it were in detail.

We now proceed to the orgia, or mysteries of Bacchus, which we shall introduce with a brief history of that deity. The original Dionysus or Bacchus was the Osiris of the Egyptians, which last was the Sun (a). Whether there was an Egyptian monarch of that name, as Diodorus Siculus affirms $, has no manner of connection with the present disquisition. The Greek name of that deity, plainly oriental, being compounded of Οσίρις, "right," and νάφας or νάφα, in the Aeolic dialect νάφα, "a prince." This name was imported from the east by Orpheus, Cadmus, or by whoever else communicated the worship of Osiris to the Greeks. That the Dionysus of the Greeks was the same with the Osiris of the Egyptians, is universally allowed. Herodotus tells us expressly $, that Osiris is Dionysus in the Greek language; Martianus Capellus, quoted above, expresses the very same idea $. The original Osiris was the fun; but the Dionysus or Bacchus of the Greeks was the same with the Osiris of the Egyptians; therefore the Bacchus or Dionysus of the Greeks was likewise the Osiris of the same name.

The name Osiris has much embarrassed critics and etymologists. The learned Jablonski $, instead of delineating the character, attributes, operations, adventures, exploits, and peculiar department assigned this deity by his votaries, has spent much of his pains on trying to investigate the etymology of his name. If it is granted, which is highly probable, that the Hebrew and Egyptian tongues are cognate dialects, we should imagine that it is actually the Chaldean Osiris of the former language, which imports, "to make rich, to become rich." Indeed the words Osiris and Isis were not the vulgar names of the sun and moon among the Egyptians, but only epithets importing their qualities. The name of the fun among that people was Phric or Phry, and that of the moon Isis, whence the Greek Is. The term Osiris was applied both to the sun and to the river Nile; both which by their influence contributed respectively to enrich and fertilize the land of Egypt.

It was a general custom among the orientals to denominate their princes and great men from their gods, deities, heroes, &c. When the former were advanced to divine honours, they were in process of time confounded with their archetypes. The original divinities were forgotten, and their upstart deities usurped their place and prerogatives. In the earliest pe-

(c) Men and women dressed in the habits of those rural deities.

(d) Many have thought this expedition fabulous; but the numberless monuments of Egyptian architecture, sculpture, statuary, lately discovered in the eft, confirm it.
The mysteries of Isis and Osiris established in commemoration of those adventures.

Ofiris was rescued from the banks of the Nile by her husband, who, of course, carried her back to Egypt; but the mischiefous Typhon, ever on watch, found her on the banks of the Nile; and having robbed her of her charge, cut the body into 14 parts, and flattered them up and down. Now, once more, according to the fable, Isis set out in quest of those parts, all of which, only one excepted, she found and inferred in the place where she found them: and hence the many tombs of Osiris in that country. These tombs were denominated tepelines by the natives. Many other fabulous adventures were ascribed to those two personages, which is not our province to enumerate at present. If our readers should wish to be more minutely informed on this subject, they may have recourse to the authors mentioned in the last quoted author, or to the learned Mr Bryant’s Analysis of Ancient Mythology, and M. Cour de Gebelin, where they will find matter enough to gratify their curiosity.

To commemorate those adventures, the mysteries of Isis and Osiris were establised; and from them both those of Bacchus and Ceres, among the Greeks were derived. Of the Egyptian solemnity, we have an exact epitome of the mysteries of Isis and Osiris. They observe annually, with deep lamentations and shaved heads, the catastrophe of Osiris over a buried statue of that monarch. They beat their breasts, mangle their arms; tear open the scars of their former wounds; that by annual lamentations the catastrophe of his miserable and fatal death may be revived in their minds. When they have practised these things a certain number of days, then they pretend that they have found the remains of his mangled body; and having found them, their forrows are lulled asleep, and they break out into immediate joy.” What Maxims of morality, secrets of physiognomy, or phenomena of astronony, were couched under this allegorical process, is not our business to investigate in this place. We shall only observe, that, in all probability, Isis and Osiris were sovereigns of Egypt at a very early period: that they had conferred many signal benefits on their subjects, who, influenced by a sense of gratitude, paid them divine honours after their decease; that in process of time they were confounded with the sun and the moon; and that their adventures were at length magnified beyond all credibility, interlarded with fables, and allegories, and employed in the mysteries as channels to convey a variety of instructions to the initiated.

Be that as it may, it is certain that the very same mode of worship was established at Byblus, and in after ages transferred to Tyre. The Mizraim and Cannaanim were nearly connected by blood, and their religious ceremonies were derived from the very same source. By what medium the worship of Osiris at Abydus and Tyre was connected, we shall leave others to explain; we shall only observe, that among the Phoenicians this deity obtained the names Adonis and Bacchus. The former is rather an epithet than a name; the latter is evidently an allusion to the weeping and lamentation (e) with which the rites were performed. We find another name of that divinity mentioned in Scripture (r), but that term is plainly of Egyptian original; we shall now proceed to the mysteries of Osiris as they were celebrated among the Greeks and Thracians, under the name of the Original of Dionysus or Bacchus.

Orpheus the celebrated Thracian philosopher had travelled into Egypt in quest of knowledge: and from that country, according to the most authentic accounts, he imported the bacchanalian rites and institutions. Some have affirmed that this same Orpheus being intimately acquainted with the family of Cadmus, communicated these rites to them, and endeavoured to transfer them to the grandion of that hero, which grandion became afterwards the Greecian Bacchus. It is, however, we think, much more probable, that those rites were imported from Egypt or Phoenicia, by (c) Cadmus himself, who was a native of the former country, and is told to have spent some time in the latter, before he emigrated in quest of a settlement in Bacotia. It is said that Semele, the daughter of Cadmus, and the mother of the Grecian Bacchus, was struck with lightning at the very instant of his birth. The child, was in all probability named Bacchus, from the sorrow and lamentation this melancholy accident had occasioned in the family. Cadmus, in order to conceal the dishonour of his daughter, might, we imagine, convey away his infant grandion to some of his relations in Phoenicia or

(c) For the conquests and adventures of Osiris and Isis, we must fend our learned readers to Diod. Sic. Bib, i. i, and Plut. Isis and Osiris, p. 256 et seq. which we have been obliged to abridge, in consequence of the limits prescribed us.

(f) Adonis is evidently the Hebrew Adoni, “my lord,” and imports the sovereignty of the deity.

(g) Bacchus is derived from the Phoenician word bophab, “to weep.” This was the name embraced by the Romans.

(h) Exek chap. 8. ver. 14. lammas is the name of one of the months of the Egyptian year.

(i) Cadmus and Melampus, who were both Egyptians, introduced the Bacchanalia into Greece. The Egyptian or oriental name of Bacchus was Dinys, that is “the prince of light.” Cadmus had learned the name Bacchus from the Phoenicians.

(k) We have omitted the immense farrago of fable relating to the connexion between Jupiter and Semele, as of little importance to our readers.
or Egypt. There he was educated and instructed in all the mysteries of Isis and Osiris, and at the same time initiated in all the magical or juggling tricks of the Egyptian priests and Hierophants. This accomplished, when he arrived at manhood he returned to Thebes with the traditional retinue of the original deity of the same name; and claimed divine honours accordingly. This claim, however, was not admitted without much opposition; Pentheus, another grandson of Cadmus, was torn to pieces by the frantic women. Some fan of Cadmus, was privy to the whole plan, when he arrived out of this combination was formed a species of adventures disgraceful to human nature, absurd, and inconsistent. Indeed the younger or Théban Bacchus seems to have been a monster of debauchery; whereas the Egyptian is represented as a person of an opposite character. Of course the mysteries of the former were attended with the most shocking abominations.

The mysteries, as has been observed above, were first celebrated at Thebes the capital of Boeotia, under the auspices of the family of Cadmus. From this country they gradually found their way into Greece, and all the neighbouring parts of Europe. They were celebrated once every three years (1), because at the end of three years Osiris returned from his Indian expedition. As the Greeks had impudently transferred the actions of the Egyptian hero to their upstart divinity, the same period of time was observed for the celebration of those rites in Greece that had been ordained for the same purpose in Egypt.

When the day appointed for the celebration of the orgia (a) approached, the priests issued a proclamation, enjoining all the initiated to equip themselves according to the ritual, and attend the procession on that day appointed. The votaries were to dress themselves in coats of deer-skins, to loose the fillets of their hair, to cover their legs with the same stuff with their coats, and to arm themselves with thyrsi, which were a kind of spears wholly of wood entwined with leaves and twigs of the vine or ivy. It is said that the Bacchanalians, especially the Thracians, used often to quarrel and commit murder in their drunken revels: and that in order to prevent those unlucky accidents, a law was enacted, that the votaries instead of real spears should arm themselves with those sham weapons which were comparatively inoffensive. The figure of the deity, which was always covered with vine or ivy leaves, was now taken down from its pedestal, and elevated on the shoulders of the priest. The cavalcade then proceeded nearly in the following manner:

First of all, hymns were chanted in honour of Bacchus, who was called the \textit{Power of dance, saltis, and jells}; while at the same time he was deemed equally qualified for the exploits of war and heroism. Horace, in some of his dithyrambic odes, has concisely pointed out the subjects of these Bacchalian songs. In the collection of hymns fabulously attributed to Orpheus, we find several addressed to this deity (p).

\begin{itemize}
  \item \textit{Nannus}, an Egyptian of Pentapolis, has collected all the fabulous adventures of Bacchus, and exhibited them in a beautiful but incorrect poem: To this we must refer our learned reader. Of the Dionysiacs we have a most judicious sketch, \textit{Greeks. Calend. p. 553. et al.}
  \item \textit{Mysteries of Bacchus}. (a) The orgia belonged to all the Myrones, but to those of Bacchus in a peculiar manner.
  \item \textit{Telexerion}. (b) According to Clem. Alexander. Cohort. p. 12. Pott. the word \textit{orgia} is derived from \textit{argos}, which signifies "anger," and originated from the resentment of Ceres against Jupiter, in consequence of a most outrageous insult he had offered her with force. We should rather imagine it derived from the Hebrew word \textit{argos}, signifying a "cheet or coffer," alluding to the casket which contained the sacred ymb is of the god.
  \item The Egyptians or Phenicians might write and pronounce, \textit{argos, argos}, or in some manner nearly resembling \textit{orgia}.
  \item \textit{Pentheus}, another grandson of Cadmus, was privy to the whole plan.
\end{itemize}
Mysteries.

As it may, we learn from Porphyry*, that in the island of Chios they used to sacrifice a man to Bacchus, and that they used to mangle and tear him limb from limb.

This was no doubt practised in commemoration of the catastrophe mentioned above.

The orgia of this Pagan god were originally simple enough; but this unfacilitated mode was of no long continuance, for riches soon introduced luxury, which quickly infected even the ceremonies of religion. On the day set apart for this solemnity, men and women crowned with ivy, their hair dishevelled, and their bodies almost naked, ran about the streets, roaring aloud. Books (v) of Bacchus. In this rout were to be seen people intoxicated at once with wine and enthusiasm, dressed like Satyrs, Fauns, and Silenus, in such scandalous postures and attitudes, with so little regard to modesty and even common decency, that we are persuaded our readers will readily enough forgive our omitting to describe them. Next followed a company mounted upon asse, attended by Fauns, Bacchanauls, Thyades, Mimallonides, Naiads, Tityri, &c. who made the adjacent places echo to their frantic shrieks and howlings. After this tumultuous herd were carried the statues of victory and altars in form of vine-sheds crowned with ivy, smoking with incense and other aromatics. Then appeared several chariots loaded with thyrsi, arms, garlands, cauls, pitchers, and other vases, tripods, and vases. The chariots were followed by young virgins of quality, who carried the baskets and little boxes, which in general contained the mysterious articles above enumerated. These, from their office, were called ephiphone. The phallophori (x) followed them, with a chorus of Itholphophori habited like Fauns, counterfeiting drunk persons, singing in honour of Bacchus songs and dances suited to the occasion. The procession was closed by a troop of Bacchanalians crowned with ivy, interwoven with branches of yew and with serpents*. Upon some occasions, at those scandalous festivals, naked women whipped themselves, and tore their skin in a most barbarous manner. The procession terminated on mount Citheron, where it fell out from the Thébes; and in other places, in some distant unfrequented desert, where the votaries practised every species of debauchery with fever.
MYSTERIES.

cercy and impunity. Orpheus saw the degeneracy of those ceremonies; and in endeavouring to reform them he probably lost his life. Pentheus suffered in the like attempt, being torn in pieces by the Bacchantines on the mount Citheron, among whom were his own mother and his aunts. The Greeks, who were an airy jovial people, seem to have paid little regard to the plaintive part of the orgia; or rather, we believe, they acted with howling and frantic exclamations, often enhanced by a combination of drunkenness, ecstacy, and enthusiastic fury.

What secrets, religious, moral, political, or physical were communicated to the votaries, it is impossible to determine with any degree of certainty.—One thing we may admit, namely, that the doctrines discovered and inculcated in the orgia, were originally the very same which the apostles of the sect had insinuated in Egypt and Phoenicia; and of which we have given a brief account near the beginning of this article. It is however probable that the famous or Theban Bacchus had superadded a great deal of his own invention, which, we may believe, was not altogether fo found and fabulous as the original doctrine. However that may be, the initiates were made to believe that they were to derive wonderful advantages from the participation of these rites, both in this life and that which is to come. Of this, however, we shall talk more at length by and by in our account of the Eleusinian mysteries.

To detail the etymology of the names of this Pagan deity, the fables relating to his birth, his education, his transformations, his wars, peregrinations, adventures, the various and multiform rites with which he was worshipped, would swell this article to a most immoderate size. If any of our readers should wish to be more minutely and more accurately acquainted with this subject, we must beg leave to remit them to Diod. Sic. Apollod. Bibl. Euripid. Aristophane Ran. Nonn Dionys. and among the moderns, to Bau. Mythol. Voss. de. orig. Idol. Mont. Fourmount, Reflexions sur l'origine anciens peuples, Mr Bryant's Analyzy: and especially to Mons Cour de Gbelin, Calendries ou Almanach. That prince of etymologists, in his account of the festival of Bacchus, has given a most acute and ingenious explication of the names and epithets of that deity. For our part, we have endeavoured to collate and exhibit such as we judged most important, most entertaining, and most instructive, to the less enlightened classes of our readers.

We now proceed to the Eleusinian mysteries, which, among the ancient Greeks and Romans, were treated with a superior degree of awe and veneration. These were instituted in honour of Ceres, the goddess of corn; who, according to the most authentic accounts, was the Isis of the Egyptians. The mysteries of Olymivs and Isis have been hinted at in the preceding part of this article. They were originally instituted in honour of the sun and moon, and afterwards conferred on an Egyptian prince and princess, who, in consequence of their merits, had been deified by that people. We know of no more exact and brilliant description of the ceremonies of that goddess, in the most polished ages of the Egyptian superstition, than what we meet with in the witty and florid Apuleius*, to which we must take the liberty to refer our more curious readers. Our business at present shall be to try to investigate by what means, and upon what occasion those mysteries were introduced into Attica, and established at Eleusis. A passage from Diodorus Siculus §, which we shall here translate, will, we think, throw no inconsiderable light on that abstruse part of the subject.

"In like manner with him (Cecrops), says that judicious historian, they tell us, that Eretheus, a prince of Egyptian extraction, once reigned at Athens. Of this fact they produce the following evidence:—A searing drought, during the reign of this prince, On what prevaild over almost all the habitable world, except occasion introduced into Attica."

We now proceed to the Eleusinian mysteries, which, among the ancient Greeks and Romans, were treated with a superior degree of awe and veneration. These were instituted in honour of Ceres, the goddess of corn; who, according to the most authentic accounts, was the Isis of the Egyptians. The mysteries of Olymivs and Isis have been hinted at in the preceding part of this article. They were originally instituted in honour of the sun and moon, and afterwards conferred on an Egyptian prince and princess, who, in consequence of their merits, had been deified by that people. We know of no more exact and brilliant description of the ceremonies of that goddess, in the most polished ages of the Egyptian superstition, than what we meet with in the witty and florid Apuleius*, to which we must take the liberty to refer our more curious readers. Our business at present shall be to try to investigate by what means, and upon what occasion those mysteries were introduced into Attica, and established at Eleusis. A passage from Diodorus Siculus §, which we shall here translate, will, we think, throw no inconsiderable light on that abstruse part of the subject.

Here then we have the whole mystery of the arrival of Ceres in Attica, and the institution of her mystery at Eleusis unveiled. The whole is evidently an oriental allegory. The fruits of the earth had been destroyed by a long course of drought; Egypt, by its peculiar situation, had been preferred from that dreadful calamity. Eretheus, in consequence of his relation to the Egyptians, imported from their country a quantity of grain, not only sufficient for the consumption of his own subjects, but also a great overplus to export to other parts of Greece, Sicily, Italy, Spain, &c. Triptolemus, another Egyptian, was appointed by Eretheus to export this superfluous store. That hero, according to Pherecydes, was the son of Oceanus and Tellus, that is, of the sea and the earth; he caused his parents were not known, and because he came to Eleusis by sea. The ship in which he sailed, after he had distributed his corn to the western parts of the world, was decorated with the figure of a winged dragon: therefore, in the allegorical style of his country he was said to be wafted through the air in a chariot drawn by dragons. Those creatures, every body knows, were held sacred by the Egyptians.

Wherever Triptolemus disposed of his corn thither were extended the wanderings of Ceres. In order to elucidate
Mysteries.

At this point, we must observe that along with the grain imported from Egypt, Erebuthus, or Triptolemus, or both transported into Attica a cargo of priests and priestesses from the temples of Bubiris, a city which lay in the 5th centre of the Delta, where the goddess Isis had a number of chapels erected for her worship. The presidents of these ceremonies, like all other bigots, gladly laid hold on this opportunity of propagating their religious rites, and disseminating the worship of the deities of their country. The Egyptian priests were zealous in propagating the dogmas of their superstition, abundantly evident from the extensive spreading of their rites and ceremonies over almost all Asia and a considerable part of Europe. The Greek and Roman deity is known to have originated from them; and numberless monuments of their impious worship are still extant in Persia, India, Japan, Tartary, &c. Our inference then is, that the worship of Isis was introduced into every country where Triptolemus sold or disposed of his commodities. Hence the wanderings of Ceres in search of her daughter Proserpine, who is generally called Core. The famine occasioned by the drought destroying the fruits of the ground, imports the loss of Proserpine. The restoration of the corn in various parts of the earth, by fresh supplies from Egypt, from time to time, imports the wanderings of Ceres in quest of Proserpine. The whole process is an oriental allegory. The dis-appearing of the fruits of the earth, of which Proserpine, or Persephone (y), or Paryphone (v), is the emblem, is the allegorical rape of that goddess. She was seized and carried off by Pluto, sovereign of the infernal regions. The seed committed to the earth in that dry season appeared no more, and was, consequently, laid to dwell under ground with Pluto. It was then that Ceres, that is, corn imported from Egypt, set out in quest of her daughter. Again, when the earth recovered its prime fertility, the Core, or maid, was found by her mother Ceres, that is, the earth; for Isis, among the Egyptians, frequently signified the earth. The wanderings of Isis in search of Olyris furnished the model for the pereginations of Ceres.

Ceres, the Roman name of the goddess of corn, was unknown to the modern Greeks, They always denominated her Damater (z), which is rather an epithet than a proper name. The Greeks, who always affected to use only names of originals, we think suppressed the Egyptian name on purpose, to conceal the country of that deity. As a proof of the probability of this conjecture it may be observed, that they metamorphosed the wanderings of Isis in search of Olyris into the pereginations of Ceres in quest of Proserpine. The Romans, who were less ambitious of the character of originality, retained one of her oriental names (a). Ceres, says Diodorus, appeared thrice in Attica during the reign of Erebuthus; which seems to import, that fleets loaded with corn had thrice arrived in that country from Egypt during that period.

Cecrops the first king of Attica had established the worship of the Saitic Athena or Minerva in that region and consecrated his capital to that deity. Erebuthus, in his turn introduced the worship of Isis or Damater who in all appearance was the tutelar deity of Bubiris his native city. The subjets of Cecrops were a colony of Saites, and readily embraced the worship of Minerva; but the aborigines of that district being accustomed to a maritime, perhaps to a piratical course of life, were more inclined to consecrate their city to Neptune the god of the sea, and to constitute him their guardian and protector. Cecrops by a stratagem secured the preference to Minerva his favourite divinity. Erebuthus, in order to give equal importance to his patrons, had the address to institute the Eleusinian mysteries; and to accomplish his design laid hold on the opportunity abovementioned. This appears to us the most probable account of the origin and institution of the Eleusinian mysteries; for which the Sicilian historian has indeed furnished the clue. We shall now proceed to detail some other circumstances which attended the original institution of these far-famed ceremonies.

The archpriests who perforated the newly imported deity was entertained by one Celeus (4), who was either viceroy of that petty district of which Eleusis was the capital, or some considerable personage in that city or its neighbourhood. Upon her immediate arrival, according to the fabulous relations of the Greeks, a farce was acted not altogether suitable to the character of a goddess whose mysteries were one day to be deemed so sacred and awful. These coarse receptions, and other indecencies attending the first appearance of the goddess, that is the Egyptian dame who assumed her character, were copied from the like unhallowed modes of behaviour practised on occasion of the solemn proceedings of her native country. These solemnities, or coarse jokes, had an allegorical signification in Egypt; and among the most ancient Greeks the very same spirit was universally diffused by the oriental colonists who from time to time arrived and settled among them. In process of time they abandoned the figurative and allegorical style, in consequence of their acquaintance with philosophy and abstract reasoning.

(y) This word seems to be formed of two Hebrew terms, pler "fruit," and tzaphon or naphon, "abundance, recondite, reconditius, recondite, recondite;"

(a) Damater is compounded of the Chaldæan particle de "the," and mäter "mother." As Isis often signified the earth, the Greeks naturally adopted that title; because, according to them, that element is the mother of all living. In the very same manner they disdained the word Juna, an original title of the moon; and substituted Hera, which intimates "mistress or lady."

(A) According to some of the Latin etymologists, Ceres, or rather Ceres, is derived from gena "to bear, to carry," because the earth bears all things; or because that element is the general fruit-bearer. But as this term came to Italy immediately from the east, and not by the medium of Greece, we would rather incline to adopt an oriental etymology. The Hebrew word cheres signifies arare "to plow:" a name naturally applicable to the goddess of husbandry.
reasoning. In the ceremonies of religion, however, the same allegorical and typical representations which had been imported from the east were retained; but the Greek hierophants in a short time lost every idea of their latent import, and religious, moral, or physical interpretation. Accordingly, this unlearned re-encounter between Ceres and Banbo (a), or Jambhe, was retained in the mysteries, though we think it was copied from Egypt, as was said above, where even that obscene action was probably an allegorical representation of something very different, from what appeared to the Greeks.

At the same time that Ceres arrived in Attica, Bacchus likewise made his appearance in that country. He was entertained by one Ierous; whom, as a reward for his hospitality, he instructed in the art of cultivating the vine, and the method of manufacturing wine. Thus it appears that both agriculture and the art of managing the vintage were introduced into Athens much about the same time. Ceres was no other than a priestess of Isis; Bacchus was no doubt a priest of Osiris. The arrival of these two personages from Egypt, with a number of inferior priests in their train, produced a memorable revolution in Athens, both with respect to life, manners, and religion. The sacred rites of Isis, afterwards so famous under the name of the Eleusinian mysteries, date their institution from this period.

When this company of propagandists arrived at Eleusis, they were entertained by some of the most respectable persons who then inhabited that district. Their names, according to Clem. Alexand., were Banbo, Dyfalus, Tripotlemus, Eumolpus, and Eubulus. From Eumolpus were descended a race of priests called Eumolpides, who figured at Athens many ages after. Tripotlemus was an ox-herd, Eumolpus a shepherd, and Eubulus a wine-herd. These were the first apostles of the Eleusinian mysteries. They were instructed by the Egyptian missionaries; and they, in their turn, instructed their successors. Ereuteus, or, as some say, Pandion, continued the sanctuary, and built a small temple for its accommodation in Eleusis, a city of Attica, a few miles west of Athens, and originally one of the twelve districts into which that territory was divided. Here then we have arrived at the scene of those renowned mysteries, which for the space of near 2000 years were the pride of Athens and the wonder of the world.

The mysteries were divided into the greater and lesser. The latter were celebrated at Agrae, a small town on the river Ilyius; the former were celebrated in the month which the Athenians called Boedromion (c); the latter in the month Anthesterion (d). The lesser mysteries, according to the fabulous legends of the Greeks, were instituted in favour of the celebrated Hercules. That hero being commanded by Eurytheus to bring up Cerberus from the infernal regions, was defirous of being initiated in the Eleusinian mysteries before he engaged in that perilous undertaking. He addressed himself to Ennomus the hierophant for that purpose. There was a law among the Eleusinians prohibiting the initiation of foreigners. The priest not daring to refuse the benefit to Hercules, who was both a friend and benefactor to the Athenians, advised the hero to get himself adopted by a native of the place, and so elude the force of the law. He was accordingly adopted by one Pyollus, and so was initiated in the lesser mysteries which were instituted for the first time upon that occasion. This account has all the air of a fable. The lesser mysteries were initiated by way of preparation for the greater.

The person who was to be initiated in the lesser mysteries, as well as in the greater, was obliged to undergo a previous to initiation. Besides, he was to bind himself by the most solemn vows not to divulge any part of the mysteries. At the same time, however, according to the original institution, to be a person of unblemished moral character. These were preliminaries indispensably necessary in order to admission. A bull was sacrificed to Jupiter, and the hide of that animal called by a peculiar name (dic kebolos), was carefully preserved and carried to Eleusis, where it was spread under the feet of the initiated. The candidate was then purified by bathing in the river Ilyius, by associations with salt water or salt, with laurel barley, and passing through the fire: all which rites were attended with incantations and other usages equally insignificant and ridiculous. Last of all, a young sow was sacrificed to Ceres; and this animal, according to the ritual, belonged to be with pigs; and before it was killed it was to be walked in Cantharus, one of the three harbours which formed the Piraeus.

All these ceremonies duly performed, the candidate was carried into the hall appointed for the purpose of initiation. There he was taught the first elements of those arcana which were afterwards to be more fully and more clearly revealed in the more august mysteries of Eleusis. The pupils at Agrae were called Mylai, which may intimate probationers; whereas those of Eleusis were denominated Edfcles, importing that they saw as they were seen.

The lesser mysteries were divided into several stages. There were several names of stages, with long inter
tervals between them.

With

(b) The third month of the Athenian year, answering to our September.

(d) The eighth month, answering to our February; but Meursius makes it November.
Mysteries.

With respect to the greater mysteries, it is probable that originally none but the natures of Attica were admitted to partake of them. In process of time, however, the pale was extended so far and wide as to comprehend all who spoke the Greek language. All foreigners were debarred from those sacred rites. They tell us, however, that Hercules, Bacchus, Catoftor and Polax, Aesculapius and Hippocrates, were initiated in an extraordinary manner, from a regard to their high character and heroic exploits. All barbarians, too, were excluded: yet Anacharsis the Sceythian was indulged that privilege, in consequence of his reputation for science and philosophy. All persons guilty of manslaughter, though even accidentally or involuntarily, all magicians, enchanters; in a word, all impious and profane persons, were expressly prohibited the benefit of this pagan sacrament. At last, however, the gate became wider, and crowds of people, of all nations, kinds, and languages, provided their character was fair and irreproachable, rushed in by it. In process of time the Athenians initiated even their infants; but this, we imagine, must have been a kind of purification from which it was supposed that they derived a kind of moral ablation from vice, and were thought to be under the peculiar protection of the gods.

The celebration of the mysteries began on the 15th day of the month Boedromion; and, according to the most ancient authors, lasted nine days. Meurinus has enumerated the transactions of each day, which are too numerous to fall within the compass of this article; we must therefore refer our curious reader to the author just mentioned. Some days before the commencement of the festival, the precones, or public criers, invited all the initiated, and all the pretenders to that honour, to attend the festival, with clean hands and a pure heart, and the knowledge of the Greek language.

On the evening of the 15th day of the month called Boedromion the initiations commenced. Our readers will observe, that all the most sacred and solemn rites of the pagan superstition were performed during the night: They were indeed generally works of darkness. On this day there was a solemn cavalcade of Athenian matrons from Athens to Eleusis in carriages drawn by oxen. In this procession the ladies used to rally one another in pretty loose terms, in imitation of the prophecies of the Egyptians (says he, quoting from Porphyry) they are of the following complexion. The Prep. Demiurgus, whom the Egyptians call Cneph, is figured as a man of an azure colour, shaded with black, holding in his right hand a sceptre and in his left a girdle, and having on his head a royal wing or feather wreathed round. Such, we imagine, was the equipment of the Eleusinian hierophant. This person was likewise styled Prophet. He was to be of the family of the Eumolpidae; was obliged to make a vow of perpetual chastity, and even his voice, hair, and attitude, were adjusted to the ritual.

The next minister was the Daduchus, or torch-bearer; who, according to the father above quoted, was attired like the sun. This minister resembled the sun, because that luminarv was deemed the visible type of the supreme Demiurgus, and his vicegerent in governing and arranging the affairs of this lower world.

The third was the person who officiated at the altar. He was habited like the moon. His office was to implore the favour of the gods for all the initiates. We should rather imagine, that the person at the altar, as he resembled the moon, was intended to represent the goddess herself: for the Egyptian Isis, who was the archetype of Ceres was sometimes the moon and sometimes the earth.

The sacred herald was another principal actor in this solemn exhibition. His province was to recite every thing that, according to the ritual, was to be communicated to the novices; and he probably represented Thyoth or Thoth, that is Hermes or Mercury, the interpreter of the gods.

Besides...
The ceremony.

Besides these, there were five epimeletes or curators, of whom the king was one, who jointly directed the whole ceremonial. Lastly there were ten priests to offer the sacrifices. There were no doubt many officers of inferior note employed upon these occasions, but these were only insignificant appendages, whose departments have not been transmitted to posterity.

After this detail of the ministers of this solemn service, we return to the mystæ, or candidates for initiation. Some of the fathers of the church mention a hymn composed by the celebrated Orpheus, which was sung by the mystagogus or king upon that occasion. This hymn appears to us one of those epigrammatic compositions which abounded in the first ages of Christianity, and which the pious apologists often adopted without sufficient examination. That some sacred hymn was chanted upon that occasion, we think highly probable; but that the one in question was either composed by Orpheus, or used at the opening of these ceremonies, to us appears somewhat problematical.

Before the ceremony opened, a book was produced, which contained every thing relating to the temple. This was read over in the ears of the mystæ, who were ordered to write out a copy of it for themselves. This book was kept as Eleusis in a sacred repository, formed by two stones exactly fitted to each other, and of a very large size. This repository was called petæona. At the annual celebration of the greater mysteries, these stones were taken aunder, and the book taken out; which, after being read to the mystæ, was replaced in the same cæment.

The initiations began with a representation of the wanderings of Ceres, and her bitter and loud lamentations for the loss of her beloved daughter. Upon this occasion, no doubt, a figure of that deity was displayed to the mystæ, while loud lamentations echoed from every corner of the sanctuary. One of the company having kindled a firebrand at the altar, and thus kindled a flame in the middle of the temple, waving the torch with the utmost fury, a second imitated it from him, rearing and waving it in the same frantic manner: then a third, fourth, &c. in the most rapid succession. This was done to imitate Ceres, who was said to have perambulated the globe of the earth with a flaming pine in her hand, which had lighted at mount Ætna.

When the pageant of the goddess was supposed to arrive at Eleusis, a solemn paean ensued, and a few trilling questions were put to the mystæ: What these questions were, is evident from the answers, "I have failed; I have drunk the liquor: I have taken the contents out of the cofier, and having performed the ceremony, have put them into the hamper: I have taken them out of the hamper, and put them again in the cofier." The meaning of these answers, we conjecture, was this: "I have failed as Ceres failed while in search of her daughter: I have drunk the worst of the drink when given her by Banho; I have performed what Ceres taught her first disciples to perform, when the committed to them the sacred hamper and cofier." After these interrogatories and the suitable responses, the mundus Cereris was displayed before the eyes of the mystæ, and the my/æos or hierophant; or perhaps the sacred herald by his command, read a lecture on the allegorical import of those sacred symbols. This was heard with the most profound attention; and a solemn silence prevailed throughout the scene. Such was the first act of this religious farce, which perhaps consisted originally of nothing more.

After the exposition of the mundus Cereris, and the import of her wanderings, many traditions were communicated to the mystæ concerning the origin of the universe and the nature of things. The doctrines delivered in the greater mysteries, says Clem. Alex., "relate to the nature of the universe. Here all instruction ends. Things are seen as they are; and nature and the things of nature, are given to be comprehended."

To the same purpose Cicero: "Which points being explained and reduced to the standard of reason, the nature of things, rather than that of the gods, discovered." The father of the universe, or the supreme demiurgus, was represented as forming the chaotic mass into the four elements, and producing animals, vegetables, and all kinds of organized beings, out of those materials. They say that they were informed of the secrets of the anomalies of the moon; and of eclipses of the sun and moon; and, according to Virgil,

Unde bonimentum genus, et pœcudes, unde imber et ignes.

What system of cosmogony these hierophants adopted, is evident from the passage above quoted from Eusebius: and, from the account immediately preceding, it was that of the most ancient Egyptians, and of the orientals in general. This cosmogony is beautifully and energetically exhibited in Plato's Timæus, and in the genuine spirit of poetry by Ovid in the beginning of his Metamorphoses.

The next scene exhibited upon the stage, on this Exploits of solemn occasion, consist of the exploits and adventures of the gods, the deities of the gods, demigods, and heroes, who had, and from time to time, been advanced to divine honours. These were displayed as passing before the mystæ in pageants fabricated for that important purpose. This was the original mode among the Egyptians, and was no doubt followed by their Eleusinian pupils. Those adventures were probably demonstrated to have been allegorical, symbolic, hiero-glyphical, &c. at least they were exhibited in such a favourable point of view as to elicit those absurdities and incongruities with which they were foopplicated by the poets and the vulgar.

With respect to the origin of those fictitious deities, it was discovered that they had been originally rigid, men who had been exalted to the rank of divinity, in consequence of their heroic exploits, their useful inventions, their beneficent actions, &c. This is so clear from the two passages quoted from Cicero, by bishop Warburton, that the fact cannot be controversy. But that prelate has not informed us so precisely, whether the mystagogues represented them as nothing more than dead men, in their present state, or as beings who were actually existing in a defined state, and executing the functions assigned them in the bosom of paganism. Another query naturally occurs, that is, to what purpose did the mystagogues apply this communication? That the hierophants di
Mysteries.

actually represent those deified mortals in the latter prædication, is obvious from another passage quoted from Cicero by the same prelate, which we shall trancribe as translated by him: "What think you of those who assert that valiant, or famous, or powerful men, have obtained diverse honours after death: and that these are the very gods now become the objects of our worship, our prayers, and adoration? Euhemerus tells us, when these gods died, and where they lie buried. I forbear to speak of the sacred and unguilt rites of Eleusis. I pass by Samothrace and the mysteries of Lemnos, whose hidden rites are celebrated in darkness, and amidst the thick shades of groves and forests." If, then those deified mortals were become the objects of worship and prayers, there can be no doubt of the belief of their deified existence. The allusion to the Eleusinian and other pagan mysteries towards the close of the quotation, places the question beyond the reach of controversy. But though, according to this account, "there were gods many and lords many;" yet it is evident from the passage quoted from Euhemerus in the preceding part of this article, that the unity of the Supreme Being was maintained, exhibited, and incultated. This was the original doctrine of the Hierophants of Egypt: It was maintained by Thales and all the retainers of the Ionian school. It was the doctrine of Pythagoras, who, probably gleaned it up in the country just mentioned, in connexion with many other dogmas which he had the assurance to claim as his own.

But however the unity, and perhaps some of the most obvious attributes of the Supreme Author of nature, might be illustrated and incultated, the tribute of homage and veneration due to the subordiinate divinities was by no means neglected. The initiates were taught to look to the dìi majorum gentium with a superior degree of awe and veneration, as beings endowed with an ineffable measure of power, wisdom, purity, goodness, &c. There were, if we may use the expression, the prime favourites of the Monarch of the universe, who were admitted into his immediate presence, and who received his benefits from his own mouth, and communicated them to his subordinate officers, prefects, lieutenants, &c. These they were exhorted to adore; to them they were to offer sacrifices, prayers, and every other act of devotion, both on account of the excellency of the nature and the high rank they bore at the court of heaven. They were instructed to look up to hero-gods and demi-gods, as beings exalted to the high rank of governors of different parts of nature, as the immediate guardians and protectors of the human race; in short, as gods near at hand, as prompters to a virtuous course, and all who observed it; as ready upon all occasions to confer blessings upon the virtuous and deserving. Such were the doctrines taught in the teleæ with respect to the nature of the Pagan divinities, and the worship and devotion enjoined to be offered them by the mysteries.

As the two principal ends proposed by these initiations were the exercise of heroic virtues in mortal life, and the practice of sincere and uniform piety by the candidates for immortal happiness, the hierophants had adopted a plan of operations exceptionally accommodated to both these purposes. The virtuous conduct and heroic exploits of the great men and demi-gods of early antiquity, were magnified by the most pompous eloquiums, enforced with suitable exhortations to animate the votaries to imitate so noble and alluring an example. But this was not all; the heroes and demigods themselves were displayed in pagants, or vehicles of celestial light. Their honours, offices, habitations, attendants, and other appendages, in the capacity of demons, were exhibited with all the pomp and splendor that the sacerdotal college were able to devise. The sudden glare of mimetick light, the melting music stealing upon the ear, the artificial thunders reverberated from the roof and walls of the temple, the appearance of fire and ethereal radiance the vehicles of flame, the effigies of heroes and demons adorned with crowns of laurel emitting rays from every spar, the fragrant odours and aromatic gales, which breathed from every quarter, all dexterously counterfeited by sacerdotal mechanism, must have filled the imagination of the afohnified votaries with pictures at once tremendous and transporting; Add to this, that every thing was transfigured in the dead of night amidst a dismal gloom: whence the most bright effulgence instantaneously burst upon the sight. By this arrangement the aspirants to initiation were wonderfully animated to the practice of virtue while they lived, and inspired with the hope of a blest immortality when they died. At the same time, their awe and veneration for the gods of their country was wonderfully enhanced by reflecting on the appearances above described. Accordingly Strabo very judiciously observes, "that the mythical secrecy of the sacred rites preserves the majesty of the Deity, imitating its nature, which escapes our apprehension. For these reasons, in celebrating the teleæ, the demons were introduced in their deified or glorified state.

But as all the candidates for initiation might not aspire to the rank of heroes and demigods, a more easy and a more attainable mode of conduct, in order to arrive at the palace of happiness, behoved to be opened. Private virtues were incultated, and these too were to meet a condign reward. But alas, this present life is too often a chequered scene, where virtue is depressed and trodden under foot, and vice lifts up its head and rides triumphant. It is a dictate of common sense, that virtue should sooner or later emerge, and vice sink into contempt and misery. Here then the conductors of the mysteries properly and naturally, adopted the doctrine of a future state of rewards and punishments. The dogma of the immortality of the human soul was elucidated, and carefully and pathetically incultated. This doctrine was likewise imported from Egypt; for Herodotus informs us, "that the Egyptians were the first people who maintained the immortality of the human soul." The Egyptian immortality, however, according to him, was only the metempsychosis or transmigration of souls. This was not the system of the ancient Egyptians, nor indeed of the teleæ. In theo, a metempsychosis was admitted; but that was carried forward to a very distant period, to wit, to the grand Egyptian period of 36,000 years.

As the Mystagogues well knew that the human mind is more powerfully affected by objects presented to the eyes than by the most engaging instructions conveyed by
Mysteries.

by the ear, they made the emblems of Elyium and Tartarus pass in review before the eyes of their novices. There the Elyrian scenes, so nobly described by the Roman poet, appeared in mimic splendor; and on the other hand, the gloom of Tartarus, Charon's boat, the dog of hell, the fires with tresses of snakes, the tribunal of Minos and Rhadamantus, &c. were displayed in all their terrific state. Tantalus, Ixion, Siyphus, the daughters of Danaus, &c. were represented in pageants before their eyes. These exhibitions were accompanied with most horrible cries and howlings, thunders, lightning, and other objects of terror, which we shall mention in their proper place.

No contrivance could be better accommodated to animate the pupils to the practice of virtue on the one hand, or to deter them from indulging vicious passions on the other. It resembled opening heaven and hell to a hardened sinner. The practices inculcated in celebrating the mysteries are too numerous to be detailed in this imperfect sketch. The worship of the gods was strictly enjoined, as has been shown above. The three laws imported from Eleusinia were warmly recommended in the oracles of predestination, and were actually observed. 1. To honour their parents; 2. To treat the gods with the utmost respect; 3. Not to treat brute animals with cruelty. These laws were imported from Egypt, and were communicated to the Eleusinians by the original missionaries. Cicero makes the civilization of mankind one of the most beneficial effects of the Eleusinian institutions: "Nolum mihi, cum multa eximia divinaque videntur Athenaeque peperifeti; tum nihil melius illius mysteriis, quibus ex agrelli immanque vita, exculsi ad humanitatem, et mitigati fumus; inatiaque, ut appellantur, ita revera principia vitae cognovimus; neque solum cum feptificium vi-vendi rationem acceppimus, fed etiam cum sfe meliore moriendo." Hence it is evident, that the precepts of humanity and morality were warmly recommended in these institutions. The virtue of humanity was extended, one may say, even to the brute creation; as appears from the law of Triptolemus's laws above quoted. Some articles were enjoined in the teletas which may appear to us of least importance, which, however, in the symbolic style of the Egyptians, were abundantly significant. The initiated were "commanded to abstain from the flesh of certain birds and fishes; from beans, from pomegranates and apples, which were deemed equally polluting. It was taught, that to touch the plant of asparagus was as dangerous as the most deadly poison. Now, says Porphyry, who ever is versed in the history of the e phés, knows for what reason they were commanded to abstain from the flesh of birds."

The initiated bound themselves by dreadful oaths to observe most conscientiously and to practice every precept tendered to them in the course of the teletas; and at the same time never to divulge one article of all that had been heard or seen by them upon that occasion. In this they were exceedingly jealous, that Elecyblius the tragedian was in danger of capital punishment for having only alluded to one of the Eleusinian scenes in a tragedy of his; and one of the articles of indiction again Diogoras the Molian was, his having spoken disrespectfully of the mysteries, and diffused people from partaking of them. It must then be allowed, that the institution of the mysteries was of infinite advantage to the pagan world. They were indeed a kind of sacraments, by which the initiated bound themselves by a solemn vow to practice piety towards the gods, justice and humanity towards their fellow-men, and gentleness and tenderness towards the inoffensive part of the brute creation. The pagans themselves were so thoroughly convinced of this fact, that in their disputes with the apologists for Christianity, they often appealed to the teletas, and contrasted their maxims with the most sublime doctrines of that heavenly institution.

In order to impress these maxims the more deeply upon the minds of the novices, and to fix their attention more fastidiously upon the lectures which were delivered to them by the mystagogue or the sacred herald, a mechanical operation was played off at proper intervals during the course of the celebration. "Towards the end of the celebration (says Sibbeus), the whole scene is terrible; all is trembling, shuddering, sweat, and astonishment. Many horrible spectres are seen, and strange cries and howlings uttered. Light succeeds darkness; and again the blackest darkness the most glaring light. Now appear open plains, flowery meads, and waving groves; where are seen dances and choruses; and various holy phantasmagoria chant the chant. Melodious notes are heard from far, with all the sublime simphonies of the sacred hymns. The pupil now is completely perfected, is initiated, becomes free, released, and walks about with a crown on his head, and is admitted to bear a part in the sacred rites. A-fritides de Myt. Eleus. calls Elyium "a kind of temple of the whole earth, and of all that man beholds done in the most dreadful and the most exhilarating manner. In what other place have the records of so many things so marvelously? or in what region upon earth have the objects presented to the eye bore a more exact resemblance to the sounds which strike the ear? What object of sight have the numberless generations of men and women beheld comparable to those exhibited in the ineffable mysteries?" To the same purpose, Pheus, in the oracles of Zoroastro, informs us, "that frightful and shadowy apparitions, in a variety of forms, used to be displayed to the eye in the course of their initiation. And a little after, he adds, "that thunder and lightning and fire, and every thing terrible which might be held symbolical of the divine presence, was introduced." Claudian, in his poem De Raptu Proserpina, gives an elegant though brief description of this phenomenon, which throws some light on the passages above quoted.

"... Jam mibi ceramum trespides delubra movent... Sedibus et claram dis pergore culmina lucem... Adventum tegeta Deo, jam magnus ab imis... Auditor forum terris, templaque remusit... Cerespium..."

The sight of those appearances was called the Antipfas, or "the real presence;" hence those rites were sometimes called Epoonitis. The Egyptians were actually initiated, and were admitted into the Sacrum Scelorum, and bore a part in the ceremonial; whereas the Mysteries, who had only been initiated in the lesser Mysteries at Agræ, were obliged to take their station in the porch of...
MYSTERIES.

Let us to flow't meads repair,
With deathless roses blooming,
Whose balmy sweets impregn the air,
Both hills and dales perfuming.

Since fate benign our choir has joint'd,
We'll trip in mystic measure:
In sweetest harmony combin'd
We'll quaff full draughts of pleasure.

For us alone the pow'r of day
A milder light dispenses;
And sheds a benight a mellow'd ray
To cheer our ravi'ld senses:
For we behold the mystic flow,
And brav'd Eleusin' dangers.
We do and know the deeds we owe
To neighbours, friends, and strangers.

Euripides, in his Bacchae (e), introduces the chorus extolling the happiness of those who had been acquainted with God by participating in the holy mysteries, and whose minds had been enlightened by the mythical rites. They boast, "that they had led a holy and unblemished life, from the time that they had been initiated in the sacred rites of Jupiter Idæus, and from the time that they had relinquished celebrating the nocturnal rites of Bacchos, and the banquets of raw flesh torn off living animals." To this fainthood of life they had no doubt engaged themselves, when they were initiated in the mysteries of that god. The Eleusinian Eaptes derived the same advantages from their sacramental engagements. Fourthly, the initiated were imagined to be the peculiar wards of the Eleusinian goddesses. These deities were supposed to watch over them, and often to avert impending danger, and to rescue them when beset with troubles.

Our readers will not imagine that the initiated reaped much benefit from the protection of his Eleusinian tutelary deities; but it was sufficient that they believed the fact, and actually depended upon their intercession. Fifthly, the happy influences of the telete, were supposed to administer consolation to the Eaptes in the hour of dissolution; for, says Iphocrates "Ceres bestowed upon the Athenians two gifts of the greatest importance; the fruits of the earth, which were the cause of our no longer leading a savage course of life; and the telete, for they who partake of these entertain more pleasant hopes both at the end of life, and eternity afterwards." Another author tells us, "At the time of the Mysteries the importance of the Mysteries was heightened by the fact that the initiated were not only often rescued from death and danger, but were also given the boon of a happy condition." Sixthly, After death, in the Elysian fields, they were to enjoy superior degrees of felicity, and to be bathed in eternal sunshine, to quaff nectar, and feast upon ambrosia, &c.

The priests were not altogether dishonored in this salutary process. They made their disciples believe, that the souls of the initiated, when they arrived in the infernal regions, should roll in mire and dirt, and with very great difficulty arrive at their destined mansion.

(a) Act I near the beginning, and in many other places.
When the Athenians advised Diogenes to get himself initiated, and enforced their arguments with the above considerations, "It will be pretty enough (replied the philosopher) to see Ageiathus and Epaminondas wallowing in the mire, while the most contemptible rascals who have been initiated are strutting in the islands of bliss."

When Antithenes was to be initiated in the Orphic mysteries, and the priest was bestowing of the many altroning benefits which the initiated should enjoy in a future state (says Antithenes), "Why, forsooth, (says Antithenes), 'tis wonder your reverence don't e'en hang yourself in order to come at them the sooner."

When such benefits were expected to be derived from the mysteries, no wonder if all the world crowded to the Eleusinian standard. After the Macedonian conquests, the Hierarchans abated much of their original strictness. By the age of Cicero, Eleusis was a temple whether all nations referred to partake of the benefits of that institution. We find that almost all the great men of Rome were initiated. The Hierophants, however, would not admit Nero on account of the profaneness of his character. Few others were refused that honour; even the children of the Athenians were admitted. But this, we think, was rather a lufturation or consecration, than an initiation. Perhaps it paved the way for the more august ceremony, as the Christian baptism does among us for the other sacrament.

That this institution gradually degenerated, can hardly be questioned; but how much, and in what points, we have not been able to investigate. The fathers of the church, from whom that charge is chiefly to be collected, are not always to be trusted, especially when they set themselves to arraign the institutions of Paganism. There were indeed several ancient authors, such as Melanthus, Minander, Socrates, &c. who wrote purposely on the subject in question, but their works are long since irrecoverably lost. For this reason, modern writers, who have professedly handled it, have not always been successful in their researches. The two who havelaboured most indefatigably, and perhaps most successfully, in this field, are Murchius and Warburton. The former, in his Liber Singularis, has collected everything that can be gleaned from antiquity relating to the ceremonial of these institutions, without, however, pointing out theiroriginal, or elucidating the end and import of their establishment. The latter has drawn them into

the vortex of a system which has in many instances led him to ascribe to them a higher degree of merit than we think they deserve. These instances we would willingly have noticed in our progress, had the limits prescribed us admitted such a diffusion.

If we may believe Diodorus the Sicilian, these mysteries, which were celebrated with such wonderful secrecy at Eleusis, were communicated to all mankind among the Cretans. This, however, we think, is rather problematical. We imagine that excellent historian has confounded the mysteries of Cybele with those of the Eleusinian Ceres. These two deities were undoubtedly one and the same, that is, the moon or the earth. Hence it is probable, that there was a striking resemblance between the sacred mysteries of the Cretans and Eleusinians.

This institution continued in high reputation to the age of St Jerome, as appears from the following passage; "Hierophantes quoque Atheniensium legantique hodie ciceretur fortes attiro." The emperor Valentinianus intended to have suppressed them; but Zosimus informs us, that he was diverted from this design by the proconsul of Greece. At length Theodosius the elder, by an imperial edict prohibited the celebration of these as well as all the other mysteries, introduced in the reign of Eusebius, maintained their ground to the period just mentioned, that is, near 2000 years; during which space, the celebration of them never had been interrupted but once. When Alexander the Great massacred the Thebans and razed their city, the Athenians were so much affected with this melancholy event, that they neglected the celebration of that festival.

There were almost numberless other mysterious institutions among the ancient Pagans, of which these sketched above were the most celebrated. The Samothracian mysteries, instituted in honour of the Cabiri, were like-wise of considerable celebrity, and were supposed to confer much the same blessing with the Eleusinian, but were not of equal celebrity. The Cabiri were Phaenician and like-wise Egyptian deities. The learned Bochart has explained their origin, number, names and some part of their worship. The Orphic mysteries were like-wise famous among the Thracians. Orpheus learned them in Egypt, and they were nearly the same with the sacra Bacchanaalia of the Greeks. There were likewise the mysteries of Jupiter Idaeus in great request among the Cretans, those of the Magna Mater or Cybele, celebrated in Phrygia. To enumerate and detail all these would require a complete volume. We hope our readers will be fully satisfied with the specimen exhibited above. We are convinced many things have been omitted which might have been inserted, but we have collected the most curious and the most important.

Every one of the politians might have been authenticated by quotations from authors of the most unquestionable credibility, but that process would have swelled the whole article beyond all proportion.
Mystics, something mysterious or allegorical.

Some of the commentators on the facred writings, besides a literal find also a mythical meaning. The sense of scripture, nay they, is either that immediately signified by the words and expressions in the common use of language; or it is mediate, sublime, typical, and mystical. The literal sense they again divide into proper literal, which is contained in the words taken simply and properly; and metaphorical literal, where the words are to be taken in a figurative and metaphorical sense. The mystical sense of scripture they divide into three kinds: the first corresponding to faith, and called allegorical; the second to hope, called anagogical; and the third to charity, called the tropological sense. And sometimes they take the same word in scripture in all the four senses; thus the word Jerusalem, literally signifies the capital of Judea: allegorically, the church militant: tropologically, a believer; and anagogically, heaven.

The mystics, to excite their fanatic ecstases and amorous extravagancies, allege that passage of St. Paul, The Spirit pray in us by sighs and groans that are unutterable. Now if the Spirit, say they, pray in us, we must resign ourselves to its motions, and be swayed and guided by its impulse, by remaining in a state of mere inaction.

Pulvis contemplation is that state of perfection to which the mystics all aspire.

The authors of this mystical science, which sprang up towards the close of the third century, are not known; but the principles from which it was formed are manifest. Its first promoters proceeded from the known doctrine of the Platonic school, which was also adopted by Origen and his disciples, that the divine nature was diffused through all human souls, or that the faculty of reason, from which proceeded the health and vigour of the mind, was an emanation from God into the human soul, and comprehended in it the principles and elements of all truth, human and divine. They denied that men could by labour or study excite this celestial flame in the breast; and therefore they disapproved highly of the attempts of those, who by definitions, abstract theorems, and profound speculations, endeavoured to form distinct notions of truth, and to discover its hidden nature. On the contrary, they maintained that silence, tranquillity, repose, and solitude, accompanied with such acts as might tend to extirpate and exhaust the body, were the means by which the hidden and internal word was excited to produce its latent virtues, and to instruct men in the knowledge of divine things. For thus they reasoned; those who behold with a noble contempt all human affairs, who turn away their eyes from terrestrial vanities, and shut all the avenues of the outward senses against the contagious influences of material world, muti necessarily return to God, when the spirit is thus disengaged from the impediments that prevented that happy union. And in this blessed frame they not only enjoy inexpressible raptures from their communion with the Supreme Being, but also are invested with the ineffable privilege of contemplating truth undisguised and uncorrupted in its native purity, while others behold it in a vitiated and delusive form.

The number of the mystics increased in the fourteenth century, under the influence of the Grecian fanatic, who gave himself out for Dionysius the Areopagite, disciple of St. Paul, and probably lived about this period: and by pretending to higher degrees of perfection than other Christians, and professing greater austerity, their cause gained ground, especially in the eastern provinces, in the fifth century. A copy of the pretended works of Dionysius was sent by Balbus to Lewis the Meek in the year 824, which kindled the holy flame of mysticism in the western provinces, and filled the Latins with the most enthusiastic admiration of this new religion.

In the twelfth century, these mystics took the lead in their method of expanding scripture; and by searching for mysteries and hidden meanings in the plainest expressions, forced the word of God into a conformity with their visionary doctrines, their enthusiastic feelings, and the system of discipline which they had drawn from the excursions of their irregular fancies. In the thirteenth century, they were the most formidable antagonists of the schoolmen, and towards the close of the fourteenth, many of them refided and propagated their tenets almost in every part of Europe. They had, in the fifteenth century, many persons of distinguished merit in their number; and in the sixteenth century, previous to the reformation, if any sparks of real piety subsisted under the despotic empire of superstition, they were only to be found among the mystics.

The principles of this sect were adopted by those called Quakers in the seventeenth century, and, under different modifications, by the Quakers and Methodists.

MYSTRUM, a liquid measure among the ancients, containing the fourth part of the Cyathus, and weighing two drams and an half of oil, or two drams two scruples of water or wine. It nearly answers to our spoonful.

MYTELENE See MYTELONE.

MYTENS (Daniel), of the Hague, was an admired painter in the reigns of king James and king Charles. He had certainly (Mr. Walpole says) studied the works of Rubens before his coming over. His landscape in the back grounds of his portraits is evidently in the style of that school; and some of his works have been taken for Vandyck's. The date of his arrival is not certain. At Hampton-court are several whole lengths of princes and princesesses of the house of Brunswick-Lunenburgh, and the portrait of Charles Howard earl of Nottingham; at Kensington is Mytens's own head. At Knowsle, Lionel Cranfield earl of Middlesex, lord treasurer, with his white staff, whole length. At Lady Elizabeth Germaine, niece to Drayton is a very fine whole length of Henry, rich earl of Holland, in a striped habit, with a walking stick. At St James's is Jeffery Hudson the dwarf, holding a dog by a string, in a landscape, coloured warmly and freely like Snyder or Rubens. Mytens drew the same figure in a very large picture of Charles I. and his Queen,
MYTHOLOGY.

Definition. A term compounded of two Greek words, and in its original import it signifies any kind of fabulous doctrine: in its more appropriated sense, it means those fabulous details concerning the objects of worshipping which were invented and propagated by men who lived in the early ages of the world, and by them transmitted to succeeding generations, either by written records or by oral tradition.

As the theology and mythology of the ancients are almost inseparably connected, it will be impossible for us to develope the latter, without often introducing some observations relating to the former. We must therefore intreat the indulgence of our readers, if upon many occasions we should hazard a few frictions on the names, characters, adventures, and functions of such pagan divinities as may have furnished materials for those fabulous narrations which the nature of the subject may lead us to discuss.

Origin of fable. With respect to fable, it may be observed in general, that it is a creation of the human imagination, and derives its birth from that love of the marvellous which is in a manner congenial to the soul of man.—The appearances of nature which every day occur, objects, actions, and events, which succeed each other, by a kind of rotine, are too familiar, too obvious, and uninteresting, either to gratify curiosity or to excite admiration. On the other hand, when the most common phenomena in nature or life are new modelled by the plastic power of a warm imagination: when they are diversified, compounded, embellished, or even arranged and moulded into forms which seldom or perhaps never occur in the ordinary course of things—novelty generates admiration, a passion always attended with delightful sensations. Here then we imagine we have discovered the very source of fiction and fable.—They originated from that powerful propensity in our nature towards the new and surprising, animated by the delight with which the contemplation of them is generally attended.

Many circumstances contributed to extend and establish the empire of fable. The legislator laid hold on this bias of human nature, and of course employed fable and fiction as the most effectual means to civilize a rude, unpolished world. The philosopher, the theologian, the poet, the musician, each in his turn, made use of this vehicle to convey his maxims and instructions to the savage tribes. They knew that truth, simple and unadorned, is not poissied of charms powerful enough to captivate the heart of man in his present corrupt and degenerate state. This consideration, which did indeed result from the character of their audience, naturally led them to employ fiction and allegory from this was derived the allegorical taste of the ancients, and especially of the primary ages of the east.

Though almost every nation on the face of the globe, however remote from the centre of population, however savage and averse from cultivation, has fabricated and
and adopted its own system of mythology; the Orientals, however, have distinguished themselves in a peculiar manner, by the boldness, the inconsistency, and the extravagance of their mythology. The genial warmth of those happy climes, the fertility of the soil, which afforded every necessity, every convenience, and often every luxury of life, without depressing their spirits by laborious exertions; the face of nature perpetually blooming around them, the skies smiling with uninterrupted serenity; all contributed to inspire the Orientals with a glow of fancy and a vigour of imagination rarely to be met with in less happy regions. Hence every object was swelled beyond its natural dimensions. Nothing was great or little in moderation, but every sentiment was heightened with incredible hyperbole. The magnificent the sublime, the vast, the enormous, the marvellous, therosse, the magnificent the sublime, the vast, the enormous, the marvellous, the roose, the were the veil which hid the hidden springs of the world. The Oriental mythology was the groundwork of that impenetrable covering.

As the allegorical tales of the eastern nations had sprung from their propensities to fable, and as that propensity had in its turn originated from the love of the marvellous; so did allegory in process of time contribute its influence towards multiplying fables and fiction almost in infinitum. The latent import of the allegorical scenes being in a few ages lost and obliterated, what was originally a moral or theological system, assumed the air and habit of a personal adventure.

The propensities towards personification, almost universal among the orientals, was another fruitful source of fable and allegory. That the people of the east were strongly inclined to personify inanimate objects and abstract ideas, we imagine will be readily granted, when it is considered, that in the formation of language they have generally annexed the affection of sex to those objects. Hence the distinction of grammatical genders, which is known to have originated in the eastern parts of the world. The practice of personifying virtues, vices, religious and moral affections, was necessary to support that allegorical style which universally prevailed in those countries. This mode of writing was in high reputation even in Europe some centuries ago; and to it we are indebted for some of the most noble poetical compositions now extant in our own language. Those productions, however, are but faint imitations of the original mode of writing still current among the eastern nations. The Egyptians derived this species of composition from the Moorish inhabitants of Spain, who imported it from Arabia, their original country.

The general use of hieroglyphics in the east, must have contributed largely towards extending the empire of mythology. As the import of the figures employed in this method of delineating the signs of ideas was in a great measure arbitrary, mistakes must have been frequently committed in ascertaining the notions which they were at the first intended to represent. When the development of these arbitrary signs happened to be attended with uncommon difficulty, the expounders were obliged to have recourse to conjecture. Those conjectural explications were for the most part tinctured with some bias towards the marvellous which universally prevailed among the primitive men. This we find is the case even at this day, when moderns attempt to develop the purport of emblematical figures, preferred on ancient medals, engravings, &c.

The wise men of the east delighted in obscure enigmatical sentences. They seem to have derived every sentiment, obvious to vulgar apprehension, from the word of the wise, and their dark sayings, often occur in the most ancient records both sacred and profane. The fages of antiquity used to vie with each other for the prize of superior widom, by propounding riddles, and dark and mysterious questions, as subjects of investigation. The contest between Solomon and Hi- sered, and that between Amaša king of Egypt and Polycrates tyrant of Samos, are universally known,—As the import of those enigmatical propositions was often absolutely lost, in ages when the art of writing was little known, and still less practised, nothing remained but fancy and conjecture, which always verged towards the regions of fable. This then, we think, was another source of mythology.

The Pagan priests, especially in Egypt, were probably the first who reduced mythology to a kind of system. The facerdotial tribe, among that people, a kind of whose fages of religion were the veil which covered the mystic depositories of learning as well as of virtue, and mythology. That order of men monopolized all the arts and sciences. They seem to have formed a conspiracy among themselves to preclude the laity from all the avenues of intellectual improvement. This plan was adopted with a view to keep the laity in subjection, and to enhance their own importance. To accomplish this end, they contrived to perform all the ministrations of their religion in an unknown tongue, and to conceal them with a thick veil of fable and allegory. The language of Ethiopia became their sacred dialect, and hieroglyphics their sacred character.—Egypt, of course, became a kind of fairyland, where all was jugglery, magic, and enchantment. The initiated alone were admitted to the knowledge of the occult mystical exhibitions, which, in their hands, constituted the essence of their religion. From thence the vulgar and profane were prohibited by the most rigorous penalties (See Mysteries). The Egyptians, and indeed all the ancients without exception, deemed the mysteries of religion too sacred and solemn to be communicated to the herd of mankind, naked and unrefined; a mode by which they imagined those sacred and sublime oracles would have been defiled and degraded. "Procul, o procul or procul, Odi profundum vulgus et arceo." Egypt was the land of graven images; allegory and mythology were the veil which concealed religion from the eyes of the vulgar; fable was the groundwork of that impenetrable covering.

In the earliest and most unpolluted age of society we cannot suppose fable to have existed among men. Fables are always tales of other times, but at this period other times did not reach far enough backward to afford those fruits of the imagination sufficient time to arrive at maturity. Fable requires a considerable space of time to acquire credibility, and to rise into reputation. Accordingly, we find that both the Chinese...
and Egyptians, the two most ancient nations whose annals have reached our times, were altogether unacquainted with fabulous details in the most early and least improved periods of their respective monarchies. It has been shown almost to a demonstration, by a variety of learned men, that both the one and the other people, during some centuries after the general deluge, retained and practiced the primitive Noachic religion, in which fable and fancy could find no place; all was genuine unpolluted truth.

As soon as the authentic tradition concerning the origin of the universe was either in a great measure lost, or at least adulterated by the inventions of men, fable and fiction began to prevail. The Egyptian Tneb or T thief, or Mercury Trismegistus, and Mochus the Phanician, undertook to account for the formation and arrangement of the universe, upon principles purely mechanical. Here fable began to usurp the place of genuine historical truth. Accordingly, we find that all the historians of antiquity, who have undertaken to give a general detail of the affairs of the world, have adhered in their narration with a fabulous cosmogony. Here imagination ranged unconfined over the boundless extent of the primary chaos. To be looked into Sanchoniathon’s Cosmogony, Euseb- Thoth mythology, or fabulous traditions, we must, without the historians, who pretend to have seen the most considerable periods of the primary creation. This emperor, according to the Chincfe history, was a circumst ance which rivetted the esteem of all that posterity.

The Chinefe, if any credit be due to their own univerfe was either in a great 

The Chinefe, if any credit be due to their own univerfe was either in a great 

The Chinefe mythology, or fabulous traditions, we shall proceed to lay before our readers a brief detail of the mythology of the most respectable nations of antiquity, following the natural order of their situation.

The Chinefe, if any credit be due to their own annals, or to the mithological church of Rome, who pretend to have copied from them, were the first of the nations. Their fabulous records reach upwards many myriads of years before the Mosaic era of the creation. The events during that period of time, if any had been recorded, must have been fabulous as the period itself. These, however, are buried in eternal oblivion. The mithological religions, who are the sole sources of our information with relation to the earliest periods of the Chinefe history, represent those people as having retained the religion of Noah many centuries after the foundation of their empire. Upon this supposition, their cosmogony must have been found and genuine, without the least tincture of those fabulous ingredients which have both disguised and disgraced the cosmogonies of most other nations.

According to the most authentic accounts, Foh or Fohi laid the foundation of that empire about 4000 years ago. This emperor, according to the Chinefe, was conceived in a miraculous manner. His mother, say they, one day as she was walking in a deserted place, was surrounded by a rainbow; and, being impregnated by this meteor, was in due time delivered of that celebrated legislator. This personage, like the Athenian Cecrops, was half a man and half a serpent. His intellectual powers were truly hyperbolical. In one day he discovered 50 different species of poisonous herbs. He taught his countrymen the whole art of agriculture in the space of a very few years. He instructed them how to sow five different sorts of grain, his invention boats and arts for building the art of fabricating porcelain, the management of silk-worms, the manufacturing of silk, &c. In a word that wonderful personage was inspired by Heaven with knowledge, which qualified him for composing that incomparable body of laws which are even at this day the wonder of the world. Our readers will admit, that this whole detail is fabulous and chimerical. The most learned part of them will readily observe, that the Chinefe, in ascribing the invention of all the useful arts to their Fohi, are perfectly agreed with almost all the other nations of antiquity. The Indians ascribe every invention to Budha, or Vishnu, or Foh; the Persians to Zoroas ter; the Chaldeans to their man of the sea, whom they call Osiris; the Egyptians to Tho thor of Thoth; the Phocnicians to Meliboeus; the Greeks to the family of the Titan; and the Scandinavians to Odin, &c.

About 55 years before the Christian era, appeared the famous Chinefe philosopher Confucius, or Confu- cius. Concerning the birth of this prince of philosophers, the Chinefe have propagated the following legendary tale. His mother walking in a solitary place was impregnated by the vivifying influence of the heavens. The babe, thus produced, spake and reasoned as soon as it was born. Confucius, however, wrought no miracles, performed no romantic exploits, but lived an austere ascetic life, taught and inculcated the doctrines of pure morality, and died, remarkable only for superior wisdom, religious, moral, and political.

About the year of Christ 601, flourished the Searfury Lao-kizm. His mother carried him 30 years in her womb, and he was delivered of him under a plum tree. This philosopher was the Epicurus of the Chinefe. His disciples, who were denominated Faohs, i.e. heavenly doctors, were the first who corrupted the religion of the Chinefe. They were addicted to magic, and introduced the worship of good and bad demons. Their doctrine was embraced by a long succession of emperors. One of these princes, called Toudi, had been deprived by death of a favourite mistress, whom he loved with the most extravagant passion. The emperor, by the magical skill of one of these doctors, obtained an interview with his deceased mistress, a circumstance which rivetted the whole order in the affection and esteem of the deluded prince. Here our reader will observe the exact counterpart of the fable of Eurydice, so famous in the mythology of the Greeks and Romans. That such a system of religious principles must have abounded with mythical adventures is highly probable; but as the mithological religions, to whom we are chiefly indebted for our information relating to the religion of the Chinefe, have not taken the pains to record them, we find it impossible to gratify the curiosity of our readers on that head.

The worship of the idol Foh, or Foh, was transplanted from India into China about the 5th year of the Christian era, upon the following occasion. One of the doctors of the Foh-fo had promised a prince of the family of the Tchou, and brother of the emperor, that he would make him consult into communion with the spirits. At his solicitation a ambassador was dispatched into India, in order to inquire where the true religion...
M Y T H O L O G Y.

A gnol was to be found. There had been a tradition, say the missionaries, ever since the age of Confucius, that the true religion was to be found in the west.—The ambassador from India: and finding that the god Foe was in high reputation in that country, he collected several images of that deity painted on chintz, and with it 42 chapters of the canonical books of the Hindoos, which, together with the images, he laid on a white elephant, and transported into his native country. At the same time he imported from the same quarter the doctrine of the transmigration of souls, which is firmly believed in China to this day. The doctrine and worship of Foe, thus introduced, made a most rapid progress all over China, Japan, Siam, &c. The priests of Foe are called among the Siamese, Talopins; by the Tartars, Lama; by the Chineese, Ho-chang; and by the people of Japan, Bonzes. By this last appellation they are generally known in Europe.

An infinitude of fable was invented and propagated by the disciples of Foe, concerning the life and adventures of their master. If the earlier ages of the Chineese history are barren of mythological incidents, the later periods, after the introduction of the worship of Foe, furnished an inexhaustible store of miracles, monsters, fables, intrigues, exploits, and adventures, of the most villainous complexion. Indeed, most of them are so absurd, so ridiculous, and at the same time so interesting as to absorb the attention of the hearer, even from a wish to investigate the truth of the narration. Such as may find themselves disposed to rake into this abominable pulpit, we must refer to the reverend fathers du Halde, Couplet, Amiot, Kircher, and other members of the propaganda, in whose writings they will find where, withal to satisfy, and even to forfeit, their appetites.

The Hindoos, like the other nations of the east, for a long time retained the worship of the true God. At length, however, idolatry broke in, and, like an impetuous torrent, overwhelmed the country. First of all, the ancient history of the origin of the universe was either utterly lost, or disguised under a variety of fictions and allegories. We are told that Brimba, the supreme deity of the Hindoos, after several previous efforts, at last succeeded in creating four perfons, whom he appointed to rule over all the inferior creatures. Afterwards Brimba joined his efficient power with Bifhol and Rudler; and by their united exertions they produced ten men, whose general appellation is Muni, that is, the inspired. The same being, according to another mythology, produced four other persons, as imaginary as the former; one from his breath, one from his back, one from his lip, and one from his heart. These children were denominated Bungis; the import of which word we cannot pretend to determine. According to another tradition, Brimba produced the Bramins from his mouth, to pray, to read, to instruct; the Chiltren from his arms, to draw the bow, to fight, to govern; the Bice from his belly or thighs, to nourish, to provide the necessaries of life by agriculture and commerce; the Soder from his feet, for subjection to servile, to labour, to travel. 

The reader will see at once, in these allegorical persons, the four calls or septs into which the Hindoo nation has, time immemorial, been divided. These are, some of their most celebrated mythological traditions with relation to the origin of the universe.

The Hindoos have likewise some mythological opinions which seem to relate to the general deluge. They tell us, that during the preservation of herds of four-legged animals, of genii and of virtuous men, of vedas of deluge, &c. the law, and of precious things, the Lord of the universe assumes many bodily shapes; but though he pervades, like the air, a variety of beings, yet he is himself unvaried, since he has no quality in him subject to change. At the close of the last calpa, there was a general destruction, occasioned by the sleep of Brahme, whence his creatures in different worlds were drowned in a vast ocean. Brahme being inclined to slumber after a lapse of so many ages, the strong demon Hayagriva came near him, and stole the vedas which had flowed from his lips. When Heri, the preserver of the universe, discovered this deed of the prince of Dahnavas, he took the shape of a minute wind called Sap-hari. After various transformations, and an enormous increase of size in each of them, the Lord of the universe loving the righteous man (a); who had still adhered to him under all these various shapes, and intending to preserve him from the sea of destruction caused by the depravity of the age, thus told him how he was to act: “In seven days from the present time, O thou Saker of enemies! the three worlds will be plunged in an ocean of death; but in the midst of the deitroying waves a large veiled tent by me for thy use shall stand before thee.” The remaining part of the mythology so nearly resembles the Mosaic history of Noah and the general deluge, that the former may be a strong confirmation of the truth of the latter. To dry up the waters of the deluge, the power of the Deity descends in the form of a boar, the emblem of strength, to draw up and support on his tusks the whole earth, which had been sunk beneath the ocean. Again, the same power is represented as a tortoise sustaining the globe, which had been convulsed by the violent assaults of demons, while the gods charmed the sea with the mountain Mandar, and forced it to divide the sacred things and animals, together with the water of life which it had swallowed. All these stories, we think relate to the same event, shadowed by a moral, a metaphorical, and an astronomical allegory; and all three seem connected with the hieroglyphical sculptures of the old Egyptians.

The Hindoos divide the duration of the world into four ages or Jugis, or Jetus, or Jegues, each consisting of a prodigious number of years. In each of these periods, the age and stature of the human race have been gradually diminished; and in each of them mankind has gradually declined in virtue and piety, as well in age and stature. The present period they call the Colle, i.e. the corrupt Jogue, which they say is to last 400,000

(a) He was Sovereign of the world. His name was Mana, or Stattagrava; his patronymic name was Vajatra, son or child of the Sun.
MYTHOLOGY.

400,000 years, of which near 5000 years are already past. In the last part of the preceding Jogue, which they call the Dwa paar, the age of man was contracted into 1000 years, as in the present it is confined to 100. From this proportional diminution of the length of the human life, our readers will probably infer, that the two last Jogues bear a pretty near resemblance to the Mosaic history of the age of the antediluvian and postdiluvian patriarchs; and that the two first are imaginary periods prior to the creation of the world, like those of the Chinefe, Chaldeans, and Egyptians.

The world subject to various dilutions and refutations.

According to the mythology of the Hindoos, the system of the world is subject to various dilutions and refutations. At the conclusion of the Collae Jogue, say they, a grand revolution will take place, when the solar system will be confumed by fire, and all the elements reduced to their original constituent atoms. Upon the back of these revolutions, Brahma, the supreme deity of the Hindoos, is sometimes represented as a new born infant, with his toe in his mouth, floating on a camala or water flower, sometimes only on a leaf, of that plant, on the surface of the vault of abyss. At other times he is figured as coming forth of a winding shell; and again as blowing up the mundane foam with a pipe at his mouth. Some of these emblematical figures and attitudes, our learned readers will probably observe, nearly resembhe those of the ancient Egyptians.

But the vulgar religion of the ancient Hindoos was of a very different complexion; and opens a large field of mythological adventures. We have observed above, that the Fœ or Foe of the Chinefe was imported from India; and now we shall give a brief detail of the mythological origin of that divinity. We have no certain account of the birth-place of this imaginary deity.—His followers relate, that he was born in one of the kingdoms of India near the line, and that his father was one of that country. His mother brought him into the world by the left side, and expired soon after her delivery. At the time of her conception, she dreamed that she had swallowed a white elephant; a circumstance which is supposed to have given birth to the veneration which the kings of India have always shown for a white animal of that species. As soonas he was born, he had strength enough to fland erect without assistance. He walked abroad at seven, and pointing with one hand to the heavens, and with the other to the earth, he cried out. "In the heavens, and on the earth there is no one but me who deserves to be honoured." At the age of 30, he felt himself all on a sudden filled with the divinity; and now he was metamorphosed into Fœ or Pagod, according to the explication of the Hindoos. He had no sooner declared himself a divinity, than he thought of propagating his doctrine, and proving his divine mission by miracles. The number of his disciples was immense; and they soon spread their dogmas over all India, and even to the higher extremities of Asia.

One of the principle doctrines which Fœ and his disciples propagated, was the metempsychosis or transmigration of souls. This doctrine, some imagine, has given rise to the multitude of idols reverenced in every country where the worship of Fœ is established. Quadrupeds, birds, reptiles, and the vilest animals, had temples erected for them because, say they, the soul of the god, in his numerous transmigrations, may have at one time or other inhabited their bodies.

Both the doctrine of transmigration and of the worship of animals seems, however, to have been imported from Egypt into India. If the intercourse between these two countries was begun at so early a period as some very late writers have endeavoured to prove, such a supposition is by no means improbable. The doctrine of the transmigration of souls was early established among the Egyptians. It was, indeed, the only idea they formed of the soul's immortality. The worship of animals among them seems to have been still more ancient. If such an intercourse did actually exist, we may naturally suppose that colonies of Egyptian priests found their way into India, as they did afterwards into Afia Minor, Italy and Greece. That colonies of Egyptians did actually penetrate into their country, and settle there, many centuries before the nativity, is a fact that cannot be called in question, for reasons which the bounds prescribed us on this article will not allow us to enumerate. We shall only observe, that from the hieroglyphical representations of the Egyptian deities seem to have originated those monstrous idols which from time immemorial have been worshipped in India, China, Japan, Siam, and even in the remotest parts of Asiatic Tartary.

Fœ is often called Budha, Buddha, and sometimes Visnou; perhaps, indeed, he may be distinguished by nations of many other names, according to the variety of dialects of the different nations among which his worship was established. An innumerable of fables was propagated by his disciples concerning him after his death. They pretended that their master was still alive; that he had been already born 8000 times; and that he had successively appeared under the figure of an ape, a lion, a dragon, an elephant, a boar, &c. These were called the incarnations of Visnou. At length he was confounded with the Supreme God; and all the titles, attributes, operations, perfections, and ensigns of the Most High were ascribed to him. Sometimes he is called Amida, and represented with the head of a dog, and worshipped as the guardian of mankind. He sometimes appears as a princely perfage, issuing from the mouth of a fish. At other times, he wears a lunette on his head, in which are seen cities, mountains, towers, trees, in short, all that the world contains. These transformations are evidently the children of allegorical or hieroglyphical emblems, and form an exact counterpart to the symbolical worship of the Egyptians.

The enormous mafs of the mythological traditions which have in a manner deluged the west continent of India, would fill many volumes: We have selected the preceding articles as a specimen only, by which our readers may be qualified to judge of the rest. If they find themselves disposed to indulge their curiosity at greater length, we must refer them to Thevenot's and Hamilton's Travels, to Mont. Aqueulis in his Zond. Aveila Halide's Introduction to his translation of the Code of Gentoo Laws, Col. Dow's History of Hindoostan, Grofsés Voyage to the East Indies, Asiatic Researches, vol. 1. and 2.
The mythology of the Persians is, if possible, still more extravagant than that of the Hindoos. It supposes the world to have been repeatedly destroyed, and repeopled by creatures of different formation, who were successively annihilated or banished for their disobedience to the Supreme Being. The monstrous griffin *Sinergb* tells the hero *Caherman* that he had already lived to see the earth seven times filled with creatures and seven times a perfect void; that, before the creation of Adam, this globe was inhabited by a race of beings called *Peri and Dives* whose character formed a perfect contrast. The *Peri* are described as beautiful and benevolent: the *Dives* are deformed, malevolent, and mischievous, differing from infernal demons only in this, that they are not as yet confined to the pit of hell. They are for ever ranging over the world, to scatter discord and misery among the sons of men. The *Peri* nearly resemble the fairies of Europe; and perhaps the *Dives* gave birth to the giants and magicians of the middle ages. The sons of men. The myth of the world was formed, malevolent, and evil-omnipotent; the *Dives* are the sons of men. The myth of the world was formed, malevolent, and evil-omnipotent; the *Dives* are distributed, malevolent, and mischievous, differing from the infernal demons only in this, that they are not as yet confined to the pit of hell.

When the *Peri* are in danger of being overpowered by their foes, they solicit the alliance of some mortal hero; which produces a series of mythological adventures, highly ornamental to the strain of the *Persian* bards, and which, at the same time, furnishes an inexhaustible fund of the most diversified machinery.

One of the most celebrated adventurers in the mythology of Persia is *Tabunara*, one of their most ancient monarchs. This prince performs a variety of exploits, while he endeavours to recover the fairy *Merjan*. He attacks the *Dive Demruft* in his own cave; where, having vanquished the giant or demon, he finds vast piles of hoarded wealth: these he carries off with the fairest captive. The battles, labours, and adventures of *Roftan*, another Persian worthy, who lived many ages after the former, are celebrated by the Persian bards with the fame extravagance of hyperbole with which the labours of *Hercules* have been sung by the poets of Greece and Rome.

The adventures of the Persian heroes breathe all the wildness of achievement recorded of the knights of Gothic romance. The doctrine of enchantments, transformations, &c. exhibited in both, is a characteristic symptom of one common original. Persia is the genuine classic ground of eastern mythology, and the source of the ideas of chivalry and romance: from which they were propagated to the regions of Scandinavia, and indeed to the remotest corners of Europe towards the west.

Perhaps our readers may be of our opinion, when we offer it as a conjecture, that the tales of the war of the *Peri and Dives* originated from a vague tradition concerning good and bad angels: nor is it, in our opinion, improbable that the fable of the wars between the gods and giants, so famous in the mythology of Greece and Italy, was imported into the former of these countries from the same quarter. For a more particular account of the Persian mythology, our readers may consult Dr Hyde de Relig. vet. Peri. Med. &c. D. Herbelet's *Bibl. Orient*, and Mr Richard-
laws and religious ceremonies, and explained to them the principles of mathematics, geometry and astronomy. In a word, he communicated to them every thing necessary, useful and ornamental: and so universal were his instructions, that not one single article had ever been added to them since the time they were first communicated. Helladius is of opinion that this strange performance, whoever he was, came to be represented under the figure of a fish, not because he was actually believed to be such, but because he was clothed with the skin of a seal. By this account our readers will see that the Babylonian Cunaxa is the exact counterpart of the Osiris of the Chaldees, and the Typhon or Mercury Trismegistus of the Egyptians. It is likewise apparent, that the idea of the monitor compounded of the man and the fish has originated from some hieroglyphic of that form grafted upon the appearance of man. Some modern mythologists have been of opinion that Cunaxa was actually Noah the great preacher of righteousness: who as some think, settled under the figure of a fish, not because he was regarded as a prophet from that people, we must be convinced that they also, as well as the other nations of the east, abounded in fabulous relations and romantic compositions. The natives of that country have always been enthusiastically addicted to poetry, of which fable is the essence. Wherever the muses have erected their throne, fables and miracles have always appeared in their train. In the Koran we meet with frequent allusions to well-known traditional fables. These had been transmitted from generation to generation by the bards and rhapsodists for the entertainment of the vulgar. In Arabia, from the earliest ages, it has always been one of the favourite entertainments of the common people, to assemble in the serene evenings around their tents, or on the platforms with which their houses are generally covered, or in large halls erected for the purpose, in order to amuse themselves with traditional narrations of the most distinguished actions of their most remote ancestors. Oriental imagery always embellished their romantic details. The glow of fancy, the love of the marvellous, the propensity towards the hyperbolic, and the vaft, which constitute the essence of oriental description, must ever have drawn the relation aside into the devious regions of fiction and fairy-land. The religion of Mahomet beat down the original fabric of idolatry and mythology together. The Arabians fables current in modern times, are borrowed or imitated from Persian compositions; Persia being full the grand nursery of romance in the east.

In Egypt we find idolatry, theology, and mythology, almost inseparably blended together. The inhabitants of this region, too, as well as of others in the vicinity of the centre of population, adored for several centuries to the worship of the true God. At last, however, conscious of their own ignorance, impurity, imperfection, and total unfitness to approach an infinitely perfect Being, distant, as they imagined, and invisible, they began to cast about for some beings more exalted and more perfect than themselves, by whose mediation they might prefer their prayers to the supreme Majesty of heaven. The luminaries of heaven, which they imagined were animated beings, naturally presented themselves. These were splendid and glorious beings. They were thought to partake of the divine nature: they were revered as the saviors,
M Y T H O L O G Y.

prefects, and representatives of the supreme Lord of the
universe. They were visible, they were benefi-
cient; they dwelt nearer to the gods, they were near
at hand, and always accessible. These were, of course,
employed as mediators and intercessors between the
supreme Divinity and his humble subjects of this lower
world. Thus employed, they might claim a subordinate
share of worship, which was accordingly assigned to
them. In course of time, however, that worship, which
was originally addressed to the Supreme Deity
by the mediation of the heavenly bodies, was in a
great measure forgotten, and the adoration of man-
kind ultimately terminated on those illustrious crea-
tures. To this circumstance, we think, we may ascribe
the origin of that species of idolatry called Zabifs, or
the worship of the host of heaven, which overspread
the world early and almost universally. In Egypt
this mode of worship was adopted in all its most ab-
surd and most enthusiastic forms: and at the same
time the most heterogeneous mythology appeared in,
its train. The mythology of the ancient Egyptians
was so various and multiform, so complicated and so
mysterious, that it would require many volumes even
to give a superficial account of its origin and progress,
not only in its mother country, but even in many oth-
ner parts of the eastern and western world. Besides,
the idolatry and mythology of that wonderful country
are so closely connected and so inseparably blended to-
gether, that it is impossible to describe the latter with-
out at the same time developing the former. We hope,
therefore, our readers will not be disappointed if, in
a work of this nature, we touched only upon some of
the leading or most interesting articles of this compli-
cated subject.

The Egyptians confounded the revolutions of the
heavenly bodies with the reigns of their most early
monarchs. Hence the incredible number of years in-
cluded in the reign of their eight superior gods, who,
according to them, filled the Egyptian throne succe-
sively in the most early periods of time. To these,
according to their system, succeeded twelve demigods,
who likewise reigned an amazing number of years.
These imaginary reigns were no other than the perio-
dical revolutions of the heavenly bodies preferred in
their almanacks, which might be carried back, and actu-
ally were carried back, at pleasure. Hence the fab-
ulous antiquity of that kingdom. The imaginary
exploits and adventures of these gods and demigods
furnished an inexhaustible fund of mythological ro-
mances. To the demigods succeeded the kings of the
cyclic cycle, perfomages equally chimerical with the
former. The import of this ephebet has greatly per-
plexed critics and etymologists. We apprehend it
is an oriental word importing royal dignity, elevation of
rank. This appellation intimated, that the mon-
archs of that cycle, admitting that they actually ex-
isted, were more powerful and more highly revered
than their successors. After the princes of the cyclic
cycle comes another race, denominated Nebthes, a title
likewise implying royal, splendid, glorious. These
cycles figure high in the mythological annals of the
Egyptians, and have furnished materials for a variety
of learned and ingenious disquisitions. The wars and
adventures of Osiris, Orus, Typhon, and other alle-
gorical personages who figure in the Egyptian rubric;
the wanderings of Isis, the sifter and wife of Osiris;
the transformation of the gods into diverse kinds of
animals; their birth, education, peregrinations, and
exploits; compose a body of mythological fictions
so various, so complicated, so ridiculous, and often so
apparently absurd, that all attempts to develop and
explain them have hitherto proved unsuccessfuL All,
the greatest part of those extravagant fables, are the
offspring of hieroglyphical emblematic symbols de-
vised by the priests and sages of that nation, with
a view to conceal the mysteries of their religion from
that class of men whom they stigmatized with the name
of the unintituated rabbles.

The worship of brute animals and of certain vege-
tables universal among the Egyptians, was another ex-
ample of the same source of mythological adventures. The E-
imals, &c, Egyptians, many of whom were likewise profound
philosophers, observed or pretended to observe, a kind
of analogy between the qualities of certain animals and
vegetables, and those of some of their subordinate di-
vinities. Such animals and vegetables they adopted,
and consecrated to the deities to whom they were sus-
pensed to bear this analogical resemblance: and in pro-
cess of time they considered them as the visible emblems
of those deities to which they were consecrated. By
these the vulgar addressed their archetypes: in the same
manner, as in other countries, pictures and statues were
employed for the very same purpose. The mob, in
process of time, forgetting the emblematical character
of those brutes and vegetables, addressed their devotion
immediately to them; and of course these became the
ultimate objects of vulgar adoration.

Aft after these objects, animate or inanimate, were
consecrated as the visible symbols of the deities, it soon
became fashionable to make use of their figures to re-
prent those deities to which they were consecrated.
This practice was the natural consequence of the hier-
oglyphical style which universally prevailed among
the ancient Egyptians. Hence Jupiter Ammon was
represented under the figure of a ram, Apis under that of
a cow, Osiris of a bull, Pan of a goat, Thoth or
Mercury of an ibis, Bubastis or Diana of a cat, &c.
It was likewise a common practice among those de-
clined to people to dignify these objects, by giving them
the names of those deities which they represented.
By
this mode of dignifying these sacred emblems, the
veneration of the rabble was considerably enhanced,
and the ardour of their devotion inflamed in propor-
tion. From these two sources, we think, are derived
the fabulous transformations of the gods, so generally
celebrated in the Egyptian mythology, and from it
imported into Greece and Italy. In consequence of
this practice, their mythological system was rendered
at once enormous and unintelligible.

Their Thoth, or Mercury Trismegistus, was, in our
opinion, the inventor of this unhappv system. This
Trismegist-
us was the origi-
nal author of letters, geometry, astrononuy, music, ar-
culture in a word, of all the elegant and useful
arts, and of all the branches of science and philosophy.
He it was who first discovered the analogy between
the divine affections, influences, appearances, opera-
tions, and the corresponding properties, qualities, and
indincts
MYTHOLOGY.

infinite of certain animals, and the propriety of dedicating particular kinds of vegetables to the service of particular deities.

The priests, whose province it was to expound the mysteries of that allegorical hieroglyphical religion (see Mysterie), gradually lost all knowledge of the primary import of the emblematical characters. To supply this defect, and at the same time to veil their own ignorance, the fardelous instructors had recourse to fable and fiction. They heaped fable upon fable, till their religion became an accumulated chaos of mythological absurdities.

Two of the most learned and most acute of the ancient philosophers have attempted a rational explication of the latent import of the Egyptian mythology; but both have failed in the attempt; nor have the moderns, who have laboured in the same field, performed their part with much better success. Instead, therefore, of prosecuting this inexplicable subject, which we shall dwell this article beyond all proportion, we must beg leave to refer those who are desirous of further information to the following authors, where they will find enough to gratify their curiosity, if not to inform their judgment: Herodotus, lib. ii. Diodorus Siculus, lib. ii. Plut. Isis and Osiris; Jamblicitus de Myth. Egypt. Horapollo Hieroglypis. Egypt. Macrobi. Sat. cap. 23. among the ancients; and among the moderns, Kircher’s Oedip. Voifi. de orig. et prog. Idol. Mr. Bryant’s Annals of Anc. Mythol. Mont. Gebelin Monde prin. and above all, to the learned Jahnblot’s Panh. Egyptiurn.

The elements of Phoenician mythology have been preserved by Enoebin, Prep. Evang. sub. init. In the large excerpt which that learned father hath copied from Philo Bibilius’s translation of Sanchoniathos’s History of Phoenicia, we are furnished with several articles of mythology. Some of these throw considerable light on several passages of the sacred history; and all of them are distinctly connected with the mythology of the Greeks and Romans. There we have preferred a brief but entertaining detail of the fabulous adventures of Uranus, Cronus, Dagon, Thoth or Mercury, probably the same with the Egyptian hero of that name. Here we find Muth or Pluto, Aephectus or Vulcan, Ekelapius, Nereus, Poseidon or Neptune &c. Atlaire, or Venus Urania, makes a conspicuous figure in the catalogue of Phoenician worthies: Pallas or Minerva is planted on the territory of Attica; in a word, all the branches of the family of the Titans, who in after ages figured in the rubric of the Greeks, are brought upon the stage, and their exploits and adventures briefly detailed.

By comparing this fragment with the mythology of the Atlanteans and that of the Cretans preferred by Diodorus the Sicilian, lib. vi. we think there is good reason to conclude, that the family of the Titans, the several branches of which seem to have been both the authors and objects of a great part of the Grecian idolatry, originally emigrated from Phoenicia. This conjecture would receive additional strength, when it is considered, that almost all their names recorded in the fabulous records of Greece, may be easily traced up to a Phoenician original. We agree with Herodotus, that a considerable part of the idolatry of Greece may have been borrowed from the Egyptians; at the same time, we imagine it highly probable, that the idolatry of the Egyptians and Phoenicians were, in their original constitution, nearly the same. Both systems were Sabian, or the worship of the host of heaven. The Pelagi according to Herodotus, learned the names of the gods from the Egyptians; but in this conjecture it is certain was warped by his partiality for that people. Had those names been imported from Egypt, they would no doubt have bewrayed their Egyptian original; whereas, every etymologist will be convinced that every one is of Phoenician extraction.

The adventures of Jupiter, Juno Mercury, Apollo, Diana, Mars, Minerva, or Pallas, Venus, Bacchus, Ceres, Proserpine, Pluto, Neptune, and the other descendants and coadjuvants of the ambitious family of the Titans, furnih by far the greatest part of the mythology of Greece. They left Phoenicia, we think, about the age of Moses; they settled in Crete, a large and fertile island; from this region they made their way into Greece, which, according to the most authentic accounts, was at that time inhabited by a race of savages. The arts and inventions which they communicated to the natives; the mystic arts of which the ancients were so inculcated; the laws, customs, polity, and good order, which they established; in short, the blessings of humanity and civilisation, which they everywhere disseminated in proofs of time, inspired the unpolished inhabitants with a kind of divine admiration. Those ambitious mortals improved this admiration into divine homage and adoration. The greater part of the worship, which had been formerly addressed to the luminaries of heaven, was now transferred to those illustrious personages. They claimed and obtained divine honours from the deluded rabble of enthusiastic Greeks. Hence sprang an inexhaustible fund of the most inconsistent and irreconcilable fictions.

The fables and frailties of the deified mortals were hence transmitted to posterity, incorporated as the pompous attributes of supreme divinity. Hence the heterogeneous mixture of the mighty and the mean which cheques the characters of the heroes of the Iliad and Odyssey. The Greeks adopted the oriental fables; the import of which they did not understand. These they accommodated to heroes and illustrious personages, who had figured in their own country in the earliest periods. The labours of Hercules originated in Egypt, and evidently relate to the annual progress of the sun in the zodiac, though the vain glorius Greeks accommodated them to a hero of their own, the reputed son of Jupiter and Alcmena. The expedition of Osiris they borrowed from the Egyptians, and transferred to their Bacchus, the son of Jupiter and Semle the daughter of Cadmus. The transformation and wanderings of Io are evidently transcribed from the Egyptian romance of the travels of Isis in quest of the body of Osiris, or of the Phoenician Atlaire, drawn from Sanchoniathos. Io or Is is in reality the Egyptian name of the moon; and Atlaire was the name of the same planet among the Phoenicians. Both these fables are allegorical representations of the anomalies of the lunar planet, or perhaps of the progress of the worship of that planet in different parts of the world. The fable of the configuration occasioned by Phaeton is clearly of oriental extraction, and alludes to an excessive drought which in the early periods.
periods of time scorched Ethiopia and the adjacent countries. The fabulous adventures of Perseus are said to have happened in the same regions, and are allegorical representations of the influence of the solar luminary; for the original Perseus was the sun. The rape of Proserpine and the wanderings of Ceres: the Eleusinian mysteries; the oria or sacred rites of Bacchus; the rites and worship of the Cabiri—were imported from Egypt and Phenicia; but strangely garbled and disfigured by the Hierophants of Greece. The gigantic, or war between the gods and the giants, and all the fabulous events, and varieties of that war, form an exact counterpart to the battles of the Peri and Dives, celebrated in the romantic annals of Persia.

The Greeks A considerable part of the mythology of the Greeks sprang from their ignorance of the oriental languages. They disdained to apply themselves to the study of languages spoken by people whom, in the pride of their heart, they stigmatized with the epithet barbarians. This aversion to every foreign dialect was highly detrimental to their progress in the sciences. The same neglect or aversion has, we imagine, proved an irreparable injury to the republic of letters in all succeeding ages. The aoids or strolling bards laid hold on those oriental legends, which they sophificated with their own additions and improvements, in order to accommodate them to the popular taste. These wonderful tales figured in their rhapsodical compositions, and were greedily swallowed down by the credulous vulgar. These fictions, as they rolled down, were constantly augmented with fresh materials, till in process of time their original import was either forgotten or buried in impenetrable darkness. A multitude of these Hefiod has collected in his Theogonia, or generation of the gods, which unhappily became the religious creed of the illiterate part of the Greeks. Indeed, fable was fo closely interwoven with the religion of that airy volatile people, that it seems to have contaminated not only their religious and moral, but even their political tenets.

The celebrated oracle of Dodona was copied from that of Ammon of Thebes in Egypt: The oracle of Apollo at Delphos was an emanation from the same source: The celebrated Apollo Pythius of the Greeks was no other than Od or Aub of the Egyptians, who denounced the baflfick or royal snake Oui Cai, because it was held sacred to the sun. Od or Aub is still retained in the Coptic dialect, and is one of the many names or epithets of that luminary. In short, the groundwork of the Greek mythology is to be traced in the eel. Only a small part of it was fabricated in the country; and what was imported pure and genuine was miserably sophificated by the hands through which it passed, in order to give it a Grecian air, and to accommodate its style to the Grecian taste. To enlarge upon this topic would be altogether superfluous, as our learned readers must be well acquainted with it already, and the unlearned may without much trouble or expense furnish themselves with books upon that subject.

The Roman mythology was borrowed from the Greeks. That people had addicted themselves for many centuries to the arts of war and civil polity, science and philosophy were either neglected or unacknowledged. At last they conquered Greece, the native land of science, and then "Greece capta ferum, victor empi arte at intulit agrifeti Latii." This being the case, their mythology was, upon the whole, a transcript from that of Greece. They had indeed gleaned a few fables from the Pelagi and Hetruicans, which, however, are of so little consequence, that they are scarcely worth the trouble of transcribing.

The mythology of the Celtic nations is in a good measure lost. There may possibly still remain some vestiges of the Druidical superstitious in the remotest parts of the Highlands and islands of Scotland; and perhaps in the uncivilized places of Ireland. These we presume, would afford our readers little entertainment, and still less instruction. Instead therefore of giving a detail of those uninteresting articles, we shall beg leave to refer our readers to Ollan's Poems, and Col. Valency's Collections of Irish Antiquities, for satisfaction on that subject.

The mythology of the northern nations, i.e. of the Norwegians, Danes, Swedes, Icelanders, &c. are uncommonly curious and entertaining. The Edda and Volupa contain a complete collection of fables which have not the smallest affinity with those of the Greeks and Romans. They are wholly of an oriental complexion, and seem almost congenial with the tales of the Perisans above described. The Edda was compiled in Iceland in the 13th century. It is a kind of Sylen of the Scandinavian mythology: and has been reckoned, and we believe justly, a commentary on the Volupa, which was the Bible of the northern nations. Odin or Othin, or Woden or Waden, was the supreme divinity of those people. His exploits and adventures furnish the far greatest part of their mythological creed. That hero is supposed to have emigrated from the east; but from what country or at what period is not certainly known. His achievements are magnified beyond all credibility. He is represented as the god of battles, and as slaying thousands at a blow. His palace is called Valhal: it is situated in the city of Midgard, where, according to the fable, the souls of heroes who had bravely fallen in battle enjoy supreme felicity. They spend the day in mimic hunting-matches, or imaginary combats. At night they assemble in the palace of Valhalla, where they feast on the most delicious viands, dressed and served up by the Valkyries, virgins adorned with celestial charms, and flushed with the bloom of everlasting youth. They obliterate themselves with drinking mead out of the ikulls of enemies whom they killed in their days of nature. Meat, it seems, was the nectar of the Scandinavian heroes.

Sleeping, the horse of Odin, is celebrated along with his matter. Heia, the Hell of the Scandinavians, affords a variety of fables equally shocking and heterogeneous. Loke, the evil genius or devil of the northern people, nearly resembles the Typhon of the Egyptians. Sigma or Sina is the comfort of Loke; from this name the English word fa is derived. The giants Weymur, Ferbanter, Belopher, and Helhunda, perform a variety of exploits, and are exhibited in the most frightful attitudes. One would be tempted to imagine, that they perform the exact counterpart of the giants of the Greek and Roman mythologies. Instead of glancing at these ridiculous and uninteresting fables,
MYTHOLOGY.

In America, the only countries must be Mexico and Peru. The other parts of that large continent were originally inhabited by savages, most of them as remote from religion as from civilization. The two vast empires of Mexico and Peru had existed about 400 years only before the Spanish invasion. In neither of them was the use of letters understood; and of course the ancient opinions of the natives relating to the origin of the universe, the changes which succeeded, and every other monument of antiquity, was obliterated and lost. Clavigero has indeed enumerated a vast number of singular gods worshipped by the Mexicans; but produces nothing either entertaining or interesting with respect to their mythology. The information to be derived from any other quarter is little to be depended upon. It passes through the hands of bigoted missionaries or other ecclesiastics, who were so deeply infatuated with fanaticism, that they viewed every action, every sentiment, every custom, every religious opinion and ceremony of those half civilized people, through a false medium. They often imagined they discovered resemblances and analogies between the rites of those savages and the dogmas of Christianity, which too weakly excite but in their own heated imagination.

The only remarkable piece of mythology in the annals of the Peruvians, is the pretended existence of Manco Capac the first Inca of Peru, and of Rama Oculla his consort. These two illustrious personages appeared first on the banks of the lake Titicaca. They were persons of a majestic stature, and clothed in decent garments. They declared themselves to be the children of the Sun, sent by their beneficent parent, who beheld with pity the miseries of the human race, to instruct and to reclaim them. Thus we find these two legislators availed themselves of a pretence which had often been employed in more civilized regions to the very same purposes. The idolatry of Peru was gentle and beneficent, that of Mexico gloomy and singular. Hence we may see, that every mode of superstition, where a divine revelation is not concerned, borrows its complexion from the characters of its professors.

In the course of this article, our readers will observe that we have not much enlarged upon the mythology of the Greeks and Romans; that subject, we imagine to be so universally known by the learned and so little valued by the vulgar, that a minute discussion of it would be altogether superfluous. Besides, we hope it will be remembered that the narrowness of the limits precluded us would fear not admit of a more copious detail. We would flatter ourselves, that in the course of our disquisitions we have thrown out a few reflections and observations, which may perhaps prove more acceptable to both descriptions of readers.

44 Mytilus, the Mussel, in ichthyology: a genus of animals, belonging to the order of vermes teffacea. The animal is an affida: the shell bivalve often affixed to some substance by a beard; the hinge without a tooth, marked by a longitudinal hollow line. Of these animals there are a great many species, some of them inhabiting the seas, others the rivers and ponds. Several of them are remarkable for the beauty of their internal shell, and for the pearls which are sometimes found in them.

1. The edulis, or edible mussel, has a strong shell, slightly incurved on one side, and angulated on the other.
The modiolus, or great mussel, with a strong shell, blunted at the upper end; one side angulated near the middle; from thence dilating towards the end, which is rounded. It dwells in the Mediterranean, Indian, European, and American seas: and its shell, which is a deep orange colour, is eatable. It is the greatest of the mussels known in Britain; being from six to seven inches in length; it lies at great depths; often seizes the baits of ground-lines, and is taken up with the hooks.

The cygnus, or swan mussel, with a thin brittle shell, very broad and convex, marked with concentric furrows; attenuated towards one end, dilated towards the other; decorticated about the hinge; the colour a dull green; the length six inches, breadth three and a half. It is an inhabitant of the European rivers, frequented chiefly their mouths.

The anatina, or duck mussel, has a shell more oblong and less convex than the last; is very brittle and semitransparent; the space round the hinges like the last; the length about five inches, breadth two. It is found in Europe in fresh waters. Both it and the cygnus are devoured by swans and ducks; whence their names; crows also feed on these mussels, as well as on different other shell fishes: and it is diverting to observe, that when the shell is too hard for their bills they fly with it to a great height, drop the shell on a rock, and pick out the meat when the shell is fractured by the fall.

The cryttagalli, or cock's-comb mussel, has the shell folded or plaited as it were, spinous, and both lips rugged. It makes its abode the coral beds of the Indian ocean.

The margaritiferus, or pearl bearing mussel, has the shell compressed and flat, nearly orbicular, the base transversely, and imbricated with dentated coats. It dwells in the ocean of either India. This is the murrea-pearlum of Rumphius, or mother-of-pearl shell. On the inside it is exquisitely polished, and of the whitenss and water of pearl itself. It has also the same lustre on the outside after the external epidermis have been taken off by aquafortis and the lapidary's mill. Mother-of-pearl is used in inlaid works, and in several toys, as nutcrackers, &c.

The lithophagus, or stone-eating mussel, has the shell cyllindric, the extremities both ways being rounded. It inhabits the Indian, European, and Mediterranean seas, penetrating and eating away marbles, &c. The Indian shell is softer and nearly tough like leather, but the European is more brittle.

The violaceus, or violet mussel, has the shell longitudinally furrowed, the rim very obtuse, somewhat formed like the mytilus edulis, but considerably larger and more flattened, of a beautiful violet colour. It inhabits the southern ocean. There are about 50 other species.

Mussels not only open and shut their shells at pleasure, but they have also a progressive motion; they can fasten themselves where they please; they respire water like fishes; and some even flutter about on its surface so as to inhale air. If they lie in shallow places, a small circular motion is seen above the heel of the shell: and a few moments after, they cast out the water by one single stroke at the other end of the shell. The mouth is situated near the sharp angle of the animal, and is furnished with four floating fringes in the shape of multiochios which may perhaps answer the purpose of lips. The bars which surround the edge of almost half the mussel, are a wonderful web of hollow fibres which serve as fins or organs of respiration, as vessels for the circulation of the fluids, and probably, as some philosophers suppose, as wedges for opening their shells; for we observe two large muscles or tendons for the purpose of swelling them; but we in vain look for their antagonists, or those which are defined to open them. When the mussel wishes to open itself, it relaxes the two muscles or tendons, and swells the fringes, which act as wedges and separate the shells. The animal fits up itself by the contraction of two thick fibrous muscles which are fixed internally to each end of the shells; and these shells are lined all around with a membrane or epidermis, which unites them so closely together when they are soaked in water, that not the smallest drop can escape from the mussel. When mussels choose to walk (a), they often contrive to raise themselves on the sharp edge of their shells, and put forth a feathery substance susceptible of extension, which serves them as a leg to drag themselves along, in a kind of groove or furrow which they form in the sand or mud, and which supports the shell on both sides. In ponds, these furrows are very observable. From the same member or leg hanging the threads...
The experiment proved the power of fastening themselves either to stones, or to another’s shells, in a very strong and firm manner; but the method of doing this was not well understood till the observations of Mr. Reaumur explained it. Every one who opens and examines a common mussel, will find, that in the middle of the fish there is placed a little blackish or brownish body resembling a tongue. This is large mussels is near half an inch long, and a little more than the sixth of an inch in breadth, and is narrower at the origin than at the extremity: from the root of this tongue, or that part of it which is fastened to the body of the fish, there are produced a great number of threads, which, when fixed to any solid substance, hold the mussel firmly in its place; these threads are usually from an inch to two inches in length, and in thicknesses from that of a hair to that of a hog’s bristle. They issue out of the shell in that part which is naturally open, and fix themselves to any thing that lies in their way, to stones, to fragments of shells, or which is the most common case, to the shells of other mussels: whence it happens that there are usually such large quantities of mussels found together. These threads are expanded on every side, and are usually very numerous, 150 having been found sitting from one shell: they serve the office of so many cables; and, each pulling in a proper direction, they keep the mussel fixed against any force that can be offered from whatever part it come. The filaments are well known to all who eat mussels, who ever carefully separate them under the name of the beard; and Mr. Reaumur has found that while the animal is living in the sea, if they are all torn away by any accident, the creature has a power of substituting others in their room; he found that if a quantity of mussels were detached from one another and put into a vessel of any kind, and in that plunged into the sea, they in a little time fastened themselves both to the sides of the vessel and to one another’s shells; the extremity of each thread seemed in this case to serve in the manner of a hand to seize upon any thing that it would fix to, and the other part, which was slender and smaller, to do the office of an arm in conducting it.

To know the manner of the mussels performing this operation, this diligent observer put some mussels into a vessel in his chamber, and covered them with sea water; he there saw that they soon began to open their shells, and each put forth that little body, before described by its resemblance to a tongue, and at the root of which these threads grow; they extended and shortened this part several times, and thrust it out every way, often giving it not less than two inches in length, and trying before, behind, and on every side with it, what were the proper places to fix threads at: at the end of these trials, they let it remain fixed for some time on the spot which they chose for that purpose, and then drawing it back into the shell with great quickness, was easy to see that they were then fastened by one of these threads to the spot where they had before touched and remained fixed for a few minutes; and in repeating this workmanship the threads are increased in number one at every time, and being fixed in different places they sustain the fish at rest against any common force.

The several threads were found to be very different from one another; the new formed ones being ever whiter, more glossy, and more transparent than the others: and it appeared on a close examination, that it was not, as might have been most naturally supposed, the office of the tongue to convey the old threads one by one to the new places where they now were to be fixed, but that these in reality were now become useless; and that every thread we see now formed, is a new one made at this time; and in fine, that nature has given to some sea-urchins, as well as to many land-insects, a power of spinning those threads for their necessary use, and that mussels and the like fish are under water, what caterpillars and spiders are at land.

To be well assured of this, however, Mr. Reaumur cut off the beard or old threads of a mussel as close as he could, without injuring the part; and the proof of the opinion of their spinning new ones at pleasure was now brought to this easy trial, whether these mussels, so deprived of their old ones, could fix themselves as soon as others which were poisified of theirs, and cold throw out their threads to as considerable distances.

The experiment proved the truth of the conjecture; for those whose beards or old threads were cut off, fixed.
fixed to the shell of another. The fringed edge of the mussel, which Lewenhoeck calls the beard, has in every minute part of it such variety of motions as is inconceivable; for being composed of long fibres, each fibre has on both sides a vast many moving particles.

The mussel is infected by several enemies in its own element; according to Reaumur it is in particular the prey of a small shell-fish of the trochus kind. This animal attaches itself to the shell of the mussel, pierces it with a round hole, and introduces a fort of tube five or fix lines long, which it turns in a spiral direction, and with which it sucks the substance of the mussel. Muscles are also subject to certain diseases, which have been supposed to be the cause of those bad effects which sometimes happen from the eating of them. These are directed by Dr Meckring, in the 7th vol. of the German Ephemerides, to be the mops and the scab. The roots of the mops being introduced into the shell the water penetrates through the openings, and gradually dissolves the mussel. The scab is formed by a fort of tubercles which are produced by the dissolution of the shell. Certain small crabs, which are sometimes found in muscles, likewise tend to make them unwholesome.

The

fixed themselves as soon as those in which they were left, and spread their threads to as great a distance every way.

When the mechanism of this manufacture was thus far understood, it became a natural desire to inquire into the nature of the part by which it was performed. This has hitherto been mentioned under the name of the tongue, from its shape; but it is truly the arm of the fifth; and whenever it happens to be loosened from its company, or fixed in a wrong place, it serves the animal to drag its whole body shell and all along, and to perform its several motions. It fixes itself to some solid body; and then strongly contracting its length, the whole fifth must necessarily follow it, and be pulled towards the place where it is fixed. This is an arm, however, that this part is so rarely put to, that it is not properly to be esteemed a leg or an arm for this; but, according to its more frequent employment, may much better be denominated the organ by which the threads are spun. Though this body is flat in the manner of a tongue for the greater part of its length, it is however rounded or cylindrical about the base or insertion, and it is much smaller there than in any other part: there are several muscular ligaments fastened to it about the root or base, which hold it firmly against the middle of the back of the shell; of these ligaments there are four which are particularly observable, and which serve to move the body in any direction. There runs all along this body a slit or crack, which pierces very deeply into its substance, and divides it as it were into two longitudinal sections; this is properly a canal, and along this is thrown the liquor which serves to form the threads; and it is in this canal or slit that these threads are moulded into their form. Externally, this appears only a small crack or slit, because the two flabby fleshes of the parts almost meet and cover it; but it is rounded and deep within, and is surrounded with circular fibres. This canal is carried regularly on from the tip of the tongue, as it is called, to its base, where it becomes cylindrical; the cylinder in this part being no other than a close tube or pipe, in which this open canal terminates. The cylindrical tube contains a round oblong body, of the nature of the threads, except that it is much larger; and from the extremity of this all the threads are produced, this serving as a great cable to which all the other little cordages derivered towards different parts are fixed. The tube or pipe in which this large thread is lodged, seems the reservoir of the liquor of which the other threads are formed; all its internal surface being furnished with glands for its secretion.

The mussel, like many other sea-fishes, abounds in this liquor; and if at any time one touch with a finger the base of this spinning organ, one draws away with it a viscous liquor in form of several threads, like those of the caterpillar, spider, and the other spinning land-animals. The threads fix themselves with equal ease to the most smooth and glossy, as to rougher bodies; if the muscles are kept in glass-jars of sea-water, they as firmly fasten themselves to the glass as to any other body. Muscles, be they ever so young, have this property of spinning; and by this means they fasten themselves in vast numbers to any thing which they find in the sea. Mr Reaumur has seen them, when as small as millet-seeds, spin plentifully, though their threads, proportioned to their own weight, are much finer and smaller than those of larger muscles.
The eating of mussels has sometimes produced erysipelas, eruptions, and itching all over the body, great restlessness and agitation; and though these complaints are easily removed by oil, milk, and emetics, and have seldom or never proved mortal, yet they have an alarming aspect, and make the patient suffer grievously. These noxious effects have been supposed to be owing to the mussels or part of them having been diseased. Some authors however have pretended that these effects never take place but between the vernal and autumnal equinox: and M. Bennie, physician at Antwerp, in a memoir on this subject, seems inclined to adopt this opinion; for he recommends abstinence from mussels during the months of May, June, July, and August. The cause of these noxious effects in the mussel is, according to this author, altogether accidental. They are occasioned, he says, by a kind of flelta marina, a little sea insect pretty common about the mouth of the Scheldt, which sometimes lodges itself in the mussel in quest of food; and whose spawn is so caustic and inflammatory, that, even when applied outwardly to the skin, it produces itching and swellings that are painful in a high degree. The itching occasioned by touching the spawn of the flelta marina is removed by vinegar; and this known fact induced Dr. Bennie to prescribe the internal use of vinegar, after bleeding, evacuations, and emetics. His method consists in recommending a large quantity of refreshing beverage, and, every hour, three ounces of vinegar diluted in water. The remedy, however, seems rather to confirm the opinion of those who impute the disorder in question to an unperceived commencement of putrefaction in the mussel; as vinegar is known to be a powerful antiseptic, and there is no sort of putrefaction more noxious and offensive than that of fish.—Upon the whole, the edulis, or eatable mussel, though a rich food, is difficult of digestion. In its best state it is even noxious to some constitutions; and when affected by disease is in some degree poisonous. Mussels are apt to do most harm when eaten raw. They ought always to be boiled with onions, well washed with vinegar, and seasoned with pepper; and even thus qualified, they should not be eaten too often or too frequently.

MYT

The n is a nasal consonant; its sound is that of a, paffed through the nose; so that when the nose is stopped by a cold, or the like, it is usual to pronounce d for n. M. l'Abbe de Dangeau observes, that in the French, the n is frequently a mere nasal vowel, without any thing of the consonant in it. He calls it the Slavonic vowel. The Hebrews call their n nun, which signifies child, as being supposed the offspring of m; partly on account of the resemblance of sound, and partly on that of the figure. Thus from the n, by omitting the last column, is formed m; and thus from the capital N, by omitting the first column, is formed the Greek minucex. Hence for biennem, &c. the Latins frequently use limus; &c. and the same people convert the Greek λ, at the end of a word, into an m, as γαμυτος, pharmacum, &c. See M.

N before p, b, and m, the Latins change into m, and frequently into f and r: as in italia, illids, inrigs.
NAB [614] NAB

NABARD, NABARD, NABARD, or N Nabard, (anc. geog.), a town situated on the confines of Syria and Mesopotamia, and Babylonians; populous, and with a rich and extensive territory, not easily to be attacked by an enemy, being surrounded on all sides by the Euphrates and strong walls (Josephus). In the lower age the Jews had a celebrated school there.

NAAS, a borough and port town of Ireland, in the county of Kildare, and province of Leinster. It is the chief town of that county, and alternately with Athy the affixes town. It is distant above 15 miles south west of Dublin, in N. Lat. 53° 10′ W. Long. 6° 50′. It sends two members to parliament; and gives title of viscount to the family of Burke. It has five fairs in the year.—This place was anciently the residence of the kings of Leinster; the name signifies "the place of elders." For here the states of that province assembled during the 6th, 7th, and 8th centuries, after the Nafleighan of Carmen had been mathematicalized by the Christian clergy. On the arrival of the English it was fortified; many castles were reared, the ruins of which are still visible; and parliaments were held there. At the foot of the mount or rath are the ruins of a house founded in 1484, for emerites of the order of St. Augutin. In the 17th century the lord of Naas founded a priory dedicated to St John the baptist, for Augutinian regular canons. In the centre of this town the family of Eiflace erected a monastery for Dominican friars, dedicated to St. Euflacbus; and it appears that their possessions in Naas were granted them in the year 1355. This place was a strong hold during the civil wars.

NABATENE, or REGIO NABATRORUM, according to Jerome, comprised all the country lying between the Euphrates and the Red Sea, and thus contained Arabia Deserta, with a part of the Petrae; so called from Nabaitoth, the first born of Ismael. According to Dio­dorus, it was situated between Syria and Egypt. The people Nabati (i.e. Maccabees, Diodorus Siculus); inhabiting a desert and barren country; they lived by plundering their neighbours according to Diodorus. Nabathens the aciphet.

NABIS, tyrant of Sparta, reigned about 204 B.C.; and is reported to have exceeded all other tyrants so far, that upon comparison, he left the epithets of grateful and merciful to Dionysius and Phalaris. He is said to have contrived an instrument of torture in the form of a flame of a beautiful woman whose rich dress concealed a number of iron spikes in her bosom and arms. When any one therefore opposed his demands, he would say "If I have not talents enough to prevail with you, perhaps my woman Apega may peruse you." The statue then appeared; which Nabas taking by the hand, led up to the person, who being embraced by it, was thus tortured into compliance. To render his tyranny less unpopular, Nabas made an alliance with Flaminius the Roman general, and purdied with the most inverte enmity the war which he had undertaken against the Acha­eans. He befeiged Tyre, and defeated Philopela­men in a naval battle. His triumph was short, the general of the Achaean soon repaired his looses, and Nabas was defeated in an engagement, and killed as, he attempted to save his life by flight, about 194 years before the Christian era.

NABLOUS, a province of Syria anciently celebrated under the name of the kingdom of Samaria. Its capital, likewise called Nablus, is situated near to Sichem on the ruins of the Neopolis of the Greeks, and is the residence of a shah, who is subordinate to the pacha of Damascus, from whom he farms the tribute to the province.

NABLUM, in Hebrew, Nebel, was an instrument of music among the Jews; it had strings like the harp, and was played upon by both hands. Its form was that of a Greek v. In the Septuagint and vulgate, it is called nablum, psalterium, lyra; and sometimes cicibara.

NABO, or Neb, in mythology, a deity of the Babylonians, who presided over the next rank to Bel. It is mentioned by Isai. chap. xlviii. Voglios apprehends that Nabas was the moon, and Bel the Sun; but Grodias supposes that Nabas was some celebrated prophet of the country; which opinion is confirmed by the etymology of the name, signifying, according to Jerome, "one that presides over prophecy."

NABOB, properly NAB, the plural of Nab, a deputy. As used in Bengal, it is the same as Nazim. It is a title also given to the wives and daughters of princes, as well as to the princes themselves.

NABONASSAR, first king of the Chaldeans or Babylonians; memorable for the Jewish era which bears his name, which is generally fixed in 3257, beginning on Wednesday February 26th in the 3967th of the Julian period, 747 years before Christ. The Babylonians revolting from the Medes, who had overthrown the Assyrian monarchy, did, under Nabonassar found a dominion, which was much increased under Nebuchadnezzar. It is probable, that this Nabonassar is that Balaad in the second of Kings xx. 12. father of Merodach, who sent ambassadors to Hezekiah. See 2 Chron. xxxii.

NABOPOLASSAR, king of Babylon: he joined with Astyages the Mede, to destroy the empire of Ass­yria; which having accomplished, they founded the two empires of the Medes under Astyages, and the Chaldeans under Nabopolassar, 627 B.C.

NABUCHADNEZzar, or Nabuchodonosor, II. king of Assyria, son of Nabopolassar, and styled the Great, was associated by his father in the empire, 607 B.C.; and the following year he took Jehoiakim king
It is 'buried near it under an altar, admiration. Tarquin fragments left of his works he at length died, fed Metellus on account of the satyrical ridicule of the Romans of his preternatural power, cut a verse, and a great number of comedies: which cut with great diligence. He They were generally directly over our heads. But as he was admiring his own magnificence, and when they are red, black, &c. Their shapes are various; some refembling strawberries, others grapes, &c. Hieffer advises their removal by means of a ligature, a cautery, or a knife, as circumstances best suit.

As to the tumor called a wen, its different species are distinguished by their contents. They are encysted tumors; the matter contained in the first three following is infipid lymph, and that in the fourth is only fat. Mont. Lître was the first who particularly described the fourth kind; and to the following purpose he speaks of them all. A wen is said to be of three sorts, according to the kind of matter it contains: that whose contents resemble boiled rice, or curds, or a bread-poultice, is called atheroma; if it resembles honey, it is named meliteris; and if it is like fat, it is denominated flatoma; but there is a fourth sort, which may be called lipome, because of its fat contents resembling grease. He says that he has seen one on the shoulders of a man, which was a thin bag, of a tender texture, full of a soft fat, and that it had all the qualities of common grease. And though the fat in the lipome resembles that in the flatoma, yet they cannot be the same: for the matter of the flatoma is not inflammable, nor does it melt; or if it does, it is with great difficulty and imperfectly; whereas it is the contrary with the lipome. When the man who had the above named lipome was fattigued, or had drank freely of strong liquors, his lipome was inflamed for some days after, and its contents rarefy increased the size of the tumor.

The lipome seems to be no other than an enlargement of one or more of the cells of the adipose membrane, which is filled only with its natural contents. Its softness and largeness distinguish it in general from the other species, though sometimes the fatty contents will be so hard as to deceive. As this kind of wen does not run between the muscles, nor is posseffed of any considerable blood-veins, it may always be cut off with ease and safety.

As to the other kind of wens, their extirpation may or may not be attempted, according as their situation is with respect to adjacent vessels, the wounding of which would endanger the patient's life.

NAGERA, or Nagara, a town of Spain, in Old Caltilis, and the territory of RIOJA, with the title of a dutchy and fortress; famous for a battle fought in its neighbourhood in 1569. It is situated in a fertile country, on a brook called Naferilla. W. Long. 2. 20. N. Lat. 42. 25.

NAGRACUT, a town of India, the capital of a kingdom of the same name in the dominions of the Great
Nahum

Great Mogul, with a rich temple to which the Indians go in pilgrimage. It is seated on the river Ravi. E. Long. 78° 10'. N. Lat. 33° 12'.

NAHUM, or the Prophecy of Nahum, a canonical book of the Old Testament.

Nahum, the seventh of the 12 lesser prophets, was a native of Elkohai, a little village of Galilee. The subject of his prophecy is the destruction of Nineveh, which he describes in the most lively and pathetic manner: his style is bold and figurative, and cannot be exceeded by the most perfect masters of oratory. This prophecy was verified at the siege of that city by Assyges, in the year of the world 3378, 622 years before Christ.

NAIADES (nab. hijt.), certain inferior deities who presided over rivers, springs, wells, and fountains. The Naiades generally inhabited the country, and resorted to the woods or meadows near the stream over which they presided. They are represented as young and beautiful virgins, often leaning upon an urn from which flows a stream of water. Agle was the fairest of the Naiades, according to Virgil. Their name seems to be derived from nauin, to flow. They were held in great veneration among the ancients; and often sacrifices of goats and lambs were offered to them, with libations of wine, honey, and oil. Sometimes they received only offerings of milk, fruit, and flowers.

NAIANT, in heraldry, a term used in blazoning fitches, when borne in an horizontal posture, as if swimming.

NAIAS, in botany: A genus of the monandria order, belonging to the dicciae class of plants; and in the natural method ranking with those of which the order is doubtful. The male calyx is cylindrical and biform; the corolla quadrifid; there is no filament; nor is there any female calyx or corolla; there is one pistil; and the capsule is ovate and unilocular.

NAID, the interior of the great desert of Arabia, inhabited by a few scattered tribes of feebile and wretched Arabs. See Arabia.

NAIL, ungus, in anatomy. See there, no 81.

NAILS, in building, &c. small spikes of iron, brass, &c. which being drove into wood, serve to bind several pieces together, or to fasten something upon them. Nails were made use of by the ancient Hebrews for cancelling bonds; and the ceremony was performed by striking them through the writing. This seems to be alluded to in scripture, where God is said by our crucified Saviour to have "blotted out the handwriting of ordinances that was against us, and to have taken it out of the way, nailing it to his cross." Col. ii. 14.

For the cause and ceremony of driving the annual nail, or clavus annalis, among the Romans, see ANNUIS CLAVIS.

NAI, is also a measure of length, containing the 16th part of a yard.

NAILING OF CANNON. When circumstances make it necessary to abandon cannon, or when the enemy's artillery are feized, and it is not however possible to take them away, it is proper to nail them up, in order to render them useless: which is done by driving a large nail or iron spike into the vent of a piece of artillery, to render it un serviceable. There are various contrivances to force the nail out, as also sundry machines invented for that purpose, but they have never been found of general use; so that the best method is to drill a new vent.

One Gaifer Vimerculus was the first who invented the nailing of cannon. He was a native of Bremen and made use of his invention first in nailing up the artillery of Sigismond Malatesta.

NAIN (Lewis Belwi), one of the most learned and judicious critics and historians France has produced, was the son of a master of the requests, and born at Paris in 1637. At ten years old he went to school at Port Royal, and became one of the best writers of that institution. Sacy, his intimate friend and counsellor, prevailed with him in 1676 to receive the priesthood; which, it seems, his great humility would not before suffer him to aspire to. This virtue he seems to have possessed in the extreme; so that Boisfet, seeing one of his letters to father Damis with whom he had some little dispute, befought him merely "not be always upon his knees before his adversary, but raise himself now and then up." He was solicited to publish himself in the church, and Buzaval, bishop of Beauvais, wished to have him for his successor; but Nain, regardless of dignities, wished for nothing but retirement. In this he did indeed most effectually bury himself; and, joining the mortifications of a religious life to an indefatigable pursuit of letters, he wore himself entirely out, so as to die in 1698, aged 61, though he was formed for a longer life. His principal works are, 1. Memoirs on the ecclesiastical history of the first six ages of the church, 16 vols 4to. 2. The history of the emperors, 6 vols 4to. These works are deduced from original sources, and composed with the utmost fidelity and exactness.

NAIN or NAIM, situated at the bottom of mount Hermon on the north side, was anciently a city of the tribe of Issachar, in the province of Galilee. It was near the gates of this city that our Saviour reflored to life the only son of a widow, and where he inspired Mary Magdalene to come and mourn for her sins at his feet. These circumstances alone make this place worthy of notice: for at present Nain is only a hamlet inhabited by Christians, Mahometans, and Hebrews, where there is not a single monument to attract the curiosity of the traveller.

NAIRES, NAHERS, or NAIERS, in modern history, a name which is given by the Malabarians to the military of their country, who form a very numerous class or tribe, out of which the sovereigns of Malabar choose their body-guard.

NAIRN, a county of Scotland, comprehending the west part of Murray. It is bounded on the north by Murray frith, on the west and south by Inverness, and on the east by Elgin. The length of it amounts to 20 miles, and the breadth to 14. The air is temperate and salubrious, and the winters are remarkably mild.

The face of the country is rough and mountainous; yet there are some fruitful firths, or valleys, which produce good crops of oats and barley: but in general the country is much better adapted for pasture. Here are also large woods of fir, and other trees, that afford shelter to the game, of which there is great plenty. A firth is a long, narrow valley, with a river running through the bottom. Of these, the most remarkable
remarkable in this county, are Strathmarn, on the river 
of that name, in the south-west part of the shire; and 
on the south-east side, Strathlom, on both sides of 
Findhorn river. Nairn is well watered with burns, 
rivulets, and lakes, abounding with fish. In the southern 
part there is a small lake, called Aly, surrounding an 
island, on which there is a castle belonging to the lord 
of Minto; but the greater part of the shire is peopled 
by the Frasers, a warlike Highland clan, whose 
chief, the Lord Lovat, but his life on a scaffold for 
having been concerned in the late rebellion. There 
are a great number of villages; but few towns of note 
except Nairn, supposed to be the Tweed of Pohorny, 
situated at the mouth of the river which bears the same 
name; a royal borough, which gave a title of lord to 
an ancient family, forfeited in the rebellion of 1715. 
The harbour, which opened in the Murray frith, is 
now choked up with sand; and the commerce of the 
town is too inconsiderable to deserve notice. The 
people in general subsist by feeding sheep and black 
cattle. About four miles from Nairn stands the 
castle of Calder, on the river of that name, belonging to 
a branch of the family of Cumbell. In this 
neighbourhood we find a quarry of free-stone, and many 
signs of copper. About six miles to the north west 
of Nairn, a new fort has been lately built by order 
of the government, at a place called Ardosier, a small 
ithmus upon the Murray frith, which it is intended 
to command.

NAISSANT, in heraldry, is applied to any animal 
issuing out of the midst of some ordinary, and 
showing only his head, shoulders, fore-feet, and legs, 
with the tip of his tail; the rest of his body being hid in 
the shield, or some charge upon it; in which it differs 
from issuant, which denotes a living creature arising out 
of the bottom of any ordinary or charge. 
NAISSUS (anc. geog.) a town of Dardania, 
a district of Macedonia, said to be the birth-place 
of Constantine the Great, which seems probable from 
his often residing at that place. Naissian, the people 
(Coin). Now called Nijia, a city of Servia. E. Long. 
23° N. Lat. 43°.

NAKED SEEDS, in botany, those that are not inclu 
ded in any pod or cafe.

NAKIB, in the oriental dignities, the name of an 
officer who is a deputy to the calendicifer, or, as he 
may be called, the lord high chancellor of Egypt, 
appointed by the grand signior. His office is to carry 
the standard of Mahomet.

NAKOUS, an Egyptian musical instrument, made 
like two plates of brass, and of all sizes, from two 
inches to a foot in diameter; they hold them by strings 
fasted to their middles, and strike them together so 
as to beat time. They are used in the Coptic churches 
and in the Mahometan proceedings.

NAMA, in botany: A genus of the digynia or 
order, belonging to the pentandria class of plants: and 
in the natural method, ranking under the 13th order, 
Succulenta. The calyx is pentaphyllous, the corolla 
quinkquerate, the capsule molleculare and bivalved.

NAME, denotes a word whereby men have agreed 
to express some idea; or which serves to denote or 
signify a thing or subject spoken of. See Word. 
This the grammarians usually call a noun, nomen, 
Vol. XII.

though their noun is not of quite so much extent as 
our name. See Noun.

Seneca, Lib. II. de Beneficiis, observes that there are 
great number of things which have no name; and 
which, therefore, we are forced to call by other bor 
rrowed names. Ingenius (fays he) verum est, quae 
non nominant, quae cum praestis et appellatibus signant 
non passu, alius accommodatius at omnis: which may show 
why, in the course of this dictionary, we frequently 
give divers names to the same word.

Names are distinguished into proper and appellative.

Proper Names, are those which represent some 
individual thing or person, so as to distinguish it from all 
other things of the same species; as, Socrates, which 
represents a certain philosopher.

Appellative or General Names, are those which 
signify common ideas; or which are common to several 
individuals of the same species; as, botes, animal, man, 
oak, &c.

Proper names are either called Christian, as being 
given at baptism; or surnames: The first imposed for 
distinction of persons answering to the Roman pre 
nomen; the second, for the distinction of families, an 
twering to the nomen of the Romans, and the patrionymic 
ics of the Greeks.

Originally every person had but one name; as among 
the Jews, Adam, &c. among the Egyptians, Bcrfris; 
among the Chaldees, Nina; the Medes, Aflugae; 
the Greeks, Diomedes; the Romans, Romanus; the 
Gauls, Divinitus; the Germans, Ariovistus; the Bri 
ts, Cuffidones; the English, Hengist, &c. And thus 
of other nations, except those savages of Mount Atlas, 
whom Pliny and Marcellinus represent as amanis, 
"named ors.

The Jews gave the name at the circumcision; viz. 
eight days after the birth: the Romans, to females the 
first name, to males the ninth; at which time they 
held a feast, called nomis.

Since Christianity has obtained, most nations have fol 
lowed the Jews, baptizing and giving the name on the 
eighth day after the birth; except our English ances 
tors, who till of late, baptized and gave the name on the 
birth day.

The first imposition of names was founded on differ 
ent views, among different people; the most common 
was to mark the good wishes of the parents, or to ent 
itle the children to the good fortune a happy name 
seemed to promise. Hence, Victor, Caesar, Faustus, 
Statius, Probus, &c.

Accordingly, we find such names, by Cicero called 
bona nomen, and By Tacitus fauia nomen, were 
first enrolled and ranged in the Roman musters; first 
called to serve at the sacrifices, in the foundation of 
colonies, &c. And, on the contrary, Livy calls Atrius 
Umber, alominandi omnis nomen; and Plautus, on oc 
casion of a person named Lyco, i. e. " greedy wolf," 
says;

Vos sum nunc facete, quae dilectum est eum 
Quo-id fit dominus, cui Lyco nomen sit.

Hence, Plato recommends it to men to be careful in 
giving happy names; and the Pythagoreans taught 
expressly, that the minds, actions, and successes of men 
were according to their names, genius, and fate. Thus
Panormitan, ex bono nomine vivitur bona presumpitio; and the common proverb, Bonum nominis bonum omen: and hence the foundation of the onomomantia. See ONOMOMANTIA.

It is an observation deserving attention, says the Abbé Barthélemy, that the greater part of names found in Homer are marks of distinction. They were given in honour of the qualities most esteemed in the heroic ages. From the word pelema, which signifies war, have been formed Tlepolemus and Archepol, the names of two heroes mentioned in the Iliad. The former name signifies able to support, and the latter, able to direct, the labours of war. By adding to the word mache, or battle, certain prepositions and different parts of speech, which modify the sense in a manner always honourable, are composed the names Amphilochus, Animachus, Promachus, Telenachus. Proceeding in the same way with the word honor, "strength or intrepidity," they formed the names Agapenes, "he who exerts valour:" Agenor, "he who directs it." From these, "swift," are derived Alexeobis, Panteobis, Periboeis, &c.

From nom, "mind or intelligence," come Alfinos, Arfinoes, Atiines, &c. From medes, "counsel," Agamedes, Eumedes, Lycoinedes, Thalmyomedes; and from elis, "glory," Amphiloch, Agales, Iphileos, Patroclus, Cleobulus, with many others.

Hence Camden takes it for granted, that the names, in all nations and languages, are significative, and not simple sounds for mere distinction sake. This holds not only among the Jews, Greeks, Latins, &c. but even among the Turks; among whom, Abdalla signifies God's servant; Soliman, peaceable; Mahomet, glorified, &c. And the favages of Hispaniola, and throughout America, who, in their languages, name their children, Glittering Light, Sun Bright, Fine Gold, &c.; and they of Congo, by the names of precious stones, flow er, &c.

To supposes names given without any meaning, however by the alternation of languages their significative may be lost, that learned author thinks is to reproach our ancestors; and that contrary to the sense of all ancient writers. Porphyry notes, that the barbarous names, as he calls them, were very emphatical, and very concise; and accordingly it was esteemed a duty to be Griswells, or sui nominis homines; as Severus, Probus, and Aurelius, are called sui nominis imperatores.

It was the usual way of giving names, to which the children might discharge their names. Thus when Gunther king of France named Clotharius at the font, he said, Crescat puer, & bujas fit dominus executor.

The ancient Britons, Camden says generally took their names from colours, because they painted themselves; which names are now lost, or remain hid among the Welsh. When they were subdued by the Romans, they took Roman names, some of which full remain, corrupted: though the greatest part became extinct upon the admission of the English Saxons, who introduced the German names, as Orilla, Penda, Oxford, Edward, &c.-The Danes, too, brought with them their names; as Swane, Harold, Knute, &c. The Normans, at the Conquest, brought in other German names, as originally using the German tongue: such as Robert, William, Richard, Henry, Hugh, &c. after the same manner as the Greek names: Alfynus, Beor­thius, Symmachus, &c. were introduced into Italy upon the division of the empire. After the Conquest, our nation, which had ever been averse to foreign names, as deeming them unlucky, began to take Hebrew names; as Matthew, David, Sampson, &c. The various names anciently or at present obtaining among us, from what language or people forever borrowed, are explained by Camden in his Remains. As to the period when names began to be multiplied, and surnames introduced, &c. see SURNAME.

Of late years it has obtained among us to give surnames for Christian names; which some dislike, on account of the confusion it may introduce. Camden relates it as an opinion, that the practice first began in the reign of Edward VI. by such as would godfathers, when they were more than half fathers. Upon which some were persuaded to change their names at confirmation; which, it seems, is usual in other countries.—Thus, two sons of Henry II. of France, christened Alexander and Hercules, changed them at confirmation into Henry and Francis. In monasteries, the religious assume new names at their admittance, to shew they are about to lead a new life, and have renounced the world, their family, and even their name: e.g., after Mary of the incarnation, brother Henry of the Holy Sacrament, &c. The popes also changed their names at their exaltation to the pontificate; a custom first introduced by pope Sergius, whose name till then, as Platina informs us, was Swine­fat. But Onuphrius refers it to John XII. or XIII. and at the same time adds a different reason for it from that of Platina, viz. That it was done in imitation of St Peter and St Paul, who were first called Simon and Saul.

Among the ancients, those deified by the Heathen confecrations had new names given them; as Romulus was called Quirinus; Melicertes, Portus or Portum­nus, &c.

New names were also given in adoptions, and sometimes by baptism: thus L. Æmilinus, adopted by Scipio, took the name of Scipio Africanus; and thus Auguflus, who at first was called C. Ovidius Thurinus, being adopted by the baptism of Julius Caesar into his name and family, took the name of Caius Julius Caesar Octavianus.

Names were also changed at enfranchisements into new cities. Thus Lucumo, at his first being made free of Rome, took the name Lucius Tarchynius Priscus, &c.; and flavus, when made free, usually assumed their masters names. Thole called to the equestrian order, if they had base names, were always new named, nomine ingeniorum veterumque Romanorum. And among the primitive Christians, it was the practice to change the names of the catechumens: Thus the renegado Lucianus, till his baptism, was called Lucius.

Toward the middle of the 15th century, it was the fancy of the wits and learned men of the age, particularly in Italy, to change their baptismal names for classical ones. As Sanazarus, for instance, who altered his own plain name to Attius Synarius. Numbers did the same, and among the rest Platina the historian at Rome, who, not without a solemn ce­remomial,
NAMPTWICH, or NANTWICH, a town of Cheshire in England, situated on the Weever river, 14 miles S. E. from Chester and 162 miles from London. It lies in the Vale-Royal, and is one of the largest and best built towns in the county, the streets being very regular, and adorned with many gentlemen's houses. The inhabitants drive a trade, not only by its large market on Saturday for corn and cattle, and its great thoroughfare to Ireland, but by its cheeze and its fine white salt, which are made here to the greatest perfection; and by shoes made here and sent to London to the warehousers. It is governed by a confiable, &c. who are guardians of the free-fringes. It is divided by the Weever into two equal parts, which is not navigable any farther than Winsford bridge. The Chester canal, lately completed, terminates in a handsome broad bason near this place. In this town were several religious foundations, no more. The church is a handsome pile of building in the form of a crofs, with a circular tower in the middle. There are here three fairs.

NAMUR, a province of the Netherlands, lying between the rivers Sambre and Meafe; bounded on the north by Brabant, on the east and south by the bishoprie of Leigue, and on the west by Hainault. It is very pretty, has several forests, marble quarries, and mines of iron, lead, and pit-coal; and is about 30 miles long and 20 broad. Namur is the capital town.

Namur, a large, rich, and very strong town of the Netherlands, capital of the county of Namur, with a strong castle, several forts, and a bishop's see. The most considerable forts are, Fort-William, Fort-Maeve, Fort Coqueler, and Fort-Epinoir. The castle is built in the middle of the town, on a craggy rock. It was besieged by king William in 1695, who took it in the sight of an army of 100,000 French, though there were 60,000 men in garrison. Namur is now a barrier-town, and has a Dutch garrigon. It was ceded to the house of Austria in 1713, but taken by the French in 1746; and restored by the treaty of Aix-la-Chapelle. It is situated between two mountains, at the confluence of the rivers Meafe and Sambre, in E. Long. 4° 57' N. Lat. 50° 25'.

NAN-CHANG-FOU, the capital of Kiang-Si, a province of China. This city has no trade but that of porcelain, which is made in the neighbourhood of Jao-tcheou. It is the residence of a vicerey, and comprehends in its district eight cities; seven of which are of the third class, and only one of the second. So much of the country is cultivated, that the plateers left are scarcely sufficient for the rocks.

NANNI, a town of France, and capital of Lorraine, is situated on the river Meuse, in the centre of the province. It is divided into the Old and New Towns. The first, though irregularly built, is very populous, and contains the ducal palace; the streets of the New Town are as straight as a line, adorned with handsome buildings, and a very fine square. The principal church is a magnificent structure, and in that of the Cordeliers are the tombs of the ancient dukes. The two towns are separated by a canal; and the new town was very well fortified, but the king of France has demolished the fortifications. It has been taken and retaken several times; particularly by the French, to whom it was ceded in 1756, to enjoy it after the death of Stanislaus.

NANI (John-Baptist), was born in 1616. His father was procurator of St Mark, and ambassadoir from Venice to Rome. He was educated with attention, and made considerable improvement. Urban VIII. was a just valuer of merit, soon perceived that of young Nani. He was admitted into the college of cardinals in 1641, and was shortly after nominated ambassadoir in France, where he signified himself by his compliant manners. He procured considerable succours for the war of Candia against the Turks; and became, after his return to Venice, superintendent of the war office and of finances. He was afterward ambassadoir to the empire, where he rendered those services to his country which, as a zealous and intelligent citizen, he was well qualified to discharge. He was again sent into France in 1660 to solicit fresh succours for Candia; and on his return was appointed procurator of St Mark. He died November 5, 1671, at the age of 63, much regretted by his countrymen. The Senate had appointed him to write the History of the Republic; which he executed to the satisfaction of the Venetians, although the work was less admired by foreigners, who were not proper judges of the accuracy with which he related the facts, of the purity of his diction, nor of the simplicity of his style; although it must be acknowledged that his narrative is much interrupted by too frequent parenthesis. In writing his history of Venice he has given an universal history of his times, especially with respect to the affairs of the French in Italy. This History which is continued from 1613 to 1671, was printed at Venice in 2 vols 4to, in the years 1662 and 1679.

NAN-KING, a city of China, and capital of the province of King-nan, is said to have been formerly one of the most beautiful and flourishing cities in the world. When the Chinese speak of its extent they say, if two horsemen should go out by the same gate, and ride round it on full speed, taking different directions, they would not meet before night. This account is evidently exaggerated; but it is certain, that Nan-king surpasses in extent all the other cities of China. We are assured that its walls are five leagues and a half in circumference.

This city is situated at the distance of a league from the river Yang-tse-kiang; it is of an irregular figure; the mountains which are within its circumference by ving prevented its being built on a regular plan. It was formerly the imperial city; for this reason it was called Hon-King, which signifies, "the Southern Court."
NANTIES, an ancient, rich, and very considerable town of France, in Bretagne, with a bishop's see, an university, and a mint. It is one of the most considerable places in the kingdom; contains the richest merchants; and was formerly the residence of the dukes of Bretagne, where they built a very strong caftle on the side of the river, and which is strongly fortified. There are several parishes, and a great many religious houses, and the cathedral contains the tombs of the ancient dukes. There are several fine bridges over the river Loire, which is navigable. The suburbs are so large, on account of the number of people that come from all parts to settle here, that they exceed the city. The Spaniards trade here, with wine, fine wool, iron, silk, oil, oranges, and lemons: and they carry back cloth, fuffs, corn, and hard-ware. The Dutch send salt fish, and all sorts of spices: and in return have wine and brandy. The Swedes bring copper; and the English lead, tin, and pit-coal. It was in this place that Henry IV. promulged the famous edict in 1598, called the Edict of Nantes, and which was revoked in 1685. Nantes was anciently, like almost every considerable city, extremely very strongly fortified. Peter de Dreux, one of the dukes of Bretagne, surrounded it with walls, which have only been demolished within these few years. The bridge is an object of curiosity. It is near a mile and a half in length, being continued across all the little islands in the Loire, from north to south. The territory of Nantes lies on both sides the Loire, and feeds a great number of cattle. Large vessels can come no higher than Port Launai, which is 12 miles from Nantes.

NANTUEIL (Robert), the celebrated designer and engraver to the cabinet of Louis XIV. was born at Rheims in 1630. His father, though but a petty shopkeeper, gave his son a liberal education; who having a taste for drawing, cultivated it with such success, that he became the admiration of the whole town: but marrying young, and not being able to maintain his talents known by a stratagem.—Seeing several abbés at the door of an eating-house, he asked the mistresses for an ecclesiastic of Rheims, whose name he had forgotten, but that the might easily know him by a picture of him which he showed: the abbés crowding round, were so charmed with it, that he seized the opportunity of offering to draw any of their pictures for a small matter. Customers came so fast, that he soon raised his price, and brought his family to Paris, where his reputation was quickly established. He applied himself particularly to taking portraits in crayons, which he afterwards engraved for the use of academical theses; and in this way he did the portrait of the king, and afterwards engraved it as big as the life; a thing never before attempted. The king was so pleased with it, that he created the place of designer and engraver to the cabinet for him, with a pension of 1000 livres. He died in 1678: and an entire collection of his prints amounts to upwards of 240.

NAPAEA, in botany: A genius of the Polyandra order, belonging to the Polydeltphia class of plants: and in the natural method ranking under the 37th order, Clonanifera. The calyx is fingle and cylindric the
NAP [ ]

Naphtha. the arilli coagulated and monoporous. There are two species, both of them with perennial roots, composed of many thick fleshy fibres, which strike deep into the ground, and are connected at the top into large heads; the flowers grow to seven or eight feet high, producing white flowers, tubulous at bottom, but spreading open at top, and dividing into five obetute segments. Both these plants are natives of Virginia and other parts of North America: from the bark of some of the Indian kinds a fort of fine hemp might be procured, capable of being woven into very strong cloth. They are easily propagated by seed, which will thrive in any situation.

Naphtha, an inflammable substance of the bituminous kind, of a light brown colour, and incapable of decomposition, though frequently adulterated with heterogeneous mixtures. By long keeping it hardens in the air into a mass which being the lightest oil, is capable of being woven into very strong cloth. It is said to be of an extremely fragrant and agreeable smell though very different in this respect from vegetable oils. It is also transparent, extremely inflammable, dissolves resins and balsams, but not gum-resins nor elastic gum. It dissolves in the essential oils of thyme and lavender, but is insoluble in spirit of wine and ether. It burns with a bluish flame, and is as inflammable as ether, like which it also dissolves and dissolves in aqua-regia.

Naphtha, according to Cronsted, is collected from the surface of some wells in Persia; but Mr Kirwan informs us, that it issuing out of white, yellow, or black clays, in Persia and Media. The finest is brought from a peninsula in the Caspian Sea, called by Kempfer, *elpea.* It issues out through the earth into cisterns and wells, purposely excavated for collecting it at Aku in Persia. Different kinds of this substance are also found in Italy, in the duchy of Modena, and in Mount Ciaro, 12 leagues from Plaisance.

The formation of naphtha and petroleum is by most naturalists and chemists ascribed to the decomposition of solid bitumens by the action of subterranean fires; naphtha being the lightest oil, which the fire deteriorates first; what follows gradually acquiring the colour and consistence of petrol. Lastly, the petroleum, united with some earthy substances, or altered by acids, attains the appearance of mineral pitch, papahlalum, &c. This opinion seems to be supported by the phenomena attending the distillation of amber; where the first liquor that rises is a true naphtha; then a petroleum of a more or less brown colour; and lastly, a black substance like jet, which being further urged by the fire leaves a dry fleshy matter, &c. It is further observed that nature frequently produces all the different kinds of petroleum near the same place; of which we have an instance at Mount Teffin in the duchy of Modena in Italy. Some, however, are of opinion, that these mineral oils or bitumens are formed from the vitriolic acid, and various oily and fat substances found in the bowels of the earth.

NAPHTHALI, or NAPHTHALI (Joel xii.), one of the tribes of Israel; having Zabulon on the south, Asher on the west, the Jordan on the east, and on the north Antilibanus.

NAPIER (John), baron of Merchiston, in Scotland, inventor of the logarithms, was the eldest son of Sir Archibald Naper of Merchiston, and born in the year 1550. Having given early discoveries of great natural parts, his father was careful to have them cultivated by a liberal education. After going through the ordinary courses of philosophy at the university of St Andrew's, he made the tour of France, Italy, and Germany. Upon his return to his native country, his literature and other fine accomplishments soon rendered him conspicuous, and might have raised him to the highest offices in the state; but declining all civil employments, and the bustle of the court, he retired from the world to pursue literary researches, in which he made an uncommon progress, so as to have rendered himself useful to mankind, and to have earned for himself a place in the annals of science. He applied himself chiefly to the study of mathematics; but at the same time he did not neglect that of the Holy Scriptures. In both these he hath discovered the greatest knowledge profound penetration. His essay upon the book of the Apocalypse, indicates the most acute investigation, and an uncommon strength of judgment; though time hath discovered, that his calculations concerning particular events had proceeded upon fallacious data. This work has been printed abroad in several languages; particularly in French at Rochelle in the year 1653, 8vo, announced in the title as revised by himself. Nothing, says lord Buchan, could be more agreeable to the Rochellers or to the Huguenots of France at this time, than the author's announcement of the pope as antichrist, which in this book he has endeavoured to set forth with much zeal and erudition. But what has principally rendered his name famous, was his great and fortunate discovery of logarithms in trigonometry, by which the ease and expedition in calculation have so wonderfully assisted the science of astronomy and the arts of practical geometry and navigation. That he had begun the year 1593 the train of enquiry which led him to that great achievement in arithmetic, appears from a letter to Crugerus from Kepler in the year 1624, wherein, mentioning the Canon Mirrorius, he writes thus: "Nihil autem supra Neperianam rationem effe puto; et quod quidem litteris ad Tycho nom, anno 1593, scripsit: sect. Canop. n. m. i. e. in the book "Canon Mirrorius," which allusion agrees with the idle story mentioned by Wood in his Athenae Oxonienses, and explains it in a way perfectly consonant to the rights of Napier as the inventor.

When Napier had communicated to Mr Henry Briggs, mathematical professor in Gresham college, his wonderful canon for the logarithms, that learned professor set himself to apply the rules in his Infracop Napi, and in a letter to archbishop Ushar, in the year 1615, he writes thus: "Napier, baron of Merchiston, hath set his head and hands at work with his new and admirable logarithms. I hope to see him this summer if it please God; for I never saw a book which pleased me better, and made me more wonder." The following passage from the life of Lilly the astrologer is quoted by lord Buchan as giving a philosophical
Napier was the inventor of the logarithms at Merchiston near Edinburgh. "I will acquaint you (says Lilly) with one memorable story related unto me by John Marr, an excellent mathematician and geometrician, whom I conceive you remember. He was servant to King James I. and Charles I. When Merchiston first published his logarithms, Mr. Briggs, then reader of the astronomy lectures at gresham college in London, was so much surprized with admiration of them, that he could have no quietness in himself until he had seen that noble person whose only invention they were: he acquaints John Marr therewith, who went into Scotland before Mr. Briggs, purposely to be there when these two so learned persons should meet. Mr. Briggs appoints a certain day when to meet at Edinburgh; but failing thereof, Merchiston was fearful he would not come. It happened one day as John Marr and the baron Napier were speaking of Mr. Briggs: 'Ah, John (said Merchiston), Mr. Briggs will not now come.' At the very instant one knocks at the gate; John Marr hauled down, and proved to be Mr. Briggs to his great contentment. He brings Mr. Briggs up to the Baron's chamber, where almost one quarter of an hour was spent, each beholding the other with admiration before one word was spoken. At last Mr. Briggs began: 'Sir, I have undertaken this long journey purposely to see your person, and to know by what engines of wit or ingenuity you came first to think of this most excellent help into astronomy, viz., the logarithms; but Sir, being by you found out, I wonder nobody else found it out before, when now being known it appears so easy.' He was nobly entertained by Mr. Briggs, and was expressly to Scotland to visit him."

There is a passage in the life of Tycho Brahe by Gaffendi which may mislead an attentive reader to suppose that Napier's method had been explored by Herwart at Hoenburg: It is in Gaffendi's Observations on a Letter from Tycho to Herwart of the last day of August 1599: " Dixit Herwartus nihil morari se solvendi caujiquam trianguli difficultatem: solere esse enim multiplicationem, ac divisionem vicin aditionum, subtrahenam, et additionem, ut etiam plerumque in logaritmonorum canone Neperus." But Herwart here alludes to his work after wards published in the year 1610, which solves triangles by prolaphareis, a mode totally different from that of the logarithms.

Kepler dedicated his Ephemerides to Napier, which were published in the year 1617; and it appears from many passages in his letter about this time that he held him to be the greatest man of his age in the particular department to which he applied his abilities. "And indeed (says our noble biographer), if we consider that Napier's discovery was not like those of Kepler or of Newton, connected with any analogies or coincidences which might have led him to it, but the fruit of unaided reason and science, we shall be vindicated in placing him in one of the highest niches in the temple of fame. Kepler had made many unsuccessful attempts to discover his canon for the periodic motions of the planets, and hit upon it at last as he himself candidly owns on the 13th of May 1618: and Newton applied the palpable tendency of heavy bodies to the earth to the system of the universe in general: but Napier fought out his admirable rules by a flow scientific progress arising from the gradual evolution of truth."

The last literary exertion of this eminent person was the publication of his Rhetologus and Promptuary in the year 1617, which he dedicated to the Chancellor Seton; and soon after died at Merchiston on the 3d of April O.S. of the same year, in the 68th year of his age and 23d of his happy invention. - The particular titles of his published works are: 1. A plain discovery of the Revelation of St. John. 2. Miscellanea canonum confrucrorum et logaritmonicorum ad naturae simorum numeros habituadis. 3. Apparatus ad aliqua quaedam logariahromorum specie constitutam, in qua collectae unitas logarithmorum eff. 4. Rhetologus. 5. Apparatus ad aliqua quaedam logarithmorum eff.

This eminent person was twice married. By his first wife, who was a daughter of Sir James Stirling of Keir, he had only one son named Archibald, who succeeded to the estate. By his second wife, a daughter of Sir James Chisholm of Cromlix, he had a numerous issue. - Archibald Napier, the only son of the first marriage, was a person of fine parts and learning. Having more a turn to public business than his father had, he was raised to be a privy councilor by James VI. under whose reign he also held the offices of treasurer-depute, justice-clerk, and senatus of the college of justice. By Charles I. he was raised to the peerage by the title of Lord Napier.

Napier's Rods, or Bones, an instrument invented by Baron Napier, whereby the multiplication and division of large numbers is much facilitated.

As to the Construction of Napier's Rods: Suppose the common table of multiplication to be made upon a plate of metal, ivory, or pailleboard, and then conceive the several columns (standing downwards from the digits on the head) to be cut off under and these are what we call Napier's Rod for Multiplication. But then there must be a good number of each; for as many times as any figure is in the multiplicand, so many rods of that species (i.e., with that figure on the top of it) must we have; though fix rods of each species will be sufficient for any example in common affairs; there must be also as many rods of 0's.

But before we explain the way of using these rods, there is another thing to be known, viz., that the figures on every rod are written in an order different from that in the table. Thus the little square space or division in which the several products of every column are written, is divided into two parts by a line across from the upper angle on the right to the lower on the left; and if the product is a digit, it is set in
Napier.

1835680

To make the use of the rods yet more regular and easy, they are kept in a flat square box, whose breadth is that of ten rods, and the length that of one rod, as thick as to hold fix (or as many as you please) the capacity of the box being divided into ten cells, for the different species of rods. When the rods are put up in the box (each species in its own cell distinguished by the first figure of the rod set before it on the face of the box near the top), as much of every rod stands without the box as shows the first figure of that rod: also upon one of the flat sides without and near the edge, upon the left hand, the index rod is fixed; and along the foot there is a small ledge; so that the rods when applied are laid upon this side, and supported by the ledge which makes the practice very easy; but in case the multiplicand should have more than nine places, that upper face of the box may be made broader.

Some make the roads with four different faces, and figures on each for different purposes.

To make the use of the rods yet more regular and easy, they are kept in a flat square box, whose breadth is that of ten rods, and the length that of one rod, as thick as to hold fix (or as many as you please) the capacity of the box being divided into ten cells, for the different species of rods. When the rods are put up in the box (each species in its own cell distinguished by the first figure of the rod set before it on the face of the box near the top), as much of every rod stands without the box as shows the first figure of that rod: also upon one of the flat sides without and near the edge, upon the left hand, the index rod is fixed; and along the foot there is a small ledge; so that the rods when applied are laid upon this side, and supported by the ledge which makes the practice very easy; but in case the multiplicand should have more than nine places, that upper face of the box may be made broader.

Some make the roads with four different faces, and figures on each for different purposes.

...the dukedoms of Gaeta, Naples, and Amalfi, which were very inconsiderable, and extended along the shore only about 100 miles, and were interrupted by the Gulf of Otranto or of Capua.

This flourishing and extensive dukedom was at this time governed by Arechis, who had married one of the daughters of the last king of the Lombards, and had submitted, and taken the oath of allegiance to the emperor Charles. However, a few years after, he renounced his allegiance to the Franks, declared himself an independent sovereign, and was acknowledged as such by all the inhabitants of his duchy. To strengthen himself against Pepin king of Italy, who resided at Ravenna, he enlarged and fortified the city of Benevento, and likewise built Salerno on the sea coast surrounding it with a very strong and high wall. He engaged in several wars with the Greeks, whom he sometimes obliged to give him hostages; but having invaded the territories of the pope, whom Pepin could not affright, Charlemagne was prevailed on to return to Italy. Arechis, unable to oppose such a formidable enemy, sent his eldest son, Romauld, to Rome, with an offer of submission: but, at the intimation of the pope, Charles refused the,
NAP [624] NAP

offer, and detained his son prisoner; after which he ravaged the country, and made himself master of Capua. Other deputies, however, proved more successful; and in the year 787, a peace was concluded on these conditions. That Arechis and the Beneventans should renew their allegiance to the Franks, that he should pay a yearly tribute to Pepin; deliver up all his treasure; and give his son Grimoald and his daughter Adelgisa, with twelve others, as hostages for his fidelity: however after many intreaties, Adelgisa was restored to her father.

Charles had no sooner left Italy, than Arechis forgot all his engagements, and began to negotiate with Irene, empress of Constantinople, and her son Constantine, for expelling the Franks out of Italy. For himself, he defined the honour of patriciate, and the dukedom of Naples with all its dependencies; and, in return, promised to acknowledge the Greek emperor as his sovereign, and to live after the manner of the Greeks. He required, however, to be supported by a Greek army; and that his brother-in-law Adalgisius, son to Defiderius the last king of the Lombards, should be sent over into Italy, to raise a party among his countrymen. These conditions were readily accepted, on condition that prince Romuald should be sent as a hostage; ambassadors were sent to Naples with the envoys of the patrician order, namely the mantle of cloth of gold, the sword, the comb, and the sandals; but before the ceremony could be performed, prince Romuald died, and soon after him his father: whose death was supposed to have been haftened by that of his son.

After the death of Arechis, the Beneventans sent a most submissive embassy to Charlemagne, intimating to him to send Grimoald, the late king's son, and only lawful heir to his crown; threatening at the same time to revolt if their prince was denied them. Charles readily granted their request, and allowed Grimoald to depart, after he had agreed to the following conditions, viz: That he should oblige the Lombards to shew their breasts; that in writings, and on money, the name of the king should be put before that of the prince; and that he should cause the walls of Salerno, Acerno, and Conflia, to be entirely demolished:—The new king was received by his subjects with the utmost joy; and for some time continued faithful to his engagements, excepting only the lat article, which he either neglected or eluded. So far, however, was he from alienating the Greeks, that he gave notice of their machinations to Pepin king of Italy; raised an army to oppose his uncle Adalgisius; and being joined by Hildebrand duke of Spoleto, and Vinigile the general of Pepin, he attacked the Greeks in Calabria soon after they had landed, entirely defeated and took his uncle prisoner, and, as is said, put him to a cruel death. Yet in a short time Grimoald contracted an alliance with the Greek emperor by marrying his niece Wanisia; and in the fifth year of his reign a war broke out between him and Pepin, which continued for twelve years; at the end of which time a truce was concluded. Grimoald survived this pacification only three years, and was succeeded by his treasurer Grimoald II. who submitted to Charlemagne after the death of Pepin; and from this time the Beneventans were looked upon as tributaries of the western emperors.

As yet, however, the city of Naples did not own allegiance to the dukes of Benevento, but was held by the eastern emperors; and frequent wars took place between the Beneventans and Neapolitans. This happened to be the case when Grimoald II. ascended the throne. He concluded an alliance with the Greeks, which however was of no long continuance; for Theodore, governor of Naples, having granted pretentions to Dauserius a noble Beneventan, who had been concerned in a conspiracy against his prince, Grimoald marched against the city of Naples, and invested it by sea and land. Theodore still refused to deliver up the traitor, and a general engagement both by land and sea was the consequence; in which the Neapolitans were defeated with so great a slaughter, that the sea was stained with their blood for more than seven days. Theodore then contented to deliver up Dauserius, with 8000 crowns for the expenses of the war; and Grimoald not only pardoned Dauserius, but received him into favour; the traitor, however, reflecting on the misfortunes of his crime, was seized with remorse; and went a pilgrimage to the holy land, carrying a large stone in his mouth, by way of penance, which he never took out but at his meals.

In the year 821, Grimoald was murdered by Radchelis count of Conflia, and Sico gaufdal of Acervento, and succeeded by Sico. Radchelis being soon after seized with remorse, became a monk; while Sico associated his son Sicardo with him in the government; and both, being of an ambitious and refractory disposition, fought a pretence for attacking the Neapolitans. This was soon found, and the city was invested by sea and land. The walls were furiously battered; and part of them being blown down, Sico prepared for a general assault. Stephe, at that time duke of Naples, pretended to submit; but that he might prevent the city from being pillaged, intreated Sico to put off his entry till the morning, and in the mean time sent out his mother and his two children as hostages. Sico consented to his request; but next morning found the breach built up, and the Neapolitans prepared for their defence. Exasperated at their perfidy, he renewed his attacks with vigour, but without any success; the besieged defending themselves with the utmost obstinacy. At last, perceiving that they should not be able to hold out much longer, they consented to a peace on the following conditions, viz: That the Neapolitans should pay an annual tribute to the princes of Benevento, and consent to the transporting of the body of St Januarius from his church without the walls of Naples to Benevento. These conditions being ratified, Sico returned with great honour to Benevento; but soon after renewed the war, under pretence that the Neapolitans had neglected to pay the stipulated sum; and hostilities continued till his death, which happened in 833.

Sico was succeeded in the government of Benevento and by his son Sicardo, who had married the daughter of succeder for Dauserius; and being influenced by the evil counsels of Roffrid his wife's brother, oppressed his subjects to such a degree that they conspired against his life. He besieged Naples with a powerful army, and took possession of Acerra and Atella, both of which he fortified. But Bonus, the Neapolitan duke, defended himself
The Saracens called in by the duke of Naples had caned over from Africa to his city, and Constanza. The boundary between Benevento and Capua was fixed at St. Angelo and Cerros; Alii Pergrius was made the boundary between Benevento and Salerno, and Staffolo between Benevento and Consta. The monasteries of Monte Cassino and St. Vincent were declared to be immediately under the protection of the emperor; both princes stipulated that no hostilities should be committed by either against the subjects of each other; and promised to join their forces in order to drive out the Saracens. Soon after this pacification, however, both Radelchis and Siconolphus died; the former appointing his son Radelgarius, or Radelcar, to succeed him; and the latter leaving an infant son, Sico, to the care of his godfather, Peter.

The war with the Saracens proved very unsuccessful; neither the united efforts of the princes, nor the affiliation of the emperor Lewis himself, being able to expel the infidels; and, in 854, Adelgise the second son of Radelchis, who had now succeeded, on the death of his brother Radelcar, to the principality of Benevento, was obliged to pay them an annual subsidy. Two years after, Landolfo Count of Capua, revolted from the prince of Salerno, and St. Steffano. The Saracens, being entirely reduced, in the mean time, Sico, the lawful prince of Salerno, had been poisoned by Count Landolfo, and the principality usurped by Ademarius, the son of Peter above mentioned; but in 861, Ademarius himself was seized and imprisoned by Gauferius, the son of Daferius formerly mentioned. This was occasioned by his cruelty and rapacity, which entirely alienated the hearts of his subjects from him, and encouraged Gauferius to become the head of the conspirators. The Saracens in the mean time committed terrible ravages throughout the Beneventan territories; which at last obliged Adelgise to enter into an alliance with Gauferius, and both together sent a most humble embassy to the emperor Lewis, requiring him to take them under his protection. About the same time an embassy arrived from Constantinople, proposing a junction of the forces of the eastern and western empires against the infidels; upon which Lewis gave orders for assembling a formidable army. But in the mean time Adelgise fell off from his alliance, and made peace with the Saracens; nay, according to some he encouraged them in their inquisitions, and it was at his desire that they invaded the duchy of Capua, and afterwards that of Naples, which they ravaged in a most barbarous manner. The Neapolitans in conjunction with the duke of Spoleto and the Count of Mari, endeavoured to oppose them; but being defeated, the Saracens continued their ravages with redoubled fury, and retired to Bari, which was their capital city with an immense booty.

In 866, Lewis arrived at Sora, with his army; and having marched to Capua, was there joined by Landolfo, the bishop and count, with a body of Capuans; but Landolfo soon after persuading his countrymen to desert, Lewis marched against that city, which he took after a siege of three months, and almost totally destroyed. In the end of the year he was joined by Gauferius with his quota of troops, having ordered the eyes of Ademarius to be put out in his absence. Lewis confirmed him in the principality, and marched with his army to Benevento, where Adelgise received...

Naples. They are at last expelled.

inconsiderable places belonging to the Saracens, Lewis
soon after invaded Bari; but as the Saracens received
continual supplies from their countrymen settled in Si-
cily, and besides were protected by the Neapolitans,
he could not reduce the place till the year 871, though
he had received considerable assistance from his brother
lotharius, and the Greek emperor had sent him a fleet
of 200 sail. The expulsion of the Saracens was com-
pleted the same year by the taking of Tarento; after
which the emperor returned with great glory to Bene-
vento, resolving next to carry his arms into Sicily, and
expel the infidels from thence also. But his future
schemes of conquest were frustrated by a quarrel be-
tween him and Adelgise. The latter, pretending to
have been insulted by the empress, and
the Greek governor of Bari and Otranto, took
different sides in the quarrel, as they thought most
proper: and to complete the confusion, the new bishop
was expelled, and his brother, though a layman,
chosen to that office, and even consecrated by the pope
who wrote to Gaufridus, forbidding him to attack Ca-
pua under pain of excommunication. But though Gau-
fridus was, in general, obedient to the pope's com-
mands, he proved refractory in this particular, and laid
siege to Capua, for two years successively.

Thus the Capuan territories were reduced to the
most miserable situation; being obliged to maintain at
the same time the armies of the prince of Beneven-
to and the duke of Spoleto. The Saracens, in the mean-
time, took the opportunity of strengthening themselves
in Italy: and Athanaisius, notwithstanding the great
commendations he had received from the pope for put-
ting out his brother's eyes, contented to enter into an
alliance with them, in conjunction with whom he rav-
ged the territories of the pope as well as those of
Benevento and Spoleto, plundering all the churches,
monasteries, towns, and villages, through which they
passed. At the same time the prince of Salerno was
obliged to grant them a settlement in the neighbour-
hood of his capital; the duke of Geeta invited them to
his assistance, being oppressed by the count of Capua
and even the pope himself was obliged to make peace
with them, and to grant them a settlement on the north
side of the Carigliano, where they fortified themselves,
and continued for more than 40 years.

To put a stop to the confusion which reigned in I-

taly, the pope now thought proper to restore the bi-

ishop of Capua, who had been expelled, but allowed
his brother to reside in the city, and govern one half of
the diocese; but notwithstanding this partition, the
civil dissensions continued with the utmost violence, the
neatest relations murdering or banishing each other
according as the fortune of the one or the other pre-
valied.—Athanaisius, notwithstanding all the pope's re-

demands, continued his alliance with the Saracens;
conjunction with whom he ravaged the territory of
Benevento, and fomented the divisions in Capua, in
hopes of being able to make a conquest of it. At last
his holiness thought proper to issue a sentence of ex-
communication against him, but this attached him to
the Saracens more than ever; insomuch that he sent
to Suchaim, king of the Saracens in Sicily, defi-
ing him to come over and command a great body of
his countrymen who had settled at the foot of Mount Ve-
fusius. Suchaim accepted the invitation, and im-
mEDIATELY turned his arms against Athanaisius; allow-
ing his troops to live at discretion in the territory of
Naples where they ravished the women and plunder-
ed the inhabitants. These calamities were, by the
superfluous Neapolitans, imagined to be a consequence
of the sentence of excommunication; and therefore
they used their utmost endeavours to persuade the pre-
late to conclude a league with some Christian prince
and renounce all connexion with the infidels. In this
they at last proved successful, and Athanaisius con-
cluded an alliance with Guaimarius prince of Saler-
in order to allure the valiant Normans to leave their own country. This kind invitation encouraged a Norman chief, named Omoine Drenoet, to settle in Italy about the year 1015; having killed another lord in a duel, which obliged him to leave his own country, in order to avoid the resentment of his sovereign, Robert duke of Normandy. In the mean time, the city of Bari had revolted from the Greeks, and chosen one Mello for their leader, whose wife and children happened soon after to fall into the hands of their enemies, and were sent prisoners to Constantinople. No sooner, therefore, did Mello hear of the arrival of these adventurers, than he engaged them to assist him; and having drawn together a considerable army, defeated the Greeks with great slaughter, and obliged them to abandon their camp. In this engagement, the Normans distinguished themselves by their bravery: and the news of their success soon brought from Normandy an innumerable multitude of their countrymen with their wives and children. By this reinforcement, Mello gained two other victories, took a great many towns; and obliged the Greeks to abandon a large territory; but, in 1019, they were utterly defeated, and every thing recovered by the Greeks. The Greek general, Bajanus, continued to go on with such surprising successes, that he almost entirely re-established the affairs of his countrymen in Italy, and made a distinct province of the western part of Puglia, which he called Caputnata, and which to this day retains the name of Capitanata. His great progress at last alarmed the emperors of Germany; and, in 1027, Pandulphus prince of Capua made himself master of Naples; but was obliged three years afterwards, to leave it, by the Normans, who built the city of Averia, which was now erected into a county. In consequence of this piece of good fortune, great numbers of Norman adventurers migrated into Italy among whom were William, Drogo, and Umbert, three of the sons of Tancred duke of Hautville, from whose posterity those princes were descended, who first conquered the island of Sicily from the Saracens, and formed the present kingdom of Naples.

In 1040, the Greek emperor Michael Paleologus, in order to secure the affection of his fickle subjects, undertook the conquest of Italy from the Saracens, and for that purpose sent a general named Michael Maniacus into Sicily. This commander, hearing of the great reputation of the Normans, sent to Guaimarius, prince of Salerno, intreating him to grant him some of those warriors. His request was most willingly heard to by the prince of Salerno, who, to encourage the Normans to engage in the expedition promised them some additional rewards besides the emperor's pay. William, Drogo, and Umbert, accordingly marched from Salerno with 300 of their countrymen; and passing over into Sicily, distinguished themselves most remarkably in the conquest of that island. Maniacus acknowledged, that the recovery of Messina was chiefly owing to their valor: and William with his Normans gained a complete victory over the Saracens before Syracuse, where he killed the governor of the city in single combat. Maniacus made himself master of Syracuse, and almost entirely reduced the whole island; but being accused of treason, was next year carried prisoner to Constantinople. His successor Doceanus, being
The Normans having now conquered the greatest part of Puglia, proceeded to make a division of their conquest, in which, after each commander had got his proper share, the city of Melhis was left common to all, and appropriated as a place for assembling to consult about the most important affairs of the nation. Argyrus alone was neglected in this division; but he, having gained the favour of the emperor by expelling the rebel Maniacus from Italy, was by him created duke of Bar, on purpose to check the power of the Normans, with the title of prince and duke of Puglia. The Normans, however, were too powerful to be much awed by Argyrus, and behaved with great insolence to the neighbouring princes; but as they could not be expelled by force, and were confirmed in their conquests by Henry II. emperor of Germany in 1047, the Greek emperor attempted to get rid of them, by sending Argyrus with large sums of money to bribe them to enter into his service against the Perrians. But they, perceiving the snare, replied, that they were resolved not to leave Italy unless they were expelled by force; upon which Argyrus made use of the same money in bribing the Puglians to assassinate these invaders. This brought on a massacre, in which greater numbers of Normans perished than had fallen in all the late wars. Argyrus attempted to take advantage of the confusion produced by this massacre, but was defeated; after which he had recourse to Pope Leo, beseeching him to deliver Italy from these cruel tyrants; but this proved still more unsuccessful than the others had been; for the pope himself was defeated and taken prisoner; and, in consequence of the respect showed him by the Normans, granted them, as a sign of the holy see, all the conquests they had made or should make in Calabria and Sicily.

Soon after this, the Norman power became extremely formidable; the famous Robert Guiscard attended the throne in 1056. He made great progress in the conquest of Calabria, and reduced most of the cities which held for the Greeks in these parts. About the same time the counts of Capua were expelled from their territory; and the abbot Defiderius mentions his having seen the children of Landolphus V. the last count, going about as vagabonds, and begging for their support. The pope, alarmed at these conquests, excommunicated the Normans in wholesale, pretending that they had seized some of the territories belonging to the church; but, by the pretended submission of Robert, he not only was persuaded to take off the sentence of excommunication, but it even sufficed to get him with the provinces of Apulia, Calabria, and Sicily. After this, he continued the war against the Greeks with great success. In 1071, in conjunction with his brother Roger, he conquered the island of Sicily, and gave the investiture of the whole island to him, with the title of count, referring to himself only the half of Palermo, Melitina, and the valley of Demons. The like success attended his arms against Salerno in 1074; but after this, having unwarily taken some places from the pope, he again fell under the sentence of excommunication; yet he was reconciled to him in 1080, and received
NAP [ 629 ]

Naples, received a second time the investiture of all his dominions. The next year he undertook an expedition against the Greeks; and though the emperor was affiicted by a Venetian fleet, Robert made himself master of the island of Corfu, reduced Durazzo, and, great part of the island of Lefkland, where he was created emperor in consequence of his arms, and his near approach to Constantinople, he struck a universal terror among the Greeks. But while Robert was thus extending his conquests, he was alarmed by the news of a formidable rebellion in Italy, and that the emperor Henry had taken the city of Rome, and closely shut up the pope in the castle of St. Angelo. Robert therefore, leaving the command of the army to his son Boemund, returned to Italy, where he immediately dispersed the rebels, and releasted the pope, while his son gained a considerable victory over the Greeks. After this Robert made great preparations for another expedition into Greece, in order to secon his son Boemund Alexius Camenius, who was about this time declared emperor by the Greek army, being affiicted by the Venetian fleet, endeavoured to opposte his passage, but was entirely defeated, with the loss of a great many galleys. But a final sloop was now put to his enterprises by his death, which happened in the island of Corfu in 1085.

Though the power of the Normans was thus thoroughly established in Italy and Sicily, and though the prince of Benevento was in 1130 invested by the the pope with the title of king of Sicily; yet by reason of the civil divisions which took place among themselves and the general confusion which reigned in Italy in those ages, they were obliged, notwithstanding standing all their valour, to submit to the emperor in 1195. By him the Sicilians were treated with so great cruelty, that the empress Constance was induced to conspire against him in 1197, took him prisoner, and releasted him only on condition of his leaving off his army immediately for the Holy Land. This was complied with; but the emperor did not long survive that resolution, being poisoned, as was supposed, by order of the empress.

In 1254 the pope claimed the kingdom as a fief by the death of pope Nicholas. The new pope, Nicholas IV. was entirely in the interest of Charles, on whom, in 1281, he conferred the senatoral dignity of Rome. As he well knew the enmity which subsisted between the pope and king Charles, he disdosed his design to his holiness; who readily entered into his measures, wrote to Peter to hasten his armament, promising him the investiture of the island as soon as he had taken possession of it; and by refusing the assistance he had promised to Charles, obliged him for the present to delay his expedition. In the beginning of the year 1280, Procida returned to Arragon, and by showing the letters from the pope and Sicilian barons, prevailed on Peter to embark in his design, by affurting him of the assistance of Paleologus. The king of Arragon accordingly prepared a formidable fleet under pretence of invading Africa, and is even said to have received 20,000 ducats from Charles, in order to assist him in his preparations.

But while John went on thus successfully with his scheme, all his measures were in danger of being broke by the death of pope Nicholas. The new pope, Martin IV. was entirely in the interest of Charles, on whom, in 1281, he conferred the senatoral dignity of Rome. As he well knew the enmity which subsisted between the pope and king Charles, he disdosed his design to his holiness; who readily entered into his measures, wrote to Peter to hasten his armament, promising him the investiture of the island as soon as he had taken possession of it; and by refusing the assistance he had promised to Charles, obliged him for the present to delay his expedition. his preparations with great diligence, intending to put to sea the following summer. Procida had returned to Palermo, to wait for a favourable opportunity of putting his design in execution, which was soon afforded him by the French. On Easter Monday, March 30th, 1282, the chief conspirators had assembled at Palermo; and, after dinner, both the Palermitans and French went in a grand procession to the church of Monreale, about three miles without the city. While they were sporting in the fields, a bride happened to pass by with her train, who being observed by one Drochettus, a Frenchman, he ran to her, and began to use her in a rude manner, under pretence of searching for concealed arms. A young Sicilian, exasperated at this affront, stabbed him with his own sword; and a tumult ensuing, 200 French were immediately murdered. The enraged populace then ran to the city crying out, "Let the French die, let the French die!" and, without distinction of age or sex, slaughtered all of that nation they could find, even such as had fled to the churches. The conspirators then left Palermo, and excited the inhabitants to murder the French all over the island, excepting in Messina, which city at first refused to be concerned in the revolt. But, being invited by the Palermitans to throw off the French yoke, a few weeks after, the citizens in a tumultuous manner destroyed some of the French; and pulling down the arms of Charles, and erecting those of the city, chose one Baldwin for their governor, who saved the remaining French from the fury of the populace, and allowed them to transport themselves, with their wives and children, to Italy. Eight thousand persons are said to have been murdered on this occasion.

Immediately after this massacre, the Sicilians offered their allegiance to the king of Aragon; who accepted of the invitation, and landed with his forces at Trapani. From thence he went to Palermo, where he was crowned king of Sicily with great solemnity, and Charles left the island with precipitation. The day after he landed his army in Italy, the Aragonian fleet arrived, took 29 of his galleys, and the next day burnt 80 transports in presence of his army. Soon after this Charles sent an embassy to Peter, accusing him of perfidy, in invading his dominions in time of peace; and, according to some, challenged him at the same time to decide the matter by single combat. Others say, that the challenge was given by Peter. Certain it is, however, that a challenge was given, and to appearance accepted; but Peter determined to employ much more effectual means in support of his pretensions than trusting to a duel; and therefore pushed on his operations most vigorously, while his adversary trifled away his time: and thus he at last became master of the contested kingdom; which, however, he did not long enjoy, dying about the end of the year 1285.

By his will, Peter left the kingdom of Aragon to his eldest son Alphonus, and Sicily to Don James his other son, who was also to succeed to the kingdom of Aragon in case Alphonus should die without male issue. Accordingly, Don James was solemnly crowned at Palermo the 24 of February 1286. In 1295, however, he deserted them, and tamely resigned up his right to Charles, son to him abovementioned, in a manner perhaps unparalleled. On his resignation the Sicilians conferred the crown upon his brother Don Frederic: after the war continued with great violence till the year 1303, when a peace was concluded, and the kingdoms of Naples and Sicily formally disjoined; Frederic being allowed to keep the latter under the name of Trinacria; and Charles being confirmed in the possession of the former which he quietly enjoyed till his death in 1309.

Naples continued to be governed by its own kings till the beginning of the 16th century, when the kings of France and Spain contended for the sovereignty of this country. Frederic, at that time king of Naples, resigned the sovereignty to Louis XII. on being created duke of Anjou, and receiving an annual pension of 30,000 ducats. But, in 1504, the French were entirely defeated by the Spaniards, and obliged to evacuate the kingdom; and the following year Louis renounced all pretensions to the crown, which from that time hath remained almost constantly in the hands of the Spaniards.

The government of the Spaniards proved no less oppressive to the Neapolitans than that of others had been. The kings of Spain set no bounds to their exactions, and of consequence the people were loaded with all manner of taxes; even the most indelible necessities of life not being exempted. In 1647, a new tax was laid on fruit; which the people looked upon as the most grievous oppression, the chief part of their subsistence, during the summer months, being fruit which in the kingdom of Naples is very plentiful and delicious. The edict for collecting the new duty was sooner published, than the people began to murmur. A general revolt, however, followed, as usual, they surrounded his coach, bawling out to have their grievances redressed. They were encouraged in their sedition, by the news that the citizens of Palermo had actually revolted on account of the imposition of new duties. The viceroy, therefore, apprehensive of greater disorders, began to think of taking off the tax; but those who farmed the taxes, being bribed some of his favourites, he was by their means persuaded not to abolish it. The indignation of the people, who had suspected his intention, was now greatly increased, especially as they were privately excited by several malcontents. The farmers of the revenue, and those concerned in raising the taxes, had incurred the hatred and detestation of the people, particularly of Tommaso Aniello, commonly called Maffaniello, who had been discovered in smuggling a small quantity of meal, was imprisioned, looted, and condemned to pay a fine of one hundred ducats.

Maffaniello, a few years before, had come to Naples from Amalfi, where his father had been a fisherman. At this time he was about 24 years of age, and the father of four children. He was of a middling stature, and an agreeable aspect; was distinguished for his boldness, activity, and integrity; and had a great influence with his companions, by whom he was beloved and esteemed. As he was obliged even to sell his furniture to pay the heavy fine, he had conceived an implacable hatred against the farmers of the taxes, and was also moved with compassion for the miserable state of the city and kingdom. He therefore formed a design, with some of his companions, to raise a tumult in the market-place on the festival-day of the Carmelites, usually celebrated about the middle of July, when between
Naples. between 500 and 600 youths entertain the people by a mock-fight; one half of them in the character of Turks, one half in a Character of Christians. Maffaniello being appointed captain of one of these parties, and one Pione, who was privy to his design, commanding the other, for several weeks before the festival they were very diligent in reviewing and training their followers, who were armed with sticks and reeds: but a small and unforeseen accident tempted them to begin their enterprise without waiting for the festival.

On the 7th of July a dispute happening in the market-place between the tax-gatherers and some gardeners of Pozzuolo who had brought some figs into the city, whether the buyer or seller should pay the duty; after the tumult had continued several hours, Maffaniello, who was present with his company, excited the mob to pillage the office built in the market for receiving the duty, and to drive away the officers with stones. The elder of the people, who by deciding against the gardeners, had incited the tumult ran from it, and informed the viceroy, who most imprudently neglected all means of putting a stop to the commotion. Maffaniello, in the mean time, being joined by great numbers of people, ordered his young troopers to light fire to all the offices for the taxes through the city; which command being executed with dispatch, he then conduited them directly to the palace, where the viceroy, instead of ordering his Spanish and German guards to disperse them, encouraged their insolence by timidly granting their demands. As they rushed into the palace in a furious manner, he fleaped by a private door, and endeavoured to save himself in the Casa del OllO; but being overtaken by the rioters in the streets, he was trampled upon by them, and pulled by the hair and whiskers. However, by throwing some handfuls of gold among them, he again escaped, and took sanctuary in a convent of Minims, where, being joined by the archbishop of Naples, cardinal Filomini, and several nobles by their advice he signed a bond, by which he abolished all taxes upon provisions. As a means to quell the tumult, he likewise desired the cardinal to offer Maffaniello a pension of 2400 crowns, who generously rejected the bribe, and declared, that if the viceroy would keep his word, he would find them obedient subjects.

It was now expected that the tumult would cease; but Maffaniello, upon his return to the market-place, being joined by several malcontents, among whom were Genuino and one Pione, who had formerly been captains of the Sibirri, he advised by them to order the houses of those concerned in raising the tax to be burned; which were accordingly in a few days reduced to ashes, with all their rich furniture. Maffaniello being now absolute master of the whole city, and being joined by great numbers of people of desperate fortunes, he required the viceroy who had retired to the Casa del OllO, to abolish all the taxes, and deliver up the writ of exemption granted by Charles V. This new demand greatly exasperated the viceroy; but to appease the people he drew up a false deed in letters of gold, and sent it to them by their favourite the duke of Matalone, who had before been in confinement. The fraud, however, being discovered, the duke was pulled from his horse and maltreated by the mob, and at length committed as a prisoner to Perone. This accident, to the great joy of the viceroy, enraged the people against the nobility, several of whom they killed, burnt the houses of others, and threatened to extirpate them all. Maffaniello, in the mean time tattered and half naked, commanded his followers, who were now well armed, and reckoned about 100,000 men, with a most absolute sway. He eat and slept little, gave his orders with great precision and judgment, appeared full of moderation, without ambition and interested views. But the duke of Matalone having procured his liberty by bribing Perone, the viceroy imitated his example, and secretly corrupted Genuino to betray his chief. A conspiracy was accordingly formed against Maffaniello by Matalone and Perone; the duke, who was equally exasperated against the viceroy, proposing, that after his death his brother D. Joseph should head the rebels.

Maffaniello in the mean time by means of the cardinal archbishop, was negotiating a general peace and accommodation; but while both parties were bargaining, the banditti hired by Matalone made an unsuccessful attempt upon Maffaniello's life. His folk were immediately killed 150 of them. Perone and D. Joseph being discovered to be concerned in the conspiracy were likewise put to death, and the duke with great difficulty escaped. Maffaniello by this conspiracy was rendered more fupicious and severe. He began to abuse his power by putting several persons to death upon flight, and, to force the viceroy to an accommodation, he cut off all communication with the castles, which were unprovided with provision and ammunition.

The viceroy, whose goods were espoused left the French should take advantage of the commotion, earnestly desired to agree to a treaty: which was accordingly concluded on the fifth day of the inundation, by the mediation of the archbishop. By the treaty it was stipulated that all duties imposed since the time of Charles V. should be abolished; that the writ of exemption granted by that emperor should be delivered to the people; that for the future no new taxes should be imposed; that the vote of the elect of the people should be equal to the votes of the nobility; that an act of oblivion should be granted for all that was past; and that the people should continue in arms under Maffaniello till the ratification of the treaty by the king.

By this treaty, no less than 10,000 persons, who fattened upon the blood of the public, were ruined. The people, when it was solemnly published, manifested an extreme joy, believing they had now recovered all their ancient rights and privileges. Maffaniello, at the desire of the viceroy, went to the palace to visit him, accompanied by the archbishop, who was obliged to threaten him with excommunication, before he would consent to lay aside his arms and assume a magnificent dress. He was received by the viceroy with the greatest demonstrations of respect and friendship, while the duchess entertained his wife, and presented her with a robe of cloth of silver, and some jewels.

The viceroy to preserve some shadow of authority, Maffaniello appointed him captain-general; and at his departure made him a present of a golden chain of great value, which with great difficulty he was prevailed upon to accept.
Naples.

accept; but yielded at length to the intreaties of the cardinal. Next day in consequence of the commission granted him by the viceroy, he began to exercise all the functions of sovereign authority; and having caused a scaffold to be erected in one of the streets, and several gibbets, he judged all crimes, whether civil or military, in the last resort: and ordered the guilty to be immediately put to death, which was the punishment he assigned to all offences. Though he neglected all forms of law, and even frequently judged by phyligion, yet he is said not to have overlooked any criminal or punished any innocent person.

34 His grandeur and prosperity was of very short continuance; for his becoming disdained and dелиritous for two or three days, he committed a great many mad and extravagant actions; and on the 18th of July was assassinated with the consent of the viceroy.

The tumult did not end with the death of Maffaniello; on the contrary, the people now expelled the Spaniards from most of the cities throughout the kingdom; and this general intestine being the subject of discussion at Rome, the duke of Guise, who happened then to be at the pope's court, took the opportunity, at the instigation of his bolines, to offer his service to the Neapolitans against the Spaniards. The duke was prompted by his ambition to engage in this enterprise, especially as he himself had some distant pretensions to the crown. The Spaniards in the mean time made a vigorous attack on the city; but were repelled by the people, who now formally renounced their allegiance to them. In a short time, however, their city being surprized by the new viceroy, the count d'O巨型, and the duke of Guise himself taken prisoner, the people returned to their allegiance, and thus all the attempts of the French on Naples were frustrated. Since that time the Spaniards continued in peaceable possession of the kingdom till the year 1707, when it was taken from them by prince Eugene. It was formally ceded to the emperor by the treaty of Rastadt in 1713; but was recovered by the Spaniards in 1714, and the king of Spain's eldest son is now king of Naples and Sicily, for a particular account of their revolutions, see the articles Spain and Sicily.

The climate of Naples is extremely hot, especially in July, August, and September. In winter there is seldom any ice or snow, except on the mountains. On account of its fertility it is justly termed an earthly paradise; for it abounds with all sorts of grain, the finest fruit and garden productions of every kind, with rice, flax, oil, and wine, in the greatest plenty and perfection. It affords also l'itron, manna, alum, vitriol, sulphur, rock crystal, marble and several sorts of minerals, together with fine wool, and silk. The hordes of his country are famous, and the flocks and herds very numerous. Besides these products, of which a considerable part is exported, there are manufactures of fluff, snap and glass wares. Weighcots, caps, flockings, and gloves, are also made of the hair or filaments of a shell fish, which are warmer than those of wool, and of a beautiful glossy green. In this kingdom likewise is found that called the Phrygian fluff, or pinca, fragilera, which, being laid in a damp place, will yield mushrooms, sometimes of a very large size, especially if the same is sprinkled with hot water. See AGARICUS.

As to the mountains of this country, the principal are those of the Apennine, which traverse it from South to North; and Mount Vesuvius, which, as is well known, is a noted Volcano, five Italian miles from Naples. The site of the mountain next the sea yields wine, particularly the two famed wines called Vino Greco and Lucryma Chisifi. One of the greatest inconveniences to which this kingdom is exposed is earthquakes, which the eruptions of Mount Vesuvius contribute in some measure, to prevent. Another inconvenience, which however is common to it with other hot countries, is the great number of reptiles and other insects, of which some are very poisonous.

With respect to religion, it is on a very bad footing here. The number of convents and monasteries is astonishing. It is said the clergy and convents possess two thirds of the whole kingdom; nay, some maintain, that were the kingdom divided into five parts, four would be found in the hands of the church. Notwithstanding this power and influence of the clergy, they have not been able hitherto to get the inquisition established here. In the year 1731, measures were taken for levying the number of convents; and lately the order of Jesuits have been suppressed. The papal bulls cannot be made public without the king's permission; nor are Protestants compelled to kneel in the churches, or at meeting the hoff; and in Lent they can easily procure fish meat. In the year 1740, the Jews were allowed to settle in the kingdom during the term of 50 years, and several privileges were granted them during that period; but the expiration of which the grant is supposed to be renewed unless they were expressly ordered to quit the country.

The revenue of the kingdom is generally computed at 3,000,000 of crowns: but, as Mr. Addison observes, there is no country in Europe which pays greater taxes, and where, at the same time, the public is left the better for them, most of them going to the enriching of the private persons to whom they are mortgaged.

The military force of this kingdom is said to consist of about 30,000 men of which the Swis regiments are the best. As to the marine, it consists only of a few galleys. The only order here is that of St. Janarius, which was instituted by Don Carlos in the year 1738.

The king of Naples, or of the two Sicilies, is an hereditary monarch. The high colleges are the council of State, the privy-council, the treasury, the Sicily-council, the council of war, &c. This kingdom is a papal fief; and the king in acknowledgment of the pope's feudal right, sends him every year a white palfry, and a purée of 6000 ducats. The title of the king's eldest son is prince of Calabria. The number both of the high and low nobility in the kingdom of Naples is very great. (I am assured, says Dr. Moore.)
The ladies and gentlemen within the coaches glitter in their attendants, the richness of their painted, gilt, varnished, and lined, in either in England or in France. They are often drawn by fix and sometimes by eight horses. Before the carriage, it is the mode to have two running footmen, and behind three or four servants in the richest liveries. The ladies and gentlemen within the coaches glitter in all the brilliance of lace, embroidery, and jewels.—This finery is not confined to the persons within and without the coaches; it is extended to the horses, whole heads, manes, and tails, are ornamented with the rarest plumes, and let off with ribbons and artificial flowers.

We shall mention a circumstance from which an idea may be formed of the grandeur of a Neapolitan palace, and the number of domestics which some of the nobility retain. "I dined (continues our author) at the prince Iacchi's, where we passed through 12 or 13 large rooms before we arrived at the dining-room. There were 36 persons at table served by the prince's domestics, and each guest had a footman behind his chair, while other domestics belonging to the prince remained in the adjacent rooms and in the hall. No estate in England could support such a number of servants, paid and fed as English servants are; but in Naples the wages are very moderate indeed, and the greater number of men-servants, belonging to the first families, give their attendance through the day only, and find beds and provisions for themselves. It must be remembered also, that few of the nobles give any entertainments; and those who do not are said to live very sparingly; so that the whole of their revenue, whatever it may be, is expended on articles of show."

In the kingdom of Naples, the hereditary jurisdiction of the nobles over their vassals subsists in the full rigour of the feudal government. The peasants therefore are poor; and it depends entirely on the personal character of the master, whether their property be not the least of their grievances. As this power is too often abused, the importance of the nobility depends in a great measure on the favour of the king, who, under pretence of any offence, can confine them to their estates, or imprison them at pleasure. Unless this prince were so very impolitic as to disquiet all the nobility at once, and so unite the whole body against him, he has little to fear from their resentment. Even in cases of such an union, as the nobles have left the affection of their vassals, what could they do in opposition to a standing army of 30,000 men, entirely devoted to the crown? The government of Naples, therefore, is in fact a despotic monarchy, though something like the form of a feudal constitution in its ancient purity is still kept up by the biennial summons of the general assembly. This convention, which consists of the nobility and commons, is called together every two years, to deliberate on the customary free-gift to the crown.

The inhabitants of this country have at all times borne but an indifferent character among other nations. "From the few hints dropped by the clastic authors, we collect that the ancient Neapolitans were a race of Ephesians, of a soft indolent turn, averse from martial exercises, passionately fond of theatrical amusements and music, expert in all the refined arts that administer to the caprices of luxury, extravagant in their expensives and costumes, and dupes to various sorts of superstition. If we make allowances for a quantity of northern blood which has joined the original Grecian stream, and imparted a roughness not yet worn off by the mildness of the climate, we shall find the modern Neapolitans very like the ancient—Provisions being here plentiful and cheap, the lower classes of people work but little. Their delight is to bask in the sun, and do nothing. Perfons of a middle rank frequent places of public resort; and very few of any rank attend to their proper business with the zeal and activity we are wont to meet with in the professional men of colder countries. Gluttony is a predominant vice, while infinances of chastity are comparatively rare. In the female sex, the passion for finery is almost superior to every other; and, though chaste is not the characteristic virtue of the country, Mr Swinburne doubts whether a Neapolitan woman would not nine times out of ten prefer a present to a lover. That furious jealousy for which the nation is famous, is now greatly abated. The breach of the conjugal vow sometimes occasions quarrels and affallations among people of an inferior station; and in the metropolis, affallations are often perpetrated from much lefs cogent motives. Of these vices, many are doubtless owing to that slavery and oppression under which they groan, and to a radical defect in the administration of justice, though the kingdom is divided into 12 provinces or jurisdictions.

NAPLES, anciently Parthenope, afterwards Neapolis, the capital of the kingdom of that name in Italy, lies in the province called Terra di Lavoro, which is the richest and best inhabited of the whole kingdom, and comprehends a part of the ancient Campania Felix, or the Happy. This city is fabled to owe its foundation to a syren, and to have received its ancient name from its supernaturalfoundrels. Whatever be its origin, it is the first for neatness, and the second for extent, of all the cities in Italy. It was formerly a place of strength; but its walls at present being of no real defence, its safety depends of course upon the force of its armies. It is most advantageously situated, having a delicious country on one side, and a noble bay of the Mediterranean on the other, with an excellent harbour. The circumference, including the suburbs, is said not to be less than 18 Italian miles, and the number of the inhabitants therein little less than 400,000. The houses are of stone, flat-roofed, and generally lofty and uniform; but many of them have balconies, with lattice-windows. The streets are well paved; but they are not lighted at night, and in the day-time are disfigured, in many places, by stalls on which provisions are exposed to sale. Here are a great number of fine churches, convents, fountains, and palaces of the nobility, many of whom constantly reside here. It is usual to walk on the tops of the houses in the evenings, to breathe the sweet cool air, after a hot sultry day. The climate here is so mild and warm, even in the winter, that plenty of green peas, artichokes, asparagus, and other vegetables, may
may be hazed so early as the beginning of the new year, and even all the winter. This city swarms with monks and nunns of all orders, to such a degree, that there are 10 left than 15 convents of the Dominicans alone, 18 of the Franciscus, 8 of the Augustinians, and an equal proportion of the rest. The magnificence of many of the churches exceeds imagination. In a cloyster of the Cuthonian monastery is a crucifix, said to be done by Michael Angelo, of inimitable workmanship.

To repel hostile attempts by sea, which, from its situation, maritime powers might be tempted to make, Naples has, to the west, the Caftel del Uovo, a con- fused pile of ancient buildings, and some modern batteries. The rock upon which this fortress stands was originally called Magna, then Lucullanum, and was considered as a place of strength so early as in the year 475. Along the line of the f June towards the east are some batteries on the points of land, the bastions of the arsenal, and above it the lofty wall of the Caftel Nuovo. This last fortress has been the usual refuge of the sovereigns and viceroys in all civil wars and tumults; for which reason they have long fixed their residence near its walls. A block-house and Batteries defend the mouth of the harbour, and at the eastern extremity of the town is the Torrione de Carmine, better known by the figure it made in Maffaniello's rebellion than by its extent or military strength. The caftle of Saint Elmo commands Naples in every direction, and is in reality calculated rather to annoy and awe the citizens than to defend them from foreign invaders. The city is indeed far from being secure against a bombardment; for the sea is so deep, that a large vessel may come up to the very mole in a port, and at the extremity has a high lantern to direct ships safely into the harbour. Luxury here is restrained by severe fumptuary laws, and the women are more closely confined than in any other city of Italy. Here is an university and two academies of wits, the one called Gli Ardeni, and the other Gli Otto. The nunnery for ladies of quality is said to be the largest in the whole world, containing no less than 350 nunns, besides servants. The Mount of Piety, or the office for advancing money to the poor, on pledges, at a low interest, or without any, has an income of upwards of 50,000 ducats. The arsenal is said to contain arms for 50,000 men. The walls of the city consist of hard black quarry stones, called piffero. Instead of ice, vast quantities of snow are used for cooling their liquors, not so much as water being drunk without it; so that, it is said, a scarcity of it would as soon occasion a mutiny as a dearth of money.

NAP [634] NAP

NAPLES (anc. geog.), a town of the Volce Tectofages, called also Narbo Martius, from the Legio Martia, the colony led thither 59 years before the confulate of Cæsar, (Velleius) ; increased with a colony of the Decuman or tenth legion by Cæsar. An ancient trading town on the Atax, which discharges itself into the sea through the Lacus Rubreus, or Rubrensis. Capital of the Gallia Narbonensis; formerly called Coniaria Julia Paterna, from Julius Cæsar, the father of Augustus by adoption. Now called Narbonne, a city of Languedoc.

NARBONNE, a city of France in Lower Languedoc, with an archbishop's see, and is particularly famous for its honey. It is seated on a canal cut from the river Aude, which being but three miles from the sea, vessels come up it laden with merchandise, which renders it a place of some trade. But though it pretends to the most remote antiquity under the Celtic kings, in ages anterior even to the Roman conquests, which under these latter matters gave its name to all, the Gallia Narbonensis, and was a colony of the first consideration, it is now dwindled to a wretched solitary town, containing scarce 8000 inhabitants, of whom three fourths are priests and women. The streets and buildings are mean and ruinous; it has indeed a communica-

fiery temper of the inhabitants. There are five piazzas or squares in the city, appropriated to the nobility, viz. those called Capuana, Nido, Montagna, Porta, and Porta Nova. Of all the palaces, that of the king is not only the most magnificent, but also in the best style of architecture. The cathedral, though Gothic, is a very grand splendid edifice. It is here that the head and blood of St. Januarus, the tutelary saint of Naples, are kept, the latter in two glass or crystal vials. The pretended liquefaction of the dried blood, as soon as brought near the head of the saint, is a thing well known; Mr. Addison says, it is one of the most bungling tricks he ever saw. The harbour is spacious, and kept in good repair. It is fortified with a mole, which runs above a quarter of a mile into the sea, and at the extremity has a high lantern to direct ships safely into the harbour. Luxury here is restrained by severe fumptuary laws, and the women are more closely confined than in any other city of Italy. Here is an university and two academies of wits, the one called Gli Ardeni, and the other Gli Otto. The nunnery for ladies of quality is said to be the largest in the whole world, containing no less than 350 nunns, besides servants. The Mount of Piety, or the office for advancing money to the poor, on pledges, at a low interest, or without any, has an income of upwards of 50,000 ducats. The arsenal is said to contain arms for 50,000 men. The walls of the city consist of hard black quarry stones, called piffero. Instead of ice, vast quantities of snow are used for cooling their liquors, not so much as water being drunk without it; so that, it is said, a scarcity of it would as soon occasion a mutiny as a dearth of money.
NARCISSUS. In fabulous fistory, the son of the river Cephisius and Liriope the daughter of Oceanus, was a youth of great beauty. Tiresias foretold that he should live till he saw himself. He despised all the nymphae of the country; and made Echo languish till she became a mere sound, by refusing to return her passion; but one day coming weary and fatigued from the chase, he floated on the bank of a fountain to quench his thirst; when, seeing his own form in the water, he became so in love with the shadowy image that he languished till he died. On which the gods, being moved at his death, changed him into the flower which bears his name.

**Narcissus**, in botany: A genus of the monogynia order, belonging to the herbaceous class of plants; and in the natural method ranking under the 9th order, Spatheceae. There are six petals; the nectarium is funnel-shaped, and monophylous; the flamen are within the nectarium. The most remarkable species are.

1. The bastard narcissus, or common yellow English daffodil, grows wild in great plenty in many of the woods and coppices; and under hedges in several parts of England. In the counties round London the herb folks bring prodigious quantities in the spring of the year, when in bloom, root and all, and sell them about the streets. Its commonness renders it of but little esteem with many; considered, however, as an early and elegant flower, of exceeding hardiness and easy culture, it merits a place in every garden.

2. The bicolor, or two-coloured incomparable narcissus, hath a large, oblong, bulbous root; crowned with long, narrow, dark-green leaves, 12 or 14 inches long; an upright flower-stalk, about 15 inches high, terminated by an uniflorous spathe, protruding one yellow flower, having the nectarium much larger than the petals, and very broad and spreading at the brim; flowering in April. From the large spreading nectarium of this species, which being three or four times longer than the petals, narrow at bottom, and widening gradually to the brim, so as to resemble the shape of some old fashioned hoop peticoats, it obtained the name hoop-petticoat narcissus.

3. The ferotinus, or late-flowering small autumnal narcissus, hath a small bulbous root; crowned with a few narrow leaves; amid them a jointed flower-stalk eight or nine inches high, terminated by an uniflorous spathe, protruding one white flower, having a short, five-parted, yellow nectarium; flowering in autumn.

4. The tazetta, or multiflorous daffodil, commonly called *polyanthus narcissus*, hath a very large, roundish, bulbous root; long, narrow plain leaves; an upright flower-stalk, rising from 10 or 12 inches to a foot and a half high; terminated by a multiflorous spathe, protruding in many large, spreading, white and yellow flowers, in a cluster, having bell-shaped nectaria shorter than the corolla; flowering in February, March and April, and is very fragrant. The varieties of this are very numerous, consisting of about eight or nine principal sorts, each of which having many intermediate varieties: amount in the whole greatly above an hundred in the Dutch florists' catalogues, each variety distinguished by a name according to the fancy of the first raiser of it. They are all very pretty flowers, and make a charming appearance in the flower-borders, &c. they are also finely adapted for blowing in glasses of water, or in pots, to ornament rooms in winter.

5. The jonquilla, or jonquil, sometimes called *raff*, *leaved daffodil*, hath an oblong, bulbous, brown root, fending up several long, semi-taper, ruff-like, bright-green leaves; amid them an upright green flower-stalk, a foot or 15 inches high; terminated by a multiflorous spathe, protruding many yellow flowers, often expanded like a radius, each having a hemispherical, crenated nectarium, shorter than the petals; flowering in April, and profuse of a fine fragrance. The varieties are, jonquil minor with single flower—jonquilla major with single flower—barry flowered—white and yellow flowered—white flowered—semi-double-flowered—double flowered—and large double inodorous jonquil: all of them multiflorous, the fingle in particular; but sometimes the doubles produce only two or three flowers from a spathe, and the singles commonly fix or eight. All the sorts have so fine a shape, so soft a colour, and so sweet a front, that they are some of the most agreeable spring-flowers.

6. The calathinus, or multiflorous yellow narcissus, hath a large bulbous root; crowned with long, narrow, plane leaves; and amid them an erect, robust flower-stalk, terminated by a multiflorous spathe, protruding many large, entire, yellow flowers, having a bell-shaped, slightly crenated nectarium, equal in length with the petals.

7. The odoratus, or sweet-scented, narrow yellow narcissus, hath a bulbous root; narrow leaves; erect flower-stalk, a foot or more high, terminated by a sub-multiflorous spathe, protruding sometimes but

8. The chace, he stopped on the bank

9. The daffodil, grows wild in great plenty in several parts of England. From the large spreading nectarium of this species, which being three or four times longer than the petals, narrow at bottom, and widening gradually to the brim, so as to resemble the shape of some old-fashioned hoop peticoats, it obtained the name hoop-petticoat narcissus.

10. The bastard narcissus, or common yellow English daffodil, grows wild in great plenty in many of the woods and coppices; and under hedges in several parts of England. In the counties round London the herb folks bring prodigious quantities in the spring of the year, when in bloom, root and all, and sell them about the streets. Its commonness renders it of but little esteem with many; considered, however, as an early and elegant flower, of exceeding hardiness and easy culture, it merits a place in every garden.

11. The bicolor, or two-coloured incomparable narcissus, hath a large, oblong, bulbous root; crowned with long, narrow, dark-green leaves, 12 or 14 inches long; an upright flower-stalk, about 15 inches high, terminated by an uniflorous spathe, protruding one yellow flower, having the nectarium much larger than the petals, and very broad and spreading at the brim; flowering in April. From the large spreading nectarium of this species, which being three or four times longer than the petals, narrow at bottom, and widening gradually to the brim, so as to resemble the shape of some old-fashioned hoop peticoats, it obtained the name hoop-petticoat narcissus.

12. The ferotinus, or late-flowering small autumnal narcissus, hath a small bulbous root; crowned with a few narrow leaves; amid them a jointed flower-stalk eight or nine inches high, terminated by an uniflorous spathe, protruding one white flower, having a short, five-parted, yellow nectarium; flowering in autumn.

13. The tazetta, or multiflorous daffodil, commonly called *polyanthus narcissus*, hath a very large, roundish, bulbous root; long, narrow plain leaves; an upright flower-stalk, rising from 10 or 12 inches to a foot and a half high; terminated by a multiflorous spathe, protruding in many large, spreading, white and yellow flowers, in a cluster, having bell-shaped nectarium shorter than the corolla; flowering in February, March and April, and is very fragrant. The varieties of this are very numerous, consisting of about eight or nine principal sorts, each of which having many intermediate varieties: amount in the whole greatly above an hundred in the Dutch florists' catalogues, each variety distinguished by a name according to the fancy of the first raiser of it. They are all very pretty flowers, and make a charming appearance in the flower-borders, &c. they are also finely adapted for blowing in glasses of water, or in pots, to ornament rooms in winter.

14. The jonquilla, or jonquil, sometimes called *raff*, *leaved daffodil*, hath an oblong, bulbous, brown root, sending up several long, semi-taper, ruff-like, bright-green leaves; amid them an upright green flower-stalk, a foot or 15 inches high; terminated by a multiflorous spathe, protruding many yellow flowers, often expanded like a radius, each having a hemispherical, crenated nectarium, shorter than the petals; flowering in April, and profuse of a fine fragrance. The varieties are, jonquil minor with single flower—jonquilla major with single flower—barry flowered—white and yellow flowered—white flowered—semi-double-flowered—double flowered—and large double inodorous jonquil: all of them multiflorous, the single in particular; but sometimes the doubles produce only two or three flowers from a spathe, and the singles commonly fix or eight. All the sorts have so fine a shape, so soft a colour, and so sweet a front, that they are some of the most agreeable spring-flowers.

15. The calathinus, or multiflorous yellow narcissus, hath a large bulbous root; crowned with long, narrow, plane leaves; and amid them an erect, robust flower-stalk, terminated by a multiflorous spathe, protruding many large, entire, yellow flowers, having a bell-shaped, slightly crenated nectarium, equal in length with the petals.

16. The odoratus, or sweet-scented, narrow yellow narcissus, hath a bulbous root; narrow leaves; erect flower-stalk, a foot or more high, terminated by a sub-multiflorous spathe, protruding sometimes but
The triandrus, or triandrous rush-leaved white narcissus, hath a bulbous root; very narrow, rush-like leaves; erect flower-stalk, terminated by an uniflorous spathe, protruding one flowery-white flower, having a bell-shaped, created nectarium, half the length of the petals, and with modestly triandrous or three-flowered leaf-stalks. 

The triolobus, or trilobate yellow narcissus, hath a bulbous root; narrow rush-like leaves; erect flower-stalks, terminated by a sub-multiflorous spathe protruding sometimes but one or two, and sometimes several, yellow flowers, having a bell-shaped, three-lobed nectarium, half the length of the petals.

The minor, or yellow winter daffodil, hath a small bulbous root; plane leaves eight or ten inches long, and more than half a one broad; an erect flower-stalk, terminated by an uniflorous spathe protruding one nodding yellow flower, with spear-shaped petals, having an obconic, fixed-petalled, waved nectarium, equal to the length of the corolla; flowering in winter, or very early in spring.

All these 12 species of narcissus are of the bulbous-rooted tribe, and univerally perennial in root, but annual in leaf and flower-stalk; all of them riling annually in spring, immediately from the crown of the bulb, 1ift the leaves and in the midst of them the flower-stalks, none from each root, entirely naked or leafless, each terminated by a spathe or sheath, which opens on one side to protrude the flowers, and then withers; the flowers, as before observed, are all hexagonal, each furnished with a nectarium in the centre, and are universally hermaphrodite; they are large and conspicuous, appearing mostly in the spring-leaflu, generally from March or April until June, succeeded by ripe seed in July; then the leaves and flower-stalks decay, and the roots defeat from growing for some time; at which period of rest is the only proper time to take up or transplant the roots from one place to another or to separate the offsets; for they all multiply abundantly by offset young bulbs from the main root, infomuch that a single bulb will in one or two years be increased into a large cluster of several bulbs, closely placed together, and which every second or third year should be taken up at the above period in order to be separated; and each offset so separated commences a distinct plant: which being planted again in autumn, produces flowers the following summer, alike in every respect to those of their respective parent bulbs. All the species are so hardy that they proper in any common soil of a garden: observing, however, to allow the finer sorts of polyanthus narcissus, in particular, principally a warm dry situation, all the others may be planted any where in the open dry borders, and flower-beds.

NARCOTICS, in medicine, soporiferous drugs, which bring on a stupefaction. Among narcotics the most eminent are those usually prepared for medicinal uses from the poppy, especially opium; as also all those prepared from mandragoras, hyoscynamus, droso­nomum, and datura.

NARDO, a pretty populous town in the kingdom of Naples, and in the Terra d'Otranto, with the title of a duchy and a bishop's see. E. Long. 18. 27. N. Lat. 45. 28.

In this little city are 8000 inhabitants. The steeple of its cathedral is built in a very uncommon but flowy style of Gothic architecture. Luca Giordano and Sol­limeri have adorned the church with some agreeable painting. This place was part of the Balzo estate. The Aquavras were the next possessors: they are thought to have come from the Marcia di Ancona. In 1401, in consideration of their relationship to Pope Bo­niface IX. Laudalau erected their manor of Ari into a dukedom, an honour till then seldom granted to any but princes of the blood royal. Claudius Aquaviva, a famous general of the Jesuits, who died in 1615, was of this family.

NARDUS, in botany: A genus of the monogy­nia order, belonging to the triandria class of plants; and in the natural method ranking under the 4th order, Gramina. There is no calyx; the corolla is bi-valved.

This plant was highly valued by the ancients, both as an article of luxury and medicine. The unguentum nardum was used at baths and feails as a favourite perfume. Its value is evident from that passage of scripture, where our Saviour's head was anointed with a box of it, with which Judas found fault. From that passage in Horae it appears that this ointment was so valuable among the Romans, that as much as could be contained in a small box of precious stone was considered as a sort of equivalent for a large vessel of wine, and a proper quota for a guest to contribute at an entertainment, according to the ancient custom;

---Nardus ina merebere.

Nardi parues onyx eliciet cadum.

The plant had a great character among the ancients as a medicine, both internally taken and externally applied. It has a place in the list of all antidotes from those of Hippocrates (given on the authority of My­repus and Nicholas Alexandrinus) to the officinals which have kept their ground till lately, under the names of Mithridate and Venice treacle. Galen and Alexander Trallian recommend it in the dropsy and gravel; Cellus and Galen in pains of the stomach and bowels, both internally given and externally applied. Galen prescribed the oleum nardium to the emperor Marcus Aurelius when afflicted with a cholera mor­bus. It was externally applied to the stomach on wool; and the success was so great, that he ever afterwards enjoyed the highest confidence of that emperor. In a work attributed to Galen, also, it is mentioned that a medicine composed of this and some other aromatics was found useful in long protracted fevers; and the natives of India at present consider it as very efficacious remedy in fevers. Its sensible qualities, indeed, promise it to be of considerable efficacy in some feals, as it has a pungency of taste superior to contrayerva, and little inferior to ferpentaria.

But though the name of this plant, with the uses and virtues of it, has long been familiar in the writings of botanists and physicians, the genus and species of the plant have only been ascertained very lately. In the Philosophical Transactions for 1799, Dr Blane gives an account of it from a letter sent him by his brother from Lucknow, dated in December 1798.---

According to this gentleman's relation, being one day
NARDUS

on a hunting party with the nabob viceroy, after crossing the river Rapti, about 20 miles from the foot of the northern mountains, he was surprised to find the air perfumed with an aromatic smell, which, as he was told, proceeded from the roots of the grasses that were bruised or torn out of the ground by the nabob’s elephants and horses. The country was wild, uncultivated, and entirely covered with this kind of grasses, which grew in large tufts close to each other, and from three to four feet long. As none of it was in flower, it being then the winter season, and the grasses having besides been burnt down by order of the nabob, our author caufed some of the roots to be dug up, in order to plant it in his garden at Lucknow. Here it pro provere exceedingly; and shot up spikes to the height of six feet. A specimen was sent to Sir Joseph Banks, who found it to belong to the genus of andropogon, different from any species hitherto described by botanists. “There is great reason, however (says Dr Blane), to think that it is the true nardus Indica of the ancients; for, 1. The circumstance of its discovery corresponds in a striking manner with an occurrence related by Arrian in his History of Alexander’s expedition into India. During the march of that hero through the deserts of Gedrosia, the air was perfumed by the spikenard, which was trampled under foot by the army; and the Phœnicians, who accompanied them, collected great quantities of it, as well as of myrrh, to carry them into their own country to make merchandise of them. This last circumstance seems further to ascertain it to have been the true nardus; for the Phœnicians, who even in war appear to have retained their true genius for commerce, could no doubt distinguish the proper quality of this commodity. I am informed by Major Rennel, that Gedrosia answers to the modern Mackran, or Kedge-mackran, a maritime province of Persia, situated between Kermon (the ancient Carmania), and the river Indus, being of course the frontier province of Persia towards India; and that it appears from Arrian’s account, and from a Turkish map of Persia, that this defart lies in the middle tract of country between the river Indus and the Persian gulf, and within a few days march of the Arabian or Erythraean sea. By this the ancients meant the northern part of the Ethiopic ocean, which washes the southern coasts of Arabia and Persia; not what we now call the Red Sea, as its name would seem to imply, for this by the ancients was called the Arabian Gulf. 2. Though the accounts of the ancients concerning this plant are very defective, it is plain that it was of the natural order of grammica; for the term arisi, so often applied to it, was appropriated by them to the fructification of grains and grasses, and seems to be a word of Greek original, to denote the most excellent portion of those plants, which are the most useful in the vegetable creation for the fullness of animal life; and nature has also kindly made them the most abundant in all parts of the habitable earth. Galen says, that though there are various sorts of nardus, the term saufa, sauz, or spikenard, should not be applied to any but the nardus Indica. It would appear that the nardus Celica was a plant of a quite different habit, and is supposed to have been a species of valeriana.

The description of the Nardus Indica by Pliny does not indeed correspond with the appearance of our specimen; for he says it is frutes radice pingui et rofather, whereas ours has small fibrous roots. But as Italy is very remote from the native country of this plant, it is reasonable to suppose that others more easily procurable used to be substituted for it; and the same author says, that there were nine different plants by which it could be imitated and adulterated. There is a Nardus Africca mentioned by Horace; and Dioscorides mentions the Nardus Syriaca as a species different from the Indian, which certainly was brought from some of the remote parts of India; for both Dioscorides and Galen, by way of fixing more particularly the country from whence it came, call it the Nardus Gangis. 3. Garcias de Herios, a Portuguese who resided many years at Goa in the 16th century, has given a figure of the roots or rather of the lower parts of the spikes, which corresponds with our specimen, and he says that there is but one species of nardus known in India, either for the consumption of the natives, or for exportation to Persia and Arabia. 4. The sensible qualities of this are superior to what commonly passes for it in the shops, being poisseled both of more fragrance and pungency, which seems to account for the preference given to it by the ancients.

“There is a question, concerning which Mathilios, the commentator of Dioscorides, beffows a good deal of argument, viz. whether the roots or spikes were the parts esteemed for use, the testimony of the ancients themselves on this head being ambiguous. The roots of this specimen are very small, and poiffes sensible qualities inferior to the root of the plant; yet it is mentioned in the account above recited, that the virtues reside principally in the hufty roots. It is evident, that by the husky roots must here be meant the lower part of the spikes and leaves, where they unite to the roots; and it is probably a flight ambiguity of this kind that has given occasion to the ambiguity that occurs in the ancient accounts.”

The sensible qualities of this plant do not depend upon an essential oil, but on some fixed principle like those of cardamom or ginger. Dr Blane tried to extract its virtues with boiling water, maceration in wine or proof spirits, but it yielded them sparingly and with difficulty to any of these menstrua. The Indians gave an infusion of it in hot water, with a small quantity of black pepper as a refrefhing.

NAREA, the most southerly province of the empire of Abyssinia; a kingdom still governed by its own princes, who have the title of Benares. Its territory was formerly more extensive than at present, the Galla having almost quite surrounded it, especially on the south-east and north. The country to the west is the most unknown part of Africa; the kingdom itself stands like a fortified place in the middle of a plain, being an high and mountainous country. A great many rivers, rising in the fourth and fifth degrees of north latitude, spread themselves over the level part of the country, and fill it with marshes all the way from south by east to north, or north-west. These marshes are bounded by mountains, of which those nearest the marshes are overgrown with coffee trees, the largest, if not the only ones, which grow in this country. The kingdom of Narea Proper is intersected with many, unequal streams, but very fertile valleys.
NARRATION. [ 638 ]

Narathm. 

valleys. The mountainous country of Caffa adjoins immediately to Narathm, and is said to be governed by a separate prince: but the Galla having settled themselves in all the flat ground to the very edge of the marines, have in a great measure cut off the communication with Abyssinia for a long time past. The Nareans, who inhabit the mountainous country, have the lightest complexion of any people in Abyssinia; but those who inhabit the borders of the marines are perfectly black, and have the features and woolly heads of negroes; but the mountaineers of Narathm, and much more those of Caffa, are fair complexioned, more so than even the Neapolitans or Sicilians. It is said that now has been seen to lie on some of the mountains of Caffa; but Mr. Bruce imagines this to be a mistake, and thinks that it must have been hail.

Narathm abounds with cattle, grain and all kinds of provisions, both in the high and low country. The medium of commerce is gold, which they fell by weight; but the principal articles of trade are coarse cotton cloths, antimony, beads, and incense, which are carried from this country to the kingdom of Angola, and the parts of the African continent towards the Atlantic. The people are exceedingly brave; and though they had been driven out of the low country by multitudes of Galla, they now bid them defiance, and drive them from their frontiers whenever they come too near. The Narean prisoners taken in these skirmishes are sold to the Mahometan merchants at Gondar; and at Constantinople, Cairo, or in India, the women are more esteemed than those of any other part of the world. Both sexes have a cheerful, kind disposition, and attach themselves inviolably to their masters, if properly treated. The people of Narathm and Caffa speak a language peculiar to themselves.

NARRATION, in oratory, poetry, and history, a recital or rehearsal of a fact as it happened, or as it is supposed to have happened. See ORATORY, 

Concerine NARRATION and DESCRIPTION, we have the following rules and observations in the Elements of Criticism:

1. The first rule is, That in history the reflections ought to be chaste and solid; for while the mind is intent upon truth, it is little disposed to the operation of the imagination. Strada's Belge history is full of poetical images, which, being discordant with the subject, are unpleasant; and they have a still worse effect, by giving an air of fiction to a genuine history. Such flowers ought to be scattered with a sparing hand, even in epic poetry; and at no rate are they proper till the reader be warmed, and by an elevated imagination be prepared to relish them: in that state of mind, they are agreeable; but while we are fated and attentive to an historical chain of facts, we reject with disdain every fiction.

2. Vidu, following Horace, recommends a modest commencement of an epic poem; giving for a reason, that the writer ought to husband his fire. Besides, bold thoughts and figures are never relished till the mind be heated and thoroughly engaged, which is not the reader's case at the commencement. Homer introduces not a single simile in the first book of the Iliad, nor in the first book of the Odyssey. On the other hand, Shakespeare begins one of his plays with a sentiment too bold for the most heated imagination:

Bedford. Hung be the heav'n's with black, yield day to night!

Comets, importing change of times and states,

Brandish your crystal tresses in the sky,

And with them scourge the bad revolted stars,

That have contended into Henry's death!

Henry the Fifth, too famous to live long!

England ne'er lost a king of so much worth.

First part Henry V.

The passage with which Strada begins his history, is too poetical for a subject of that kind: and at any rate too high for the beginning of a grave performance.

3. A third rule or observation is, That where the subject is intended for entertainment solely, not for instruction, a thing ought to be described as it appears, not as it is in reality. In running, for example, the impulse upon the ground is proportioned in some degree to the celerity of motion; though in appearance it is otherwise, for a person in swift motion seems to skim the ground, and scarcely to touch it. Virgil, with great taste, describes quick running according to appearance; and raises an image far more lively than by adhering scrupulously to truth:

Hos super adventit volvis de gente Camilla,

Agmen agens equitum et florentes

Ferreet iter; celeris nec tingeret

Grammina: nec teneras curfu

Vel intaete fedegis per summa volaret

Gramminar: nec tenebras curfu aristas;

Vel mare per medium, fluentus tenuit

Ferret iter: celeris nec tingueret sequestra plantas.

Aeneid. vii. 807.

4. In narration as well as in description, objects ought to be painted so accurately as to form in the mind of the reader distinct and lively images. Every niche's circumstance ought indeed to be suppressed, because every such circumstance loads the narration; but if a circumstance be necessary, however slight, it cannot be described too minutely. The force of language consists in raising complete images, which have the effect to transport the reader as by magic into the very place of the important action, and to convert him as it were into a spectator, beholding every thing that passes. The narrative in an epic poem ought to rival a picture in the liveliness and accuracy of its representations: no circumstance must be omitted that tends to make a complete image; because an imperfect image, as well as any other imperfect conception, is cold and intermitting. We shall illustrate this rule by several examples giving the first place to a beautiful passage from Virgil:

Qualis populo matres Philomela sub umbra

Amilios queritur focus, quos durus ara ort

Obiervans nido implumes detract.

Georg. l. 1. 511.

The poplar, plowman, and unshedded young, though not essential in the description, tend to make a complete image, and upon that account are an embellishment.

Again:
Narration.

Again:

Hic viridem Æneas fondoni ex ilice metam
Constituit, signum mutis.

Horace addrefling to fortune:

Te pauper ambit
Sufpiiret: Eheu, ne ruJis agradam
Sponfus
Ruris

— Illum ex mænibus hofitis
Matrona bellantis tyranni
Propficiens, et adulta virgo,
Sufpirat: Eheu, ne ruJis agradam
Sponfus lacef-fat regius alperum
Tacto leonum, quem cruenta
Per medias rapiit ira caedes.

Shakespeare fays, “You may as well go about to turn
the fun to ice by faming in his face with a peacock's
feather.” The peacock’s feather, not to mention the
beauty of the object, completes the image: an accurate
image cannot be formed of that fanciful operation,
without conceiving a particular feather; and
one is at a loss when this is neglected in the defcrip-
tion. Again, “The rogues flighted me into the river
with as little remorse, as they would have drown'd a
bitch's blind puppies, fifteen 'tis litter.”

Old Lady. You would not be a queen.

Anne. No, not for all the riches under heaven.

Old Lady. 'Tis strange: a three-pence bow’d would
hire me, old as I am, to queen it.

Henry VIII. ad. 2. fc. 5.

In the following paffage, the action, with all its ma-
terial circumstances, is reprefented fo much to the life,
that it would scarce appear more diftinct to a real spec-
tator; and it is the manner of defcription that con-
tributes greatly to the fulblimity of the paffage.

He fpake; and, to confirm his words, out flew
Millions of flaming fwords, drawn from the thighs
Of mighty cherubin; the fudden blaze
Far round illum’d hell: highly they rag’d
Againft the Highft, and fierce with graffed arms,
Clad’d on their founding shields the dim of war,
Hurling defiance toward the vault of heav’n.

Milton. b. 1.

The following paffage from Shakespeare falls not
much short of that now mentioned in particularity of
defcription:

O you hard hearts! you cruel men of Rome!
Knew you not Pompey? Many a time and oft
Have you climb’d up to walls and battlements,
To tow'rs and windows, yes, to chimney-tops,
Your infants in your arms: and there have fat
The live-long day with patient expectation
To fee great Pompey pass the streets of Rome;
And when you saw his chariot but appear,
Have you not made an universal shout,
That Tyber trembled underneath his banks,
To hear the replication of your founds,
Made in his concave flore?

Julius Cæsar, adv. 1. fo 1.

The following paffage is scarce inferior to either of Narration.

“Far before the reft, the fon of Offian comes:
bright in the smiles of youth, fair as the firft beams
of the fun. His long hair waves on his back: his
dark brow is half beneath his helmet. The fword
hangs loofe on the hero’s tide; and his spear glitters
as he moves. I fled from his terrible eye, King of
high Temora.”

Fingal.

The Henricade of Voltaire errs greatly against the
foregoing rule; every incident is touched in a fum-
mary way, without ever defcending to circumfances.
This manner is good in a general history, the purpofe
of which is to record important tranfactions: but in a
fable it is cold and uinterefling; because it is imprac-
ticable to form deftrict images of persons or things re-
prefented in a manner fo superficial.

It is obferved above, that every ufefles circumfance
ought to be fuppreffed. The crowding such circum-
fances is, on the one hand, not lefs to be avoided,
than the concifenes for which Voltaire is blamed, on
the other. “In the Æneid, Barce, the nurfe of Si-
claus, whom we never hear of before nor after, is
introduced for a purpofe not more important than to call
Anna to her fifter Dido: and that it might not be
thought unjuft in Dido, even in this trivial circum-
fance, to prefer her husband’s nurfe before her own,
the poet takes care to inform his reader, that Dido’s
nurfe was dead. To this may be oppofed a beautiful
paffage in the fame book, where, after Dido’s laft
speech, the poet, without detaining his readers by de-
scribing the manner of her death, haults to the la-
mentation of her attendants:

Dixerat: atque illum media inter talia ferro
Collapfam afpiciunt comites, enfemque eruore
Spumantem, fparfaque manus. It clamor ad alta
Atria, concufiam bacchatur fama per urbem;
Lamentis gemituque et femineo ululatu
Teeta fremunt, refonat magnis plangoribus æther.

Lib. 4. 1. 66g.

As an appendix to the foregoing rule, may be added
the following obfervation. That to make a fudden and
strong impression, fome fingle circumfance, happily
flected, has more power than the molt laboured de-
scription. Macbeth, mentioning to his lady fome
voices he heard while he was murdering the King,
says,

There’s one did laugh in sleep, and one cry’d Murder!
They wak’d each other; and I ftood and heard them;
But they did fay their prayers, and addrefl them
Again to fleep.

Lady. There are two lodg’d together.

Macbeth. One cry’d, God blefs us! and, Amen!
the other;

As they had feen me with thefe hangman’s hands.
Listening their fear, I could not fay, Amen,
When they did fay, God blefs us.

Lady. Consider it not fo deeply.

Macbeth. But wherefore could not I pronounce
Amen?

I had most need of bleffing, and Amen
Stuck in my throat.

Lady.
In the following passage, a character is completed by

Narration:

Shallow. O the mad days that I have spent; and to see how many of mine old acquaintance are dead.

Silence. We shall all follow, cousin.

Shallow. Certain, 'tis certain, very sure, very sure; Death (as the Psalmist faith) is certain to all: all shall die. How good a yoke of bullocks at Stamford fair?

Silence. Truly, cousin, I was not there.

Shallow. Death is certain. Is old Double of your town living yet?

Silence. Dead, Sir.

Shallow. Dead! see, see; he drew a good bow: and dead. He flot a fine floot. How a score of ewes now?

Silence. Thereafter they be. A score of good ewes may be worth ten pounds.

Shallow. And is old Double dead?

Second Part Henry IV. act 3. sc. 3.

Describing a jealous husband:

Congreve has an inimitable stroke of this kind in his comedy of Love for Love:

Ben Legend. Well, father, and how do all at home? how does brother Dick, and brother Val?

Sir Sampfon. Dick, body o' me, Dick has been dead these two years. I writ you word when you were at Leghorn.

Ben. Mefs, that's true; marry, I had forgot. Dick's dead, as you say.

Shallow. And is old Double dead?

Second Part Henry IV. act 3. sc. 3.

Falstaff speaking of Ancient Pifto:

"He's no swaggerer, ho!tels; a tame chearier i'faith; you may troo him as quietly as a puppy-greyl.; and he will not swagger in a Barbary hen, if her feathers turn back in any show of relintence."

Second Part Henry IV. act 2. sc. 9.

Offian among his other excellencies is eminently succesful in drawing characters; and he never fails to delight his reader with the beautiful attitudes of his heroes. Take the following instances:

"O Ofcar! bend the strong in arm; but spare the feeble hand. Be thou a dream of many tides against the foes of thy people; but like the gale that moves the grafs to those who ask thine aid.—So Tremnor lived; fuch Trathal was; and fuch has Fingal been. My arm was the support of the injured; and the weak refled behind the lighting of my feel."

"We heard the voice of joy on the coast, and we thought that the mighty Cathmor came. Cathmor the friend of strangers! the brother of red-haired Cairbar! But their foes were not the fame; for the light of heaven was in the bofom of Cathmor. His towers rofe on the banks of Atha; seven paths led to his hills; seven chiefs flood on thefe paths, and called the stranger to the feat. But Cathmor dwelt in the wood to avoid the voice of praise."

"Dermid and Ofcar were one: they reaped the battle together. Their friendfhip was strong as their
As words are intimately connected with the ideas they represent, the emotions raised by the sound and by the sense ought to be concordant. An elevated subject requires an elevated style; what is familiar, ought to be familiarly expressed: a subject that is serious and important, ought to be clothed in plain nervous language: a description, on the other hand, addressed to the imagination, is susceptible of the highest ornaments that sounding words and figurative expression can bestow upon it.

We shall give a few examples of the foregoing rules.

A poet of any genius is not apt to dress a high subject in low words; and yet blemishes of that kind are found even in classical works. Horace observing that men are satisfied with themselves, but seldom with their condition, introduces Jupiter indulging to each his own choice:

Jam faciam quad vultis; eris tu, qui modo miles, Mercator; tu, confultus modo, ruficus; hic vos, Vos hinc mutatis dicetides partes: eia,
Quid static? nolint: atqui licet esse beatis.
Quid caufe et, merito quin illius Jupiter ambas
Irvius bucas inflet? neque fe fore pothac
Tam facienc dicat, votis ut praebat aurem?

Sat. lib. 1. sat. 1. l. 16.

Jupiter in wrath puffing up both cheeks, is a low and even ludicrous exprefion, far from suitable to the gravity and importance of the subject; every one must feel the discordance. The following couplet, finding far below the subject, is no less ludicrous:

Not one looks backward, onward full he goes.
Yet ne'er looks forward farther than his nose.

Essay on man, ep. iv. 223.

On the other hand, to raise the expression above the tone of the subject, is a fault than which none is more common. Take the following instances:

Orcan le plus fidel à fervir les defeins,
Ne fous le ciel brillant des plus noirs Africains.

Bajazet alt 3. ft. 8.

Les ombres par trois fois ont obscure cette
Depuis que le fommeil n'a point entre dans vos yeux;
Et le jour a trois fois châble la nuit obscure.
Depuis que vos corps languis dans nourriture.

Phedra, alt 1. f. 7.

Affarirs. Ce mortel, qui montra tant de zele pour moi, Vit-il encore?

Afaph.—Voil l'autre qui vous clairea.

Efsber, alt 2. ft. 3.

Oui, c'est Agamemnon c'est ton roi qui te tivre;
Viens, reconnais la voix qui frappe ton oreille.

Epigone.

No jocund health that Denmark drinks to-day,
But the great cannon to the clouds shall tell;
And the king's rowde the heav'n shall bruit again,
Repeaking earthly thunder.

Hamlet, alt 1. f. 2.

——— In the inner room,
If yf a winking lamp, that weakly strikes
The ambient air, scarce kindling into light.
Southerne, Fate of Cupid, alt 3.

In the funeral orations of the bishop of Meaux, the following passages are raised far above the tone of the subject:

"L'Oceane ettomé de fe voir traversé tant de fois, en
The passage we have in view begins l. 116. But let

It is proper to be observed upon this head, that writers of inferior rank are continually upon the stretch to enliven and enforce their subject by exaggeration and superlatives. This unluckily has an effect contrary to what is intended: the reader, dazed with language that swells above the subject, is led by contrast to think more meanly of the subject than it may possibly deserve. A man of prudence, before, will be no less careful to hush his strength in writing than in walking: a writer, too liberal of superlatives, exhausts his whole stock upon ordinary incidents, and reserves no share to express, with greater energy, matters of importance.

Many writers of that kind abound so in epithets, as if poetry consisted entirely in high-sounding words. Take the following instance:

When black-brow'd night her dusky mantle spread,
And wrapt in solemn gloom the sable sky;
When soothing sleep her opiate dews had shed,
And fear'd in silken flumber every eye;
Nor the sweet bliss of soft oblivion share:
But watchful wo disfraits my aching breast,
My heart the subject of corroding care:
From haunts of men with wandering steps and flow
I solitarily steal, and soothe my penive wo.

Here every substantive is faithfully attended by some tumatic epithet.

We proceed to a second remark, not less important than the former. No peron of reflection but must be sensible, that an incident makes a stronger impression on an eye witness, than when heard at second hand. Writers of genius, sensible that the eye is the beat avenue to the heart, represent every thing as passing in our sight; and, from readers or hearers, transform us as it were into spectators: a skilful writer conceals himself, and presents his personages: in a word, every thing becomes dramatic as much as possible. Plutarch, de gloria Atheniense, observes, that Thucydides makes his reader a spectator, and inspires him with the same passions as if he were an eye-witness.

In the fine arts, it is a rule to put the capital objects in the strongest point of view; and even to present them oftener than once, where it can be done. In history-painting, the principal figure is placed in the front, and in the belt light: an equestrian statue is placed in a centre of streets, that it may be seen from many places at once. In no composition is there greater opportunity for this rule than in writing:

--- Sequitur pulcherrimus Aitur,
Aitur quo fidens et verificoloribus armis.

--- Full many a lady
I've ey'd with belt regard, and many a time
Th' harmony of their tongues hath into bondage
Brought my too diligent ear: for several virtues
Have I lik'd several women; never any
With so full soul, but some defect in her
Did quarrel with the noblest grace the ow'n'd,
And put it to the foil. But you, 0 you,
So perfect, and so peerless, are created
Of every creature's belt.
Narration.

Odesse. — Whate'er you are
That, in the dear incredible,
Under the shade of melancholy boughs,
Lost and neglected the creeping hours of time;
If every hour you have look'd on better days;
If ever been where bells have knoll'd to church;
If ever sat at any good man's feast;
If ever from your eye-lids wip'd a tear,
And know what 'tis to pity, and be pity'd;
Lost gentleness by strong inclemence be,
In which I hope I blin'd, and hide my sword.

Duke fen. True is it that we have seen better days;
And have with holy bell been knoll'd to church;
And fat on good men's feasts; and wip'd our eyes
Of drops that faced pity had engender'd;
And therefore you down in gentleness,
And take upon command what help we have,
That to your wanting may be ministr'd.

As you like it.

With thee conversing I forget all time;
All taxes and their change, all plea'se alike.
Sweet is the breath of morn, her rising sweet;
With charm of carill'd birds; pleasant the fun.
When first on this delightful land he spreads
His orient beams on herb, tree, fruit, and flow'r;
Glistring with dew; fragrant the fertile earth
After soft show'rs; and sweet the coming on
Of grateful evening mild, the silent night
With this her solemn bird, and this fair moon,
And the gems of heav'n, her ftarry train:
The blaze of armour fha'd with the red sun,
As when the piercing blasts of Boreas blow.
And like the moon, the broad refulent shield
Blaz'd with long rays, and gleam'd athwart the field.

The blaze of armour fha'd against the day.

As when the piercing blasts of Boreas blow.
And like the moon, the broad refulent shield
Blaz'd with long rays, and gleam'd athwart the field.

No—could our swiftness o'er the winds prevail,
Or beat the pinions of the western gale,
All were in vain——
The humid fweat from ev'ry pore descends.

A concife comprehensive stile is a great ornament
in narration; and a superfluity of unnecessary words,
not less than of circumstances, a great nuisance. A
judicious felection of the striking circumstances, clothed
in a nervous stile, is delightful. In this stile, Tacitus
exceeds all writers, ancient and modern. Infances are
number'd: take the following fir'ment:

"Crebra hinc praefidet, et sefius in modum latrecinii:
per faltus, per paludes: ut cuife fors aut virtus: te-
meré, provifio, ob iurnm, ob pradam, jiffus el aliquid
ducibus."

After Tacitus, Oflian in that respects judily merit the
place of dilinition. One cannot go wrong for ex-
mples in any part of the book.

If a concife or nervous stile be a beauty, tautology
must be a blemish; and yet writers, fettered by verfe,
are not sufficiently careful to avoid this flowo'ny prac-
tice: they may be pitted, but they cannot be jufified.
Take for a fir'ment the following infances, from the
bell poet, for verification at leafl, that England has
boast'd off:

High on his helm celestial lightnings play,
His beamy shield emits a living ray:
Th' unweary'd blaze incessant streams supplies,
Like the red fcar that fires the autumnal fikes.

No—could our swiftness o'er the winds prevail,
Or beat the pinions of the western gale,
All were in vain——
The humid fweat from ev'ry pore descends.

Ibid. xix. 627.

We close this article with a curious inquiry. An ob-
ject, however ugly to the fight, is far from being fo
when repreffented by colours or by words. What is
the caufe of this difference? With refpect to painting,
the caufe is obvious: a good picture, whatever the
objeet be, is agreeable by the pleafure we take in
 imitation; and this pleafure overbalancing the dis-
agreeableness of the objeet, makes the picture upon
the whole agreeable. With refpect to the decription
of an ugly objeet, the caufe follows. To connec't indi-
viduals in the focial flate, no particular contributes
more than language, by the power it poiffes of an
expeditious communication of thought, and a lively
repreffentation of transac'tions. But nature hath not

4 M 2

been
Narration, been satisfied to recommend language by its utility merely: independent of utility, it is made susceptible of many beauties, which are directly felt, without any intervening reflection. And this unfolds the mystery; for the pleasure of language is so great, as in a lively description to overbalance the disagreeableness of the image raised by it. This, however, is no encouragement to choose a disagreeable subject; for the pleasure is incomparably greater where the subject and the description are both of them agreeable.

The following description is upon the whole agreeable, though the subject described is in itself dismal:

Nine times the space that measures day and night
To mortal men, he with his horrid crew
Lay vanquish'd, rolling in the fiery gulf,
Confounded though immortal! but his doom
Referr'd him to more wrath; for now the thought
Both of loft happiness and lafiting pain
Torments him; round he throws his baleful eyes
That witness'd huge affliction and difmay:
Mix'd with obdurate pride and fledfast hate:
At once as far as angels ken he views
The diabolical situation waite and wild:
A dungeon horrible, on all sides round
As one great furnace flam'd; yet from those flames
No light, but rather darknes visible
Serv'd only to discover lights of wo,
Regions of sorrow, dolorous shades, where peace
And reit can never dwell, hope never comes
That comes to all; but torture without end
Still urges, and a fiery deluge, fed
With ever-burning sulphur unconsum'd
Such place eternal justice had prepar'd
For those rebellious. Paradise Lost, book 1. l. 50.

An unmanny depreffion of spirits in time of danger
is not an agreeable sight; and yet a fine description or representation of it will be relished.

K. Richard. What must the king do now? must he submit?
The king shall do it; must he be depos'd?
The king shall be contented: must he lose
The name of king? o' God's name let it go;
I'll give my jewels for a fet of beads;
My gorgeous palace for a hermitage;
My gay apparel, for an almsman's gown;
My gar'dens, for a dirth of wood;
My sceptre, for a palmer's walking-staff;
My mbjects, for a pair of carved fants;
And my large kingdom, for a little grave;
A little, little grave.—an obscure grave.
Or I'll be bury'd in the king's highway;
Some way of common tred, where subjects feet
May hourly trample on their sovereign's head;
For on my heart they tread now, whilst I live;
And, bury'd once, why not upon my head?

Richard II. act. 3. fe. 6.

Objects that strike terror in a spectator, have in poetry and painting a fine effect. The picture, by raising a flight emotion of terror, agitates the mind; and in that condition every beauty makes a deep impression. May not contrariety heighten the pleasure, by opposing our present security to the danger of encountering the object represented?

The other shape,
If shape it might be call'd that shape had none
Distinguishing in member, joint, or limb;
Or substance might be call'd that shadow feem'd,
For each feem'd either; black it flood as night,
Fierce as ten furies, terrible as hell,
And shook a dreadful dart. Par. Left, b. 2. l. 666.

Now flaming fury roar,
And clamour such as heard in heaven till now
Was never: arms on clamour claffing Bray'd
Horrible discord, and the madding wheels
Of brazen chariots rage; dire was the noise
Of conflict; overhead the diabolical
Of fiery darts in flaming volleys flew,
And flying vaulted either hoft with fire.
So under fiery copre together ruth'd
Both battles main, with ruinous assault
And inextinguishable rage: all heaven
Refounded, and had earth been then, all earth
Had to her centre shook. Ibid. book 6 l. 207.

Ghoft. But that I am forbid
To tell the secrets of my prinon-house
I could a tale unfold, whole lightest word
Would scarce a word, froze thy young blood,
Make thy two eyes, like flars, dart from their spheres;
Thy knotty and combined locks to part,
This sight would make him do a desperate turn:
Yea, curse his better angel from his side,
And fall to reprobation.

Othello, act. 5. fe. 8.

Objects of horror must be excepted from the foregoing theory; for no description, however lively, is sufficient to overbalance the delight raised even by the idea of such objects. Everything horrible ought therefore to be avoided in a description.

NARSES, the eunuch who rivalled Belisarius in heroism under the reign of the emperor Julian, emerged from obscurity A. D. 538. From the domestic service of the palace, and the administration of the private revenue, he was suddenly exalted to the head of an army. He is ranked among the few eunuchs who have refused that unhappy name from the contempt and hatred of mankind. A feeble diminutive body concealed the soul of a statesman and a warrior. His youth had been employed in the management of the loom and didiaf, in the cares of the household, and the service of female luxury; but, while his hands were busy, he secretly exercised the faculties of a vigorous and discerning mind. A stranger to the schools and the camp, he studied in the palace to diffuse, to flatter, and to persuade; and as soon as he approached the person of the emperor, Julian listened with surpris and pleasure to the manifold counsels of his chamberlain and private treasurer. The talents of Narfes were tried and improved in frequent embassys; he led an army into Italy, acquired a practical
Nasés

Nassau.

Nasés defeated the Goths, the Franks, and the Alemannii: the Italian cities opened their gates to the conqueror; he entered the capital in triumph: and having Established the seat of his government at Ravenna, continued 15 years to govern Italy under the title of Emperor.

His virtues, we are told, were stained with avarice: and in this province he accumulated a treasure of gold and silver which surpassed the modesty of a private fortune. His government was oppressive or unpopular: and the general discontent was expressed with freedom by the deputies of Rome. Before the throne of Justinian they boldly declared, that their prince, on account of this principality also and Dietz, had princes of its own; but unless their father succeeded to a seat of his government at Orange, the inhabitants would consult their allies, and the preparations were not unworthy of the ancient majesty of the empire.

confident with that order which we are apt to consider as inseparably connected with good economy, yet we must certainly allow them to have been at least so far frugal as not commonly to have spent their whole income. Some part of this money, perhaps, they spent in purchasing the few objects of vanity and luxury with which the circumstances of the times could furnish them; but some part of it they seem commonly to have hoarded. They could not well indeed do any thing else but hoard whatever money they saved. To trade was disgraceful to a gentleman; and to lend money at interest, which at that time was considered as usury and prohibited by law, would have been still more so.

The same disposition to save and to hoard prevailed in the sovereign as well as in the subjects. Among nations to whom commerce and manufactures are little known, the sovereign is in a situation which naturally disposes him to the parsimony requisite for accumulation. In that situation the ex pense even of a sovereign cannot be directed by that vanity which delights in the gaudy finery of a court. The ignorance of the times affords but few of the trinkets in which that finery delights. Standing armies are not then necessary; so that the ex pense even of a sovereign, like that of any other great lord, can be employed in fearce any thing but bounty to his tenants and hospitality to his retainers. But bounty and hospitality very seldom lead to extravagance: though vanity almost always does. All the ancient sovereigns of Europe accordingly had treasuries. Every Tartar chief in the present times is said to have one.

In a commercial country abounding with every sort of expensive luxury, the sovereign, in the same manner as almost all the great proprietors in his dominions, naturally spends a great part of his revenue in purchasing those luxuries. His own and the neighbouring countries supply him abundantly with all the costly trinkets which compose the splendid but insignific ant pageantry of a court. His ordinary ex pense becomes equal to his ordinary revenue, and it is well if it does not frequently exceed it. The amassing of treasure can no longer be expedient; and when extraordinary exigencies require extraordinary expenses, he must necessarily call upon his subjects for an extraordinary aid. The late king of Prussia and his father as principals, on a very large sum of money to government. Hence the ability in the subjects of a commercial state to lend.

The progress of the enormous debts which at present oppresses, and will in the long run probably ruin, all the great nations of Europe has been pretty uniform. In England, after the Revolution, when new connexions with Europe introduced a new system of foreign politics, the ex pense of the nation, not only in settling the new establishments, but in maintaining long wars, as principals, on the continent, for the security of the Dutch barrier, reducing the French monarchy, settling the Spanish succession, supporting the house of Austria, maintaining the liberties of the German body, and other purposes, increased to an unual degree; insomuch that it was not thought advisable to raise all the ex pense of any one year by taxes to be levied within that year, lest the unaccustomed weight of them should create mur murs among the people. It was therefore the policy of the states to anticipate the ex pense of that year by the revenue of the next.
National sums for the current service of the state, and to lay no more taxes upon the subject than would suffice to pay the annual interest of the sums so borrowed; by this means converting the principal debt into new specie of property, transferable from one man to another at any time and in any quantity. This system indeed seems to have had its original in the state of Florence, A.D. 1344: which government then owed about L.60,000 Sterling; and being unable to pay it, formed the principal into an aggregate sum, called metaphorically a mount or bank, the shares whereof were transferable like our stocks, with interest at 5 per cent., the prices varying according to the exigencies of the state. This laid the foundation of what is called the national debt: for a few long annuities created in the reign of Charles II. will hardly deserve that name.

Nations, like private men, have generally begun to borrow upon what may be called perpetual credit, without affigning or mortgaging any particular fund for the payment of the debt; and when this resource has failed them, they have gone on to borrow upon affignments or mortgages of particular funds.

What is called the unfunded debt of Great Britain, is contrived in the manner of those two ways. It consists partly in a debt which bears, or is supposed to bear, no interest, and which resembles the debts that a private man contracts upon account; and partly in a debt which bears interest, and which resembles what a private man contracts upon his bill or promissory note. The debts which are due either for extraordinary services, or for services either not provided for or not paid at the time when they are performed; part of the extraordinaries of the army, navy, and ornavance, the arrears of subsidies to foreign princes, those of seamen wages, &c. usually constitute a debt of the first kind. Navy and exchequer bills, which are issued sometimes in payment of a part of such debts, and sometimes for other purposes, constitute a debt of the second kind; exchequer bills bearing interest from the day on which they are issued, and navy bills six months after they are issued. The bank of England, either by voluntarily discounting those bills at their current value, or by agreeing with government for certain considerations to circulate exchequer bills, that is, to receive them at par, paying the interest which happens to be due upon them, keeps up their value, and facilitates their circulation, and thereby frequently enables government to contract a very large debt of this kind. During the great reconage in King William's time, when the bank of England thought proper to put a stop to its actual transations, exchequer bills and tallies are said to have sold from 25 to 60 per cent. discount; and partly, no doubt, to the supposed infallibility of the new government established by the Revolution, but partly too to the want of the support of the bank of England.

When this resource is exhausted, and it becomes neccessary, in order to raise money, to affign or mortgage some particular branch of the public revenue for the payment of the debt, government has upon different occasions done this in two different ways. Sometimes it has made this affignment or mortgage for a short period of time only, a year or a few years, for example; and sometimes for perpetuity. In the one case, the fund was supposed sufficient to pay within the limited time both principal and interest of the money borrowed: In the other, it was supposed sufficient to pay the interest only, or a perpetual annuity equivalent to the interest; government being at liberty to redeem at any time this annuity upon paying back the principal sum borrowed. When money was raised in the one way, it was said to be raised by anticipation; when in the other, by perpetual funding, or, more shortly, by vending.

In the reign of King William, when the debt began to be amass'd, and during a great part of that of Queen Anne, before we had become so familiar as we are now with the practice of perpetual funding, the greater part of the new taxes were imposed but for a short period of time (for four, five, six, or seven years only); and a great part of the grants of every year con/med in loans upon anticipation of the produce of those taxes. The produce being frequently insufficient for paying within the limited term the principal and interest of the money borrowed, deficiencies arose; to make good which it became necessary to prolong the terms.

On the 3d of December 1697, the funded and unfunded debts amounted to L.215,157,742: 13: 8½: at the same time, in 1714, they were L.53,681,027, 56. 6½: d. In 1755, before the breaking out of the war, they amounted to L.72,389,673; and on the 2d of January 1763, at the conclusion of the peace, they had accumulated to L.122,603,356; 8: 24 of funded debt, and of unfunded L.130,027,589; 2: 2 more. In 1775, they were nearly 130 millions; and the late American war added upwards of 120 millions more to that enormous sum: to pay the interest of which, and the charges of management, amounting annually to nearly eight millions and an half, the extraordinary revenues elsewhere enumerated (excepting only the land-tax and annual malt-tax) are in the first place. ven! mortgaged and made perpetual by parliament. Perpetual we say; but still redeemable by the same authority that imposed them; which, if it at any time can pay off the capital, will abolish those taxes which are raised to discharge the interest.

By this means, then, the quantity of property in the kingdom is greatly increased in idea compared with former times; yea, if we coolly consider it, not at all increased in reality. We may boast of large fortunes, and quantities of money in the funds. But where does this money exist? It exists only in name, in paper, in public faith, in parliamentary security; and that is undoubtedly sufficient for the creditors of the public to rely on. But then what is the pledge which the public faith has pawned for the security of these debts? The land, the trade, and the personal industry of the subject; from which the money must arise that supplies t.c several taxes. In these, therefore, and the only, the property of the public creditors does really and intrinsically exist; and of course the land, the trade, and the personal industry of individuals, are diminished in their true value just so much as they are pledged to answer. If A's income amounts to L.100 per annum; and he is so far indebted to B, that he pays him L.50 per annum for his interest; one half of the value of A's property is transferred to B the creditor. The creditor's property exists in the demand which he has upon the debtor, and no where else; and the debtor is only a trustee to his creditor for one half
of the value of his income. In short, the property of a creditor of the public consists in a certain portion of the national taxes; by how much therefore he is the richer, by so much the nation, which pays these taxes, is the poorer.

The only advantage that can result to a nation from public debts, is the increase of circulation, by multiplying the cash of the kingdom, and creating a new species of currency, available at any time and in any quantity; always therefore ready to be employed in any beneficial undertaking, by means of this its transferrable quality; and yet producing some profit even when it lies idle and unemployed. A certain proportion of debt seems to be highly useful to a trading people; but what that proportion is, it is not for us to determine. This much is indubitably certain, that the present magnitude of our national incumbrances very far exceeds all calculations of commercial benefit, and is productive of the greatest inconveniences. For, firstly, the enormous taxes that are raised upon the necessaries of life for the payment of the interest of this debt, are a hurt both to trade and manufactures, by raising the price as well of the artificers' subsistence as of the raw material, and of course in a much greater proportion, the price of the commodity itself. Nay, the very increase of paper-circulation itself, when extended beyond what is requisite for commerce or foreign exchange, has a natural tendency to increase the price of provisions as well as of all other merchandise. For as its effect is to multiply the cash of the kingdom, and this to such an extent that much must remain unemployed, that cash (which is the universal measure of the respective values of all other commodities) must necessarily sink in its own value, and every thing grow comparatively dearer. Secondly, if part of this debt be owing to foreigners, either they draw out of the kingdom annually a considerable quantity of specie for the interest; or else it is made an argument to grant them unreasonable privileges in order to induce them to reside here. Thirdly, if the whole be owing to subjects only, it is then charged on the active and industrious subject, who pays his share of the taxes to maintain the indolent and idle creditor who receives them. Lastly, and principally, it weakens the internal strength of a state, by anticipating those resources which should be reserved to defend it in case of necessity. The interest we now pay for our debts would undoubtedly be sufficient to maintain the most vigorous war that any national motives could possibly require. If indeed our ancestors in King William's time had annually paid, so long as their exigencies lasted, a far less sum than we now annually raise upon their accounts, they would not in time of war have borne so great burdens as they have been hallowed to and saddled upon their posterity in time of peace; and might have been eased the inestimable hindrance the exaction was ever. See Funds.

On the whole, then, the national debt is undoubtedly a subject of vast importance, and as such it has been always considered; for much of it has been laid and written upon it, and many schemes have been proposed at various times and by various persons for gradually removing it, being considered by the most judicious as a most pernicious incumbrance to a commercial country. Some we are aware, think it of vast utility; but this opinion is too eccentric, and in our estimation too feebly supported to be convincing. The public debt is indubitably a great grievance; and every lever of his country must freely wish to see it removed; the period, however, when this blessing shall take place, if indeed it ever arrive, must at least be very distant.

It is neither our business nor intention (even if the limits prescribed to the article did not prevent it) to be minute on the subject, or to propose any schemes for alleviating the burdens of the nation. That indeed has been already done by far abler hands than we profess to be: we must therefore refer such as wish for farther information on this interesting topic to those (and they are not a few) who have treated of it at full length. Smith's Wealth of Nations, and Sir John Sinclair's History of the Revenue, go to the bottom of the matter. The writings of Dr Price likewise deserve considerable attention, especially as one of his plans for the reduction of the debt has in fact been adopted, and in consequence established, by the legislature: His three plans may be found in a late pamphlet by William Morgan, intitled, A Review of Dr Price's Writings on the Subject of the Finances of this Kingdom.

NATIVITY, or NATAL DAY, the day of a person's birth. The word nativity is chiefly used in speaking of the facts; as, the nativity of St John the Baptist, &c. But when we say the nativity, it is understood of that of Jesus Christ, or the feast of Christmas.

Nativity, nativitas, in ancient law-books, signifies bondage or servitude.

Nativity, in astrology, the theme or figure of the heavens, and particularly of the twelve houses, at the moment when a person was born; called also the horoscope.

Calling the nativity, or by calculation seeking to know how long the queen should live, &c. was made felony, an. 23 Eliz. c. 2.

NATIVO NASENDO, in law, a writ directed to the sheriff, for a lord compensated for the inherited in any villain, when a villain was run away from the lord. For the apprehending and restoring him to the lord.

NATIX, in natural history, a name given by some old writers to the serin.

NATOLIA, the modern name of the Lesser Asia, being the most westerly part of Turkey in Asia, and confilting of a large peninsula which extends from the river Euphrates as far as the Archipelago, the seas of Marmora, the straits of Galipoli and of Constantinople, which separate it from Europe on the west. It is bounded on the north by the Black sea, and on the south by the Mediterranean.

NATRIX, in botany, the name given by Rivinus to a genus of plants nearly allied to the anonis, and comprehended with it in one genus by Linnaeus, under the name of anonis. See Rist-harrow

Natrix, in zoology, the name of the common or water-snake, called also torquata, from the ring about its neck. It is not a water animal, properly speaking, but a land one, which being able to swim very well, often takes the water to hunt about for frogs, which are its principal food. It grows to be much longer and larger than the viper, and does not bring forth live young ones, but great numbers of eggs, which it lays in dung-

NAT
regard to its influence on the passions and affection, *is to rear a tree for its blossoms, which is capable of yielding the richest and most valuable fruit.* Physical and moral beauty bear to intimate a relation to each other, that they may be considered as different gradations in the scale of excellence: and the knowledge and relish of the former should be deemed only a step to the nobler and more permanent enjoyments of the latter.

"Whoever has visited the Leafoves, in Warwickshire, must have felt the force and propriety of an inscription which meets the eye at the entrance into those delightful grounds.

Would you then taste the tranquil scene?  
Be sure your blossoms be serene;  
Devoid of hate, devoid of strife;  
Devoid of all that poisons life;  
And much it *val* you, in their place,  
To graft the love of human race.

"Now such scenes contribute powerfully to inspire that serenity which is necessary to enjoy and to heighten their beauties. By a secret contagion, the foul catches the harmony which he contemplates; and the frame within assimilates itself to that which is without. For,  
Who can forbear to smile with Nature? Can  
The formy passions in the bosom roll,  
While every gale is peace, and every grove  
Is melody?

"In this state of sweet composure, we become susceptible of virtuous impressions, from almost every surrounding object. The patient ox is viewed with generous complacency; the guileless sheep with pity; and the playful lamb raises emotions of tenderness and love. We rejoice with the horse, in his liberty and exemption from toil, while he ranges at large through enamelled pastures; and the frolicks of the colt would afford unmixed delight, did we not recollect the bondage which he is soon to undergo. We are charmed with the song of birds, footed with the buzz of insects, and pleased with the sportive motions of flies, because these are expressions of enjoyment; and we exult in the felicity of the whole animated creation. Thus an equal and extensive benevolence is called forth into exultation; and having felt a common interest in the gratifications of inferior beings, we shall be no longer indifferent to their sufferings, or became wanton interminably in producing them.

"It seems to be the intention of Providence, that the lower order of animals should be subservient to the comfort, convenience, and safety of man. But his right of dominion extends no farther; and if this right be exercised with mildness, humanity, and justice, the subjects of his power will be no less benefited than himself. For various species of living creatures are annually multiplied by human art, improved in their perceptive powers by human culture, and plentifully fed by human industry. The relation, therefore, is reciprocal between such animals and man: and he may supply his own wants by the use of their labour, the produce of their bodies, and even the sacrifice of their lives, whilst he co-operates with all-gracious Heaven in promoting happiness, the great end of existence.

"But though it be true, that partial evil, with respect to different orders of sensitive beings, may be universal good; and that it is a wife and benevolent institution of nature, to make destruction itself, within certain limitations, the cause of an increase of life and enjoyment: yet a generous perfon will extend his compassionate regards to every individual that suffers for his sake: and, whilst he figths

Even for the kid or lamb that parts its life
Beneath the bloody knife,  
he will naturally be solicitous to mitigate pain, both in duration and degree, by the gentlest modes of inflicting it.

"We are inclined to believe, however, that this sense of humanity would soon be obliterated, and that the heart would grow callous to every soft impression, were it not for the benignant influence of the smiling face of nature. The count de Lauzun, when imprisoned by Louis XIV. in the castle of Pigecrol, assisted himself, during a long period of time with catching flies, and delivering them to be devoured by a rapacious spider. Such an entertainment was equally singular and cruel.

Such an entertainment was equally singular, and cruel.  
For various species of living creatures are at times  
employed for their sport; for naturahbeauty is

"Most of these are at times employed for their sport; for natural beauty is

"It is useful, so it is a continual source of real enjoyment; for a more rational pleasure cannot possibly occupy the attention or captivate the affections of mankind, than that which arises from a due consideration of the works of nature. Pleasure, we know, is a necessary ingredient in human life, in order in some measure to counterbalance the pains, the evils, and little necessities, which are at times perhaps unavoidable, and in order to render life tolerable. It is the part then of the

NATURAL HISTORY.

Natural history, in its most extensive signification, denotes a knowledge and description of the whole universe. Matters of fact respecting the heavens, meteors; the atmosphere, the earth, respecting all the phenomena, indeed, which occur in the world, and even of the external parts and actions of man himself, as far as reason can discover them, belong to the province of natural history; but when we leave the simple recital of effects, and endeavour to investigate the causes of such and such phenomena, we then leave natural history, and enter on philosophy. The object of our article, therefore, in the sense we have here given it, is as extensive as nature itself. But, in its more appropriated sense, it is well known that its province obly extends to the surface of the earth, the works on it, and the inhabitants of it. It treats of those substances of which, as far as our researches have led us, the earth is composed, and of those organized bodies, whether vegetable or animal, which adorn its surface, which rise into the air, or live in the bosom of the waters. But as a science so various and comprehensive could neither with propriety nor advantage be completely discussed under the general title, we have to refer the reader to the article Kingdoms (in Natural History), where he will be directed to the different articles which constitute either the branches or the objects of the science, and which are all treated under their respective names. In the present article it is proposed to give a general and philosophical view of the subject: To set forth, in a summary way, whatever curious, worthy to be known; or not obvious to every observer, occurs in the three kingdoms of nature: with their constitution, laws, and economy; or, in other words, that all-wise disposition of the Creator in relation to natural things, by which they are fitted to produce general ends and reciprocal uses.

Sect. I. Of the Terraqueous Globe in general, and its changes.

The world, or the terraqueous globe, which we inhabit, is everywhere surrounded with elements, and contains in its superficies the three Kingdoms of Nature, as they are called: the fossil, which constitutes the crust of the earth; the vegetable, which adorns the face of it, and draws the greatest part of its nourishment from the fossil kingdom; and the animal, which is sustained by the vegetable kingdom. Thus, then, these three grand divisions, or, as they are commonly called, kingdoms; cover, adorn, and vary, the surface of the earth.

As to the strata of the earth and mountains, as far as we have hitherto been able to discover, the upper parts consist of rhyolite; the next of slate; the third of marble filled with petrifactions; the fourth again, of slate; and lastly, the lowest of tree stone.
The habitable part of the earth, though it is scooped into various inequalities, yet is everywhere high in comparison with the sea; and the farther it is from the sea it is generally higher. Thus the waters in the lower places are not at rest, unless some obstacle confines them, and by that means form lakes and marishes. The sea surrounds the continent, and takes up the greatest part of the earth's surface, as geographers inform us. Nay, that it once spread over much of the greatest part, we may be convinced by its yearly decrease, by the rubbish left by the tides, by shells, strata, and other circumstances.

The sea-shores are usually full of dead terebaceous animals, wreck, and such like bodies, which are yearly thrown out of the sea. They are also covered with sand of various kinds, stones, &c. It happens, moreover, that while the more rapid rivers run through narrow valleys, they wear away the tides; and thus the friable and soft earth falls in, and its ruins are carried to distant and winds up. This happens sooner when the scene is continued their way.

The clouds collected from exhalations, chiefly from the sea, but likewise from other waters, and moist grounds, and condensed in the lower regions of the atmosphere, supple the earth with rain; but since they are attracted by the mountainous parts of the earth, it necessarily follows, that those parts must have, as is fit, a larger share of water than the rest. Springs, which generally run out at the foot of mountains, take their rise from this very rain-water, and vapours condensed, that trickle through the holes and interstices of loose bodies, and are received into caverns.

These afford a pure water purged by straining; and rarely dry up in summer, or freeze in winter, so that animals never want a wholesome and refreshing liquor.

The chief sources of rivers are fountains and rills growing by gradual supplies into still larger and larger streams; till at last, after the confluent of a vast number of them, they find no stop, but falling into the sea with such rapidity, they there deposit the united foles they have gathered, along with foreign matter, and such earthly substan rices as they tore off in their way. Thus the water returns in a circle whence it first drew its origin, that it may act over the same scene in continued succession.

Marishes arising from water retained in low grounds, are filled with moistumps, which are brought down by the water from the higher parts, or are produced by putrefied plants.

We often see new meadows arise from marshes dried up. This happens sooner when the sodagnum (a kind of moss) has laid a foundation; for this in process of time changes into a very porous mould, till almost the whole marsh is filled with it. After that the rush strikes root, and along with the cotton-grasses constitutes a turf, raised in such a manner that the roots get continually higher, and thus lay a more firm foundation for other plants, till the whole marsh is changed into a fine and delightful meadow; especially if the water happens to work itself a new passage.

Hilllocks, that abound in low grounds, occasion the earth to increase yearly, more than the countryman would wish, and seem to do hurt; but in this the great industry of nature deserves to be taken notice of. For by this means the barren spots become fomer rich meadow and pasturage land. Thee hilllocks are formed by the ant, by stones and roots, and the trampling of cattle; but the principal cause is the force of the winter-cold, which in the spring raises the roots of plants so high above the ground, that being exposed to the air, they grow, and perish; after which the golden-maidenhairs fill the vacant places.

Mountains, hills, valleys, and all the inequalities of the earth, though some think they take away much from its beauty, are so far from producing such an effect, that on the contrary they give a more pleasing aspect, and confer great advantages. For thus the terrestrial superficies is larger; different kinds of plants thrive better, and are more easily watered; and the rain-waters run in continual streams into the sea; not to mention many other uses in relation to winds, heat, and c. &d. Alps are the highest mountains, that reach to the second region of the air, where trees cannot grow erec. The higher these Alps are, the colder they are. Hence the Alps in Sweden, Siberia, Switzerland, Peru, Brazil, Armenia, Asia, Africa, are perpetually covered with snow, which becomes almost as hard as ice. But if by chance the summer heat be greater than ordinary, some part of these fles melts, and runs through rivers into the lower regions, which by this means are much refreshed.

It is scarcely to be doubted, but that the rocks and stones dispersed over the globe were formed originally in, and from, the earth; but when torrents of rain have softened, as they easily do, the soluble earth, and carried it down into the lower parts, we imagine it happens, that these solid and heavy bodies, being laid bare, stick out above the surface. We might also take notice of the wonderful effect of the tide, such as we see happen from time to time on the sea-shore, which being daily and nightly assaulted with repeated blows, at length gives way, and breaks off. Hence we see in most places the rubble of the sea, and shores.

The winter by its frost prepares the earth and mould, which thence are broken into very minute particles, and thus, being put into a mouldering state, become more fit for the nourishment of plants; nay, by its snow it covers the seeds and roots of plants, and thus by cold defends them from the force of cold. We must add also, that the piercing frost of the winter purifies the atmosphere and putrid waters, and makes them more wholesome for animals.

The perpetual succession of heat and cold with us renders the summers more pleasing: and tho' the winter deprives us of many plants and animals, yet the perpetual summer within the tropics is not much more agreeable, as it often destroys men and other animals by its immoderate heat; though it must be confessed, that those regions abound with exquisite fruits. Our winters though very troublesome to a great part of the globe on account of their vehement and intense cold, yet are less hurtful to the inhabitants of the northern parts, as experience testifies. Hence it happens,
en pens, that we may live very conveniently on every part of the earth, as every different country has different advantages from nature.

The seasons, like every thing else, have their vicissitudes; their beginnings, their progress, and their end.

The age of man begins from the cradle; pleasuring childhood succeeds; then active, youth; afterwards manhood, firm, severe, and intent upon felt preservation; lastly, old age creeps on, debilitates, and at length totally destroys our towering bodies.

The seasons of the year proceed in the same way. Spring, the jovial, playful infancy of all living creatures, represents childhood and youth; for then plants spread forth their luxuriant flowers, flies exult, birds sing, every part of nature is intent upon generation. The summer, like middle age, exhibits plants, and trees every where cloathed with green; it gives vigour, to animals, and plumps them up; fruits then ripen, on the quarters. The day proceeds with the autumn, the here and there in fields and pastures; the heat puts them upon indulging their ease, and even necessity obliges them to. Evening follows, and makes every thing more sluggish; flowers shut up*, and animals retire to their lurking places. Thus the firing, the morning, and youth are proper for generation; the summer, noon, and manhood, are proper for preservation; and autumn, evening, and old age, are not unfittedly likened to destruction.

In order to perpetuate the established course of nature in a continued series, the Divine Wisdom has thought fit that all living creatures should constantly be employed in producing individuals: that all natural things should contribute and lend a helping hand towards preserving every species: and lastly, that the death and destruction of one thing should always be subservient to the production of another. Hence the objects of our present inquiry fall to be considered in a threefold view, that of propagation, preservation, and death or destruction.

Sect. II. The Fossil Kingdom.

1. Propagation.

It is agreed on all hands, that stones are not organical bodies, like plants and animals; and therefore it is as clear that they are not produced from an egg, like the tribes of the other kingdoms. Hence the variety of fossils is proportionate to the different combinations of calcareous particles; and hence the species in the fossil kingdom are not so distinct as in the other two. Hence also the laws of generation in relation to fossils have been in all ages extremely difficult to explain; and lastly, hence have risen so many different opinions about them, that it would be endless to enumerate them all. We therefore, for the present, shall content ourselves with giving a very few observations on this subject.

Some people suppose that clay is the sediment of the sea; and observation so far seems to go along with this opinion, for great plenty of it is generally found along the coasts. Seamen who have been so accurate as to keep journals, have observed, that a very minute sand covers the bottom of the ocean; and seem to think that it is daily crystallized from the water. It is now generally acknowledged, that extensive bodies and petrifications resembling animals were once real animals or vegetables. It has been supposed indeed, that shells being of a calcareous nature, changed the adjacent clay, sand, or mould, into the same kind of substance. Hence it appears certain, that marbles may be generated from petrifactions; and therefore it is often full of them. Ragstone, the common matter of our rocks, appears to be formed from a sandy kind of clay; most frequently, however, this appears to happen where the earth is impregnated with iron. Free-stone seems to be the product of sand: and, the deeper the bed where it is found, the more compact it becomes; and the more dense the sand, the more easily it concretizes. But if an alkaline clay chances to be mixed with the sand, the freestone is generated more readily, as in that called calcairet particuus argille-grése. The flint is almost the only kind of stone, certainly the most common, in chalky mountains. It would appear therefore from this to be produced from chalk: but whether it can be reduced to chalk again, is left for others to enquire.

Stalactites, or drop-stone, is composed of calcareous particles, adhering to a dry, and generally a vegetable body, and is deposited by dropping water; from which circumstance it seems to have derived its vulgar name.

Incrustations (Syf. Nat. 32. 5. 6. 7. 8.), are, in general, it appears, generated where a vitriolic water connects clayey and earthy particles together. Slate, by the vegetables that are often enclosed in it, seems to take its origin from a marly mould. Metals vary according to the nature of the matrix in which they adhere; e. g. the pyrites cupri Fahlmenus contains frequently sulphur, arsenic, iron, copper, a little gold, vitriol, alum, sometimes lead ore, silver and zinc. Thus gold, copper, iron, zinc, arsenic, pyrites, vitriol, come out of the same vein. That very rich iron ore, at Normark in Vermilionia, where it was cut directly by a vein of clay, was changed into pure silver. The number therefore of species and varieties of fossils, each serving different purposes according to their different natures, will be in proportion as the different kinds of earths and stones are variously combined.

II. Preservation.

As fossils are definite of life and organization, are hard, and not obnoxious to petrifaction; so they last longer than any other kind of bodies. How far the air contributes to this duration, it is easy to perceive; since air hardens many stones upon the surface.
face of the earth, and makes them more solid, compact, and able to refit the injuries of time. Thus it is known from vulgar observation, that lime that has been long exposed to the air becomes hardened. The chalky marl which they use in Flanders and about Bath for building houses, as long as it continues in the quarry is friable; but when dug up and exposed to the air it grows gradually harder.

However ignorant we may be of the cause why large rocks are everywhere to be seen split, whence wall fragments are frequently torn off; yet we may observe, that figures are closed up by water, which gets between them, and is detained there; forming crytal and spar. Hence we scarcely ever find any crytal, but in those stones which have retained for some time in its chips, water loaded with stony particles. In the same manner crytal fills the cavities in mines, and concrete into quartz or a debarded crytal.

It is manifest that stones are not only generated, augmented, and changed perpetually, from inculations brought upon moss, but are also increased by crytal and spar. Not to mention that the adjacent earth, especially if it be impregnated with iron particles, is commonly changed into a solid stone.

It is said, that the marble quarries in Italy, from whence fragments are cut, grow up again. Ores grow by little and little, whenever the mineral particles conveyed by the means of water through the crests of mountains are retailed there, so that adhering to the homogenous matter a long while, as last they take its figure, and are changed into a similar substance.

III. Destruction.

Fossils, although they are the hardest of bodies, yet are found subject to the laws of destruction, as well as all other created substances. For they are dissolved in various ways by the elements exerting their force upon them, as by water, air, and the solar rays; as also by the rapidity of rivers, violence of cataracts, and eddies which continually beat upon, and at last reduce to powder the hardest rocks. The agitation of the seas and lakes, and the vehemence of the waves, excited by turbulent winds, together with these, as evidently appears by their roundness along the shore. Nay, as the poet says,

The hardest stone intenbly gives way To the last drops that frequent on it play. So that we ought not to wonder that these very hard bodies moulder away into powder, and are obnoxious like others to the consuming tooth of time.

Sand is formed of free-stone, which is destroyed partly by frost, making it friable; partly by the agitation of water and waves, which calieth away, disolve, and reduce into minute particles what the frost had made friable.

Chalk is in general supposed to be formed of rough marble, which the air, the sun, and the winds have dissolved. Tho flat earth, or humus schiif, (Synt. Nat. 512.) owes its origin to flat, flowers, air, and snow melted.

Olive is formed of metals dissolved, and presents the very same colors which we always find the ore tinting when exposed to the air. Vitriol in the same manner mixes with water from ore destroyed.

The musa fascilis (Synt. Nat. 14. 6.), a kind of talky stone, yielding fowl in the parts that are turned to the fun, is dissolved into sand, which falls by little and little upon the earth till the whole is consumed; not to mention other kinds of fossils. Lastly, from these there arise new fossils, as we mentioned before; so that the destruction of one thing serves for the generation of another.

Teffaceous worms ought not to be passed over on this occasion, for they eat away the hardest rocks. That species of shell-fish called the roser-fell bores through stones in Italy, and hides itself within them so that the people who eat them are obliged to break the stones before they can come at them. The coxlews, (Faenh. Succ. 1292.), a kind of snail that lives on craggy rocks, eats and bores through the chalky hills, as worms 'do through wood. This is made evident by the observations of the celebrated de Geer. It ought to be observed here, that there are often found dead insects in the hearts of the hardest rocks, without any visible trace of the manner of their getting there; from whence many have supposed that stones were originally fluid. Concerning such matters, about which we have but little data, there will always be a great diversity of opinions. It's not our business, at least in this place, to give an opinion on a doubtful subject: the fact is so; of the cause let others judge.

T. Propagation.

Anatomy abundantly proves, that all plants are organic and living bodies, and that all organic bodies are propagated from an egg has been sufficiently demonstrated by the industry of modern writers. We therefore the rather, according to the opinion of the skillful, reject the equivocal generation of plants, and the more so, as it's certain that every living thing is produced from an egg. Now the seeds of vegetables are called eggs, there are different in every different plant, that the means being the same, each may multiply its species, and produce an offspring like its parent. We do not deny, that very many plants pull forth from their roots fresh offsets for two or more years. Nay, not a few plants may be propagated by branches, buds suckers, and leaves, fixed in the ground, as likewise many trees. Hence their stems being divided into branches, may be looked on as roots above ground for in the same way the roots creep under ground, and divide into branches. And there is the more reason for thinking so, because we know that a tree will grow in an inverted situation, viz. the roots being placed upwards, and the head downwards, and buried in the ground; for then the branches will become roots, and the roots will produce leaves and flowers. The lime-tree will serve for an example, on which gardeners have chiefly made an experiment. Yet this by no means overturns the doctrine, that all vegetables are propagated by seeds; since it is clear, that is each of the foregoing influences nothing vegetates but what was
NATURAL HISTOR Y.

was the part of a plant, formerly produced from seed; for that accurately speaking, without seed no new plant is produced.

Then again plants produce seeds; but they are entirely unfit for propagation, unless fecundation precedes, which is performed by an intercourse between different sexes, as experience testifies. Plants therefore must be provided with organs of generation; in which respect they are analogous to animals.—

Since in every plant the flower always precedes the fruit, and the fecundated seeds visibly arise from the fruit; it is evident that the organs of generation are contained in the flower, which organs are called anthera and stigma, and that the impregnation is accomplished within the flower. This impregnation is performed by means of the dust of the anthera falling upon the moist stigma, where the dust adheres, is built, and sends forth a very subtle matter, which is absorbed by the style, and is conveyed down to the rudiments of the seed, and thus renders it fertile. When this operation is over, the organs of generation wither and fall, may a change in the whole flower from fleshes. We must, however, observe, that in the vegetable kingdom one and the same flower does not always contain the organs of generation of both sexes, but oftentimes the male organs are on one plant and the female on another. But that the benefits of impregnation may go on successfully, and that no plant may be deprived of the necessary dust, the whole most elegant apparatus of the anthera and stigma in every flower is contrived with wonderful wildom.

For in moist flowers the stamina surround the pistilla, and are of about the same height: but there are many plants in which the pistilla is longer than the stamina; and in these it is wonderful to observe, that the Creator has made the flowers recline, in order that the dust may the more easily fall into the stigma, e.g. in the campanula, cowslip, &c. This curious phenomenon did not escape the poetical eye of Milton, who describes it in the following enlivened imagery:

With cowslips wan, that hang the penitve head.

But when the fecundation is completed, the flowers rise again, that the ripe seeds may not fall out before they are dispersed by the winds. In other flowers, on the contrary, the pistilla is shorter, and there the flowers preserve an erect situation; nay, when the flowering comes on, they become erect, though before they were drooping, or immersed under water. Lastly, whenever the male flowers are placed below the female ones, the leaves are exceedingly small and narrow, that they may not hinder the dust from flying upwards like smoke; as we see in the pine, fir, yew, fea-grape, juniper, cypress, &c. And when in one and the same species one plant is male and the other female, and consequent-ly may be far from one another; there the dust, without which there is no impregnation, is carried in abundance by the help of the wind from the male to the female; as in the whole dircocious clas. Again, a more difficult impregnation is compensated by the longevity of the individuals, and the continuation of life by buds, suckers, and roots; so that we may observe every thing most wisely disposed in this affair. Moreover, we cannot without admiration observe, that moist flowers expand themselves when the sun shines forth; whereas when clouds, rain, or the evening comes on, they close up, lest the genial dust should be coagulated

Vid. a treatise on the Spongii, 

Although all such kinds of metamorphoses are repugnant to the laws of generation; not considering, that there is another cause of this phenomenon, viz. that the ground perhaps has been manured with horse-dung, in which the seeds of oats, coming entire from the horse,
NATURAL HISTORY.

Sect. III.

Greenland Alps. And Tournefort found at the bottom of Mount Ararat the common plants of Armenia, a little way up those of Italy, higher those which grow about Paris, afterwards the Swedish plants, and lastly on the top the Lapland Alpine plants; and myself, adds the author, from the plants growing on the Dalecarlian Alps could collect how much lower they were than the Alps of Lapland. He then proceeds to show how from one plant of each species, the immense number of individuals now existing might arise. He gives some instances of the furprising fertility of certain plants; e.g. the elecampane, one plant of which produced 3000 seeds; of spelt, 2000 seeds; of the funflower, 4000; of the poppy, 3200; of tobacco, 40,520. But supposing any annual plant producing yearly only two seeds, even of this, after 20 years, there would be 1,048,576 individuals. For they would increase yearly in a duplicate proportion, viz. 2, 4, 8, 16, 32, &c. He then gives some instances of plants brought from America, that are now become common over many parts of Europe. Lastly, he enters upon a detail of the several methods which nature has taken to propagate vegetables, which is extremely curious, but too long to insert in this place.

II. Preservation.

The great Author and Parent of all things decreed, that the whole earth should be covered with plants, and that no place should be void, none barren. But since all countries have not the same changes of feasons, and every soil is not equally fit for every plant; he therefore, that no place should be without some, gave to every one of them such a nature, as might be chiefly adapted to the climate; so that some of them can bear an intense cold, others an equal degree of heat; some delight in dry ground, others in moist, &c. Hence the same plants grow only where there are the same feasons of the year, and the same soil.

The Alpine plants live only in high and cold situations; and therefore often on the Alps of Armenia, Switzerland, the Pyrenees, &c. whose tops are equally covered with eternal snows as those of the Lapland Alps, plants of the same kind are found, and it would be in vain to seek for them anywhere else. It is remarkable, in relation to the Alpine plants, that they blow, and ripen their seeds very early, left the winter, should feast upon them a sudden, and destroy them.

Our northern plants, although they are extremely rare everywhere else, yet are found in Siberia, and about Hudson's Bay; as the arbutus, bramble, wintergreen, &c.

Plants impatient of cold live within the torrid zones; hence both the Indies, though at such a distance from one another, have plants in common. The Cape of Good Hope, we know not from what cause, produces plants peculiar to itself; as all the meSEMBRYTHANMA, and almost all the species of aloes. Grafts, the most common of all plants, can bear almost any temperature of air; in which the good providence of the Creator particularly appears; for all over the globe, they above all plants are necessary for the nourishment of cattle; and the same thing is seen in relation to our moist common grains.

Thus neither the scorching sun, nor the pinching cold, hinders any country from having its vegetables.
be a shelter to animals in the winter. They lose their leaves only every third year, as their seeds are sufficiently guarded by the moths, and do not want any other covering. The palms in the hot countries perpetually keep their leaves, for there the seeds stand in no need of any shelter whatever.

Many plants and shrubs are armed with thorns, e.g., the buckthorn, hawthorn, carduus, cotton-thistle, &c., that they may keep off the animals which otherwise would destroy their fruit. These at the same time cover many other plants, especially of the annual kind, under their branches. Nay it has frequently been observed upon commons where forage grows, that wherever there was a bulwark untouched for years by the commoner, some tree has sprung up being favored by the prickles of that shrub from the bite of cattle. So that while the adjacent grounds are robbed of all plants by the voracity of animals, some may be preferred to ripe flowers and fruit, and flock the parts about with seeds, which otherwise would be quite extinguished.

All herbs cover the ground with their leaves, and by their shade hinder it from being totally deprived of that moisture which is necessary to their nourishment. They are moreover an ornament to the earth, especially as leaves have a more agreeable verdure on the upper than on the under side.

The moths which adorn the most barren places, at the same time, prefer the leffer plants when they begin to shoot, from cold and drought; as we find by experience in our gardens, that plants are preferred in the same way. They also hinder the fermenting earth from forcing the roots of plants upwards in the spring, as we see happen annually to trunks of trees, and other things put into the ground. Hence very few moths grow in the warmer climates, as not being so necessary to that end in those places.

The English sea mat-wood, or marram, will bear no foil but pure sand, which nature has allotted to it. Sand, the produce of the sea, is blown by winds oftentimes to very remote parts, and deluges, as it were, woods and fields. But where this grafs grows, it frequently fixes the sand, gathers it into hillocks, and thrives so much, that by means of this alone at last an entire hill of sand is raised. Thus the sand is kept in bounds, other plants are preferred free from it, the ground is increased, and the sea is repelled by this wonderful disposition of nature. This seems to be the same plant which is called in Scotland lent, and is particularly useful for the purpose above-mentioned, and only grows among sand along the sea-coast.

How folicitous nature is about the preservation of graffes is abundantly evident from hence, that the more the leaves of the perennial graffes are eat, the more creep by the roots, and sends forth offsets. For the Author of nature intended that vegetables of this kind, which have very slender and erect leaves should be copious, and very thick set, covering the ground like a carpet; and thus afford food sufficient for so vast a quantity of grazing animals. But what chiefly increases our wonder is, that although the graffes are the principal food of such animals, yet they are forbid as it were to touch the flower and seed-bearing items, that to the seeds may ripen and be sown.

The caterpillar or grub of the moth, although it feeds upon graffes, to the great destruction of them
in meadows yet it seems to be formed in order to keep a due proportion between these and other plants; for graffes, when left to grow freely, increase to that degree, that they exclude all other plants; which would consequently be extirpated, unless this insect sometimes prepared a place for them. Hence always more speces of plants appear in those places where this caterpillar has laid waife the pastures the preceding year than at any other time.

III. Destruction.

Daily experience teaches us, that all plants, as well as other created things, must submit to death. They spring up, they grow, they flourish they ripen their fruit, they wither, and at last, having finished their course they die, and return to the dust again, from whence they first took their rise. Thus all black mould, which everywhere covers the earth, for the greatest part is owing to dead vegetables. For all roots descend into the sand by their branches, and after a plant has loft its item the root remains; but this too rots at last; and changes into mould. By this means this kind of earth is mixed with sand, by the contrivance of nature, nearly in the same way as dung thrown upon fields is wrought into the earth by the industry of the husbandman. The earth thus prepared offers again to plants from its bosom what it has received from them. For when seeds are committed to the earth, they draw to themselves, accommodate to their nature, and turn into plants, the more subtle parts of this mould by the co-operation of the fun and rains; so that the tallest tree is, properly speaking, nothing but mould wonderfully compounded with air and water, and modified by a virtue communicated to a small feed by the Creator. From these plants when they die, just the same kind of mould is formed as gave birth to them originally; whence fertility remains continually uninterrupted. Whereas the earth could not make good its annual consumption, unless it were constantly recruited by new supplies.

The crustaceous liverworts are the first foundation of vegetation; and therefore are plants of the utmost consequence in the economy of nature, though so despised by us. When rocks first immerse out of the sea, they are so polished by the force of the waves, that scarce any herb can find a fixed habitation upon them; as we may observe every where near the sea. But the very minute crustaceous liverworts begin soon to cover these dry rocks, although they have no other nourishment but that small quantity of mould and imperceptible particles which the rain and the air bring thither. Their liverworts dying at last turn into very fine earth; on this earth the imbricated liverworts find a bed to strike their roots in. Their alse die after a time and turn to mould; and then the various kinds of mosses, e.g. the hypna, the brya, polychrissa, find a proper place and nourishment. Lastly thetce ihning in their turn, and rotting, afford such plenty of new-formed mould, that herbs and shrubs easily root and live upon it.

That trees, when they are dry or are cut down, may not remain useless to the world, and lie as it were melancholy spectacles, nature hailsen on their destruction in a singular way: first, the liverworts begin to strike root in them; afterwards the moss is drawn out of them; whence putrefaction follows. Then the mushroom kinds find a fit place for nourishment on them and corrupt them still more. The beetle called der-vejtos next makes himself a way between the bark and the wood. The milk-beetle, the copper tale-beetle, and the caterpillar or coffa 812 (S. N.) bores an infinite number of holes through the trunk. Lastly, the woodpeckers come, and, while they are seeking for insects, wear away the tree already corrupted: till the whole paifies into earth. Such industry does nature use to destroy the trunk of a tree! Nay, trees immered in water would scarcely ever be destroyed, were it not for the worm which eats chips, which performs this work; as the sailor knows by fad experience.

Thistles, as the most useful of plants, are armed and guarded by nature herself. Suppose there were a heap of clay, on which for many years no plant has sprung up; let the seeds of the thistle blow there, and grow, the thistles by their leaves attract the moisture out of the air, fend it into the clay by means of their roots, will thrive themselves, and afford a shade. Let now other plants come hither, and they will soon cover the ground.

All succulent plants make ground fine, of a good quality, and in great plenty; as sedum, crafula, aloe, alge. But dry plants make it more barren, as heath, pines, mois; and therefore nature has placed the succulent plants on rocks and the driest hills.

Sect. IV. The Animal Kingdom.

I. Propagation.

1. The generation of animals holds the first place among all things that raise our admiration when we consider the works of the Creator; and chiefly that appointment by which he has regulated the conception of the foetus, and its exclusion, that it should be adapted to the disposition and way of living of each animal, is most worthy of our attention.

We find no species of animals exempt from the flings of love, which is put into them to the end that the Creator's mandate may be executed, Increase and multiply: and that the egg, in which is contained the rudiment of the foetus, may be fecundated; for without fecundation all eggs are unfit to produce any offspring.

Foxes and wolves, struck with these flings, every where howl in the woods; crowds of dogs follow the female, bulls show a terrible convenience, and very different from that of oxen. Stags every year have new horns, which they lose after rutting time. Birds look more beautiful than ordinary, and warble all day long through lasciviousness. Thus small birds labour to outing one another, and cocks to outcrow. Peacocks spread forth again their gay and glorious trains. Fitches gather together, and exult in the water; and grasshoppers chirp, and pipe, as it were, amongst the herbs. The ants gather again into colonies, and repair to their citadels. We pass over many other particulars which this subject affords, to avoid prolixity.

2. The fecundated egg requires a certain and proportionate degree of heat for the expansion of the flamina
The cetaceous and animal framina.

The females of quadrupeds have an uterus, contrived for early gestation, temperate and cherishing warmth, and proper nourishment of the fetus, as most of them live upon the earth, and are there fed.

Birds, in order to get subsistence, and for other reasons, are under a necessity of shifting place; and that not upon their feet, but wings. Gestation therefore would be barrenfome to them. For this reason they lay eggs, covered with a hard shell. These they fit upon by a natural instinct, and cherish till the young one comes forth.

The ostrich and cassowary are almost the only birds that do not observe this law; these commit their eggs to the sand, where the intense heat of the sun excludes the fetus.

Fishes inhabit cold waters, and most of them have cold blood; whence it happens that they have not heat sufficient to produce the fetus. The all-wise Creator therefore has ordained, that most of them should lay their eggs near the shore, where, by means of the solar rays, the water is warmer, and also fit for that purpose; and also because water-insects abound more there, which afford the young fry nourishment.

Salmon, when they are about to lay their eggs, are led by instinct to go up the stream, where the water is fresh and more pure.

The butterfly-fly is an exception, for that brings forth its fetus alive.

The fish of the ocean, which cannot reach the shores by reason of the distance, are also exempt from this law. The Author of nature has given to this kind eggs that swim; so that they are hatched amidst the swimming fauna, called argoze. The cetaceous fish have warm blood; and therefore they bring forth their young alive, and suckle them with their teats.

Many amphibious animals bring forth live fetuses, as the viper and the toad, &c. But the species that lay eggs, lay them in places where the heat of the sun supplies the warmth of the parent.

Thus the red of the frog kind, and the lizard kind, lay their eggs in warm waters; the common salamander, in dungdrills, and such like warm places; and give them up to nature, as a provident nurse, to take care of them. The crocodile and sea-tortoises go ashore to lay their eggs under the sand, where the heat of the sun hatches them.

Most of the insect kind neither bear young nor hatch eggs; yet their tribes are the mostnumerous of all living creatures; insomuch, that if the bulk of their bodies were proportionate to their quantity, they would scarce leave room for any other kind of animals. Let us see therefore with what wisdom the Creator has managed about the propagation of these minute creatures. The females by natural instinct meet and copulate with the males; and afterwards lay their eggs; but not indiscriminately in every place. For they all know how to choose such places as may supply their offspring in its tender age with nourishment, and other things necessary to satisfy their natural wants: for the mother, soon after she has laid her eggs, dies; and were she to live, she would not have it, in her power to take care of her young.

Butterflies, moths, some beetles, weevils, bugs, cock-combs, insects, galls-insects, tree-bugs, &c. lay their eggs on the leaves of plants, and every different tribe chooses its own species of plant. Nay, there is scarce any plant which does not afford nourishment to some insect; and still more, there is scarcely any part of a plant which is not preferred by some of them. Thus one insect feeds upon the flower; another upon the trunk; another upon the root; and another upon the leaves. But we cannot help wondering particularly, when we see how the leaves of some trees and plants, after eggs have been let into them, grow into galls; and form dwellings, as it were, for the young ones. Thus when the gall-insect has fixed her eggs in the leaves of an oak, the wound of the leaf swells, and a knob like an apple arises, which includes and nourishes the embryo.

When the tree-bug has deposited its eggs in the boughs of the fir-tree, excrences rise shaped like pearls. When another species of the tree-bug has deposited its eggs in the mouse-ea hickweed or the speedwell, the leaves contract in a wonderful manner into the shape of a head. The water-spider excludes eggs either on the extremities of the juniper, which from thence forms a lodging, that looks like the arrow-headed grass; or on the leaves of the poplar, from whence a red globe is produced. The tree-loose lays its eggs on the leaves of the black poplar, which turn into a kind of inflated bag; and so in other instances. Nor is it upon plants only that insects live and lay their eggs. The gnats commit theirs to flagrating waters. The water-insect called monocusus often increases so immensely on pools, that the red legions of them have the appearance of blood. Others lay their eggs in other places: e.g. the beetle, in dungdrills; the dermetles, in skins; the flesh fly, in putrified flesh; the cheese-maggot, in the cracks of cheese, from whence the caterpillars issuing forth, oftentimes consume the whole cheese, and deceive many people, who fancy the worms are produced from the particles of the cheese itself, by a generation called equusovis, which is extremely absurd. Others exclude their eggs upon certain animals. The mill-beetle lays its eggs between the scales of fishes; the species of grasshopper, upon the back of cattle; the species 1025 (S. N.) on the back of the rein-deer; the species 1026, in the nozes of sheep. The species 1028 lodges during the winter in the intestinal tube, or the throat of hares, nor can it be driven out till the summer comes on. Nay, insects themselves are often surrounded with the eggs of other insects, infomuch that there is scarcely an animal to be found which does not afford food for other animals. Almost all the eggs of insects, when laid, are ordained to undergo, by a wonderful law of nature, various metamorphoses, e.g. the egg of the butterfly, being laid in the cabbage, first of all becomes a caterpillar, that feeds on the herb, crawls, and has 16 feet. This afterwards changes into a nymph, that has no feet, is smooth, and eats nothing; and lastly, this bursts into a butterfly that flies, has variety of colours, is hairy, and lives upon honey. What can be more worthy of admiration than that one and the same animal should appear on the stage of life under so many characters,
The laws of generation of worms are still very obscure; as we find they are sometimes produced by eggs, sometimes by offsets, just in the same manner as happens to trees. It has been observed with the greatest admiration, that the polypus or hydra (S. N. 221) lets down floats and live branches, by which it is multiplied. Nay more, if it be cut into many parts, each segment, put into the water, grows into a perfect animal; so that the parts which were torn off are restored, and form a complete and perfect animal like that from which it was torn.

3. The multiplication of animals is not tied down to the same rules in all; for some have a remarkable power of propagating, others are confined within narrow limits in this respect. Yet in general we find, that nature observes this order, that the least animals, and those which are useful and serve for nourishment to the greatest number of other animals, are endowed with a greater power of propagating than others.

Mites, and many other insects, will multiply to a thousand within the compass of a very few days; while the elephant scarcely produces one young in two years.

The hawk-kind generally lay not above two eggs, at most four; while the poultry kind produce from 50 to 100.

The diver, or loon, which is eaten by few animals, lays also two eggs; but the duck kind, the moor-game, partridges, &c. and small birds, lay a very large number.

If you suppose two pigeons to hatch nine times a year, they may produce in four years 14,760 young. They are ended with this remarkable fertility, that they may serve for food, not only for man, but for hawks and other birds of prey. Nature has made harmless and efculent animals fruitful. She has forbid the bird kinds to fall short of the number of eggs allotted to each species; and therefore, if the eggs which they intend to fit upon be taken away a certain number of times, they presently lay others in their room, as may be seen in the swallow, duck, and small birds.

II. Preservation.

1. Preservation follows generation: this appears chiefly in the tender age, while the young are unable to provide for their own support. For then their parents, though otherwise ever so fierce in their disposition, are affected with a wonderful tenderness or sense of love towards their progeny, and spare no pains to provide for, guard, and preserve them; and that not by an imaginary law, but one given by the Lord of nature himself.

Quadrupeds give suck to their tender young, and support them by a liquor perfectly easy of digestion, till nature enables them to digest what is more solid. Nay, their love toward them is so great, that they endeavor to repel with the utmost force every thing which threatens danger or destruction to them. The ewe, which brings forth two lambs at a time, will not admit one to her teats unless the other be present and suck also; left one should famish, while the other grows fat.

Birds build their nests in the most artificial manner, and line them as soft as possible, for fear the eggs should get any damage. Nor do they build promiscuously in any place, but there only where they may quietly lie concealed and be safe from the attacks of their enemies.

The hanging bird makes its nest of the fibres of withered plants, and the down of the poplar seeds, and fixes it upon the bough of some tree hanging over the water, that it may be out of reach.

The diver places its swimming nest upon the water itself, amongst the rushes. We designedly pass over many instances of the like kind.

Again, birds sit on their eggs with so much patience, that many of them choose to perish with hunger, rather than expose the eggs to danger by going to seek for food.

The male rooks and crows, at the time of incubation, bring food to the females.

Pigeons, small birds, and other birds which pair, sit by turns; but where polygamy prevails, the males scarcely take any care of the young.

Most of the duck kind pluck off their feathers in great quantity, and cover their eggs with them, lest they should be damaged by the cold when they quit their nests for the sake of food; and when the young are hatched, who knows not how solicitous they are in providing for them till they are able to fly and shift for themselves?

Young pigeons would not be able to make use of hard seeds for nourishment, unless the parents were to prepare them in their crops, and thence feed them.

The owl called the eagle-owl makes its nest on the highest precipices of mountains, and in the warmest spot, facing the sun; that the dead bodies brought there may by the heat melt into a soft pulp, and become fit nourishment for the young.

As an exception indeed to this fostering care of animals, may be mentioned the cuckow, which lays its eggs in the nest of other small birds, generally the wag-tail, yellow hammer, or white-throat, and leaves the incubation or preservation of the young to them. This custom of the cuckow is so extraordinary, and out of the common course of nature, that it would not be credible were it not for the testimony of the most knowing and curious natural-historians, such as Ray, Willoughby, Gessner, Aldrovandus, Arifolce, &c. But this seeming want of instinct is accounted for from the structure and situation of its stomach, which disqualifies it for incubation; and its infignitive care is still conspicuous in providing a proper, though a foreign, nidus for its eggs.

Amphibious animals, fishes, and insects, which cannot come under the care of their parents, yet owe this to them, that they are put in places where they easily find nourishment.

2. As soon as animals come to maturity, and want no longer the care of their parents, they attend with the utmost labour and industry, according to the law and economy appointed for every species, to the preservation.
fervation of their lives. But so great a number of them, which occur everywhere, may be supported, and a certain and fixed order may be kept up amongst them, behold the wonderful disposition of the Creator, in assigning to each species certain kinds of food, and in putting limits to their appetites. So that some live on particular species of plants, which particular regions and soils only produce; some on particular animalcula; others on carcasses; and some even on mud and dung. For this reason, Providence has ordained that some should swim in certain regions of the watery element; others should fly; some should inhabit the torrid, the frigid, or the temperate zones; and others should frequent deserts, mountains, woods, pools, or meadows, according as the food proper to their nature is found in sufficient quantity. By this means there is no terrestrial tract, no sea, no river, no country, but what contains and nourishes various kinds of animals. Hence also an animal of one kind cannot rob those of another kind of its aliment; which, if it happened, would endanger their lives or health; and thus the world at all times affords nourishment to so many and so large inhabitants, at the same time that nothing which it produces is useless or superfluous.

It will not be here amiss to produce some instances by which it will appear how providentially the Creator has furnished every animal with such clothing as is proper for the country where they live, and also how excellently the structure of their bodies is adapted to their particular way of life; so that they seem to be defined solely to the places where they are found. Monkeys, elephants, and rhinoceroses, feed upon vegetables that grow in hot countries, and therefore therein they have their allotted places. When the fun darts forth its most fervid rays, these animals are of such a nature and disposition, that it does them no manner of hurt; nay, with the rest of the inhabitants of those parts, they go naked; whereas, were they covered with hairy skins, they must perish with heat.

On the contrary, the place of rein-deer is fixed in the coldest part of Lapland, because their chief food is the livewort, which grows nowhere abundantly as there; and where, as the cold is most intense, the rein-deer are clothed, like the other northern animals, with skins filled with the densest hair, by the help of which they easily defend the keenest of the winter. In like manner the rough-legged partridge paves its life in the very Lapland Alps, feeding upon the seeds of the dwarf birch; and, that they may run up and down safely amidst the snow, their feet are feathered.

The camel frequents the sandy and burning desarts, in order to get the barren camel's-hay. How wisely has the Creator contrived for him! he is obliged to go through the desarts, where oftentimes no water is found for many miles about. All other animals would perish with thirst in such a journey; but the camel can undergo it without suffering; for his belly is full of cells, where he reserves water for many days. It is reported by travellers, that the Arabs, when in travelling they want water, are forced to kill their camels, and take water out of their bellies that is perfectly good to drink, and not, at all corrupted.

The pelican likewise lives in desert and dry places; and is obliged to build her nest far from the sea, in order to procure a greater share of heat to her eggs. She is therefore forced to bring water from afar for herself and her young; for which reason providence has furnished her with an extremity most adapted to this purpose: She has a large bag under her throat, which the fills with a quantity of water sufficient for many days; and this she pours into the nest, to refresh her young, and teach them to swim.

The wild beasts, lions, and tygers, come to this nest to quench their thirst, but do no hurt to the young.

Oxen delight in low grounds, because there the food most palatable to them grows. Sheep prefer naked hills, where they find a particular kind of grases called the fijina, which they love above all things.

Goats climb up the precipices of mountains, that they may browse on the tender shrubs; and in order to fit them for it, they have feet made for jumping.

Horses chiefly resort to woods, and feed upon leafy plants.

Nay, so various is the appetite of animals, that there is scarcely any plant which is not chosen by some and left untouched by others. The horse gives up the water-hemlock to the goat. The cow gives up the long-leaved water-hemlock to the sheep. The wild goat gives up the monks-head to the horse, &c.; for that certain animals grow fat upon, others abhor as poison. Hence no plant is absolutely poisonous, but only respectively. Thus the spurge, that is noxious to man, is a most wholesome nourishment to the caterpillar. That animals may not destroy themselves for want of knowing this law, each of them is guarded by such a delicacy of taste and smell, that they can easily distinguish what is pernicious from what is wholesome; and when it happens that different animals live upon the same plants, still one kind always leaves something for the other; as the mouths of all are not equally adapted to lay hold of the grass; by which means there is sufficient food for all. To this may be referred an economical experiment well known to the Dutch, that when eight cows have been in a pasture, and can no longer get nourishment, two horses will do very well there for some days; and when nothing is left for the horses, four sheep will live upon it.

Swine get provision by turning up the earth: for there they find the succulent roots, which to them are very delicious.

The leaves and fruits of trees are intended as food for some animals, as the floth, the squirrel; and these last have feet given them fit for climbing.

Besides myriads of fishes, the callor, the sea-call, and others, inhabit the water, that they may there be fed; and their hinder-feet are fit for swimming, and perfectly adapted to their manner of life.

The whole order of the goose-kind, as ducks, merganser, &c. pass their lives in water, as feeding upon water-insects, fishes, and their eggs. Who does not see, that attends ever so little, how exactly the wonderful formation of their beaks, their necks, their feet, and their feathers, suit their kind of life; which...
The way of living of the sea-swallow deserves to be particularly taken notice of; for as he cannot so commodiously plunge into the water, and catch fish, as other aquatic birds, the Creator has appointed the sea-gull to be his caterer, in the following manner: When this bird is pursued by the former, he is forced to throw up part of his prey, which the other catches; but in the autumn, when the silkes hide themselves in deep places, the merganer supplies the gull with food, as being able to plunge deeper into the sea.

The chief granary of small birds is the knot-grass, that bears heavy seeds, like those of the black-bindweed. It is a very common plant, not easily destroyed, either by the road-side by trampling upon it, or any where else; and is extremely plentiful after harvest in fields, to which it gives a reddish hue by its numerous seeds. These fall upon the ground, and are gathered all the year round by the small birds. To which we may add, that many small birds feed upon the seeds of plantain, particularly Linnet. It is generally known that the goldfinch lives upon the feed of thistles, from which he has its name in Latin and French. Thus bountiful nature feeds the numerous seeds.

The Creator has taken no less care of some amphibious animals, as the snake and frog kind; which, as they have neither wings to fly, nor feet to run swiftly and commodiously, would scarcely have any means of taking their prey, were it not that some animals run, as it were, of their own accord, into their mouths. When the rattle-snake, a native of America, with open jaws fixes his eyes upon a bird, fly, or squirrel, sitting on a tree, they fly down his throat, being rendered stupefied, and giving themselves up as delitute of all refuge. How dreadful this serpent is to other animals will appear by an account we have in a treatise entitled, Radix Sanguis. Where the author (Aman. Academ. tom. 2.) says, one of these terrible serpents got clandestinely into the house of governor Blake at Carolina; where it would have long lain concealed, had it not been that all the domestic animals, as dogs, hogs, turkeys, and fowls, admittid the family by their unusual cries, equally showing their horror and consternation, their hair, brittles, and crests, standing up on end. On the other hand, we cannot but adore the Creator's great goodness towards man, when we consider the rattle which terminates this serpent's tail; for by means of that we have an opportunity of guarding against this dreadful enemy; the found warning us to fly; which if we were not to do, and we should be wounded by him, the whole body would be turned into a putrid corruption in fix hours, nay sometimes in half an hour.

The limits of this article will not permit us to produce more examples of this kind. But whoever will be at the pains to take ever so slight a view of the wonderful works of the Author of nature, will readily see how wisely the plan, order, and fitness of things with divine ends, are disposed.

3. We cannot without the utmost admiration behold how providentially the Creator has acted as to the preservation of those animals which, at a certain time of the year, are by the rigours of the season excluded from the necessaries of life. Thus the bear in the autumn creeps into the moos which he has gathered, and there lies all winter; subsisting upon no other nourishment but his fat, collected during the summer in the cellular membrane, and which without doubt, during his fast, circulates through his vessels, and supplies the place of food; to which perhaps is added that fat juice which he eats out of the bottom of his feet.

The hedge-hog, badger, and mole, in the same manner fill their winter-quarters with vegetables, and sleep during the frosts. The bat seems cold and quite dead all the winter. Most of the amphibious animals get into dens, or to the bottom of lakes and pools.

In the autumn, as the cold approaches, and insects disappear, swallows migrate into other climes in search of food and a temperature of air more friendly to their constitution: though the latter hatches, or those young birds which are incapable of distant flights, seek for an asylum against the violence of the cold in the bottom of lakes amidst the reeds and rushes; from whence, by the wonderful appointment of nature, they come forth again. See the article Hirundo. The periodic motion of the bowels ceases in all these animals while they are obliged to fast; whence the appetite is diminished, and so they suffer the least from hunger. To this head may be referred the observation of the celebrated Linf_on concerning those animals. That their blood, when let into a vessel, does not congeal, as that of all other animals; and so is no less fit for circulation than before.

The moor-fowls work themselves out walks under the very snow. They moult in the summer; so that about the month of August they cannot fly, and are therefore obliged to run into the woods; but then the moor-berryba and bilberries are ripe, from whence they are abundantly supplied with food. Whereas the young do not moult the first summer; and therefore, though they cannot run so well, are able to escape danger by flight.

The seat of the birds who feed upon insects migrate every year to foreign regions, in order to seek for food in a milder climate; while all the northern parts, where they live well in the summer, are covered with snow.

By these migrations, birds also become useful to many different countries, and are distributed over almost all the globe. And it must excite our admiration that all of them exactly observe the times of coming and going, and that they do not mistake their way.

Insects in the winter generally lie hid within their caves, and are nourished by the surrounding liquor like the fustus of other animals; from whence, at the approach of spring, they awake, and fly forth, to the abonishment of every one.

However, all animals which lie hid in winter do not observe these laws of falling. Some provide florefous!es in summer and autumn, from which they take what is necessary; as mice, jays, squirrels, bees.

III. DESTRUCTION.

1. We have observed above, that all animals do not live upon vegetables, but that there are some which feed
It deserves also to be remarked, how much some animals confult their safety by night. When horses sleep in woods, one by turn remains awake, and, as it were, keeps watch. When monkeys in Brazil sleep upon trees, one of them keeps awake, in order to give the sign when the tiger creeps towards them; and in case the guard should be caught asleep, the rest tear him to pieces. Hence rapacious animals are not always successful in their hunting, and are often obliged to labour for a whole day to no purpose. For this reason the Creator has given them such a nature, that, they can bear fasting a long time. Thus the lion lurks for many days without famishing; and the wolf, when he has once well satisfied his hunger, can fast for many weeks without any difficulty.

If we consider the end for which it pleased the Supreme Being to constitute such an order of nature; that some animals should be, as it were, created only to be miserably butchered by others, it seems that his Providence not only aimed at sustaining, but also keeping a just proportion among all the species; and to prevent any one of them from increasing too much, to the detriment of men and other animals. For if it be true, as it most assuredly is, that the surface of the earth can support only a certain number of inhabitants, they must all perish if the same number were doubled or trebled.

There are some viviparous flies which bring forth 1000 young. These in a little time would fill the air, and like clouds intercept the rays of the sun, unless they were devoured by birds, spiders, and many other animals.

Storks and cranes free Egypt from frogs, which, after the inundation of the Nile, cover the whole country. Falcons clear Palæstine of mice. Belzoni on this subject says: “The storks come to Egypt in such abundance, that the fields and meadows are white with them. Yet the Egyptians are not displeased with this fidget; as frogs are generated in such numbers there, that did not the storks devour them, they would over-run every thing. Besides, they also catch and eat serpents. Between Belba and Gaza, the fields of Palæstine are often deferted on account of the abundance of mice and rats; and were they not destroyed by the falcons that come here by instinct, the inhabitants could have no harveft.”

The white fox is of equal advantage in the Lapland Alps; as it destroys the Norway rats, which are generated there in great abundance, and thus hinder them from increasing too much in proportion, which would be the destruction of vegetables.

It is sufficient for us, that nothing is made by Providence in vain; and that whatever is made, is made with supreme wisdom. For it does not become us to pry too boldly into all the designs of God. Let us not imagine, when these rapacious animals sometimes do us mischief, that the Creator planned the order of nature according to our private principles of economy; for the Laplanders have one way of living; the European husbandman another, the Hottentots and savages a third; whereas the stupendous economy of the Deity is one throughout the globe; and if Providence does not always calculate exactly according to our way of reckoning, we ought to consider this affair in the same light, as when different elements,
men wait for a fair wind, every one with respect to the part he is bound to, who plainly fear cannot all be satisfied.

2. The whole earth would be overwhelmed with carcasses and flinking bodies, if some animals did not delight to feed upon them. Therefore, when an animal dies, bears, wolves, foxes, ravens, &c. do not lose a moment till they have taken all away. But if a horse dies near the public road, you will find him, after a few days, swin, burial, and at last filled with innumerable grubs of carnivorous flies, by which he is entirely consumed, and removed out of the way, that he may not become a nuisance to passengers by his poisonous stench.

When the carcasses of fishes are driven upon the shore, the voracious kinds, such as the thornback, the hound-fish, the conger-eel, &c. gather about and eat them. But because the flux and reflux soon change the state of the sea, they themselves are often detained in pits, and become a prey to the wild beasts that frequent the shores. Thus the earth is not only kept clean from the putrefaction of carcasses, but at the same time, by the economy of nature, the necessaries of life are provided for many animals. In the like manner many insects at once promote their own good, and that of other animals. Thus gnats lay their eggs in stagnant water, putting the grubs in one, and taking them all out of the other; for then he will soon find the water that is full of grubs pure and without any stench, while the water that has no grubs will continue flinking.

Lice increase in a wonderful manner in the heads of children that are scabby; nor are they without their use, for they consume the redundant humours.

The beetle kind in summer extract all moist and glutinous matter out of the dung of cattle, so that it becomes like dust, and is spread by the wind over the ground. Were it not for this, the vegetables that lie under the dung would be so far from thriving that all that is put would be rendered barren.

As the excrements of dogs is of so filthy and feculent a nature that no insect will touch them, and therefore they cannot be dispersed by that means, care is taken that these animals should exonerate upon flies, trunks of trees or some high place that vegetables may not be hurt by them.

Cats bury their dung. Nothing is so mean, nothing so little in which the wonderful order and wise disposition of nature do not shine forth.

Lastly, all these treasures of nature, so artfully contrived, so wonderfully propagated, so providentially supported throughout her three kingdoms, seem intended by the Creator for the fake of man. Every thing may be made subservient to his use, if not immediately, yet mediately; not fo to that of other animals. By the help of reason man tames the fiercest animals; pursues and catches the fwietsell; nay, he is able to reach even those which lie hid in the bottom of the sea.

By the help of reason, he increases the number of vegetables immediaety, and does that by art which nature left to herfelf, could scarcely effect. By ingenuity he obtains from vegetables whatever is convenient or necessary for food, drink, clothing, medicine, navigation, and a thousand other purposes.

He has found the means of going down into the abyss of the earth, and almost searching its very bowels. With what artifice has he learned to get fragments from the most rocky mountains, to make the hardest stones fluid like water, to separate the useful metal from the useless dross, and to turn the finest sand to some use! In short, when we follow the series of created things, and consider how providentially one is made for the fake of another, the matter comes to this, that all things are made for the fake of man; and for this end more especially, that he, by admiring the works of the Creator, shall extol his glory, and at once enjoy all those things of which he stands in need, in order to pass his life conveniently and pleasantly.

Besides general natural histories, which we have here given a specimen of, as those of Pliny, &c. there are likewise particular ones, and those of two kinds. The first, those which only consider one kind of things; such as the History of Shells, by Dr Lillie; of Fishes, by Willougby; that of Birds, by the same; that of Plants, by Ray; those of insects, by Swammerdam and Moufett; that of Animals, by Gifner; that of Pollis, by Agricola, Mercatus, &c.

The second, those which consider the several kinds of natural things found in particular countries or provinces: as, the Natural History of Dauphine, by Chrier; the Natural History of the Antilles, by F. De Tettre, and M. Louisilliers De Poincy; that of Oxfordshire and Staffordshire, by Dr Plot; that of Lancashire, by Leigh of Northamptonshire, by Morton; that of the Western Islands, by Martin, &c.

The natural history only of one particular place is a subject very extensive in its materials, and not to be set about without great care and circumspection. Mr Boyle has favoured the world with a list of the heads under which to arrange things, and what to enquire after on such an occasion.

The general heads under which he comprehends the articles of this history are four; the things which regard to the heavens, the air, the waters and the earth. To these general heads Mr Boyle imagines should be added, inquires into traditions in the country, of any thing relating to it, whether peculiar to it, or only more common there than elsewhere; and where those require learning or skill in the answerer, the utmost care is to be taken to put the people in a way to give their accounts in a satisfactory manner; for a false or bad account of any thing is always much worse than no account at all.

This subject concerning the works of nature, a very small part of which we have been able to touch upon, is of such importance and dignity that if it were to be properly treated in all its parts, men would find where withal to employ almost all the powers of the mind; nay, time itself would fail before, with the mott acute human sagacity, we should be able to discover the amazing economy, laws, and exquisite structure, even of the least insect, since, as Pliny observes, nature nowhere appears more herself than in her most minute works.

Summary
Sec. IV.

NATURAL HISTORY.

We shall add to this article the following description of a museum: The windows ought to be in the two longest sides of the building; that it may be equally lighted during the whole day.

On one wing of the museum must be placed eleven presses, with shelves supported on wooden brackets. These presses are intended for containing the eleven following classes of the mineral kingdom (a kingdom which forms the original basis of every thing pertaining to this globe: minerals have neither organization nor life).

1. Waters.
2. Earths.
3. Sands.
4. Stones.
5. Salts.
6. Pyrites.
7. Semimetals.
10. Volcanic productions.
11. Petrifications, fossils, and minerals.

We at once perceive the advantage of such an arrangement, where every thing is distinct and distributed in the manner most advantageous for the inspection of the student. The presses must be provided with a wire grate, or covered with glafs: and each of them must have a title on the cornice, indicating the class which it contains. Besides this, each shelf in the press ought to have a small title on the edge, specifying the kind of substances which are placed on it; and these should be kept in clear glass-bottles, well sealed and furnished with proper titles also. In them are to be seen earths, clays, turfs, ochres, chalks, marls, lapis, malachite, and pyrites; the whole produced by a natural cause and after its kind, as in the various kinds of opaque, green, &c. lead, the ore of nickel, collections of coloured pyrites, the stone called the Isa's stone, beautiful specimens of cobalt, bismuth, zinc, antimony, ore of fluid quicksilver, and cinna bar in crystals; the whole properly titled and arranged according to their classes.

The presses for metals ought to present us in the same order with feldspar and rare specimens of the ores of white, green, &c. lead, the ore of nickel, collections of crystallized tin, the flores ferris, beautiful needles of hematite, a powerful rough leadstone, with some platiniferous, the filky copper of China, and a collection of malachite; likewise virgin silver, in vegetation and red silver, together with a collection of golden ore. These substances form a spectacle equally varied and instructive: in this department of her works nature is as rich and brilliant as in the various kinds of stones.

The presses for bitumens may in like manner contain specimens of jet polished on one side: amber of different colours (which when it is transparent, and contains defects, ought to be polished on the two opposite surfaces); a beautiful specimen of ambergris, together with pieces of transparent red and yellow sulphur.

In the presses for petrifications or for fossils, we must likewise place, on semicircular shelves, the rarest and
The best preserved pieces? such as lilium lapideum and kreopes, transparent belemnites, fossil urchias, the articulated nautilis, cornua ammonis fawed and polished, hydrolitic, lapis lenticulari, gyryphites calculi or bezoars, turquoites, leadstones, glio-petrites; in short all kinds of figured stones, and also petrified wood.

In the press for fences, which has a similar apparatus of shelves, we see different kinds of crystals, and all the precious stones in the matrix. Those which are detached and cut are placed in cabinets or watch-glasses; but those which have been cut and set are to be put in a jewel box or open case for rings. The same polished be observed with regard to pieces, cups, cisterns or polished plates of agate, cornelian, jade, fardosyx, onyx, chaledony, jasper, porphyry, granite, lapis lazuli, marble, alabaster, and Iceland crystal. Here likewise are to be placed the Bologna stone, the Labrador stone, the serpentine stone, tare, amianthus, zeolite, basaltes, touch-stone, together with Egyptian and English flints. With regard to impressed petrifications, large arborizations, and Florence stones, if they are in good preservation: they should be framed and suspended by hooks on the pilasters which connect the press of the mineral kingdom. These press are of an uniform height; but their breadth is proportioned to the size or number of the materials composing the clasts which it contains, and they are supported as well as those which are placed all around, on a chest of drawers below high. These drawers must correspond to the press above them, and contain substances of the same clasts. This methodical arrangement is a great help to the memory: because it occasionally supplies the place of a numbered catalogue, and because in a great multitude of objects it is the only means of finding at once what we want.

In the mineral kingdom, these drawers are very useful for containing earths, belemnites, entroches, affroites, and other polymorphous fossils, univalve, bi-valve, and multivalve shells, polished petrifications of bones and pieces of wood, collections of marbles and polished flints, collections of fluel, sands, and amber, together with pieces procured from the melting of ores, such as regulus, drôts, &c. Some parts of the mineral kingdom, such as the earths and certain clasts, make not a brilliant figure in a museum; they are notwithstanding the most scientific parts of it, and the most interesting to those who prefer the solid satisfaction of tracing nature in her most important productions, and her fundamental operations, to the empty spectacle of gaudy colours and agreeable figures.

Minerals in general require to be kept with great care, and so as not to be intermixed. Some of them, such as the faith, easily dissolve; and others, as the pyrites, are subject to efflorescence. Vegetables and animals are likewise more or less liable to corruption; and to prevent this inconvenience, great pains must be taken in preserving certain pieces which are subject to speedy decay.

On the second wing of the cabinet are to be placed ten press, distributed like those of the mineral kingdom, and intended for containing the ten following divisions of the vegetable kingdom. Vegetables are organized bodies, but they possess not, like animals spontaneous motion or feeling.

1. Roots.
2. Barks.
3. Woods and stalks.
4. Leaves.
5. Flowers.
6. Fruits and seeds.
7. Parasite plants, also agaries and mushrooms.
8. The juices of vegetables; such as balsams and solid resins, resinous, gums, and gums properly so called.
10. Marine plants, and plants growing on the shores of the sea.

In this kingdom, the same order of press, the same symmetrical arrangement, are to be observed as in the mineral kingdom. The semicircular shelves in the bottom of the press are here very useful for containing in small square phials China varnish, essential oils, and other peculiar aromatics, whether of Arabia or India; together with the roots of cumbou, mandragora, certain fruits either monstrous or natural, which grow in the East Indies, and which the natives ripen in large bottles with narrow necks, preserved in spirits, such as the cashew-nut, &c. Here likewise are placed a number of fruits, remarkable for their rarity or great size; as cocoa nuts, gourds, the fruit of the baltard locust-tree, the fruit of the sand-box-tree, banana figs, pine-apples, coloquintida apple, dogbane, vegetable tumors or wens, and a branch of los de dentes, in which the three parts of the bark, especially the liber, are distinctly separated.

As the number of vegetables greatly exceeds that of minerals, we seldom put any thing in bottles but the dried parts of exotic plants, which are used either in medicine or in the arts, and those likewise which we cultivate merely from curiosity. With regard to indigeneous plants, an herbat is formed of land and sea plants, pasted or laid between leaves of paper collected in a book, and arranged according to the system of the botanists. To make this herbal as convenient as possible, it is proper to put the dried plants between two folds of dry paper, and, arranging them according to their families, genera, and species, to pile them one upon another, either openly on the shelves or in large band-boxes. On the back of these band-boxes must be a title indicating the family, at the extremity another with the name of the genus, and on each leaf the name of the species which it contains: the paper must be loose, that they may be changed at pleasure. The drawers are useful partly for holding different kinds of woods with the bark, cut in such a manner as that the grain and contexture of it may easily be distinguished, and for containing a collection of the woods of both Indies in small polished pieces with proper titles. One part of the drawers has several divisions within for the purpose of holding seeds; and a small title is inscribed on each of these divisions.

Sea-weeds, and small marine plants of an elegant shape, which from their colour and variety form agreeable pictures, may be framed and suspended by hooks to the pilasters of the presses. In the animal kingdom, particularly insects, it is well known, are attended with irreparable devatations. Butterflies,
Sec. IV.  

Natural History.

Animal Kingdom.  

Still more than the most beautiful birds, are not only subject to destruction in this way, but are also exposed to great danger from the rays of the sun, either direct or reflected, which alter their colour, make them lose all their splendor, and, in some species, render it impossible to distinguish them. In general, we cannot prevent the destruction of vegetables and animals, but by drying them as much as possible, or by putting them in prepared liquors, which must not be allowed to evaporate. But dried animals and vegetables require still a greater care: a great multitude of insects, which are bred in the month of April feed upon them and destroy them internally before they are perceived; they ought to be carefully watched during the continuance of this plague, which is about five months. In like manner, the moister of winter and the heat of summer make it necessary that the presses of museums should be kept carefully shut, except perhaps those which front to the north. Besides, the vapour of sulphur in combustion will kill these destructive insects either before or after they become perfect ones: the fumigations must be carefully performed during dry weather, and in a box made on purpose, into which only the specimens involved are introduced.  

On the third wing of the cabinet are placed presses for containing the ten following divisions of the animal kingdom (the kingdom which derived the substance necessary to its existence either mediately or immediately from the vegetable kingdom.—Animals possess feeling and spontaneous motion.)

In the presses the fame external decoration and distribution may be observed as in the preceding ones.

The presses for the Lythophytes must be arranged in such a manner as to present at one view the history of the lythophytes, madrepores, and coral, either rough or smooth, their covering; the whole placed on small wooden pedestals, blackened or gilded. Coralines, as well as lythophytes, may be pafted on a bit of paper, and put into a frame; such pictures, when suspended by hooks to the outside of the cabinets, always attract the attention of the spectators. If we have a considerable collection of them, it will be necessary to make a kind of herbal of them.

The presses for Zoophytes contains sponges, the marine jet d'eau, the Lena marina, holothurias, and all those substances which are called animal plants, mollusks, worms, &c. These productions must be preserved in rectified spirit of wine, which will be sufficiently weakened by the water contained in them. Upon the sponges are sea-plants, both prickly and smooth, with several sorts, from the corals, &c.  

The Tefaceous animals are preserved in bottles among fungoids. On the semicircular shelves at the bottom of the presses are placed large shells, and small ones with their marine covering.  

The presses for Crustaceous animals contain almost entirely of semicircular shelves, and contain crabs, cray.  

Small lobsters, squilla, and all small crustaceous animals, excepting the hermit crab, are put in frames.

Two kinds of insects are found in the presses delineated for them. The first kind, after being dried, are put in small wooden frames, which are varnished and glazed on two sides, that we may have in our power to examine the insect on both sides; of this kind are flies, mantises, beetles, butterflies with their nymphs or chrysalides, &c. (These animals form the most brilliant part of the cabinet, while the presses for bird is the most striking; but great pains must be used in their preservation.) Other insects, such as grasshoppers, scorpions, salamanders, spiders, tarantulas, caterpillars, and especially all soft insects, must be preserved in spirits, and placed on semicircular shelves at the bottom of the presses. Here also are deposited honey-combs, wasps' nests, and branches furnished with the nests of those insects, which produce the gum-lac.  

In the presses for Fishes are to be seen bottles containing foreign fishes, which are always few, three in spirits. The soft fishes of our own country are preserved in the same manner. The skin of large fishes, whether found in salt or fresh water, is taken off and printed on a bit of paper: the two parts are sometimes folded together, and the colours are renewed by means of varnish. The flying fish must be suspended about the top of the presses; and armed fishes, with otarion, on the shelves below.  

The presses for Amphibious animals contains, in bottles full of spirit of wine diluted with alum water, serpents, vipers, adders, frogs, toads, lizards, small land or water turtles, and a small tortoise with its shell. The lower shelves are furnished with a small rattle-shake, a camelion, a crocodile, a beaver, a sea-lion, a sea cow, &c. The presses for Birds is filled with animals of that class both foreign and natives, stuffed and provided with glass eyes. The skin covered with the feathers may be preserved perfect and dry by being fitted to a mould of tree moss, or filled with cotton and sprinkled on the inside with pepper, camphor, and corrosive sublimate, to diftend it from the attack of moss, grubs, woodlice, and desmidies. The spring and autumn are the best seasons for this operation; the mussel's spring is very improper, because it is unfavorable to the beautiful colour and the preservation of the feathers, which moreover are then full of blood. The birds, when thus prepared, and when the brain has been taken out, are then placed on their supports.—Some females may be placed in their nests in the attitude of incubation; these which are accustomed to perch may be placed on artificial trees; a wooden supporter covered with moss, turf, or artificial reeds, may be given to those which live among such places.  

Swimming birds are placed on the lower shelf, which must be covered with pieces of mirrors or silver glasses, in imitation of water. We must be careful to give each animal the most fructiferous attitude: to preserve the proportions, together with the natural position of the legs, wings, head, body, and tail; to observe an equilibrium in those which are attached, and to avoid it in those which have a fighting attitude. We must characterize the animal, represent his habits, 

Clavubus,
dispositions, graces, boldness, or timidity. In short, we must endeavour to express that beautiful tout ensemble which gives the appearance of life and motion to the whole. The deception ought to be such, that those who examine the particulars of the collection may apply to each what was said on another occasion—Nature is dead, but Art is alive. THESE obserations on birds are equally applicable to the other animals; but all of them must be arranged in a methodical order, which posesses the advantage necessary in such collections of uniting pleasure with instruction.

The lower shelves contain the eggs and nests of birds; and a collection of feathers is made in a book in the same manner as an herbal.

The press for quadrupeds contains, preserved in bottles, small animals, such as mice, rats, the opossum, &c. Other animals are stuffed, such as the cat, the squirrel, the hedge hog, the porcupine, the armadillo, the Guinea pig, the wolf, the fox, the roe-buck, the hare, the dog, &c.

The press containing the history of man consists of a complete mythology of a head separately injected, of a brain and the organs of generation in both sexes, of a head separately injected, of a human body.

The preservation of subjects in bottles with spirit of wine does not always succeed, because they spoil as the spirit of wine evaporates, unless particular care be taken to examine the vessels wherein they are contained, which requires time and pains, and is attended with expense. Mr. Lewis Nicola, in the Philadelphia Transactions for the year 1771, recommends, after using the different methods pointed out by M. Reaumur of putting subjects intended for preservation in bottles filled with spirit of wine, to wipe well the neck of the bottle, and put a layer of putty, two lines thick, over the piece of skin or bladder which covers it. The bottle is then revered in a wooden cup, which they fill with melted tallow, or with a mixture of tallow and wax to prevent the spirit of wine from evaporating.

The drawers under the press of the animal kingdom contain small detached parts of animals, such as teeth, small horns, jaw-bones, claws, beaks, nails, vertebrae, hairs, scales, balls of hair, and a collection of bones remarkable for blows, fractures, deformities, and diseases.

To decorate a cabinet to the greatest advantage, and to make one complete whole, the walls must be furnished throughout their whole extent. For this purpose the tops of the pressies are commonly ornamented with shells of a very great size, foreign wafis-hives, the horn of a rhinoceros, an elephant's trunk, the horn of an unicorn, horns and buils of alabaster, jasper, marble, porphyry, or serpentine stone. Here likewise are placed figures of antique bronze, large lyophytes, animals made of shells, bouquets made of the wings of Scarabeus, grulls cut into two, painted, and made into bowls, plates, vases, and as they are used by savages; little trunks of bark, books made of the leaves of the palm-tree, globes, spheres, &c. The multiplicity and singularity of the objects never fail to arrest the attention of the spectator.

The circumference of the cabinet being furnished in the manner we have described, the floor may likewise be paved with different kinds of common stones which are susceptible of a polish.

The ceiling, which must be very white, is divided into three spaces, furnished with hooks and brass wires. Here may be distributed in order different vegetable and animal productions, which are of too great a size to be contained in the pressies; such as,

1. The sugar-cane, a branch of the palm-tree, together with that called the Chine's fan, large cossos both simple and with a double lobe, the leaf of the banana-tree, Indian and European flocks, remarkable for the knots, tubercles, and spiral wreaths, which cover their whole length, a bamboo root divided longitudinally into two parts, and the different species of reed-canes.

2. The skins of large animals: also stuffed animals, such as lizards, whether a crocodile or caiman and scaly lizard, a shark, a sword-fish, a sea-calf, a sea-tortoise, large and long serpents, the horns of deer, wild goats, roe-bucks, and reindeer.

3. The third space is filled with Indian rackets, hampmocks, dressers, and tufts of feathers; with calumets or pipes; with quivers, bows, and arrows; with head-pieces, cups with feathers, aprons, necklaces, Chineze necessaries, fans made of the leaves of the palm-tree, a gargeoulette of Indo-pan, a Polish whip, Indian canoes, Chineze musical instruments, lances, weapons, Indian furniture and utensils; and in short, various curiosities from nations ancient and modern, if they can be found; various furniture and utensils of different nations, ancient and modern.

As the great extent of a fine collection requires that there be no empty space, stands may be placed in different parts of the room, especially at the corners, for supporting large vertebre, the head of a sea-cow, very large madreporos, or considerable collections of rock chrysal or of minerals.

In the middle of the room is placed a receptacle for shells, which is a large table or bureau with raised edges. The surface of this table is divided into 27 separate cases, of different sizes, and proportioned to the 27 families of marine shells to be deposited in them. These divisions are made with wood or pasteboard painted blue, and are sometimes in the form of shelves; the bottom is covered with blue cotton or green flaxen, or, what is still simpler, with white linen, sufficiently rough to keep the shells in their place. In some cabinets, these shelves are covered with mirrors on all their different surfaces, which shows the objects double, and gives us an opportunity of viewing them on the two opposite sides. In other cabinets the cases for each family are distributed into a number of smaller divisions, for containing the several species separate from each other. The sea-shells, contained in the receptacle for shells, are all cleaned and preserved, in the variety of their figure and colours, together with their inequality, an agreeable and enchanting picture, so much the more charming that it unites a methodical distribution to a symmetrical order. The upper part of this table is filled by a net-work
work of braids wire covered with forge, or, what is still better, by a glass frame, to defend the shells from dust.

We must not omit to mention, that in the middle of the table there is a long elevated square box, containing land and river shells. From the middle of each compartment, or at each family of shells, arises a pyramidal wooden pillar, on the top of which is an elevated piece of plate glass, or of flat glass, denoting the kind of shells belonging to that division. Each family is distinguished from the adjoining one by those kind of ornaments of silk called catterpillars. By means of the different tints, we perceive the limits and extent of each family in the same manner as the colours in a geographical map enable us to distinguish the several provinces of the same empire. An exhibition of this kind was to be seen from 1768 to 1774, in a museum belonging to the prince of Condé at Chantilly.

Under the table for shells, on the side of the windows, is a glazed cage, large enough to contain the skeletons of an animal belonging to each class, viz., a fish, an amphibious animal, a reptile, a bird, and a quadruped. When to these we can add, for the fake of the comparative zoology, the skeletons of the intermediate individuals of these animals, together with those which make the neatest approaches to man, such as the monkey and the bear, we greatly increase both the pleasure and instruction. Below this table are likewise placed the best books connected with the different branches of natural history, especially such as have illuminated plates. The difficulty of acquiring the most valuable objects, and of preventing their destruction when once acquired, obliges us to have recourse to figures, in order to preserve a representation of them. This is an infallible method of communicating, not only to our cotemporaries, but also to posterity, the discoveries of the age in which the work was composed. Here also may be deposited the herbarium and the collection of feathers, arranged in the form of books.

The space above the door is furnished with a large frame, filled with the skins of rare fishes, which are dried, varnished, and pasted on paper. The piers of the windows are furnished with one or two shelves, which are provided with shelves, and contain different kinds of instruments employed in physics, such as an air-pump, a burning mirror, a perspective glass, a magnifier, a microscope, a telescope, magnets both natural and artificial, &c.

On the semicircular shelves below are placed stones formerly used by savages for hatchets. Some curious pieces of lacquer work, Indian pagodas, trinkets belonging to the savages of the north and to the Chinese, which are made of ivory or yellow amber, or of coral mounted with gold, silver, porcelain-clay, kr Ark's of Siam, and Turkish rings, which are kind of pendants, Indian curiosities of silver, and the gildings which the Turks and Persians use in smoking tobacco and aloe.

The drawers under this shelf contain a collection of medals, china ink, lachrymatory phials, and the most beautiful engraved stones of Europe, or an impression of them in wax or sulphur, counters, cameos, antiquities, talismans, ancient weights and measures, idols, urns, lamps, instruments of sacrifice, and false jewels.

A glance at the whole, the embasures of the windows must be furnished with pictures of stones in connected pieces. Here likewise, as well as in the embasures and pannels of the door, may be put tubes hermetically sealed, containing rare reptiles preferred in proper liquors.

The reader will by this time have some idea of the prodigious extent of the science of natural history; it is extensive is it, indeed, that the longest life is far from being sufficient to enable us to acquire a perfect knowledge of it: it is important beyond dispute, because its business is with the works of God. In all the articles connected with the present, as forming particular parts of it, and to which we refer, we have made great use of the works of the celebrated Linnaeus, who is well known arranged the three kingdoms into regular systems, of which botany is the most complete. The world in general seems to have been most satisfied with the animal kingdom: he himself, in the course of a variety of editions, made many important alterations. Some men of considerable note, for example Buffon, have written on this subject without any regard to systematic arrangement. Dr. Berkenhout's work on this part of science are very useful; in a particular manner, because he translates Latin names, &c. Bonn's new edition of his Natural History, in 19 vols. octavo, a work of considerable importance, was published in 1791.

The most complete system, however, of natural history which has been yet given to the public, is undoubtedly that of Linnaeus, in his Systema Naturæ, of which a new and improved edition is actually publishing by — Gmelin. A short view of this elaborate work will, we presume, not be unacceptable to the reader, as it will present him, in a very small compass, an abstract of whatever is at present known in the six first classes of natural history.

**Class I. Mammalia.**

Natural Philosophy, is commonly defined to be that art or science which considers the powers and properties of natural bodies, and their mutual actions on one another. The province of moral philosophy is the mind of man; its inquiries and researches are into the nature of virtue, the causes and effects of vice, to propose remedies for it, and to point out the mode of attaining happiness, which only can be the result of virtuous conduct. The Naturalist, on the contrary, has nothing to do with spirit; his business is solely about body or matter; and he ought to have a solid and accurate knowledge of all material substances, together with their affections and properties; and, if possible, he is to investigate the reasons of such and such appearances.—Indeed, the first and principal part of this science is to collect all the manifold and sensible appearances of things, and reduce them into a body of natural history. Philosophy, it has often been said, and it is even now very generally thought, to mean an inquiry into all the causes of things; but experience informs us, that though we are acquainted with a good number of effects, we can trace but few of their causes; so that philosophy itself will really be found to be in general but a collection of facts. Still, however, it differs from natural history in its appropriated sense; the business of which is only to observe the appearances of natural bodies separately; and from these appearances to clafs them with other bodies: natural philosophy goes farther, and recites the action of two or more bodies of the same or different kinds upon one another; and though it can never investigate nor point out the causes of those effects, whatever they are, yet, from mathematical reasoning combined with experience, it can be demonstrated, that in such circumstances such effects must always take place. There are evidently two ways of making observations on the material world: the first is, when we view things nearly as they happen to turn up, without any design or intervention of our own; in which way, indeed, no great improvements can be expected in the art, because chance having the direction, only exhibits occasional or extemporary properties. The other method is, when, after a thorough acquaintance with bodies, we apply them to other bodies equally known, diligently attending to the result, and observing whether any thing new arises. Such seems to be in general the nature of our article; nor is it our intention to be much more particular at present. We must therefore refer our readers respettively to those parts of the subject, respecting which they will for more satisfaction and minute details. The ancient and modern definitions of the word "philosophy," together with its origin, as well as the manner of philosophizing in former times as well as at present, with the gradual improvement of science, particularly natural, we shall introduce, we think, more properly under the words "philosophy" and "physics." We need only add under the present article, what however is well known, that natural philosophy was till lately divided only into four parts, commonly called the four branches, viz. 1. Mechanics; 2. Hydrostatics; 3. Optics; and 4. Astronomy; and these again are subdivided into various parts. Modern discoveries have added, however, two more parts to the number, viz. magnetism and electricity, whose properties and effects, &c. have been wunderfully unfolded of late years.—It is remarkable, that in the English universities these two latter branches are never taken notice of in lecturing on natural philosophy, the old division being still retained, without any mention of these two important articles. The reason may be, that they are only subject to experiment; and not yet reduced to mathematical reasoning; which is the method of teaching philosophy in one of these celebrated seminaries. Of these branches of this extensive science, it is not our intention to take even a general view in this place. We must

In the new French Encyclopédie par ordre de Matières, the editors promised to give a description of more than 18,000 plants. Dr. Berkenhout, in the last edition of his Synopsis, says, that in Great Britain and Ireland there are about 54 species of the mammalia, 250 of birds, 50 of the amphibia, 600 of insects, 150 of fishes, and 1600 species of plants; but in every class he is probably much within the number.
NATURALIZATION, in the English law, the act of naturalizing an alien, or putting him into the condition of a natural born subject, and investing him with the rights and privileges thereof. But none can be naturalized unless they have received the sacrament within one month before the bringing in of the bill, and taken the oaths of allegiance and supremacy in the presence of the parliament. A person who is naturalized may have lands by descent, as heir at law, as well as obtain them by purchase; but he is disenabled from being a member of the privy council or parliament; or from holding offices, 7 Jac. I. cap. 2. Will. III. cap. 2. All children born out of the king's dominions, whose fathers were or are subjects of this kingdom at the time of their birth, are adjudged to be natural born subjects of this realm, except children of parents attainted of treason, or that in the actual service of a foreign prince at enmity with us, 4 Geo. II. cap. 21. Every foreign seaman, who in time of war serves two years on board an English ship, is ipso facto naturalized, 13 Geo. II. cap. 3. And all foreign Protestants and Jews upon their residing seven years in any of the British colonies, without being absent above two months at a time, or serving two years in a military capacity there, are upon taking the oaths naturalized to all intents and purposes, as if they had been born in this kingdom; and therefore are admissible to all such privileges, and no other as Protestants or Jews born in this kingdom are intituled to. See ALIEN and DESIGNE.

In France, before the Revolution, naturalization was the king's prerogative; in England it is only done by act of parliament. In the former of those places, before their government was overturned, Swift, Savoyards, and Scots, did not require naturalization, being reputed regicides, or natives.

NATURALS, among physicians, whatever naturally belongs to an animal, in opposition to non-naturals. See NON-NATURALS.

NATURE, according to Mr. Boyle, has eight different significations; it being used: 1. For the Author of nature, whom the schoolmen call Natura Naturae, being the same with God. 2. By the nature of a thing, we sometimes mean its essence; that is, the attributes which make it what it is, whether the thing be corporeal or not; as when we attempt to define the nature of a fluid, of a triangle, &c. 3. Sometimes we confound that which a man has by nature with what accrues to him by birth; as when we say, that such a man is noble by nature. 4. Sometimes we take nature for an internal principle of motion; as when we say, that a stone by nature falls to the earth. 5. Sometimes we understand, by nature, the established course of things. 6. Sometimes we take nature for an aggregate of powers belonging to a body, especially a living one, in which sense physicians say, that nature is strong, weak, or spent; or that, in such or such diseases, nature left to herself will perform the cure. 7. Sometimes we use the term nature for the universe, or whole system of the corporeal works of God; as when it is said of a phoenix, or chimera, that there is no such thing in nature.

Sometimes too, and that most commonly, we express by the word nature a kind of semi-deity, or other strange kind of being.

If, says the same philosopher, I were to propose a notion of nature less ambiguous than those already mentioned, and with regard to which many axioms relating to that word may be conveniently understood, I should first distinguish between the universal and the particular nature of things. Universal nature I would define to be the aggregate of the bodies that make up the world in its present state, considered as a principle; by virtue whereof they act and suffer, according to the laws of motion prescribed by the Author of all things. And this makes way for the other subordinate notion; since the particular nature of an individual consists in the general nature applied to a distinct portion of the universe; or, which is the same thing, it is a particular embellishment of the mechanical properties of matter, as figure, motion, &c.

Kingdoms of Nature. See Kingdoms.

Conduct or operations of Nature. See Natural History.

NAVA (anc. geog.) Tacitus; a river of Belgica, which runs north-east into the left or west side of the Rhine. Now the Nahe, rising at the village of Naheweiler, on the borders of the bishopric of Trier, running through the Lower Palatinate, the duchy of Simmeren, by the small town of Beng, into the Rhine.

NAVA, something relating to a ship; whence, Naval Architecture. See Ship-Building.

Naval-Camp, in antiquity, a fortification, consisting of a ditch and parapet on the land side, or a wall built in the form of a semicircle, and extended from one point of the sea to another. This was sometimes defended with towers, and beautified with gates, through which they issued forth to attack their enemies. Homer has left us a remarkable description of the Grecian fortifications of this fort, in the Trojan war, beginning at v. 436, Iliad.

Then, to secure the camp and naval powers,
They rais'd embattled walls with lofty towers:
From space to space were ample gates around,
For pacing chariots; and a trench profound,
Of large extent, and deep in earth below;
Strong piles inclin'd flood adverse to the foe.

Pope's Translat.

Towards the sea, or within it, they fixed great pales of wood, like those in their artificial harbours; before these the vessels of burden were placed in such order, as that they might be instead of a wall, and give protection to those within; in which manner Nicias is reported by Thucydides to have encompassed himself: but this seems only to have been practised when the enemy was thought superior in strength, and raised great apprehensions of danger in them. When their fortifications were thought strong enough to defend them from the assaults of enemies, it was frequent to drag their ships to shore, which the Greeks called XERAXION, the Romans campitum. Around the ships the soldiers pitched their tents, as appears every where in Homer: but this seems only to have been practised in winter, when their enemy's fleet was laid up and could not assail them; or in long sieges, and when they lay in no danger from their enemies by sea;
as in the Trojan war, where the defenders of Troy never once attempted to encounter the Grecians in a sea-fight.

The adjacent places were usually filled with inns and flew well flocked with females, that profited themselves to the mariners, merchants, and artificers of all sorts who flocked thither in great numbers; this, however, appears to have happened only in times of peace.

**NAVARRE.**—See TACTICS (Naval).

**NAVAL Stores,** comprehend all those particulars made use of, not only in the navy, but in every other kind of navigation; as timber and iron for shipping, pitch, tar, hemp, cordage, full-cloth, gunpowder, ordnance, and fire-arms of every fort, ship-chandlery wares, &c.

**Naval Tactics,** the military operations of fleets. See TACTICS (Naval.).

**NAVAN,** a borough, port, and fair town of Ireland, in the county of Meath and province of Leinster; situated about 23 miles north-west of Dublin, on the river Boyne. It consists of two chief streets, which intersect each other at right angles. The Tholsel, or town-house, is a handsome stone building. This place was formerly in great repute, and walled in by Hugh de Lacy. An abbey for regular canons, dedicated to the Virgin Mary, was erected here; but whether antecedent to the end of the 12th century is not certain; about that period, however, it was either founded or re-edified by Joceline de Angulo or Nangle. In the burial-ground are the remains of many ancient tombs, with figures in alto relievo; and the present barric for one troop of horse is built on the site of the abbey. Navan sends two members to parliament; patronage in the Presbyterian family. Here are four fairs held.

**NAVARRE,** a province of Spain, part of the ancient kingdom of Navarre, erected soon after the invasion of the Moors; and is otherwise called Upper Navarre, to distinguish it from Lower Navarre belonging to the French. It is bounded on the south and east by Arragon, on the north by the Pyrenees, and on the west by Old Castile and Biscay; extending from south to north about 80 miles, and from east to west about 75. It abounds in sheep and cattle; game of all kinds, as boars, flags, and roebucks; and in wild-fowl, horses, and honey; yielding also some grain, wine, oil, and a variety of minerals, medicinal waters, and hot baths. Some of the ancient chiefs of this country were called Sobrarbes, from the custom, as it is supposed which prevailed among some of those free nations of chafing and swearing their princes under some particular tree. The name of the province is supposed to be a contraction of Navia Errata, signifying, in the language of the Viscanes, its ancient inhabitants, "a land of valleys."—For the particulars of its history, see the article Spain.

**NAVARRE (Peter),** an officer of eminence in the 16th century, and particularly celebrated for his dexterity in the direction of springing of mines. He was a native of Biscay, and of low extraction. According to Paul Jove, who affirms that he had an account of the matter from his own mouth, he was first a laborer; but being disguised with that employment, he fought his fortune in Italy, when poverty compelled him to become footman to the cardinal of Arragon. He afterwards relieved himself a folder in the Housline army; and having served there for some time, went to sea again, and distinguished himself by his courage. The reputation of his valor having reached the ears of Gonfulvo de Cordova, this general employed him in the war against Naples, and raised him to the rank of a captain. Having contributed greatly to the taking of that city by very opportunely springing a mine, the emperor rewarded him for this signal service with the cardinal of Alvieta, situated in that kingdom, and gave him the title of count of Navarre. Having the command of a naval expedition against the Moors in Africa, he was at first very successful, and took possession of Oran, Tripoli, and some other places; but being afterwards shipwrecked on the island of Gerbes, the great heat and the Moorish cavalry destroyed a part of his army. Our hero was equally unfortunate in Italy: He was made prisoner at the famous battle of Ravenna, in 1512, and languished in France for the space of two years. When finding that the king of Spain, who had been prejudiced against him by his couriers, would do nothing towards his ransom, he went into the service of Francis I who gave him the command of twenty companies of infantry, consisting of Gafoons, Biscayans, and the inhabitants of the Pyrenean mountains. He distinguished himself in several successful expeditions, until the year 1522, when having been sent to the relief of the Geneves, he was taken by the Imperialists. They conducted him to Naples, where he remained a prisoner for three years in the castle of Oeuf. From this confinement he was released by the treaty of Madrid, and afterwards fought at the siege of Naples under Ludovic in 1528; but being again made prisoner at the unfortunate retreat from Averia, he was conducted a second time to the castle of Oeuf. Here the prince of Orange having, by order of the emperor, caused several persons of the Aragonian faction to be beheaded, our hero would undoubtedly have suffered the same fate, if the governor, seeing his distressed situation, and feeling for the misfortunes of so great a man, had not saved him the flame of this last punishment by allowing him to die a natural death. Others pretend that he was strangled in his bed, having arrived at a very advanced age. Paul Jove and Philip Thomafini have written his life. This last informs us, that he was of a tall size, had a swarthy countenance, black eyes, beard, and hair. A duke of Seffa, in the last century being desirous to honour his memory and that of the marshal de Lautree, caused a monument to be erected to each of them in the church of Sainte-Marie-le-Neuve at Naples, where they had been interred without any funeral honours.

**NAVARRE (furnamed Martin Aspilcutti),** became a monk in the kingdom which bears that name, successively professor of jurisprudence at Toulouse, Salamanca, and Coimbra, was confuted from all quarters as the oracle of law. For a part of his knowledge he was indebted to the schools of Caibors and Toulouse,
in which he had studied. His friend Barthelmi Carewza, a D. minican, and archbishop of Toledo, having been charged with heresy by the court of inquisition at Rome, Navarre set out at the age of 80 years to defend him. Pius V. appointed him a peer of cardinal Francis Aciat, vice-penitentiary. Gregory XIII. never paid his gate without finding for him; and sometimes would converse with him for an hour together on the street: he even deigned to visit him, accompanied by several cardinals. These honours did not render him more haughty. His character became so eminent, that even in his own time the greatest encomium that could be paid to a man of learning was to say that he was a Navarre: this name thus included the idea of erudition, as that of Rofcius formerly marked an accomplished comedian. Azpilcucta was the oracle of the city of Rome, and of the whole Christian world. For the influence which he had acquired, he was indebted not only to his knowledge, but also to his probity and virtue. Faithful to the duties which the church prescribed, his temperance and frugality preferred him a vigorous constitution; and at a very advanced age his genius was equal to the severest study. His savings enabled him to give liberal assistance to the poor. His charities, indeed, were so great, that his mule, it is said, would drop as soon as the perceived a beggar. He died at Rome in 1586, at the age of 92. His works were collected and printed in 6 vols folio at Lyons in 1597, and at Venice in 1602. They display more learning than judgement, and are now very seldom consulted. Navarre was uncle by the mother's side to St Francis of Sales. See Sales.

NAUCRATES (John), defended of a noble family of Suabia, was professor of the university of that city. His original name was Vergy; but this name, which in German signifies "sailor," he changed into Nauclerus, a word of the same signification in Greek. He was alive in 1501. We have from him a Latin Chronicle from Adam to the year 1500, of which Basilio wrote a continuation down to 1514, and Surius to 1564. It possesses greater accuracy than any historical compilation which had appeared prior to his time; but still it is only a compilation. It is chiefly valued for what regards the occurrences of the 15th century. It was printed at Cologne in folio in 1564 and 1579.

NAUCRARI, among the Athenians, was the name given to the chief magistrates of the city, "boroughs or townships," called Neuropolis, because each was obliged, besides two horsemen, to furnish out one ship for the public service.

NAUCRATES, a Greek poet, who was employed by Artemia to write a panegyric upon Mauelous. An orator who endeavoured to alienate the cities of Lycia from the interest of Brutus.

NAUCRATIS, a city of Egypt on the left side of the Canopic mouth of the Nile. It was celebrated for its commerce, and no ship was permitted to land at any other place, but was obliged to sail directly to the city there to deposit its cargo. It gave birth to Athenaeus.

NAUCRATITES Nomos (anc. geog.), Pliny; Vol. XIL

a division of the Delta, so called from the town Naukratis; though Ptolemy comprises it under the Nomos Saites.

NAUCYDES, a statuary who lived about four centuries before the Christian era.

NAUDE (Gabriel), descended of a respectable family, and born at Paris, February 12th, 1600. His parents observing his fondness for reading and inclination to letters, resolved to breed him in that way; and accordingly sent him to a religious community, to learn the first rudiments of grammar and the principles of Christianity. Thence he was removed to the university; where he applied himself with great success to classical learning; and having learned philosophy, was created master of arts very young. As soon as he had finished his course in philosophy, he remained some time at a fland what profession to choose, being advised by his friends to divinity; but his inclination being more turned to physic, he fixed at length upon that faculty. However, this choice did not prevent him from indulging his genius in other branches of learning: in reality, the plan of his studies was very extensive, suited to his comprehensive talents and indefatigable industry: and he soon distinguished himself therein so much, that Henry de Meieres, president a mortier, hearing his character, made him keeper of his library, and took him into his family. Naude was the more pleased with this post, as it gave him an opportunity of gratifying his bookish taste in general, and at the same time furnished him both with means and leisure to improve himself as he could with, in the science which he had embraced in particular. He quitted it in 1625, in order to go to Padua to perfect himself therein: but he did not continue long in that university, the death of his father and his domestic affairs calling him back to Paris before the expiration of the year.

In 1628 the faculty of physic appointed him to make the customary discourse on the reception of licentiates; which performance entirely answered their expectations from him, and was made public. In 1631, Cardinal Bagno made him his librarian and Latin secretary, and carried him with him to Rome in the spring of that year. Naude continued in this service till the death of the cardinal, which happened July 24, 1641; and in the interim made an excursion to Padua, to take his doctor of phyllic's degree, in order to support with a better grace the quality with which he had been honoured by Louis XIII. who had made him his physician. The ceremony of this appointment was performed March 25, 1633, and we have the speech he pronounced on the occasion. After the death of his patron, he had thoughts of returning to France; but was detained in Italy by several advantageous offers made to him by persons of consideration in that country. Among these he preferred those of Cardinal Barberini, and closed with his eminence. However, as soon as Cardinal Richelieu sent for him to be his librarian, he immediately returned to Paris; but he happened not to be long in the service of the prime minister, if it be true that he arrived at Paris in March 1642, since Cardinal Richelieu died in December following; notwithstanding, he succeeded to the like post under Mazarine, for whom he

4Q formed
formed a most rich library, which he raised from the first volume in the space of seven years to the number of 40,000.

His design was nearly completed before the Cardinal gave him two small benefices, a canonry of Verdun and the priory of Artigue in the Limousin; and we know how much this ungenerosity affected him, from a letter of Patin to Charles Spon, dated March 22, 1648, where he writes thus of our librarian: "I have seen one thing in him which I am very sorry for; especially as I have known him along lightherto at a great distance from such a disposition: it is, that he begins to complain of his fortune, and of his master's avarice, from whom he had never received any more than 1200 livres a year in benefices; not forbearing to declare, that his life was sacrificed for too small a matter. I think (continues Patin) what grieves him is, the apprehension of dying before he has raised something for his brothers and his nephews, of whom he has a great number. However that be, Naude had the grief to see this library, which he had collected with so much pains and care, totally disfigured. Upon the disgrace of Mazarine it was sold: Patin, in a letter of March 5, 1651, observes, that Naude had bought all the books in physic for 3500 livres. Christinna queen of Sweden, who sent herseft to draw into her dominions all the literati of Europe, procured a proposal to be made to Naude of being her library keeper: and as he was then out of all employ, he accepted the proposal, and went to Cop. But he soon grew out of humour with his residence in Sweden: the manners of the people, so very different from his, gave him great disgust; and seeing France become more quiet than it had been: he resolved to return. Accordingly he quitted Sweden loaded with presents from the queen, and several perfons of distinction; but the fatigue of the journey threw him into a fever, which obliged him to flop at Abbeville; and he died there July 29, 1653.

As to his character, he was very prudent and regular in his conduif, sober, never drinking any thing but water. Study was his principal occupation, and he was indeed a true Helesto librorum: so that he understood them perfectly well. He spoke his mind with great freedom, and that freedom sometimes showed itself upon religious subjects, in such a manner as might have occasioned some disadvantageous thoughts of him; but the Christian sentiments in which he died left room to believe that his heart was never corrupted, and had no share in the free expressions which sometimes escaped from him; especially in the philosophical raillery which passed sometimes between him, Guy Patin, and Gaffendi. He wrote a great number of books, a catalogue of which may be seen in Niceron's Memoires, tom. ix. Voltaire says, that "of all his books, the Apologie des grands Hommes et cceurs de Magie is almost the only one which continues to be read."

NAVE, in architecture, the body of a church, where the people are disposed, reaching from the baluster, or rail of the door, to the chief choir. Some derive the word from the Greek &gamma; &alpha; τεμπλον, and others from &alph; &upsilon; a ship," by reason the vault or roof of a church bears some resemblance to a ship.

NAVEL, in anatomy, the centre of the lower part of the abdomen; being that part where the umbilical vessels passed out of the placenta of the mother. See ANATOMY, p. 725.

NAVEL-Wort in botany. See COXYLEDON.

NAVEW, in botany. See BRASSICA, of which it is a species.

NAVIGATION.

IS the art of conducting or carrying a ship from one port to another.

HISTORY.

The poets refer the invention of the art of navigation to Neptune, some to Bacchus, others to Hercules, others to Jason, and others to Janus, who is said to have made the first ship. Historians ascribe it to the Egyptians, the Phoenicians, Tyrians, and the ancient inhabitants of Britain. Some will have it, the first hint was taken from the flight of the kite; others, as Oppian, De pfeibulis, lib. 1.) from the fish called nau­tilus others ascribe it to accident. Scripture refers the origin of so useful an invention to God himself, who gave the first specimen thereof in the ark built by Noah under his direction. For the raillery the good man underwent on account of his enterprise shows evidently enough the world was then ignorant of any thing like navigation, and that they even thought it impossible. However, profane history represents the Phoenicians, especially those of their capital Tyre, as the first navigators; being urged to seek a foreign commerce by the narrowness and poverty of a slip of ground they possessed along the coasts; as well as by the convenience of two or three good ports, and by their natural genius to traffic. Accordingly, Lebanon, and the other neighbouring mountains, furnishing them with excellent wood for ship-building, in a short time they were masters of a numerous fleet; and constantly hazarding new navigations, and setting new trades, they soon arrived at an incredible pitch of opulence and populousness: insomuch as to be in a condition to send out colonies, the principal of which was that of Carthage; which keeping up their Phoenician spirit of commerce, in time not only equalled Tyre itself, but vastly surpassed it; sending its merchant-fleets through Hercules's pillars, now the straits of Gibraltar, along the western coasts of Africa and Europe; and even, if we believe some authors, to America itself.

Tyre, whose immense riches and power are represented in such lofty terms both in sacred and profane authors, being destroyed by Alexander the Great, its navigation and commerce were transferred by the conqueror to Alexandria, a new city, admirably fituated for those purposes; proposed for the capital of the empire of Asia, which Alexander then meditated. And
And thus arose the navigation of the Egyptians; which was afterwards so cultivated by the Phcenicians, that Tyre and Carthage were quite forgotten.

Egypt being reduced into a Roman province after the battle of Actium, its trade and navigation fell into the hands of Augustus; in whose time Alexandria was only inferior to Rome: and the magnificence of the capital of the world were wholly supplied with merchandizes from the capital of Egypt.

At length, Alexandria itself underwent the fate of Tyre and Carthage; being surprized by the Saracens, who, in spite of the emperor Heracleus, overpassed the northern coasts of Africa, &c. whence the merchants being driven, Alexandria has ever since been in a languishing state, though it still has a considerable part of the commerce of the Christian merchants trading to the Levant.

The fall of Rome and its empire drew all with it not only that of learning and the polite arts, but that of navigation; the barbarians, into whose hands it fell, contenting themselves with the spoils of the industry of their predecessors.

But no sooner were the more brave among those nations well settled in their new provinces; some in Gaul, as the Franks; others in Spain, as the Goths; and others in Italy, as the Lombards; but they began to learn the advantages of navigation and commerce, and the methods of managing them, from the people they subdued; and this with so much success, that in a little time some of them became able to give new lessons, and set on foot new institutions for its advantage. Thus it is to the Lombards we usually ascribe the invention and use of banks, book-keeping, exchanges, rechanges, &c.

It does not appear which of the European people, after the settlement of their new masters, first betook themselves to navigation and commerce.—Some think it began with the French; though the Italians seem to have the juiciest title to it; and are accordingly ordinarily looked on as the forerunners thereof, as well as of the polite arts, which had been banished together from the time the empire was torn asunder. It is the people of Italy then, and particularly those of Venice and Genoa, who have the glory of this invention; and it is to their advantageous situation for navigation, that they in great measure owe their glory. In the bottom of the Adriatic were a great number of marshy islands, onely separated by narrow channels, but those well formed, and almost inaccessible, the residence of some fishermen, who here supported themselves by a little trade of fish and salt, which they found in some of these islands. Thither the Veneti, a people inhabiting that part of Italy along the coasts of the Gulf, retired, when Alaric king of the Goths, and afterwards Attila king of the Huns, ravaged Italy.

These new settlers, little imagining that this was to be their fixed residence, did not think of compositing any body politic; but each of the 73 islands of this little Archipelago continued a long time under its several masters; each making a distinct commonwealth. When their commerce was become considerable enough to give jealousy to their neighbours, they began to think of uniting into a body. And it was this union first begun in the sixth century, but not completed till the eighth, that laid the sure foundation of the future grandeur of the state of Venice. From the time of this union, their fleets of merchantmen were sent to all the parts of the Mediterranean; and at last to those of Egypt, particularly Cairo, a new city, built by the Saracen princes on the eastern banks of the Nile, where they traded for their spices and other productions of the Indies. Thus they flourished, increased their commerce, their navigation, and their conquests on the terra firma, till the league of Cambrai in 1509, when a number of jealous princes joined to their ruin; which was the more easily effected by the diminution of their East India commerce, of which the Portuguese had got one part and the French another. Genoa, which had applied itself to navigation at the same time with Venice, and that with equal success, was a long time its dangerous rival, disputed with it the empire of the sea, and shared with it the trade of Egypt and other parts both of the east and west.

Jealousy soon began to break out; and the two republics coming to blows, there was almost continual war for three centuries before the superiority was ascertained; when, towards the end of the 14th century, the battle of Chioza ended the strife; the Genoese, who till then had usually the advantage, having now loft all; and the Venetians, almost become desperate, at one happy blow, beyond all expectation, secured to themselves the empire of the sea, and superiority in commerce.

About the same time that navigation was retrieved in the southern parts of Europe, a new society of merchants was formed in the north, which not only carried commerce to the greatest perfection; it was capable of till the discovery of the East and West Indies, but also formed a new scheme of laws for the regulation thereof, which still obtains under the names of juris et Customs of the Sea. This society is that famous league of the Hanse-towns, commonly supposed to have begun about the year 1164. See Hanse.

For the modern state of navigation in England, Holland, France, Spain, Portugal, &c. See Commerce, Company, &c.

We shall only add, that, in examining the reasons of commerce's falling successively from the Venetians, Genoese and Hanse towns, to the Portuguese and Spaniards, and from these again to the English and Dutch, it may be established as a maxim, that the relation between commerce and navigation, or, if we may be allowed to say it, their union is so intimate, that the fall of the one inevitably draws after it that of the other; and that they will always either flourish or dwindle together. Hence so many laws, ordinances, statutes, &c. for its regulation; and hence particularly that celebrated act of navigation, which an eminent foreign author calls the poladim or tat for deely of the commerce of England; which is the standing rule not only of the British among themselves, but also of other nations with whom they traffic.

The art of navigation hath been exceedingly improved in modern times, both with regard to the form of the vessels themselves, and with regard to the methods of working them. The use of towers is now entirely superceded by the improvements made in the formation of the sails, rigging, &c. by which the
the ships can not only fail much faster than formerly, but can tack in any direction with the greatest facility. It is also very probable that the ancients were neither so well skilled in finding the latitudes, nor in steering their vessels in places of difficult navigation, as the moderns have over the ancients are from the mariner’s compass, by which they are enabled to find their way with as great facility in the midst of an immeasurable ocean, as the ancients could have done by creeping along the coast, and never going out of sight of land. Some people indeed contend, that this is no new invention, but the ancients were acquainted with it. They say, that it was impossible for Solomon to have sent ships to Ophir, Tarshish, and Parvaim, which last they will have to be *Perú,* without this useful instrument. They infer, that it was impossible for the ancients to be acquainted with the attractive virtue of the magnet, and to be ignorant of its polarity. Nay, they affirm, that this property of the magnet is plainly mentioned in the book of Job, when the loadstone is mentioned by the name of *topas,* or the stone that turns itself. But it is certain, that the Romans, who conquered the Juedes, were ignorant of this instrument, and it is very improbable, that such an useful invention, if once it had been commonly known to any nation, would have been forgot, or perfectly concealed from such a prudent people as the Romans, who were so much interested in the discovery of it.

Among those who do agree that the mariner’s compass is a modern invention, it hath been much disputed who was the inventor. Some give the honour of it to Flavio Gioia of Amalfi in Campania*, who lived about the beginning of the 14th century; while others say that it came from the east, and was earlier known in Europe. But, at whatever time it was invented, it is certain, that the mariner’s compass was not commonly used in navigation before the year 1420. In that year the science was considerably improved under the auspices of Henry duke of Viseo, brother to the king of Portugal. In the year 1485, Roderic and Joseph, physicians to John II. king of Portugal, together with one Martin de Bohemia, a Portuguese, native of the island of Faro, and scholar to Regiomontanus, calculated tables of the sun’s declination for the use of sailors, and recommended the astrolabe for taking observations at sea. Of the instructions of Martin, the celebrated Christopher Columbus is said to have availed himself, and to have improved the Spaniards in the knowledge of the art; for the further progress of which a lecture was afterwards founded at Seville by the emperor Charles V.

The discovery of the variation is claimed by Columbus, and by Sebastian Cabot. The former certainly did observe this variation without having heard of it from any other person, on the 14th of September 1492, and it is very probable that Cabot might do the same. At that time it was found that there was no variation at the Azores, where some geographers have thought proper to place the first meridian; though it hath since been observed that the variation alters in time. The use of the crofs-staff now began to be introduced among sailors. This ancient instrument is described by John Werner of Nuremberg, in his annotations on the first book of Ptolemy’s Geography, printed in 1514. He recommends it for observing the distance between the moon and some star, in order thence to determine the longitude.

At this time the art of navigation was very imperfect on account of the inaccuracies of the plane chart, which was the only one then known, and which, by its great errors, must have greatly misled the mariner, especially in voyages far distant from the equator. Its precepts were probably at first only set down on the sea-charts, as is the custom at this day: but at length there were two Spanish treatises published in 1545; one by Pedro de Medina; the other by Martin Cortes, which contained a complete system of the art, as far as it was then known. These seem to have been the earliest writers who fully handled the art; for Medina, in his dedication to Philip prince of Spain, laments that multitudes of ships daily perished at sea, because there were neither teachers of the art nor books by which it might be learned; and Cortes, in his dedication, boasts to the emperor, that he was the first who had reduced navigation into a compendium, valuing himself much on what he had performed. Medina defended the plane chart; but he was opposed by Cortes, who showed its errors, and endeavoured to account for the variation of the compass, by supposing the needle to be influenced by the magnetic pole (which he called the *point attracteur*) different from that of the world; which notion hath been farther prosecuted by others. Medina’s book was soon translated into Italian, French, and Flemish, and served for a long time as a guide to foreign navigators. However, Cortes was the favourite author of the English nation, and was translated in 1561; while Medina’s work was entirely neglected, though translated also within a short time of the other. At that time the system of navigation consisted of the following particulars, and others similar: an account of the Ptolemaic hypothesis, and the circles of the sphere; of the roundness of the earth, the latitudes, climates, &c, and eclipses of the luminaries: a calendar; the method of finding the prime, equinoctial, moon’s age, and tides; a description of the compass, an account of its variation, for the discovering of which Cortes said an instrument might easily be contrived; tables of the sun’s declination, calculated for the equinoctial, in order to find the latitude from his meridian altitude; directions to find the sun by certain stars; of the course of the sun and moon; the length of the days; time and its divisions; the method of finding the hour of the day and night; and lastly, a description of the sea-chart, on which to discover where the ship is, they made use of a small table, that showed, upon an alteration of one degree of the latitude, how many leagues were run in each thumb, together with the departure from the meridian. Besides, some instruments were described, especially by Cortes; such as one to find the place and declination of the sun, with the days, and place of the moon; certain dials, the astrolabe, and crofs-staff; with a complex machine to discover the hour and latitude at once.

About the same time were made proposals for finding the longitude by observations of the moon.—In 1530, Gemma Frisius advised the keeping of the time by means of small clocks or watches, then, as he says, newly invented. He also contrived a new sort of

---

*See Mariner’s Compass.*
of cross-staff and an instrument called the nautical quadrant; which last was much praised by William Cunningham, in his Astronomical Glass, printed in the year 1559.

In 1577 Pedro Nuex or Nonius, published a book in the Portuguese language, to explain a difficulty in navigation proposed to him by the commander Don Martin Alphonso de Sua. In this he exposes the errors of the plane chart, and likewise gives the solution of several curious astronomical problems; amongst which is that of determining the latitude from two observations of the sun’s altitude and intermediate azimuth being given. He observed, that though the rhumbs are spiral lines, yet the direct course of a ship will always be in the arch of a great circle, whereby the angle with the meridians will continually change: all that the seaman can here do for the preferring of the original rhumb, is to correct these deviations as soon as they appear sensible. But thus the ship will in reality describe a course without the rhumb-line intended; and therefore his calculations for affigning the latitude, where any rhumb line crosses the several meridians, will be in some measure erroneous. He invented a method of dividing a quadrant by means of concentric circles, which, after being much improved by Dr Halley, is used at present, and is called a nonius.

In 1577, Mr William Bourne published a treatise, in which, by considering the irregularities in the moon’s motion, he shews the errors of the sailors in finding her age by the epact, and also in determining the hour from observing on what point of the compass the sun and moon appeared. He advises, in falling towards the high latitudes, to keep the reckoning by the globe, as the place of the sun chart is most erroneous. He depairs of our ever being able to find the longitude, unless the variation of the compass should be occasioned by some such attractive point, as Cortes had imagined; of which, however, he doubts: but as he had shown how to find the variation at all times, he advises to keep an account of the observations, as useful for finding the place of the ship, which advice was prosecuted at large by Simon Stevin, in a treatise published at Leyden in 1599: the substance of which was the same year printed at London in English by Mr Edward Wright, intituled the Haven finding Art. In this ancient treat also is described the way by which our sailors estimate the rate of a ship in her course, by an instrument called the log. This was so named from the piece of wood or log that floats in the water while the time is reckoned during which the line that is fastened to it is veering out. The author of this contrivance is not known; neither was it taken notice of till 1607, in an East India voyage published by Purchas; but from this time it became famous, and was much taken notice of by almost all writers on navigation in every country: and it still continues to be used as at first, though many attempts have been made to improve it, and contrivances proposed to supply its place; many of which have succeeded in quiet water but proved useless in a stormy sea.

In 1581 Michael Coigne, a native of Antwerp, published a treatise, in which he animadverted on Medina. In this he showed that as the rhumbs are spirals, making endless revolutions about the poles, numerous errors must arise from their being represented by straight lines on the sea-charts; but though he hoped to find a remedy for these errors, he was of opinion that the propositions of Nonius were scarcely practicable, and therefore in a great measure useless. In treating of the sun’s declination, he took notice of the gradual decrease in the obliquity of the ecliptic; he also described the cross-staff with three transverse pieces, as it is at present made, and which he owned to have been then in common use among the sailors. He likewise gave some instruments of his own invention; but all of them are now laid aside, excepting perhaps his nocturnal. He constructed a sea-table to be used by such as sailed beyond the 60th degree of latitude; and at the end of the book is delivered a method of falling on a parallel of latitude by means of a ring dial and a 24 hour-glass. The same year the discovery of the dipping needle was made by Mr Robert Norman * in his publication on that art he maintains in opposition to Cortes, that the variation of the compass was caused by some point on the surface of the earth, and not in the heavens: he also made considerable improvements in the construction of compasses themselves; showing especially the danger of not fixing, on account of the variation, the wire directly under the fleur-de-luce; as compasses made in different countries have it placed differently. To this performance of Norman’s is always prefixed a discourse on the variation of the magnetic needle by Mr William Burrough, in which he shows how to determine the variation in many different ways. He also points out many errors in the practice of navigation at that time, and speaks in very severe terms concerning those who had published upon it.

All this time the Spaniards continued to publish treatises on the art. In 1585 an excellent compendium was published by Roderico Zamorano, which contributed greatly towards the improvement of the art, particularly in the sea charts. Globes of an improved kind, and of a much larger size than those formerly used, were now constructed, and many improvements were made in other instruments; however the plane chart continued still to be followed, though its errors were frequently complained of. Methods of removing these errors had indeed been sought after; and Gerhard Mercator seems to have been the first who found the true method of doing this so as to answer the purposes of seamen. His method was to represent the parallels both of latitude and longitude by parallel straight lines, but gradually to augment the former as they approached the pole. Thus the rhumbs, which otherwise ought to have been curves, were now also extended into straight lines; and thus a straight line drawn between any two places marked upon the chart would make an angle with the meridians, expressing the rhumb leading from the one to the other. But though, in 1569, Mercator published an universal map constructed in this manner, it doth not appear that he was acquainted with the principles on which this proceeded; and it is now generally believed, that the true principles on which the construction of what is called Mercator’s chart depends, were first discovered by an Englishman, Mr Edward Wright.

Mr Wright supposes, but according to the general opinion, without sufficient grounds, that this enlargement of the degrees of latitude was known and mentioned by Ptolemy, and that the same thing had also been spoken of by Cortes. The expressions of Ptolemy...
Imly alluded to, relate indeed to the proportion between the distances of the parallels and meridians; but instead of propoling any gradual enlargement of the parallels of latitude, in a general chart, he speaks only of particular maps; and advises not to confine a system of such maps to one and the fame scale, but to plan them out by a different measure, as occasion might require: only with this precaution, that the degrees of longitude in each should bear some proportion to those of latitude; and this proportion is to be deduced from that which the magnitude of the respective parallels bear to a great circle of the sphere. He adds that in particular maps, if this proportion be observed with regard to the middle parallel, the inconveniences will not be great though the meridians should be straight lines parallel to each other. Here he is laid only to mean, that the maps should in some measure represent the figures of the countries for which they are drawn. In this fefte Mercator, who drew maps for Ptolemy's tables, understood him; thinking it, however, an improvement not to regulate the meridians by one parallel, but by two; one distant from the northern, the other from the southern extremity of the map by a fourth part of the whole depth: by which means, in his maps, though the meridians are straight lines, yet they are generally drawn inclining to each other towards the poles. With regard, to Cortes, he speaks only of the number of degrees of latitude, and not of the extent of them; nay, he gives express directions that they should all be laid down by equal measurement on scale of leagues adapted to the map.

For some time after the appearance of Mercator's map, it was not rightly understood, and it was even thought to be entirely useless, if not detrimental. However, about the year 1592, its utility began to be perceived; and seven years after, Mr Wright printed his famous treatife entitled, The Correftion of certain Errors in Navigation, where he fully explained the reason of extending the length of the parallels of latitude, and the uses of it to navigators. In 1610, a second edition of Mr Wright's book was published with improvements. An excellent method was proposed of determining the magnitude of the earth; at the same time it was judiciously proposed to make our common measures in some proportion to a degree on its surface, that they might not depend on the uncertain length of a barley-corn. Some of his other improvements were, "The Table of latitudes for dividing the meridian computed to minutes;" whereas it had only been divided to every tenth minute. He also published a description of an instrument which he calls the sea-rings; and by which the variation of the compass; altitude of the sun and time of the day, may be determined readily at once in any place, provided the latitude is known. He showed also how to correct the errors arising from the eccentricity of the eye in observing by the cross-feft. He made a total amendment in the table of the declinations and places of the sun and stars from his own observations made with a fix-foot quadrant, in the years 1594, 95, 96, and 97. A sea quadrant to take altitudes by a forward or backward observation; and likewise with a contrivance for the ready finding the latitude by the height of the pole-star, when not upon the meridian. To this edition was subjoined a translation of Zamorano's Compendium above mentioned, in which he corrected some mistakes in the original, adding a large table of the variation of the compass observed in very different parts of the world, to show that it was not occasioned by any magnetic pole. Thefe improvements soon became known abroad. In 1608, a treatife intitled, Hypomnemata Mathematica, was published by Simon Stevin, for the ufe of Prince Maurice. In that part relating to navigation, the author having treated of falling on a great circle, and shewn how to draw the rhumbs on a globe mechanically, sets down Wright's two tables of latitudes and of rhumbs, in order to defcribe these lines more accurately, pretending even to have discovered an error in Wright's table. But all Stevin's objections were fully anfwered by the author himfelf, who showed that they arose from the gross way of calculating made use of by the former. In 1624, the learned Wellebrodus Snellius, professor of mathematics at Leyden, published a treatife of navigation on Wright's plan, but somewhat obscurely; and as he did not particularly mention all the discoveries of Wright, the latter was thought by fome to have taken the hint of all his discoveries from Snellius. But this fuppofition is long ago refuted; and Wright enjoys the honour of those discoveries which is juftly his due.

Mr Wright having shewn how to find the place of the ship on his chart, observed that the fame might be performed more accurately by calculation: but considering, as he says, that the latitudes, and especially, the courses at sea, could not be determined fo precisely, he forbore setting down particular examples; as the mariner may be allowed to solve himself this trouble, and only mark out upon his chart the ship's way, after the manner then usually practifed. However, in 1614, Mr Raile Handfon, among his nautical quaffons subjoined to a translation of Fiducius's trigonometry, solved very difficultly every cafe of navigation by applying arithmetical calculations to Wright's table of latitudes, or of meridional parts, as it was then called. Though the method discovered by Wright for finding the change of longitude by a ship falling on a rhumb is the proper way of performing it, Handfon also proposes two ways of approximation to it without the affiftance of Wright's division of the meridian line. The first was computed by the arithmetical mean between the confines of both latitudes; the other by the fame mean between the secants as an alternative, when Wright's book was not at hand; though this latter is wider from the truth than the first. By the fame calculations also he showed how much each of these compendiums deviates from the truth, and also how widely the computations on the erroneous principles of the plane chart differ from them all. The method, however, commonly ufed by our sailors is commonly called the mid-line-atitude; which, though it errs more than by the arithmetical mean between the two co-lines, is preferred on account of its being less operofe; yet in high latitudes it is more likely to ufe that of the arithmetical mean between the logarithmic co-lines equivalent to the geometrical mean between the co-lines themselves: a method fince proposed by Mr John Baffat. The computation by the middle latitude will always fall short of the true change of longitude; that by the geometrical mean will al-ways
ways exceed; but that by the arithmetical mean falls short in latitudes above 45 degrees, and exceeds in lesser latitudes. However, none of these methods will differ much from the truth when the change of latitude is sufficiently small.

About this time logarithms were invented by John Napier, baron of Merchilton in Scotland, and proved of the utmost service to the art of navigation. From which Mr Edmund Gunter contrived a table of logarithmic lines and tangents to every minute of the quadrant, which he published in 1620. In this work he applied to navigation, and other branches of mathematics, his admirable ruler known by the name of Gunter’s scale; on which are described lines of logarithmic lines, of logarithmic lines and tangents, of meridional parts, &c. He greatly improved the design for the same purposes. He shewed also how to take a back-obseruction by the cross-haft, whereby the error arising from the eccentricity of the eye is avoided. He described likewise another instrument, of his own invention, called the cross bow, for taking altitudes of the sun or stars, with some contrivances for the more ready collecting the latitude from the observation. The discoveries concerning logarithmic lines were carried to France in 1624 by Mr Edmund Wingate, who published two small tracts in that year at Paris. In one of them he taught the use of Gunter’s scale; and in the other, of the tables of artificial lines and tangents, as modelled according to Napier’s last form, erroneously attributed by Wingate to Briggs.

Gunter’s rule was projected into a circular arch by the Reverend Mr William Oughtred in 1623, and its uses fully shown in a pamphlet intituled, The Circum of Navigation, where, in an appendix, are well treated several important points in navigation. It has also been made in the form of a sliding ruler.

The logarithmic tables were first applied to the different cases of sailing by Mr Thomas Addison, in his treatise intituled, Arithmetical navigation, printed in 1625. He also gives two traverse tables, with their uses; the one to quarter points of the compass, the other to degrees. Mr Henry Gellibrand published his discovery of the changes of the variation of the compass, in a small quarto pamphlet, intituled, A discourse mathematical on the variation of the magnetic medal, printed in 1635. This extraordinary phenomenon he found out by comparing the observations made at different times near the same place by Mr Burrough, Mr Gunter, and himself, all persons of great skill and experience in these matters. This discovery was likewise soon known abroad; For Father Athanasius Kircher, in his treatise intituled, Magna, first printed at Rome in 1641, informs us, that he had been told it by Mr John Graves; and then gives a letter of the famous Marinus Merianus, containing a very distinct account of the same.

As altitudes of the sun are taken on shipboard by observing his elevation above the visible horizon, to obtain from thence the sun’s true altitude with corretions, Wright observes it to be necessary that the dip of the visible horizon below the horizontal plane passing through the observer’s eye should be brought into the account, which cannot be calculated without knowing the magnitude of the earth. Hence he was induced to propose different methods for finding this; but complains that the most effectual was out of his power to execute; and therefore contented himself with a rude attempt, in some measure sufficient for his purpose: and the dimensions of the earth deduced by him corresponded very well with the usual divisions of the log-line; however, as he wrote not an express treatise on navigation, but only for the correcting such errors as prevailed in general practice, the log-line did not fall under his notice. Mr Richard Norwood, however, put in execution the method recommended by Mr Wright as the most perfect for measuring the dimensions of the earth, with the true length of the degrees of a great circle upon it; and, in 1635, he actually measured the distance between London and York; from whence, and the summer solstitial altitudes of the sun observed on the meridian at both places, he found a degree on a great circle of the earth to contain 357,156 English feet, equal to 57,300 French fathoms or tortolos: which is very exact, as appears from many measures that have been made since that time. Of all this Mr Norwood gave a full account in his treatise called Th- Seaman’s Practice, published in 1637. He there shews the reason why Snellius had failed in his attempt; he points out also various uses of his discovery, particularly for correcting the gross errors hitherto committed in the divisions of the log-line. But necessary amendments have been little attended to by seamen, whose obstinacy in adhering to established errors has been complained of by the best writers on navigation. This improvement has at length, however, made its way into practice, and few navigators of reputation now make use of the old measure of 42 feet to a knot. In that treatise also Mr Norwood describes his own excellent method of setting down and perfecting a sea-reckoning, by using a traverse table; which method he had followed and taught for many years. He shews also how to rectify the course by the variation of the compass being considered; as also how to discover currents, and to make proper allowance on their account. This treatise, and another on trigonometry, were continually reprinted, as the principal books for learning scientifically the art of navigation. What he had delivered, especially in the latter of them, concerning this subject, was contracted as a manual for sailors, in a very small piece called his Epitome; which useful performance has gone through a great number of editions. No alterations were ever made in the Seaman’s Practice till the 12th edition in 1676, when the following paragraph was inserted in a smaller character: “About the year 1672, Monsieur Picart has published an account in French, concerning the measure of the earth, a breviate whereof may be seen in the Philosophical Transactions, No 112. wherein he concludes one degree to contain 357,184 English feet, nearly agreeing with Mr Norwood’s experiment,” and this advertisement is continued through the subsequent editions as late as the year 1732.

About the year 1645, Mr Bond published in Norwood’s epitome a very great improvement in Wright’s method by a property in his meridian line, whereby its divisions are more scientifically affigned than the author himself was able to effect; which was from this theorem, that these divisions are analogous to the excels of the logarithmic tangents of half the respective latitudes augmented by 45 degrees above the logarithm of the radius.
dius. This he afterwards explained more fully in the
third edition of Gunter's works, printed in 1653; where,
after observing that the logarithmic tangents
from \(45^\circ\) upwards increase in the same manner that
the secants added together do, if every half degree
be accounted as a whole degree of Mercator's meri-
dional line. His rule for computing the meridional
parts belonging to any two latitudes, supposed on
the same side of the equator, is to the following
effect: "Take the logarithmic tangent, rejecting the
radius, of half each latitude, augmented by \(45^\circ\) degrees; di-
vide the difference of those numbers by the logarith-
mic tangent of \(45^\circ\ 30'\), the radius being likewise re-
jected; and the quotient will be the meridional parts
required, expressed in degrees." This rule is the im-
mediate consequence from the general theorem, That
the degrees of latitude bear to one degree (or 60 minutes,
which in Wright's table stands for the meridional
parts of one degree), the same proportion as the loga-
rithmic tangent of half any latitude augmented by \(45^\circ\) degrees,
and the radius neglected, to the like tangent of half a
degree augmented by \(45^\circ\) degrees, with the radius like-
wise rejected. But here was farther wanting the demon-
stration of this general theorem, which was at length
supplied by Mr James Gregory of Aberdeen in his Exer-
citationes Geometricae, printed at London in 1668; and
afterwards more concisely demonstrated, together
with a scientific determination of the divisor, by Dr
Halley in the Philosophical Transactions for 1695,
N° 219, from the consideration of the spirals into
which the rhumbs are transformed in the stereographic
projection of the sphere upon the plane of the equi-
atorial; and which is rendered still more simple by
Mr Roger Cotes, in his Logometria, first published in
the Philosophical Transactions for 1714, N° 488. It
is moreover added in Gunter's book, that if \(\phi\) be the
degree of this division, which does not sensibly differ from
the logarithmic tangent of \(45^\circ\ 1'\ 30''\) (with the radius sub-
tracted from it), be used, the quotient will exhibit the
meridional parts expressed in leagues; and this is the
divisor set down in Norwood's Epitome. After the
same manner the meridional parts will be found in
minutes, if the like logarithmic tangent of \(45^\circ\ 1'\ 30''\),
 diminished by the radius, be taken; that is, the num-er used by others being 12633, when the logarithmic
tables consist of eight places of figures besides the
index.

In an edition of the Seamen's Kalendar, Mr Bond
declared, that he had discovered the longitudes by ha-
olding found out the true theory of the magnetic varia-
tion; and to g in credit to his assertion, he foresaw,
that at London in 1657 there would be no variation of
the compass, and from that time it would gradually
increase the other way; which happened accordingly.

Again, in the Philosophical Transactions for 1668,
N° 40, he published a table of the variation for 40
years to come. Thus he acquired such reputation, that
his treatise, intitled, The Longitude Found, was in 1676
published by the special command of Charles II. and
approved by many celebrated mathematicians. It was
not long, however, before it met with opposition; and
in 1678 another treatise, intitled, The Longitude not
Found, made its appearance; and as Mr Bond's hy-
pebthesis did not in any manner answer his author's fan-
guine expectations, the affair was undertaken by Dr
Halley. The result of his speculation was, that the
magnetic needle is influenced by four poles; but this
wonderful phenomenon seems hitherto to have eluded
all our researches. In 1700, however, Dr Halley pub-
lished a general map, with curve lines expressing the
paths where the magnetic needle had the same varia-
tion; which was received with universal applause. But
as the positions of these curves vary from time to time,
they should frequently be corrected by skillful per sons;
as was done in 1744 and 1756, by Mr William
Mountaine, and Mr James Dodson, F. R. S. In the Phi-
losophical Transactions for 1690, Dr Halley also gave
a dissertation on the monsoons; containing many very
useful observations for such as fall to places subject
to these winds.

After the true principles of the art were settled by
Wright, Bond, and Norwood, the authors on naviga-
tion became so numerous, that it would be impossible
to enumerate them. New improvements were daily
made, and every thing relative to it was furthered with
an accuracy not only unknown to former ages, but
which would have been reckoned utterly impossible.
The earth being found to be a spheroid, and not a
perfect sphere, with the shortest diameter passing thro'
the poles, a tract was published in 1741 by the Rev.
Doctor Patrick Murdoch, wherein he accommodated
Wright's failing to such a figure; and Mr Colin Mac-
laurin, the same year, in the Philosophical Transac-
tions, N° 461, gave a rule for determining the meri-
dional parts of a spheroid; which speculation is farther
treated of in his book of Fluxions, printed at Edin-
burgh in 1742.

Among the later discoveries in navigation, that of
finding the longitude both by lunar observations and
by time keepers is the principal. It is owing chiefly
to the rewards offered by the British parliament that
this has attained the present degree of perfection. We
are indebted to Dr Stukelyne for putting the first
of these methods in practice, and for other important
improvements in navigation. The time keepers,
constructed by Harrison for this express purpose, were
found to answer so well, that he obtained the parlia-
mentary reward.

**The Theory of Navigation.**

The motion of a ship in the water is well known
to depend upon the action of the wind upon its
sails, regulated by the direction of the helm. As the
water is a resisting medium, and the bulk of the ship
very considerable, it thence follows, that there is al-
ways a great resistance on her fore-part; and when
this resistance becomes sufficient to balance the moving
force of the wind upon the sails, the ship attains her
utmost degree of velocity, and her motion is no longer
accelerated. This velocity is different according to
the different strength of the wind; but the stronger
the wind, the greater resistance is made to the ship's
passage through the water: and hence, though the
wind should blow ever so strongly, there is also a limit
to
N A V I G A T I O N.

in the same place. In proportion to the swiftness of
the ship, then the lee-way will be the less: but if the
wind is very strong, the velocity of the ship bears but
a small proportion to that of the current of air; and
the same effects must follow as though the ship moved
slowly, and the wind was gentle; that is, the ship
must make a great deal of lee-way.—The same thing
happens when the sea rife high, whether the wind is
strong or not; for then the whole water of the ocean,
as far as the swell reaches, hath acquired a motion in
a certain direction, and that to a very considerable
depth. The mountainous waves will not fail to carry
the ship very much out of her course; and this devia-
tion will certainly be according to their velocity and
magnitude. In all cases of a rough sea, therefore, a
great deal of lee way is made.—Another circumstance
also makes a variation in the quantity of the lee-way;
namely, the lightness or heaviness of the ship; it being
evident, that when the ship sinks deep in the water, a
much greater quantity of that element is to be put in
motion before she can make any lee-way, than when
she swims on the surface. As therefore it is impossible
to calculate all these things with mathematical exact-
ness, it is plain that the real course of a ship is exceed-
ingly difficult to be found, and frequent errors must
be made, which only can be corrected by celestial ob-
servations.

In many places of the ocean there are currents, or
places where the water, instead of remaining at rest,
rises with a very considerable velocity for a great way
in some particular direction, and which will certainly
carry the ship greatly out of her course. This occa-
sions an error of the same nature with the lee-way;
and therefore, whenever a current is perceived, its
velocity ought to be determined, and the proper al-
lowances made.

Another source of error in reckoning the course of
a ship proceeds from the variation of the compas.
There are a few parts of the world where the needle
points exactly north; and in those where the variation
is known, it is subject to very considerable alterations.
By these means the course of the ship is mistaken; for
as the sailors have no other standard to direct them
than the compass, if the needle, instead of pointing
due north, should point northeast, a pregiuous error
would be occasioned during the course of the voyage,
and the ship would not come near the port to which
she was bound. To avoid errors of this kind the only
method is, to observe the fan's amplitude and azimuth
as frequently as possible, by which the variation of
the compass will be perceived, and the proper allow-
ances can then be made for errors in the course which
this may have occasioned.

Errors will arise in the reckoning of a ship, espe-
cially when she fails in high latitudes, from the sphero-
idal figure of the earth; for as the polar diameter
of our globe is found to be considerably shorter than
the equatorial one, it thence follows, that the further
we remove from the equator, the longer are the degrees
of latitude. Of consequence, if a navigator aligns
any certain number of miles for the length of a degree
of latitude near the equator, he must vary that mea-
ture as he approaches towards the poles, otherwise
he will imagine that he hath not sailed so far as he
actually hath done. It would therefore be necessary

BOOK I. Containing the various Methods of Sailing.

INTRODUCTION.

The art of navigation depends upon astronomical and mathematical principles. The places of the sun and fixed stars are deduced from observation and calculation, and arranged in tables, the use of which is absolutely necessary in reducing observations taken at sea, for the purpose of ascertaining the latitude and longitude of the ship, and the variation of the compass. The problems in the various sailings are resolved either by trigonometrical calculation, or by tables or rules formed by the assistance of trigonometry. By mathematics, the necessary tables are constructed, and rules investigated for performing the more difficult parts of navigation. For these several branches of science, and for logarithmic tables, the reader is referred to the respective articles in this work. A few tables are given at the end of this article; but as the other tables necessary for the practice of navigation are to be found in almost every treatise on that subject, it therefore seems unnecessary to insert them in this place.

CHAP. I. Preliminary Principles.

SECT. I. Of the Latitude and Longitude of a Place.

The situation of a place on the surface of the earth is estimated by its distance from two imaginary lines intersecting each other at right angles: the one of these is called the equator, and the other the first meridian. The situation of the equator is fixed, but that of the first meridian is arbitrary, and therefore different nations assume different first meridians. In Britain, that which passes through the royal observatory at Greenwich is esteemed to be the first meridian.

The equator divides the earth into two equal parts, called the northern and southern hemispheres; and the latitude of a place is its distance from the equator, reckoned on a meridian in degrees and parts of a degree; and is either north or south, according as it is in the northern or southern hemisphere.

The first meridian being commenced round the globe, divides it into two equal parts, called the eastern and western hemispheres; and the longitude of a place is that portion of the equator contained between the first meridian and the meridian of the given place, and is either east or west; according as it is in the eastern or western hemisphere, respectively to the first meridian.

PROB. I. The latitudes of two places being given, to find the difference of latitude.

RULE. Subtract the less latitude from the greater, if the latitudes be of the same name, but add them if of contrary; and the remainder or sum will be the difference of latitude.

EXAMPLE I. Required the difference of Latitude between the Lizard, in latitude 49° 57' N. and Cape St Vincent, in latitude 37° 2' N.

<table>
<thead>
<tr>
<th>Latitude of the Lizard</th>
<th>49° 57' N.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Latitude of Cape St Vincent</td>
<td>37° 2' N.</td>
</tr>
</tbody>
</table>

Difference of latitude 12° 35' = 775 miles.

EXAMPLE II. What is the difference of latitude between Funkal, in latitude 32° 38' N. and the Cape of Good Hope, in latitude 34° 29' S?

Latitude
NAVIGATION

Difference of latitude 67° 7' = 4027 miles.

Example I. A ship from latitude 90° 22' N. failed due north 560 miles—Required the latitude come to?

Example II. A ship from latitude 7° 19' N. failed 854 miles south—Required the latitude come to?

Example III. The longitudes of two places being given, to find their difference of longitude.

Example I. Required the difference of longitude between Edinburgh and New York, their longitude being 3° 14' W. and 74° 10' W. respectively?

Example II. What is the difference of longitude between Mafkelyne's Isles, in longitude 167° 59' E. and Olindo, in longitude 35° 5' W.?

Example III. Required the time of new moon at Saloquine in May 1793?

Example IV. What is the time of the last quarter of the moon at Resolution Bay in October 1793?

Table VII, which applied to the time of high water, indicates the equation answering to this difference.

Find the equation answering to this difference in

Table VII, which applied to the time of high water.
Tides.

Now take the interval between the reduced time of the phase and the approximate time of high water; and the corresponding equation, which applied as before to the nautical time of high water, will give the time of the afternoon high water.

If the time of the morning high water is required, increase the last interval by 12 hours, if the given day falls before the phase, or diminish it by 12 hours when after that phase; and the equation to this time, applied to the nautical time, gives the morning time of high water.

Example I. Required the morning and afternoon times of high water at Leith, 11th December 1793.

Nearest phase to 11th Dec. is 1st quart. 9d 20h 29'.

Longitude of Leith in time = o 0 13

Time at Leith of 1st quarter = 9 20 16

Given day = 11 0 0

Difference = 1 3 44

Time of H. W. at Leith pier on fyz. = 0 2 20

Equat. from Tab. to 1st 3h 44' = +0 6 32

Approximate time of high water = 11 8 52

Reduced time of 1st quarter = 9 20 16

Interval = 1 12 36

Time of high water at Leith = 0 2 20

Equat. from the Tab. to 1st 12h 36' = 0 7 0

Time of high water at Leith = 9 20 P.M.

Time of H. W. at Leith at full & change = 2 20

Equat. to 1st 12h 36' - 12h 1d 0h 36' = 6 22

High water at Leith, Dec. 11th, at 8 42 A.M.
The time of high water found by the common method is about an hour and a half sooner.

Example II. Required the time of high water at Funchal, 15th November 1793.
The nearest phase to 15th November is that of full moon, 17d 8h 46'.
Longitude of Funchal in time = 0 1 8 W.

Time of full moon at Funchal = 17 7 38

Given day, November = 15 0 0

Difference = 2 7 38

Time of high water at Funchal at full and change = 0 12 4

Equation from the Table to 2d 7h 38' before full moon = 0 1 35

Approx. time of high water, Nov. 15 = 0 10 29

Reduced time of full moon = 17 7 38

Interval = 1 11 9

Time of high water at full and change = 0 12 4

Equat. to 1st 11h before full moon = 0 0 56

Time of high water, = 0 11 8 P.M.

Equation to 1st 11h + 12 h. = 1d. 23 h. is 1h, 15'

and 12 h. 4'-1 h. 15'=10 h. 49'=time of high Siph's Run water in the forenoon.

Example III. Required the time of high water at Dufkey Bay, 24th of October 1793.
The nearest phase to the 24th October is the last quarter - 26d 5h 47'.
Longitude of Dufkey Bay in time = 0 1 1 5 E.

Reduced time of first quarter of moon = 26 16 52

Given day = 24 0 0

Difference = 2 16 52

Time of high water at full and change, 1st 6h 7'

Equation to 2d 16h 52' before last quarter, = + 2 52

Approximate time of high water = 1 49

Change of equation to app. time 1h 49' = 3

Time of high water in the afternoon = 1 52

Change of equation to 12 hours, = 20

Time of high water in the morning = 1 32

Sect. III. Of measuring a Ship's Run in a given time.
The method commonly used at sea to find the distance failed in a given time, is by means of a log-line and half-minute-glass. A description of these is given under the articles Log and Log-line, which see.

It has been already observed, that the interval between each knot on the line ought to be 50 feet, in order to adapt it to a glass that runs 30 seconds. But although the line and glass be at any time perfectly adjusted to each other, yet as the line shrinks after being wet, and as the weather has a considerable effect upon the glass, it will therefore be necessary to examine them from time to time; and the distance given by them must be corrected accordingly. The distance may therefore be affected by an error in the glass, or in the line, or in both. The true distance may, however, be found as follows.

Rule. Multiply the distance failed by the log, and the seconds run by the glass, being given, to find the true distance, the line being supposed right.

Example I. The distance failed by the log is 73 miles, and the glass runs out in 35 seconds. Required the true rate of failing?

\[
\frac{35 	imes 270 \text{(7.7 = true rate of failing)}}{30} = \text{true distance.}
\]

Example II. The distance failed by the log is 73 miles, and the glass runs out in 26 seconds. Sought the true distance?

\[
\frac{73 	imes 2190 \text{(84.2 the true distance)}}{30} = \text{true distance.}
\]
Practice.

**Navigation.**

Plane Sailing.

From and come to; and is reckoned either north or south, according as the course is in the northern or southern hemisphere.

The departure is the distance of the ship from the meridian of the place she left, reckoned on a parallel of latitude. In this failing, the departure and difference of longitude are esteemed equal.

In order to illustrate the subject, let A (fig. 1) represent the position of any given place, and AB the meridian passing through that place; also let AC represent the line described by a ship, and C the point arrived at. From C draw CB perpendicular to AB. Now in the triangle ABC, the angle BAC represents the course, the side AC the distance, AB the difference of latitude, and BC the departure.

In constructing a figure relating to a ship's course, let the upper part of what the figure is to be drawn on represent the north, then the lower part will be south, the right-hand side east, and the left-hand side west.

A north and south line is to be drawn to represent the meridian of the place from which the ship failed; and the upper or lower part of this line, according as the course is southerly or northerly, is to be marked as the position of that place. From this point as a centre, with the chord of 60°, an arch is to be described from the meridian towards the right or left, according as the course is easterly or westerly; and the course taken from the line of chords if given in degrees, but from the line of rhumbs, if expressed in points of the compass, is to be laid upon this arch, beginning at the meridian. A line drawn through this point and that from which the ship failed, will represent the distance, which if given must be laid thereon, beginning at the point failed from. A line is to be drawn from the extremity of the distance perpendicular to the meridian; and hence the difference of latitude and departure will be obtained.

If the difference of latitude is given, it is to be laid upon the meridian, beginning at the point representing the place the ship left; and a line drawn from the extremity of the difference of latitude perpendicular to the meridian, till it meets the distance produced, will limit the figure.

If the departure is given, it is to be laid off on a parallel, and a line drawn through its extremity will limit the distance. When either the distance and difference of latitude, distance and departure, or difference of latitude and departure, are given, the measure of each is to be taken from a scale of equal parts, is to be laid off on its respective line, and the extremities connected. Hence the figure will be formed.

**Prob.**

Given the course and distance, to find the difference of latitude and departure.

**Example.** A ship from St Helena, latitude 15° 55' S. failed S. W. by S. 158 miles. Required the latitude come to, and departure?

By Construction.

Draw the meridian AB (fig. 2.), and with the chord of 60° describe the arch m n, and make it equal to the rhumb of 3 points, and through e draw AC equal to 158 miles; from C draw CB perpendicular to AB; then AB applied to the scale from which AC was taken, will be found to measure 151.4 and BC 87.8.

---

**Rule.** Multiply twice the distance failed by the measured length of a knot, point off two figures to the right, and the remainder will be the true distance.

**Example I.** The hourly rate of failing by the log is five knots, and the interval between knot and knot measures 53 feet. Required the true rate of failing?

1. Measured interval = 53
2. Twice hourly rate = 10

3. True rate of failing, = 530

**Example II.** The distance failed is 64 miles, by a log-line which measures 42 feet to a knot. Required the true distance?

1. Twice given distance, = 128
2. Measured interval, = 42

3. True distance, = 53.76

**Prob. III.** Given the length of a knot, the number of seconds run by the glass in half a minute, and the distance failed by the log; to find the true distance.

**Rule.** Multiply the distance failed by the log by six times the measured length of a knot, and divide the product by the seconds run by the glass, the quotient, pointing off one figure to the right, will be the true distance.

**Example.** The distance failed by the log is 159 miles, the measured length of a knot is 42 feet, and the glass runs 33 seconds in half a minute. Required the true distance?

1. Distance by the log, = 159
2. Six times length of a knot, = 42 × 6 = 252

3. Second run by the glass = 3340068 (121.4 =

4. True distance.

---

**Chap. II. Of Plane Sailing.**

Plane sailing is the art of navigating a ship upon principles deduced from the notion of the earth's being an extended plane. On this supposition the meridians are esteemed as parallel right lines. The parallels of latitude are at right angles to the meridians; the lengths of the degrees on the meridians, equator, and parallels of latitude, are every where equal; and the degrees of longitude are reckoned on the parallels of latitude, as well as on the equator. In this sailing four things are principally concerned, namely, the course, distance, difference of latitude, and departure.

The course is the angle contained between the meridian and the line described by the ship, and is usually expressed in points of the compass.

The distance is the number of miles a ship has failed on a direct course in a given time.

The difference of latitude is the portion of a meridian contained between the parallels of latitude failed.
NAVIGATION.

By Gunter’s Scale.

Extend the compasses from 4½ points, the complement of the course to 8 points on fine rhumbs, that extent will reach from the difference of latitude 218 miles to the distance 282 miles in numbers; and the extent from 4 points to the course 3½ points on the line of tangent rhumbs (marked T. R.) will reach from 218 miles to 178.9, the departure on numbers.

PROB. III. Given course and departure, to find the distance and difference of latitude?

EXAMPLE. A ship from Palma, in latitude 28° 37’ N failed NW by W, and made 192 miles of departure; Required the distance, run, and latitude come to?

By Construction.

Make the departure BC (fig. 4.) equal to 192 miles, draw BA perpendicular to BC, and from the centre C, with the chord of 60°, describe the arch m n, which make equal to the rhumb of 3 points, the complement of the course; draw a line through C, which produce till it meets BA in A: then the distance AC being measured, will be equal to 231 m. and the difference of latitude AB will be 128.3 miles.

By Calculation.

To find the distance.

As the line of the course 5 points is to radius 7.91985
so is the departure — 192 — 2.28330

As the tangent of the course 5 points is to radius 10.00000
so is the departure — 192 — 2.28330

As the difference of latitude 8.3 is to radius 18.9
so is the difference of latitude — 218.9 — 2.10819

By Inspection.

Find the departure 192 m. in its proper column above the given course 5 points; and opposite thereto is the distance 231 miles, and difference of latitude 128.3, in their respective columns.

By Gunter’s Scale.

The extent from 5 points to 8 points on the line of fine rhumbs being laid from the departure 192 on numbers, will reach to the distance 231 on the same line; and the extent from 5 points to 4 points on the line of tangent rhumbs will reach from the departure 192 to the difference of latitude 128.3 on numbers.

Latitude of Palma — 28° 37’ N
Difference of latitude — 2.8 N

Latitude come to — 30 45” N

PROB. IV. Given the distance and difference of latitude, to find the course and departure.

EXAMPLE. A ship from a place in latitude 43° 15’ N, fails between the north and east 285 miles; and is then by observation found to be in latitude 45° 31’ N: Required the course and departure?

Latitude failed from — 43° 13’ N
Latitude by observation — 45° 31’ N

Difference of latitude — 3 18 = 198 miles.

By Construction.

Draw the portion of the meridian AB (fig. 5.) equal to 198 miles; from B draw BC perpendicular to
NAVICATI0N

To find the difference of latitude.

As radius

is the course

to the departure

is the difference

to the difference of latitude

By Inspection.

Seek in the traverse table until the nearest to the given departure is found in the same line with the given distance 260. This is found to be in the page marked 47° at the bottom, which is the course; and the corresponding difference of latitude is 177°.

By Gunter's scale.

The extent of the compass, from the distance 260 to the departure 190 on the line of numbers, will reach from 90° to 47°, the course on the line of fives; and the extent from 90° to 43°, the complement of the course on fives, will reach from the distance 260 to the difference of latitude 177° on the line of numbers.

46° 57'
to the departure 132 on the line of numbers, will reach from 45° to 28°, the course on the line of tangents; and the extent from 62°, the complement of the course, to 90° on lines, will reach from the difference of latitude 247 to the distance 280 on numbers.

Chap. III. Of Traverse Sailing.

If a ship falls upon two or more courses in a given time, the irregular track she describes is called a traverse; and to resolve a traverse is the method of reducing these several courses, and the distances run, into a single course and distance. The method chiefly used for this purpose at sea is by inspection, which shall therefore be principally adhered to; and is as follows.

Make a table of a breadth and depth sufficient to contain the several courses, &c. This table is to be divided into six columns; the several courses are to be put in the first, and the corresponding distances in the second column; the third and fourth columns are to contain the differences of latitude, and the two last the departures.

Now, the several courses and their corresponding distances being properly arranged in the table, find the difference of latitude and departure answering to each in the traverse table; remembering that the difference of latitude is to be put in a north or south column, according as the course is in the northern or southern hemisphere; and that the departure is to be put in an east column if the course is easterly, but in a west column if the course is westerly. Observing also, that the departure is less than the difference of latitude when the course is less than 4 points or 45°; otherwise greater.

Add up the columns of northings, southeings, eastings, and westings, and set down the sum of each at its bottom; then the difference between the sums of the north and south columns will be the difference of latitude made good, of the same name with the greater; and the difference between the sums of the east and west columns, is the departure made good, of the same name with the greater sum.

Now seek in the traverse table, till a difference of latitude and departure are found to agree as nearly as possible with those above; then the distance will be found on the same line, and the course at the top or bottom of the page according as the difference of latitude is greater or less than the departure.

In order to resolve a traverse by construction, describe a circle with the chord of 60°, in which draw two diameters at right angles to each other, the one representing the meridian, and the other the parallel of latitude of the place failed from. Take each course from the line of rhumbs, lay it off on the circumference from its proper meridian, and number it in order 1, 2, 3, 4. Upon the first rhumb C₁, lay the first distance from C to A; through it draw the second distance AB parallel to C₂, and equal to 110 miles; through B draw BD equal to 180 miles, and parallel to C₃; and draw DE parallel to C₄, and equal to 68 miles. Now CE being measured, will represent the distance made good; which applied to the scale will measure 281 miles. The arc S₅, which represents the course, being measured on the line of chords, will be found equal to 414°. From E draw EF perpendicular to CS produced; then CF will be the difference of latitude, and FE the departure made good; which applied to the scale will be found to measure 210 and 180 respectively.

As the method by construction is scarcely ever practiced at sea, it therefore seems unnecessary to apply it to the solution of the following examples.
### NAVIGATION

#### II. A ship from latitude 1° 38' S, failed as under.

Required her present latitude, course, and distance made good?

#### CHAP. IV. Of Parallel Sailing.

The figure of the earth is spherical, and the meridians gradually approach each other, and meet at the poles. The difference of longitude between any two places is the angle at the pole contained between the meridians of those places; or it is the arch of the equator intercepted between the meridians of the given places; and the meridian distance between two places in the same parallel, is the arch thereof contained between their meridians. It hence follows, that the meridian distance, answering to the same difference of longitude, will be variable with the latitude of the parallel upon which it is reckoned; and the same meridian distance will not answer to a given meridian distance when reckoned upon different parallels.

Parallel sailing is therefore the method of finding the difference between two places lying in the same parallel whose longitudes are known; or, to find the difference of longitude answering to a given distance, run in an east or west direction. This sailing is particularly useful in making low or small islands.

In order to illustrate the principles of parallel sailing, let CABF (fig. 9.) represent a section of one fourth part of the earth, the arch ABF being part of a meridian; CA the equatorial; and CP the polar semiaxis. Also let B be the situation of any given place on the earth; and join BC, which will be equal to CA or CP (a). The arch AB, or angle ACB, is the measure of the latitude of the place B; and the arch BP, or angle BCP, is that of its complement. If BD be drawn from B perpendicular to CP, it will represent the cofine of latitude to the radius BC or CA.

Now since circles and similar portions of circles are in the direct ratio of their radii; therefore, as radius is to the co-fine of latitude, so is any given portion of the equator to a similar portion of the given parallel.

![Plate CXXVII.]

(a) This is not strictly true, as the figure of the earth is that of an oblate spheroid; and therefore the radius of curvature is variable with the latitude. The difference between CA and CP, according to Sir Isaac Newton's hypothesis, is about 17 miles.
NAVIGATION

But the difference of longitude is an arch of the equator: and the distance between any two places under the same parallel, is a similar portion of that parallel.

Hence $\cos \text{latitude} : \text{Diff. longitude} : \text{Distance}.$

And by inversion,

$\cos \text{latitude} : R : \text{Distance} : \text{Diff. of longitude}.$

Also,

$\text{Diff. of longitude} : \text{Distance} :: R : \cos \text{latitude}.$

**Example I.** Required the number of miles contained in a degree of longitude in latitude $55^\circ$ $58'$.

By Construction.

Draw the indefinite right line $AB$ (fig. 10): make the angle $BAC$ equal to the given latitude, and $AC$ equal to the number of miles contained in a portion of the equator, the angle $BAC$ equal to the given distance $342$ miles, and make the angle $BAC$ equal $45^\circ$ $52'$, the given latitude: from $B$ draw $BC$ perpendicular to $AB$, meeting $AC$ in $C$; then $AC$ applied to the scale will measure 466, the difference of longitude required.

**Calculation.**

As $R$ is to the secant of latitude $45^\circ$ $52'$, so is the distance $342$ to the difference of longitude 466, the difference of longitude required.

The nearest degree to the given latitude is $45^\circ$; under which, and opposite to $171$, half the given distance in a latitude column, is 234 in a distance column, which doubled gives 468, the difference of longitude.

If the proportional part answering to the difference between the given altitude and that used be applied to the above, the same result will with that found by calculation will be obtained.

**By Gunter's Scale.**

The extent from $47^\circ$ $8'$, the complement of latitude to $90^\circ$ on the line of fives, being laid the same way from the distance 342, will reach to the difference of longitude 468 on the line of numbers.

Longitude Cape Finisterre 9° $17'$

Difference of longitude 7 $47'$

Longitude come to 17 $4'$

**Example:** A ship sailed due east 358 miles, and was found by observation to have differed her longitude $8^\circ 42'$. Required the latitude of the parallel.

By Construction.

Make the line $AB$ (fig. 12) equal to the given distance; to which let $BC$ be drawn perpendicular, with an extent equal to 522, the difference of longitude; describe an arch from the centre $A$ cutting $BC$ in $C$; then the angle $BAC$ being measured by means of the line of chords, will be found equal to $45^\circ$, the required latitude.

**Calculation.**

As the distance $358$ is to the difference of longitude $522$, so is radius $2.53288$ to the secant of the latitude $46^\circ$ $42'$. The difference of longitude is 358, 2.53288.

The difference of longitude and distance exceed the limits of the table, let therefore the half of each be taken; these are 261 and 179 respectively. Now, by entering the table with these quantities, the latitude will be found to be between 46 and 47 degrees. Therefore, to latitude $46^\circ$, and distance 261 miles, the corresponding difference of latitude is 181, which exceeds the half of the given distance by 2'. Again, to latitude $47^\circ$, and distance 261, the difference of latitude is 178.5, being 1.0 less than the half of that given: therefore the change of distance answering to a change of $1'$ of latitude is 3'.

Now, as 3' is to 2': 3' is to 1': 42'.

Hence the latitude required is $46^\circ$ 42'.
Practice.

By Gunter's Scale.

The extent from 322 to 358 on the line of numbers, will reach from 90° to about 43°, the complement of which 46° is the latitude required?

Prob. IV. Given the number of miles contained in the portion of a known parallel, to find the length of a similar portion of another known parallel.

Example. From two parts in latitude 33° 58' N, distance 348 miles, two ships fail directly north till they are in latitude 48° 23' N. Required their distance?

By Construction.

Draw the lines CB, CE (fig. 13.), making angles with CP equal to the complements of the given latitudes, namely, 56° 2' and 41° 37' respectively: make BD equal to the given distance 348 miles, and perpendicular to CP; now from the centre C, with the radius CB, describe an arch intersecting CE in E; then EF drawn from the point E, perpendicular to CP, will represent the distance required; and which being applied to the scale, will measure 278 6/10 miles.

By Calculation.

As the cosine of the latitude left 33° 58'

\[ \text{is to the cosine of the latitude } \frac{9.91874}{9.91874} \]

to the distance required \[ \frac{48.23}{348} \]

so is the given distance 348 to the distance required 278 6/10 by Gunter's Scale.

The extent from 34°, and opposite to 174°, half the given distance in a latitude column is 210 in a distance column; being half the difference of longitude answering thereto. Now, find the difference of latitude to distance 210 miles over 48° of latitude, which is 140° 51' from which 1° (the proportional part answering to 22 minutes of latitude) being subtracted, gives 139° 45', which doubled is 278 6/10, the distance required.

By Calculation.

Under 48°, and opposite to 174°, half the given distance in a latitude column is 210 in a distance column; being half the difference of longitude answering thereto. Now, find the difference of latitude to distance 210 miles over 48° of latitude, which is 140° 51' from which 1° (the proportional part answering to 22 minutes of latitude) being subtracted, gives 139° 45', which doubled is 278 6/10, the distance required.

By Calculation.

Under 48°, and opposite to 174°, half the given distance in a latitude column is 210 in a distance column; being half the difference of longitude answering thereto. Now, find the difference of latitude to distance 210 miles over 48° of latitude, which is 140° 51' from which 1° (the proportional part answering to 22 minutes of latitude) being subtracted, gives 139° 45', which doubled is 278 6/10, the distance required.

By Calculation.

Under 48°, and opposite to 174°, half the given distance in a latitude column is 210 in a distance column; being half the difference of longitude answering thereto. Now, find the difference of latitude to distance 210 miles over 48° of latitude, which is 140° 51' from which 1° (the proportional part answering to 22 minutes of latitude) being subtracted, gives 139° 45', which doubled is 278 6/10, the distance required.

By Calculation.

As the cosine of the latitude left 33° 58'

\[ \text{is to the cosine of the latitude } \frac{9.91874}{9.91874} \]

to the distance required \[ \frac{48.23}{348} \]

so is the given distance 348 to the distance required 278 6/10 by Gunter's Scale.

The extent from 180 to 232 on the line of numbers, being laid in the same direction on the line of fines, from 34°, the complement of the latitude failed from, will reach to 46° 7', the complement of the latitude come to.

Chap. V. Of Middle Latitude Sailing.

The earth is a sphere, and the meridians meet at the poles; and since a rhumb-line makes equal angles with every meridian, the line a ship describes is therefore that kind of a curve called a spiral.

Let AB (fig. 15.) be any given distance sailed upon an oblique rhumb, PBN, PAM the extreme meridians, MN a portion of the equator, and PCK, PEL two meridians intersecting the distance AB in the points CE infinitely near each other. If the arches BS, CD, and AR, be described parallel to the equator, it is hence evident, that AS is the difference of latitude, and the arch MN of the equator the difference of longitude, answering to the given distance AB and course PAB.

Now, since CE represents a very small portion of the distance AB, DE will be the corresponding part of a meridian: hence the triangle EDC may be considered as rectilinear. If the distance be supposed to be divided into an infinite number of parts, each equal to CE, and upon these, triangles be constructed whose sides are portions of a meridian and parallel, it is evident these triangles will be equal and similar; for, besides the right angle, and hypothenuse which is the same in each, the course or angle CED is also the same. Hence, by the 12th of V. Euclid, the sum of all the hypothenuses CE, or the distance AB, is to the sum of all the fides DE, or the difference of latitude AS, as one of the hypothenuses CE is to the corresponding side DE. Now, let the triangle G1H (fig. 16.) be constructed similar to the triangle CDE, having the angle G equal to the course; then as GH: GI: CE: DC:: AB: AS.

Hence, if GH be made equal to the given distance AB, then GI will be the corresponding difference of latitude.

In like manner, the sum of all the hypothenuses CE, or the distance AB, is to the sum of all the fides CD,
NAVIGATION.

Middle
Longitude Isle of May - 2 37 W
Latitude Naze of Norway - 7 27 E
Difference of longitude - 10 7 = 60°

By Construction.

Draw the right line AD (fig. 18.) to represent the meridian of the May, with the chord of 60° describe the arch m n, upon which lay off the chord of 32° 59', the complement of the middle latitude from m to n: from D through n draw the line DC equal to 60°', the difference of longitude, and from C draw CB perpendicular to AC: make BA equal to 98', the difference of latitude, and join AC; which applied to the scale will measure 343 miles, the distance sought: and the angle A being measured by means of the line of chords, will be found equal to 73° 24', the required course.

By Calculation.

To find the course (b).

As the difference of latitude - 98' - 1.99123
is to the difference of longitude 60°' - 2.78104
so is the cosine of middle latitude
- - - - 57° 1' 9.73591

As radius - - - - 10.52572

to the tangent of the cosine 73' 24' 10.54411

As radius - - - - 1.99123

To find the distance.

As the difference of latitude 98' - 1.99123
is to the secant of the course 73° 24' 10.54411
so is the difference of latitude - - - 343 2.53534

By Inversion.

To middle latitude 57°, and 151 one-fourth of the difference of longitude in a distance column, the corresponding difference of latitude is 82°.

Now 24° 5', one-fourth of the difference of latitude, and 82° 2, taken in a departure column, are found to agree nearest on table marked 6i: points at the bottom, which is the cosine; and the corresponding distance 854 multiplied by 4 gives 343 miles, the distance.

By Gunter's Scale.

The extent from 98° the difference of latitude, to 60° the difference of longitude on numbers, being laid the same way from 35°, the complement of the middle latitude on lines, will reach to a certain point beyond the termination of the lines on the scale. Now the extent between this point and 90° on lines, will reach from 45° to 73° 24', the course on the line of tangents. And the extent from 73° 24' the course, to 35° the complement of the middle latitude on the line of lines, being laid the same way from 60° the difference of longitude, will reach to 343 the distance on the line of numbers.

The true course, therefore, from the island of May to the Naze of Norway is N 73° 24 E, or ENE; E nearly; but as the variation at the May is 2° points well.

PROB. I. Given the latitudes and the longitudes of two places, to find the course and distance between them.

EXAMPLE. Required the course and distance from the island of May, in latitude 35° 0' 12 N, and longitude 37° 50', to the Naze of Norway, in latitude 57° 0' 50 N, and longitude 7° 27 E?

Latitude Isle of May - 35° 0' 12 N - 56° 0' 12
Latitude Naze of Norway - 57° 0' 50 N - 57° 50

Difference of latitude 1° 38' 58' - 114. 2
Middle latitude 56° 50' 50' 57° 1
Practice.

Middle

Latitude

Sailing.

NAVIGATION.

well, therefore the course per compass from the May is E; S.

PROB. II. Given one latitude, course, and distance failed, to find the other latitude and difference of longitude.

Example. A ship from Brest, in latitude 48° 23' N. and longitude 4° 30' W. failed SW' W 238 miles. Required the latitude and longitude come to?

By Construction. With the course and distance construct the triangle ABC (fig. 20.), and the difference of latitude AB being measured, will be found equal to 142 miles; hence the latitude come to is 46° 1' N., and the middle latitude 47° 12'. Now make the angle DCB equal to 47° 12'; and DC being measured, will be 281, the difference of longitude: hence the longitude come to is 9° 11' W.

By Calculation.

To find the difference of latitude.

As the cosine of middle latitude 281 on numbers.

So is the difference of long. 10,00000

Hence the latitude come to is 46° 1' N., and middle lat. 47° 12'.

To find the difference of longitude (d).

As the cosine of Mid. Lat. 47° 12' 9.83215

so is the distance, 47 points 9.90489

to the difference of longitude 141.8 2.15161

Latitude of Brest, 48° 23' N. 48° 23' N.

Difference of Lat. 2 22 S. half 1 11 S.

Lat. come to 46° 1' N. Mid. Lat. 47 12'.

To find the difference of longitude (d).

As the cosine of Mid. Lat. 47° 12' 9.83215

so is the distance, 47 points 9.90489

to the difference of longitude 141.8 2.15161

Longitude of Brest - 48° 23' 1.3 49527

Difference of longitude - 4 41 W.

Longitude come to - 9 11 W.

By Inversion.

To the course 47 points, and distance 238 miles, the difference of latitude is 141.8, and the departure 191.1. Hence the latitude come to is 46° 1' N., and middle latitude 47° 12'. Then to middle latitude 47° 12', and departure 191.1 in a latitude column, the corresponding distance is 281', which is the difference of longitude.

By Gunter's Scale.

The extent from 8 points to 32 points, the complement of the course on fine rhumbs, being laid the same way from the distance 238, will reach to the difference of latitude 142 on the line of numbers; and the extent from 42° 48' the complement of the middle latitude, to 53° 26', the course on the line of rhumbs will reach from the distance 238 to the difference of longitude 281 on numbers.

PROB. III. Given both latitudes and course, required the distance and difference of longitude?

Example. A ship from St. Antonio, in latitude 17° 0' N., and longitude 24° 25' W., failed NW', N. till by observation her latitude is found to be 28° 34' N.

Required the distance failed, and longitude come to?

Latitude St. Antonio 17° 0' N. 17° 0' N.

Latitude by observation 28 34 N. 28 34 N.

Difference of lat. 11 34 = 604 m 45 34

Middle lat. 22 47

By Construction.

Construct the triangle triangle ABC (fig. 19), with the given course and difference of latitude, and make the angle BCD equal to the middle latitude. Now the distance AC and difference of longitude DC being measured, will be found equal to 864 and 558 respectively.

By Calculation.

To find the distance. As radius, - 10,00000

Is to the secant of the course 34 points 10,09517

So is the difference of lat. 694 2.84136

To the distance 864 2.93653

To find the difference of longitude.

As the cosine of middle latitude 22° 47' 9.96472

Is to the tangent of the course 34 points 9.87020

So is the difference of latitude 694 2.84136

To the difference of longitude 558.3 2.74664

Longitude of St. Antonio - 24° 25' W.

Difference of longitude, - 9 18 W.

Longitude come to - 33 43 W.

By Inversion.

To course 34 points, and difference of latitude 231,3 one th. of that given, the departure is 171.6, and distance 288, which multiplied by 3 is 864 miles.

Again to the middle latitude 22° 47', or 23°, and departure 171.6 in a latitude column, the distance is 186, which multiplied by 3 is 558, the difference of longitude.

By Gunter's Scale.

The extent from 47 points, the complement of the course, to 8 points on the line of fine rhumbs, will reach from the difference of latitude 694 to the distance 864 on numbers; and the extent from the course 36° 34' to 65° 15', the complement of middle latitude on rhumbs, will reach from the distance 864 to the difference of longitude 558 on numbers.

PROB. IV. Given one latitude, course, and departure, to find the other latitude, distance, and difference of longitude.

Example. A ship from latitude 26° 30' N. and longitude 45° 30' W. failed NE; N. till her departure was 216 miles. Required the distance run, and latitude and longitude come to?

By Construction.

With the course and departure construct the triangle ABC (fig. 20.), and the difference of latitude being measured, will be found equal to 340 and 363 respectively. Hence the latitude come to is 30° 53' and middle latitude 28° 42'. Now make the angle BCD equal to the middle latitude, and the difference of longitude DC applied to the scale will measure 24° 46'.

By

(v) This proportion is obvious, by considering the whole figure as an oblique angled triangle.
NAVIGATION.

By Calculation.

To find the distance.

As the sine of the course is to radius, so is the departure.

To find the difference of latitude.

As the tangent of the course is to radius, so is the departure.

To find the difference of longitude.

As the tangent of the course is to radius, so is the departure.

Difference of latitude.

Latitude come to

39° 53' M Id.lat. 28° 42'

To find the difference of longitude.

As radius is to the second of the middle lat. 28° 42', so is the departure.

To find the difference of longitude.

Longitude left,

45° 30' W.

Difference of longitude

4° 6 E.

Longitude come to

41° 24' W.

By Inspecion.

Under the course 3½ points, and opposite to 108 half the departure, the distance is 170, and difference of latitude 131'; which doubled, give 340 and 263 for the difference of the course and difference of latitude respectively.

Again, to middle latitude 28° 42', and departure 108, the distance is 123; which doubled is 246 the difference of longitude.

By Gunter's Scale.

The extent from the course 3½ points, on fine rhumbs, to the departure 216 on numbers, will reach from 8 points on fine rhumbs to about 340, the difference on numbers; and the same extent will reach from 45 points, the complement of the course, to 263, the difference of latitude on numbers; and the extent from 61° 18' the complement of the middle latitude, to 90° 30' on fines, will reach from the departure 216 to the difference of longitude 246 on numbers.

Prob. V. Given both latitudes and distance; to find the course and difference of longitude.

Example. From Cape Sable, in latitude 43° 34' N., and longitude 65° 39' W., a ship sailed 246 miles on a direct course between the south and east, and is then by observation in latitude 40° 48' N. Required the course and longitude in?

Latitude Cape Sable,

43° 48' N.

Latitude by observation,

40° 48' N.

Difference of latitude,

2° 36' = 156° 24' 12".

Middle latitude 42° 6'

By Construction.

Make AB (fig. 22.) equal to 156 miles; draw BC perpendicular to AB, and make AC equal to 246 miles. Draw CD, making with CB an angle of 42° 6' the middle latitude. Now DC will be found to measure 256, and the course or angle A will measure 50° 39'.

By Calculation.

To find the course.

As the difference of latitude 156 is to the difference of latitude 156, so is the tangent of the course to the tangent of the course.

To find the difference of longitude.

As the difference of longitude 246 is to the difference of longitude 246, so is the tangent of the course to the tangent of the course.

Longitude Cape Sable,

256° 24' 8° 26'

Difference of longitude

5° 39' W.

Longitude come to

61° 23 W.

By Inspecion.

The distance 246, and difference of latitude 156, are found to correspond above 41 points, and the departure is 193.1. Now, to the middle latitude 43° 34', and departure 190.1 in a latitude column, the corresponding distance is 256, which is the difference of longitude required.

By Gunter's scale.

The distance from 246, the difference to 156, the difference of latitude on numbers, will reach from 90° 30' to about 39° 1', the complement of the course on the line of fines; and the extent from 246°, the complement of the middle latitude, to 50° 39', the course on fines, will reach from the distance 246 to the difference of longitude 256 on numbers.

Prob. VI. Given both latitudes and departure; fought the course, distance, and difference of longitude.

Example. A ship from Cape St. Vincent, in latitude 37° 2' N., longitude 9° 2' W., sails between the south and west; the latitude come to is 15° 16', and departure 838 miles. Required the course and distance run, and longitude come to?

Latitude Cape St. Vincent,

37° 2' N.

Latitude come to

18° 16 N.

Difference of latitude

18° 46' 1126

Middle latitude 27° 39'

By Construction.

Make AB (fig. 22.) equal to the difference of latitude 1126 miles, and BC equal to the departure 838, and join AC; draw CD so as to make an angle with CB equal to the middle latitude 27° 39'. Then the course being measured on chords is about 35° 21', and the distance and difference of longitude, measured on the line of equal parts, are found to be 1403 and 945 respectively.

By Calculation.

To find the course.

As the difference of latitude 1126 is to the departure 838, so is the tangent of the course to the tangent of the course.

To the tangent of the course 36° 39'

9.87170

To find the distance.

As radius - - - 10.00000
is the secant of the course 36° 39'
so is the difference of latitude 1126
- 3.01514

to the distance - 1403
To find the difference of longitude.

As radius - - - 10.00000
is the secant of the mid. lat. 27° 39'
so is the departure - 838
- 2.52324

to the difference of longitude 946
Longitude Cape St Vincent - 9° 2 W.
Difference of longitude - - 15 46 W.

Longitude come to - 24 48 W.

By Inversion.

One-tenth of the difference of latitude 112.6, and of the departure 83.8, are found to agree under 31 points, and the corresponding distance is 140, which multiplied by 10 gives 1400 miles. And to middle latitude 27° 39', and 209.5 one-fourth of the departure in a latitude column, the distance is 236.5; which multiplied by 4 is 946, the difference of longitude.

By Gunter's Scale.

The extent from the difference of latitude 1126 to the departure 838 on numbers, will reach from 45° to 36°; the course on tangents; and the extent from 53° 41', the complement of the course to 90° on lines, will reach from 1126 to 1403 the distance on numbers. Lastly, the extent from 62° 3' the complement of the middle latitude, to 90° on lines, will reach from the departure 838 to the difference of longitude 946 on numbers.

PROB. VII. Given one latitude, distance, and departure, to find the other latitude, course, and difference of longitude.

Example. A ship from Bordeaux in latitude 44° 50' N, and longitude 0° 35' W, failed between the north and west 374 miles, and made 210 miles of sailing.

Required the course and latitude and longitude come to?

By Construction.

With the given distance and departure make the triangle ABC (fig. 23.) Now the course being measured on the line of chords is about 34° 21; and the difference of latitude on the line of numbers is 309 miles: hence the latitude come to, is 49° 55' N, and middle latitude 47° 25'. Then make the angle BCD equal to 47° 25', and DC measured will be 310 miles, the difference of longitude.

By Calculation.

To find the course.

As the distance - 374 - 2.57287
is to the departure - 210 - 2.32222
so is radius - - - 10.00000

to the fine of the course 34° 10' - 9.74935
To find the difference of latitude.

As radius - - - 10.00000
is to the cosine of the course 34° 10'
so is the distance - 374
- 2.57287

to the difference of latitude 309.4 - 2.49599

<tr>
<td>Latitude failed from 51 40</td>
</tr>
<tr>
<td>Latitude come to 46 16</td>
</tr>
</tbody>
</table>

**By Infection.**

To the course 3° points, and half the distance 219 miles, the departure is 147°, and difference of latitude 162.2°; which doubled is 324.4°. Again, to half the difference of longitude 224 in a distance column, the difference of latitude is 149.9 above 48°, and 146.9 over 49°.

Now, as 30 : 29 : 60 : 38

Hence the middle latitude is 48° 38'; the latitude failed from is therefore 51° 40', and latitude come to 46° 16'.

**By Gunter's Scale.**

The extent from 8 points to 45 points, the complement of the course on fine rhumbs, will reach from the distance 438 miles to the difference of latitude 3245 on numbers. And the extent from the difference of longitude 448, to the distance 438 on numbers, will reach from the course 42° 11' to the complement of the middle latitude 41° 2' on fine. Hence the latitude left is 51° 40', and that come to 46° 16'.

**Example.** From a port in south latitude a ship sailed SWW, and has made 690 miles of difference of latitude, and 20° 38' of difference of longitude.—Required both latitudes and distance?

**By Construction.**

Construct the triangle ABC (fig. 26.) with the given course and difference of latitude, and make CD equal to 1228 the difference of longitude. Then AC applied to the scale will measure 1088 miles; and the middle latitude BCD will measure 40° 47'. Hence the latitude left is 41° 2', and the latitude come to 54° 32'.

**By Calculation.**

To find the distance.

As radius 10.000000

is to the secant of the course 41 pts. 10.01764
fo is the difference of latitude 690 2.83885

to the distance 1088 3.03649
To find the middle latitude.

As the difference of longitude 1228 3.08920
is to the distance 1088 3.03649
fo is the fine of the course 41 pts. 9.88819

to the cosine of the middle latitude 46° 47' 9.83548
Half difference of latitude 5 45

Latitude failed from 41 2
Latitude come to 52 32

**By Infection.**

To the course 41 points, and one-fourth of the given difference of latitude 172.5 the departure is 210.2
Middle Latitude.

By Gunter's Scale.

The extent from the distance 458 to the difference of latitude 296 on numbers, will reach from 90° to 40° 16 the complement of the course on lines: and the extent from the difference of longitude 437 to the distance 458 on numbers, will reach from the course 49° 44' to the complement of the middle latitude 53° 6 on the line of lines: Hence the latitudes are 34° 20' and 39° 22' respectively.

Prob. XII. Given the distance, middle latitude, and difference of longitude, to find both latitudes and course.

Example. The distance is 384 miles between the south and east, the middle latitude 54° 6', and difference of longitude 6° 36'. Required both latitude and course.

By Construction.

With the middle latitude 54° 6', and difference of longitude 396, construct the triangle BCD (fig. 28.), and make AC equal to the given distance 384 miles. Then the course BAC will be found to measure 37° 12', and the difference of latitude AB 306 miles. Hence the latitude failed from is 56° 39', and that come to 51° 33'.

By Calculation.

To find the course.

As the distance is to the difference of longitude

so is the course of middle latitude

hence the course is 37° 12'.

To find the difference of latitude.

As radius is to the distance

so is the difference of latitude

hence the difference is 384.

Prob. XIII. To determine the difference of longitude made good upon compound courses, by middle latitude failing.

4 T

RUL

Rule
The above method is that always practiced to find the difference of longitude made good in the course of a day's run; and will, no doubt, give the difference of longitude tolerably exact in any probable run a ship may make in that time, especially near the equator. But in a high latitude, when the distances are considerable, this method is not to be depended on.-

To illustrate this, let a ship be supposed to fail from latitude 57° N, as follows: E 240 miles, N 240 miles, W 240 miles, and S 240 miles; then, by the above method, the ship will be come to the same place left. It will, however, appear evident from the following consideration, that this is by no means the case; for let two ships, from latitude 61° N, and distant 240 miles, sail directly south till they are in latitude 57° N; now their distance being computed by Problem IV. of Parallel Sailing, will be 296.6 miles; and, therefore, if the ship failed as above, she will be 29.6 miles west of the place failed from; and the error in longitude will be equal to 296 x secant 61 — secant 57° = 29.6 x secant 57°.

Theorems might be investigated for computing the errors to which the above method is liable. These corrections may, however, be avoided, by using the following method.

Rule II. Complete the traverse table as before, to which annex five columns: the first column is to contain the several latitudes the ship is in at the end of each course and distance; the second, the sums of each following pair of latitude; the third, half the sums, or the difference of the sums of the columns, according to the name of the departure. Then the difference of the sums of the east and west columns will be the difference of longitude made good, of the same name with the greater.

Ex. A ship from Halliford in Iceland, in lat. 64° 30' N, long. 27° 15' W, failed as follows: SSW 46 miles, SW 61 miles, SW 59 miles, SE 86 miles, SE 76 miles. Required the lat. and long. come to?

NAVIGATION.

That is, the difference of longitude is equal to the meridional difference of latitude multiplied by the tangent of the course, and divided by the radius.

This equation answers to a right-angled rectilinear triangle, having an angle equal to the course; the adjacent fide equal to the meridional difference of latitude, and the opposite fide the difference of longitude. This triangle is therefore similar to a triangle constructed, with the course and difference of latitude, according to the principles of plane sailing, and the homologous fides will be proportional. Hence if, in fig. 29, the angle \( A \) represents the course \( AB \) the difference of latitude, and if \( AD \) be made equal to the meridional difference of latitude; then \( DE \), drawn perpendicular to \( AD \), meeting the distance produced to \( E \), will be the difference of longitude.

It is scarce necessary to observe, that the meridional difference of latitude is found by the same rules as the proper difference of latitude; that is, if the given latitudes be of the same name, the difference of the corresponding meridional parts will be the meridional difference of latitude; but if the latitudes are of a contrary denomination, the sum of these parts will be the meridional difference of latitude.

**Example.** Required the course and distance between Cape Finisterre, in latitude 43° 52' N, longitude 9° 17' W, and Port Praya in the island of St Jago, in latitude 14° 54' N, and longitude 23° 29' W.

<table>
<thead>
<tr>
<th>Latitude Port Praya</th>

</tr>
</tbody>
</table>

**By Correction.**

Draw the straight line \( AD \) (fig. 29.) to represent the meridian of Cape Finisterre, upon which lay off \( AB \), \( AD \) equal to 1678 and 1948, the proper and meridional differences of latitude; from \( D \) draw \( DE \) perpendicular to \( AD \), and equal to the difference of longitude 852 join \( AE \), and draw \( BC \) parallel to \( DE \); then the distance \( AC \) will measure 1831 miles, and the course \( BAC \) 23° 37'.

**By Calculation.**

To find the course.

As the meridian difference of lat. 1948 3.28959
is to the difference of longitude 852 2.93044
fo is radius - - 10.00000
to the tangent of the course 23° 37' 9.64085
To find the distance.

As radius - - 10.00000
is to the fect of the course 23° 37' 10.03798
fo is the difference of latitude 1678 3.22479
to the distance - 1851 3.26277

Plate CCCCXXXVIII.
NAVIGATION.

By Inspection.

As the meridian difference of latitude and difference of longitude are too large to be found in the tables, let the tenth of each be taken; these are 194.8 and 85.2 respectively. Now these are found to agree nearest under 24°; and to 167.8, one tenth of the proper difference of latitude, the distance is about 183 miles, which multiplied by 10 is 1830 miles.

By Gunter's Scale.

The extent 1948, the meridional difference of latitude, to 852, the difference of longitude, on the line of numbers, will reach from 45° to 23° 37', the course on the line of tangents. And the extent from 66° 25', the complement of the course to 90° on lines, will reach from 1678, the proper difference of latitude, to 1831, the distance on the line of numbers.

PROB. II. Given the course and distance failed from a place whose situation is known, to find the latitude and longitude of the place come to.

Example. A ship from Cape Hinlopen in Virginia, in latitude 38° 47' N, longitude 75° 4' W, failed 267 miles NEbN. Required the ship's present place?

By Conjunction.

With the course and distance failed compute the triangle ABC (fig. 30.); and the difference of latitude AB being measured, is 222 miles; hence the latitude come to is 43° 20' N, and the meridional difference of latitude 293. Make AD equal to 293; and draw DE perpendicular to AD, and meeting AC produced in E; then the difference of longitude DE being applied to the scale of equal parts will measure 196; the longitude come to is therefore 71° 48' W.

By Calculation.

To find the difference of latitude,

As radius

is to the cosine of the course, 3 points

so is the distance

to the difference of latitude 222

Lat. Cape Hinlopen = 38° 47' N. Mer. parts 2528

Difference of lat. 3 42 N.

Latitude come to 42° 29' N. Mer. parts 281

Meridional difference of lat. 293

To find the difference of longitude,

As radius

to the tangent of the course, 3 points

so is the mer. diff. of latitude

to the difference of longitude 195.8

Longitude Cape Hinlopen 75° 4' W

Difference of longitude - 3 16 E

Longitude come to 71° 48 W

By Gunter's Scale.

To the course 3 points, and distance 267 miles, the difference of latitude is 2.22 miles: hence the latitude in, is 43° 20', and the meridional difference of latitude 293. Again, to course 3 points, and 146.6 half the mer. difference of latitude, the departure is 97-9, which doubled is 195.8, the difference of longitude.

By Gunter's Scale.

The extent from 8 points to the complement of the course 5 points on fine rhumbs, will reach from the distance 267 to the difference of latitude 222 on numbers; and the extent from 4 points to 3 points on tangent rhumbs, will reach from the meridional difference of latitude 293 to the difference of longitude 196 on numbers.

PROB. III. Given the latitudes and bearing of two places, to find their distance and difference of longitude.

Example. A ship from Port Canfo in Nova Scotia, in latitude 45° 20' N, longitude 60° 55' W, failed SE 45° 14' N. Required the distance failed, and longitude come to?

Lat. Port Canfo - 45° 20' N. Mer. parts 3058

Lat. in by observation 41° 14 N. Mer. parts 2720

Difference of lat. - 4 6 Mer. diff. lat. 338

By Conjunction.

Make AB (fig. 31.) equal to 246, and AD equal to 338; draw AE, making an angle with AD equal to 32 points, and draw BC, DE perpendicular to AD. Now AC being applied to the scale, will measure 332, and DE 306.

By Calculation.

To find the distance,

As radius

is to the secant of the course, 3 4 points

so is the difference of latitude

to the distance 332

Longitude Port Canfo - 60° 55' W

Difference of longitude - 5 6 E

Longitude in - 55° 49 W

By Inspection.

Under the course 32 points, and opposite to half the difference of latitude, 123 in a latitude column is 166 in a distance column, which doubled is 332 the distance; and opposite to 169, half the meridional difference of latitude in a latitude column, is 153 in a departure column, which doubled is 306, the difference of longitude.

By Gunter's Scale.

The extent from the complement of the course 42 points to 8 points on fine rhumbs, will reach from the difference of latitude 246 m. to the distance 332 on numbers; and the extent from 4 points to 3 points on tangent rhumbs, will reach from the meridional difference of latitude 338 to the difference of longitude 306 on numbers.

PROB. IV. Given the latitude and longitude of the place failed from, the course, and departure; to find the distance, and the latitude and longitude of the place come to.

Example. A ship failed from Sallee in Latitude 35° 58' N, longitude 6° 20' W, the corrected course was NWbW, and departure 420 miles. Required the
Mercator's Practice.

NAVIGATION.

Mercator's the distance run, and the latitude and longitude come Sailing to?

By Construction.

With the course and departure construct the triangle Plate ABC (fig. 32.) now AC and AB being measured, will be found equal to 476 and 224 respectively; hence the radius to is 37° 42' N, and meridional difference of latitude 276. Make AD equal to 276; and draw DE perpendicular thereto, meeting the distance produced in E; then DE applied to the scale will be found to measure 516'. The longitude in therefore is 14° 56' W.

By Calculation.

To find the distance.

As radius - - 10,00000
is to the co-tangent of the course, 51 pts 10,05457
so is the departure - - 420 2,62325

to the distance - - 576.2 2,67782
To find the difference of latitude.

As radius - - 10,00000
is to the co-tangent of the course, 51 pts 9,72796
so is the departure - - 420 2,62325

to the difference of latitude - - 224-5 2,35121

Lat. of Sallee 33° 58' N Mer. parts 2169
Diff. of lat. 8 44 N

Latitude in 37 42 N Mer. parts 2445

Mer. difference of latitude 276
To find the difference of longitude.

As radius - - 10,00000
is to the tangent of the course, 51 pts 10,27204
so is the mer. diff. of latitude 276 2,44901

to the difference of longitude 516.3 2,71295

Longitude of Sallee - - 6° 20' W
Difference of longitude - - 8 36 W

Longitude in - - 14 56 W

By Inspection.

Above 51 points the course, and opposite to 210 half the departure, are 238 and 112; which doubled, we have 476 and 224, the distance and difference of latitude respectively. And to the same course, and opposite to 138, half the meridional difference of latitude, in a latitude column, is 258 in a departure column; which being doubled is 516, the difference of longitude.

By Gunter's Scale.

The extent from 51 points the course, and opposite to 420 on numbers, will reach from 8 points on fine rhumbs to the distance 476 on numbers; and from the complement of the course 21 points on fine rhumbs to the difference of latitude 224 on numbers.

Again, the extent from difference of latitude 224 to the meridional difference of latitude 276 on numbers, will reach from the departure 420 to the difference of longitude 516 on the same line.

PROB. V. Given the latitudes of two places, and their distance, to find the course and difference of longitude.

Example. A ship from St Mary's, in latitude 36° 57' N, longitude 25° 9' W, sailed on a direct course between the north and east 1162 miles, and is then by observation in latitude 49° 57' N. Required the course and longitude come to?

Lat. of St Mary's - 36° 57' N Mer. parts 3470
Lat. come to - 49 57 N Mer. parts 2380

Difference of lat. 13 0 Mer. diff. lat. 1081

By Construction.

Make AB (fig. 33.) equal to 780, and AD equal to 1162; draw BC, DE perpendicular to AD; make AC equal to 1162 m. and through AC draw ACE. Then the course or angle A being measured, will be found equal to 47° 50', and the difference of longitude DE will be 1194.

By Calculation.

To find the course.

As the distance - - 1162 3,06521
is to the difference of latitude, 780 2,89209
so is radius - - - 10,00000

to the cosine of the course - - 47° 50' 9,82688

To find the difference of longitude.

As radius - - - 10,00000
is to the tangent of the course, 47° 50' 10,03022
so is the mer. diff. of latitude 1081 3,0383

to the difference of longitude 1194 3,07685

Longitude of St Mary's - 25° 9' W
Difference of longitude - 19 54 E

Longitude in - - 5 15 W

By Inspection.

Because the distance and difference of latitude exceed the limits of the table, take the tenth of each; there are 116.2 and 78.0. Now these are found to agree nearest above 45 points, which is therefore the course; and to this course, and opposite to 108.1, one tenth of the meridional difference of latitude, in a latitude column, is 119.3 in a departure column, which multiplied by 10 is 1193, the difference of longitude.

By Gunter's Scale.

The extent from the distance 1162 m. to the difference of latitude 780 m. on numbers, will reach from 90° to 42° 10' in the line of lines. And the extent 45°, to the course 47° 50' on the line of tangents, will reach from the meridional difference of latitude 1081 to the difference of longitude 1194 on numbers.

PROB. VI. Given the latitudes of two places, and the departure; to find the course, distance, and difference of longitude.

Example. From Aberdeen, in latitude 57° 9' N, longitude 3° 9' W. a ship sailed between the south and east till her departure is 146 miles, and latitude come to 58° 32'. Required the course and distance run, and longitude come to?

Latitude Aberdeen 57° 0' N mer. parts 4199
Latitude come to 58° 32 N mer. parts 817

Difference of latitude 3 37 mer. diff. of lat. 382,
NAVIGATION.

By Construction.

With the difference of latitude 217', and departure 146', construct the triangle ABC (fig. 34.), make AD equal to 382, draw DE parallel to BC, and produce AC to E: Then the course BAC will measure 33° 56', the distance AC 261', and the difference of longitude DE 257'.

By Calculation.

To find the course.

As the difference of latitude 217, is to the tangent of the course 33° 56' to find the distance. 257.

As the difference of latitude 217, is to the tangent of the course 33° 56', so is radius - to - - - 10,00000.

to the tangent of the course 33° 56', so is radius 9.82789.

As radius - - - 10,00000.

to the tangent of the course 33° 56', so is radius - - - 10,08109.

to the tangent of the course 33° 56', so is radius 2.33646.

Longitudes of Aberdeen Difference of longitude

2° 9' W 4° 17' E

Longitude come to 2° 8' E

By Inspection.

The difference of latitude 217, and departure 146, are found to agree nearest under 34°, and the corresponding distance is 262 miles. To the same course, and opposite to 190°, the nearest to 191 half the meridional difference of latitude is 128.6 in a departure column, which doubled is 257, the difference of longitude.

By Gunter's Scale.

The extent from the difference of latitude 217, to the departure 146 on numbers, will reach from 45° to about 34°, the course on the line of tangents; and the same extent will reach from the meridional difference of latitude 382 to 257, the difference of longitude on numbers.—Again, the extent from the course 34° to 90 on fines, will reach from the departure 146 to the distance 261 on numbers.

Prob. VII. Given one latitude, distance, and departure; to find the other latitude, course, and difference of longitude.

Example. A ship from Naples, in latitude 40° 51' N, longitude 14° 14' E, sailed 252 miles on a direct course between the south and west, and made 173 miles of weighting. Required the course made good, and the latitude and longitude come to?

By Construction.

With the distance and departure make the triangle ABC (fig. 35.) as formerly.—Now the course BAC being measured by means of a line of chords will be found equal to 43° 21', and the difference of latitude applied to the scale of equal parts will measure 183°; hence the latitude come to is 37° 48' N, and meridional difference of latitude 237°—Make AD equal to 237, and complete the figure, and the difference of longitude will measure 224°; hence the longitude in is 10° 30' E.

By Calculation.

As the distance 252, is to the departure 173, so is radius - to - - - 10,00000.

to the sine of the course 43° 21', so is radius 9.82665.

To find the difference of latitude.

As radius - - - 10,00000.

is to the tangent of the course 43° 21', so is the difference of latitude 146° to 9.82664.

is to the mer. diff. of latitude 237, so is the distance 252, to 2.40140.

to the difference of longitude 183.2, so is the distance 2.26304.

Latitude of Naples 40° 51' N. Mer. parts 2690.

Difference of latitude 3° 3'.

Latitude come to 37° 48' N. Mer. parts 2453.

Meridional difference of latitude 237°.

To find the difference of longitude.

As radius - - - 10,00000.

is to the tangent of the course 43° 21', so is the mer. diff. of latitude 237, to 9.82664.

is to the mer. diff. of latitude 237, so is the sine of the course 43° 21', to 10.00000.

is to the mer. diff. of latitude 237, so is the sine of the course 43° 21', to 9.97497.

is to the mer. diff. of latitude 237, so is the sine of the course 43° 21', to 2.34972.

Longitude of Naples 14° 14'. E.

Difference of longitude 3° 44', W.

Longitude in 10° 30' E.

By Inspection.

Under 45° and opposite to the distance 252 m. the departure is 173.8, and under 44°, and opposite to the same distance, the departure is 175.0.

Then as 3.2 : 1.2 :: 60 : 22.

Hence the course is 43° 22'.

Again, under 45° and opposite to 118.5, half the meridional difference of latitude in a latitude column, is 110.5 in a departure column; also under 44°, and opposite to 118.5 is 114.4.

Then as 3.2 : 1.2 :: 3.9 : 1.5.

And 110.5 + 1.5 = 112, which doubled is 224, the difference of longitude.

By Gunter's Scale.

The extent from the distance 252 on numbers to 90 on fines will reach from the departure 173 on numbers to the course 43° on fines; and the same extent that will reach from the complement of the course 46° on fines will reach to the difference of latitude on numbers.—Again, the extent from 45° to 43° on tangents will reach from the meridional difference of latitude 237 to the difference of longitude 224 on numbers.

Prob. VIII. Given one latitude, course and difference of longitude, to find the other latitude and distance.

Example. A ship from Tercera, in latitude 38° 45' N, longitude 27° 6' W, sailed on a direct course, which, when corrected, was N 32° E, and is found by observation to be in longitude 18° 24' W. Required the latitude came to, and distance sailed?

Longitude of Tercera 27° 6' W.

Longitude in 18° 24' W.}

Difference of longitude - - - 8 42 = 522.

By
Mercator's Conformity. By Construction.

Make the right angled triangle ADE (fig. 36) having the angle A equal to the course 32°, and the side DE equal to the difference of longitude 522, then AD will measure 855, which added to the meridional parts of the latitude left, will give the difference of latitude come to 48° 46', hence the difference of latitude is 601: make AB equal thereto, to which let BC be drawn perpendicular; then AC applied to the scale will measure 708 miles.

By Calculation.

To find the meridional difference of latitude.

As radius, is to the co-tangent of the course 32° 0' 10.00000
so is the difference of longitude 5 22 2.71767
to the mer. difference of latitude 835 2.92188
Latitude of Tercera 38° 45' N Mer. parts 2526
Mer. diff. of lat. 835

Latitude come to 48 46 N. Mer. parts. 3361

Difference of latitude 10 1 = 601 miles.

To find the distance.

As radius, is to the secant of the course 32° 0' 10.00000
so is the difference of latitude 601 2.77887
to the distance 707.7 2.85045

By Inspection.

To course 32°, and opposite to 130.5, one fourth of the given difference of latitude in a departure column, the difference of latitude is 208.8, which multiplied by 4 is 835, the meridional difference of latitude; hence the latitude in is 48° 46' N, and difference of latitude 601.

Again, to the same course, and opposite to 200, one third of the difference of latitude, the distance is 236, which multiplied by 3 gives 708 miles.

By Gunter's Scale.

The extent from the course 32° to 45° on tangents will reach from the difference of longitude 522 to the meridional difference of latitude 835 on numbers.—And the extent from the complement of the course 58° to 90° on lines, will reach from the difference of latitude 601 to the distance 708 miles on numbers.

Prob. IX. To find the difference of longitude made good upon compound courses.

Rule. With the several courses and distances, complete the Traverse Table, and find the difference of latitude, departure, and course made good, and the latitude come to as in Traverse Sailing. Find also the meridional difference of latitude.

Now, to the course and meridional difference of latitude in a latitude column, the corresponding departure will be the difference of longitude, which applied to the longitude left will give the ship's present longitude.

Example. A ship from Port St Julian, in latitude 49° 10' S, longitude 68° 44' W, failed as follows, ESE 53 miles, SE by E 74 miles, E by N 68 m. SE by E 47 miles, and E 84 miles. Required the ship's present place?

Although the above method is that usually employed at sea to find the difference of longitude, yet as it has been already observed, it is not to be depended on, especially in high latitudes; in which case the following method becomes necessary.

Rule II. Complete the Traverse Table as before, to which annex five columns. Now with the latitude left, and the several differences of latitude, find the successive latitudes, which are to be placed in the first of the annexed columns; in the second the meridional parts corresponding to each latitude is to be put; and in the third, the meridional differences of latitude.

Then to each course, and corresponding meridional difference of latitude, find the difference of longitude, which place in the fourth or fifth columns, according as the course is easterly or westerly; and the difference between the sums of these columns will be the difference of longitude made good upon the whole of the same name with the greater.

Remarks.

1. When the course is north or south, there is no difference of longitude.

2. When the course is east or west, the difference of longitude cannot be found by Mercator's Sailing; in this case the following rule is to be used.

To the nearest degree to the given latitude taken as a course, find the distance answering to the departure in a latitude column: this distance will be the difference of longitude.
**EXAMPLE II.** A ship from latitude 78° 15' N, longitude 28° 84' E, sailed the following courses and distances. The latitude come to is required, and the longitude, by both methods: the bearing and distance of Hcluit's head-land, in latitude 79° 55' N, longitude 11° 55' E, is also required.

**Traverse Table.**

</tbody>
</table>

By Rule 1st.

Latitude left 78° 15' N, Mer. pts = 7817

Diff. of latitude 2 7 N.

Lat. come to 80 22 N, Mer. pts = 8504

Meridional diff. of latitude 687

As difference of lat. 126.9

is to mer. diff. of latit. 2.10346

so is the departure 264.6

so is the diff. of longitude 242256

Latitude left 315606

Longitude left 28° 14' E.

Longitude in 4 22 E.

The error of this method in the present example, is therefore 1° 23'.

Longitude left - 28° 14' E.

Difference of longitude - 22 29 W.

Longitude in - 5 45 E.

To find the bearing and distance of Hcluit's head-land.

Lat. H H. = 79° 55' N, M. P. 8347 Long. 11° 55' E.

Lat. ship = 80 22 N, M. P. 8504 Long. 5 45 E.

Diff. lat. 0 27 M. D. L. 157 D. L. 6 10

Now to 78.5 half the meridional difference of latitude, and 185.0 half the difference of longitude, the course 65°, and opposite to the difference of latitude 27, the distance is 69 miles. Hence Hcluit's head-land bears S 67° E, distant 69 miles.
PROBLEMS OF MERCEER'S SAILING.

CHAP. VII. Containing the Method of resolving the several Problems of Mercator's Sailing, by the Assistance of a Table of Logarithmic Tangents.

Prop. The constant quantity 12.633114 (6) is to the difference or sum of the logarithmic tangents of half the co-latitudes of two places, according as those latitudes are of the same, or a contrary denomination; as the tangent of the course is to the difference of longitude.

Demonstr. Let CABP, Plate CCCXXXVIII. fig. 37, be a section of one fourth of the earth in the plane of the meridian; and let AC be the radius of the equator, and B any given place whose latitude is therefore AB. Draw BD perpendicular to AC, and BE parallel to it; and let BB be a very small portion of the meridian, as one minute. — Now put CA = r, DB = x, BE = y, and z = meridional parts answering to Method of resolving the Problems of Mercator's Sailing.

Then, \( \frac{r}{x} = \frac{r}{x} \times \frac{r + y}{x} \times bn \)

but, \( \frac{r}{x} = \frac{r}{x} \times \frac{r + y}{r - y} \times bn \) is correspondent portion of the enlarged meridian. Now these being put into fluxions, we have:

\[ \frac{1}{r} = \frac{r + y}{x} \times \log \left( \frac{r + y}{r - y} \right) \]

Of which the fluent is,

\[ \frac{1}{r} = \frac{2.302585 \times r \times \log \left( \frac{r + y}{r - y} \right)}{2} \]

Now as the meridional parts are expressed in parts of the equator, this equation becomes,

\[ z = \frac{2.302585 \times x \times \log \left( \frac{r + y}{r - y} \right)}{3.15149} \times \text{log.} \frac{r + y}{r - y} \]

But \( \frac{r + y}{r - y} = \text{log.} \frac{r + \text{fine} \ AB}{r - \text{fine} \ AB} = \text{log.} \frac{\tan \left( 45 + \frac{1}{2} \ AB \right)}{\tan \left( 45 - \frac{1}{2} \ AB \right)} \)

And the tang. \( \left( 45 + \frac{1}{2} \ AB \right) = \frac{1}{\text{log. tang.} \left( 45 + \frac{1}{2} \ AB \right)} = \frac{1}{\text{log. tang.} \left( 45 - \frac{1}{2} \ AB \right)} \)

Therefore \( z = \frac{2.302585 \times x \times \log \left( \frac{r + y}{r - y} \right)}{3.15149} \times \text{log.} \frac{r + y}{r - y} \)

Hence the meridional parts answering to any given latitude, is found by dividing the difference between the log. of the radius and the log. tangent of half the complement of latitude, by the constant quantity .001263314, &c.; and the meridional difference of latitude is obtained by dividing the difference or sum of the logarithmic tangents of half the co-latitudes, according as they are of the same or a contrary name, by the above quantity.

And the meridional difference of latitude multiplied

In
Method of solving the Problem of Mercator's sailing.

In the triangle A to co. course 48° and alt. corr. 1° 55', the second correction is 2; to course 41° and diff. long. 5°, the number is 6, of which \( \frac{1}{9} \) (Tab. B) being taken gives 1.

True course 9. 43 33 W

To find the difference of latitude.

As radius is to the cosine of the course 43° 33' = 9.86020

so is the distance 209, 2.6240

to the difference of latitude 30.6 30.6

Latitude left 70.6 30.6

Difference of latitude 10.0 0.0

Latitude come to 60. 0. 0

It was intended in this place to have given rules, to make allowance for the spheroidal figure of the earth, but as the ratio of the polar to the equatorial semiaxis is not as yet determined with sufficient accuracy, neither is it known if both hemispheres be similar figures; therefore these rules would be grounded on assumption only, and which might probably err more from the truth than those adapted to the spherical hypothesis. This therefore is supposed to be a sufficient apology for not inserting them.

Chap. VIII. Of Oblique Sailing.

Oblique sailing is the application of oblique angled plane triangles to the solution of problems at sea. This failing will be found particularly useful in going along shore, and in surveying coasts and harbours, &c.

Example I. At 11th A. M. the Girdlens bore W NW, and at 2h P. M. it bore NW; and to 15 miles the distance failed. From H draw HF in a NW direction, and the point F will represent the Girdlens. Now the distances CF, HF will measure 19.1 and 26.5 miles respectively.

Calculation.

In the triangle FCH are given the distance CH 15 miles; the angle FCH equal to 9 points, the interval between the SW and WNW points; and the angle CHF equal to 4 points, being the supplement of the angle contained between the SW and WNW points; hence CFH is 3 points; to find the distances CF, FH.

To find the distance CF.

As the fine of CFH 3 points = 9.74474

so is the fine of CH 15 miles = 1.17609

to the distance CF 19.07 = 1.28083

To find the distance FH.

As the fine of CH 15 points = 9.74474

so is the fine of FCH 9 points = 9.99157

Practice.

To the distance FH 26.48 = 1.42292

Example II. The distance between the SE point of the island of Jersey and the island of Brehat is 13 leagues; and the correct bearing and distance of Cape Frehel from the island of Brehat is SE 26°.

It is also known that the SE point of Jersey bears NNE from Cape Frehel; from whence the distance of these two is required, together with the bearing of the said point from the island of Brehat.

By Construction.

Describe a circle, (fig. 39) and draw two diameters at right angles, the extant of which will represent the cardinal points, north being uppermost. Let the centre B represent Brehat, from which draw the SE line BF equal to 26 miles, and the point F will represent Cape Frehel, from which draw the NNE line FI; make BI equal to 39 miles. Then FI applied to the scale will measure 34.1 miles, and the inclination of BI to the meridian will be found equal to 63°.

By Calculation.

In the triangle BIF are given BI and BF equal to 39 miles, and 26 miles respectively; and the angle BFI equal to 7 points to find the sides FI, and angle FBI.

To find the angle BFI.

As the distance BI 39 = 1.59106

is to the distance BF 26 = 1.41407

so is the fine of BFI 78° 45' = 9.99157

to the fine of BFI 40 50 = 9.81548

Sum \( \frac{1}{2} \) = 119 35

Angle FBI = 60 25

---

EBF = 33 45

Difference, or EBI = 26 40

Bearing of Jersey from Brehat N 63° 20 E

To find the distance FI.

As the fine of BFI 78° 45' = 9.99157

is to the fine of EBI 60 25 = 9.33934

so is the distance BI 39 miles = 1.59106

to the distance FI 34.58 = 1.53883

Example III. At noon Dungeness bore per compass NW distance 5 leagues; and having run NW 7 knots an hour, at 5 P. M. we were up with Beachyhead. Required the bearing and distance of Beachyhead from Dungeness.

By Construction.

Describe a circle (fig. 40) to represent the horizon; from the centre C draw the NW line CD equal to 15 miles; and the NW line CB equal to 35 miles; join DB, which applied to the scale will measure about 26.1 miles; and the inclination of DB to the meridian will be found equal to N 79° W.

By Calculation.

In the triangle DBC are given the distances CD, CB equal to 15 and 35 miles respectively; and the angle BCD equal to 4 points; to find the angles B and D, and the distance BD.

To
Practice.

Navigation.

Oblique Sailing.

Distance CB = 45 points of the ast, 16 points
CD = 15 angle C 4

Sum 50 angles B and D 12
Difference 20 half sum 6 pts. = 6° 30' 1.69807
As the sum of the distances is to their difference 50 20 1.30103
so is the tangent of half sum angles 67 30 10.38378
to the tangent of half their differ. 44 0 9.68484
Angle CDB - - 111 30
Supplement - - 68 30
Angle NCD - - 11 15

Magnetic bearing, N 79° 45' W. Or by
Allowing 2° points of weekly variation, the true bearing of
Beauchamp from Dungeness will be W 1° 3 nearly.

To find the distance.
As the sine of CBD = 111° 30' 9.68688
is to the sine of BCD 45° 9.84948
so is the distance BC = 35 1.54407
to the distance BD = 26.6 1.44347

Example IV. Running up Channel E8S per compas at the rate of 5 knots an hour. At 11 A.M.
the Eddystone light-house bore N66°E, and the Star point N68°E; and at 4 P.M. the Eddystone bore
N00°N, and the Star N 14°. Required the distance and bearing of the Eddystone, the variation being 2° points W?

By Construction.

Let the point C (fig. 41.) represent the first station, from which draw the N86°E line CA, the N86°E
line CB, and the E8S line CD, which make equal to 25 miles, the distance run in the elapsed time; then from
D draw the N80° line DA intersecting CA in A, which represents the Eddystone; and from the same
point draw the N81°E line DB cutting CB in B, which therefore represents the Star. Now the distance AB
applied to the scale will measure 22.9, and the bearing per compas BAF will measure 73° 37'

By Calculation.

In the triangle CAD are given CD equal to 25 miles, the angle CAD equal to 45° points, the distance
between N66°E and N00°N; and the angle ADC equal to 4 points, the distance between the N00°N
and W82°; to find the distance CA.

As the sine of CAD = 45° points 9.86979
is to the sine of CDA 4 points 9.84948
so is the distance CD = 25 miles 1.37763
to the distance CA = 23.86 1.37763

In the triangle BCD are given the distance CD 25 miles, the angle CBD 4° points the interval between
N86°E and N81°E; and CDB 71 points, the distance between W82° and N80°E; to find the distance CD.

As the sine of CDB = 4° points 9.88819
is to the sine of CDB 71 points 9.99956
so is the distance CD = 25 miles 1.39794
to the distance CB = 32.3 1.50922

In the triangle CAB, the distances CA, CB, are
given, together with the included angle ACB, equal to
4 points, the distance between N86°E and N81°E; to
find the angle CAB and distance AB.

Distance CB = 32.3 Angle ACB = 45° 0'
Distance CA = 23.86 Sum of CAB and ABC 135°

Sum - 56.16 Half - 67 30
Difference 8.44
As the sum of the distances is to their difference 56.16 8.44 0.92634
so is the tangent of half sum angles 67 30 10.38278
to the tangent of half diff. 19.56 9.55969
Angle CAB - 87.26
Angle CAF - + 4

Bearing per compas = S 73° 22' E or ESE; E; and the variation 2° points being allowed to the left of
E8S ESE gives E3N, the true bearing of the Start from the Eddystone.

To find the distance.
As the sine of CAB = 87° 26' 9.99956
is to the sine of ACB 45° 9.84948
so is the distance CB = 32.3 1.50922
to the distance AB = 22.86 1.35914

Example V. A ship from a port in latitude 57°
9' N, longitude 2° 9' W, sailed 82 miles on a direct
course, and spoke a ship that had run 100 miles from
a port in latitude 56° 21' N, longitude 2° 53' W.—
Required the course of each ship, and the latitude and
longitude come to?

Lat. = 57° 9' N Mer. parts 4199 Lon. 2° 9' W
56° 21' N 4112 2° 50 W

Diff. of lat. 48 Mer. diff. lat. 87 Diff. lon. 41

By Construction.

With the meridional difference of latitude, the differ
ence of longitude, and difference of latitude, con
struct the triangles ADE, ABC (fig. 42.) as in Mer
cator's Sailing; then A will represent the northern
moll, and C the southernmost port. The distance
AC applied to the scale will measure 53 miles, and
the bearing BCA will be 25° 47'. From the points A
and C, with distances equal to 82 and 100 miles re
spectively, describe arches intersecting each other in
M, which will therefore be the place of meeting.
Now the angle ABM, the ship's course from the
southernmost port, will measure N 80° 8' E; and the
other ship's course, or angle BAM, will be 67° 4',
or ESE. From M draw the parallel MNP, and AN
will be the difference of latitude made by the one ship,
and CP that by the other ship; hence either of the
being measured and applied to its correspondent latitude,
will give 50° 38', the latitude in. Make AF
equal to 57, the meridional difference of latitude be
 tween the southernmost port and latitude in: from F
draw FG perpendicular to AF, and produce AM to
G, then FG will be the difference of longitude, which
applied to the scale will measure 159; hence the lon
itude in is 8° 10' E.
NAVIGATION

By Calculation.

In the triangles ADE, ABC, are given AD equal to 87, DE equal to 41, and AB equal to 48; to find the angle BAC and distance AC.

To find the bearing of the ports.
As the meridional diff. of lat. 87, fo is radius 1.93952
is to the diff. of long. - 41, fo is radius 1.61278
fo is the mer. diff. of lat. 57, to the diff. of long. - 1.75587
Windward Sailing.

Longitude left - - 139.8 2.14547
Difference of longitude - - 2° 9' W
Longitude in - - 0 11 E

CHAP. IX. Of Windward Sailing.

WINDWARD failing is, when a ship by reason of a contrary wind is obliged to sail on different tacks in order to gain her intended port; and the object of this failing is to find the proper course and distance to be run on each tack.

Example I. A ship is bound to a port 48 miles directly to the windward, the wind being SSW, which it is intended to reach on two boards; and the ship can lie within 6 points of the wind. Required the course and distance on each tack?

By Construction.

Draw the SSW line CB (fig. 43.) equal to 48 miles. Plate Make the angles ACB, ABC, each equal to 6 points. Hence the first course will be W, and the second SE: also the distance CA, or AB, applied to the scale will measure 62° 7 1.79737 miles, the distance to be sailed on each board.

By Calculation.

From A draw AD perpendicular to BC; then in the triangle ADC are given CD, equal to 24 miles; and the angle ACD, equal to 6 points, to find the distance AC.
As radius - - 10.00000
is to the secant of C - 6 points - 10.41716
fo is CD - 24 miles - 1.38021

EXAMPLE II. The wind at NW, a ship bound to a port 64 miles to the windward, proposes to reach it on three boards; two on the larboard, and one on the portboard tack, and each within 5 points of the wind. Required the course and distance on each tack?

By Construction.

Draw the NW line CA (fig. 44.) equal to 64 miles; from C draw CB W&S, and from A draw AD parallel thereto, and in an opposite direction; bisect AC in E, and draw BED parallel to the NE rhumb, meeting CB, AD in the points B and D: then CB=AD applied to the scale will measure 36° 4 1.38021 miles, and BD=2CB=72° 7 1.79737 miles.

By Calculation.

From B draw BF perpendicular to AC; then in the triangle BCF are given the angle BCF equal to 5 points, and CF equal to one fourth of CA=16 m. to find CB.
As radius - - 10.00000
is to the secant of BCF, - 5 points - 10.25526
fo is CF - 16 m. - 1.20412

EXAMPLE III. A ship which can lie within 5 1.55938 points of the wind, is bound to a port 36 miles to the windward, the wind being NE&N, which it is intended to reach

Longitude left - - 193.0 2.14547
Difference of longitude - - 2° 9' W
Longitude in - - 0 11 E

By Calculation.

From A draw AD perpendicular to BC; then in the triangle ADC are given CD, equal to 24 miles; and the angle ACD, equal to 6 points, to find the distance AC.
As radius - - 10.00000
is to the secant of C - 6 points - 10.41716
fo is CD - 24 miles - 1.38021

EXAMPLE IV. A ship is bound to a port 36 miles directly to the leeward, the wind being NSE, which it is intended to reach...
Practise.

Windward sailing.

Draw the N2E line CA (fig. 46.) equal to 36 miles, and bisection it in B; from C and B draw lines parallel to the E:SE rhumb; and from A and B draw lines parallel to the SSE; E point, meeting the former in the points D and E. Now the distances AD, BD, BE, and CE, are equal; and any one of them applied to the scale will measure 19.1 miles.

By Calculation.

From E draw EF perpendicular to AC; and in the triangle CFE given CF=9 m. and the angle FCE = 51°, to find CE.

As the radius

\[ 10,00000 \]

is to the secant of FCE

\[ 51 \text{ points} \]

so is CF

\[ 9 \text{ miles} \]

\[ 0.95424 \]

to the distance CE

\[ 19.1 \text{ miles} \]

1.28085

Example IV. A ship bound to a port bearing NW distant 40 miles, with the wind at NSE; E intends to reach it on two boards. Required the course and distance on each tack, the ship lying within 5° points of the wind.

By Construction.

Draw the NW line CA (fig. 46.) equal to 40 miles; and because the wind is SSW; E, and the ship can lie within 5° points of the wind, the course on the larboard tack will be EEN, and on the starboard NW. Therefore, from the centre C draw the ESN line CB, and from it draw the NW line AB, meeting CB in B; then CB and AB applied to the scale will measure 26.7 and 45.1 miles respectively.

By Calculation.

In the triangle ACB, given AC = 40 miles, and the angles A, B, and C, equal to 31°, 56°, and 8 points respectively, to find AB and BC.

To find the distance CB.

As the sine of B

\[ 5 \text{ points} \]

is to the sine of A

\[ 3 \text{ points} \]

so is the distance CA

\[ 40 \text{ miles} \]

\[ 1.60206 \]

to the distance CB

\[ 26.73 \]

1.42695

To find the distance AB.

As the sine of B

\[ 5 \text{ points} \]

is to the sine of C

\[ 8 \text{ points} \]

so is the distance CA

\[ 40 \text{ miles} \]

\[ 1.60206 \]

to the distance AB

\[ 48.11 \]

1.08212

Example V. A ship close hailed within 5 points of the wind, and making one point of lee-ways, is bound to a port bearing SSW, distant 54 miles, the wind being SSW; E. It is intended to make the port at three boards, the first of which must be on the larboard tack in order to avoid a reef of rocks. Required the course and distance on each tack.

By Calculation.

Draw the SSW line CA (fig. 47.) equal to 54 m. and as the wind is SSW, and the ship makes her course good within 6 points of the wind, therefore the course on the larboard tack will be SSW, and on the starboard ESE: hence from C draw the SSW line CB, and from A draw AD parallel thereto; bisection CA in E. and draw BED parallel to the ESE line; then will

CB and AD be the distances on the larboard tack, which applied to the scale, each will be found to measure 37.4; and the distance on the starboard tack BD will measure 42.4 miles.

By Calculation.

The triangles CBE, EAD are equal and similar; hence the ratio of these are given CE, equal to 27 miles, half the distance between the ship and port; the angles C, B, and E, equal to 31°, 46°, and 9 points respectively, to find CB and BE.

To find CB, the distance on the larboard tack.

As the fine of B

\[ 4 \text{ points} \]

is to the fine of E

\[ 9 \text{ points} \]

so is the distance CE

\[ 27 \text{ miles} \]

\[ 1.43135 \]

to the distance BC

\[ 37.45 \]

1.57345

To find BE half the distance on the starboard tack.

As the fine of B

\[ 4 \text{ points} \]

is to the fine of C

\[ 3 \text{ points} \]

so is the distance CE

\[ 27 \text{ miles} \]

\[ 1.43135 \]

to the distance BE

\[ 21.21 \]

1.32662

Whole distance AC

\[ 42.42 \]

Example VI. A ship plying to the windward, with the wind at NNE, after sailing 51 miles on each of two tacks, found by observation to have made 36 miles of difference of latitude. How near the wind did she make her way good?

By Construction.

Make CA (fig. 48.) equal to 36 miles; draw AB perpendicular to CA, and draw the NNE line CB, meeting AB in B; make CD, BD each equal to 51 miles; and these being measured, will be found equal to 6 points.

By Calculation.

In the triangles CAB, BCD, are given AB equal to 36m. CD=BD=51, and the angle ACB equal to 2 points, to find the angle BCD.

As the distance CD

\[ 51 \text{ miles} \]

is to the differ. of latitude CA

\[ 18 \text{ miles} \]

so is the secant of ACB

\[ 2 \text{ points} \]

\[ 10,03438 \]

to the cosecant of BCD

\[ 67° 59' \]

9.58208

Example VII. A ship that makes her way good within 6 points of the wind, reaches her port on two boards; first being on the larboard tack 35 miles, and the other on the starboard tack 39 miles; and the difference of latitude 21 miles north. Required the bearing of the port, and direction of the wind?

By Construction.

With the given distances 25 and 38 miles and the included angle equal to 16°-2 x 6° = 3 points, construct the triangle BCD (fig. 49.); hence CB will be known.

Draw CA equal to 21 miles, the given difference of latitude; from A draw AB perpendicular to CA, and make CB equal to what it was before determined; make DE=DC, and draw the line CE, which will represent the direction of the wind, and the angle ACB is the bearing of the port, now ACE will be found equal to 52°; and ACB 18°.

By Calculation.

In the triangle BCD are given BC=25m. BD=38m. and the angle D=3 points, to find the angle BCD, and distance CB.
Chap. X. Of Current Sailing.

The computations in the preceding chapters have been performed upon the assumption that the water has no motion. This may not always answer tolerably well in those places where the ebings and flowings are regular, as then the effect of the tide will be nearly counterbalanced. But in places where there is a constant current or setting of the sea towards the same point, an allowance for the change of the ship's place arising therefrom must be made: And the method of resolving these problems, in which the effect of a current, or heave of the sea, is taken into consideration, is called current sailing.

In a calm, it is evident a ship will be carried in the direction and with the velocity of the current. Hence, if a ship fails in a direction, of the current, her rate will be augmented by the rate of the current; but in failing directly against it, the distance made good will be equal to the difference between the ship's rate as given by the log and that of the current. And the absolute motion of the ship will be a head, if her rate exceeds that of the current; but if less, the ship will make sternway. If the ship's course be oblique to the current, the distance made good in a given time will be represented by the third side of a triangle, whereof the distance given by the log, and the drift of the current in the same time, are the other sides; and the true course will be the angle contained between the meridian and the line actually described by the ship.

Example I. A ship sailed NNE at the rate of 8 knots an hour, during 18 hours, in a current setting 

Example II. A ship from a port in latitude 42° 52' N, sailed SW, W 17 miles in 7 hours, in a current setting between the north and west; and then the same port bore ENE, and the ship's latitude by observation was 42° 42' N. Required the setting and drift of the current?

By Construction.

Draw the SSW line CA (fig. 51) equal to 17 x 8 = 136 miles; and from A draw AB parallel to the NW line, and equal to 18 x 2 = 45 miles: now BC being joined will be the distance, and NBC the course. The drift of this will measure 159 miles, and the second 6° 23'.

By Calculation.

In the triangle ACB, given AC = 144 miles, AB = 45 miles, and the angle CAB = 9 points, to find BAC and BC.

To find the course made good.

Diff. AC 144
Angle BAC = 9 pts = 101° 15'
Diff. AB 45
Sum 189
B + C 78 45
Diff. 99 2

As the sum of the sides is to the difference of the sides, so is the tan. of the half sum angles to the tan. of the half diff. angles.

To find the distance.

As the sine of BCD is to the sine of BDC, so is the distance BD to the distance BC.

To find the angle ACB, the bearing of the port.

Angle ACB = 16° 7'
Angle ACN = 22° 30'

Course made good = N 6° 23' E

To find the distance.

As the sine of ACB = 16° 7' = 0.2766 is to the sine of CAB = 101° 15' = 0.999563, so is the distance AB = 45 to the distance BC = 159.

Example II. A ship from a port in latitude 42° 52' N, sailed SW, W 17 miles in 7 hours, in a current setting between the north and west; and then the same port bore ENE, and the ship's latitude by observation was 42° 42' N. Required the setting and drift of the current?

By Construction.

Draw the SSW line CA (fig. 51) equal to 17 x 8 = 136 miles; and from A draw AB parallel to the NW line, and equal to 18 x 2 = 45 miles: now BC being joined will be the distance, and NBC the course. The drift of this will measure 159 miles, and the second 6° 23'.

By Calculation.

In the triangle CBD, given CB = 10 miles, and the angle cabinet AB = 6 points; to find the distance CD.

As radius = 10,0000 is to the secant of BCD = 6 points = 10.441710, so is the diff. of lat. CB = 10 miles = 1,000000, to the distance CD = 26.13 = 1,41710.

Again, in the triangle ACD are given the distance AC = 17 miles, CD = 26.13, and the angle ACD 47 points; to find the remaining parts.
Now, in the triangle CDB are given the difference of latitude and departure; to find the course and distance.

To find the course.

As the difference of latitude CD = 38° 14' to the tangent of the course 9.94279

To find the distance.

As radius = 10,00000 to the secant of the course 41° 14' = 10,12376

By Calculation.

In the triangle ABC, given BB = 20 m, AC = 22 m, and the included angle A = 3 points; to find the remaining parts.

To find the setting of the current.

Distance AC = 22 m. Included angle = 3 points.

By Calculation.

From A (fig. 53.) draw the SE5S line AB = 20, which will represent the ship's apparent track through the water; draw AC equal to 22 miles south, and C will be the ship's real place; and BC being joined will be the current's drift in four hours; which applied to the scale will measure 12.3; from A draw AD parallel to BC, and the angle CAD will be the direction of the current, and will be found to measure 64° 41'.

To find the drift of the current.

Hence the hourly rate of the current is 20.2 = 2.9 knots.

EXAMPLE III. A ship, from latitude 38° 20' N, sailed 24 hours in a current setting NW/N, and by account is in latitude 38° 42' N, having made 44 miles of sailing; but the latitude by observation is 38° 58' N. Required the course and distance made good, and the drift of the current.

By Calculation.

Make CE (fig. 53.) equal to 22 miles, the difference of latitude by D R, and EA = 44 miles, the departure, and join CA; make CD = 38 miles, the difference of latitude by observation; draw the parallel of latitude DB, and from A draw the NW5S line AB, interferring DB in B, and AB will be the drift of the current in 24 hours; CB being joined, will be the distance made good, and the angle DCB the true course. Now, AB and CB applied to the scale, will measure 19.2 and 50.5 respectively; and the angle DCB will be 41° 14'.

By Calculation.

From B draw BF perpendicular to AE, then in the triangle ABF are given BF = 16 miles, and the angle ABF = 3 points; to find AB and AF.

To find the drift of the current AB.

As radius = 10,00000

is to the secent of ABF = 3 points 10.08015

fo is BF = 16 miles 1.20412

Hence the hourly rate of AB = 19.24 = 0.8.

To find AF.

As radius = 10,00000

is to the tangent of ABF = 3 points 9.82489

fo is BF = 16 1.20412

Hence the hourly rate of AF = 10.69 = 0.8.

By Calculation.

To find the course.

As the difference of latitude CD = 38° 14' = 9.94279

To find the distance.

As radius = 10,00000 to the tangent of the course 41° 14' = 10,12376

EXAMPLE IV. In the Straits of Sunda, at 2 P.M. steering SE5S at the rate of 5 knots an hour, I pulled close by the SE of the small island off Hog point. At 6, not having changed our course, came to anchor on the Java shore. Upon setting the said island from this anchoring place, I find it bears due north, its distance by the chart being 22 miles. It follows from hence, that our course has been affected by a current. Required its velocity and direction?

By Confirmation.

EXAMPLE V. A ship bound from Dover to Calais, lying
NAVIGATION

Plate XXXI.

Plate SDB

Course SDB = 39 14 = SE 8.
In the triangle DBC, given DC = 21 miles, the angle BDC = DFE = 22° 38, and the angle DCB = 63°.
As the hourly rate of failing is to the hourly rate of the current 6 m. : 21 m.
As the distance DBC = DFE = 22° 38, and the distance DB = DB.
As the distance by the log DB = 19.4 m.
Example VI. A ship at sea in the night has sight of Scilly light, bearing NE, distant 4 leagues, it being then flood tide, setting ENE 2 miles an hour. What course and distance must the ship sail to make the Lizard, which bears from Scilly E, distance 17 leagues?

By Construction.
Draw the NE line AS = 12 miles (fig. 55), hence S will represent Scilly; from S draw SL = 51 miles, and parallel to the E S S ; then L will represent the Lizard; draw LC parallel to the ENE, and equal to 2 miles, and make CD = 5 miles; from A draw AB parallel to CD, meeting LC produced in B; then AB will be the distance, and the angle SAB the course: the first of these applied to the scale will measure 41.9 miles, and the course will be S 88° E.

By Calculation.
In the triangle SAL are given the sides AS, SL = 12 and 51 miles respectively, and the angle ASL = 101 points; to find the other parts.

To find the angles.
Distance SL = 51 m. Angle ASL = 101 points.
As = 12 m. SL + SLA = 51
Sum 63 m. SL + SLA = 51
Difference 39 m.
As the sum of the sides is to the difference of the sides 63 : 39.
As the tangent of half the sum of the angles 1.79934 : 1.59106.
As the tangent of half the difference 9.77763.
Angle SAL = 31 17.

Practice.
Instruments to solve Problems in Sailage, Independent of Calculation.

VARIOUS methods, beside those already given, have been proposed to save the trouble of calculation.—One of these methods is by means of an instrument composed of rulers, so disposed as to form a right-angled triangle, having numbers in a regular progression marked on their sides. These instruments are made of different materials, such as paper, wood, brass, &c. and are differently constructed, according to the fancy of the inventor. Among instruments of this kind, that by John Cook, Esq. seems to be the best.

A number of other instruments, very differently constructed, have been proposed for the same purpose; of these, however, we shall only take notice of the rectangular instrument, by And. Mackay, A. M., F. R. S. E.

I. Of Cook's Triangular Instrument.

Description. The block a b c d (fig. 56) is a parallelepiped: The length from a to b is two feet, the breadth from a to d two inches, and the depth is one inch and a half. The block is perforated longitudinally, so as to be capable of containing within it e f, a cylindrical piece of wood one inch diameter; g b is an aperture on the surface of the block about a quarter of an inch wide, which difdoses one-twelfth part.
of the surface of the cylinder contained; the edge $de$ is divided into twelve parts, each of these is subdivided into six parts, and each of these again into ten parts. The surface of the cylinder is divided longitudinally into twelve parts, and on each of them is engraved a portion of a line of meridional degree of 22 feet long, which contains the meridional parts for every minute from the equator as far towards the pole as navigation is practicable; and the smallest division on is not less than $\frac{1}{10}$ th of an inch. By rolling and sliding this cylinder, any part of any line on it may be brought into any position which may be required: the box $i$ is engraved into the edge of the block $a$, so that it may move freely from $a$ to $b$; a limb from this box extends to $k$, which serves to mark that degree of the perpendicular $l$ which is parallel to the centre of the semicircle $m$; $ll$ is two feet long, and graduated on both edges as the block; it is perpendicular to the block, and is fixed in the box $i$, by which it may be moved from $a$ to $b$; $o$ $p$ $n$ is a semicircle of six inches radius, engraved, as appears in the plate, which slides freely from $c$ to $d$ in a groove in the edge of the block $c$ $d$; $m$ $q$ is the index moving on the centre $m$, the edge of which marks the course on the semicircle; it is two feet long, and divided into 72 parts; and there are subdivided in the same manner as those on the block and perpendicular to which they are equal; $p$ is a vernier attached to the index to show minutes; $s$ is a vernier composed of concentric semicircles, which slides along the edge $g$, to the intersection of the perpendicular and index, where it serves as a vernier to both. Below the side of ivory, with a mark on it to point out the degree of the line $d$, which is perpendicular under the centre of the semicircle. Fig. 57, is a view of the back part of the instrument.

_U/s_ - The method of working every cafe which occurs in navigation, is to make the instrument similar to that ideal triangle which is composed of the difference of latitude, departure, and distance; or, to that composed of the meridional difference of latitude, difference of longitude, and enlarged distance; or, to that composed of the difference of longitude, departure, and fine, of the middle Latitude; which is done by means of the data procured from the compass, log-line, and quadrant: whence it follows, from the nature of similar triangles, or from the relation which exists between the sides of triangles and the lines of their opposite angles, that the parts of the instrument become proportional to those which they represent; and will ascertain the length of the lines, or the extent of the angles sought, by its graduations.

In the practice of this instrument, a small square is necessary, in order to bring the centre of the semicircle perpendicularly over the meridional degree corresponding to the latitude.

_Prob. I._ The course and distance failed being given, to find the difference of latitude and departure.

_Example._ A ship from latitude $24^\circ 18'$ failed NW by N 168 miles. Required the latitude come to, and departure?

Set the centre of the semicircle perpendicularly over the given latitude $24^\circ 18'$, and the index to the course 3 points; move the perpendicular until it cut the index at the given distance 168; then at the point of intersection on the perpendicular is 93.3 miles, the departure, and on the base, by the edge of the box, is $2.3^\circ 38'$, the latitude come to.

_Prob. II._ Both latitudes and course given, to find the distance and departure.

_Example._ Let the latitude failed from be $43^\circ 50'$, that come to $47^\circ 8'$ N, and the course NNE. Required the distance and departure?

Move the centre of the semicircle to the latitude left $43^\circ 50'$, and the edge of the box to the latitude come to $47^\circ 8'$; fix the index at the given course 2 points; then at the point of intersection of the index and the departure 214 miles on the index, and the departure 82 miles on the perpendicular.

_Prob. III._ Given the course and departure, to find the distance and difference of latitude.

_Example._ Let the latitude failed from be $32^\circ 30'$ N, the course SW by S, and the departure 200 miles. Required the distance and latitude come to?

Move the centre of the semicircle to the latitude left $32^\circ 30'$, set the index to the given course 3 points, and move the perpendicular till the given departure 200 cuts the index; at this point on the index is 560 miles, and the edge of the box will cut the latitude come to $27^\circ 39'$ N.

_Prob. IV._ Given the difference of latitude and distance, to find the course and departure.

_Example._ Let the latitude left be $17^\circ 10'$ N, the latitude come to $21^\circ 40'$ N, and the distance failed on a direct course between the north and west 300 miles. Required the course and departure?

Move the semicircle and box to the given latitudes, and the index until the distance found thereon meets the perpendicular, then at the point of contact on the perpendicular is $130.8$, the departure, and on the semicircle by the index is $25^\circ 50'$, the course.

_Prob. V._ The distance and departure given, to find the course and difference of latitude.

_Example._ The distance failed is 256 miles between the south and east, the departure is 158 miles, and the latitude left $51^\circ 10'$ N. Required the course and latitude come to?

Set the centre of the semicircle to $51^\circ 10'$, the latitude failed from; find the distance 246 on the index, and the departure 138 on the perpendicular; then move both till these points meet, and the course $34^\circ 10'$ will be found on the semicircle by the index, and the latitude in $47^\circ 47'$ N, by the edge of the box.

_Prob. VI._ Both latitudes and departure given, to find the course and distance.

_Example._ A ship from latitude $43^\circ 10'$ N, failed between the north and west till she is in latitude $47^\circ 14'$ N, and has made 170 miles of departure. Required the course and distance?

Move the centre of the semicircle over $43^\circ 10'$, and the edge of the box to $47^\circ 14'$; find the departure on the perpendicular, and bring the edge of the index thereto; now at the point of intersection is the distance 297.4 miles on the index, and the course $34^\circ 52'$ on the semicircle.

_Traverse Sailing._

_Example._ A ship from latitude $46^\circ 48'$ N failed NW by N 168 miles. Required the latitude come to, and departure?

Set the centre of the semicircle perpendicularly over the given latitude $46^\circ 48'$, and the index to the course 3 points; move the perpendicular until it cut the index at the given distance 168; then at the point of intersection on the perpendicular is 93.3 miles, the departure, and on the base, by the edge of the box, is $2.3^\circ 38'$, the latitude come to.
NAVI GHzATION.

Practice.

Instruments to solve problems in sailing, independent of calculation.

Pro. I. The latitudes and longitudes of two places given, to find the direct course and distance between them.

Example. Required the course and distance between two places whose latitudes and longitudes are 50° 30' N, 19° 0' W, and 54° 30' N, 15° 30' W, respectively.

By Mercator’s Sailing.
To find the course.
Move the centre of the semicircle perpendicularly over the meridional degree answering to latitude 50° 30' N, then move the box until the edge of the perpendicular cuts the meridional parts of the other latitude 54° 30' N, and move the index until it cuts the difference of longitude 3° 30' on the perpendicular, and the index will mark the course 30° 10', or NNE:E nearly, on the semicircle.

To find the distance.
Screw the index to this course, and move the centre of the semicircle to the latitude 50° 30' N, and the edge of the perpendicular to the latitude 54° 30' N, then the perpendicular will cut the distance 534.7 on the index.

By Middle Latitude Sailing.
To find the departure.
Move the centre of the semicircle to the latitude 50° 30' N, and the edge of the index to the complement of the middle latitude 37° 20' on the semicircle; then move the box until the edge of the perpendicular intersects the termination of the difference of longitude 210° miles on the index, which point of intersection will mark the departure 121 on the perpendicular.

To find the course and distance.
Move the edge of the perpendicular to the other latitude 54° 30', and the index until it cuts the departure 128 on the perpendicular; then will the perpendicular mark the index on the perpendicular 254.7 miles, and the index will mark the course on the semicircle 30° 10', or NNE:E nearly.

Pro. II. Both latitudes and course given, to find the distance and difference of longitude.

Example. A ship from latitude 50° 30' N, longitude 19° 0' W, sailed N 30° 10' E, until she is in latitude 54° 30' N. Required the distance and difference of longitude?

By Mercator’s Sailing.
To find the difference of longitude.
Move the box and semicircle as in the former problem to the meridional parts of the given latitudes, then set the index to the course, and it will mark the difference of longitude 3° 30' on the perpendicular; hence the longitude in is 17° 30' W.

To find the distance.
Move the perpendicular and semicircle to the given latitudes, and put the index to the given course; then the perpendicular will cut the distance 254.7 miles on the index.

By Middle Latitude Sailing.
To find the distance and departure.
Move the semicircle and perpendicular to the given latitudes, and the index to the course; then the perpendicular will show the departure 128, and the
the index the distance 254.7 miles at the point of intersection.

To find the difference of longitude.

Set the index to the complement of the middle latitude on the semicircle, and move the box until the termination of the departure on the perpendicular meets the index, which will mark the difference of longitude thereon 210 m. or 3° 30'.

Example. From latitude 5° 30' N, longitude 35° 0' W, a ship sailed 254.7 miles between the north and east, and by observation is in latitude 54° 30' N. Required the course and difference of longitude?

By Mercator's Sailing.
To find the course.
Move the perpendicular and semicircle to the given latitudes, and the index until the distance sailed marked on it meets the perpendicular; then the index will mark the course N. 36° 10' E. on the semicircle.

To find the difference of longitude.
Screw the index to the course, move the perpendicular and semicircle to the meridional parts of the given latitudes, and the space intercepted between the limb of the box and the index will be the difference of longitude 3° 30'.

By Middle Latitude Sailing.
To find the departure and course.
Move the semicircle and perpendicular to the given latitudes, and the index until the distance sailed marked on it is perpendicular; then the perpendicular will show the departure 128 miles, and the semicircle the course N. 36° 10' E.

To find the difference of longitude.
Set the index to 37° 20', the complement of the middle latitude on the semicircle, and move the perpendicular until the termination of the departure on it is perpendicular; then the point of intersection will mark the difference of longitude 210 miles on the index.

Example. Let the latitude and longitude failed from be 56° 40' S, longitude 28° 55' E, the course S 31° 35' E, and distance 328 m. Required the latitude and longitude come to?

By Mercator's Sailing.
To find the latitude come to.
Set the semicircle to the latitude failed from, and the index to the course, and bring the perpendicular to the distance, which at the same time will mark the latitude come to 61° 20' S.

To find the difference of longitude.
Screw the index to the course, and move the semicircle and perpendicular to the meridional parts of both latitudes; then the index will cut the difference of longitude on the perpendicular 5° 35'.

By Middle Latitude Sailing.
The latitude arrived at is found as above.
To find the departure.
The semicircle and perpendicular being set to both latitudes, and the index to the course, it will show the departure 172.7 on the perpendicular.

To find the difference of longitude.
Set the index to 31°, the complement of the middle latitude on the semicircle, and move the perpendicular until the departure marked on it cuts the index, and the division on the index at the point of intersection will be the difference of longitude 335;

Problem. One latitude, course, and distance given, to find the difference, difference of latitude, and difference of longitude.
Example. Let the latitude failed from be 56° 40' S, longitude 28° 55' E, the course N 31° 35' W, and departure 172.7. Required the distance, and the latitude and longitude come to?

By Mercator's Sailing.
To find the distance and latitude come to.
Move the semicircle to the latitude left, and the index to the course; mark the departure on the perpendicular, and move it until the termination thereof meets the index; then the point of intersection will show the distance 329 miles on the index, and the perpendicular will show the latitude arrived at 61° 20' N on the bafe.

To find the difference of longitude.
Screw the index, and move the perpendicular and semicircle to the meridional parts of both latitudes, then the index will cut the difference of longitude 5° 35' on the perpendicular.

By Middle Latitude Sailing.
Find the distance sailed and latitude in as above, and

(a) In southern latitudes, the end of the cylinder where the numbers begin must be turned towards the north, pointed out by the semicircle; and in northern latitudes, it must be reversed.
NA V I G A T I O N.

Instruments to solve problems in Sailing.

and the difference of longitude as in Problem IV. by middle latitude sailing.

PROB. VII. One latitude the distance failed, and departure given, to find the course, difference of latitude, and difference of longitude.

Example. The latitude failed from is 48° 30' N, and longitude 14° 40' W, the distance run is 345 miles between the south and east, and the departure 200 miles. Required the course, and the latitude and longitude come to?

By Mercator's Sailing,

To find the course and latitude come to.

Move the semicircle to the latitude left, mark the distance on the index, and the departure on the perpendicular, move both until these points meet; then will the index show the course 35° 26' E on the semicircle, and the latitude come to 43° 49' on the base.

The difference of longitude is found as in the preceding problem.

By Middle Latitude Sailing,

The course and latitude come to are found as above, and the difference of longitude as in Problem IV. by middle latitude sailing.

II. Of Mackay's Rectangular Instrument.

Description. Fig. 58, is a representation of this instrument, of about one-third of the original size—The length CA is divided into 100 equal parts, and the breadth CB into 70; but in this plate every second division only is marked, in order to avoid confusion; through these divisions parallels are drawn, terminating at the opposite sides of the instrument. Upon the upper and right-hand sides are two scales; the first contains the degrees of the quadrant, and the other the points and quarters of the compass. M is an index movable about the centre C, and divided in the same manner as the sides (1). Fig. 59, is a portion of the enlarged meridian, so constructed that the first degree is equal to three divisions on the instrument, and therefore, in the use of this line, each division on the instrument is to be accounted 20 minutes. The size of the plate would not admit of the continuation of the line.

Use. From a bare inspection of this instrument, it is evident that any triangle whatever may be formed on it. In applying it to nautical problems, the course is to be found at top, or right-hand side, in the column of degrees or points, according as it is expressed; the distance is to be found on the index, the difference of latitude at either side column, and the departure at the head or foot of the instrument. The numbers in these columns may represent miles, leagues, &c.; but when used in conjunction with the enlarged meridional line, then 10 is to be accounted 100 miles, 20 is to be esteemed 200 miles, and so on, each number being increased in a tenfold ratio; and the intermediate numbers are to be reckoned accordingly.

Plane Sailing.

PROB. I. The course and distance failed given, to find the difference of latitude and departure.

Nautical Practice.

Example. Let the course be NE ½ N, distance 44 miles. Required the difference of latitude and departure?

Move the index until the graduated edge is over 34 points, and find the given distance 44 miles on the instrument: this distance will be found to cut the parallel of 34 miles, the difference of latitude in the side column, and that of 28 miles, the departure at the top.

PROB. II. Given the course and difference of latitude, to find the distance and departure.

Example. Required the distance and departure answering to the course 28°, and difference of latitude 60 miles.

Lay the index over the given course 28°; find the difference of latitude 60 miles in the side column; its parallel will cut the index at 68 miles, the distance and the corresponding departure at the top is 32 miles.

PROB. III. The course and departure given, to find the distance and difference of latitude?

Example. Let the course be SSW and the departure 36 miles. Required the distance and difference of latitude?

Lay the index over two points; find the departure at the top, and its parallel will cut the index at 94 miles, the distance and the difference of latitude on the side column is 87 miles.

PROB. IV. Given the distance and difference of latitude, to find the course and departure.

Example. The distance is 33 leagues, and the difference of latitude 30 leagues. Required the course and departure?

Bring 33 leagues on the index to the parallel of 30 leagues in the side; then the departure at the top is 18 leagues and the course by the edge of the index on the line of rhumbs is 23° points.

PROB. V. Given the distance and departure, to find the course and difference of latitude?

Example. Let the distance be 58 miles, and the departure 15 miles. Required the course and difference of latitude?

Move the index until 58 found thereon cuts the parallel of 15 from the top: this will be found to intersect the parallel of 56 miles, the difference of latitude, and the course by the edge of the ruler is 15°.

PROB. VI. The difference of latitude and departure being given, to find the course and distance?

Example. Let the difference of latitude be 30 miles, the departure 28 miles. Required the course and distance?

Bring the index to the intersection of the parallels of 30 and 28; then the distance on the index is 41 miles, and the course by its edge is 43°.

Traverse Sailing.

Find the difference of latitude and departure answering to each course and distance by Problem I. of Plane Sailing, and from thence find the difference of latitude and departure made good; with which find the course and distance by the last problem.

An example is unnecessary.

Parallel

(1) In the original instrument are two slips, divided like the side and end of the instrument. One of these slips is moveable in a direction parallel to the side of the instrument, and the other parallel to the end.
**Practice.**

**Parallel Sailing.**

**PROB. I.** Given the difference of longitude between two places on the same parallel, to find the distance between them.

**Example.** Let the latitude of a parallel be 48°, and the difference of longitude between two places on it 3° 40'. Required their distance?

Put the index to 48°, the given latitude, and find the difference of longitude 320 on the index, and the corresponding parallel from the side will be 147, the distance required.

**PROB. II.** The latitude of a parallel, and the distance between two places on that parallel, being given, to find the difference of longitude between them.

**Example.** The latitude of a parallel is 56°, and the distance between two places on it 200 miles. Required their difference of longitude?

Put the index to the given latitude, and find the distance in the side column, and the intersection of its parallel with the index will give 358, the difference of longitude sought.

**PROB. III.** Given the distance and difference of longitude between two places on the same parallel, to find the latitude of that parallel.

**Example.** The number of miles in a degree of longitude is 46.5. Required the latitude of the parallel?

Bring 60 on the index to cut the parallel of 46.5 from the side, then the edge of the index will give 39° 11', the latitude required.

**Middle Latitude and Mercator's Sailing.**

**PROB. I.** The latitudes and longitudes of two places being given, to find the course and distance between them.

**Example.** Required the course and distance between Genoa, in latitude 44° 25' N, longitude 8° 36'E, and Palermo, in latitude 38° 10' N, longitude 13° 38'E?

**By Mercator's Sailing.**

Take the interval between 38° 10' and 44° 25' on the enlarged meridian, which laid off from C upwards will reach to 500; now find the difference of longitude 302 at the top, and bring the divided edge of the index to the intersection of the corresponding parallels, and the index will show the course 31° 8' on the line of degrees; then find the difference of latitude 375 on the side column, and its parallel will intersect the index at 438, the distance.

**By Middle Latitude Sailing.**

Put the index to 43° 18', the complement of the middle latitude on degrees, and the difference of longitude 302 on the index will intersect the parallel of 227, the departure, in the side column. Now move the index to the intersection of the parallels of 375 and 227, the first being found in the side column, and the other at top or bottom; then the distance answering thereto on the index will be 438, and the course on the scale of degrees is 41° 10'.

**PROB. II.** Given one latitude, course, and distance, to find the other latitude and difference of longitude.

**Example.** Let the latitude and longitude failed from be 39° 22' N and 12° 8' W, respectively, the course NW, and distance 500 miles. Required the latitude and longitude come to?
particular, will intersect the index at 230, the difference of
longitude.

Pro. V. Both latitudes and distance given, to find
the course and difference of longitude.

EXAMPLE. The distance failed is 500 miles between
the north and west; the latitude and longitude left are
N. 40° 18' W., and 9° 20' W. respectively, and the latitude
in is 46° 40 N. Required the course and longitude in?

By Mercator's Sailing.

Bring the distance 500 on the index to intersect
the horizontal parallel of the difference of latitude
46°; then the course 500 is found on the line of
degrees by the edge of the index, and the vertical
parallel of the above point of intersection is that
numbering to 313, the departure.

Take the interval between the latitudes 40° 18', and
46° 40', which lay off from the centre C, and its
horizontal parallel will intersect the vertical parallel of
46°, the difference of longitude, by the edge of the
index, it being in the same position as before. Hence
the longitude in is 16° 31' W.

By Middle Latitude Sailing.

The course and departure are found as formerly,
and the middle latitude is 43° 25', to which bring
the edge of the index, and the horizontal parallel of
313, the departure, will intersect the index at 431,
the difference of longitude.

Pro. VI. Both latitudes and departure given, to
find the course, distance, and difference of longitude.

EXAMPLE. Let the latitude failed from be 42° 54' N.
long. 19° 17' W., the distance 250 miles W, and the
latitude come to 36° 18' N. Required the course and
distance failed, and the longitude come to?

By Mercator's Sailing.

Find the point of intersection of the horizontal
parallel of 36°, the difference of latitude, and the
vertical parallel of 250, the departure; to this point
bring the index, and the corresponding division thereon
will be 467 miles, and the course on the scale of
degrees by the edge of the index will be 32° 24'.

Take the interval between the latitudes on the
enlarged meridian, which being laid off from the centre
will reach to 512: now the horizontal parallel of 512
will intersect the vertical parallel of 325, the difference
of longitude, at the edge of the index. The longitude
come to is therefore 14° 42' W.

By Middle Latitude Sailing.

The course and distance are to be found in the same
manner as above. Then bring the index to 30° 35',
the middle latitude, and the horizontal parallel of 250
will intersect the edge of the index at 324°, the
difference of longitude.

Pro. VII. Given one latitude, distance, and
departure, to find the other latitude, course, and
difference of longitude.

EXAMPLE. A ship from latitude 32° 48' N., longi-
tude 17° 6' W., failed 586 miles between the south and
west, and made 346 miles of departure:—Required
the course, and the latitude and longitude come to?

By Mercator's Sailing.

Move the index till the distance 386 intercepts the
vertical parallel of the departure 316; then the corre-
ponding horizontal parallel will be 580, the difference
of latitude, and the course 35°. Hence the latitude
in is 24° 35' N.

Now take the interval between the latitudes on
the entered meridian, which laid off from the centre
will reach to 547, the horizontal parallel of which
will cut the vertical parallel of 386, the difference
of longitude. The longitude in is therefore 23° 29' W.

By Middle Latitude Sailing.

Find the course and difference of latitude as before,
and hence the middle latitude is 28° 38', to which
bring the index, and the horizontal parallel of 336,
the departure, will intersect the index at 383, the
difference of longitude.

It seems unnecessary to enlarge any further on the
use of this instrument, as the above will make it
sufficiently understood.

CHAPTER XII. Of Great Circle Sailing.

The application of spherical trigonometry to the
solution of triangles formed upon the surface of the
earth is called Great Circle Sailing.

The earth being supposed an exact sphere, the
shortest distance between two places is the arch of a
great circle intercepted between them; and therefore
the distance failed upon a direct course from one place
to another, will always be longer than the arch of a
great circle contained between them, except when the
shortest course coincides with a great circle, which can
only happen when the ship falls on a meridian or on the
equator.

Although it is impossible to make a ship describe
an arch of a great circle, yet she may be kept so near it
as to make the error almost insensible.

The terms that enter into this sailing are, the lati-
tudes of the places, their difference of longitude, and the
angles contained between the distance and the meridians
of the places, called the angles of position.

Pro. I. Given the common latitude of two places
on the same parallel, and their difference of longitude,
to find the distance and angle of position (k).

EXAMPLE. Required the distance between St Ma-
ry's, in latitude 36° 57' N., longitude 25° 9' W., and
Cape Henry, in latitude 36° 57' N., and longitude
76° 27' W.

By Conjunction.

Describe the circle EQR (Fig. 60.) to represent
the meridian of one of the places; draw the equator
Plate DQ, and the earth's axis PS at right angles thereto; CCCXL
make ED, Qs, each equal to the chord of 36° 57'; the

(k) This problem may be expressed thus:—Two places lying on the same parallel, and of these four,
the latitudes, difference of longitude, distance, and angle of position, any two being given to find the other
two.—Now this problem contains four different cases, the most usual of which is given above. The others
serve rather as exercises in spherical trigonometry than of any real utility in navigation, and are therefore
omitted. The same is to be understood of the following problems.
Great Circle
Sailing.

Pr~ice.

Great Circle
Sailing.

The given latitude, and draw the parallel of latitude ABD, the radius of which is the tangent of $53^\circ 3'$, the co-latitude; describe the meridian PBS with the

the meridian of one of the places; make $EA = 32^\circ 35'$, and $A$ will represent Bermuda; make $EA$, $QB$ each equal to $49^\circ 57'$; then with the tangent of the co-latitude $40^\circ 3'$ draw the parallel of latitude of the Lizard, and with the secant of $58^\circ 13'$, the given difference of longitude, draw the oblique circle PBS, intersecting the parallel of latitude in $B$; which will be the position of the Lizard. Draw the diameter $AF$, and through the points $A$, $B$, $F$describe a circle: and the arch $AB$ will be the distance, and the angles $A$ and $B$ the angles of position, which are measured as before.

By Calculation.

In the oblique-angled spherical triangle $APB$ are $AP$, $BP$, the co-latitudes, and the angle $APB$ the difference of longitude; to find the distance $AB$, and the angles of position $PAB$, $PBA$.

1. To find the distance.

Distance $AB$ $40^{28}$

2. To find the angle of position.

As radius $- 10.00000$

is to the sine of $AP$ $53^\circ 3'$ $9.90263$

so is the sine of $APG$ $25^\circ 39'$ $9.63636$

to the sine of $AG$ $20^14'$ $9.53899$

2. To find the angle of position at St. Thomas.

As radius $- 10.00000$

is to the sine of $AE$ $66^\circ 10'$ $9.66046$

so is the cotangent of $EB$ $48^51'$ $9.81185$

to the cotangent of $AE$ $66^610'$ $9.96112$

9.90263

3. To find the angle of position at Port St Julian.

As radius $- 10.00000$

is to the sine $EB$ $48^51'$ $9.87679$

so is the cotangent of $AE$ $66^610'$ $9.64517$

to the cotangent of $ABE$ $71^36'$ $9.52196$

Hence a ship from St Thomas to Port St Julian must first steer $38^638'$ W, and then by constantly altering her course towards the west, so as to arrive at Port St Julian on a course $71^656'$ W, she will have failed the shortest distance between those places.

EXAMPLE. What is the shortest distance between the Lizard, in latitude $49^657'$ N, longitude $5^615'$ W, and Bermuda, in latitude $32^635'$ N, and longitude $63^628'$ W?

By Construction.

Describe the primitive circle (fig. 61.) to represent the meridian of one of the places; make $EA = 32^635'$, and $A$ will represent Bermuda; make $EA$, $QB$ each equal to $49^657'$; then with the tangent of the co-latitude $40^63'$ draw the parallel of latitude of the Lizard, and with the secant of $58^613'$, the given difference of longitude, draw the oblique circle PBS, intersecting the parallel of latitude in $B$; which will be the position of the Lizard. Draw the diameter $AF$, and through the points $A$, $B$, $F$ described a circle; and the arch $AB$ will be the distance, and the angles $A$ and $B$ the angles of position, which are measured as before.

By Calculation.

In the oblique-angled spherical triangle $APB$ are $AP$, $BP$, the co-latitudes, and the angle $APB$ the difference of longitude; to find the distance $AB$, and the angles of position $PAB$, $PBA$.

1. To find the distance.

Difference of long. $58^613'$

Verfed fine $9.67573$

AP $57^57'$

BP $40^3$ fine $9.86082$

Difference $17^22$ nat. v. fine $0459^9$

25661 $9.40928$

Distance $AB$ $45^45$ nat. v. fine $03220^*$. *See MacKay's Circumference of the Longitude, where a complete Table of Nat. Verfed Sines is given.

1. To find the angle of position at the Lizard.

As the line of $AB$ $45^45'$ $9.85106$

is to the sine of $AP$ $57^57'$ $9.92326$

so is the sine of $P$ $58^13'$ $9.92944$

to the sine of $B$ $89^20'$ $9.99997$

3. To find the angle of position at Bermuda.

As the line of $AB$ $45^45'$ $9.85106$

is to the sine of $BP$ $40^3$ $9.86082$

so is the sine of $P$ $58^13'$ $9.92944$

to the sine of $A$ $49^47'$ $9.88786$

The shortest distance between the Lizard and Bermuda is $45^45'$ or $2745$ miles, which is $56$ miles less than

Vol. XII.
The triangle APB (Fig. 63,) being described, and the computation made as in Problem I., the distance will be found equal to 40° 6', and the angle of position A or B=73° 9'.—Now the triangle APB being isosceles, the perpendicular PI falls in the middle of AB; and the latitudes, courses, and distances being known in the half BI, those in the half IA will also be known.

Let the points a, b, c, d, &c. be the points arrived at on each alteration of five degrees of longitude; then will the arches Pa, Pb, Pc, Pd, &c. be the respective co-latitudes of those places, and are the hypothenuses of the right-angled spherical triangles PLa, PIB, PIC, PID, &c.

Now in the triangle PIB, given PB=53° 3', the angle PBI=73° 9', to find PI.

Since radius is to the sine of PBI 73° 9' = 9.98094, so is the sine of PB 53° 0' = 0.900235 to the sine of PI 49° 51' = 9.88329.

The angle IPB=63° 27', angle IPa=21° 43', 1° 51', IPb=1° 43', 1', IPc=11° 43', 1', IPd=6° 43', are the several polar angles.

To find the latitude of the point a.

As radius is to the cotangent of PI 49° 51' = 9.93612, so is the cosine first polar angle 21° 43' = 9.96800 to the tangent of 1st latitude 38° 5' = 9.89452.

By continuing the operation with the other polar angles, the successive latitudes from a to I will be 38° 56', 39° 33', 39° 57'.

Now with the several latitudes, and respective differences of longitude, compute the courses and distances. The results are entered in the following Table; the calculations being performed on a piece of waste paper.

The courses, and the first distance, are found by Mercator's Sailing; but as the other courses are near the parallel, the distances cannot be very exactly found by this method; another method is therefore used. The sum of the distances is 1263.1, which doubled is 2526.2, agreeing with the distance found as before. It may be observed, that the distance found by this method cannot be less than the last distance, or that given by Great Circle Sailing, as some authors have found it.

Example II. A ship from the Lizard, in latitude 49° 57' N., longitude 5° 15' W., bound to a place in latitude 32° 25' N., and longitude 60° 39' W., proceeds to fail on a great circle, and to alter her course at every
NAVIGATION.

To find the polar angle $\Phi_{\text{PI}}$.

As radius

is to the co-tangent of $\Phi_{\text{PI}}$.

so is the tangent of $\Phi_{\text{PA}}$.

to the co-tangent of $\Phi_{\text{PA}}$.

Now the polar angle $\Phi_{\text{PI}}$, or the difference of longitude between the perpendicular and the meridian of the place bound to, $57^\circ 49'$, being taken from $61^\circ 24'$, the whole difference of longitude, leaves $3^\circ 35'$ for the difference of longitude between the Lizard and the perpendicular; $\mu 116^\circ 5^\circ$, the proposed alteration of longitude, being subtracted as often as it can be from $57^\circ 49'$, leaves the several polar angles; with which and the perpendicular $\Phi_{\text{PI}}$ the several latitudes arrived at are found as in the preceding example; then with these latitudes and the differences of longitude between them, find the successive courses and distances. The several results are placed in the following Table; the calculations being performed on a piece of waste paper.

As the four first courses are near the parallel, the corresponding distances were not found by Mercator's Sailing. The sum of the distances 2874 3 agrees every way with, and is not less than, 47° 54', or 287 4 miles, the shortest distance between the places.

CHAP. XIII. Of Sea-Charts.

The charts usually employed in the practice of navigation are of two kinds, namely, Plane and Mercator's Charts. The first of these is adapted to represent a portion of the earth's surface near the equator; and the last for all portions of the earth's surface. For a particular description of these, reference has already been made from the article Chart, to those of Plane and Mercator; and as these charts are particularly described under the above articles, it is therefore sufficient in this place to describe their use.

Use of the Plane Chart.

PROB. I. To find the latitude of a place on the chart.

Rule. Take the least distance between the given place and the nearest parallel of latitude: now this distance applied the same way on the graduated meridian, from the extremity of the parallel, will give the latitude of the proposed place.

Thus the distance between Bona Vista and the parallel of 15 degrees, being laid from that parallel upon the graduated meridian, will reach to 16° 5', the latitude required.

PROB. II. To find the course and distance between two given places on the chart.

Rule. Lay a ruler over the given places, and take the nearest distance between the centre of any of the compasses on the chart and the edge of the ruler; move this extent along, so as one point of the compass may touch the edge of the rule, and the straight line joining their points may be perpendicular there-to; then will the other point throw the course: The interval between the places, being applied to the scale, will give the required distance.

Thus the course from Palma to St Vincent will be found to be about SSW 4 W. and the distance 13°, or 795 m.

PROB. III. The course and distance failed from a known place being given, to find the ship's place on the chart.

Rule. Lay a ruler over the place failed from, parallel
NAVIGATION.

Practice.

RULE. The ruler being laid over the place failed from and in the direction of the given course, take the distance failed from the equator, put the point of the compass at the intersection of any parallel with the ruler, and the other point of the compass will reach to a certain place by the edge of the ruler. Now this point remaining in the same position, draw in the other point of the compass until it just touches the above parallel when swept round: apply this extent to the equator, and it will give the difference of latitude. Hence the latitude in will be known, and the intersection of the corresponding parallel with the edge of the ruler will be the ship's present place.

The other problems of Mercator's sailing may be very easily resolved by this chart; but as they are of less use than those given, they are therefore omitted, and may serve as an exercise to the student.

BOOK II.

Containing the method of finding the Latitude and Longitude of a Ship at Sea, and the Variation of the Compass.

CHAPTER I. Of Hadley's Quadrant.

Hadley's quadrant is the chief instrument in use at present for observing altitudes at sea. The form of this instrument, according to the present mode of construction, is an octagonal sector of a circle, and therefore contains 45 degrees; but because of the double reflection, the limb is divided into 90 degrees.

See ASTRONOMY and QUADRANT. Fig. 65, represents a quadrant of the common construction, of which the following are the principal parts.

1. ABC, the frame of the quadrant.
2. BC, the arch or limb.
3. D, the index; a b, the subdividing scale.
4. E, the index-glass.
5. F, the fore horizon-glass.
6. G, the back horizon-glass.
7. K, the coloured or dark glasses.
8. HI, the vanes or sights.

Of the Frame of the Quadrant.

The frame of the quadrant consists of an arch BC, firmly attached to the two radii AB, AC, which are bound together by the braces LM, in order to strengthen it, and prevent it from warping.

Of the Index D.

The index is a flat bar of brass, and turns on the centre of the quadrant: at the lower end of the index there is an oblong opening; to one side of this opening the vernier scale is fixed, to subdivide the divisions of the arch; at the end of the index there is a piece of brass, which bends under the arch, carrying a spring to make the subdividing scale lie close to the divisions. It is also furnished with a screw to fix the index in any desired position. The bevel instruments have an adjusting screw fitted to the index, that it may be moved more slowly, and with greater regularity and accuracy, than by the hand. It is proper, however, to observe, that the index must be previously fixed, near its right position by the abovementioned screw.
NA VIG AT I ON.

Method of finding the Latitude and Longitude at Sea.

Upon the index, and near its axis of motion, is fixed a plane speculum, or mirror of glass quicksilvered. It is set in a brass frame, and is placed so that its face is perpendicular to the plane of the instrument. This mirror being fixed to the index moves along with it, and has its direction changed by the motion thereof; and the intention of this glass is to receive the image of the sun, or any other object, and reflect it upon either of the two horizon-glasses, according to the nature of the observation.

The brass frame with the glass is fixed to the index by the screw c; the other screw serves to replace it in a perpendicular position, if by any accident it has been deranged.

Of the Horizon Glasses F, G.

On the radius AB of the clock are two small speculums: the surface of the upper one is parallel to the index glas, and that of the lower one perpendicular thereto, when o on the index coincides with o on the limb. These mirrors receive the reflected rays, and transmit them to the observer.

The horizon-glasses are not entirely quicksilvered; the upper one F is only silvered on its lower half, or that next the plane of the quadrant, the other half being left transparent, and the back part of the frame cut away, that nothing may impede the sight through the unfilivered part of the glasses. The edge of the foil of this glass is nearly parallel to the plane of the instrument, and ought to be very sharp, and without a flaw. The other horizon-glass is silvered at both ends. In the middle there is a transparent slit, through which the horizon may be seen.

Each of these glasses is set in a brass frame, to which there is an axis passing through the wood work, and is fitted to a lever on the under side of the quadrant, by which the glasses may be turned a few degrees on its axis, in order to set it parallel to the index-glass. The lever has a contrivance to turn it slowly, and a button to fix it. To set the glasses perpendicular to the plane of the instrument, there are two screw cuts, one before and one behind each glass: these screws pass through the plate on which the frame is fixed into another plate; so that by loosening one and tightening the other of these screws, the direction of the frame with its mirror may be altered, and set perpendicular to the plane of the instrument.

Of the Coloured Glasses K.

There are usually three coloured glasses, two of which are tinged red and the other green. They are used to prevent the solar rays from hurting the eye at the time of observation. These glasses are set in a frame, which turns on a centre, so that they may be used separately or together as the brightness of the sun may require. The green glass is particularly useful in observations of the moon; it may be also used in observations of the sun, if that object be very faint.

In the fore-observations, these glasses are fixed as in fig. 65; but when the back-observation is used, they are removed to N.

Of the two Sight Vanes H, I.

Each of these vanes is a perforated piece of brass, designed to direct the light parallel to the plane of the quadrant. That which is fixed at I is used for the fore, and the other for the back observation. The vanes have two holes, one exactly at the height of the silvered part of the horizon-glass, the other a little higher, to direct the light to the middle of the transparent part of the mirror.

Of the Divisions on the Limb of the Quadrant.

The limb of the quadrant is divided from right to left into 90 primary divisions, which are to be considered as degrees, and each degree is subdivided into three equal parts, which are therefore of 20 minutes each: the intermediate minutes are obtained by means of the scale of divisions at the end of the index.

Of the Vernier or Subdividing Scale.

The dividing scale contains a space equal to 21 divisions of the limb, and is divided into 20 equal parts. Hence the difference between a division on the dividing scale and a division on the limb is one twentieth of a division on the limb, or one minute. The degree and minute pointed out by the dividing scale may be easily found thus.

Observe what minute on the dividing scale coincides with a division on the limb; this division being added to the degree and part of a degree on the limb, immediately preceding the first division on the dividing scale, will be the degree and minute required.

Thus suppose the fourteenth minute on the dividing scale coincided with a division on the limb, and that the preceding division on the limb to o on the vernier was 56° 40'; hence the division flown by the vernier is 56° 54'. A magnifying glass will assist the observer to read off the coinciding divisions with more accuracy.

Adjustments of Hadley's Quadrant.

The adjustments of the quadrant consist in placing the mirrors perpendicular to the plane of the instrument. The fore horizon-glass must be set parallel to the speculum, and the planes of the speculum and back horizon glass must be perfectly perpendicular to each other when the index is at o.

Adjustment I. To set the index-glass perpendicular to the plane of the quadrant.

Method I. Set the index towards the middle of the limb, and hold the quadrant so that its plane may be nearly parallel to the horizon: then look into the index-glass i and if the portion of the limb seen by reflection appears in the same plane with that seen directly, the speculum is perpendicular to the plane of the instrument. If they do not appear in the same plane, the error is to be rectified by altering the position of the screws behind the frame of the glass.

Method II. This is performed by means of the two adjusting tools fig. 66, 67, which are two wooden frames, having two lines on each, exactly at the same distance from the bottom.

Place the quadrant in a horizontal position on a table; put the index about the middle of the arch; turn back the dark glasses; place one of the above-mentioned tools near one end of the arch, and the other at the opposite end, the side with the lines being towards the index-glass; then look into the index-glasses, directing the light parallel to the plane of the instrument, and one of the tools will be seen by direct vision, and the other by reflection. By moving the index a little, they may be brought exactly togethe
NAVIGATION.

Method of finding the Latitude and Longitude at Sea.

Adjustment II. To set the fore horizon-glass perpendicular to the plane of the instrument.

Set the index to \( \theta \); hold the plane of the quadrant parallel to the horizon; direct the fight to a well-defined part of the horizon; then if the horizon be seen directly and by reflection are apparently in the same straight line, the fore horizon-glass is perpendicular to the plane of the instrument; if not, one of the horizons will appear higher than the other. Now if the horizon be seen by reflection is higher than that seen directly, release the nearest screw in the pedestal of the glas, and screw up that on the farther side, till the direct and reflected horizons appear to make one continuous straight line. But if the reflected horizon is lower than that seen directly, unscrew the farthest screw, and screw up the nearest till the coincidence of the horizons is perfect, observing to leave both screws equally tight, and the fore horizon-glass will be perpendicular to the plane of the quadrant.

Adjustment III. To set the fore horizon-glass parallel to the index-glass, the index being at \( \theta \).

Set \( \theta \) on the index exactly to \( \theta \) on the limb, and fix it in that position by the screw at the under side; hold the plane of the quadrant in a vertical position, and direct the sight to a well-defined part of the horizon; then if the horizon be seen directly and coincide with that seen through the transparent part, the fore horizon-glass is adjusted; but if the horizons do not coincide, unscrew the milled screw in the middle of the lever on the other side of the quadrant, and turn the nut at the end of the lever until both horizons coincide, and fix the lever in this position by tightening the milled screw.

As the position of the glas is liable to be altered by fixing the lever, it will therefore be necessary to re-examine it, and if the horizons do not coincide, it will be necessary either to repeat the adjustment, or rather to find the error of adjustment, or, as it is usually called, the index error; which may be done thus:

Direct the sight to the horizon, and move the index until the reflected horizon coincides with that seen directly; then the difference between \( \theta \) on the limb and \( \theta \) on the vernier is the index error; which is additive when the beginning of the vernier is to the right of \( \theta \) on the limb, otherwise subtractive.

Adjustment IV. To set the back horizon-glass perpendicular to the plane of the instrument.

Put the index to \( \theta \); hold the plane of the quadrant parallel to the horizon, and direct the sight to the horizon through the back vane. Now if the reflected horizon is in the same straight line with that seen through the transparent part, the glas is perpendicular to the plane of the instrument: If the horizons do not unite, turn the funk screws in the pedestal of the glas until they are apparently in the same straight line.

Adjustment V. To set the back horizon-glass perpendicular to the plane of the index-glass produced, the index being at \( \theta \).

Let the index be put as much to the right of \( \theta \) as twice the dip of the horizon amounts to; hold the quadrant in a vertical position, and apply the eye to the back vane; then if the reflected horizon coincides with that seen directly, the glas is adjusted; if they do not coincide, the screw in the middle of the lever on the other side of the quadrant must be released, and the nut at its extremity turned till both horizons coincide. It may be observed, that the reflected horizon will be inverted; that is, the sea will be apparently uppermost and the sky lowermost.

As this method of adjustment is esteemed troublesome, and is often found to be very difficult to perform at sea, various contrivances have therefore been proposed to render this adjustment more simple. Some of these are the following.

1. Mr Dollond's method of adjusting the back horizon-glass.

In this method an index is applied to the back horizon-glass, by which it may be moved so as to be parallel to the index-glass, when \( \theta \) on the vernier coincides with \( \theta \) on the limb. When this is effected, the index of the back horizon-glass is to be moved exactly 90° from its former position, which is known by means of a divided arch for that purpose; and then the plane of the back horizon-glass will be perpendicular to the plane of the index-glass produced.

2. Mr Blair's method of adjusting the back horizon-glass.

All that is required in this method is to polish the lower edge of the index-glass, and expose it to view. The back horizon-glass is adjusted by means of a reflection from this polished edge, in the very same method as the fore horizon-glass is adjusted by the common method.

In order to illustrate this, let R I H E (fig. 68.) represent a pencil of rays emitted from the object \( R \), incident on the index-glass \( I \), from which it is reflected to the fore horizon-glass \( H \), and thence to the eye at \( E \). By this double reflection, an image of the object is formed at \( E \). RHE represents another pencil from the same object \( R \), coming directly through the fore horizon-glass to the eye at \( E \); so that the doubly reflected image \( E \) appears coincident with the object \( R \) itself, seen directly.

When this coincidence is perfect, and the object \( R \) is very distant as to make the angle \( IRH \) incontinent, the position of the speculum \( I \) and \( H \) will differ insensibly from parallelism; that is, the quadrant will be adjusted for the fore-observation. Now it is from the ease and accuracy with which this adjustment can at any time be made, that the fore-observation derives its superiority over the back-observation. But by grinding the edge of the index-glass perpendicular to its reflecting surface, and polishing it, the back-observation is rendered capable of an adjustment equally easy and accurate as the fore-horizon-glass; for by a pencil of rays emitted from the object \( S \), incident on the reflecting edge of the index-glass \( D \), thence reflected to the back horizon-glass \( B \), and from that to the eye at \( E \), an image will be formed at \( E \); which image being made to coincide with the object \( S \) itself, seen directly, ascertains the position of the back horizon-glass relative to the index-glass with the same precision, and in a manner equally direct, as the former operation does that of the fore horizon-glass.

Directions for adjusting the Back Horizon-Glases.

The method of adjusting the quadrant for the back-observation
NAVIGATION

Method of finding the Latitude and Longitude at Sea.

Practice.

observation is this. If it is to be done without making use of the telescope, place the index at a, and applying the eye to the hole in the sight-vane (r), or tube for directing the sight, direct it through the back horizon-glaes to the horizon, if that is the object to be used for adjusting. The two horizons are then to be made to coincide, holding the quadrant first in a vertical and then in an horizontal position; by which means both adjustments will be effected as in the fore-observation.

There will be no difficulty in finding the reflected horizon, if the observer first directs his eye to that part of the horizon-glaes where he observes the image of the polished edge of the index-glaes, which will appear double. When the directed horizon is made to appear in this space, the reflected one will be seen close by it, unless the instrument wants a great adjustment. In this case, a little motion of the back horizon-glaes backwards and forwards will presently bring it in view.

When the horizon, or any obscure terrestrial object, is to be made use of for adjusting by means of the reflecting edge, there is a precaution to be taken, without which the observer will sometimes meet with what will appear an unaccountable difficulty; for if the sky, or other object behind him, should happen to be pretty bright, he will not be able to discern the horizon at all. This arises from the image of the object behind him, which is reflected from the silvered surface of the index-glaes, appearing to coincide with the horizon; in which case, the bright picture of the former, which is formed in the bottom of the eye, prevents the fainter impression of the latter from being perceived. This will be avoided, either by applying a black screen over the silvered surface of the index-glaes, or, without being at this trouble, by standing at a door or window, so that only the dark objects within can be reflected from the index-glaes: but if the observation is to be made in the open air, or in a hat, or any thick dark obstacle, held before the silvered surface of the index-glaes, will very effectually remove this inconvenience.

It may be remarked, that some observers, instead of making the principal adjustment, place the speculum parallel, by moving the index without altering the position of the horizon-glaes: and the difference between or on the verniers and or the limb is the index error, which must be subtracted from all angles measured by the back-observation, when or on the index is to the right of or on the limb; and added when to the left.

3. Mr Wright's method of adjusting the back horizon-glaes of his improved patent quadrant.

Plate CCXI.

Fig. 69. is a representation of the quadrant complete in all its parts for use. A, is the reflecting surface of the index-glaes, which is made of the usual length, and of an inch broad. The bottom part is covered in front by the brass frame; and the reflecting surface is c, on the back. B, the fore horizon-glaes, placed as usual; O, the back horizon-glaes, now placed under the fore-sight vane on the first radius of the quadrant: C, the sight-vane of the fore-horizon-glaes; D, the sight-vane of the back horizon-glaes; E, the coloured glassed in a brass frame, in the proper place for the fore-observation: F, a hole in the frame to receive the coloured glaes when an observation is to be taken with the back horizon-glaes in the common way, by turning the back to the fun: G, a hole in the frame of the farther radius K, to receive the coloured glaes when an observation is to be taken by the new method; which is by looking through the lower hole in the sight-vane of the back horizon-glaes, directed at the fun in the line of sight DN: the horizon from behind will then be reflected from the back of the index-glaes to the horizon-glaes, and from thence to the eye. (See fig. 73.) H, a brass clamp on the upper end of the index, having a milled screw underneath, which fastens the round plate to the index when required. (See fig. 70.) I K, the graduated arch of the quadrant divided into 90 degrees: L, the brass index which moves over the graduated arch: M, the vernier to subdivide the divisions on the arch into single minutes of a degree.

Fig. 70. shows the upper part of the index L on a larger scale, with part of the brass frame that fastens the index-glaes, and the three adjusting screws D to adjust its axis vertical to the plane of the quadrant: B, the centre on which the milled plate O moves over the index: The dotted line BF is the distance it is required to move: K, the adjusting screw to fix it in its proper place for adjusting the back observation-glaes: G, a piece of brass fastened to the index opposite to the clamp H, to keep the plate O always close to the index L.

Fig. 71. represents the parallel position of the index and horizon-glaes after adjustment by the fun: BC, a ray from the sun incident on the index-glaes C, and from thence reflected to the fore horizon glaes D, and again to the eye at E, in the line DE, where the eye sees the fun at A by direct vision, and the image by reflection in one; the parallel lines AE and BC being so near to each other, that no apparent angle can be observed in the planes of the index and horizon-glaes, when adjusted by a distant object.

In fig. 72. the index-glaes is removed 45 degrees from the plane of the fore horizon-glaes, and fixed in its proper place for adjusting the back horizon-glaes parallel to its plane, in the same manner as the fore horizon-glaes is adjusted.

In fig. 73. the index-glaes (after the adjustment of the fore and back horizon-glaes) is carried forward by the index on the arch 90 degrees, and makes an angle of 45° with the plane of the fore horizon-glaes, and is at right angles to the plane of the back horizon-glaes. The eye at E now sees the sun in the horizon at H, reflected by the index and horizon-glaes from the zenith at Z, the image and object being 90 degrees.

(x) Besides the hole in the sight-vane commonly made, there must be another nearer to the horizon-glaes, and so placed that an eye directed through it to the centre of the horizon-glaes shall there perceive the image of the polished edge of the index-glaes. This hole must not be made small like the other, but equal to the ordinary size of the pupil of the eye, there being on some occasions no light to spare.
NAVIGATION.

Method of finding the Latitude and Longitude at Sea.

The back horizon $K$ is now reflected from the back surface of the index-glass $C$ to the horizon-glasses $M$, and from thence to the eye at $D$, in a right line with the fore horizon $F$. In order to make an exact contact of the fore and back horizons at $F$, the index must be advanced beyond the 90th degree on the arc, by a quantity equal to twice the dip of the horizon.

The quadrant is adjusted for the fore-observation as usual, having previously fixed the index-glass in its proper place by the milled screw at $H$, as represented in fig. 70.

To adjust the Quadrant for the Back-observation.

Turn the index to go $0°$ on the limb; loosen the screw $H$ (fig. 70.), and turn the plate $O$ by the milled edge until the end of the adjusting-screw $K$ touches the edge of the clamp $M$; and by means of a distant object observe if the glasses are then parallel, as at fig. 71.: if they are, fasten the screw $H$; if not, with a screw-driver turn the screw $K$ gently to the right or left to make them perfect, and then fasten the screw. Now remove the index back to $O$ on the limb, and the index-glass will be parallel to the back-horizon-glass $E$, fig. 72.: if not, make them so by turning the adjusting-screw of the glass $E$, the eye being at the upper hole in the right-vane $D$, and the sight directed to the horizon, or any distant object in the direction $DN$ (fig. 69.).

Now the index remaining in this position, the index-glass is to be returned, to drop at the pin $E$, and it will be parallel to the fore-horizon-glass as at first: then the quadrant will be adjusted for both methods of observation.

To observe the Sun's Altitude by the Back-observation.

Remove the coloured glasses to $G$ (fig. 69.), and look through the lower hole in the right-vane $D$, in the line of direction $DN$, directly to the sun, and move the index forward on the arc exactly in the same manner as in the fore-observation: make the contact of the sun's limb and the back-horizon-glass, and the minutes shown by the index on the limb is the sun's zenith distance. It may be observed, that the horizon will be inverted. If the sun's lower limb be observed, the semidiameter is to be subtracted from the zenith distance; but if the upper limb is observed, the semidiameter is to be added.

The observation may be made in the usual manner, by turning the back to the sun. In this case the coloured glasses are to be shifted to $F$, and proceed according to the directions formerly given.

Use of Hadley's Quadrant.

The altitude of any object is determined by the position of the index on the limb, when by reflection that object appears to be in contact with the horizon.

If the object whose altitude is to be observed be the sun, and if so bright that its image may be seen in the transparent part of the fore-horizon-glass, the eye is to be applied to the upper hole in the right-vane; otherwise, to the lower hole: and in this case, the quadrant is to be held so that the sun may be bisected by the line of separation of the silvered and transparent parts of the glass. The moon is to be kept as nearly as possible in the same position; and the image of the star is to be observed in the silvered part of the glass adjacent to the line of separation of the two parts.

There are two different methods of taking observations with the quadrant. In the first of these the face of the observer is directed towards that part of the horizon immediately under the sun, and is therefore called the fore observation. In the other method, the observer's back is to the sun, and it is hence called the back observation. This last method of observation is to be used only when the horizon under the sun is obscured, or rendered indistinct by fog or any other impediment.

In taking the sun's altitude, whether by the fore or back observation, the observer must turn the quadrant about upon the axis of vision, and at the same time turn himself about upon his heel, so as to keep the sun always in that part of the horizon glass which is at the same distance as the eye from the plane of the quadrant.

In this way the reflected sun will describe an arch of a parallel circle round the true sun, whole convex sides will be downwards in the fore-observation and upwards in the back; and consequently, when moving the index, the lowest point of the arch in the fore-observation, or highest in the back, is made to touch the horizon, the quadrant will stand in a vertical plane, and the altitude above the visible horizon will be properly observed. The reason of these operations may be thus explained: The image of the sun being always kept in the axis of vision, the index will always show on the quadrant the distance between the sun and any object seen directly which its image appears to touch, therefore, as long as the index remains unmoved, the image of the sun will describe an arch everywhere equidistant from the sun in the heavens, and consequently a parallel circle about the sun, as a pole. Such a translation of the sun's image can only be produced by the quadrant's being turned about upon a line drawn from the eye to the sun, as an axis. A motion of rotation upon this line may be resolved into two, one upon the axis of vision, and the other upon a line in the quadrant perpendicular to the axis of vision; and consequently a proper combination of these two motions will keep the image of the sun constantly in the axis of vision, and cause both jointly to run over a parallel circle about the sun in the heavens; but when the quadrant is vertical, a line thereon perpendicular to the axis of vision becomes a vertical axis; and as a small motion of the quadrant is all that is wanted, it will never differ much in practice from a vertical axis. The observer is directed to perform two motions rather than the single one equivalent to them on a line drawn from the eye to the sun; because we are not capable, while looking towards the horizon, of judging how to turn the quadrant about upon the elevated line going to the sun as an axis, by any other means than by combining the two motions abovementioned, so as to keep the sun's image always in the proper part of the horizon-glass. When the sun is near the horizon, the line going from the eye to the sun will not be far removed from the axis of vision; and consequently the principal motion of the quadrant will be performed on the axis of vision, and the part of motion made on the vertical axis will be but small. On the contrary, when the sun is near the zenith, the line going to the sun is not far removed from a vertical line, and conseq
quently the principal motion of the quadrant will be performed on a vertical axis, by the observer's turning himself about, and the part of the motion made on the axis of vision will be but small. In intermediate altitudes of the sun, the motions of the quadrant on the axis of vision, and on the vertical axis, will be more equally divided.

Observations taken with the quadrant are liable to errors, arising from the bending and elasticity of the index, and the resistance it meets with in turning round its centre; whence the extremity of the index, or being pushed along the arch, will feebly advance before the index-glass begins to move, and may be seen to recoil when the force acting on it is removed. Mr. Hadley seems to have been apprehensive that his instrument would be liable to errors from this cause; and in order to avoid them, gives particular directions that the index be made broad at the end next the centre, and that the centre, or axis itself, have as easy a motion as is consistent with steadiness; that is, an entire freedom from looseness, or shake, as the workmen term it. By strictly complying with these directions the error question may indeed be greatly diminished; so far, perhaps, as to render it nearly inoffensive, where the index is made strong, and the proper medium between the two extremes of a shake at the centre on one hand, and too much stiffness there on the other, is nicely hit; but it cannot be entirely corrected. For to more or less of bending the index will always be subject; and some degree of fluctuation will remain at the centre, unless the friction there could be totally removed, which is impossible.

Of the reality of the error to which he is liable from this cause, the observer, if he is provided with a quadrant furnished with a screw for moving the index gradually, may thus satisfy himself. After finishing the observation, lay the quadrant on a table, and note the angle; then cautiously loosen the screw which fastens the index, and it will immediately, if the quadrant is not remarkably well constructed, be seen to start from its former situation, more or less according to the perfection of the joint and the strength of the index. This starting, which is owing to the index recoiling after being released from the confined state it was in during the observation will sometimes amount to several minutes; and its direction will be opposite to that in which the index was moved by the screw at the time of finishing the observation. But how far it affects the truth of the observation, depends on the manner in which the index was moved in setting it to $a$, for adjusting the instrument, or in finishing the observations necessary for finding the index error.

The safest and best rule to avoid these errors seems to be this: In all observations made by Hadley's quadrant, let the observer take notice constantly to check his observations, by moving the index in the same direction which was used in setting it to $a$ for adjusting; or in the observations necessary for finding the index error. If this rule is observed, the error arising from the spring of the index will be obviated. For as the index was bent the same way, and in the same degree in adjusting as in observing, the truth of the observations will not be affected by this bending.

Vol. XII.

N A V I G A T I O N.

To take Altitudes by the Fore-observation.

I. Of the Sun.

Turn down either of the coloured glasses before the horizon-glasses, according to the brightness of the sun; direct the sight to that part of the horizon which is under the sun, and move the index until the coloured image of the sun appears in the horizon-glasses; then give the quadrant a slow vibratory motion about the axis of vision; move the index until the lower or upper limb of the sun is in contact with the horizon, at the lowest part of the arch described by this motion; and the degrees and minutes shown by the index on the limbs will be the altitude of the sun.

II. Of the Moon.

Put the index to $a$, turn down the green glass, place the eye at the lower hole in the sight-vane, and observe the moon in the silvered part of the horizon-glasses; move the index gradually, and follow the moon's reflected image until the enlightened limb is in contact with the horizon, at the lower part of the arch described by the vibratory motion as before, and the index will show the altitude of the observed limb of the moon. If the observation is made in the daytime, the coloured glass is unnecessary.

III. Of a Star or Planet.

The index being put to $o$, direct the sight to the star through the lower hole in the sight-vane and transparent part of the horizon-glasses; move the plane of the quadrant a very little to the left, and the image of the star will appear in the silvered part of the glafes. Now move the index, and the image of the star will appear to descend; continue moving the index gradually until the star is in contact with the horizon at the lowest part of the arch described; and the degrees and minutes shown by the index on the limbs will be the altitude of the star.

To take Altitudes by the Back-observation.

I. Of the Sun.

Put the stem of the coloured glasses into the perforation between the horizon-glasses, turn down either according to the brightness of the sun, and hold the quadrant vertically; then direct the sight to the hole in the back sight-vane, and the transparent slit in the horizon-glasses so that part of the horizon which is opposite to the sun; now move the index till the sun is in the silvered part of the glafes, and by giving the quadrant a vibratory motion, the axis of which is that of vision, the image of the sun will describe an arch whose convex side is upwards; bring the limb of the sun, when in the upper part of this arch, in contact with the horizon; and the index will show the altitude of the other limb of the sun.

II. Of the Moon.

The altitude of the moon is observed in the same manner as that of the sun, with this difference only, that the use of the coloured glass is unnecessary unless the moon is very bright; and that the enlightened limb,
NA VIGATION

Method of finding the Latitude and Longitude at Sea.

III. Of a Star or Planet.

Look directly to the star through the vane and transparent slit in the horizon-glass, move the index until the opposite horizon, with respect to the star, is seen in the silvered part of the glass; and make the contact perfect as formerly. If the altitude of the star is known nearly, the index may be set to that altitude, the sight directed to the opposite horizon, and the observation made as before.

Sect. II. Of finding the Latitude of a Place.

The observation necessary for ascertaining the latitude of a place, is that of the meridional altitude of a known celestial object; or two altitudes when the object is out of the meridian. The latitude is deduced with more certainty and with less trouble from the first of these methods, than from the second; and the fun, for various reasons, is the object most proper for this purpose at sea. It, however, frequently happens, that by the interpolation of clouds, the sun is obscured at noon; and by this means the meridian altitude is lost. In this case, therefore, the method by double altitudes becomes necessary. The latitude may be deduced from three altitudes of an unknown object, or from double altitudes, the apparent times of observation being given.

The altitude of the limb of an object observed at sea, requires four separate corrections in order to obtain the true altitude of its centre: these are for semidiameter, dips, refraction, and parallax. (See Astronomy, and the respective articles). The first and last of these corrections vanish when the observed object is a fixed star.

When the altitude of the lower limb of any object is observed, its semidiameter is to be added thereto in order to obtain the central altitude; but if the upper limb be observed, the semidiameter is to be subtracted. If the altitude be taken by the back-observation, the contrary rule is to be applied. The dip is to be subtracted from, or added to, the observed altitude, according as the fore or back-observation is used. The refraction is always to be subtracted from, and the parallax added to, the observed altitude.

Prob. I. To reduce the sun's declination to any given meridian.

Rule. Find the number in Table IX, answering to the longitude in the table nearest to that given, and to the nearest day of the month. Now, if the longitude is west, and the declination increasing, that is, from the 20th of March to the 22d of June, and from the 22d of September to the 23d of December, the above number is to be added to the declination: during the other part of the year, or while the declination is decreasing, this number is to be subtracted. In east longitude, the contrary rule is to be applied.

Example I. Required the sun's declination at noon 15th April 1793, in longitude 84° W?

Sun's declination at noon at Greenwich 10° 1.8 N

Reduced declination 10° 6.3 N

Example II. Required the sun's declination at noon 22d March 1793, in longitude 15° E?

Sun's declination at noon at Greenwich 0° 56' N

Reduced declination 0° 46' N

Prob. II. Given the sun's meridian altitude, to find the latitude of the place of observation.

Rule. The sun's semidiameter is to be added to, or subtracted from, the observed altitude, according as the lower or upper limb is observed; the dip answering to the time from Table V. is to be subtracted if the fore-observation is used; otherwise, it is to be added; and the refraction answering to the altitude from Table IV. is to be subtracted; hence the true altitude of the sun's centre will be obtained. Call the altitude south or north, according as the sun is south or north at the time of observation; which subtracted from 90°, will give the zenith distance of a contrary denomination.

Reduce the sun's declination to the meridian of the place of observation, by Problem I.; then the sun or difference of the zenith distance and declination, according as they are of the same or of a contrary denomination, will be the latitude of the place of observation, of the same name with the greater quantity.

Example I. October 17th 1793, in longitude 32° E, the meridian altitude of the sun's lower limb was 48° 53' S, height of the eye 18 feet. Required the latitude?

Obs.alt. sun's lower limb, 48° 53' S Sun's decl. 17th Oct. noon 9° 37' S

Semidiameter +0 16

Dip and refraction — 0 5

Reduced declination 9° 35' S

True alt. sun's centre 49° 43' S Zenith distance 40° 36' N

Latitude 31° 11' N

Example II. November 16th 1793, in longitude 15° W, the meridian altitude of the sun's lower limb was 87° 37' N, height of the eye 10 feet. Required the latitude?

Obs.alt. sun's lower limb, 87° 37' N Sun's decl. 16th Nov. noon 18° 57' S

Semidiameter +0 16

Dip and refraction — 0 8

Reduced decl. 19° 5 S

True alt. sun's centre 87° 50' N Zenith distance 2° 10' S

Latitude 31° 15' S

Example III. December 15th 1793, being nearly under the meridian of Greenwich, the altitude of the sun's upper limb at noon was 4° 30' S, height of the eye 20 feet. Required the latitude?

Observed altitude of the sun's upper limb 4° 30' S

Sun's semidiameter — 0 16

Dip and refraction — 0 15

True altitude of the sun's centre — 3° 59' S

Zenith distance — 86° 1 N

Declination — 23° 27' S

Latitude — 62° 34' N

Example.
EXAMPLE IV. August 23rd 1793, in longitude 107° E, the meridian altitude of the sun's lower limb by the back-observation was 61° 8' N, and the height of the eye 14 feet. Required the latitude.

Observed the altitude sun's upper limb
Sun's semidiameter
Dip
Refration
True altitude of the sun's centre
Zenith distance
Reduced declination
Latitude
The dip in Table V. answers to an entirely open and unobstructed horizon. It, however, frequently happens, that the sun is over the land at the time of observation, and the ship nearer to the land than the visible horizon would be if unconfined. In this case, the dip will be different from what it would otherwise have been, and is to be taken from Table VI, in which the height is expressed at the top, and the distance from the land in the side column in nautical miles.—Seamen, in general, can estimate the distance of any object from the ship with sufficient accuracy for this purpose, especially when that distance is not greater than six miles, which is the greatest distance of the visible horizon from an observer on the deck of any ship.

PROB. III. Given the meridian altitude of a fixed star, to find the latitude of the place of observation.

RULE. Correct the altitude of the star by dip and refraction, and find the zenith distance of the star as formerly; take the declination of the star from Table X., and reduce it to the time of observation. Now, the sum or difference of the zenith distance and declination of the star, according as they are of the same or of a contrary name, will be the latitude of the place of observation.

EXAMPLE I. December 18th 1793, the meridian altitude of Sirius was 59° 30' S, height of the eye 14 feet. Required the latitude?

Observed altitude of Sirius
Dip and refraction
True altitude
Zenith distance
Declination
Latitude
EXAMPLE II. February 17th 1797, the meridian altitude of Procyon was 71° 15' N, the height of the eye 10 feet. Required the latitude?

Observed altitude of Procyon
Dip and refraction
True altitude
Zenith distance
Declination
Latitude

EXAMPLE V. Given the meridian altitude of a planet, to find the latitude of a place of observation.

RULE. Compute the true altitude of the planet as directed in last problem (which is sufficiently accurate for altitudes taken at sea); take its declination from the Nautical Almanac, page iv. of the month, and reduce it to the time and meridian of the place of observation; then the sum or difference of the zenith distance and declination of the planet will be the latitude as before.

EXAMPLE I. December 10th 1792, the meridian altitude of Saturn was 68° 42' N, and height of the eye 15 feet. Required the latitude?

Observed altitude of Saturn
Dip and refraction
True altitude
Zenith distance

**Example I.** July 1st 1793, in longitude 14° W, the altitude of the sun's lower limb at midnight was 8° 58', height of the eye 18 feet. Required the latitude?

*Observed altitude sun's lower limb* | 8° 58' |
| **Semidiameter** | +0 15 |
| **Dip and refraction** | -0 10 |

**True altitude of sun's centre** | 9 4 N |
| **Compl. Declination reduced to time and place** | 66 57 N |

**Latitude** | 76 1 N |

**Example II.** December 1st 1798, the altitude of the pole star below the pole was 52° 20' N, height of the eye 12 feet. Required the latitude?

*Observed altitude, pole star* | 52° 20' N |
| **Dip and refraction** | -0 4 |

**True altitude** | 52 16 N |
| **Complement of Declination** | 1 45 |

**Latitude** | 54 2 N |

**Prob. VI.** Given the latitude by account, the declination and two observed altitudes of the sun, and the interval of time between them, to find the true latitude.

**Rule.** To the log. secant of the latitude by account, add the log. secant of the sun's declination; the sum is the logarithm ratio. To this add the log. of the difference between the natural lines of the two altitudes, and the log. of the half elapsed time from its proper column.

If this sum is column of middle time, and take the time answering thereto; the difference between which and the half elapsed time will be the time from noon when the greater altitude was observed.

Take the log. answering to this time from column of rising, from which subtract the log. ratio, the remainder is the logarithm of a natural number; which being added to the natural line of the greater altitude, the sum is the natural cosine of the meridian zenith distance; from which and the sun's declination the latitude is obtained as formerly.

If the latitude thus found differs considerably from that by account, the operation is to be repeated, using the computed latitude in place of that by account (l).

**Example I.** June 4th 1795, in latitude by account

(1.) This method is only an approximation, and ought to be used under certain restrictions; namely,

The observations must be taken between nine o'clock in the forenoon and three in the afternoon. If both observations be in the forenoon, or both in the afternoon, the interval must not be less than the distance of the time of observation of the greatest altitude from moon. If one observation be in the forenoon and the other in the afternoon, the interval must not exceed four hours and a half; and in all cases, the nearer the greater altitude is to noon the better.

If the sun's meridian zenith distance be less than the latitude, the limitations are still more contracted. If the latitude be double the meridian zenith distance, the observations must be taken between half past nine in the morning and half past two in the afternoon, and the interval must not exceed three hours and a half. The observations must be taken full nearer to noon, if the latitude exceeds the zenith distance in a greater proportion. See Matheny's British Mariner's Guide, and Requisite Tables, 2d Ed.

Latitude 51° 15' N.

As the latitude by computation differs 1° 27' from that by account, the operation must be repeated.

Computed latitude 51° 15' Secant 0.2024
Declination 9° 37' Secant 0.00615

Logarithm ratio - 0.20679
Difference of nat. sines 14530 Log.
Half elapsed time 1h 43' 30" Log.

Middle time
Rising - 0 40 20 Log. 4.92927

Natural number 639
Mer. zenith. diff. 60° 52' C. 48687
Declination 9° 37'

Latitude, 51° 15' N.

As this latitude differs only 6' from that used in the computation, it may therefore be depended on as the true latitude.

PROB. VII. Given the latitude by account, the sun's declination, two observed altitudes, the elapsed time, and the course and distance run between the observations; to find the ship's latitude at the time of observation of the greater altitude.

Rule. Find the angle contained between the ship's course and the sun's bearing at the time of observation of the least altitude, with which enter the Traverse Table as a course, and the difference of latitude answering to the distance made good will be the reduction of altitude.

Now, if the least altitude be observed in the forenoon, the reduction of altitude is to be applied thereto by addition or subtraction, according as the angle between
**NA V IGAT I O N**

Method of finding the Latitude and Longitude at Sea.

The difference of longitude in time between the observations is to be applied to the elapsed time by addition or subtraction, according as it is east or west. This is, however, in many cases too inconsiderable to be neglected.

With the corrected altitudes and interval, the latitude by account and sun's declination at the time of observation of the greatest altitude, the computation is to be performed by the last problem.

**EXAMPLE I.** July 6th 1793, in latitude 58° 14' N. by account, and longitude 16° E. at 16h 54' A. M. per watch, the altitude of the sun's lower limb was 53° 17', and at 17h 17' P. M. the altitude was 52° 51', and bearing per compass SW by W; the ship's course during the elapsed time was SW by W, and the hourly rate of falling 8 knots, the height of the eye 16 feet. Required the true latitude at the time of observation of the greater altitude?

Sun's bear. at z.d. ob. SW by W. Interval bet. observ. 2h 23'.

Greatest altitude 53° 23' N, fine 80864
Method of finding the Latitude and Longitude at Sea.

Mer. Zen. diff. 35 14 N cosine 81682
Declination 3 34

Latitude - 38 48 N.

This latitude differing only 2 miles from that used in the computation, may therefore be relied on as the true latitude.

Remark. If the sun comes very near the zenith, the fmes of the altitudes will vary so little as to make it uncertain which ought to be taken as that belonging to the natural fine of the meridian altitude. In this case, the following method will be found preferable.

To the log rising of the time from noon as before, add the log. secant of half the sum of the estimated meridian altitude, and greatest observed altitude; from which subtract the log. ratio, its index being increased by 10, and the remainder will be the log. fine of an arch; which added to the greatest altitude will give the sun's meridian altitude.

Example. December 21 st 1793, in latitude 22° 40' S, by account, at 12h 57', the correct altitude of the sun's centre was 89° 10' and at 12h 40', the altitude was 88° 50'. Required the true latitude?

PR0B. VIII. To find the latitude from double altitudes of the sun and the elapsed time: one of these observations being taken near the east or west points, and the other near the meridian.

Rule. With the latitude by account, the sun's declination and least altitude, compute the apparent time of observation by Problem VII. of next chapter. From whence and the interval of time between the observations, the time from noon when the greatest altitude was observed will be known. To the logarithm rising of which, add the logarithmic cosine of the sun's declination and the latitude of the place by account; the sun will be the logarithm of a natural number, which added to the natural sine of the greater altitude, will give the natural cosine of the meridian zenith distance; and hence the latitude is found as formerly.

Or the time from noon being found, the latitude may be computed by the rule given in the preceding remark.

Example. September 18th 1793, in latitude 40° o' N by account, at 6h 5' A. M. per watch, the altitude of the sun's lower limb was 16° 21', and at 11th 41' the altitude was 59° 42'; the height of the eye 18 feet. Required the latitude?

in order to connect the observations for ascertaining the apparent time at the ship and the longitude with each other.

An observer without any assistants may very easily take all the observations, by first taking the altitudes of the objects, then the distance, and again their altitudes, and reduce the altitudes to the time of observation of the distance; or, by a single observation of the distance, the apparent time being known, the longitude may be determined.

A set of observations of the distance between the moon and a star, and their altitudes, may be taken with accuracy during the time of the evening or morning twilight; and the observer, though not much acquainted with the stars, will not find it difficult to distinguish the star from which the moon's distance is to be observed. For the time of observation nearly, and the ship's longitude by account being known, the ultimate time at Greenwich may be found; and by entering the Nautical Almanac with the reduced time, the distance between the moon and given star will be found nearly. Now set the index of the sextant to this distance, and hold the plane of the instrument so as to be nearly at right angles to the line joining the moon's cusps, direct the light to the moon, and by giving the sextant a slow vibratory motion, the axis of which being that of vision, the star, which is usually one of the brightest in that part of the heavens, will be seen in the silvered part of the horizon-glass.

Sect. II. Of the Sextant.

This instrument is constructed for the express purpose of measuring with accuracy the angular distance between the sun and moon, or between the moon and a fixed star, in order to ascertain the longitude of a place by lunar observations. It is, therefore, made with more care than the quadrant, and has some additional appendages that are wanting in that instrument.

Fig. 74 represents the sextant, so framed as not to be liable to bend (m). The arch AA is divided into 120 degrees, each degree is divided into three parts; each of these parts therefore, contains 20 minutes, which are again subdivided by the vernier into every half minute or 30 seconds. The vernier is numbered at every fifth of the longer divisions, from the right towards the left, with 5, 10, 15, and 20; the first division to the right being the beginning of the scale.

In order to observe with accuracy, and make the images come precisely in contact, an adjusting screw B is added to the index, which may thereby be moved with greater accuracy than it can be by hand; but this screw does not act until the index is fixed by the finger screw C. Care should be taken not to force the adjusting screw when it arrives at either extremity of its adjustment. When the index is to be moved any considerable quantity, the screw C at the back of the sextant must be loosened; but when the index is brought nearly to the division required, this back screw should be tightened, and then the index may be moved gradually by the adjusting screw.

(m) Troughton's patent double-framed sextants are not liable to bend.
There are four tined glasses $D$, each of which is set in a separate frame that turns on a centre. They are used to defend the eye from the brightness of the solar image and the glare of the moon, and may be used separately or together as occasion requires.

There are three more such glasses placed behind the horizon-glasses $E$, to weaken the rays of the sun or moon when they are viewed directly through the horizon-glass. The paler glass is sometimes used in observing altitudes at sea, to take glasses of the telescope and the eye.

The frame of the index-glass $I$, is firmly fixed by a strong cock to the centre plate of the index. The horizon-glass $F$ is fixed in a frame that turns on the axis or pivots, which move in an exterior frame; the holes in which the pivots move may be tightened by four screws in the exterior frame. $G$ is a screw by which the horizon glases may be set perpendicular to the plane of the instrument: should this screw become loose or move too easily, it may be easily tightened by turning the capitation-headed screw $H$, which is on one side of the socket through which the stem of the finger screw passes.

The sextant is furnished with a plain tube (fig. 75.) without any glasses; and to render the objects still more distinct, it has two telescopes, one (fig. 76.) representing the objects erect, or in their natural position; the longer one (fig. 77.) shows them inverted; it has a large field of view and other advantages, and a little ufe will soon accustomed the observer to the inverted position, and the instrument will be as readily managed by it as by the plain tube alone. By a telescope the contact of the images is more perfectly distinguished; and by the place of the images in the field of the telescope, it is easy to perceive whether the sextant is held in the proper place for observation. By folding the tube that contains the eye-glasses in the inside of the other tube, the object is suited to different eyes, and made to appear perfectly distinct and well defined.

The telescopes are to be screwed into a circular ring at $K$, this ring rests on two points against an exterior ring, and is held thereto by two screws; by turning one or other of these screws, and diminishing or increasing the space, the axes of the telescopes may be set parallel to the plane of the sextant. The exterior ring is fixed on a triangular brass plate that slides in a socket, and by means of a screw at the back of the quadrant may be raised or lowered so as to move the centre of the telescope to point to that part of the horizon-glass which shall be judged the most fit for observation.

Fig. 78. is a circular head, with tined glasses to screw on the eye end of either of the telescopes or the plain tube. The glasses are contained in a circular plate which has four holes; three of these are fitted with tined glasses, the fourth is open. By prefing the finger against the projecting edge of this plate and turning it round, the open hole, or any of the tined glasses, may be brought between the eye-glasses of the telescope and the eye.

Fig. 79. is a magnifying glass, to assist the observer to read off the angle with more accuracy; and (fig. 80.) a screw-driver.

Adjustments of the Sextant.

The adjustments of a sextant are, to set the mirrors perpendicular to its plane and parallel to each other when the index is at Zeno, and to set the axis of the telescope parallel to the plane of the instrument. The three first of these adjustments are performed nearly in the same manner as directed in the section on the quadrant: as, however, the sextant is provided with a set of coloured glasses placed behind the horizon-glass, the index-error may be more accurately determined by measuring the sun's diameter twice, with the index placed alternately before and behind the beginning of the divisions; half the difference of these two measures will be the index-error, which must be added to, or subtracted from, all observations, according as the diameter measured with the index to the left of $\theta$ is less or greater than the diameter measured with the index to the right of the beginning of the divisions.

Adjustment IV. To set the axis of the Telescope parallel to the Plane of the Instrument.

Turn the eye end of the telescope until the two wires are parallel to the plane of the instrument and let two distant objects be selected, as two stars of the first magnitude, whose distance is not less than 90° or 100°: make the contact of these objects as perfect as possible at the wire nearest the plane of the instrument; fix the index in this position; move the sextant till the objects are seen at the other wire, and if the same points are in contact, the axis of the telescope is parallel to the plane of the sextant; but if the objects are apparently separated, do partly cover each other, correct half the error by the screws in the circular part of the supporter, one of which is above and the other between the telescope and sextant; turn the adjusting screw at the end of the index till the limbs are in contact; then bring the objects to the wire next the instrument; and if the limbs are in contact, the axis of the telescope is adjusted; if not, proceed as at the other wire, and continue till no error remains.

It is sometimes necessary to know the angular distance between the wires of the telescope; to find which, place the wires perpendicular to the plane of the sextant, hold the instrument vertical, direct the sight to the horizon, and move the sextant in its own plane till the horizon and upper wire coincide; keep the sextant in this position, and move the index till the reflected horizon is covered by the lower wire; and the division shown by the index on the limb, corrected by the index error, will be the angular distance between the wires. Other and better methods will readily occur to the observer at hand.

Use of the Sextant.

When the distance between the moon and the sun or a star is to be observed, the sextant must be held so that its plane may pass through the eye of the observer and both objects; and the reflected image of the most luminous of the two is to be brought in contact with the other seen directly. To effect this, therefore, it is evident, that when the brightest object is to the right of the other, the face of the sextant must be held upwards; but if to the left downwards. When the face of the sextant is held upwards, the instrument should be supported with the right hand, and the index moved with the left hand. But when the face of the sextant is from the observer, it should be held with
PRACTICE.

Of finding the Longitude at Sea by Lunar Observations.

The left hand, and the motion of the index regulated by the right hand.

Sometimes a sitting posture will be found very convenient for the observer, particularly when the reflected object is to the right of the direct one; in this case, the instrument is supported by the right hand, the elbow may rest on the right knee, the right leg at the same time resting on the left Knee.

If the sextant is provided with a ball and socket, and a staff, one of whose ends is attached thereto, and the other rests in a belt fastened round the body of the observer, the greater part of the weight of the instrument will by this means be supported by his body.

To observe the Distance between the Moon and any celestial object.

1. Between the sun and moon.

Put the telescope in its place, and the wires parallel to the plane of the instrument; and if the sun is very bright, raise the plate before the silvered part of the speculum; direct the telescope to the transparent part of the horizon-glass, or to the line of separation of the silvered and transparent parts, according to the brightness of the sun, and turn down one of the coloured glasses, then hold the sextant so that its plane produced may pass through the sun and moon, having its face either upwards or downwards according as the sun is to the right or left of the moon; direct the sight through the telescope to the moon; and move the index till the limb of the sun is nearly in contact with the enlightened limb of the moon; now fasten the index, and by a gentle motion of the instrument make the image of the sun move alternately past the moon, and, when in that position where the limbs are nearest each other, make the coincidence of the limbs perfect by means of the adjusting screw; this being effected, read off the degrees and parts of a degree shown by the index on the limb; using the magnifying glasses; and thus the angular distance between the nearest limbs of the sun and moon is obtained.

2. Between the moon and a star.

Direct the middle of the field of the telescope to the line of separation of the silvered and transparent parts of the horizon-glass; if the moon is very bright turn down the lightest coloured glass, and hold the sextant so that its plane may be parallel to that passing through the eye of the observer and both objects; its face being upwards if the moon is to the right of the star, but if to the left, the face is to be held from the observer; now direct the sight through the telescope to the star, and move the index till the moon appears by reflection to be nearly in contact with the star; fasten the index, and turn the adjusting screw till the coincidence of the star and enlightened limb of the moon is perfect; and the degrees and parts of a degree shown by the index will be the observed distance between the moon’s enlightened limb and the star.

The contact of the limbs must always be observed in the middle between the parallel wires.

It is sometimes difficult for those not much accustomed to observations of this kind, to find the reflected image in the horizon-glass: it will perhaps in this case be found more convenient to look directly to the object, and, by moving the index, to make its image coincide with that seen directly.

Sect. III. Of the Circular Instrument of Reflection.

This instrument was proposed with a view to correct the errors to which the sextant is liable, particularly the error arising from the inaccuracy of the divisions on the limb. It consists of the following parts: a circular ring or limb, two moveable indices, two mirrors, a telescope, coloured glasses, &c.

The limb of this instrument is a complete circle of metal, and is connected with a performed central plate by fixed radii; it is divided into 360 degrees; each degree is divided into three equal parts; and the division is carried to minutes by means of the index foil as usual.

The two indices are moveable about the line axis, which passes exactly through the centre of the instrument—the first index carries the central mirror, and the other the telescope and horizon glass; each index being provided with an adjusting screw for regulating its motion, and a scale for showing the divisions on the limb.

The central mirror is placed on the first index immediately above the centre of the instrument, and its plane makes an angle of about $30^\circ$ with the middle line of the instrument. The four screws at its under end are used for making its plane perpendicular to that of the instrument having square heads, and are therefore easily turned either way by a key for that purpose.

The horizon-glass is placed on the second index near the limb, so that as few as possible may be intercepted of the rays proceeding from the reflected object when to the left. The perpendicular position of this glass is rectified in the same manner as that of the horizon-glass of a sextant, to which it is similar. It has another motion, whereby its plane may be disposed so as to make a proper angle with the axis of the telescope, and a line joining its centre, and that of the central mirror.

The telescope is attached to the other end of the index. It is an achromatic astronomical one, and therefore inverts objects; it has two parallel wires in the common focus of the glasses, whose angular distance is between two and three degrees, and which, at the time of observation, must be placed parallel to the plane of the instrument. This is easily done, by making the mark on the eye-piece coincide with that on the tube. The telescope is moveable by two screws in a vertical direction with regard to the plane of the instrument, but is not capable of receiving a lateral motion.

There are two sets of coloured glasses, each set containing four, and differing in shade from each other. The glasses of the larger set, which belongs to the central mirror, should have each about half the degree of shade with which the correspondent glasses of the set belonging to the horizon mirror are tinged. These glasses are kept tight in their places by small prehending screws, and make an angle of about $85^\circ$ with the plane of the instrument; by which means the image from the coloured glass is not reflected to the telescope. When the angle to be measured is between $5^\circ$ and $34^\circ$, one of the glasses of the largest set is to be placed before the horizon-glass.

The handle is of wood and is screwed to the back of the instrument, immediately under the centre, with which it is to be held at the time of observation.
**NAVIGATION.**

**Practice.**

Of finding the Longitude at Sea by Lunar Observations.

**Plate cccxliii.**

Fig. 81. is a plan of the instrument, wherein the limb is represented by the divided circular plate; A is the central mirror, a a, the places which receive the terms a a of the glass fig. 84; EF, the first or central index, with its scale and adjusting screw; MN, the second or horizon index; GH, the telescope; IK, the screws for moving it forwards or from the plane of the instrument; C, the place of the coloured glass fig. 83; and D, its place in certain observations.

Fig. 82. is a section of the instrument, wherein the several parts are referred to by the same letters as in fig. 81; Fig. 83. represents one of the horizon coloured glaffes; and fig. 84. one of the central coloured glaffes: Fig. 85. is the key for turning the adjusting screws of the mirrors: Fig. 86. is the handle; Fig. 87. a section of one of the radii towards its middle: Fig. 88. is used in some terrestrial observations for diminishing the light of the direct object, whose place at the time of observation is D: Fig. 89 is the tool for adjusting the central mirror, and for rectifying the position of the telescope with regard to the plane of the instrument; there is another tool exactly of the same size. The height of these is nearly equal to that of the middle of the central mirror.

Adjustments of the Circular Instrument.

I. To set the horizon-glass so that none of the rays from the central mirror shall be reflected to the telescope from the horizon mirror, without passing through the coloured glass belonging to this last mirror.—Place the coloured glass before the horizon mirror; direct the telescope to the silvered part of that mirror, and make it nearly parallel to the plane of the instrument; move the first index; and if the rays from the central mirror to the horizon-glass, and from thence to the telescope, have all the same degree of shade with that of the coloured glass used, the horizon-glass is in its proper position; otherwise the pedetal of the glass must be turned until the uncoloured images disappear.

II. Place the two adjusting tools on the limb, about 370° of the instrument distant, one on each side of the division on the left, affixing to the plane of the central mirror produced: then the eye being placed at the upper edge of the nearest tool, move the central index till one half only of the reflected image of this tool is seen in the central mirror towards the left, and move the other tool till its half to the right is hid by the same edge of the mirror; then, if the upper edges of both tools are apparently in the same straight line, the central mirror is perpendicular to the plane of the instrument; if not bring them into this position by the screws in the pedetal of the mirror.

III. To set the horizon mirror perpendicular to the plane of the instrument.—The central mirror being previously adjusted, direct the fight through the telescope to any well defined distant object; then if, by moving the central index, the reflected image passes exactly over the direct object, the mirror is perpendicular; if not, its position must be rectified by means of the screws in the pedetal of the glasses.

A planet, or star of the first magnitude, will be found a very proper object for this purpose.

IV. To make the line of collimation parallel to the plane of the instrument.—Lay the instrument horizontally on a table; place the two adjusting tools on the limb, towards the extremities of one of the diameters of the instrument; and at about 15 or 20 feet distant let a well defined mark be placed so as to be in the same straight line with the tops of the tools; then raise or lower the telescope till the plane passing through its axis and the tops of the tools is parallel to the plane of the instrument, and direct it to the fixed object; turn either or both of the fires of the telescope till the mark is apparently in the middle between the wires; then is the telescope adjusted; and the difference, if any, between the divisions pointed out by the indices of the fires will be the error of the indices. Hence this adjustment may in future be easily made.

In this process the eye tube must be so placed as to obtain distinct vision.

V. To find that division to which the second index being placed the mirrors will be parallel, the central index being at Zero.—Having placed the first index exactly to o, direct the telescope to the horizon mirror, so that its field may be bisected by the line of separation of the silvered and transparent parts of that mirror; hold the instrument vertically, and move the second index until the direct and reflected horizons agree; and the division shown by the index will be the one required.

This adjustment may be performed by measuring the sun's diameter in contrary directions, or by making the reflected and direct images of a star or planet to coincide.

Use of the Circular Instrument.

I. To observe the distance between the sun and moon.

Set a proper coloured glass before the central mirror, if the distance between the objects is less than 20°; but if above that quantity, place a coloured glass before the horizon mirror: make the mirrors parallel, the first index being at o, and hold the instrument so that its plane may be directed to the objects, with its face downwards, or from the observer: direct the sight through the telescope to the moon: move the second index, according to the order of the divisions on the limb, till the nearest limbs of the sun and moon are almost in contact: then set that index, and make the coincidence of the limbs perfect by the adjusting screw belonging thereto: then invert the instrument, and move the central index towards the second by a quantity equal to twice the arch passed over by that index: direct the plane of the instrument to the objects: look directly to the moon, and the sun will be seen in the field of the telescope: move the contact of the same two limbs by means of the adjusting screw: Then half the angle shown by the central index will be the distance between the nearest limbs of the sun and moon.

II. The sun being to the left of the moon.

Hold the instrument with its face upwards, so that its plane may pass through both objects: direct the telescope to the moon, and make its limb coincide with the nearest limb of the sun's reflected image, by moving the second index: now put the instrument in an opposite position: direct its plane to the objects, and the sight to the moon, the central index being previously moved towards the second by a quantity equal to twice the measured distance: and make the same two limbs
Of finding the Longitude at Sea by Lunar Observations.

To observe the angular Distance between the Moon and a Fixed Star or Planet.

I. The star being to the right of the moon.

In this case the star is to be considered as the direct object; and the enlightened limb of the moon's reflected image is to be brought in contact with the star or planet, both by a direct and inverted position of the instrument, exactly in the same manner as described in the last article. If the moon's image is very bright, the lightest tinged glass is to be used.

II. The star being to the left of the moon.

Proceed in the same manner as directed for observing the distance between the sun and moon, using the lightest image is to be brought in the clock or watch, or to which the sun or moon, using the lightest tinged glass if necessary.

Sec. IV. Of the Method of determining the Longitude from Observation.

Prob. I. To convert degrees or parts of a degree into time.

Rule. Multiply the degrees and parts of a degree by 4, beginning at the lowest denomination, and the product will be the corresponding time. Observing that minutes multiplied by 4 produce seconds of time, and degrees multiplied by 4 give minutes.

Example I. Let 26° 45' be reduced to time. 26° 45' = 4

1h 47' 0"=time required.

Example II. Reduce 83° 37' to time. 83° 37' = 4

Corresponding time = 5 34 28.

Prob. II. To convert time into degrees.

Rule. Multiply the given time by 45, beginning to which add the half of the product. The sum will be the corresponding degrees.

Example I. Let 3h 4' 28" be reduced to degrees. 3h 4' 28" = 10

Half = 15 22 20

Corresponding deg. = 46 7 0

Example II. Reduce 8h 42' 36" to degrees. 8h 42' 36" = 10

87 6 0

43 3 0

Answer 130 39 0

Prob. III. Given the time under any known meridian, to find the corresponding time at Greenwich.

Rule. Let the given time be reckoned from the preceding noon, to which the longitude of the place in time is to be applied by addition or subtraction, according as it is east or west; and the sum or difference will be the corresponding time at Greenwich.

Example. What time at Greenwich answers to 6h 15' at a ship in longitude 76° 45' W?

Time at ship = 6h 15'

Longitude in time = 5 7 W.

Time at Greenwich, 11 22

Example II. Required the time at Greenwich answering to 5h 46' 39" of May 1st, at Canton, whose longitude is 113° 2' 15" E?

Time at Canton, May 1st = 5h 46' 39"

Longitude in time = 7 32 9 E.

Time at Greenwich, April 30. 22 14 30

Prob. IV. To reduce the time at Greenwich to that under any given meridian.

Rule. Reckon the given time for the preceding noon, to which add the longitude in time if east, but subtract it if west; and the sum or remainder will be the corresponding time under the given meridian.

Example I. What is the expected time of the beginning of the lunar eclipse of February 25, 1793, at a ship in longitude 109° 48' E?

Beg. of eclipse at Greenwich per Naut Alm. 9h 23' 45" Ship's longitude in time, = - 7 19 12

Time of beginning of eclipse at ship, 16 42 57

Example II. At what time may the immersion of the first satellite of Jupiter be observed at Port St Julian, in longitude 68° 44' W. by the Nautical Almanac happens at Greenwich 24th March 1792, at 17h 53' 1?.

App. time of immersion at Greenwich 17h 53' 1" Longitude of Port St Julian in time, 4 34 56 W.

App. time ofimmer, at Port St Julian, 13 18 5

Prob. V. To find the equation of equal latitudes.

Rule. To the co-secant of half the interval of time in degrees add the tangent of the latitude, and to the cotangent of half the interval add the tangent of the declination. Now if the latitude and declination be of a contrary name, add the corresponding natural numbers; but if of the same name, subtract them. Then to the ar. co-log. of this sum or difference add the proportional logarithm of one-fourth of the interval expressed in time, and the proportional logarithm of the daily variation of declination, the sum will be the proportional logarithm of the equation of equal altitudes in minutes and seconds, which are to be esteemed seconds and thirds.

Example. Let the latitude of the place of observation be 57° 9' N, the interval of time between the observations of the equal altitudes 5h 17', the sun's declination 17° 48' S, and the daily change of declination 16° 19' 3: Required the equation of equal altitudes?

Half the interval = 2h 38' 1" = 39° 37'

½ int. = 39° 37' cos'. 0.19545 cotang. 0.08209

Lat. 57° 9' tan. 0.18997 dec. 17° 48' 32°. 9° 56 32' 0.38 73 24 38 63 38 79 9.58 08 86

Sum - - 2.8167 ar. co. lo. 9.55 03 One-
The document appears to be a page from a navigation or astronomy text, discussing methods for determining the error of a watch by equal altitudes of the sun. It includes practical examples and rules for calculating the error.

### Table

| Rule | In the morning when the sun is more than two hours distant from the meridian, let a set of observations be taken, confessing, for the sake of greater accuracy, of at least three altitudes, which, together with the corresponding times per watch, are to be written regularly, the time of each observation being increased by 12 hours. In the afternoon, observe the time per watch of apparent noon, the difference between which and noon will be the time per watch of apparent time, and the error of the watch. |
| Rule | If the latitude and declination are of different names, let their sun be taken; otherwise, their difference. From the natural cosine of this sun or difference subtract the natural fine of the corrected altitude, and find the logarithm of the remainder; to which add the log. secants of the latitude and declination: the sun will be the log. rising of the horary distance of the object from the meridian, and hence the apparent time will be known. |

### Example I
January 29, 1786, in lat. 57° 9' N, the following equal altitudes of the sun were observed:

- Required the error of the watch?

### Example II
September 15th 1792, in latitude 33° 56' S, and longitude 18° 22' E, the mean of the times per watch was 8h 12° 10' A.M. and that of the altitudes of the sun's lower limb 24° 14' 15; height of the eye 24 feet. Required the error of the watch?

**Prob. VIII.** Given the latitude of a place, the altitude of a known fixed star, and the sun's right ascension, to find the apparent time of observation and error of the watch.

**Rule.** Correct the observed altitude of the star, and reduce its right ascension and declination to the time of observation.

With the latitude of the place, the true altitude and declination of the star, compute its horary distance from meridian by half problem; which being added to or subtracted from its right ascension according as it was observed in the western or eastern hemisphere, the sum or remainder will be the right ascension of the meridian.

From the right ascension of the meridian subtract the sun's right ascension as given in the Nautical Almanac for the moon of the given day, and the remainder will be the approximate time of observation; from which subtract the proportional part of the daily variation of right ascension anfwering thereto, and let the proportional part anfwering to the longitude be added or subtracted according as the longitude is east or west, and the result will be the apparent time of observation; and hence the error of the watch will be known.

**Example I.** December 12th 1792, in latitude 37° 46 N. and longitude 21° 15 E, the altitude of Arcturus east of the meridian was 34° 6.4, the height of the eye 10 feet. Required the apparent time of observation?

- Observed alt. of Arcturus 34° 6.4
- Dip and refraction — 4.4
- True altitude — 34° 2.0
- Latitude — 37° 46.0 N. sec. 0.10209

**Prob. IX.** Given the altitude of the moon, the latitude of a place, and the apparent time at Greenwich, to find the apparent time at the place of observation.

**Rule.** Correct the altitude of the moon's limb by Problem V. p. 731, and reduce its right ascension and declination, and the sun's right ascension to the Greenwich time of observation. Now with the latitude of the place, the declination and altitude of the moon, compute its meridian distance as before; Which being applied to its right ascension by addition or subtraction, according as it is in the western or eastern hemisphere, will give the right ascension of the meridian. Then the sun's right ascension subtracted from the right ascension of the meridian, will give the apparent time of observation.

**Prob. XI.** To find the time at Greenwich answering to a given distance between the moon and the sun, or one of the stars, used in the Nautical Almanac.

**Rule.** If the given distance is found in the Nautical Almanac opposite to the given day of the month, or to that which immediately precedes or follows it, the time is found at the top of the page. But if this distance is not found exactly in the ephemeris, subtract the prop. log. of the difference between the distances which immediately precede and follow the given distance; from the prop. log. of the difference between the given and preceding distances, the remainder will be the prop. log. of the excess of the time
corresponding to the given distance, above that answering to the preceding distance: And hence the apparent time at Greenwich is known.

**Example.** September 21, 1792, the true distance between the centres of the sun and moon was 68° 13' 8". Required the apparent time at Greenwich?

**Prob. XII.** The latitude of a place and its longitude by account being given, together with the distance between, and the altitude of the moon and the sun, or one of the stars in the Nautical Almanac; to find the true longitude of the place of observation.

**Rule.** Reduce the estimate time of observation to the meridian of Greenwich by Problem III., and to this time, take from the Nautical Almanac page vii. of finding the longitude at sea by lunar observations, of the month, the moon's horizontal parallax and semidiameter. Increase the semidiameter by the augmentation answering to the moon's altitude.

Find the apparent and true altitudes of each object's centre, and the apparent central distance; with which compute the true distance by Problem X., and find the apparent time at Greenwich answering thereto by the last problem.

If the sun or star be at a proper distance from the meridian at the time of observation of the distance, compute the apparent time at the ship. If not, the error of the watch may be found from observations taken either before or after that of the distance; or the apparent time may be inferred from the moon's altitude taken with the distance, by Problem IX.

The difference between the apparent times of observation at the ship and Greenwich, will be the longitude of the ship in time; which is east or west according as the time at the ship is later or earlier than the Greenwich time.

**Example I.** March 17, 1792, in latitude 34° 23' N, and longitude by account 27° W, about 9h A.M. the distance between the nearest limbs of the sun and moon was 68° 32'; the altitude of the sun's lower limb 33° 18'; that of the moon's upper limb 31° 3'; and the height of the eye 12 feet. Required the true longitude of the ship?

The variation of the compass is the deviation of the points of the maker's compass from the corresponding points of the horizon; and is denominated east or west variation, according as the north point of the compass is to the east or west of the true north point of the horizon.

A particular account of the variation, and of the several instruments used for determining it from observation, may be seen under the articles Azimuth, Compass, and Variation; and for the method of communicating magnetism to compass needles, see Magnetics.

**Probl. I.** Given the latitude of a place, and the sun's magnetic amplitude, to find the variation of the compass.

**Rule.** To the log, secant of the latitude, add the log, cosine of the sun's declination; the sum will be the log, cosine of the true amplitude; to be reckoned from the north or south according as the declination is north or south.

The difference between the true and observed amplitudes reckoned from the same point, and if of the same name, is the variation; but if of a different name, the sum is the variation.

If the observation be made in the eastern hemisphere, the variation will be east or west according as the observed amplitude is nearer to or more remote from the north than the true amplitude. The contrary rule holds good in observations taken in the western hemisphere.

**Example I.** May 15. 1784, in latitude 33° 10' N., longitude 18° W., about 5½ A. M. the sun was observed to rise E.N. Required the variation?

Sun's dec. 8° 15 at noon 19° 5' N.  
Equation to noon 4  

To the log, cosine of the sun's declination add the log, cosine of the latitude; the sum, added to the observed amplitude, will be the true amplitude; half the sum of the latitudes will be the true amplitude of the sun in latitude 33° 10' N.

To find the sun's true amplitude, subtract the log, cosine of the latitude from the log, cosine of the sun's declination; and if the result is positive, the true amplitude is the sun's declination; if negative, the sun's declination is greater than the true amplitude.

**Example II.** December 20. 1793, in latitude 31° 38' N., longitude 85° W., the sun was observed to set west. Required the variation?

**Solution.**  
Latitude 31° 38' N.  
Dec. 23° 28 Sine 9.60012  
Variation 17° 7' W.; which is east, as the observed amplitude is farther from the north than the true amplitude, the observation being made at sun-setting.

It may be remarked, that the sun's amplitude ought to be observed at the instant the altitude of its lower limb is equal to the sum of 15 minutes and the dip of the horizon. Thus, if an observer be elevated 18 feet above the surface of the sea, the amplitude should be taken at the instant the altitude of the sun's lower limb is 15 minutes.

**Example III.** July 15. 1794, in latitude 33° 10' N., longitude 18° W., 10 A. M. the sun was observed to rise E.N. Required the variation?

Sun's declination 8° 15 at noon 19° 5' N.  
Equation to noon 4  

To the log, cosine of the sun's declination add the log, cosine of the latitude; the sum, added to the observed amplitude, will be the true amplitude; half the sum of the latitudes will be the true amplitude of the sun in latitude 33° 10' N.

To find the sun's true amplitude, subtract the log, cosine of the latitude from the log, cosine of the sun's declination; and if the result is positive, the true amplitude is the sun's declination; if negative, the sun's declination is greater than the true amplitude.

The difference between the true and observed amplitudes will be the variation as formerly.
NAVIGATION.

Example I. November 18, 1793, in latitude 50° 22' N, longitude 25° 30' W, about three quarters past eight A.M. the altitude of the sun's lower limb was 8° 10', and bearing for compass S 25° 18' E; height of the eye 200 feet. Required the variation of the compass?

Sun's declination 18th Nov. at noon 19° 25' S. Observed alt. sun's lower limb - = 8° 10'

Equation to 34th from noon - 2 Semidiameter - - 2 + 16

Variation - 15 39 W.

CHAP. IV. Of a Ship's Journal.

A JOURNAL is a regular and exact register of all the various transactions that happen aboard a ship whether at sea or land, and more particularly that which concerns a ship's way, from whence her place at noon or any other time may be justly ascertained.

That part of the account which is kept at sea is called sea-work; and the remarks taken down while the ship is in port are called harbour-work.

At sea, the day begins at noon, and ends at the noon of the following day: the first 12 hours, or those contained between noon and midnight, are denoted by P.M. signifying after mid-day; and the other 12 hours, or those from midnight to noon, are denoted by A.M. signifying before mid-day. A day's work marked Wednesday March 6, began on Tuesday at noon, and ended on Wednesday at noon. The days of the week are usually represented by astronomical characters. Thus O represents Sunday; @ Monday; @ Tuesday; @ Wednesday; @ Thursday; @ Friday; and @ Saturday.

When a ship is bound to a port so situated that she will be out of sight of land, the bearing and distance of the port must be found. This may be done by Mercator's or Middle-latitude Sailing: but the most expeditious method is by a chart. If islands, capes, or headlands intervene, it will be necessary to find the several courses and distances between each successively.
NAVIGATION.

Practically. The true course between the places must be reduced to the course per compass, by allowing the variation to the right or left of the true course, according as it is west or east.

At the time of leaving the land, the bearing of some known place is to be observed, and its distance is usually found by estimation. As perhaps the distance thus found will be liable to some error, particularly in hazy or foggy weather, or when that distance is considerable, it will therefore be proper to use the following method for this purpose.

Let the bearing be observed of the place from which the departure is to be taken; and the ship having run a certain distance on a direct course, the bearing of the same place is to be again observed. Now having one side of a plane triangle, namely the distance sailed and all the angles, the other distances may be found by Prob. I. of Oblique Sailing.

The method of finding the course and distance sailed in a given time is by the compass, the log line, and half-minute-glasses. These have already been described in the royal navy, and in ships in the service of the East India company; the log is hove once every hour; but in most other trading vessels only every two hours.

The several courses and distances sailed in the course of 24 hours, or between noon and noon, and whatever remarks that are thought worthy of notice, are set down with chalk on a board painted black called the log-board, which is usually divided into six columns: the first column on the left hand contains the hours from noon to noon; the second and third the knots and parts of a knot sailed every hour, or every two hours, according as the log is marked; the fourth column contains the courses steered; the fifth the winds; and in the sixth the various remarks and phenomena are written. The log-board is transcriber every day at noon into the log-book, which is ruled and divided after the same manner.

The courses steered must be corrected by the variation of the compass and leeway. If the variation is west, it must be allowed to the left hand of the course steered; but if east, to the right hand in order to obtain the true course. The leeway is to be allowed to the right or left of the course steered according as the ship is on the larboard or starboard tack. The method of finding the variation, which should be determined daily if possible, is given in the preceding chapter; and the leeway may be understood from what follows.

When a ship is close hauled, that part of the wind which acts upon the hull and rigging, together with a considerable part of the force which is exerted on the sails, tends to drive her to the leeward. But since the bow of a ship exposes less surface to the water than her side, the resistance will be less in the fore part than in the second: the velocity in the direction of her head will therefore in most cases be greater than the velocity in the direction of her side; and the ship's real course will between the two directions. The angle formed between the line of her apparent course and the line she really describes through the water is called the angle of leeway, or simply the leeway.

There are many circumstances which prevent the laving down rules for the allowance of leeway. The conduction of different vessels, their trim with regard to the nature and quantity of their cargo, the position and magnitude of the sail set, and the velocity of the ship together with the swell of the sea, are all susceptible of great variation, and very much affect the leeway. The following rules are, however, usually given for this purpose.

1. When a ship is close hauled, has all her sails set, the water smooth, with a little breeze of wind, she is then supposed to make little or no leeway.
2. Allow one point when the top gallant sails are hauled.
3. Allow two points when under close reefsed topsails.
4. Allow two points and a half when one top-sail is hauled.
5. Allow three points and a half when both top-sails are hauled.
6. Allow four points when the fore course is hauled.
7. Allow five points when under the main-sail only.
8. Allow six points when under-balanced mizen.
9. Allow seven points when under bare poles.

These allowances may be of some use to work up the day's works of a journal which has been neglected, but a prudent navigator will never be guilty of this neglect. A very good method of estimating the leeway is to observe the bearing of the ship's wake as frequently as may be judged necessary; which may be conveniently enough done by drawing a small semicircle on the taffarel, with its diameter at right angles to the ship's length, and dividing its circumference into points and quarters. The angle contained between the semidiameter which points right aft and that which points in the direction of the wake is the leeway.

But the best and most rational way of bringing the leeway into the day's log is to have a compass or semicircle on the taffarel, as before described, with a low crutch or swivel in its centre; after heaving the log, the line may be flipped into the crutch just before it is drawn in, and the angle it makes on the limb with the line drawn right aft will show the leeway very accurately: which as a necessary article, ought to be entered into a separate column against the hourly distance on the log-board.

In hard blowing weather, with a contrary wind and a high sea, it is impossible to gain any advantage by failing. In such cases, therefore, the object is to avoid as much as possible being driven back. With this intention it is usual to lie to under no more sail than is sufficient to prevent the violent rolling which the vessel would otherwise acquire, to the endangering her masts, and straining her timbers, &c. When a ship is brought to, the tiller is put close over to the leeward, which brings her head round to the wind. The wind having then very little power on the sails, the ship loses her way through the water; which ceasing to act on the rudder, her head falls off from the wind, the sail which she has set fills, and gives her fresh way through the water; which acting on the rudder brings her head again to the wind. Thus the ship has a kind of vibratory motion, coming up to the wind and falling off from it again alternately. Now the middle point between those upon which she comes up and falls off is

VOL. XII.
It will be proper, however, for the navigator to determine the longitude of the ship from observation as often as possible; and the reckoning is to be carried forward in the usual manner from the last good observation; yet it will perhaps be very satisfactory to keep a separate account of the longitude by dead-reckoning.

General Rules for working a Day's Work.

Correct the several courses for variation and leeway; place them, and the corresponding distances, in a table prepared for that purpose. From whence, by Traverse Sailing, find the difference of latitude and departure made good; hence the corresponding course and distance, and the ship's present latitude, will be known. Find the middle latitude at the top or bottom of the Traverse Table, and the distance answering to the departure found in a latitude column, will be the difference of longitude; or, the departure answering to the course made good, and the meridional difference of latitude in a latitude column, is the difference of longitude. The sum, or difference of which, and the longitude left, according as they are of the same or of a contrary name, will be the ship's present longitude of the same name with the greater.

Compute the difference of latitude between the ship and the intended port, or any other place whose bearing and distance may be required; find also the meridional difference of latitude and the difference of longitude. Now the course answering the meridional difference of latitude found in a latitude column, and the difference of longitude in a departure column, will be the bearing of the place, and the distance answering to the difference of latitude will be the distance of the ship from the proposed place. If these numbers exceed the limits of the Table, it will be necessary to take aliquot parts of them; and the distance is to be multiplied by the number by which the difference of latitude is divided.

It will sometimes be necessary to keep an account of the meridian distance, especially in the Baltic or Mediterranean trade, where charts are used in which the longitude is not marked. The meridian distance on the first day is that day's departure; and any other day it is equal to the sum or difference of the preceding day's meridian distance and the day's departure, according as they are of the same or of a contrary denomination.

As there is no land in sight this day at noon, and from the course and distance run since the last bearing of the Eddystone light was taken, it is not to be supposed that any part of England will be seen, the departure is therefore taken from the Eddystone; and the distance of the ship from that place is found by resolving an oblique angled plane triangle, in which all the angles are given, and one side, namely, the distance run (16 miles) between the observations. Hence the distance from the Eddystone at the time the last bearing of the light was taken will be found equal to 18 miles; and as the bearing of the Eddystone from the ship at that time was NE, the ship's bearing from the Eddystone was SE. Now the variation 27 points W. being allowed to the left of SW. gives SW1/2 W, the true course. The other courses are in like manner to be corrected, and inserted in the following table, together with their respective distances, beginning at 10 o'clock A.M. the time when the last bearing of the Eddystone was taken. The difference of latitude, departure, course, and distance, made good, are to be found by Traverse Sailing.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Latitude of Eddystone: 50° 8' N.

Latitude by account: 49° 11' N.

Sum: 99° 19' W.

Middle latitude: 49° 10' W.

Now to middle latitude as a course, and the departure 74m. in a latitude column, the difference of longitude is 114° = 19° 54' W.

Longitude of Eddystone: 4° 24' W.

Longitude in by account: 6° 18' W.
The courses being corrected for variation, and the distances summed up, the work will be as under.

<table>
<thead>

</tr>
<tr>
<td></td>
<td></td>
<td>61.6</td>
</tr>
</tbody>
</table>

It is now necessary to find the bearing and distance of the intended port, namely Funchal; but as that place is on the opposite side of the island with respect to the ship, it is therefore more proper to find the bearing of the east or west end of Madeira; the west end is, however, preferable. But as the small island of Porto Sancho lies a little to the NE of the east end of Madeira, it therefore seems more eligible to find the bearing and distance of that island.

To find the bearing and distance of Porto Sancho.

Latitude of ship 47° 51' N. Mer. parts 3278 North of Porto Sancho 7° 51' W.

Difference of latitude 12° 53' = 893 M.D. lat 118' Difference of long. 8° 34' 514

The course answering to the meridional difference of latitude and difference of longitude is about S 2° 23' W; and the variation, because west being allowed to the right hand, gives SW 2° W nearly, the bearing for compass, and which is the course that ought to be steered.

To find the bearing and distance of Porto Sânto.

- **Latitude of ship**: 47° 28' N.
- **Mer. parts**: 3244
- **Longitude**: 8° 58' W.
- **Latitude of Porto Sânto**: 32° 58' N.
- **Mer. parts**: 2097
- **Longitude**: 16° 25' W.

**Difference of latitude**: 14° 30' = 87° M. D. lat. 1147

Hence the bearing of Porto Sânto is S. 21° W., and distance 932 miles. The course per compass is therefore S. W. nearly.

<tbody>
<tr>
<td>W&amp;N.</td>
<td>43</td>
<td>12</td>
<td>41</td>
<td>W. Long. 61° 59'</td>
</tr>
</tbody>
</table>

There is no leeway allowed until 2 o'clock P. M. when the top-gallant fails are taken in; from 2 to 3 one point is allowed; from 3 to 6, one and a half points are allowed; from 6 to 8 one and three-fourth points are allowed: from 8 to 9, three points; from nine to 10 four and an half points; from 10 to 12, five points; from 12 to 10 A. M. three and an half points; and from thence to noon two points leeway are allowed. Now the several courses being corrected by variation and leeway will be as under; but as the corrected courses from 2 to 3 P. M. and from 10 to 12 A. M. are the same, namely, west; this, therefore, is inferred in the table, together with the sum of the distances, as a single course and distance. In like manner, the courses from 12 to 2, and from 5 to 8 being the same, are inferred as a single course and distance.

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>W&amp;N.</td>
<td>43</td>
<td>1</td>
<td>41.5</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Lat. by account 47° 30' N.</th>
</tr>
</thead>
<tbody>
<tr>
<td>To middle latitude 47° 34' and departure 41.5 the difference of longitude is (61° = 1° 1' W.)</td>
</tr>
<tr>
<td>Yesterday's longitude (8 58 W.)</td>
</tr>
<tr>
<td>Longitude in by account (9 59 W.)</td>
</tr>
</tbody>
</table>
Two points leeway are allowed on the first course, one on the second; and as the ship is 7 points from the wind on the third course, there is no leeway allowed on it. The opposite point to NW, that from which the swell set, with the variation allowed upon it, is the last course in the Traverse Table.

To find the bearing and distance of Porto Sancto.

\[
\begin{align*}
\text{To middle latitude } & \quad 47 \text{ } 24, \quad \text{departure } 103.6, \quad \text{the difference of longitude is } 153^\circ = 2^\circ 33 W. \\
\text{Yesterdays longitude} & \quad - \quad 9 \text{ } 59 W. \\
\text{Longitude in} & \quad - \quad 12 \text{ } 32 W.
\end{align*}
\]

Hence the bearing of Porto Sancto is S 12° W. and distance 870 miles; the course per compass is therefore about SWW.

</tbody>
</table>

**Course.**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>S 12° 45' W.</td>
<td>128</td>
<td>125</td>
<td>28</td>
<td>45° 4'</td>
<td>44° 59'</td>
<td>41° W.</td>
<td>13° 13'</td>
<td>12° 59'</td>
<td>21°</td>
<td>S 12° W.</td>
</tr>
</tbody>
</table>

The observed variation S 21° being allowed to the left of SW<sub>W</sub>S. gives 12° 45' W, the corrected course and the distance summed up is 127,9, or 128 miles. Hence the difference of latitude is +124.8, and the departure 28.2. The latitude by account is therefore 45° 4' N, and the middle latitude 46° 6', to which, and the departure 28.2; in a latitude column, the difference of longitude in a distance column is 41° W; which being added to 12° 32' W, the yesterday's longitude, gives 13° 13' W, the longitude in by account. But the longitude by observation was 12° 28' W. at half past 8 P. M.; since that time the ship has run 96 miles; hence the departure in that interval is 21.2 m. Now half the difference of latitude 47 m. added to 44° 59', the latitude by observation at noon, the sun 45° 46' is the middle latitude; with which and the departure 21.2, the difference of longitude is found to be 31° W; which therefore added to 12° 28', the longitude observed, the sun is 12° 59' W, the longitude by observation reduced to noon.

To find the bearing and distance of Porto Santo:

**Latitude ship** 44° 59' N. **Mer. parts** 3028 **Longitude** 12° 59' W.

**Lat. of Porto Santo** 32° 58' N. **Mer. parts** 2097 **Longitude** 16° 25' W.

Difference latitude 12° 1 = 721 M. D. lat. 931 D. longitude 3° 26=205.

Hence the bearing of Porto Santo is S. 12° W, and distance 737 miles. The course to be steered is therefore 833° W, or SW<sub>W</sub>W.nearly.

---

</thead>
<tbody>
<tr>
<td>S 13° 31' W.</td>
<td>183</td>
<td>178</td>
<td>43</td>
<td>42° 1'</td>
<td>59 W.</td>
<td>14° 12' 13° 58'</td>
<td>20° 14' 15° 27'</td>
<td>S 12° W.</td>
<td>555 m.</td>
<td></td>
</tr>
</tbody>
</table>

The course corrected by variation is S 13° 31' W, and the distance run is 113 miles: hence the difference of latitude is 177.9, and the departure 42.8.

Yesterday’s latitude by observation - 44° 59' N. Mer. parts - - - 3028

Difference of latitude - - 2 58 S.

Latitude in by account - - 42 1 N. Mer. parts - - 2783

Meridional difference of latitude - - 245

Now to course 13° 2', and meridional difference of latitude 245 in a latitude column, the difference of longitude in a departure column is 59 W: hence the yesterday’s longitudes by account and observation, reduced to the noon of this day, will be 14° 12' W. and 13° 58' respективly.

To find the bearing and distance of Porto Santo.

Latitude ship - 42° 1' N. Mer. parts - 2783 Longitude - 13° 58' W.

Lat. Porto Santo 32° 58 N. Mer. parts - 2097 Longitude - 16° 25 W.

Difference of latitude 9 3°=545 M. D. latitude - 686 D. longitude 2 27=147.

The meridional difference of latitude and difference of longitude will be found to agree nearest under 12°, the correct bearing of Porto Santo; and the variation being allowed to the right hand of S. 12° W, gives 832° W, the bearing per compass; and the distance answering to the difference of latitude 545, under 12 degrees, is 555 miles.
N A V I G A T I O N.

A Journal from England towards Madeira.

The mean of the variations is about 14 points W; hence the course corrected is SSWW; with which and the distance run 184 miles, the difference of latitude is 178.5, and the departure 44.7.

Yesterday's latitude 42° 1' N. Mer. parts | 2783

Difference of latitude - 2 58 S.

Latitude in by account - 39 3 N. Mer. parts | 2549

Meridional difference of latitude

Now, to course 14 points, and meridional difference of latitude is 234, the difference of longitude is about 59 m.; which, added to the yesterday's longitude by account 14° 12' W, the sum 15° 11' W, is the longitude in by account noon. The longitudes by observation are reduced to noon as follows:

The distance run between noon and 3h 34 P. M. is 29 miles; to which, and the course 14 points, the difference of latitude is 28°.

Yesterday's latitude at noon - 42° 1 N.

Latitude at time of observation - 41° 33 N. Mer. parts | 2746

Latitude at noon - 39° 3 N. Mer. parts | 2549

Meridional difference of latitude

Then, to course 14 points, and meridional difference of latitude 197 in a latitude column, the difference of longitude in a departure column is 49 W.; which added to 14° 1' W, the longitude by observation, the sum 14° 50' W, is the longitude reduced to noon.

Again, the distance run between the preceding noon and 9h 22' P. M. is 75 miles; hence the corresponding difference of latitude is 72.8, or 73 miles; the ship's latitude at that time is therefore 40° 48' N.

Latitude at time of observation - 40° 48 N. Mer. parts | 2686

Latitude at noon - 39° 3 N. Mer. parts | 2549

Meridional difference of latitude

Now with the corrected course, and meridional difference of latitude the difference of longitude is 34 W.; which added to 14° 20' W, the sum is 14° 54' W, the reduced longitude. The mean of which and the former reduced longitude is 14° 52' W, the correct longitude.

<tr>
<td>Difference of longitude</td>
<td>41 W.</td>
<td>41 W.</td>
</tr>
<tr>
<td>Longitude in</td>
<td>15</td>
<td>22</td>
</tr>
</tbody>
</table>

The latitude by observation at 11h 10 A.M. is 37° 10', and from that time till noon the ship has run about 4 miles. Hence the corresponding difference of latitude is 2 miles, which subtracted from the latitude observed, gives 37° 8', the latitude reduced to noon.

To find the bearing and distance of Porto Santo.
- Latitude of ship 37° 8' N. Mer. parts 4203
- Lat. of Porto Santo 52 58 N. Mer. parts 2097
- Difference of latitude 4° 10' = 250 M. D. Lat. 306

Hence the bearing of Porto Santo is S 10° W, or SSWW5°W nearly, per compass, and the distance is 254 n.miles.

</tbody>
</table>

Half a point of leeway is allowed on each course; but as the variation is expressed in degrees, it will be more convenient and accurate to reduce the several courses into one, leeway only being allowed upon them. The course thus found is then to be corrected for variation, with which and the distance made good the difference of latitude and departure are to be found.

To find the bearing and distance of Porto Santo.

Latitude ship 36° 47' N. Mer. parts 2376 Longitude 16° 38' W.
Lat. Porto Santo 32° 58' N. Mer. parts 2097 Longitude 16° 25' W.

Difference of latitude 3' 49'' = 229' M. D. latitude 279' D. longitude 013'

Hence the course is S 4° E, distance 229 miles; and the course per compass is SbWbW, nearly.

</tbody>
</table>

Difference of latitude 48' Mer. Diff. lat. 58' Diff. long. 0 18' 

Hence the bearing of Porto Santo is S. 17° W, and distance 50 miles.
This journal is performed by inspection agreeable to the precepts given. Other methods might have been used for the same purpose; for which the two instruments already described and explained seem well adapted. We cannot, however, omit recommending the sliding gunter, which will be found very expeditious, not only in performing a day’s work, but also in resolving most other nautical problems. See Sliding-Gunter.

It will be found very satisfactory to lay down the ship's place on a chart at the noon of each day, and her situation with respect to the place bound to, and the nearest land will be obvious. The bearing and distance of the intended or any other port, and other requisites may be easily found by the chart as already explained; and indeed, every day’s work may be performed on the chart; and thus the use of tables is superfluous.

EXPLANATION OF THE TABLES.

Table I. To reduce points of the compass to degrees, and conversely.

The two first and two last columns of this table contain the several points and quarter-points of the compass; the third column contains the corresponding number of points and quarters; and the fourth, the degrees, &c. answering thereto. The manner of using this table is obvious.

</tr>
</tbody>
</table>

Table II. The miles and parts of a mile in a degree of longitude at every degree of latitude.

The first column contains degrees of latitude, and the second the corresponding miles in a degree of longitude; the other columns are a continuation of the first and second. If the given latitude consists of degrees and minutes, a proportional part of the difference between the miles answering to the given and following degrees of latitude is to be subtracted from the miles answering to the given degree.

Example. Required the number of miles in a degree of longitude in latitude 57° 9’.

The difference between the miles answering to the latitudes of 57° and 58° is 0.89.

Then as 60° : 0.89 : 0.89

Miles answering to 57° 32.68

Miles answering to 57° 9’ 32.55

This Table may be used in parallel and Middle Latitude Sailing.

Table III. Of the Sun’s Semidiameter.

This table contains the angle subtended by the sun’s semidiameter at the earth, for every sixth day of the year. The months and days are contained in the first column, and the semidiameter expressed in minutes and seconds in the second column. It is useful in correcting...
The refraction is necessary for correcting altitudes and distances observed at sea; it is always to be subtracted from the observed altitude, or added to the zenith distance. This table is adapted to a mean state of the atmosphere in Britain, namely to 29.6 inches of mercury. If the height of the barometer, and of the thermometer. If the height of the mercury in the atmosphere in Britain, namely to 29.6 inches, is over the land, and the distance is nearer the ship than the visible horizon when unconfined: in this case, the sun's limb is to be brought in contact with the line of separation of the sea and land: the distance of that place from the ship is to be found by estimation or otherwise; and the ship answering thereto, and the height of the eye, is to be taken from Table VI.

The first of these tables contains the dip answering to the sun's limb and the moon. The numbers therein, as well as in the other table, are to be subtracted from the observed altitude, when the fore-obseration is used; but added, in the back-observation.

When the sun is over the land, and the ship nearer it than the visible horizon when unconfined; in this case, the sun's limb is to be brought in contact with the line of separation of the sea and land: the distance of that place from the ship is to be found by estimation or otherwise; and the ship answering thereto, and the height of the eye, is to be taken from Table VI.

This table contains the dip answering thereto, and the height of the mean, a correction is necessary to reduce the tabular to the true refraction. See Refraction.

Table IV. Of the Refraction in Altitude.

The refraction is necessary for correcting altitudes and distances observed at sea; it is always to be subtracted from the observed altitude, or added to the zenith distance. This table is adapted to a mean state of the atmosphere in Britain, namely to 29.6 inches of the barometer, and of the thermometer. If the height of the mercury in the atmosphere in Britain, namely to 29.6 inches, is over the land, and the distance is nearer the ship than the visible horizon when unconfined: in this case, the sun's limb is to be brought in contact with the line of separation of the sea and land: the distance of that place from the ship is to be found by estimation or otherwise; and the ship answering thereto, and the height of the eye, is to be taken from Table VI.

The first of these tables contains the dip answering to the sun's limb and the moon. The numbers therein, as well as in the other table, are to be subtracted from the observed altitude, when the fore-obseration is used; but added, in the back-observation.

TABLE IV. Of the Refraction in Altitude.

The refraction is necessary for correcting altitudes and distances observed at sea; it is always to be subtracted from the observed altitude, or added to the zenith distance. This table is adapted to a mean state of the atmosphere in Britain, namely to 29.6 inches of the barometer, and of the thermometer. If the height of the mercury in the atmosphere in Britain, namely to 29.6 inches, is over the land, and the distance is nearer the ship than the visible horizon when unconfined: in this case, the sun's limb is to be brought in contact with the line of separation of the sea and land: the distance of that place from the ship is to be found by estimation or otherwise; and the ship answering thereto, and the height of the eye, is to be taken from Table VI.

The first of these tables contains the dip answering to the sun's limb and the moon. The numbers therein, as well as in the other table, are to be subtracted from the observed altitude, when the fore-obseration is used; but added, in the back-observation.

TABLE V. VI. Of the Dip of the Horizon.

The first of these tables contains the dip answering to the sun's limb and the moon. The numbers therein, as well as in the other table, are to be subtracted from the observed altitude, when the fore-obseration is used; but added, in the back-observation.

TABLE VII. Of the Correction to be applied to the time of high water at full and change of the moon, to find the time of high water on any other day of the moon.

The first of these tables contains the dip answering to the sun's limb and the moon. The numbers therein, as well as in the other table, are to be subtracted from the observed altitude, when the fore-obseration is used; but added, in the back-observation.

TABLE VIII. IX. X. Of the Sun's declination, &c.

The first of these tables contains the dip answering to the sun's limb and the moon. The numbers therein, as well as in the other table, are to be subtracted from the observed altitude, when the fore-obseration is used; but added, in the back-observation.

TABLE XI. Of the Right Ascentions and Declinations of Fixed Stars.

This table contains the right ascensions and declinations of 60 principal fixed stars, adapted to the beginning of the year 1793. Columns fourth and fifth contain the annual variation arising from the precession of the equinoxes, and the proper motion of the stars; which serves to reduce the place of a star to a period a few years after the epoch of the table with sufficient accuracy. When the place of a star is wanted, after the beginning of 1793, the variation in right ascension is additive; and that in declination is to be applied according to its sign. The contrary rule is to be used when the given time is before 1793.

EXAMPLE. Required the right ascension and declination of Bellatrix, May 1. 1798?

Right ascension January 1. 1793 = 5h 14 3°
Variation = 3° 21 x 5° y.
Right ascension, May 1. 1798 = 5h 14 20°
Declination = 6° 8' 53° N
Variation = 4° x 5° y.
Declination, May 1. 1798 = 6° 9' 14° N

The various other tables necessary in the practice of navigation are to be found in most treatises on that subject. Those used in this article are in Mackay's Treatises on the Longitude and Navigation.

</table>
Inland Navigation.

Inland Navigation, the method of conveying commodities from one part of a country to another by means of rivers, lakes, canals, or arms of the sea, penetrating far into the internal parts. See the article Canal.

The advantages of this mode of conveyance, in an extensive and populous country, are sufficiently obvious; whether we take into account the superior cheapness, facility, or quickness with which great quantities of goods can thus be carried from one place to another; or the advantages which may accrue to agriculture and other arts, by thus conveying manures, the produce of the ground, or heavy manufactured goods, to and from distant quarters; which would be altogether, impracticable by a land-carriage, without incurring a much greater expense than commodities could bear. The good effects of inland navigation are particularly evident in the vital empire of China, and in the states of Holland. In both those countries, the multitude of canals undoubtedly contributes to the opulence of the inhabitants, both by the more free scope they give to trade, and the advantages derived from them to agriculture; not to mention, that by means of the canals themselves the ground is often meliorated and made capable of producing both corn and pasture, where otherwise it would perhaps yield neither, or at least very imperfectly. These countries, however, particularly Holland, are very flat, and thus very much fitted for this kind of navigation: Great Britain and Ireland are less so, on account of the greater inequality of their surface; though in them also the making of canals is now become very common, notwithstanding the immense expense with which such undertakings are attended.

In a late treatise upon this subject by Mr Edmund Leach surveyor, the author considers the advantages which might accrue to the kingdoms of Britain and Ireland, were their Inland navigation improved as much as it might be; and he considers both countries as exceedingly proper for improvements of this kind on account of the number of fine streams of water they contain. "Every county (says he) in each kingdom is furnished with rivers and streams of water; very few, if any, of which but may be made navigable to within a mile or two of their sources," by the method he proposes.

The method of making canals hitherto practised, is so fully described under the article Canal, that nothing needs be said upon it in this place. Mr Leach observes, that all the artificial inland navigations made in this, as well as in other kingdoms, have been done by beginning them at the foot or mouth of a river, or at the utmost extent of the ebb or flow of the tide; proceeding thence upwards, either in the ordinary course of the river by sinking, widening, and cleaning it; then with the assistance of a lock and dam to raise the boats or other vessels to a higher level. This is next to be cut, widened, and cleaned as before, till we come to a third level, when the vessels are to be raised as in the former; proceeding thus, as it were step by step, till we arrive at the extent of the intended navigation. Otherwise the navigation is carried by an artificial side-cut or canal near the course of the river, raised up by locks and dams as before. These methods, however, the author considers of very great service to the country, are attended with many and considerable inconveniences.

1. Every river or other stream is the natural receptacle of all the springs, rains, and floods, which discharge themselves into it; by which means it sometimes discharges such torrents of water as sweep everything out of its way before them. This not only interrupts the navigation for a time, but is often attended with the most intolerable expense.

2. The original making of the canal with a number of locks and dams, such as is described under the article Canal, must also be very expensive.

3. Some rivers run very rapidly in particular places; and if the descent of the bed be very great, it will require a number of the locks and dams already mentioned to make such a river navigable, though the navigation should extend but a few miles from the mouth.

4. The passing of the locks is always attended with a considerable difficulty, besides the loss of time and expence.

To obviate all these inconveniences, Mr Leach proposes to begin and carry on his canal in a manner precisely the reverse of that just now described. In his method, the canal is to be begun as near the source of the river as possible; that is, as near as there is a probability of having water in the drier seasons sufficient to fill the canal; of which there can be but little required, as a stream sufficient to turn an ordinary mill must be sufficient to answer all the purposes of such a canal. Thus the navigation may be carried up much higher than in the ordinary canals with dams and locks. If a canal be made properly and the sides and bottom plastered with a cement that may be made of the same earth and clay used in making the trunk, very little water will be requisite to keep it full. Our author supposes that a stream sufficient to turn an ordinary mill will be sufficient to keep it full, even if the canal should be 20 miles long.

To construct a canal of this kind, we must make choice of a level as near the head of the river as possible; this level must be continued for a considerable way, so that the water may not have the least current, but may absolutely stagnate. Thus the original bed of the river will soon be left at a distance, and the flagrant canal will become higher and higher with respect to it, in proportion to the descent of the ground or rapidity of the river. Having proceeded this way as far as convenient, the vessels must be let down by a machine (to be afterwards described) into the bed of the original river, or from one elevated canal to another much lower; perhaps 10, 15, or 20 fathoms.

By this perfect stagnation of the water in the canals, there will be no danger of washing off the planking from the sides and bottom, so that the only waste of water will be by evaporation, and what is required for working the machine above mentioned; which, as it is only required at particular times when vessels are to be raised or lowered, must be very trifling, and cannot bear any proportion to the constant supply at the head of the canal.

In order to keep the first level easily, and for a considerable way, it will be necessary to avoid the many valleys which are naturally to be met with near the original river, by the descent of other streams into it.
Hence canals constructed on the plan recommended by our author must run out in serpentine windings a considerable way into the country, which will augment its length greatly beyond that of the original river; and thus a much greater number of people, and larger extent of country, will reap the benefit of it than if it were continued in a straight line. "One inconvenience (says our author) attending the old inland navigations that are carried on in or nigh the original rivers, is their being confined within too small a space of land, and where, for the most part, there is the least occasion either for water to water the land, or for manner to enrich the soil; whereas, by beginning a canal near the head of a river, and by continuing it on one common level, if the river have anything of a descent, the effect (says our author) attending the old common level, if the river have any thing of a descent, if it were continued in a straight line, would be mended this as the proper place for the navigation is removed from the ground. by continuing it on

1. The first and principal expence is the digging of the trunk of the canal; but this must vary so much according to the nature of the ground, that no certain estimate of the expence can be made. Sometimes the ground may be soft, and easily cut, sometimes hard and rocky, sometimes may be taken up by stones, &c. There must also be a very considerable difference in the expence of cutting the canal, according as the ground on one side of it is more or less elevated. Mr Leach, after making the proper calculations, supposes that in every perch of a canal of the kind under consideration, there must be removed 404 cubical yards, or 1085 cubical feet, of earth. Agreements with the workmen are commonly made by the cubic yard. It is rare that a cubic yard can be removed for less than 2d. "nor (says our author) will any fort of ground require more than 2d. except in passing through a rock, which will not often happen, unless where, by the situtation of the land through which the canal may pass, it should require to be cut more than four feet under the surface, as it may sometimes happen in cutting through a hill or neck of land, whereby the course of the canal may be shortened. According to this estimate, Mr Leach has formed a table of the expence of making canals from 2d. to 2l. the cubic yard to 9d. The smallest expence of these per mile is L. 107: 115: 14; the greatest L. 483: 19: 9. Sometimes, however, the expence may be even greater: so that the mile may cost L. 600, or near it; but this must be accounted an extraordinary expence, and not often to be expected.

In digging the trunk of the canal, care must be taken to preserve all the sand, stones, and gravel, for the purpose of making drains or gutters and the towing paths; also for the making of a wall, the outside face of which is to be 21 feet distant from the edge of the canal. The design of this is to prevent the earth and rubbish from being thrown to too great a distance from the side of the canal; and likewise for the purpose of raising a bank on the lower side about 16 or 18 inches above the surface of the water in the canal, when it is full up to the drains. On the top of this bank the towing path is to be made 12 feet wide on that side of the canal, and if this wall should be raised four feet above the surface of the towing path, it would be a fence to keep the cattle off from that side. In making the towing path on the other side, the surface of the land must be sunk to within 16 or 18 inches of the surface of the water in the canal when full; and the turf, earth, stones,
2. Drains or gutters must be made under the towing paths, on both sides of the canal. On the upper side they must be made through the hedge or fence at all convenient places, for admitting springs and rivulets, as well as rain water into the canal. On the higher side, these should be about 132 feet distant from one another, exclusive of those for the admission of springs. On the lower side, it is necessary to have drains at the distance of 66 feet from each other; which will be 80 drains per mile. These may be constructed for 2s. 6d. each, which amounts to £10 per mile. On the higher side they will cost about four shillings per drain; and at the distance of 132 feet between each drain, the expense will be £8 per mile.

In making the drains on the lower side, great care must be taken to have them truly level, and parallel to the horizon; the bottom part of the drain being exactly 39 inches perpendicular above the bottom of the canal; as on the true placing of these drains, and the true level of the bottom of the canal, entirely depends the regularity of the deepness of the water.

3. The value of the ground through which the canal is to pass must also be considered. From the observations and memoranda which our author took in the year 1774, concerning the ground through which the Tamar canal was to pass, he concluded that one eighth part of the land through which the tract passed was worth 40s. per acre; another eighth, 20s.; a third eighth part, 10s.; and all the rest not worth more than five; and a great deal of it not more than two; the average of the whole being 15s. an acre. "Then (says he), if the good, indifferent, and bad land be worth on an average, 15s. an acre, and as 30 years value is a capital price for lands, it will at that rate, amount to 22l. 10s. per acre. The rippled breadth of the canal with the towing paths and hedges being, as already said, 66 feet, which is exactly a gunter's chain; then, 10 such chains in length and one in breadth form exactly a statute acre of land; and ten chains in length is a furlong; so that every mile of canal will thus take up eight acres of land, which, at 22l. 10s. per acre, amounts to 180l. per mile.

4. Bridges are likewise a considerable article of expense in the making of canals. Mr. Leach supposes that there may be one common road bridge and two swivel bridges required per mile; the former may be erected for 60l. and the latter for 50l. each; so that the expense of all together will amount to 120l. per mile.

5. As in some particular places, on account of short turns, and where docks and basins and landing places are to be made, a greater wideness will be required, our author allows half an acre more land for every furlong on this account; which brings an additional expense of 90l. per mile.

6. It will always be necessary to have sluices for emptying the canal; each of which will cost 20l. Mr. Leach allows a sluice and lock-gate for every mile; and as these cost 20l. each, we have thus a farther expense of 40l. per mile.

7. The wall on the lower side against the bank of earth and towing path may be built for three shillings per perch; and as every mile contains 320 perches, the expense of the wall will be 48l. per mile.

8. Our author calculates the towing path on the lower side at the same price; so that it also makes an addition of 48l. per mile; but as he estimates the higher towing path and hedge at 8s. per perch, this will amount to 128l. per mile.

Thus, according to our author's calculation, the whole expense of making a canal with its necessary appendages will amount to £544; 13 : 4½ per mile; and by the calculation of another engineer, the particulars of which he also enumerates, it would not exceed £1032; 13 : 4½. This our author thinks a moderate expense; but an objection naturally occurs from the great lengths to which such canals must necessarily run; a remarkable instance of which he gives in the proposed Tamar canal, where, though the distance betwixt Bude Haven and the navigable part of the river Tamar is no more than 28 miles in a straight line, the length of the canal would not have been less than 80 miles. This length, however, according to our author, "ought not to be an object of discouragement, but on the contrary an inducement and an encouragement to promote the extending of it as much as possible into the country, as it will bring a market to every man's door that it draws nigh in its passage, and be a means to improve a greater quantity of uncultivated lands; and the navigation will be thereby much more extensive, and a much larger number of inhabitants will reap the advantages thereof, than if it had been carried on upon the original river."

We have already taken notice, that in the method of constructing canals just now mentioned, there will at certain intervals be places where the vessels must be raised and lowered by means of mechanical powers, instead of the dams and locks made use of in other canals. These machines are compounded of an inclined plane and wheel in axis. The inclined plane is a parallelogram whose length reaches from the end of one canal to the beginning of another, or to the sea or navigable river, to which the vessel is next to be conveyed; the breadth ought to be 22 feet. It may be made of good oak or deal plank, and sufficiently strong to bear the weight to be laid upon it; and it must be very strongly supported by beams of oak or other wood. It ought to be divided in the middle by a ledge or rib of ten inches square, the side ribs being nine by 12 inches. The elevation must depend upon particular circumstances. Fig. 1. shows the inclined part of the machine; AB being the wooden part just described, placed between the side of the hill W and the navigable river F. According to the dimensions already given, the two paths A and B on which the vessels move are exactly ten feet wide. G represents the canal, brought perhaps from the distance of several miles to the top of the precipice WW. At the end of the canal, and quite across from R to K, must be built a very strong wall; in which are two sluices with flood-gates at K and L, to let out the water occasionally. Between the head of the plane AB, and the end of the canal G, is a horizontal platform divided into two parts, as is represented in the figure by the letters HI. At the end of the canal are six rollers.
Fig. 2. shows the vehicle by which the lighters are conveyed up and down the inclined plane, by the two paths A and B, fig. 1. AA (fig. 2.) represents part of the inclined plane, B the vehicle in the position in which it rolls up and down the paths. C is the body of the vehicle, which is made hollow, to contain a quantity of water occasionally used as a counterbalance for its corresponding vehicle. DDD are three rollers between the bottom of the vehicle and the plane, for the purpose of rolling the boats up and down. EHHH are six rollers; four on the horizontal part of the vehicle on which the boat E is to rest in its passage up and down the plane; the other two rollers are in a moveable part, which is fastened to the body of the vehicle with a pair of very strong hinges; and in the passage of the vehicle up and down the plane it turns up between the head of the boat and the gable, preventing the former from rubbing against the plane. When the vehicle gets up to the top, this moveable part falls down on the platform marked HI, becoming parallel with the horizontal part of the vehicle; after which it serves as a launch and passage to place the boat upon the rollers MN (fig. 1.) at the end of the canal. This passage part of the vehicle, together with the three rollers at the end of the canal, is likewise of great use in towing a boat out of the canal, in order to place it on the horizontal part. At the bottom of the cavity of the vehicle is a large hole F, with a valve opening inwardly. Through this hole the water enters when the vehicle, sinks into the navigable river F, for the purpose of receiving a boat on the top or horizontal part of the vehicle till it is quite full; and will then sink entirely under water, while the boat is towed in on the horizontal part. A small rope K is fastened to the valve, on purpose to lift it up, and to keep it so while the vehicle and boat are ascending up the plane out of the canal, that the ropes, fall, discharge itself till as much as is necessary be got out; or till it becomes an equal balance for the corresponding vehicle and its contents, which are descending by the other path. Hence we see, that every machine must have two of these vehicles furnished with rollers as already described, and so constructed that one may be as nearly as possible a counterbalance to the other. As it is necessary that the vehicles should be water tight, the insides, of them must be caulked very tight; and they should be capacious enough to hold as much water as will balance the largest boat with its contents. Here it may be observed, that every vessel will be balanced by as many cubic feet of water as it displaces by being put into the water when loaded. The quantity may easily be known, by observing how far the boat sinks in the water, and calculating the bulk of the part immersed.

The machine which puts the vehicles in motion, may either be constructed with an under shot or breast water-wheel, by an over shot water-wheel; or by two walking-wheels, for men to walk in, as in cranes, &c.

Fig. 3. shows a front view of the under-shot water-wheel movement: where A is the end of the axis or cylinder of the cog or spur-wheel; the diameter of which axis is four feet, and its length not less than 22 feet, as it must be extended quite across the canal from one side to the other, and placed on the top of very strong supporters on each side of the canal, about seven feet above the surface of the water, as the loaded boat is to pass backwards and forwards under the cylinder, and at a convenient distance from the wall RR (fig. 1.) and placed between the two sluices S and T; on the end of which cylinder is the cog-wheel B (fig. 3.) The wheel B is supposed to be 20 feet in diameter, having on its edge 120 cogs; and underneath the cog wheel is the breast-water one, C, 24 feet in diameter from the tip of one aller-board to the tip of its opposite. On the end of the axis of the water-wheel D is a trundle two feet and an half in diameter, with 15 rounds or flaves contained therein. This must be placed between the two sluices S and T, to let the water out of the canal; when falling on the float-boards, will turn the wheel round from the right hand towards the left, when the fluese on the left hand of the wheel is opened; but the water turns the other way when the right hand is opened. The water falling upon the boards passes along with the wheel in the circular cavity EGF, and is discharged at G, whatever way the wheel may turn.

To the axis or cylinder of this machine, which must always be horizontal, are fixed two pair of strong ropes; the ends of each pair fastened to the upper part of the cylinder; it being necessary that they should act in contrary directions. Each must extend the whole length of the plane, and their strength must be proportioned to the weight necessary to be sustained. The two vehicles already mentioned are fastened to the other ends of the ropes; so that one pair of the ropes are wound up by the cylinder turning one way, and the other by its turning the contrary way. Thus, when one of the vehicles is at the upper part of the path A, ready to discharge its boat and cargo into the upper canal, the other will be at the foot of the path B, all under water in the lower canal, and ready for the reception of a boat from the horizontal part of it; so that as one vehicle rolls up on one side of the plane, the other will roll down on the other side, and vice versa.

Fig. 4. shows the movement by means of an over-shot water-wheel. It consists of a water-wheel C, and two spur or cog-wheels A and B. The water-wheel is 18 feet in diameter, and has two rows of buckets placed contrariwise to one another, that it may turn round in contrary directions, according as the one or the other fluese, S or T, is opened. On its axis F is a trundle of three feet diameter, having 18 rounds or flaves which fall into the cogs of the second spur-wheel B, caulsing it to turn round in a direction contrary to that of the water-wheel. This second wheel is likewise 18 feet in diameter, with a trundle of three feet, having 18 rounds or flaves. The diameter of the upper spur-wheel A is also 18 feet, but the diameter of its axis is six feet. On the edge of the wheel are 108 cogs. These flave in between the cogs of the axis of the lower spur-wheel; and thus the third wheel turns round the same way with the water-wheel C. The cylinder of this upper spur-wheel
The movement of the walking-wheel is shown (fig. 5.) A1 and A2 are two wheels for men to walk in, each of them 24 feet in diameter. B1 and B2 are the axes or cylinders of the two wheels, of equal lengths; viz. 11 feet each, and four in diameter. At one end of each of the two cylinders C1 and C2, is a wheel of the same diameter with the cylinder. On the edges of these wheels are teeth of an equal number in each wheel; and as the teeth of the wheels mutually fall into each other, the revolutions of both must be performed in the same time. By this contrivance also the cylinders will turn different ways; and the ropes on the two different cylinders will constantly one pair be wound up, and the other wound down, by the natural moving of the machine. DDD is the frame that supports the whole, which must be made very firm and secure.

Let us now suppose, that there is a boat in the upper canal to be brought down, but none to go up for a balance. In this case, as one of the vehicles must be at the top to receive the boat, the other will be at the bottom to take in water. Let then any of the movements just described be set to work, and it is plain, that as the upper vehicle with its boat descends, the under vehicle will ascend with the water; the valve being in the mean time filled up till a sufficient quantity of water has flowed out, to make the one nearly a counterbalance to the other; so that the vessel may slide down gently and without any violence.

If it happens that a boat is to go up while none is to come down, one of the vehicles being at the foot of the plane under water, and in readiness to have the boat towed upon its horizontal part, one of the faucis at K or L is to be opened, and a quantity of water let into the cistern of the upper vessel sufficient to counterbalance the boat with its contents which is to ascend. This being done, the machine is set to work, the valve of the under vehicle kept open till the water is all discharged; and then the boat will roll up to the top of the plane.

From this description of the canal and machinery for raising and lowering the vessels, the reader can be at no loss to understand the principles on which it depends. It would be superfluous to adduce examples, or follow our author through his calculations relative to particular cases. We shall only observe, that the difference of time in which vessels may be raised or lowered by the machinery just described, in comparison with what can be done in the common way by dams and locks, must give a very favourable idea of the new method. According to Mr Leach's computations, a boat with its cargo weighing 10 ton might be raised by the walking-machine in 12 or 14 minutes, by the under-shot-wheel in 15 minutes, and by the over-shot-wheel in 30 minutes; and that through a space of no less than 30 fathoms measured on the inclined plane, or 114 feet perpendicular.

NAULUM, a piece of money put into the mouth of a person deceased among the Romans, to enable him to pay Charon the ferryman for his passage. It was to be of the current coin of the reigning emperor: from this money then the time of the person's death may be known. The sum for poor men was a farthing, but the rich in general were very liberal to the old tar Charon, as appears from the number of coins often found in the neighbourhood of Rome on opening the graves of great men. Charon was looked upon as a very morose and obdurate old fellow, who would not carry over any man without his fare; and hence the proverbial use of that verse in Juvenal, 

Furo offidonio pendere naulum.

A similar custom took place among the Greeks; but the money put into the mouth of the deceased was called deus.

NAUMACHIA, in antiquity, a show or spectacle among the ancient Romans, representing a sea fight. These mock sea-fights are supposed to have originated at the time of the first Punic war, when the Romans first infused their men in the knowledge of naval affairs. Afterwards they were intended to entertain the populace, as well as to improve the seamen. They were often like other shows exhibited at the expense of individuals, to increase their popularity.

In these spectacles they sometimes proved to excel each other in swiftness; and sometimes engaged in a warlike manner. The Naumachie of Claudius indeed was a most savage diversion. The combatants used to destroy each other to amuse a tyrant and a cruel mob. As they passed before him, they used this melancholy greeting, "Ave Imperator, morituris tu faulus.

The emperor replied, "Avez vos." This they understood as an answer of kindness, and a grant of their lives: but they soon discovered that it proceeded from wanton cruelty, and barbarous iniquity. In the time of the emperor Domitian, such a vast number of vessels engaged as would have nearly formed two regular fleets for a real fight, and the channel of water was equal in magnitude to a natural river. The emperor Heligabalus is reported to have filled the channel where the vessels were to ride with wine instead of water. Tritons and sea monsters were frequently exhibited during the engagement. Suetonius and Dio Cassius inform us, that at one of these sea-fights of Domitian a violent shower fell; the emperor, however, continued till the end of the engagement, often changing his clothes, nor would he suffer any one to depart; and as the rain continued for several hours, many were seized with diarrheas, and some even died, Suet. cap. 4. Dio, lib. lxvii. Naumachiae were also places fitted up for these shows, a fort of circus or amphitheatres, with seats and porticos, &c.: there were several of them at Rome; three built by Augustus, one by Claudius, another by Domitian, and another by Nero; which served for the revere of his medals. Claudius used the lake Fucinus as a Naumachia.

NAUMBURG, a town of Germany, in the circle of Upper Saxony, capital of the county of Saxe-Neumburg, situated on the river Sala, in E. Long. 11. 10. N. Lat. 51. 12.

NAUPACTUS, or NAUPACTUM, (anc. geog.) a city of Etolia, at the mouth of the Euenus. The word is derived from NAU and HPAUK, because it was there that the Heraclidæ built the first ship which carried them to Peloponnesus. It first belonged to the Leoci Ozo, and afterwards fell into the hands of the Athenians, who gave it to the Meffinians, who had, 

Inland Navigation;

NAULUM, former movement, and the two pair of ropes in the same manner.
NAU [ 776 ]

had been driven from Peloponnesus by the Lacedaemonians. It became the property of the Lacedaemonians after the battle of Argos in the year 1782, when it was restored to the Lacedaemonians. Philip of Macedon afterwards took it, and, as the Lacedaemonians were not able to recover it, the town of Nauplion was built in its neighbourhood.

NAUPLIUS, (anc. geog.), a maritime city of Laconia, the naval station of the Argives. It was the naval station of the Argive. The fountain Canathos was in its neighbourhood. It appears that the approximation of one vessel towards another, or towards the land. The existence of the meteor, and the knowledge of its different modifications, are what constitute the certainty and the precision of my informations.

If I am asked, how it is possible that the approach of a ship towards the land should give birth to any meteor whatever in the atmosphere, and what connection there can be between two objects at such a distance from each other? I reply, that I am not obliged to give an account of the how and the wherefore; that it is sufficient for me to have discovered the fact, without being obliged to account for its principle.

The writer concludes, by defining to be called on for experimental proofs, and by promising in future a complete treatise of Naupcopy, with maps, plates, &c.

This complete treatise, as far as we know, has not yet been published, nor do we expect ever to see such a treatise on the subject as will satisfy the minds of those who are perused that every effect must have an adequate cause. The administrators of the island, who gave to M. Bottineau what he calls a report, containing the most authentic and most explicit testimony of the reality of the discovery, seem to be of our opinion; and yet they speak of this discovery with doubt, and with a degree of respect to which we think it can lay no claim. Their report is in the form of a letter directed to the Marshal of Castris; and that our infidelity may not deprive the public of what, in the immense catalogue of possibilities, may lead to a useful discovery, we shall here subjoin a copy of it.

Port Louis, Island of France, the 18th February 1784.

‘My Lord, A letter which you have written on the 6th of April to M. Bottineau, employed in the King and Company’s service in this colony, obliges us not to refuse him one for you, of which he proposes being himself the bearer. The desire only of being useful to his country, is (as he says) the motive which determines him to take this step. He would be angry with himself were he to conceal a discovery which hath hitherto escaped the most enlightened persons, and of which he only is in possession. This discovery is the art of announcing the presence of one or several ships, at 100, 150, and as far as 500 leagues distance. This is by no means the result of his studies, nor the fortunate application of the principles of any particular science; his science is in his eyes only, and he can have no other; what we call perception and genius cannot make up to him what he is deficient in from education. He perceives (as he says) in nature, some signs which indicate to him the presence of the vessels, as we know that there is a fire in a place when we perceive the smoke which comes from it. This is the comparison which he makes use of himself to those who have conversed with him about his art; this (though he has kept his secret to himself)
NAU [ 777 ]

"Supposing the reality of the discovery, we do not. Nautilus, believe that its utility can be as important as M. Botin- 
neau persuades himself it is; but it might perhaps 
throw a great light upon natural history. In order to 
be useful, it would be necessary that the discovery 
should be confined to one nation, and remain unknown 
to all others. This will be impossible, if every fleet, 
every vessel, and every privateer, is obliged to carry a 
man on board who is in possession of this secret. 

We remain, with respect, my Lord, your's, &c. Le 
Vax. de Soulliac, chevalier.

NAUSEA, or sickness; a retching or propensity 
and endeavour to vomit, arising from something which 
irritates the stomach.

NAUTILUS, in zoology; a genus belonging to 
the order of vermes teftacea. The shell consists of 
one spiral valve, divided into several apartments by 
partitions. There are 17 species, chiefly distinguished 
by particularities in their shells.

Bonani observes, that this genus of shell-fish is very 
well named from the Greek ναυτίλος, which signifies 
both "a ship" and "a sailor," for that the shells of 
all the nautili carry the appearance of a ship with a 
very high poop. Different authors, both ancient and 
modern, have called the nautilus by the names of 
pomphius, nautilus, nautilus, eum polybē, polybus tēs-
cus; and the French call it le voleur. It is by some 
imagined, that men first learned the art of navigation 
from this animal.

The most remarkable division of the nautili is into 
the thin and thick-shelled kinds. The first is called 
nautilus tērāceus; and its shell is indeed no thicker 
than a piece of paper when out of the water. This 
species is not at all fastened to its shell; but there is 
an opinion, as old as the days of Pliny, that this crea-
ture creeps out of its shell, and goes on shore to feed. 
When this species is to fall, it expands two of its arms 
on high, and between these supports a membrane, 
which it throws out on this occasion; this serves for 
its fail, and the two other arms it hangs out of its 
shell, to serve occasionally as ears or as a fléer-
age; but this last office is generally served by the tail. 
When the sea is calm, it is frequent to see numbers of 
these creatures diverting themselves in this manner: 
but as soon as a storm arises, or any thing gives them 
disturbance, they draw in their legs, and take in as 
much water as makes them specifically heavier than 
that in which they float; and then they sink to the 
bottom. When they rise again, they void this water 
by a number of holes, of which their legs are full. 
The other nautilus, whose shell is thick, never quits 
that habitation. This shell is divided into 40 or more 
partitions, which grow smaller and smaller as they 
approach the extremity or centre of the shell: be-
tween every one of these cells and the adjoining ones 
there is a communication by means of a hole in the 
centre of every one of the partitions. Through this 
hole there runs a pipe of the whole length of the shell. 
It is supplied by many, that by means of this pipe 
the fish occasionally pusses from one cell to another; 
but this seems by no means probable, as the fish must 
doubtedly be crushed to death by passing through 
it. It is much more likely that the fish always occu-
pies the largest chamber in its shell; that is, that it lives 
in the cavity between the mouth and the first parti-

NAV [778] NAV

NAUXISH. See Exercise. See MARITIME-SLAWS.

NAWORTH-Castle, in Cumberland, 10 miles from Carlisle, near the Celt. This castle is still entire and inhabited. It is a large pile, square, and built round a court. On the north it stands over the river Ithing, at a great height, the banks flagged with wood. The whole house is a very irregular building, the rooms numerous, accessible by 16 staircases, with most frequent and sudden ascents and descents, &c.

The great hall has a gallery at one end, adorned with four vaults carved in wood, viz. a griffin and dolphin, with the foliolls; an unicorn, and an ox with a coronet round his neck. In front is a figure in wood of an armed man; two others, perhaps vassals, in short jackets and caps; a pouch pendant behind, and the mutilated remains of Priapus to each; one has wooden shoes. These form the ludibrium aule in those frosty days. The top and upper end of the room is painted in squires, to the number of 107, representing the Saxon kings and heroes. The chimney here is five yards and a half broad. Within this is another apartment, hung with old tapestry, a head of Ann of Cleeves; on one side of her a small picture of a lady in full length, &c. and many others. Many of these paintings were brought from Kirk-Ofwald-castle when that was demolished. The chapel has a ceiling, and part of its wainscot of the fame kind, being paintings of Patriarchs, Jewisb kings, &c. It has a floor of plater of Paris, as have some other of the rooms. Some of the apartments are very large and spacious. The small Pophis chapel is above stairs, and joining to this chapel is the library, which has a wooden roof; the books are old, there are not above one or two of the manuscripts here now. This castle was built by one of the Dacre's, about the reign of Henry III. In the garden walls were flones with Roman inscriptions, which the late earl of Carlisle gave to Sir Thomas Robinson, and were by him removed to his museum at Rookby: On one of these flones is this inscription, pedium centum quinquaginta Britanniorm, whence it appears that the Romans, when in possession of Britain, sometimes indulged the national troops with the favour of garrisoning their own territories.

NAXIA, or NAXOS, a considerable islet of the Archipelago, 25 miles in length, and 86 in circumference. The whole islet is covered with orange, olive, lemon, cedar, citron, pomegranate, fig, and mulberry trees; and there are a great many springs and brooks. This islet has no harbour; and yet they carry on a considerable trade in barley, wine, figs, cotton, silk, flax, cheese, salt, oxen, sheep, mules, and oil. They burn only oil of mastic, though olive-oil is exceeding cheap. It is inhabited both by Greeks and Latins, who live in great dread of the Turks; for when the meanest of their ships appear here, they always wear red caps like galley-slaves, and tremble before the lowest officer: but as soon as they are gone, they put on their caps of velvet. The ladies are in vain, that when they return out of the country, they
they have 40 women in their train, half on foot and half on asses; one of whom carries a napkin or two, another a petticoat, another a pair of stockings, and so on; which is a very ridiculous sight to strangers. There are four archbishops' fees in this island, and a great many villages; but so thin of people, that the whole island does not contain above 8000 inhabitants. The highest mountain is Zia, which signifies "the mountain of Jupiter." There are but few antiquities, except some small remains of the temple of Bacchus. Some say they have mines of gold and silver; however, there is one of emery, which is so common here, and so cheap, that the English often ballast their ships therewith.

NAXOS, or Naxia, a considerable town, and capital of the Isle of Naxos, over-again the Isis of Paros, with a castle and two archbishops' fees, the one Greek and the other Latin. The greatest part of the inhabitants are Greeks. E. Long. 25. 51. N. Lat. 37. 8.

NAXUS, now Naxia, formerly Strongyle, Dia, Dionysia, Callipolis, and Little Sicily. It was called Strongyle, from a Greek word, signifying "round," though in reality it is rather square than round. The names of Dia or Dione, and Dionysia, were given it as being consecrated in a peculiar manner to the fabulous god Dionysus or Bacchus. The appellation of Callipolis Pliny and Solinus derive from the metropolis of the island, formerly a most beautiful city, which is the import of the word Callipolis. The great fertility of the country gave rise to the name of Little Sicily, Naxus being the most fruitful of all the Cyclades, as Agathemerus informs us, and no less fertile than Sicily itself. As for the name of Naxus, some assert that it was borrowed from one Naxus, under whose conduct the Carians possessed themselves of the island; others pretend it received its name from Naxus, the son of Endymion. Stephanus, Suidas, and Phavorinus, derive the name of Naxos from the Greek word naxos, signifying "to sacrifice," and will have it to have been so called from the many sacrifices offered here to Bacchus. With these Bocchart agrees, as to its being called Naxos from the sacrifices performed here in honour of Bacchus, but will have the word naxos to be a corruption of the Phoenician nafs, or nafs, signifying "a sacrifice, offering." Naxos is, according to Pliny, 75, but reckoned by the present inhabitants 100, miles in compass. It has Paros to the west, Myconos and Delos to the north, and Ios to the south. This island is the most fruitful of the Archipelago, and was formerly famed for the excellent wines it produced. Archilochus, as quoted by Athenaeus, compares them to the nectar of the gods; and Aeschylus, cited by Stephanus, affures us, that Bacchus took more delight in Naxos than in any other place whatsoever, having instructed the inhabitants to cultivate their vines. The wine of Naxos maintains to this day its ancient reputation, being by some deemed the best of the Levant. Besides wine, this island abounds with all sorts of delicious fruits, the plains being covered with orange, olive, lemon, cedar, citron, pomegranate, mulberry, and fig trees. It was formerly famous for quarries of that sort of marble which the Greeks called opistho, from its being green, and speckled with white spots like the skin of a serpent. The best emerald is found here on the mountains near the western coast, whence the neighbouring cape is called by the Italians ceto marmoretis, or the emerald cape. As to the inhabitants of Naxos, Diodorus relates that the island was first peopled by the Thracians. There were in a little time subdued by a body of Thracians, who having possessed the island for the space of 200 years and upwards, were compelled to abandon it by a drought and famine.

After the Trojan war, the Carians settled here and called the island Naxos, from their king, who was the son of Poseidon. He was succeeded by his son Leucippus, and Leucippus by his son Smaradius, in whose reign Theseus, coming out of Crete, landed here with Ariadne, whom he was, in his sleep, commanded by Bacchus to leave in this island. In process of time a colony of Cnidians and Rhodians settled here under the conduct of Hippothous and Xuthus; the last of all the Ionians, who, in time, possessed the whole island; whence the Naxians are, by Herodotus, called Ionians, and ranked among the Athenian colonies. E. Long. 26. 5. N. Lat. 36. 30. It is about 95 miles in circumference and about 30 broad.

NAXUS, (anc. geog.), a town of Crete, famous for its hones, called lapsis Naxius. Another of Sicily, built by the Chalcedians; situated on the south side of Mount Taurus, destroyed by Dionysius the tyrant; from whose ruins Tauromenium, built by Timoleon, either arose or was increased, (Plutarch).

NAYLOR (James), a noted English enthusiast, was born, about 1616, in the parish of Aredley, not far from Wakefield in Yorkshire. His father, though a farmer, and the proprietor of an estate, gave his son not a mean education; which is perhaps to be regretted, for his parts were very considerable. He married when very young and settled in Wakefield parish. In 1641, he was a private soldier under Lord Fairfax, being then a presbyterian: but he afterwards became an independent, and was made quarter-marshal under General Lambert. In 1651-2, he was converted by George Fox the apostle of the quakers, and soon commenced a preacher and prophet among that people. One of his prophecies was, that the last and general judgement should be on the 14th day of the ensuing November. The falsehood of this prediction was soon perceived, and of course his imposture ought to have been detected; but such is the power of enthusiasm over the human mind, that his fame rose daily; and upon his going to London in 1655, he excited to no common pitch the envy of his brethren. He had strange fancies of celestial illuminations, and considered himself as a great favourite of heaven. In 1656 he went into the west of England, but his extravagancies were so great and his opinions so blasphemous, that even in those days of fanaticical delusion, they were heard with such horror, that the author of them was imprisoned in Exeter gaol; from which however he was relieved in the space of a month. Upon this he determined to return to London: but taking Bristol in his way, he made his entrance into that city in imitation of our Saviour's entrance into Jerusalem, the people thronging the way, &c. and calling out "Holy, holy, holy; lord god of Sabaoth; huzannah in the highest, &c." So impious a conduct could
NAZ

Nazareth.

could not escape animadversion he was apprehended with fix of his acquaintances. On examination he defended all that had passed; and was soon after with his followers sent to London, imprisoned, and condemned to be whipt, and then put to hard labour. The sentence, though much petitioned against, was executed, and he recovered his senses, expired his repentance, and was again received by the Quakers, who, during his impious frenzy, had disowned him. In 1659 he was freed from prison; and the following year let off to see his wife and children; but being robbed and left bound by the way, he was found in that state and carried to a friend's house at Rippon, where he died in November 1660. He was accounted the author of several works. His eccentricities, however, rather than his writings, have preferred his character; and he stands forward to the world, not so much as a man of genius or parts, though he was in some measure possessed of both, but rather as a striking example of the power of enthusiasm over the human mind, and of the danger of giving way to the religious reveries of an overexcited imagination.

NAYRES, the nobility of the Malabar coast. We may with truth affirm that they are the oldest nobility in the world; for the most ancient writers mention them, and quote the law that permits the Nayre ladies to have many husbands; every one being allowed four. Their houses which stand tingle, have as many doors as the lady has husbands. When one of them visits her, he walks round the house, striking with his staff on his buckler; he then opens his door, and leaves a man and children; but being robbed and left bound by the way, he was found in that state and carried to a friend's house at Rippon, where he died in November 1660. He was accounted the author of several works. His eccentricities, however, rather than his writings, have preferred his character; and he stands forward to the world, not so much as a man of genius or parts, though he was in some measure possessed of both, but rather as a striking example of the power of enthusiasm over the human mind, and of the danger of giving way to the religious reveries of an overexcited imagination.

NAZARETH. A little city in the tribe of Zebulun, in Lower Galilee, to the west of Tabor, and to the east of Poolemais. Eusebius says, it is fifteen miles from Legion towards the south. This city is much celebrated in the scriptures for having been the usual place of the residence of Jesus Christ for the first 35 years of his life. Luke ii. 51. It was there our Saviour became incarnate, where he lived in obedience to Joseph and Mary, and from whence he took the name of a Nazarene. After he had begun to execute his mission, he preached there sometimes in the synagogue, id. iv. 16. But because his countrymen had no faith in him, and were offended at the meanness of his original, he did not many miracles there, Math. xiii. 54, 58. nor would he dwell therein: so he fixed his habitation at Capernaum for the latter part of his life, id. iv. 13. The city of Nazareth was situated upon an eminence; and on one side there was a precipice from whence the Nazareans one day had a delign of throwing down our Saviour, because he upbraided them with their incredulity, Luke iv. 29.

St Epiphanius says, that in his time Nazareth was only a village, and that to the reign of Constantine it was inhabited by Jews alone, exclusive of all Christians. Adamnanus, a writer of the seventh age, says, that in his time there were two great churches to be seen at Nazareth, one in the midst of the city, built upon two arches, in the place where our Saviour's house had stood. Under the two arches now mentioned, was a very fine fountain, which furnished water to the whole city, and from whence water was drawn also by the help of a pulley for the use of the church above. The second church of Nazareth was built in a place where the house stood wherein the angel Gabriel revealed to the virgin Mary the mystery of our Lord's incarnation; and we are assured that the church of incarnation, which is supported by two arches, is still in being to this day. Mr Maundrell tells us, that there is a convent built over what is said to be the place of annunciation; for the chamber where the received angel's salutation was about 1500 years ago removed from Nazareth, and, according to the Roman legends, transported by angels to Lorretto, then a small village in the pope's dominions, now become a bishop's see. However, Calmet's opinion (which is certainly the true one) upon the different translations of this famous house of Lorretto is, that they were no other than so many different buildings made up upon the model of the church of Nazareth, just as in several places episcopal seats have been in several places built upon the model of that at Jerusalem. Martini tells us, that in the eastern part of the city stands the church dedicated to the Blessed Virgin: the zeal of the Cenobites raised it from the ruins of that which had been destroyed by the Saracens. It is a very handsome building, and consists of three naves, in the middle of which is the principal altar, to which there is an ascent by two magnificent stairs, much admired for their iron balustrades, the work of an ingenious monk of the convent. The descent to the grotto or annunciation chapel below is by steps of beautiful marble, cut with great taste. Two beautiful columns of oriental granite strike the eye of the observer in the entrance. They appear to have been constructed both to support and ornament the grotto. The altar of this subterranean chapel is extremely elegant; and the different kinds of marble with which it is ornamented, receive an additional lustre from the combined light of several fire lamps presented by Christian princes. On solemn festivals, the walls and the pilasters are ornamented with various pieces of tapestry, representing the mysteries of the religion; a figure of the Virgin being presented from the House of Austria. In the western part of the city stands a Christian church, built, as is said, on the site of the ancient synagogue where Jesus showed the Jews the accomplishment of the prophecies in his person. This place served a long time as a shelter for flocks, but at present it is in good repair. In the neighbourhood may be seen a fountain of excellent water, which is, however esteemed by the people on another account. They conjecture that it was contiguous to the habitation of the Virgin, and that it was used by her. At some distance is a large stone of a round form, called the Virgin's Table.
pretended that he came hither more than once with his disciples to eat. The inhabitants of Nazareth pay it a kind of worship, by burning perfumes and incens around it. It is situated in 35° E. Long. and in 32° N. Lat.; and formerly held the third rank under the patriarchs of Jerusalem. At present it is part of the domains of the chief of Acre. The ancient city, after the ravages of fanaticism, was reduced to a miserable hamlet, containing only a few Arab huts. Under the protection of Dahir Omar, however, it recovered very considerably, and is now of far more importance.

**NAZARITE, or NAZAREAN, or NAZARENE,** a term which may signify, 1. One that is of Nazareth, or any native of this city. 2. It was given to Jesus Christ and his disciples, and is commonly taken in a sense of derivation and contempt, in such authors as have written against Christianity. 3. It has been taken for a sect of heretics called Nazareans. 4. For a Nazarite, a man that has laid himself under the obligation of a vow to observe the rules of Nazarite-ship, whether it be for his whole life, as Samson and John the Baptist, or only for a time, as those mentioned in Numbers vi. 18, 19, 20. Amos ii. 11, 12. Lastly, the name Nazarite in some passages of scripture denotes a man of particular distinction and great dignity in the court of some prince. But we must speak of these several sorts of Nazarenes something more distinctly.

The name of Nazarene belongs to Jesus Christ, not only because of his having lived the greatest part of his life at Nazareth, and because this city has always been considered as his country, but also because the prophets had foretold that he should be called a Nazarene, Matth. ii. 23. "And he came and dwelt in a city called Nazareth, that it might be fulfilled which was spoken by the prophets, He shall be called a Nazarene." We find no particular place in the prophets in which it is said that the Messiah should be called a Nazarene; and St Matthew only quotes the prophets in general. Perhaps he would intimate, that the consecration of the Nazarenes, and the great purity of which they made profession, was a type and a forerun of the of those of our Saviour, or else that the name Nazar or Nazarite given to the patriarch Joseph, Gen. xxix. 26. Deut. xxxiii. 16. was a prophecy which was to be fulfilled in the person of Jesus Christ, of whom Joseph was a figure. Lastly, St Jerom was of opinion, that St Matthew here alludes to that passage of Isaiah x. 1. and ix. 21. "And there shall come forth a rod out of the stem of Jesse, and a branch (in Hebrew Nester) shall grow out of his roots." This branch or Nester, and this rod, are certainly intended to denote Jesus Christ, by the general consent of all the fathers and interpreters.

When the word Nazarene is put for the heretics known by this name, it denotes Christians converted from Judaism, whose chief error consisted in defying the necessity or expediency of the works of the law, and who obstinately adhered to the practice of the Jewish ceremonies. The name of Nazarenes at first had nothing odious in it, and it was often given to the first Christians. The fathers frequently mention the gospel of the Nazarenes, which differs nothing from that of St Matthew, which was either in Hebrew or Syriac, for the use of the first converts, but was afterwards corrupted by the Ebionites. These Nazarenes preferred this first gospel in its primitive purity. Some of them were still in being in the time of St Jerom, who does not reproach them with any error. They were very zealous observers of the law of Moses, but had the traditions of the Pharisees in very great contempt.

Nazarite, when put to signify those under the ancient law who made a vow of observing a more than ordinary degree of purity (Numb. xdi. cirt.), denotes a man or woman who engage themselves by a vow to abstain from wine and all intoxicating liquors, to let their hair grow without cutting or shaving, not to enter into any house that was polluted by having a dead corpse in it, nor to be present at any funeral. And if by chance any one should have died in their presence, they began again the whole ceremony of their consecration and Nazarite-ship. This ceremony generally lasted eight days, sometimes a month, and sometimes more than a month. When the time of their Nazarite-ship was accomplished, the priest brought the person to the door of the temple, where there offered to the Lord a he-lamb for a burnt-offering, a she-lamb for an expiatory sacrifice, and a ram for a peace-offering. They offered likewise loaves and cakes, with wine necessary for the libations. After all this was sacrificed and offered to the Lord, the priest or some other bled the head of the Nazarite at the door of the tabernacle, and burnt his hair, throwing it upon the fire of the altar. Then the priest put into the hands of the Nazarite the shoulder of the ram roasted, with a loaf and a cake, which the Nazarite returning into the hands of the priest, he offered them to the Lord, lifting them up in the presence of the Nazarite. And from this time he might again drink wine, his Nazarite-ship being now accomplished.

As to those that were perpetual Nazarenes, as were Samson and John the Baptist, it appears that they were consecrated to their Nazarite-ship by their parents, and continued all their lives in this statute, without drinking wine or cutting their hair.

Thole that made a vow of Nazarite-ship out of Palestine, and could not come to the temple when their vow was expired, contented themselves with observing the abstinence required by the law, and after that cutting their hair in the place where they were: as to the offerings and sacrifices prescribed by Moses, which were to be offered at the temple by themselves or by others for them, they deferred this till they could have a convenient opportunity. Hence it was, that St Paul being at Corinth, and having made the vow of a Nazarite, he had his hair cut off at Cenchrea, and put off fulfilling the rest of his vow till he should arrive at Jerusalem, Acts xviii. 18. When a person found that he was not in a condition to make a vow of Nazarite-ship, or had not leisure to perform the ceremonies belonging to it, he contented himself by contributing to the expense of the sacrifice and offerings of those that had made and fulfilled this vow; and by this means he became a partner in the merit of such Nazarite-ship. When St Paul came to Jerusalem, in the year of Christ 58, the apostle St James the Less, with the other brethren, said to him, Acts xxi. 23, 24, that to quiet the minds of the converted Jews, who had been
NEALING, or Annealing, is applied to the preparation of several matters, by heating or baking them in an oven, or the like. NEALING of glass, is the baking of glass, to dry, harden, and give it the due conformation, after it has been blown, and fashioned into the proper works. This is usually performed in a kind of tower called the annealing tower, built over the melting furnace. See GLASS.

NEAL, or Baking, is also used for the art of making glases with metallic colours. One fine use of glaze is in the art of annealing upon glazes, baked to be so called by the science of its own. For prepared glazing, or the crude metal, being burned on a glaze plate, will tinge it of a fine yellow or golden colour. And there are several mineral earths, and other coarse matters of use in this art, which by means of fire impart transparent colours to glazes, and sometimes very different ones from those of the bodies themselves.

NEALING of steel, is the heating it in the fire to a blood-red heat, and then taking it out, and letting it cool gently of itself. This is done to make it softer, in order to engrave or punch upon it. See Tempering and Engraving.

NEALING is also used for the art or act of burning or baking earthen or other ware in an oven. The miners at Mendip, when they meet with a rock they cannot cut through, anneal it by laying on wood and coal, and contriving the fire so that they quit the mine before the operation begins, it being dangerous to enter it again before it be quite cleared of the smoke.

NEALING of tile is used in ancient statues for the boring of tile. The word is formed of the Saxons *nael*, to bake, and *ain*, to make, as also *anneal*, to light, burn.

NEAP, or NEAP-TIDES, are those tides which happen when the moon is in the middle of the second and fourth quarters. The neap tides are low tides, in respect of their opposites the spring-tides. As the highest of the spring-tides is three days after the full or change, so the lowest of the neap is four days before the full or change. On which occasion the seamen say that it is deep neap.

NEAPED. When a ship wants water, so that she cannot get out of the harbour, off the ground, or out of the dock, the seamen say the is neaped, or benaped.

NEAPOLIS (anc. geog.), a city of the Higher Egypt, in the Nomos Panopolitanus, between Thebæ to the south, and Panopolis to the north, on the east side of the Nile; otherwise called Cæme.—A second Neapolis of Babylonia, situated near the Euphrates on the south side. A third of Campania, an ancient town and a colony from Cæme. (See Vellesius, Pliny, Strabo.) It was accounted a Greek city, and a great thicket for Greek uilages, (see Livy, Tacitus). Its name is in nothing inferior to those of Baie, according to Strabo: at two miles distance from it stands the monument of Virgil, held in religious veneration by learned poetries. The Younger Pliny relates, that Virgil's birth-day was more religiously observed by Silius Italicus than his own, especially at Naples, where he resorted to his tomb as to a temple. The city is washed by the river Sebethos. Virgil reigns the nymph Sebethis to preside over the stream. Now Naples, capital of the kingdom of that name. See NAPLES.

— A fourth, Neapolis of Caria, near the Meander. (Ptolemy).—A fifth, an inland town of Cyrenaica, situated between Ptolemais and Airinoe, (Ptolemy); and to be distinguished from the Cænopolis, or Neapolis, on the east border of the same province, (id). A sixth, Neapolis of Ionia, (Strabo); which belonged first to the Ephesians, but afterwards to the Samians, who exchanged Marathonium, a more distant city, for a nearer. A seventh, Neapolis of Macedonia Adiachis, situated at the distance of 12 miles to the east of Philippi, (Antonine). — An eighth, Neapolis of Pididia, on the borders of Galatia, situated between Ambelada and Pappa, (Ptolemy).—A ninth, of Samaria, the ancient Sichem, which see: so called upon its restoration by the Romans, (Coin, Pliny, Jofephus).—A tenth, of Sardinia, situated on the south-west side of the island, 30 miles to the north of Metalla; now called Neapolis. — An eleventh, of the Regio Syrta, called also Lepcis. A twelfth, of Zeugitana on the Mediterranean, to the east of Clypea, and south of the Promontorium Mercurii.

NEAT, or Nat Weight, the weight of a commodity alone, clear of the cask, bag, cafe, or even filth. See Nat.

NEBIO, or NEBIO, a ruined city of Italy, on the north
NEC

[738]

NEC

Necessity:

north side of the island of Corica, with a bishop's see, whose bishop resides at San Florentzo, from which it is a mile distant.

NEBO, (anc. geog.), a very high mountain, a part of the mountains Abaris, and their highest top, whether Moses was ordered to ascend to take a view of the land of Canaan, and there die. Situated in the land of Moab, over-against Jerico; with a cognominal town at its foot (Isah) belonging to the Reubenites, which afterwards returned to the Moabites; in Jerome's time desolate: eight miles to the south of Heshbon.

NEBO, or Nabó. See NABO.

NEBUCHADNEZZAR. See NABUCHANTENZAR.

NEBULY, or Nebule, in heraldry, is when a coat is charged with several little figures, in form of words running within one another, or when the outline of a bordure, ordinary, &c. is indented or waved. NECESSITY, whatever is done by a cause or power that is irresistible; in which sense it is opposed to freedom. Man is a necessary agent, if all his action be so determined by the causes preceding each action, that not one past action could possibly not have come to pass, or have been otherwise than it hath been; nor one future action can possibly not come to pass, or be otherwise than it shall be. But he is a free agent, if it be able, at any time, under the circumstances and causes then, to do different things; or in other words, if he be not unavos tape determined in every point of time, by the circumstances he is in, and the causes he is under, to do that one thing he does, and not possibly to do any other thing. Whether a man is a necessary or a free agent, is a question which has been debated with much ingenuity by writers of the first eminence, from Hobbes and Clarke, to Priestley and Gregory. See Metaphysics, Part III. chap. 5. and Predestination.

Necessity, in mythology, a power superior to all other powers, and equally irresistible by gods and by men. Herodotus, as he is quoted by Cudworth, mentions an oracle which declared that "God himself could not slum his destined fate." And among the fragments of Philoemen collected by Le Clerc, is the following sentence:

Δεναι βασιλευε, κερν αι βασιλεις θεος, ει δει ημεις

"We are subject to kings, kings to the gods, and God to necessity." Hence it is, that in the Iliad, we find Jove himself the fire of gods and men, regretting that he was restrained by necessity from revenge his favourite son from the sword of Patroclus, Nay to such a height was this impiety carried in the reign of Greece, that we find Jove himself the fire of gods and men, being justifiably by the commands of that magistrate which endeavoured to restore Superstition, under the holy auspices of its merceless flarer, Persecution.

As to persons in private relations, the principal case where constraint of a superior is allowed as an excuse for criminal misconduct, is with regard to the matrimonial subjection of the wife to her husband; for
Necessity, for neither a son nor servant are excused for the commission of any crime, whether capital or otherwise, by the command or coercion of the parent or master; though in some cases the command or authority of the husband, either express or implied, will privilege the wife from punishment, even for capital offences. And therefore, if a woman commit theft, burglary, or other civil offences against the laws of society, by the coercion of her husband, or even in his company, which the law confines a coercion, the is not guilty of any crime; being considered as acting by compulsion, and not of her own will. Which doctrine is at least 1000 years old in this kingdom, being to be found among the laws of King Ina the West-Saxon. And it appears, that, among the northern nations on the continent this privilege extended to any woman transgressing in concert with a man, and to any servant that committed a joint offence with a freeman: the male or freeman only was punished, the female or servant exonerated.

And it seems, that, among the northern nations on the continent this privilege extended to any woman transgressing in concert with a man, and to any servant that committed a joint offence with a freeman: the male or freeman only was punished, the female or servant exonerated. But (besides that in our law, which is not less than a frailer, no impunity is given to servants, who are as much free agents as their masters) even with regard to wives, this rule admits of an exception in crimes that are male in fe, and prohibited by the law of nature; as murder, and the like: not only because these are of a deeper dye, but also, since in a state of nature no one is in subjection to another, it would be unreasonable to screen an offender from punishment due to natural crimes, by the refinements and subordinations of civil society. In treason also (the highest crime which a member of society can, as such, be guilty of), no plea in coverture shall excuse the wife: no presumption of the husband's coercion shall extenuate her guilt: as well because of the odiousness and dangerous consequence of the crime itself, as because the husband, having broken through the most sacred tie of socia community by rebellion against the state, has no right to that obedience from a wife, which he himself as a subject has forgotten to pay. In inferior misdemeanors also, we may remark another exception, that a wife may be indicted and sit in the pillory with her husband, for keeping a brothel: for this is an offence touching the domestic economy or government of the house, in which the wife has a principal share; and is also such an offence as the law presumes to be generally condoned by the intrigues of the female sex. And in all cases where the wife offends alone, without the company or coercion of her husband, she is responsible for her offence as much as any female.

Another species of compulsion or necessity is what our law calls ducus per minus; or threats and menaces, which induce a fear of death or other bodily harm, and which take away for that reason the guilt of many crimes and misdemeanors, at least before the human tribunal. But then that fear which compels a man to do an unwarrantable act ought to be just and well grounded; such, "qui cadere posset in virum confiditutum, non timidum et meticulosum," as Bradon expresses it, in the words of the civil law. Therefore, in time of war or rebellion, a man may be justified in doing many treasonable acts by compulsion of the enemy or rebels, which would admit of no excuse in the time of peace. This, however, seems only, or at least principally, to hold as to positive crimes, so created by the laws of society, and which therefore society may excuse; but not as to natural offences, so declared by the law of God, wherein human magistrates are only the executioners of divine punishment. And therefore though a man be violently assaulted, and hath no other possible means of escaping death but by killing an innocent person, this fear and force shall not acquit him of murder: for he ought rather to do him himself than escape by the murder of an innocent. But in such a case he is permitted to kill the assailant: for there the law of nature, and self-defence its primary canon, have made him his own protector.

3. There is a third species of necessity, which may be distinguished from the actual compulsion of external force or fear: being the result of reason and reflection, which act upon and constrain a man's will, and oblige him to do an action which without such obligation would be criminal. And that is, when a man has his choice of two evils set before him, and, being under a necessity of choosing one, he chooses the least pernicious of the two. Here the will cannot be said freely to exert itself, being rather passive than active; or, if active, it is rather in rejecting the greater evil than in choosing the less. Of this sort is that necessity, where a man by the commandment of the law is bound to arrest another for any capital offence, or to disperse a riot, and resistance is made to his authority: it is here justifiable, and even necessary, to beat, to wound or perhaps to kill, the offenders, rather than permit the murderer to escape, or the riot to continue. For the preservation of the peace of the kingdom, and the apprehending of notorious malefactors, are of the utmost consequence to the public; and therefore excuse the felony, which the killing would otherwise amount to.

4. There is yet another case of necessity, which has occasioned great speculation among the writers upon general law; viz. whether a man in extreme want of food or clothing may justify stealing either, to relieve his present necessities. And this both Grotius and Puffendorf, together with many other of the foreign jurists, hold in the affirmative; maintaining by many ingenious, humane, and plausible reasons, that in such cases the community of goods, by a kind of tacit concession of society, is revived. And some even of our lawyers have held the same; though it seems to be an unwarranted doctrine, borrowed from the notions of some civilians; at least it is now antiquated, the law of England admitting no such excuse at present. And this doctrine is arguable not only to the sentiments of many of the wisest ancients, particularly Cicero who holds, That "quod cuique incommendat ferendum est, potius quam de aliiuis commudar dea et caulends; but also to the Jewish law, as certified by King Solomon himself: "If a thief steal, and be hungry, he shall restore seven folds, and shall give all the substance of his house:" which was the ordinary punishment for theft in that kingdom. And this is founded upon the highest reason; for mens properties would be under a strange insecurity, if liable to be invaded according to the wants of others; of which wants no man can possibly be an adequate judge, but the party himself who pleads them. In England efpe-
especially, there would be a peculiar impurity in admitting so dubious an excuse: for by the laws such sufficient provision is made for the poor by the power of the civil magistrate, that it is impossible that the most needy stranger should ever be reduced to the necessity of thieving to support nature. The case of a stranger is, by the way, the strongest instance put to Baron Puffendorf, and whereon he builds his principal arguments: which, however they may hold upon the continent, where the parimonious industry of the Pufprenfors, and whereon he builds his principal article to repose, again whom had no advantage which is wanting in many cases of peculiar hardship. An especially those which are democratical; and these have in this privilege to the necessitous; especially when we consider, that the king, on the representation of his ministers of justice, hath a power to soften the law, and to extend mercy in cases of peculiar hardship. An advantage which is wanting in many states, particularly those which are democratical: and these have in their head introduced and adopted, in the body of the law itself, a multitude of circumstances tending to alleviate its rigour. But the founders of that constitution thought it better to veil in the crown the power of pardoning particular objects of compassion, than to countenance and establish theft by one general undistinguishing law.

NECHO, king of Egypt, began his reign 690 B.C. and was killed eight years after by Sabacon king of Ethiopia. Pharnaciaus his son succeeded him, and was the father, as Herodotus informs us, of Necho II. who reigned in the 676 B.C. This Necho II. is celebrated in history for attempting, though in vain, to cut a canal from the Nile to the Arabian gulf. He carried his arms as far as the Euphrates, and conquered the city of Carchemish. This prince is not only known in scripture under the name of Necho, but also in profane history. He no sooner succeeded to the crown than he raised great land armies, and fitted out vast fleets, as well upon the Mediterranean as upon the Red Sea: he gave battle to the Syrians near the city of Migdol; routed them, and made himself master of the city of Cadiz. The learned, however, are not agreed about this city Cadiz. Some will have it to be Cades in Arabia Petraea, others Jerusalem; and others say it is the city of Cedes, or Cadeia, in Galilee, in the tribe of Nathaniel.

The scriptures acquaint us with the whole expedition of Necho in all its particulars, 2 Kings xiii. 29. &c. and 2 Chron. xxxv. 20. 21 &c. In the year of the world 3394, this prince having drawn out his army into the field to make war with the Assyrians or Babylonians, and to take the city of Carchemish, otherwise called Ciregiun, upon the Euphrates, Josiah king of Judah, who was a tributary to the king of Babylon, marched to oppose his passage. Necho, who had no design against him, sent to tell him, What have I to do with you, King of Judah? It is not against you that I am come forth, but against another people, against whom the Lord has commanded me to make war. Leave off therefore to set yourself against me, for fear the Lord should punish you for your resistance. But Josiah would not hearken to the remonstrances of Necho, but gave him battle at Megiddo, where he received the wound of which he died. The people of Jerusalem set up Jehoahaz for king of Judah, and Necho soon passed forwards, without making any longer stay in Judea.

But at his return from his expedition, which was very successful, he halted at Riblah in Syria; and sending for Jehoahaz king of the Jews, he deposed him, loaded him with chains, and sent him into Egypt. Then coming to Jerusalem, he set up Eliakim, or Jehoiakim, in his place, and exacted the payment of 100 talents of silver and one talent of gold from the country. Jeremiah (xlvi. 1.) acquaints us, that the city of Carchemish was taken from Necho by Nebuchadnezzar king of Babylon, in the fourth year of Jehoiakim king of Judah; so that Necho did not enjoy his conquest above four years. Josephus adds, that the king of Babylon purifying his victory, brought under his dominion all the country which is between the Euphrates and Babylon, excepting Judaea. Thus Necho was again reduced within the limits of his own country.

NECK, in anatomy, is the slender part situated between the head and trunk of the body. See AnatoMy, n° 31.

NECOPHORON, in botany, a name used by Pliny and other authors for the *ficus alperea*, or rough bindweed.

NECROLOGY, nekrologium, formed of *nekros*, "dead," and *logos*, "discourse or enumeration," a book anciently kept in churches and monasteries, wherein were registered the benefactors of the time, the time of their deaths, and the days of their commemoration; as also the deaths of the priors, abbots, religious, canons, &c. This was otherwise called *colender* and *obituary*.

NECROMANCY, the art of revealing future events by a pretended communication with the dead. This superstitious and impious impertinence appears to have had its origin at a very early period in Egypt, and to have been thence propagated in every nation with the manners of which history has made us acquainted. The conquests of Selene might introduce it into India; the Israelites would naturally borrow it from the people among whom they sojourned 400 years; and it would easily find its way into Phocis from the vicinity of that country to the land of its nativity. From the Egyptians and Phcenicians it was adopted, with the other rites of paganism, by the Greeks; and it was imported into Rome with Grecian literature and manners. It was not however confined to the pagan nations of antiquity; it spread itself through all the modern nations of Europe, and took such deep root as to be long retained even after those nations were converted to the Christian faith.

Of its early antiquity we have complete evidence in the writings of Hosea, where it is severely condemned as an abomination to the Lord; and though it appears to have been even then spread into Phcenicia, we might yet conclude its birthplace to have been 11, 12. Egypt, because, at their ex 35, the Israelites were corrupted
Necromancy, corrupted only by Egyptian superstitious, and because necromancy seems to be one of those whore-doms which the prophet Ezekiel represents his countrymen as having brought with them from Egypt, and continued to practize until they were carried captives into Babylon.

If from sacred we proceed to consult profane authors, we shall find them not only affirming Egypt to have been the birth-place of necromancy, but in some degree accounting for the origin of so impious a delusion. From Diodorus the Sicilian,† we learn, that the Grecian fable of Charon, the ferry-man of hell, of Styx, Coccyx, the Elysian Fields, Tartarus, the judgement of Minos, and Kadamanthus, &c. with the whole scenery of the infernal regions, were imported from Egypt into Greece. The ancient Egyptians, and indeed all the people of the eall, made use of caves for burying places, which were well suited to the solemn fadness of the surviving friends, and proper receptacles for those who were never more to behold the light. In Egypt, many of those subterraneous cavities being dug out of the natural rock, still remain and command the admiration of travellers; and near to the pyramids in particular there are some apartments of a wonderful fabric, which though they extend in length 4400 feet, and are about 30 feet in depth, appear to have been, if not entirely dug, at least reduced to form by the chisel, or pick axe of the artif. Ic.

From the practice of burying in such caverns sprung the opinion that the infernal mansions were situated somewhere near the centre of the earth, which by the Egyptians was believed to be not very distant from its surface. In these dreary mansions, it was very easy for such adepts as the priests of Egypt to fabricate Eræbus, Tartarus, the Elysian Fields, and all those scenes which were displayed before the initiated (see Mysteries), and by them described to the million of the people. As it was in those dark abodes that necromancy was practiced, it would be no difficult matter for such magicians as withfoth Moses to impose on far upon the credulous vulgar, as to make them believe, that in consequence of their avocations they actually saw the ghosts of their friends ascend out of the earth. It appears from the book of Exodus, that the Israelitish women were, even in the wilderness, well acquainted with the use of the mirror, which was therefore undoubtedly known to the Egyptians. But a mirror of a particular form and properly illuminated at the instant required, might easily be made to reflect, in a cavern from which all other light was carefully excluded, the image of the deceased, who was called upon by the necromancer; and we can readily conceive, that with necromancy respect to the question to be proposed, a person might be concealed, prepared to give such ambiguous answers as would satisfy the inquirer, and at the same time save the credit of the oracle. The terrified imaginations of the spectators would aid the delusion, and make a very flight resemblance pass for the ghost or spirit, of their departed friend; or the necromancer might affign plausible reasons why a spirit, after having dwelt for some time in the infernal regions, should lose something of its resemblance to the body which it animated. Such juggling tricks, though performed by artists left accomplished than James and Jambres, have gained credit among people much more enlightened than the Egyptians can possibly have been when the science of necromancy was invented by their priests.

That the Israelites, notwithstanding the prohibition of their legislator, continued to practice the rites of necromancy, is apparent from Saul's transact with the witch of Endor (see Magic). From the same transaction, it is likewise apparent that the witches of Israel, and therefore in all probability the necromancers of Egypt, pretended to evoke the ghosts of the dead by a demon or familiar spirit, which they had at their command to employ upon every emergency. This demon was called əs; and therefore Saul directs his servants to find him a woman who was mistress of an os (א). It is probable that those wretched impostors had in their pay some persons who occasionally acted the part of the demon, and when the execution of the plot required their agency, emitted, by means of a cavity dug for that purpose, a low hollow voice from below the ground. Hence we find Isaiah, in his denunciations against Ariel, saying, "Thou shalt be brought down, and shall speak out of the ground; and thy voice shall be low out of the dust, and thy speech shall whisper out of the dust."

But though the Egyptian priests were undoubtedly the inventors of the whole mystery of necromancy, and though it was from them imported into Greece by the Selli or priests of Dodona, it does not appear that the Grecian necromancers pretended to be masters of os or familiar spirits. Mopsus, Orpheus, Linus, Eumolpus, &c. who either travelled into Egypt in quest of knowledge, or were actually natives of that country, instructed the early Greeks in this occult science; but whatever might be the practice of their apostles themselves, their disciples professed to do all

---

(1) The original or radical signification of this word occurs in Job xxxii. ver. 19; where Eliphaz compares his belly to new bottles, which lie calls ἀποσθ, the plural of ἀσθ. But as bottles were then made of leather, new bottles filled with wine and ready to burst, as Eliphaz describes them, would of course be of a form nearly globular. Hence it may be inferred that the original import of ἀσθ was round or globular; but əs being labials, are often changed into each other; and therefore from the Hebrew əs is derived the Greek əς, the Latin opis, a name under which the earth was worshipped. ἀποσθ was a name of Diana or the moon; the father of one of the Dioscuri was likewise ἀποσθ; but this ἀποσθ was undoubtedly the sun. Now the difference between ἀποσθ and ἀποσθ is nothing; hence we are led to believe that as they are all derived from əs, this word was employed by the early idolaters of Egypt to denote the first and greatest of Pagan gods, the sun. If so, those wretches who pretended to be mistresses of ἀποσθ, were exactly the same kind of impostors with the Pythonesses of the Greeks.
Necromancy is all the feats of magic by performing certain rites, by offering certain incantations, by muttering a certain form of words, by charms, spells, and exorcisms. By these they pretended to evocate the dead as certainly as the Egyptians and Jews did by their familiar spirits. By a small display of critical learning this might be easily proved from the popular story of Orpheus and Eurydice, which certainly was founded on one of these necromantic deceptions exhibited in a cave near Dodona, where the priests had a huta or infernal manison, in humble imitation of those with which the first of them were well acquainted in Egypt. It is indeed evident, without the aid of criticism, no man of any letters is ignorant, that whatever proved from the bottoms of their graves; and Lucan indeed evident, without the aid of criticism; no man of any letters is ignorant, that whatever proved from the bottoms of their graves; and Lucan of any letters is ignorant, that whatever proved from the bottoms of their graves; and Lucan from the same secret. This is evident from the name of the people, and a steady friend to the writer of this article, we have been informed, that not many years ago some of the Highlanders relied implicitly upon certain oracular replies, called in their language taghaim. This word seems to be compounded of ta, which in some parts of the highlands is still used to denote a spirit or ghost, and ghairm, which signifies calling upon or invoking. Taghaim, therefore, in its original import, is necromancy in the most proper sense of that word.

There were different kinds of taghaim, of which one was very lately practised in Skye. The diviner covered himself with a cow's hide, and repaired at night to some deep founding cave, whither the person who consulted him followed soon after without any attendants. At the mouth of the cave he prepared about the questions of which he wanted solutions; and the man within pronounced the responses in a tone of voice similar to that with which the one, or pretended demons of antiquity, gave from beneath the ground their oracular answers. That in the latter days of taghaim, the Gallic diviners pretended to evocate ghosts, and from them to extort solutions of difficulties proposed, we have no positive evidence; but that such was the original pretence, there can be little doubt, when we reflect either upon the place where this species of divination was practised, or upon the import of the word by which it was denominated.

As we have been led to mention taghaim, we shall beg leave to make a few observations on another species of it, called taghaim an usge, or "taghaim by water." This too was late practised in the Isle of Skye, by a man of the name of McCallum, whose ancestors had long been famous for the art. He lived near a beautiful cascade on a small river; and when consulted on any matter of consequence, he covered his whole body with a cow's hide, that necessary implement of Highland divination, and placed himself between the water of the cascade and the rock over which it flowed. Then another man with a heavy pole gave repeated strokes to the water, and the diviner behind it crying out now and then in Gaelic, "Is this a flock of arn?" This operation was continued till McCallum was perceived to be frantic or furious, when he was considered as in a condition to answer the most important questions. He was frequently consulted about felicity; and though he could not in a proper sense of the word, be called a necromancer, his responses were listened to as proceeding from something more than human. A degree of frenzy, either real or affected, seems to have accompanied the predictions of certain kinds of diviners in all ages; and we cannot help remarking the similarity between the madness of McCallum and that of the Sybil in the sixth book of the Aeneid; though we cannot...

That all these pretences, whether ancient or modern, to the power of divination by means of familiar spirits, or by the art of necromancy, were groundless as well as impious, it would be affronting the understandings of our readers to offer any proof. Under the article Magic we have said enough on the subject, and perhaps more than enough, to those who know that demons, if they have any existence, and the departed spirits of good and bad men, are all under the control of Him who governs the intellectual as well as material world by fixed and equal laws. These details of superstition, however, will not be useless, if, by showing how poor and wretched a creature man becomes when left to his own inventions, they shall make any one grateful for the benefits of good government, and the blessings of revealed religion.

NECROPOLIS, a suburb of Alexandria in Egypt. It signifies "the City of the Dead," wherein there were temples, gardens, and superb mausoleums. Here Cleopatra is said to have applied the aspho to her breast, to prevent being led in triumph by Augustus, who endeavoured to save her.

NECTORIS, πηχεχος, in medicine, a complete modification of any part; called also sideratio and sphaecula.

NECTANEBUS, or Nectanebas, a king of Egypt, who defended his country against the Persians. His grandchild of the same name made an alliance with Agesilaus king of Sparta, and with his affidavit he quelled a rebellion of his subjects. Some time after he was joined by the Sidonians, Phrenicians and inhabitants of Cyprus, who had revolted from the king of Persia. This powerful confederacy was soon attacked by Darius the king of Persia, who marched at the head of his troops. Nectanebus, to defend his frontiers against so dangerous an enemy, levied 20,000 mercenary soldiers in Greece, the same number in Libya, and 60,000 were furnished in Egypt. This numerous body was not equal to the Persian forces, and Nectanebus, defeated in a battle, gave up all hopes of resistance, and fled into Ethiopia, where he found a safe asylum. His kingdom of Egypt became from that time tributary to the king of Persia.

NECTAR, among ancient poets, the drink of the fabulous deities of the heathens; in contradistinction from their solid food, which was called ambrosia.

NECTARINE, a fruit differing in nothing from the common peach, of which it is a species, than in having a smoother rind and a firmer pulp. See Persica.

NECTARIUM, from nectar, the fabled "drink of the gods," defined by Linnaeus to be a part of the corolla, or appendage to the petals, appropriated for containing the honey, a species of vegetable fluid under Nectarium: a fluid form, that oozes from the plant, and is the principal food of bees and other insects.

Notwithstanding this definition which seems to consider the nectarium as necessary a part of the corolla as the petals; it is certain that all flowers are not provided with this appendage, neither indeed is it essential to fructification.

There is, besides, a manifest impropriety in terming the nectarium a part of the corolla. Linnaeus might Milne's with equal propriety, have termed it a part or appendage of the flamina, calyx, or pointal, as the appearance in question is confined to no particular part of the flower, but is as various in point of situation as of form. The truth is, the term nectarium is exceedingly vague: and, if any determinate meaning can be affixed to it, is expressive of all the singularities which are observed in the different parts of flowers.

The tube, or lower part of flowers with one petal, Linnaeus considers as a true nectarium, because it is generally found to contain the sweet liquor formerly mentioned. This liquor Pontedera compares to that called amnios in pregnant animals, which enters the fertile or impregnated seeds: but that this is not at least its sole use, is evident from this circumstance, that the honey or liquor in question is to be found in flowers where there are either no seeds, or those which, from the want of male organs, cannot be impregnated. Thus the male flowers of nettle and willow, the female flowers of sea-side laurel and black bryony, the male and female flowers of clivia, higgelaria, and butcher's broom, all abound with the honey or nectar alluded to.

Dr. Vaillant was of opinion, that the nectarium was an essential part of the corolla; for which reason he distinguished the singular appearances in fennel-flower and columbine by the name of petals: the coloured leaves which are now termed the petals he denominates the flower cup.

That the nectarium, however, is frequently different from the petals, is evident, both from the well known examples just mentioned, as likewise from the flowers of monkhood, hellebore, isopyrum, fennel-flower of Crete, barrenwort, grafs of Parnassus, chocolate-nut, cherleria and sauvagea.

These general observations being premised, we proceed to take a nearer and more particular view of the principal diversities, both in form and situation, of this striking appendage to the flower. 1. In many flowers the nectarium is shaped like a spur or horn; and that either in flowers of one petal, as valerian, water-milfoil (articularia), butter-wort, and calves' shout; or in such as have more than one, as lark spur, violet, fumatory, balism, and orchis. 2. In the following plants, the nectarium is properly a part of the corolla, as lying within the substance of the petals: ranunculus, lilac, iris, crown-imperial, water-leaff, mouse-tail, ananas or pine apple, dog's-tooth violet, piperdidge bush, valinfloria, hermannia, uvalaria, and serfria. 3. The nectarium is frequently placed in a series or row within the petals, though entire disconnected with their substance. In this situation it often resembles a cup, as in narcissus. A nectarium of this kind is said by Linnaeus to crown the corolla. The following are examples: daffofil, sea-daffofil, camcon, vicous campia,
only to two-thirds of the body in length. On the contrary, in those whose thorax is black, they are likewise black, and somewhat longer than the body. The thorax is margined; in some it is yellow and longer; in others it is black, shorter, and edged only with a little yellow. The elytra are blackish, somewhat clearer in the middle, and terminating in a lemon-coloured spot. The wings are rather black, something longer than the body, exceed the elytra by one-third, and are crooked one over the other. In those that have their thorax yellow, the legs and under part of the belly are so likewise. In individuals with a black thorax, the legs are black as well as the belly, which has only a little yellow on the sides. I Tuped the latter to be the males. The larva is as yet unknown."

NEDHAM (Marchmont), an English satirical writer, was born at Burford, Oxon. about the month of August 1620. His father died in 1621; but the following year his mother was again married to one Christopher Glynn, vicar and schoolmaster of Burford, who perceiving his son-in-law's pregnancy of parts and genius, took him under his own tuition, and at the age of 14 sent him to All Soul's College, Oxon. Here he was made one of the choristers, and continued till 1637, when having taken the degree of A. B., which made it inconsistent to continue in that office, he went to St Mary's Hall till he became an usher in Merchant Taylor's school, London. About the beginning of the civil wars, he became clerk to an attorney at Gray's Inn, where, writing a good court hand, he obtained a decent subsistence. Not long after this he began a weekly paper, under the title of Mercurius Britannicus, on the side of the parliament: it commenced about the middle of August 1643, coming out on Mondays, in one sheet, and continued till the end of 1646. It procured him popularity, and being an active man he was distinguished by the title of Capt. Nedham of Gray's Inn. Of these mercures (for there were a number of them published on both sides of the great question which then divided the nation) it is well observed by Johnson, that they taught many to talk whom they could not teach to judge. Nedham's was, indeed, addressed as much to the passions as to the reason; and, by telling every man that he was equal to his king, he so flattered vulgar pride, that his licentious opinions were received as the dictates of an oracle. About this time he finished phyric, and in 1645 began to pradete; by which, and his political writings, he supported a genteel figure. But, for some scorn and affront put upon him, he suddenly left his party, and, obtaining the favour of a royalist, was introduced into the king's presence at Hampton-court in 1647, and asking pardon upon his knees readily obtained it; so that being admitted to the king's favour, he wrote soon after another paper, entitled Mercurius Pragmaticus; which being equally witty with the former, as satirical against the Presbyterians, and full of loyalty, made him known and admired by the wits of that side. However, being narrowly sought after, he left London, and for a time lay concealed at the house of Dr Peter Heylin, at Minster Lovel, near Burford, till length being discovered, he was imprisoned in Newgate, and in danger of his life. Lenthall, the Speaker of the house of Commons, who knew him and his relations...
NEE [ 793 ]

relations well, and Bradshaw, president of the high court of justice, treated him favourably, and not only got his pardon, but with promise of rewards and places persuaded him to change his side once more for the independents, who then were the uppermost party.—

In this temper he published a third weekly paper, called Mecurus Pollicus, which came out every Wednesday, in two sheets 4to, commencing with the 9th of June 1649, and ending with the 6th of June 1650, which being Thursday, he began again with number 1. from Thursday June 6, to Thursday June 13, 1650, beginning, "Why should the commonwealth have "a fool, as well as the king had, &c." This paper, which contained many discourses against monarchy, and in behalf of a free state, especially those that were published before Cromwell was made protector, was carried on without any interruption till about the middle of April 1660, when, as several times before, it was prohibited by an order of the council of state. 

Upon the return of Charles II. our author lay hid, till, by virtue of some money well placed, he obtained his pardon under the great seal; after which he exercised the faculty of physic among the Delfenters, which brought him in a considerable benefit till his death, which happened suddenly in 1678. Wood, who knew him, tells us that he was a person endowed with quick natural parts, was a good humanist, poet, and boon droll; and, had he been constant to his cavalierizing principles, would have been beloved and admired by all; but being mercenary, and preferring his interest to his conscience, friendship, and love to his prince, was much hated by the royal party to the last. In short, there was no depending on this scurrilous ill-natured author. He followed whenever interest or passion led, and remains a notorious instance of the danger of brilliant parts, of which he certainly was possessed, without judgment or integrity to control them. Wood, who in his Athen. Oxon. quoted above, gives a very copious account of him, says: "At length this most seditious, mutable, and railing "author, M. Needham, died suddenly, in the house "of one Kidder, in D'Euret-court near Temple "bar, London, in 1678, and was buried near the "entrance of the chancel of the church of St Cle- "ments Danes." 

NEEDHAM (John Tuberville), was born at Lon- "don the 10th of September in the year 1713. His "parents were descended from ancient and noble fami- "lies. His father, who had once possessed a considerable patrimony at Hulton; in the county of Monmouth, was of the younger and Catholic branch of the Need- "ham family; the head of the elder and Protestant branch was lord Kilmory, created vicompt in the year 1625. The father of Mr Needham died young, and left but a small fortune to his four children. His eldest son, who is the subject of this article, prosecuted his studies under the secular clergy of the English college of Douai, where he took orders, taught rhetoric for several years, gave eminent proofs of sagaci- ty and genius, and surpassed all the other professors of that seminary in the knowledge of experimental philo- 

osophy. In 1740, he was engaged by his superiors in the service of the English mission, and was entrusted with the direction of the school erected at Twy- "ford, near Winchester, for the education of the Ro- 

man Catholic youth. In 1744, he was appointed "professor of philosophy in the English college at Lis- "bon, where, on account of his bad health, he remain- "ed only 15 months. After his return, he passed sev- "eral years at London and Paris, which were principally employed in microscopical observations and in other branches of experimental philosophy. The results of these observations and experiments were published in the Philosophical Transactions of the Royal Society of London in 1749, and in a volume in 12mo at Pa- "ris in 1750; and an account of them was also given "by M. de Buffon, in the first volumes of his Natural History. There was an intimate connection between this illustrious French naturalist and Mr Needham: they made their experiments and observations together; though the results and systems which they deduced from the same objects and operations were to- 

tally different. Mr Needham was admitted to a place in the Royal Society of London in the year 1747, and in the Antiquarian Society some time after. From the year 1751 to 1767 he was chiefly employed in finishing the education of several English and Irish noblemen, by attending them as tutor in their travels through France, Italy, and other countries. He then retired from this wandering life to the English semi- "nary at Paris, and in 1768 was chosen by the Royal Academy of Sciences in that city a corresponding member. 

When the regency of the Austrian Netherlands, in order to the revival of philosophy and literature in that country, formed the project of an Imperial academy, which was preceded by the erection of a small literary society to prepare the way for its execution, Mr Need- 

ham was invited to Brussels by Count Cobentzel and the president Neny, and was appointed successively chief director of both these foundations. He held this place, together with some ecclesiastical preferments in the Low Countries, until his death, which happened the 30th of December 1781. "His piety, tempera- "ence, and purity of manners (we follow the expres- "sion of the Abbé Mann) were eminent: his at- "tachment to the doctrines and duties of Christianity was inviolable. His zealous opposition to modern infidels was indefatigable and even passionate. His probity was untainted. He was incapable of every species of duplicity; his benevolence was universal, and his unostentatious conduct rendered him often a dupe to perfidy." These and other good qualities the panegeyric attributes to his deceased friend; and the learned authors of the Monthly review, to whom Mr Needham was known, admit the justice of the panegeyric. He was undoubtedly (say they) both a honest man and a worthy citizen; but though his de- "ath be a real loss to the literary world, yet he died feanably for himself; for had he lived to see Joseph "the 1st. and the Great making so free with the paint, "patches, and trinkets of the mother church, confiscating "her lands, abolishing her convents, suppressing her ho- "olidays, introducing common fents into her worship, "creating political conductors to disparage the thunder "of the Vatican, and achieving many other things in "this style of improvement, it would have vexed full "fore his feeling heart. For this honest man was narrow "even to superstitition and bigotry in his religious sys- "tem; and we never knew a man in whom there was such an "unaccountable
Needham, in little heaps ving twifl:ed the the too they take experience. When they are thus hardened, they are to move them from time to time. This serves to

The corners are, by force of a puncheon of well-tempered coal fire; and when taken out thence, are and a little cavity filed on each side

The sizes are from the steel are brought upon paper in a hurry, than finifhed dity nor method; his writings are rather the great of needles: obferving every time it

The dipping needle, so hung, as that, instead of playing hori-zontally, and pointing out north and south, one end dips, or inclines to the horizon, and the other points to a certain degree of elevation above it. The dipping needle was invented in the year 1776 by one Robert Norman a compa{fes-maker at

The effect led him at length to observe the percise quantity of the dip, or to measure the greatest angle which the needle would make with the horizon; and this at London he found to be 71° 50'. In 1723 Mr Graham made a great many obser-vations on the dipping-needle, and found the angle to be between 74 and 75 degrees. Mr Nairne, in 1772, found it to be somewhat above 72°. It is not certain whether the dip varies, as well as the horizontal direction, in the same place. The tripling difference between Mr For-man and Mr Nairne would lead us to imagine that the dip was unalterable; but Mr Graham, who was a very accurate observer, makes the difference more confiderable. It is certain, however, from a large number of experiments and obser-vations, that the dip is variable in different latitudes, and that it increases in going northwards. It appears from a table of ob-ser-vations made with the marine dipping-needle in a voyage

NEEDHAM, in Suffolk, 73 miles from London, stands on the Orwell, 9 miles from Ipswich, in the road to Huntingdonshire. Its market is on Wednesday, and fair in October 28.

NEEDLE, a very common little instrument or utensil made of steel, pointed at one end, and pierced at the other, used in forge, embroildery, tapestry, &c.

Needles make a very considerable article in commerce, though there be scarce any commodity cheaper, though there is scarce any commodity cheaper, though there is scarce any commodity cheaper, though there is scarce any commodity cheaper, though there is scarce any commodity cheaper, though there is scarce any commodity cheaper, though there is scarce any commodity cheaper.
Needle voyage towards the north pole in 1733, that in lat. 60° 18'. the dip was 75°; and in lat. 70° 45', it was 77° 52'; in lat. 80° 12', it was 81° 52'; and in lat. 80° 27', it was 82° 2'.

Several authors have endeavoured to apply this discovery of the dip to the finding of the latitude, and Mr Bond attempted to apply it to the finding of the longitude also; but for want of observations and experiments he could not make any progress. The affair was farther prosecuted by Mr Whitton, who published a treatise on the longitude, and for some time imagined it was possible to find it exactly by means of the dip of the needle; yet he at last despaired of it, for the following reasons. 1. The weakness of the magnetic power. 2. The concurrence of the ship, which he found it exceeding difficult to avoid so much as was necessary for the accuracy of the experiments. 3. The principal objection was an irregularity in the motions of all magnetic needles, both horizontal and dipping, by which they, within the compass of about a degree, vary uncertainly backward and forward; even sometimes, in a few hours time, without any evident cause. For a particular account of these variations both of the horizontal and dipping needle, fee the article Variation.

Mr Nairne made a dipping-needle in 1772 for the board of longitude, which was used in the voyage towards the north-pole. This is represented Plate CCCXLV, fig. 2. The needle AA is 12 inches long, and its axis, the ends BB of which are made of gold alloyed with copper, rests on friction-wheels CCCC, of four inches diameter, each end on two friction-wheels; which wheels are balanced with great care. The ends of the axes of the friction-wheels are likewise of gold alloyed with copper, and moved in small holes made in bell-metal; and opposite to the ends of the axes of the needle and the friction-wheels, are flat agates, set in at DDD, finely polished. The magnetic needle vibrates within a circle of bell-metal, EEE, divided into degrees and half degrees; and a line, passing through the middle of the needle to the ends, points to the divisors. The needle of this instrument was balanced before it was made magnetic; but by means of a crofs, the ends of which are FFFF, (contrived by the reverend Mr Mitchell) fixed on the axis of the needle, on the arms of which are very fine screws to receive small buttons, that may be screwed nearer or farther from the axis, the needle may be adjusted both ways to a great nicety, after being made magnetic, by reverting the poles, and changing the sides of the needle. GG are two levels, by which the line of 0 degrees of the instrument is set horizontal, by means of the four adjusting screws LLLL: H is the perpendicular axis by which the instrument may be turned, that the divided face of the circle may face the east or west; to this axis is fixed an index I, which points to an opposite line on the horizontal plate K when the instrument is turned half round; MMMM are screws which hold the glass-cover to keep the needle from being disturbed by the wind. When this needle is constructed for sea, it is suspended by an universal joint on a vertical thread, and adjusted vertically by a plummet-line and button above the divided circle and the dovetail work at the upper go; and the divisors on the circle are adjusted so as to be perpendicular to the horizon by the same plummet-line, and an adjoining screw; and when it is adjusted, a pointer annexed to a firew, which serves to move the divided circle, is fixed at the lowest go. Whenever the instrument is used to find the dip, it must be so placed that the needle may vibrate exactly in the magnetic meridian.

Magnetical Needles, in navigation, a needle touched with a loadstone, and sustained on a pivot or centre; on which playing at liberty, it directs itself to certain points in or under the horizon; whence the magnetical needle is of two kinds, viz. horizontal or inclinatory. See the article Magnet.

Horizontal needles are those equally balanced on each side of the pivot that sustains them; and which playing horizontally with their two extremes, point out the north and south points of the horizon. For their application and use, see the article Compass.

In the construction of the horizontal needle, a piece of pure steel is provided; of a length not exceeding six inches, left its weight should impede its volubility; very thin, to take its verticity the better; and not pierced with any holes, or the like, for ornament fake, which prevent the equal diffusion of the magnetic virtue. A perforation is then made in the middle of its length, and a brass cap or head folder on, whose inner cavity is conical, so as to play freely on a ydle or pivot headed with a fine steel point. The north point of the needle in our hemisphere is made a little lighter than the southern: the touch always depressing the balance, if well adjusted before, and rendering the north end heavier than the south, and thus occasioning the needle to dip.

The method of giving the needle its verticity or directive faculty has been shown already under the article Magnet; but if, after touching, the needle be out of its equilibrium, something must be filed off from the heavier side, till it balance evenly.

Needles in sea compasses are usually made of a rhomboidal or oblong form: we have given their structure already under the article Compass.

The needle is not found to point precisely to the north, except in very few places; but deviates from it more or less in different places, and that too at different times; which deviation is called its declination or variation from the meridian. See the article Variation.

Surgeons Needles are generally made crooked, and their points triangular; however they are of different forms and sizes, and bear different names, according to the purposes they are used for.

The largest are needles for amputation; the next, needles for wounds; the finest needles for futures. They have others very short and flat, for tendons; others, still shorter, and the eye placed in the middle, for tying together of veins, &c. Needles for couching cataracts are of various kinds: all of which have a small, broad, and sharp point or tongue; and some with a follicus at the point. Surgeons have sometimes used two needles in this operation; one with a sharp point for perforating the coats of the eye, and another with a more obtuse point for deprefling or couching the opaque crystalline lens: but care should be taken in the use of any of these, that they be first well polished with cloth or leather, before they are applied to the eye.

Mr Warner observes, that the blade of the couching needle
neede should be at least a third part larger than those generally used upon this occasion, as great advantages will be found in the depressing of the cataract, by the increased breadth of the blade of that instrument. The handle, also, if made somewhat shorter than usual, will enable the operator to perform with greater facility, than he can do with a larger handled instrument.

It is to be observed, that needles of silver pierce more easily in stitching arteries after an amputation, than those made of steel.

**Needle-Phb.** See Syngnathus.

**Needles,** sharp-pointed rocks north of the Isle of Wight. They are situated at the western extremity of the island, which is an acute point of high land, from which they have been disjoined by the washing away of the land, which is an acute point of high land, called La's Wife, which are about 120 feet above low-water mark, and in its shape resembling a needle, being undermined by the constant efforts of the waves, overfit, and totally disappeared.

**NEEDS,** or St Neots, six miles from Huntingdon, 58 miles from London, so called from the monument of a saint of that name in it, who was burnt by the Danes, is a large well-built town, having a handsome strong church, with a prodigious fine steeple, and a good stone-bridge over the Ouse, by which coaches are brought to it, and fold through the country. It has a charity-school for 25 poor children. Its market is on Thursday; fairs on Holy Thursday, Aug. 1. Corpus-Chrifti Thursday, June 13, and December 17; and it is famous for a medicinal spring.

**NEEDWOOD-FOREST,** in Staffordshire, between the Trent, Dove, and Blythe, and near Uttoxeter, is said to exceed all the forests in England in the excellence of its soil and the fineness of its turf.

**NE EXEAT REGNO,** in law, is a writ to remove one thing to be different from another: as that the soul is not matter. See Logic.

NEGATION, in logic, an act of the mind affirming one thing to be different from another: as that the soul is not matter. See Logic.

**NEGATIVE**, in general, something that implies a negation: thus we say, negative quantities, negative powers, negative signs, etc.

**NEGATIVE-Sign.** The use of the negative sign, in algebra, is attended with several consequences that at first sight are admitted with difficulty, and has sometimes given occasion to notions that seem to have no real foundation. This sign implies, that the real value of the quantity represented by the letter to which it is prefixed is to be subtracted; and it serves, with the positive sign, to keep in view what elements or parts enter into the composition of quantities, and in what manner, whether as increments or decrements, (that is, whether by addition or subtraction), which is of the greatest use in this art.

In consequence of this, it serves to express a quantity of an opposite quality to the positive, as a line in a contrary position; a motion with an opposite direction; or a centrifugal force in opposition to gravity; and thus often saves the trouble of distinguishing, and demonstrating separately, the various cases of proportions, and prefers their analogy in view. But as the proportions of lines depend on their magnitude only, without regard to their position, and motions and forces are said to be equal, or unequal, in any given ratio, without regard to their directions; and, in general, the proportion of quantity relates to their magnitude only, without determining whether they are to be considered as increments or decrements; so there is no ground to imagine any other proportion of \(-b\) and \(a\) (or of \(-1\) and \(1\)) than that of the real magnitudes of the quantities represented by \(b\) and \(a\), whether these quantities are, in any particular case, to be added or subtracted. It is the same thing to subtract a decrement, as to add an equal increment, or to subtract \(-b\) from \(b\); or to add \(+a\) to it, and because multiplying a quantity by a negative number implies only a repeated subtraction of it, the multiplying \(-b\) by \(-n\), is subtracting \(-b\) as often as there are units in \(n\); and is therefore equivalent to adding \(-b\) to many times, or the same as adding \(+n\) \(b\). But if we infer from this, that \(1\) is to \(-n\) as \(-n\) to \(n\), according to the rule, that unit is to one of the factors as the other factor is to the product, there is no ground to imagine that there is any mystery in this, or any other meaning than that the real magnitudes represented by \(b\), \(a\), \(b\), and \(n\) are proportional. For that rule relates only to the magnitudes...
The origin of the negroes, and the cause of their remarkable difference from the rest of the human species, has much perplexed the naturalists. Mr Boyle has observed, that it cannot be produced by the heat of the climate: for though the heat of the sun may darken the colour of the skin, yet experience does not show that it is sufficient to produce a new blackness like that of the negroes.

In Africa itself, many nations of Ethiopia are not black; nor were there any blacks originally in the West Indies. In many parts of Asia, under the same parallel with the African region inhabited by the blacks, the people are but tawny. He adds, that there are negroes in Africa beyond the Southern tropic; and that a river sometimes parts nations, one of which is black and the other only tawny. Dr Barriere observes, that the gall of Negroes is black, and being mixed with their blood is depofited between the skin and subcutaneous vesicles. However, Dr Mitchell of Virginia, in the Philosophical Transactions, No. 476, has endeavoured by many learned arguments to prove, that the influence of the sun in hot countries, and the manner of life of their inhabitants, are the remote caufes of the colour of the Negroes, Indians, &c., Lord Kaims, on the other hand, and fuch philosophers as he, whose genius and imagination are too lively to submit to a dry and painfuit investigation of facts, have contended, that no physical caufe is fufficient to change the colour, and what we call the regular features of white men, to the dark hue and deformity of the woolly-headed negro. Their arguments have been examined with much acutenefs and ingenuity by Dr Stanhope Smith of New Jersey, Dr Hunter, and professor Zimmerman, who have made it in a high degree probable, that the action of the fun is the original and chief caufe of the black colour, as well as diftorted features, of the negro. See America, No. 48—51, and Complexion.

True negroes are found in no quarter of the globe where the heat of the climate is not very great. They exit no where but in the Torrid zone, and only in three regions situated in that zone, to wit, in Senegal, in Guinea, and on the western shores of Africa, in Nubia, and the Papous land, or what is called New Guinea. In all these regions the atmosphere is scorching; and the heat excessive. The inhabitants of the north are whiter; and as we advance southwards towards the line, and these countries on which the fun's rays fall more perpendicularly, the complexion gradually assumes a darker shade. And the fame men, whose colour has been rendered black by the powerful action of the sun, if they remove to the north, gradually become whiter (at least their pofterity), and lose their burnt colour. Whites, when transported into the burning regions of the Torrid zone, are at first subject to fever; the skin of the face, hands, and feet, becomes burnt, hardens, and falls off in flakes. Hitherto the colour of negroes appears to be only local, extrinfic, and accidental, and their short frizzled
frizzled and sparse hair is to be accounted for in the very same manner.

Climate poises great and evident influence on the hair, not only of men, but of all other animals. If in one case these transmutations are acknowledged to be consistent with identity of kind, they ought not in the other to be esteemed criteria of different species. Nature has adapted the planety of her work to the situations in which she may require it to be placed. The beaver and sheep removed to the warm latitudes exchange, the one its fur, and the other its wool, for a coarse hair that preserves the animal in a more moderate temperature. The coarse and black flag of the bear is converted, in the arctic regions, into the fine and white fur. The colour of the hair is likewise changed by climate. The bear is white under the arctic circle; and, in high northern latitudes, foxes, hares, and rabbits, are found white. Similar effects of climate are discernible on mankind. The hair of the Danes is generally red; of the English, fair or brown; and of the French, commonly black. The hair of all people of colour is coarse and curled in a manner peculiar to themselves; but this peculiarity is analogous to the effect which a warm climate has on almost every other animal. Cold, by obstructing the perspiration, tends to throw out the perspirable matter accumulated at the skin in an additional coat of hair. A warm climate, by opening the pores, evaporates this matter before it can be converted into the substance of hair; and the lassens and aperture of the pores render the hair liable to be easily eradicated by innumerable incidents. Its curl may result in part from the nature of the secretion by which it is nourished, and from part from external heat. That it depends in some degree on the quality of the secretion is rendered highly probable from its appearance on the chin and other parts of the human body. Climate is as much distinguished by the nature and proportion of the secretions as by the degree of heat: (See Physiology, sect. 6.) Whatever be the nutriment of the hair, it is evidently combined in the torrid zone of Africa with some fluid of a highly volatile or ardent quality which produces the rank smell of many African nations. Saline secretions tend to curl and to burn the hair. The evaporation of any volatile spirits would render its surface dry and disposed to contract; whilst the centre continuing unaltered, would be made to grow inward. External and violent heat parching the extremities of the hair, tends likewise to involve it. A hair held near the fire instantly coils itself up. Africa is the hottest country on the globe; and the influence of its heat, either external or internal, or both, in giving the peculiar form to the hair of the natives, appears, not only from its sparreness and its curl, but from its colour. It is not of a thinning, but of an adult black; and its extremities tend to brown, as if it had been scorched by the fire.

The peculiarities of the negro-features and form may likewise be accounted for from the excessive heat of the climate and the state of African society. Being fagades, they have no arts to protect them from the rays of a burning sun. The heat and serenity of the sky preserving the lives of the children without much care of the parents they seem of course to be, in the interior parts of the country, negligent of their offspring. Able themselves to endure the extremes of that ardent climate, they nurse their children to it from their most tender age. They suffer them to roll in the dust and stand beneath the direct rays of a vertical sun. The mothers, if the be engaged, lays down the infant on the first spot she finds, and is seldom at the pains to seek the miserable shelter of a barren shrub, which is all that the interior country affords. When we reflect on the influence of a glare of light upon the eye, and on the constrictions of countenance produced by our efforts to retire or prevent it, we need not wonder that the plant features of a negro-infant should, by constant exposure, acquire that permanent irregularity which we term their characteristic ugliness. But besides the climate, food and clothing and modes of life have prodigious effects on the human form and features. This is apparent even in polished societies, where the poor and labouring part of the community are much more coarse in their features, and ill-formed in their limbs, than persons of better fortune and more liberal means of subsistence. What an immense difference exists in Scotland, in foreign between the chiefs and the commonalty of the Highland clans? If they had been separately found in different countries, they would have been ranged by some philosophers under different species. A similar distinction takes place between the nobility and peasantry of France, of Spain, of Italy, and of Germany.

That food and clothing, and the different modes of life, have as great an influence upon the shapes and features of the Africans as upon the natives of Europe, is evident from the different appearances of the negroes in the southern republics of America according to the stations in which they are employed. "The field slaves (says Dr Smith) are badly fed, clothed, and lodged. They live in small huts on the plantations, where they labour, remote from the society and example of their superiors. Living by themselves, they retain many of the customs and manners of their African ancestors, The domestic servants, on the other hand, who are kept near the persons, or employed in the families of their masters, are treated with great lenity; their service is light; they are fed and clothed like their superiors; they see their manners, adopt their habits, and infensibly receive the same ideas of elegance and beauty. The field slaves are, in consequence, slow in changing the aspect and figure of Africa. The domestic servants have advanced far before them in acquiring the agreeable and regular features, and the expressive countenance of civil society. The former are frequently ill-shaped, They prefer, in a great degree, the African lips, nose, and hair. Their genius is dull, and their countenance sleepy and stupid. The latter are straight and well proportioned; their hair extended to three, four, and sometimes even to fix or eight inches; the fize and shape of the mouth handsome, their features regular, their capacity good, and their look animated.”

Upon the whole, we hope that the reader, who shall candidly weigh in his own mind what we have said at present and under the article Description, will agree with us, that the black colour in the torrid zone, the sparse crisp hair of the negroes, and the peculiarities of their features and form, proceed from causes altogether extrinsic, that they depend on local temperature and the state of society; and that they are as accidental as the
Negroes are born slaves to great men, reared as such, held as property, and as property sold (see Slavery). There are indeed many circumstances by which a free man may become a slave: such as being in debt, and not the West able to pay; and in some of such cases, if the debt be large, not only the debtor, but his family likewise, become the slaves of his creditor, and may be sold. Adultery is commonly punished in the same manner, both the offending parties being sold, and the purchase money paid to the injured husband. Obi, or pretended witchcraft (in which all the negroes firmly believe, see Witchcraft), is another, and a very common offence, for which slavery is adjudged the lawful punishment; and it extends to all the family of the offender. There are various other crimes which subject the offender and his children to be sold; and it is more than probable, that if there were no buyers, the poor wretches would be murdered without mercy.

In such a state of society what dispositions can be looked for in the people, but cruelty, treachery, and revenge? Even in the civilized nations of Europe, mankind are sometimes displayed to their lordly masters of European extraction the same spirit that has been so generally displayed by the lower orders of Frenchmen to their ecclesiastics, their nobles, and the family of their murdered sovereign! When we consider that the majority of the negroes groan under the cruel slavery, both in their own country and in every other where they are to be found in considerable numbers, it can excite no surprise that they are in general treacherous, cruel, and vindictive. Such are the caprices of their tyrants at home, that they could not preserve their own lives or the lives of their families for any length of time, but by a perpetual vigilance, which must necessarily degenerate, first into cunning, and afterwards into treachery; and it is not conceivable that habits formed in Africa should be instantly thrown off in the West Indies, where they are the property of men whom some of them must consider as a different race of beings.

But

(A) 1. A white man with a negro woman, or a negro man with a white woman, produce a mulatto, half white and half black, or of a yellow-blackish colour, with black, short, frizzled hair. 2. A white man with a mulatto woman, or a negro with a mulatto woman, produce a quadroon, three fourths white and one fourth black, or three fourths black and one fourth white, or of a lighter yellow than the former. The name of ebriet is given to those who are descended from a black man and a mulatto woman, or a mulatto man and a black woman, who are three fourths black and one fourth white, and who are not so black as a negro, but blacker than a mulatto. 3. A white man with a quadroon woman, or a negro with a quadroon woman, produce a mellite, seven eighths white and one eighth black, or seven eighths black and one eighth white. 4. A white man with a mellite woman, or a negro with a mellite woman, produce, the one almost a perfect white, the other almost a perfect black, called a quinteroon. This is the last gradation, there being no visible difference between the fair quinteroons and the whites; and the children of a white and quinteroon consider themselves as free from all taint of the negro race.
But the truth is, that the ill qualities of the negroes have been greatly exaggerated. Mr Edwards, in his valuable History of the West Indies, affirms us that the Mandingo negroes display such gentleness of disposition and demeanour, as would deem the result of early education and discipline, were it not that, generally speaking, they are more prone to theft than any of the African tribes. It has been supposed that this propensity, among other vices, is natural to a state of slavery, which degrades and corrupts the human mind in a deplorable manner; but why the Mandingoes should have become more vicious in this respect than the rest of the natives of Africa in the same condition of life, is a question he cannot answer.

The circumstances which (according to the same author) distinguish the Koromantyn or Gold Coast negroes from all others, are firmness both of body and mind; a ferocioufness of disposition; but withal, activity, courage, and a hubbonness, or what an ancient Roman would have deemed an elevation of soul, which prompts them to enterprize of danger, and enables them to meet death, in its most horrible shape, with fortitude or indifference. They sometimes take to labour with great promptitude and alacrity, and have constitutions well adapted for it; for many of them have undoubtedly been slaves in Africa. But as the Gold Coast is inhabited by various tribes, which are engaged in perpetual warfare and hostility with each other, there cannot be a doubt that many of the captives taken in battle, and sold in the European settlements, were of free condition in their native country, and perhaps the owners of slaves themselves. It is not wonderful that such men should endeavour, even by means of the most desperate, to regain the freedom of which they have been deprived; nor do I conceive that any further circumstances are necessary to prompt them to action, than that of being fold into captivity in a distant country. One cannot surely but lament (says our author), that a people thus naturally intrepid, should be sunk into so deplorable a state of barbarity and oppression; and that their spirits should ever be broken down by the yoke of slavery! Whatever may be alleged concerning their ferocioufness and implacability in their present notions of right and wrong, I am persuaded that they possess qualities which are capable of, and will deserve, cultivation and improvement.

Very different from the Koromantyns are the negroes imported from the Bight of Benin, and known in the West Indies by the name of Eboes. So great is their constitutional timidity and dependancy of mind as to occasion them very frequently to seek, in a voluntary death, a refuge from their own melancholy reflections. They require therefore the gentlest and mildest treatment to reconcile them to their situation; but if their confidence be once obtained, they manifest as great fidelity, affection, and gratitude, as can reasonably be expected from men in a state of slavery. The females of this nation are better labourers than the men, probably from having been more hardly treated in Africa.

The natives of Whidah, who, in the West Indies, are generally called Papaws, are unquestionably the most docile and well-disposed slaves that are imported from any part of Africa. Without the fierce and savage manners of the Koromantyn negroes, they are also happily exempt from the timid and despising temper of the Eboes. The cheerful acquiescence with which these people apply to the labours of the field, and their constitutional aptitude for such employment, afford, without doubt, from the great attention paid to agriculture in their native country. Bofman speaks of the improved state of the soil, the number of villages, and the industry, riches, and obliging manners of the natives. He observes, however, that they are much greater thieves than thofe of the Gold Coast, and very unlike them in another respect, namely, in the dread of pain, and the apprehension of death. They are, says he, so very apprehensive of death, that they are unwilling to hear it mentioned, for fear that alone should hasten their end; and no man dares to speak of death in the presence of the king, or any great man, under the penalty of suffering it himself, as a punishment for his presumption. He relates further, that they are addicted to gaming beyond any people of Africa. All these propensities are observable in the charader of the Papaws in a state of slavery in the West Indies. That punishment which excites the Koromantyn to rebel, and drives the Ebo negro to suicide, is received by the Papaws as the chastisement of legal authority, to which it is their duty to submit patiently. The cause seems to be, that the generality of these people are in a state of absolute slavery in Africa, and, having been habituated to a life of labour, they submit to a change of situation with little reluctance.

Having recited such observations as occurred to him on contemplating the various tribes of negroes from each other, Mr Edwards thus estimates their general character, influenced as they are by circumstances which soon efface the native and original impressions which distinguished one nation from another when newly imported into the West Indies.

Notwithstanding what has been related of the firmness and courage of the natives of the Gold Coast, it is certain that the negroes in general in our islands (such of them as have not been long in a state of servitude) are of a diffitful and cowardly disposition. So degrading is the nature of slavery, that fortiitude of mind is lost as free agency is restrained. To the same cause probably must be imparted their propensity to conceal or violate the truth, which is so general, that the vice of falsehood is one of the most prominent features in their character. If a negro is asked even an indifferent question by his master, he seldom gives an immediate reply; but, affecting not to understand what is said, compels a repetition of the question, that he may have time to consider, nor what is the true answer, but what is the most politic one for him to give. The proneness observable in many of them to the vice of theft has already been noticed; and I am afraid (says our author), that evil communication makes it almost general. It is no easy matter, I confess, to discriminate those circumstances which are the result of proximate causes, from those which are the effects of national customs and early habits in savage life; but I am afraid that cowardice and slavery have been the properties of slavery in all ages, and will continue to be so to the end of the world. It is a situation that necessarily suppresses many of the best affections of the human heart.

NE
A flat coast; which of itself so refreshes the water, that ships lying at anchor, at the distance of three leagues from its mouth, generally make use of it, and fill their water there for their voyage home. When the rains are at an end, which soon happens in October, the intense heat of the sun usually dries up those stagnating waters, which lie on the higher parts, and the remainder form lakes and marshes, in which are found all sorts of dead animals. At last, those too are quite dried up; and then the effluvia that arise are almost quite insupportable. At this season the winds blow so hot from the land, that they may be compared to the heat proceeding from the mouth of an oven, and they bring with them an intolerable smell. The wolves, tigers, lions, and other wild beasts, then repair to the river, steeping their body under water, and only their snout above it for the sake of breathing. The birds soar to an immense height in the air, and fly a vast way over the sea, where they continue till the wind changes, and comes from the west.

**NEGROES White.** See **HELIOPHOB** and **ALBINO**.

**NEGROPONT,** anciently *Eubra,* an island of the Archipelago, stretching along the eastern coast of Achaia or Livadia, from which it is separated by a narrow channel called the *Euripus.* This strait is so narrow, that the island is joined to the continent by a bridge thrown over it; and here, it is thought, there was formerly an istmus. The irregularity of the tides in the Euripus hath from the remotest antiquity been very remarkable, and this irregularity is found to be connected with the age of the moon. From the three last days of the old moon to the eighth day of the new moon, and from the 14th to the 20th day inclusive, they are regular; but on the other days they are irregular, flowing 12, 13, or 14 times in the space of 24 hours, and ebbing as often. The island is 90 miles long and 25 broad in the widest part; and produces corn, oil, fruit, and cattle, in great abundance. The only place in the island worth notice is the capital, which is also called *Negropont,* and which is walled, and contains about 15,000 inhabitants; but the Christians are said to be much more numerous than the Turks. The captain-bashaw, or admiral of Turkey, who is also governor of the city, the island, and the adjacent continent of Greece, resides here; and the harbour, which is very safe and spacious, is seldom without a fleet of galleys, ready to be put to sea against the pirates and the Maltese. A part of the bridge between the city and the coast of Greece, consists of a drawbridge no longer than just to let a galley pass through.
