From the centre of concavity \( C \), draw the three right lines \( CA, Cc, CB \), touching the mirror in the same points where the foregoing rays touch it; and all these lines will be perpendicular to the surface of the mirror. Make the angle \( C\hat{A}d \) equal to the angle \( DAC \), and draw the right line \( Ad \) for the course of the reflected ray \( DA \); make the angle \( C\hat{c}d \) equal to the angle \( DcC \), and draw the right line \( ed \) for the course of the reflected ray \( Dc \); make also the angle \( C\hat{b}d \) equal to the angle \( Dcb \), and draw the right line \( Bd \) for the course of the reflected ray \( DB \). All these reflected rays will meet in the point \( d \), where they will form the extremity \( d \) of the inverted image \( ed \), similar to the extremity \( D \) of the upright object \( DE \).

If the pencil of rays \( E\hat{f}, E\hat{g}, E\hat{h} \), be also continued to the mirror, and their angles of reflection from it be made equal to their angles of incidence upon it, as in the former pencil from \( D \), they will all meet at the point \( e \) by reflection, and form the extremity \( e \) of the image \( ed \), similar to the extremity \( E \) of the object \( DE \).

And as each intermediate point of the object, between \( D \) and \( E \), sends out a pencil of rays; in like manner to every part of the mirror, the rays of each pencil will be reflected back from it, and meet in all the intermediate points between the extremities \( e \) and \( d \) of the image; and fo the whole image will be formed, not at \( d \), half the distance of the mirror from its centre of concavity \( C \), but at a greater distance, between \( i \) and the object \( DE \); and the image will be inverted with respect to the object.

This being well understood, the reader will easily see how the image is formed by the large concave mirror of the reflecting telescope, when he comes to the description of that instrument.

When the object is more remote from the mirror than its centre of concavity \( C \), the image will be less than the object, and between the object and mirror: when the object is nearer than the centre of concavity, the image will be more remote and bigger than the object. Thus, if \( ED \) be the object, \( d\hat{e} \) will be its image: For, as the object recedes from the mirror, the image approaches nearer to it; and as the object approaches nearer to the mirror, the image recedes farther from it: on account of the lesser or greater divergence of the pencils of rays which proceed from the object; for the last they diverge, the sooner they are converged to points by reflection; and the more they
PART II.

OPTICS.

They diverge, the farther they must be reflected before they meet.

If the radius of the mirror's concavity, and the distance of the object from it, be known, the distance of the image from the mirror is found by this rule: Divide the product of the distance and radius by double the distance made less by the radius, and the quotient is the distance required.

If the object be in the centre of the mirror's concavity, the image and object will be coincident, and equal in bulk.

If a man places himself directly before a large concave mirror, but farther from it than its centre of concavity, he will see an inverted image of himself in the air, between him and the mirror, of a less size than himself. And if he holds out his hand towards the mirror, the hand of the image will come out towards his hand, and coincide with it, of an equal bulk, when his hand is in the centre of concavity; and he will imagine he may take hands with his image. If he stretches his hand farther, the hand of the image will pass by his hand, and come between his hand and his body; and if he moves his hand towards either side, the hand of the image will move towards the other; so that whatever way the object moves, the image will move the contrary.

All the while a bystander will see nothing of the image, because none of the reflected rays that form it enter his eyes.

§ 3. Microscopes.

Under the word Microscope a copious detail has been given of the construction of those instruments as they are now made by the most eminent artists. In that article it fell not within our plan to treat scientifically of their magnifying powers; these can be explained only by the laws of refraction and reflection, which we shall therefore apply to a few microscopes, leaving our readers to make the application themselves to such others as they may choose to analyze by optical principles.

The first and simplest of all microscopes is nothing more than a very small globe of glass, or a convex lens whose focal distance is extremely short. The magnifying power of this microscope is thus ascertained by Dr. Smith. "A minute object ρq, seen distinctly through the glass AE by the eye put close to it, appears so much greater than it would to the naked eye, placed at the least distance qL from whence it appears sufficiently distinct, as this latter distance qL is greater than the former qE. For having put your eye close to the glass EA, in order to see as much of the object as possible at one view, remove the object ρq to and fro till it appear most distinctly, suppose at the distance qE. Then conceiving the glass AE be removed, and a thin plate, with a pin-hole in it, to be put in its place, the object will appear distinct, and as large as before, when seen through the glass, only not so bright. And in this latter case it appears so much greater than it does to the naked eye at the distance qE, either with the pin-hole or without it, as the angle qEρ is greater than the angle qEρ, or as the latter distance qL is greater than the former qE. Since the interpolation of the glass has no other effect than to render the appearance distinct, by helping the eye to increase the refraction of the rays in each pencil, it is plain that the greater apparent magnitude is entirely owing to a nearer view than could be taken by the naked eye. As the human eye is so constructed, as, for reasons already stated, to have distinct vision only when the rays which fall upon it are parallel or nearly so; it follows, that if the eye be to perfect as to see distinctly by pencils of parallel rays falling upon it, the distance qE, of the object from the glass, is then the focal distance of the glass. Now, if the glass be a small round globe, of about \( \frac{1}{4} \) th of an inch diameter, its focal distance qE, being three quarters of its diameter, is \( \frac{1}{4} \) th of an inch; and if qL be eight inches, the distance at which we usually view minute objects, this globe will magnify in the proportion of 8 to \( \frac{1}{4} \) th, or of 160 to 1.

2. The Double or Compound Microscope (fig. 8.) consists of an object-glass cd, and an eye-glass ef. The small object ab is placed at a little greater distance from the glass cd than its principal focus; so that the pencils of rays flowing from the different points of the object, and passing through the glass, may be made to converge, and unite in as many points between g and b, where the image of the object will be formed: which image is viewed by the eye through the eye-glass ef. For the eye-glasses being so placed, that the image g b may be in its focus, and the eye much about the same distance on the other side, the rays of each pencil will be parallel after going out of the eye-glass, as at e and f, till they come to the eye at k, where they will begin to converge by the refractive power of the humours; and after having crossed each other in the pupil, and passed through the crystalline and vitreous humours, they will be collected into points on the retina, and form the large inverted image AB thereon.

By this combination of lenses, the aberration of a single lens, the light from the focus of the glass, which in a single lens, a globe of the kind abovementioned is very considerable, in a compound and is, in some measure corrected. This appeared so formidable to be the case, even to former opticians, that they very soon began to make the addition of another lens. The instrument, however, receives a considerable improvement by the addition of a third lens. For, says Mr Martin, it is not only evident from the theory of this aberration, that the image of any point is rendered less confused by refraction through two lenses than by an equal refraction through one; but it also follows, from the same principle, that the same point has its image still less confused when formed by rays refracted through three lenses than by an equal refraction through two; and therefore a third lens added to the other two will contribute to make the image more distinct, and consequently the instrument more complete. At the same time the field of view is amplified, and the use of the microscope rendered more agreeable, by the addition of the other lens. Thus also we may allow a somewhat larger aperture to the object-lens, and thereby increase the brilliancy of objects, and greatly heighten the pleasure of viewing them. For the same reason, Mr Martin has, proposed a four-glass microscope, which answers the purposes of magnifying and of distinct vision still more perfectly.

The magnifying power of double microscopes is ca-
as a natural reading of the document:

In both cases we have $TQ$, $TE$, $TG$, continual proportions in some given ratio, suppose of $2$ to $1$; and also $TQ : TE : TG$, continual proportions in some other given ratio, suppose of $1$ to $m$. Then if $H$ be the usual distance at which we view minute objects distinctly with the naked eye, and $i$ the focal distance of the least eye-glasses, through which the object appears sufficiently bright and distinct, it will be magnified in the ratio of $mn : d$ to $H$.

For the object $PQ$, and its first image $pq$, are terminated on one side by the common axis of the specula, and on the other by a line $PE$, drawn through the centre of the concave $ABC$. Likewise the images $pq$ and $mn$ are terminated by the common axis and by the line $PE$, drawn through the centre of the convex $DE$. Hence, by the similar triangles $pq : mn = PE : d$.

If $PQ$, of the object, are seen through it by the rays of two pencils emerging parallel to the lines $PE$, $PQ$, respectively; that is, $PQ$ appears under an angle equal to $\alpha$, which is $\alpha = \tan \theta$, and to the naked eye at the distance $d$ from $PE$, it appears under an angle $PQ$ which is $\alpha = \frac{\theta}{d}$, and therefore is magnified in the ratio of these angles, that is, of $mn : d$ to $\alpha$.

The following easy method of ascertaining the magnifying power of such microscopes as are most in use.

The apparent magnitude of any object, as much as it appears from what hath been already delivered, is measured by the angle under which it is seen; and the larger the angle, the greater will be the magnifying power of such microscopes.

The apparent magnitude of any object, as much as it appears from what hath been already delivered, is measured by the angle under which it is seen; and the larger the angle, the greater will be the magnifying power of such microscopes.

Fig. 10. sets the reader the task of finding the eye-glass which shall cause the microscope to magnify

M times in diameter, take $\frac{mn}{d} = \frac{M}{\alpha}$. For the apparent magnitude is to the true as $M : 1 = mn : d$.

We shall conclude this part of our subject with the using of the following easy method of ascertaining the magnifying power of such microscopes as are most in use.

The apparent magnitude of any object, as much as it appears from what hath been already delivered, is measured by the angle under which it is seen; and the larger the angle, the greater will be the magnifying power of such microscopes.

For this method of finding the reason why the first or greatest magnifiers are so extremely minute; and also to calculate the magnifying power of any convex lens employed in a single microscope: For as the proportion of the natural light to the focus, such will be its power of magnifying. If the focus of a convex lens, for instance, is at one inch, and the natural light at eight inches, which is the common standard, an object may be seen through that lens at one inch distance from the eye, and will appear in its diameter eight times larger than

Microscopes.

265

Further observations on the magnifying power of microscopes.

Again, suppose a convex lens whose focus is only one-tenth of an inch distant from its centre; as in eight inches the common distance of distant vision with the naked eye, there are 80 such tenths, an object may be seen through this glass 80 times nearer than with the naked eye. It will, of consequence, appear 80 times longer, and as much broader, than it does to common sight; and therefore is 6400 times magnified. If a convex glass be so small that its focus is only 1/4 of an inch distant, we find that eight inches contains 160 of these twentieth-parts; and of consequence the length and breadth of any object seen through such a lens will be magnified 160 times, and the whole surface 25,600 times. As it is an easy matter to melt a drop or globule of a much smaller diameter than a lens can be ground, and as the focus of a globule is no further off than a quarter of its own diameter, it must of consequence magnify to a prodigious degree. But this excessive magnifying power is much more than counterbalanced by its admitting too little light, want of distinctness, and showing such a minute part of the object to be examined; for which reason, these globules, though greatly in vogue some time ago, are now almost entirely rejected.

Mr Leeuwenhoek, as has been already observed, made use only of single microscopes consisting of convex lenses, and left to the Royal Society a legacy of 26 of those glasses. Accordingly to Mr Folke’s description of these, they were all exceedingly clear, and showed the object very bright and distinct; “which (says Mr Folkes) must be owing to the great care this gentleman took in the choice of his glafs, his exactness in giving it the true figure, and afterwards, among many, referring only such for his use as upon trial he found to be most excellent. Their powers of magnifying are different, as different objects may require; and as on the one hand, being all ground glasses, none of them are so small, or consequently magnified to so great a degree, as some of those drops frequently used in other microscopes; yet, in the other hand, the distinctness of those very much exceeds what I have met with in glases of that form.” And this was what Mr Leeuwenhoek ever professed to himself; rejecting all those degrees of magnifying in which he could not so well obtain that end. For he informs us in one of his letters, that though he had above 40 years by him glasses of an extraordinary smallness, he had made but very little use of them; as having found, in a long course of experience, that the most considerable discoveries were to be made with such glases at, magnifying but moderately, exhibited the object with the greatest brightness and distinctness.

In a single microscope, if you want to learn the magnifying power of any glass, no more is necessary than to bring it to its true focus, the exact place whereof will be known by an object appearing perfectly defined and sharp when placed there. Then, with a pair of small compasses, measure, as nearly as you can, the distance from the centre of the glas to the object you were viewing, and afterwards applying the compasses to any ruler, with a diagonal scale of the parts of an inch marked on it, you will easily find how many parts of an inch the said distance is. When that is known, compute how many times those parts of an inch are contained in eight inches, the common standard of sight, and that will give you the number of times the diameter is magnified; squaring the diameter will give the superficies; and if you would learn the solid content, it will be shown by multiplying the superficies by the diameter.

The superficies of one side of an object only can be seen at one view; and to compute how much that is magnified, is most commonly sufficient; but sometimes it is satisfactory to know how many minute objects are contained in a larger; as supposing we desire to know how many animalcules are contained in the bulk of a grain of sand: and to answer this, the cube, as well as the surface, must be taken into the account. For the greater satisfaction of those who are not much versed in these matters, we shall here subjoin the following:

Table.
TABLE of the MAGNIFYING POWERS of CONVEX GLASSES, employed in Single Microscopes, according to the distance of their focus; Calculated by the scale of an inch divided into 100 parts. Showing how many times the diameter, the superficies, and the cube of an object, is magnified, when viewed through such glasses, to an eye whose natural sight is at eight inches, or 800 of the 100th parts of an inch.

</table>

The greatest magnifier in Mr. Leeuwenhoek's cabinet of microscopes, presented to the Royal Society, had its focus, as nearly as can well be measured, at one-tenth of an inch distance from its centre; and consequently magnifies the diameter of an object 160 times, and the superfiaces 25,600. But the greatest magnifier in Mr. Wilson's single microscopes, as they are now made, has usually its focus at no farther distance than about the 50th part of an inch; whereby it has a power of enlarging the diameter of an object 400, and its superfiaces 160,000 times.

The magnifying power of the solar microscope must be calculated in a different manner; for here the difference between the focus of the magnifier and the distance of the screen or seat where the image of the object is cast, is the proportion of its being magnified. Supposing, for instance, the lens made use of has its focus at half an inch, and the screen is placed at the distance of five feet, the object will then appear magnified in the proportion of five feet to half an inch; and as in five feet there are 120 half inches, the diameter will be magnified 120 times, and the superficies 14,400 times; and, by putting the screen at farther distances, you may magnify the object almost as much as you please; But Mr. Baker advises to regard distinctness more than brightness, and to place the screen just at that distance where the object is seen most distinct and clear.

With regard to the double reflecting microscope, Mr. Baker observes, that the power of the object-lens is indeed greatly increased by the addition of two eye-glasses; but as no object-lens can be used with them of to minute a diameter, or which magnifies of itself so much as those that can be used alone, the glases of this microscope, upon the whole magnify, little or nothing more than those of Mr. Wilson's single.
In the tele-scope, it will be nearly at the focal distance of the eye-glass, and the rays of each respective pencil being parallel among themselves, and their axes crossing each other in a larger angle than that at which they would cross if the object were to be seen by the naked eye, vision will be distinct, and the object will appear magnified.

The power of magnifying in this telescope is as the focal length of the eye-glass to the focal length of the eye-glasses.

**Common refracting telescope.**

267. In order to prove this, we may consider the angle \( \angle A \) as that under which the object would be seen by the naked eye; for in considering the distance of the object, the length of the telescope may be omitted, as bearing no proportion to it. Now the angle under which the object is seen by means of the telescope is \( \angle g h b \), which is to the other \( \angle A \), or its equal \( \angle g h b \), as the distance from the centre of the object-glass to that of the eye-glass.

The angle, therefore, under which an object appears to an eye adjoined by a telescope of this kind, is to that under which it would be seen without it, as the focal length of the object-glass to the focal length of the eye-glass.

It is evident from this, that the visible area, or space which can be seen at one view when we look through this telescope, depends on the breadth of the eye-glass, and not of the object-glass; for if the eye-glasses be too small to receive the rays \( g m, p b \), the extremities of the object could not have been seen at all; a larger breadth of the object-glass conduces only to the rendering each point of the image more luminous by receiving a larger pencil of rays from each point of the object.

It is in this telescope as in the compound microscope, where we see, when we look through it, not the object itself, but only an image of it at \( C E D \) now that image being inverted with respect to the object, as it is, because the axes of the pencils that flow from the object cross each other at \( A \), objects seen through a telescope of this kind necessarily appear inverted.

This is a circumstance not at all regarded by astronomers: but for viewing objects upon the earth, it is convenient that the telescope should represent them in their natural posture; to which use the telescope with three eye-glasses, as represented fig. 14, is peculiarly adapted, and the progress of the rays through it from the object to the eye is as follows:

268. \( A B \) is the object sending out the several pencils \( A c d, B e d, \) &c. which passing through the object-glass \( c d \), are collected into their respective foci in \( C D \), where they form an inverted image. From hence they proceed to the first eye-glass, whose focus being at \( I \), the rays of each pencil are rendered parallel among themselves, and their axes, which were nearly parallel before, are made to converge and cross each other; the second eye-glass \( g b \), being so placed that its focus shall fall upon \( m \), renders the axes of the pencils which diverge from thence parallel, and causes the rays of each, which were parallel among themselves, to meet again at its focus \( E F \) on the other side, where they form a second image inverted with respect to the former, but erect with respect to the object. Now this image being seen by the eye at \( a b \) through the eye-glass \( i k \), affords a direct representation of the object, and under the same angle that the first image \( D \) would have appeared, had the eye been placed at \( I \), Refracting supposing the eye-glasses to be of equal convexity; and therefore the object is seen equally magnified in this as in the former telescope, that is, as the focal distance of the object-glass to that of any one of the eye-glasses, and appears erect.

If a telescope exceeds 20 feet, it is of no use in viewing objects upon the surface of the earth; for if magnifies above 90 or 100 times, as those of that length usually do, the vapours which continually float near the earth in great plenty, will be so magnified as to render vision obscure.

2. The Galilean Telescope with the concave eye-glass is constructed as follows:

269. \( A B \) (fig. 1) is an object sending forth the pencils \( g h i, k l m, \) &c. which, after passing through the object-glass \( ed \), tend towards \( EF \) (where we will suppose the focus of it to be), in order to form an inverted image there as before: but in their way to it are made to pass through the concave glass \( ns \), so placed that its focus may fall upon \( E \), and consequently the rays of the several pencils which were converging towards those respective focal points \( e, E, f \), will be rendered parallel among themselves; but the several pencils crossing each other at \( F \), and diverging from thence, will be rendered more diverging, as represented in the figure. Now these rays entering the pupil of an eye, will form a large and distinct image \( ab \) upon the retina, which will be inverted with respect to the object, because the axis of the pencils crosses in \( F \). The object of course will be seen erect, and the angle under which it will appear will be equal to that which the lines \( aF, bF \), produced back through the eye-glass form at \( F \).

It is evident, that the less the pupil of the eye is, the less is the visible area seen through a telescope of this kind; for a less pupil would exclude such pencils as proceed from the extremities of the object \( A B \), as is evident from the figure. This is an inconvenience that renders this telescope unfit for many uses; and is only to be remedied by the telescope with the convex eye-glasses, where the rays which form the extreme parts of the image are brought together in order to enter the pupil of the eye, as explained above.

270. It is apparent also, that the nearer the eye is placed to the eye-glasses of this telescope, the larger is the area seen through it; for, being placed close to the glass, as in the figure, it admits rays that come from \( A \) and \( B \), the extremities of the object, which it could not if it was placed farther off.

The degree of magnifying in this telescope is as the magnifying power of the same proportion with that in the other, viz. as the focal distance of the object-glass to that of the eye-glasses.

For there is no other difference but this, viz. that as the extreme pencils in that telescope were made to converge and form the angle \( g h ( \text{fig. 12} ) \), or \( in \) (fig. 13), the are now made to diverge and form the angle \( aF, bF \) (fig. 1), which angle, if the concave glass in one has an equal refractive power with the convex glass, in the other, will be equal, and therefore each kind will exhibit the object magnified in the same degree.

There is a defect in all these kinds of telescopes, not to be remedied in a single lens by any means whatever, which was thought only to arise from hence,
that spherical glasses do not collect rays to one and the same point. But it was happily discovered by Sir Isaac Newton that the imperfection of this sort of telescope, so far as it arises from the spherical form of the glasses, bears almost no proportion to that which is owing to the different refrangibility of light. This diversity in the refraction of rays is about a 28th part of the whole; so that the object-glasses of a telescope cannot collect the rays which flow from any one point in the object into a least room than the circular space whose diameter is about the 56th part of the breadth of the glafs.

To show this, let A B (fig. 2.) represent a convex lens, and let C D F be a pencil of rays flowing from the point D; let H be the point at which the least refrangible rays are collected to a focus; and I, that where the most refrangible concur. Then, if IH be the 25th part of EH, IK will be a proportionate part of EC (the triangles H I K and H E C being similar); consequently L K will be the 25th part of FC. But MN will be the least space into which the rays will be collected, as appears by their progres in the figure. Now MN is but about half of KL; and therefore it is about the 56th part of CF: so that the diameter of the space into which the rays are collected will be about the 56th part of the breadth of that part of the glafs through which the rays pass; which was to be shown.

Since therefore each point of the object will be represented in so large a space, and the centres of those spaces will be contiguous, because the points in the object the rays flow from are so; it is evident, that the image of an object made by such a glass must be a most confounded representation, though it does not appear so when viewed through an eye-glafs that magnifies in a moderate degree; consequently the degree of magnifying in the eye-glass must not be too great with respect to that of the object-glass, lest the confusion become sensible.

Notwithstanding this imperfection, a dioptrical telescope may be made to magnify in any given degree, provided it be of sufficient length; for the greater the focal distance of the object-glass is, the less may be the proportion which the focal distance of the eye-glass may bear to that of the object-glass, without rendering the image obscure. Thus, an object-glass whose focal distance is about four feet, will admit of an eye-glass whose focal distance shall be little more than an inch, and consequently will magnify almost 48 times; but an object-glass of 40 feet focus will admit of an eye-glass of only four inches focus, and will therefore magnify 120 times; and an object-glass of 100 feet focus will admit of an eye-glass of little more than six inches focus, and will therefore magnify almost 200 times.

The reason of this disproportion in their several degrees of magnifying is to be explained in the following manner: Since the diameter of the spaces, into which rays flowing from the several points of an object are collected, are as the breadth of the object-glasses, it is evident that the degree of confusion in the image is as the breadth of that glass; for the degree of confusion will only be as the diameters or breadth of those spaces, and not as the spaces themselves. Now the focal length of the eye-glass, that is, its power of magnifying, must be as that degree; for, if it exceeds it, it will render the confusedness sensible; and therefore it must be as the breadth or diameter of the object glafs.

The diameter of the object-glasses, which is as the square-root of its aperture or magnitude, must be as the square-root of the power of magnifying in the telescope; for unless the aperture itself be as the power of magnifying, the image will want light: the square-root of the power of magnifying will be as the square-root of the focal distance of the object-glass; and therefore the focal distance of the eye-glass must be only as the square-root of that of the object-glass. So that in making use of an object-glass of a longer focus, suppose, than one that is given, you are not obliged to apply an eye-glass of a proportionally longer focus than what would suit the given object-glass, but such an one only whose focal distance shall be to the focal distance of that which will suit the given object-glass, as the square root of the focal length of the object-glass you make use of, is to the square-root of the focal length of the given one. And this is the reason that longer telescopes are capable of magnifying in a greater degree than shorter ones, without rendering the object confused or coloured.

3. But the inconvenience of very long telescopes is so great, that different attempts have been made to remove it. Of these, the most successful have been by Dollond and Blair: and the general principles upon which these eminent opticians proceeded have been mentioned in the historical part of this article, and in the preceding section. The public will be favour'd with a fuller account of Dr Blair's discovery from his own pen; and of Dollond's, it may be sufficient to observe, in addition to what has been already said, that the object-glasses of his telescopes are composed of three distinct lenses, two convex and one concave; of which the concave one is placed in the middle, as is represented in fig. 3, where a and c show the two convex lenses, and b b the concave one, which is by the British artists placed in the middle. The two convex ones are made of London crown glasses, and the middle one of white flint glasses; and they are all ground to spheres of different radii, according to the refractive powers of the different kinds of glass and the intended focal distance of the object-glass of the telescope. According to Boscovich, the focal distance of the parallel rays for the concave lens is one-half, and for the convex glafs one-third of the combined focus. When put together, they refract the rays in the following manner. Let a b a b (fig. 4.), be two red rays of the sun's light falling parallel on the first convex lens c. Supposing there was no other lens present but that one, they would then be conver'd into the lines b e b e, and at last meet in the focus g. Let the lines g h g h, represent two violet rays falling on the surface of the lens. These are also refracted, and will meet in a focus; but as they have a greater degree of refrangibility than the red rays, they must of course converge more by the same power of refraction in the glass, and meet sooner in a focus, suppose at r.—Let now the concave lens d d be placed in such a manner as to intercept all the rays before they come to their focus. Were this lens made of the same materials, and ground to the same radius with the convex one, it would...
OPTICS.

Reflecting Telescope.

would have the same power to cause the rays diverge that the former had to make them converge. In this case, the red rays would become parallel, and move on in the line \( o_o, o_o \). But the convex lens being made of flint glass, and upon a shorter radius, has a great refractive power, and therefore they diverge a little after they come out of it; and if no third lens was interposed, they would proceed diverging in the lines \( o_p, o_p \); but, by the interposition of the third lens \( o_o \), they are again made to converge, and meet in a focus somewhat more distant than the former, as \( x \).

By the convex lens the violet rays are also refracted, and made to diverge; but having a greater degree of refrangibility, the same power of refraction makes them diverge somewhat more than the red ones; and thus, if no third lens was interposed, they would proceed in such lines as \( l\, m, n, l, m, n \). Now as the differently coloured rays fall upon the third lens with different degrees of divergence, it is plain, that the same power of refraction in that lens will operate upon them in the same manner as to bring them all together to a focus very nearly at the same point. The red rays, it is true, require the greatest power of refraction to bring them to a focus; but they fall upon the lens with the least degree of divergence. The violet rays, though they require the least power of refraction, yet have the greatest degree of divergence; and thus all meet together at the point \( x \), or very nearly so.

But, though we have hitherto supposed the refraction of the convex lens to be greater than that of the convex ones, it is easy to see how the errors occasioned by the first lens may be corrected by it, though it should have even a less power of refraction than the convex one. Thus, let \( a, b, a, b \) (fig. 5), be two rays of red light falling upon the convex lens \( c \), and refracted into the focus \( g \); let also \( g, b, g, b \) be two violet rays converged into a focus at \( r \); it is not necessary, in order to their convergence into a common focus at \( x \), that the convex lens should make them diverge; it is sufficient if the glasses have a power of dispersing the violet rays somewhat more than the red ones; and many kinds of glasses have this power of dispersing some kinds of rays, without a very great power of refraction. It is better, however, to have the object-glasses composed of three lenses; because there is then another correction of the aberration by means of the third lens; and it might be impossible to find two lenses, the errors of which would exactly correct each other. It is also easy to see, that the effect may be the same whether the convex glasses are a portion of the same sphere with the others or not; the effect depending upon a combination of certain circumstances, of which there is an infinite variety.

By means of this correction of the errors arising from the different refrangibility of the rays of light, it is possible to shorten dioptric telescopes considerably, and yet leave them equal in magnifying power. The reason of this is, that the errors arising from the object-glass being removed, these which are occasioned by the eye-glasses are inconsiderable; for the error is always in proportion to the length of the focus in any glass; and in very long telescopes it becomes exceedingly great, being no less than \( \frac{1}{8} \)th of the whole; but in glasses of a few inches focus it becomes trifling. Refracting telescopes, which go by the name of \( \text{Dr. Dollond} ^{\text{3}} \), are therefore now constructed in the following manner. Let \( AB \) (fig. 6) represent an object-glass composed of three lenses as above described, and converging the rays \( 1, 2, 3, 4, \&c. \) to a very distant focus at \( x \). By means of the interposed lens CD, however, they are converged to one much nearer, at \( y \), where an image of the object is formed. The rays diverging from thence fall upon another lens EF, where the pencils are rendered parallel, and an eye placed near that lens would see the object magnified and very distinctly. To enlarge the magnifying power still more, however, the pencils thus become parallel are made to fall upon another at GH; by which they are again made to converge to a distant focus; but being intercepted by the lens IK, they are made to meet at the nearer one \( z \); whence diverging to LM, they are again rendered parallel, and the eye at N views the object very distinctly.

From an inspection of the figure it is evident, that Dollond's telescope thus constructed is in fact two telescopes combined together; the first ending with the lens EF, and the second with LM. In the first we do not perceive the object itself, but the image of it formed at \( y \); and in the second we perceive only the image of that image formed at \( z \). Nevertheless such telescopes are exceedingly difficult, and represent objects so clearly as to be preferred, in viewing terrestrial things, even to reflectors themselves. The latter indeed have greatly the advantage in their powers of magnifying, but they are much deficient in point of light. Much more light is lost by reflection than by refraction; and as in these telescopes the light must unavoidably suffer two refractions, a great deal of it is lost; nor is this loss counterbalanced by the greater aperture which these telescopes will bear, which enables them to receive a greater quantity of light than the refracting ones. The metals of reflecting telescopes are very much subject to tarnish, and require much more dexterity to clean them than the glasses of refractors; which makes them more troublesome and expensive, though for making discoveries in the celestial regions they are undoubtedly the only proper instruments which have hitherto contriv'd. If Dr Blair indeed shall be so fortunate as to discover a vitreous substance of the same powers with the fluid in the compound object-glass of his telescope (and from his abilities and perseverance we have every thing to hope), a refracting telescope may be constructed superior for every purpose to the bit reflector.

II. The Reflecting Telescope.

The inconveniences arising from the great length of refracting telescopes, before Dollond's discovery, are sufficiently obvious; and these, together with the difficulties occasion'd by the different refrangibility of light, induced Sir Isaac Newton to turn his attention to the subject of reflection, and endeavor to realize telescopes. He therefore contriv'd instruments, the ideas of which he communicated in a large tube, open at AD and closed at BC, and of a length at least equal to the distance of the focus from the metallic speculum. He also placed at the end DC. The rays E2, B3, &c. proceeding from a remote object at PR, intersect...
Gregory, therefore, soon obtained the preference, to reflecting telescopes. For what most purposes it is infallibly intimated, the reader will perceive from the following construction.

Let IVY Y' (fig. 9.) be a refracting tube, in which L D L D is a metallic concave speculum, perforated in the middle, and EF a lens concave mirror, so fixed by the arm or strong wire RT, which is moveable by means of a long screw on the outside of the tube, as to be moved nearer to or farther from the larger speculum L D L D, its axis being kept in the same line with that of the great one. Let AB represent a very remote object, from each part of which infuse pencils of rays, e. g. A B D, C D, from A the upper extreme of the object, and IL, I B, from the lower part B; the rays IL, CD from the extremes crossing one another before they enter the tube. These rays, falling upon the larger mirror L D, are reflected from it into the focus KH, where they form an inverted image of the object AB, as in the Newtonian telescope. From this image the rays, issuing from an object, fall upon the small mirror EF, the centre of which is at c; so that after reflection they would meet in their focus at QQ, and there form an erect image. But in this eye of that place could see but a small part of an object, in order to bring rays from more distant parts of it into the pupil, they are intercepted by the plano-convex lens MN, by which means a smaller erect image is formed at PV, which is viewed through the meniscus SS by an eye at O. This meniscus both makes the rays of each pencil parallel, and magnifies the image PV. At the place of this image all the foreign rays are intercepted by the perforated partition ZZ. For the eye reason the hole near the eye O is very narrow. When nearer objects are viewed by this telescope, the small speculum EF is removed to a greater distance from the larger LD, so that the second image may be always formed in PV; and this distance is to be adjusted (by means of the screw on the outside of the great tube) according to the form of the eye of the observer. It is also necessary, that the axis of the telescope should pass through the middle of the speculum EF, and its centre, the centre of the speculum LL, and the middle of the hole X, the centres of the lenses MN, SS, and the hole near O. As the hole X in the speculum LL can reflect none of the rays issuing from the object, that part of the image which corresponds to the middle of the object must appear to the observer more dark and confused than the extreme parts of it. Besides, the speculum EF will also intercept many rays proceeding from the object; and therefore, unless the aperture TT be large, the object must appear in some degree obscure.

In the best reflecting telescopes, the focus of the small mirror is never coincident with the focus of the great one, where the first image KH is formed, but a little beyond it (with respect to the eye), as at n; the consequence of which is, that the rays of the pencils will not be parallel after reflection from the small mirror, but converge so as to meet in points about Q O, where they would form a larger upright image than PV, if the glass R was not in their way; and this image might be viewed by means of a single eye-glass properly placed between the image and the eye; but then the field of view would be less, and consequently...
OPTICS.

We shall conclude this article with some observations

On the different merits of microscopes and telescopes compared with one another; how far we may reasonably depend on the Leporesian mode of 161 m, and what hopes we may entertain of further improvement.

The advantages arising from the use of microscopes and telescopes depend, in the first place, upon their property of magnifying the minute parts of objects, so that they can be made more distinctly viewed by the eye; and, secondly, upon their throwing more light into the pupil of the eye than what is done without them. The advantages arising from the magnifying power would be extremely limited, if they were not also accompanied by the latter; for if the same quantity of light is spread over a large portion of surface, it becomes proportionally diminished in force; and therefore the objects, though magnified, appear proportionally dim. Thus, though any magnifying glass should enlarge the diameter of the object 10 times, and consequently magnify the surface 100 times, yet if the focal distance of the glass was about eight inches (provided this was possible), and its diameter only about the fifth of that of the pupil of the eye, the object would appear 100 times more dim when we looked through the glass, than when we beheld it with our naked eyes; and, even on a supposition that the glass transmitted all the light which fell upon it, which no glass can do. But if the focal distance of the glass was only four inches, though its diameter remained as before, the inconvenience would be vastly diminished, because the glass could then be placed twice as near the object as before, and consequently would receive four times as many rays as in the former case, and therefore we would see it much brighter than before. Going on thus, still diminishing the focal distance of the glass, and keeping its diameter as large as possible, we will perceive the object more and more magnified, and at the same time very distinct and bright. It is evident, however, that with regard to optical instruments of the microscopic kind, we must sooner or later arrive at a limit which cannot be passed. This limit is fixed by the following particulars. 1. The quantity of light left in passing through the glass. 2. The diminution of the glass itself, by which it receives only a small quantity of rays. 3. The extreme shortness of the focal distance of great magnifiers, whereby the free access of the light to the object which we wish to view is impeded, and consequently the reflection of the light from it is weakened. 4. The aberrations of the rays, occasioned by their different refrangibility.

To understand this more fully, as well as to see how far these obstacles can be removed, let us suppose the lens made of such a dull kind of glass that it transmits only one half of the light which falls upon it. It is evident that such a glass, of four inches focal distance, and which magnifies the diameter of an object twice, still supposing its own breadth equal to that of the pupil of the eye, will shew it four times magnified in surface, but only half as bright as if it was seen by the naked eye at the usual distance; for the light which falls upon the eye from the object at eight inches distance, and likewise the surface of the object in its natural...
natural size, being both represented by \( \frac{1}{2} \), the surface of the magnified object will be \( \frac{4}{2} \), and the light which makes that magnified object visible only \( \frac{1}{2} \); because though the glass receives four times as much light as the naked eye does at the usual distance of distant vision, yet one half is lost in paling through the glass. The inconvenience in this respect can therefore be removed only as far as it is possible to increase the clearness of the glass, so that it shall transmit nearly all the rays which fall upon it; and how far this can be done hath not yet been ascertained.

The second obstacle to the perfection of microscopic glasses is the small size of great magnifiers, by which, notwithstanding their near approach to the object, they receive a smaller quantity of rays than might be expected. Thus, suppose a glass of only \( \frac{1}{2} \) th of an inch focal distance; such a glass would increase the visible diameter 80 times, and the surface 6400 times. If the breadth of the glass could at the same time be preferred as great as that of the pupil of the eye, which we shall suppose \( \frac{1}{2} \) th of an inch, the object would appear magnified 6400 times, at the same time that every part of it would be as bright as it appears to the naked eye. But if we suppose that this magnifying glass is only \( \frac{1}{2} \) th of an inch in diameter, it will then only receive \( \frac{1}{2} \) th of the light which otherwise would have fallen upon it; and therefore, instead of communicating to the magnified object a quantity of illumination equal to 6400, it would communicate only one equal to 1600, and the magnified object would appear four times as dim as it does to the naked eye. This inconvenience, however, is still capable of being removed, not indeed by increasing the diameter of the lens, because this must be in proportion to its focal distance, but by throwing a great quantity of light on the object. Thus, in the abovementioned example, if four times the quantity of light which naturally falls upon it could be thrown upon the object, it is plain that the reflection from it would be four times as great as in the natural way; and consequently the magnified image, at the same time that it was as many times magnified as before, would be as bright as when seen by the naked eye. In transparent objects this can be done very effectually by a concave speculum, as in the reflecting microscope already described: but in opaque objects the same is somewhat more doubtful neither do the circumstances for viewing these objects seem entirely to make up for the deficiencies of the light from the smallness of the lens and shortness of the focus.—When a microscopic lens magnifies the diameter of an object 40 times, it hath then the utmost possible magnifying power, without diminishing the natural brightness of the object.

The third obstacle arises from the shortness of the focal distance in large magnifiers: but in translucent objects, where a sufficient quantity of light is thrown on the object from below, the inconvenience arises at last from the eye which must be placed nearer the glass than it can well bear; and this entirely supercedes the use of magnifiers beyond a certain degree.

The fourth obstacle arises from the different refrangibility of the rays of light, and which frequently causes such a division from truth in the appearances of things, that many people have imagined the microbes to have made surprising discoveries, and have even published them to the world; whereas in fact they have been only as many optical deceptions, owing to the unequal refractions of the rays. For this there seems to be no remedy, except the introduction of achromatic glasses into microscopes as well as telescopes. How far this is practicable, hath not yet been tried; but when these glasses shall be introduced (if such introduction is practicable), microscopes will undoubtedly have received their ultimate degree of perfection.

With regard to telescopes, those of the refracting kind have evidently the advantage of all others, where the aperture is equal, and the aberrations of the rays are corrected according to Mr. Dollond's method; because the image is not only more perfect, but a much greater quantity of light is transmitted than what can be reflected from the best materials hitherto known. Unlike, however, the imperfections of the glass set a limit to these telescopes, as hath already been observed, so that they cannot be made above three feet and an half long. On the whole, therefore, the reflecting telescopes are preferable in this respect, that they may be made of dimensions greatly superior; by which means they can both magnify to a greater degree, and at the same time throw much more light into the eye.

With regard to the powers of telescopes, however, they are all of them exceedingly less than what we would be apt to imagine from the number of times which they magnify the object. Thus, when we hear of a telescope which magnifies 200 times, we are apt to imagine, that, on looking at any distant object through it, we should perceive it as distinctly as we would with our naked eye at the 200th part of the distance. But this is by no means the case; neither is there any theory capable of directing us in this matter: we must therefore depend entirely on experience.

The best method of trying the goodness of any telescope is by observing how much the eye is able to read with it than you can with the naked eye. But that all deception may be avoided, it is proper to choose something to be read where the imagination cannot give any assistance, such as a table of logarithms or something which contains entirely of figures; and hence the truly useful power of the telescope is easily known. In this way Mr. Short's large telescope, which magnifies the diameter of objects 2000 times, is yet unable to afford sufficient light for reading at more than 500 times the distance at which we can read with our naked eye.

With regard to the form of reflecting telescopes, the Gregorian is now generally agreed, that when the Gregorian telescopes are well constructed, they have the advantage of those of the Newtonian form. One advantage common to the Gregorian telescope, is that this type of telescope is easily known. In this way Mr. Short's large telescope, which magnifies the diameter of objects 2000 times, is yet unable to afford sufficient light for reading at more than 500 times the distance at which we can read with our naked eye.

With regard to the form of reflecting telescopes, it is the Gregorian type which is generally agreed upon, that when the Gregorian telescope is well constructed, they have the advantage of those of the Newtonian form. One advantage common to the Gregorian telescope is that it offers the advantage of greater ease than the Newtonian telescope, where we must look into the side. The unavoidable imperfection of the principal common to both, also gives the Gregorian an advantage over the Newtonian form. Notwithstanding the utmost care and labour of the workmen, it is found impossible to give the metal either a perfectly spherical or a reflector phytological form. Hence arises few

OPTICS. Part II.

Microscopes and Tele
copes compared.
some indistinctness of the image formed by the great spectum, which is frequently corrected by the little one, provided they are properly matched. But if this is not done, the error will be made much worse and hence many of the Gregorian telescopes are inferior to the Newtonian ones; namely, when the spectre have not been properly adapted to each other. There is no method by which the workman can know the spectre which will fit one another without a trial; and therefore there is a necessity for having many spectra ready made of each sort, that in fitting up a telescope those may be chosen which best suit each other.

The brightness of any object seen through a telescope, in comparison with its brightness when seen by the naked eye, may in all cases be easily found by the following formula. Let \( n \) represent the natural distance of a visible object, at which it can be distinctly seen; and let \( d \) represent its distance from the object-glass of the instrument. Let \( m \) be the magnifying power of the instrument; that is, let the visual angle subtended at the eye by the object when at the distance \( n \), and viewed without the instrument, be to the visual angle produced by the instrument as \( 1 \) to \( m \). Then

\[
\frac{\text{the brightness of natural vision being } n}{\text{the brightness of natural vision being } m} = \frac{d}{mp}.

It is proper however to add, that options were not peculiar to the camp, but were also used in a variety of other offices of life.

OPTIO, the power or faculty of wishing or choosing; or the choice a person makes of anything.

When a new suffragan bishop is consecrated, the archbishop of the province, by a customary prerogative, claims the collation of the first vacant benefice, or dignity, in that fee, according as he shall choose; which choice is called the archbishop's option.

But in case the bishop dies, or is translated, before the present incumbent of the promotion chosen by the archbishop shall die or be removed, it is generally supposed that the option is void; inasmuch as the grantor, being and by himself, could not convey any right or title beyond the term of his continuance in that fee. And if the archbishop dies before the avoidance shall happen, the right of filling up the vacancy shall go to his executors or administrators.
ORA [365] ORA

and gave four of the pears to a child of three years of age, and six pears to one of five. The next morning I examined the urine of both, and it appeared of a very lively red colour, as if tart-wine had been mixed with water. I gave likewise six pears to a negro-wench, who was sucking an infant, and first forbade her to put the child to her breast for six or eight hours; and then taking some of her milk in a teacup, and setting it by for some hours, the cream had a reddish light, though it was very faint." From the same letter we learn, that the prickly pear grows in great abundance about Carolina; and also that the cochineal insects are found upon it, though no attempt, that we know of, has hitherto been made to cure them for use as the Spaniards do.

OR, the French word for gold, by which this metal is expressed in heraldry. In engraving it is denoted by small points all over the field or bearing. It may be supposed to signify of itself, generosities, splendor, or solidity; according to G. Leigh, if it is compounded with

ORAE, in antiquity, was a term equivalent to an ounce; but it has been much debated among our antiquaries, whether the ora, the mention of which so often occurs, was a coin, or only money of account. Dr Hicks observes, that the mode of reckoning money by marks and oras was never known in England till after the Danish settlements; and by examining the old nummulary estimates among the principal Gothic states upon the Baltic, it appears, that the ora and solidus were synonymous terms, and that the ora was the eighth part of the mark. From several of the Danish laws, it likewise appears, that the Danish ora, derived by corruption from aurus, was the same as the Frank solidus of twelve pence. As a weight, the ora was regarded as the oncia or unit, by which the Danish mark was divided; and in Doomsday-book the ora is used for the ounce, or the twelfth part of the nummulary Saxon pound, and the fifteenth of the commercial: as a coin, it was an aureus, or the Frank solidus of twelve pence. And from the accidental coincidence of the Frank aureus with the eighth part of their mark, the Danes probably took occasion to give it the new name of ora. There was another ora mentioned in the rolls of the 27th of Henry III. the value of which was sixpence; and this was probably derived from the half mance of the Saxons. Such, in all appearance, was the original of these two oras; as there were no aurei of that period, to which these two denominations of money of sixteen and twelve pence can possibly be ascribed. It is observed farther, that the name ora distinguishes the gold coins in several parts of Europe to this day. The Portuguese moidore is nothing else but moda d'ora, from the Latin moneta de aure; the French Louis d'ores come from the same use of the word, and owe their appellation to the ora. See Clarke on Coins.

ORACH. See ATRIPLEX.

Wild Orach. See CHENOPODIUM.

ORACLE, among the heathens, was the answer which the gods were supposed to give to those who consulted them upon any affair of importance. It is also used for the god who was thought to give the answer, and for the place where it was given.

The credit of oracles was so great, that in all doubts and disputes their determinations were held sacred and inviolable: whence vast numbers flocked to them for advice about the management of their affairs; and no busines of any consequence was undertaken, scarce any peace concluded, any war waged, or any new form of government instituted, without the advice and approbation of some oracle. The answers were usually given by the intervention of the priest or priestess of the god who was consulted; and generally expressed in such dark and unintelligible phrases, as might be easily wrested to prove the truth of the oracle whatever was the event. It is not, therefore, to be wondered at, that the priests who delivered them were in the highest credit and esteem; and that they managed this reputation so as greatly to promote their own particular advantage. They accordingly allowed no man to consult the gods, before he had offered costly sacrifices, and made rich presents to them. And to keep up the veneration for their oracles, and to prevent their being taken unprepared, they admitted persons to consult the gods only at certain stated times; and sometimes they were so cautious, that the greatest personages could obtain no answer at all. Thus Alexander himself was peremptorily denied by the Pythia, or priestess of Apollo, till she was by downright force obliged to ascend the tripod, when, being unable to refist any longer, she cried out, "Thou art invincible: and these words were accepted instead of a farther oracle.

Of the ambiguity of oracles, the following, out of a great many examples, may be mentioned. Cteseus having received from the Pythoens this answer, That by passing the river Halys, he would destroy a great empire; he understood it to be the empire of his enemy, whereas he destroyed his own. — The oracle consulted by Pyrrhus gave him an answer, which might be equally understood of the victory of Pyrrhus, and the victory of the Romans his enemies:

Aio te, Zedile, Romanes vincere poife.

The equivocation lies in the construction of the Latin tongue, which cannot be rendered in English. — The Pythoens advised Cretes to guard against the mule. The king of Lydia understood nothing of the oracle, which denoted Cyrus descended from two different nations; from the Medes, by Mandana his mother, the daughter of Assyages; and from the Persians, by his father Cambyses, whose race was by far less grand and illustrious. — Nero had for answer from the oracle of Delphos, that seventy-three might prove fatal to him. He believed he was safe from all danger till that age; but, finding himself defeated by every one, and hearing Galba proclaimed emperor, who was 73 years of age, he was sensible of the deceit of the oracle.

When men began to be better instructed by the lights philosophy had introduced into the world, the false oracles insensibly lost their credit. Chryippus filled an entire volume with false or doubtful oracles. Oenomaus, to be revenged of some oracle that had deceived him, made a compilation of oracles, to show their
Oracle.

their ridiculous vanity. Eusebius has preserved some fragments of this criticism on oracles by Oenomaus. "I might (says Origen) have recourse to the authority of Aristotle and the Peripatetics, to make the Pythagoreans so suspicious; I might extract from the writings of Epicurus and his sectaries an abundance of things to differ oracles; and I might show that the Greeks themselves made no great account of them."

The reputation of oracles was greatly lessened when they became an artifice of politics. Themistocles, with a design of engaging the Athenians to quit Athens, and to embark, in order to be in a better condition to refit Xerxes, made the pythons deliver an oracle, commanding them to take refuge in wooden walls. Demosthenes said, that the Pythons Philip-pified; to signify that she was gained over by Philip's presents.

The cessation of oracles is attested by several profane authors; as Strabo, Juvenal, Lucan, and others. Plutarch accounts for it, by saying, that the benefits of the gods are not eternal as themselves are; or that the genii, who presided over oracles, were subject to death; or that the exhalations of the earth had been exhausted. It appears that the last reason had been alleged; but one, or woul'd be, one so

Plutarch relates, that the pilot Themis heard a voice in the air, crying out, "The great Pan is dead!" whereupon Eusebius observes, that the accounts of the death of the demons were frequent in the reign of Tiberius, when Christ drove out the wicked spirits.

The same judgment, is is said, may be passed on oracles as on poiffeia. It was on particular occasions, by the divine permission, that the Christians expelled devils, or silenced oracles, in the presence, and even by the confession, of the Pagans themselves. And thus it is we should, it seems, understand the passages of St. Jerome, Eusebius, Cyril, Theodoret, Prudentius, and other authors, who said that the coming of Christ had imposed silence on the oracles.

As to the second sort of oracles, which were pure artifices and cheats of the priests of false divinities, and which probably exceeded the number of those that immediately proceeded from demons, they did not cease till idolatry was abolished, though they had lost their credit for a considerable time before the coming of Christ. It was concerning this more common and general sort of oracles that Minutius Felix said, they began to discontinue their reproaches, according as men began to be more polite. But, however oracles were decried, impostors always found dupes, the greatest cheats having never failed.

Daniel discovered the impudence of the priests of Bel, who had a private way of getting into the temple to take away the offered meats, and who made the king believe that the idol confirmed them.—Mundus, being in love with Paulina, the eldest of the priestesses of Isis, went and told her, that the god Ambus, being passionately fond of her, commanded her to give him a meeting. She was afterwards shut up in a dark room, where her lover Mundus, whom she believed to be the god Ambus, was concealed. This impudence having been discovered, Tiberius ordered those detestable priests and priestesses to be crucified, and with them Idea, Mundus's free-woman, who had conducted the whole intrigue. He also commanded the
the temple of IIs to be levelled with the ground, and her statue to be thrown into the Tiber: and as to Mundus, he contented himself with finding him into banishment.

Theophilus, bishop of Alexandria, not only destroyed the temples of the false gods, but did over the priests; by showing that the statues, some of which were of brass, and others of wood, were hollow within, and led into dark passages made in the wall.

Lucian, in discovering the impurities of the false prophet Alexander, says, that the oracles were chiefly afraid of the fictitious of the Epicureans and Christians. This false prophet Alexander sometimes signified himself to a divinity, and by means of the herb hopewort, which he chewed, frothed at the mouth in a extraordinary manner, that the ignorant people attributed it to the fire of the god he was possessed by. He had long before prepared a head of a dragon made of linen, which opened, and that its mouth by means of a horse-hair. He went by night to a place where the foundations of a temple were digging; and having found water, either of a spring, or rain that had settled there, he hid it in a goose-egg, in which he had enclosed a little serpent that had been just hatched. The next day, very early in the morning, he came quite naked into the street, having only a scarf about his middle, holding in his hand a scythe, and tooting about his hair as the priest of Cybele; then getting atop of a high altar, he said that the place was happy to be honoured by the birth of a god.—Afterwards, running down to the place where he had hid the goose-egg, and going into the water, he began to sing the praises of Apollo and Asculapius, and to invite the latter to come and shew himself to men. With these words, he dips a bowl into the water, and takes out a mysterious egg, which a god included in it; and when he had it in his hand, he began to say that he held Asculapius. Whilist all were eager to have a sight of this fine mystery, he broke the egg, and the little serpent flaming out, twitted itself about his fingers.

These examples show clearly, that both Christians and Pagans were so far agreed as to the greater number of oracles as purely human imitations. That, in fact, all of them were so, will be concluded by those who give equal credit to demoniacal inspiration, and demonical possession. The most ancient oracle was that of Dodona (see Dodona); but the most famous was that of Delphi, to which article we also refer for further particulars on this subject, so famous in Pagan antiquity. Another celebrated one was the oracle of Trophonius, in the neighbourhood of Lebada, a city of Beotica, which was held in high estimation. It received its name from Trophonius, brother of Agamedes, who lived in a subterraneous dwelling near Lebada, and pretended to the faculty of foretelling future events. He died in his cave, and was defied as an oracular god. This oracle owed its reputation to one Simon. Those who repaired to this cave for information, were required to offer certain sacrifices, to anoint themselves with oil, and to bathe in a certain river; They were then clothed in a linen robe, took a hole in their hands, and descended into the farther most chamber by a narrow passage. Here it was that the future was unfolded to them, either by visions or extraordinary sounds. The return from the cave was by the same passage, but the persons consulting were obliged to walk backwards. They generally came out as the next day, melancholy, and dejected; hence the proverb, in τροπων περιεχομενον. The priests on their return placed them on an elevated seat, called the fest of Meryrphos, where an account was taken of what they had seen and heard. They were then conducted to the chapel of the good Genius by their companion, where, by degrees, they recovered their usual composure and cheerfulness.

Besides these three principal oracles of Greece, it is proper to take notice of that of Amphipolis at Oropus in Attica. It was so called from Amphipolus, the son of Oicles, a man skilled in magic, the interpretation of dreams, &c. and who after his death was deified and delivered oracles in a temple erected to his divinity. (See Amphiaraus.) They who applied to him for information, were to purify themselves, offer sacrifice, fast twenty-four hours, abstain from wine two days, and make an offering of a ram to Amphipolus; on the skin of which they were to sleep, and see their dream in a dream. Near the temple was Amphipolus’s fountain, which was sacred, and the waters of it forbidden to be used for ordinary purposes.

At Delos also there was an oracle of the Delian Apollo: in Milesea was that of the Branchides, with others of less note, which require not a particular description, such as that of the camps at Lacedemon, that of Nabarchus, that of Chryseis, that of Clarus in Ionia, that of Malles, that of Pateira, that of Pella, that of Phæelloides, that of Simon, that of Orpheüs’s head, &c.

Though the Romans consulted the Grecian oracles upon many occasions, and had few oracles in their own country; yet we must not omit mentioning the Cuman oracles, which were delivered by the Sibyl of Cumæ. For an account of the Sibyls, see the article Sibyl. See also Demon and Demoniac.

We have hitherto only considered the oracles of false gods, of which there was a far greater number than our limits permit us to observe, and before either Greeks or Romans had riven to any distinction. Oracle is in sacred history sometimes used for the mercy-seat, or the cover of the ark of the covenant; and by others it is taken for the sanctuary, or for the most holy place, wherein the ark was deposited.

Among the Jews we may distinguish several sorts of real oracles. They had first oracles that were delivered visio visum; as when God spake to Moses face to face, and as one friend spake to another, (Numb. xii. 8.) Secondly, Prophetic dreams sent by God; as the dreams which God sent to Joseph, and which foretold his future greatness. (Gen. xxvii. 5, 6.) Thirdly, Visions; as when a prophet in an ecstasy, being neither properly asleep nor awake, had supernatural revelations. (Gen. xxv. 1, xxvi. 2.) Fourthly, The oracle of Urim and Thummim, which was accompanied with the ephod or the ephod worn by the high-priest, and which God had endued with the gift of foretelling things.
things to come. (Numb. xii. 6. Joel ii. 28.) This manner of inquiring of the Lord was often made use of, from Joshua's time to the erection of the temple at Jerusalem. Fifthly, After the building of the temple, they generally consulted the prophets, who were frequent in the kingdoms of Judah and Israel. From Haggai, Zechariah, and Malachi, who are the last of the prophets that have any of their writings remaining, the Jews pretend that God gave them what they call Balaam, the daughter of the voice, which was a supernatural manifestation in the will of God, which was performed either by a strong inspiration or internal voice, or else by a sensible and external voice, which was heard by a number of persons sufficient to bear testimony of it. For example, such was the voice that was heard at the baptism of Jesus Christ, saying, This is my beloved son.

The scripture affords us examples likewise of profane oracles. Balaam, at the inclination of his own spirit, and urged on by his avarice, fearing to lose the recompence that he was promised by Balak king of the Moabites, suggests a diabolical expedient to this prince, of making the Israelites fall into idolatry and fornication (Num. xxiv. 14. xxxi. 16.), by which he assures him of a certain victory, or at least of considerable advantage against the people of God.

Micaiah the son of Imlah, a prophet of the Lord, says (1 Kings xxii. 21. &c.), that he saw the Almighty fitting upon his throne, and all the host of heaven round about him; and the Lord said, Who shall entreat Ahaziah king of Israel, that he may go to war with Ramoth-gilead, and fall in the battle? One answered after one manner, and another in another. At the same time an evil spirit presented himself before the Lord and said, I will seduce him. And the Lord asked him How? To which Satan answered, I will go and be a lying spirit in the mouth of his prophets. And the Lord said, Go, and thou shalt prevail. This dialogue clearly proves these two things, first, that the devil could do nothing by his own power; and, secondly, that with the permission of God, he could inspire the false prophets, forcers, and magicians, and make them deliver false oracles.

Respecting the cession of profane oracles there have been a variety of opinions; some of which we have already remarked. It has been generally held, indeed, that oracles ceased at the birth of Jesus Christ: Yet some have endeavoured to maintain the contrary, by showing that they were in being in the days of Julian, commonly called the Apostate, and that this emperor himself consulted them; nay, farther, say they, history makes mention of several laws published by the Christian emperors Theodosius, Gratian, and Valentinian, to punish persons who interrogated them, even in their days; and that the Epicureans were the first who made a jest of this superstition, and exposed the roguesy of its priests to the people. As we suspect most of the facts here asserted should be understood in a qualified sense, we shall endeavour to discuss this point of controversy as few words as possible; although it is undoubtedly a matter of some consequence.

18. The question, properly stated, is not, Whether oracles became extinct immediately upon the birth of Christ, or from the very moment he was born? but, If they fell gradually into disuse, and ceased, as
Orange. The French took it again, and expelled the Protestant inhabitants. By the treaty of Utrecht it was confirmed to the crown of France, though the title is still retained in the house of Nassau. The title was first introduced into the family of Nassau by the marriage of Claudine de Chalons, the prince of Orange's sister, with the count of Nassau, 1530. The principality is a very small district, being only twelve miles in length and nine in breadth, and the revenue amounts to about 5000 l. a-year. The country is pleasant, and abounds with corn and fruit, but is exposed to violent winds. E. Long. 4. 49. N. Lat. 44. 9.

Maurice Prince of Orange. See Maurice.

Orange-Tree. See the article Citrus.

Orange-flowers are jutly esteemed one of the finest perfumes; and though little used in medicine, yet the water distilled from them is accounted amphoteric, cordial, and carminative. The fruit is cooling, and good in febrifh disorders, and particularly in diarrheas. Orange-peel is an agreeable aromatic, proper to prepare and strengthen the stomach, and gives a very grateful flavour to any infusions or tincture into whole compositions it enters. It is particularly useful in preparations of the bark; gives an agreeable warmth to the infusion; and according to Dr Percival, considerably increases its virtue.

In the philosophical Transactions, n° 114, there is a very remarkable account of a tree standing in a grove near Florence, having an orange rock, which had been so grafted upon, that it became in its branches, leaves, flower, and fruit; three formed: fome emulating the orange, fome the lemon or citron, and fome partaking of both forms in one; and what was very remarkable, was, that these mixed fruits never produced any perfect seeds; sometimes there were no seeds at all in them, and sometimes only a few empty ones.

Orange-Peel. See Citrus and Orange-Tree.

Orange-dew, a kind of dew which falls in the spring-time from the leaves of orange and lemon trees, which is extremely fine and subtle. M de la Hiere observing this placed some flat pieces of glass under the leaves to receive it; and having procured some large drops of it, was desirous of discovering what it was. He soon found that it was not a merely aqueous fluid, because it did not evaporate in the air; and that it was not a reft, because it readily and perfectly mixed with water: it was natural then to suppose it a liquid gum; but neither did this. On examination prove to be the cafe; for being laid down on paper, it did not dry as the other liquid gums do. Its answering to none of these characters, and its being of the confidence of honey, and of a sweet sugar-like taste, gave a fulphication of its being a kind of manna; and whatever in the other tribes had proved it not a reft, a gum, &c. all equally tend to prove that it is this substance.

Orange-Seaw, in natural history, a name given by Count Marsigli to a very remarkable species of marine substance, which he denominates a plant. It is tough and firm in its structure, and in many things resembles the common fucus; but instead of growing into the branched form which the generality of those substances have, it is round and hollow, and in every respect resembles the shape of an orange. It has a way of root, fome exceeding fine filamenta, which fatten themfelves to the rocks, or to shells, stones or any thing elè that comes in the way. From these there grows no pedicle; but the body of the orange, as it is called, is fattenèd by them to the rock, or other solid substance. The orange itfelf is usually of about three or four inches in diameter; and while in the sea, is full of water and even retains it when taken up. In this fale it frequently weighs a pound and a half; but when the water is let out, and it is dried it becomes a mere membrane, weighing scarce any thing. It is bent preferred, by fuffling it with cotton as soon as the water is let out of it, and then hanging it up to dry. Its surface is irregular and rough, and its colour a dulky green on the outside, and a clearer but fomething blufh green within; and its thickness is about an eighth part of an inch. When viewed by the microscope, it is seen to be all over covered with fmall glandules, or rather composed of them for they ftand fo thick one by another as to leave no space between, and seem to make up the whole fubftance; fo that it appears very like the rough flag. Even skin ufed to cover toys. These are indeed fo many hollow ducts, through which the sea-water finds a passage into the globe formed by this skin, and by this means it is kept always full and diftended: on cutting it with a pair of fciare, the water immediately runs out, and the skins collapse; but there is something extremely remarkable in this, for the whole fubftance, near the wounded place, is in motion, and seems as if alive and fensitive of the wound. The glandules are found full of water, and resembling small transparent bottles; and what goes to the structure of the plant beside thefe, is an affembmage of a vaft number of filamenta, all which are likewise hollow, and filled with a clear and transparent thing.

There is another fubftance of this kind, mentioned and defcribed by Count Marsigli. Triumphati, and others, and called the rame or branched orange. This is very much of the nature of the former; but, instead of confifting of one round globe, it is formed of feveral oblong ones, all joined together, and reprefenting the branches of fome of the fucufes, only they are shorter; and these are all hollow and full of water, in the fame manner as the fingle globes of the common kind. This has, by way of root, certain fine and flenider filamenta, which fatten it to the stones or shells near which it is produced; and it is of a dulky greenish colour on the surface, of a fine blufh green within. The surface, viewed by the microscope appears rough, as in the other; and the glandules are of the fame kind, and are always found full of clear water. See Corallines.

Oration, in rhetoric, a speech or harangue, composed according to the rules of oratory, but spoken in public. Orations may be reduced to three kinds viz. the demonstrative deliberative, and judicial. To the demonstrative kind belong panegyrics, genethliaca, epithalama, congratulations, &c. To the deliberative kind belong periphrasis, exhortation, &c. And to the judicial kind belong accusation, condemnation, &c.

Funeral Oration. See Pompous Oration.

Orator, among the Romans, differed from a patruus: The latter was allowed only to plead caufes on behalf of his clients; whereas the former might quit the forum and ascend the rostra or tribunal, to harangue the senate or the people. The orators had rarely a profound knowledge of the law, but they were eloquent, and their style was generally correct.

Vol. XIII.
**ORA**

Orator. and concise. They were employed in causes of importance, instead of the common patrons. Orators, in the violence of eloquence, used all the warmth of gesture, and even walked backwards and forwards with great heat and emotion. This it was which occasioned a criticism of Flavius Virginius, who asked one of those walking orators, *Quot milius paullum declamasset?* “How many miles he had declaimed?” Similar to the Roman orators were the Grecian Rhetors. See Rhetoric.

Public Orators, an office of very considerable dignity, and of some emolument in the English universities.

The public orator is the principal, and in many cases the only ostensible, agent, for the university in all those matters or forms which are merely external. He carries on or superintends all correspondences which are calculated to promote the dignity, or raise the utility, of the seminary which he presides over them. Hence it is well known, that the Greeks made their orators like wise of other arts, and supposed that they presided over them. Hence they gave Mercury the titles of App., and Epmn, both which names come from words that signify “to speak.” And Aristotle calls eloquence *the gift of Mercury;* and for the same reason anciently the tongue was consecrated to him. He was likewise said to be the interpreter or messenger of the gods; which office very well suited him, as he excelled in eloquence. Hence we read in the Sacred Writings, that when the people of Lydium took Barmabas and Paul for gods in human shape, because of that sudden and surprizing cure which was wrought upon the lame man, they called Barmabas *Jupiter,* and Paul *Mercury;* for this reason, as the inspired writer tells us, “because he was the chief speaker;” that is (as the speech was then thought), the interpreter or spokesman of Barmabas.

But to pass over these fictions of the heathen deities, let us hear what Quintilian says of the *orator* of this art; who seems to give a very probable account of it in the following passage. “The faculty of speech...
Introd.

lays he) we derive from nature (a); but the art from observation. For as in physis, m.n., by seeing that some things promote health and others destroy, formed the art upon those observations: in like manner, by perceiving that some things in discourse are laid to advantage, and others not, they accordingly marked those things, in order to imitate the one and avoid the other. They also added some things from their own reason and judgment, which, being confirmed by use, they began to teach others what they knew themselves. But no certain account can be given when or by whom, this method of observation first began to take place. And Aristotle fuppôsed, not without reason, that the first improvements of the art were very rude and imperfect. Pausanias, indeed, in his Description of Greece, tells us, that Pittthus, the uncle of Theatus, taught it at Tezene a city of Peloponnesus, and wrote a book concerning it; which he read himself, as it was published by one of Epidaurus. But as Pittthus lived about 1000 years before Pausanias, who flourished in the time of the emperor Hadrian, some are of opinion he might be imposed upon by the Epidaurian, who published this book under the name of Pittthus. But be that as it will, it is very reasonable to believe, that the Greeks had the principles of this art so early as the time of Pittthus. For Theatus his nephew lived not long before the taking of Troy, which, according to Sir Isaac Newton, happened 904 years before the birth of Christ; at which time Cicero thought it was in much esteem among them. ’Homer (says he) would never have given Ulysses and Nestor in the Trojan wars so great commendations on account of their speeches (to one of whom he attributes force, and to the other sweetness of expression), if eloquence had not in those times been in great repute.’ And left any one should imagine, that in those days they made use only of such help as nature and practice could afford them, the same poet informs us, that Peleus sent Phenix with his son Achilles to the Trojan war, to instruct him not only in the art of war, but likewise of eloquence. But who were the professors of this art for some ages following is not known. For Quintilian says, that afterwards Empedocles is the first upon record who attempted any thing concerning it. And he, by Sir Isaac Newton’s account, flourished about 500 years after Troy was taken. At which time, as Cicero observes, men being now sensible of the powerful charms of oratory, and the influence it had upon the mind, there immediately arose several masters of it; the chief of whom are mentioned by Quintilian, who tells us, that ‘the oldest writers upon this art are Corax and Tisias, both of Sicily. After them came Gorgias of Leontium in the same island, who is said to have been the scholar of Empedocles, and by reason of his great age (for he lived to be 109 years old) had many contemporaries. Thrasymachus of Chalcedon, Proclus of Cea, Protagoras of Abdera, Hippias of Elis, and Aëcidamus of Elea, lived in his time; as likewise Antiphon, who first wrote orations, and into upon the art, and is said to have spoken admirably well in his own defence: and besides them, Polybius, and Theodore of Byzantium. These persons contributed different ways towards the improvement of the art. Corax and Tisias gave rules for methodizing a discourse, and adjusting its particular parts: as may be conjectured from Cicero’s account of them, who says, ‘Though some had spoken well before their time, yet none with order and method.’ But Gorgias seems to have excelled all the rest in fame and reputation: for he was so highly applauded by all Greece, that a golden statut was erected to him at Delphi, which was a distinguishing honour conferred upon him only. And he is said to have been so great a master of oratory, that in a public assembly he would undertake to decline immediately upon any subject, proposed to him. He wrote, as Cicero informs us, in the demonstrative or laudatory way; which requires most of the sublime, and makes what Diodorus Siculus says of him the more probable, that ‘he first introduced the strongest figures, members of periods opposite in sense, of an equal length, or ending with a like sound and other ornaments of that nature.’ And hence those figures, which give the greatest force and latitude to a discourse, were anciently called his name. Cicero tells us further, that Thrasymachus, and Gorgias were the first who introduced numbers into prose, which irritated afterwards brought to perfection. Quintilian likewise mentions Protagoras, Gorgias Proclus, and Thrasymachus, as the first who treated of common places, and shewed the use of them for the invention of arguments. Nor must we omit Plato, whose elegant dialogue upon this subject is still extant, which he intitules Gorgias. For though he does not lay down the common rules of the art; yet he very well explains the nature of it, and maintains its true end and use against the generality of its professors, who had greatly perverted the original design of it. Thus by the study and industry of so many and ingenious and great men, the art of oratory was then carried to a considerable height among the Greeks. Though many of these who professed it in those times employed their skill rather to promote their own reputation and applause, than to serve the real interests of truth and virtue. ‘For they proposed in an arrogant manner (as Cicero says) to teach how a bad cause might be so managed, as to get the better of a good one.’ That is, they would undertake to charm the ears and strike the passions of their hearers in so powerful a manner, by sophistical reasonings, turns of wit, and fine language, as to impose falsehood upon them for truth; than which nothing could be either more diisingenuous in itself, or prejudicial to society. But these who succeeded them seem to have consulted better, both for their own honour and that of their profession. If crates was the most renowned of

(a) If Quintilian meant that the human race speak an articulate language by nature or instinct, he certainly deceived himself (see LANGUAGE); but if his meaning was only that men have from nature a capability of speech, the observation is true but not of much value. Parrots and other birds have a capability of uttering articulate sounds.
all Gorgias's scholars, whom Cicero frequently extols with the highest commendations, as the greatest master and teacher of oratory: "whole school (as he says) like the Trojan horse, sent forth abundance of great men." Aristotle was chiefly induced to engage in this province from an emulation of his glory; and would often say in a verile of Sophocles, somewhat varied to his purpose.

To be silent it is a shame; while Icocrates gets such fame. Quintillian says they both wrote upon the art, though there is no system of the former now extant. But that of Aristotle is esteemed the best and most complete of any in the Greek language. In this age the Cretian eloquence appeared in its highest perfection. Demosthenes was an orator both of Icocrates and Plato, as also of Isocrates (ten of whole orations are yet extant); and by the assistance of a surprizing genius, joined with indefatigable industry, made that advantage of their precepts, that he has been always esteemed by the best judges the prince of Cretian orators. His great adversary and rival, Euphrates, after his banishment, is said to have gone to Rhodes, and employed his time there in teaching of rhetoric. Theodorus and Theophratus, both of them scholars of Aristotle, imitated their master in writing upon the art. And from that time the philosophers, especially the Stoics and peripatetics, applied themselves to lay down the rules of oratory; which Socrates had before separated from the province of a philosopher. And there is yet preserved a treatise upon this subject, which some have attributed to Demetrius Phalerus the peripatetic, and one other of Theophratus, though others more probably to Dionysius of Halicarnassus. Quintilian mentions several other famous rhetoricians in the following ages, who were likewise writers; as Hermagoras, Athenagoras, Apollonius Molon, Areus Cecilius, Dionysius of Halicarnassus, Apollonius of Fergamus, and Theodore of Gadara. But of these nothing now remains upon the subject of oratory, except some tracts of Dionysius, who flourished in the reign of Augustus Caesar. Nor have there been wanting some eminent writers of this kind among the Greeks since the time of Quintilian; two of whom we cannot omit to mention, Hermogenes, and Longinus the author of the incomparable treatise Of the Sublime, a book which can scarce be too much commended; or too often read. It was long before Rome received this art, and not without difficulty at first. The reason was, because the Romans were for several ages wholly addicted to military affairs, and to enlarge their territories; so that they were not only neglected to cultivate learning, but though the pursuit of it a thing of ill tendency, by diverting the minds of their youth from the cares and toils of war, to a more soft and indolent kind of life. Therefore so late as the year of their city 592, when by the industry of some Grecians the liberal arts began to flourish in Italy, a decree passed the senate, by which all philosophers and rhetoricians were ordered to depart out of Rome. But in a few years after, when Corneades, Critoelus, and Diogenes, who were not only philosophers but orators, came ambassadors from Athens to Rome. The Roman youth were so charmed with the eloquence of their languages, that they could no longer be kept from pursuing the study of oratory. And by a further acquaintance with the Greeks, it soon gained such esteem, that persons of the first quality employed their time and pains to acquire it. And a young gentleman, who was ambitious to advance himself in the service of his country, could have little hopes of success, under he had laid the foundation of his future prospects in this study.

Seneca tells us, that Lucius Plotinus, a Gaul, was the first who taught the art of oratory at Rome in Latin; which Cicero says, was while he was a boy, and when the most studious persons went to bear him he lamented that he could not go with them; being prevented by the regard he paid to the opinion of some of his friends, who thought that greater improvements were made by exercises in the Greek language under Cretian masters. Seneca adds, that this profession continued for some time in the hands of freedmen; and that the first Roman who engaged in it was Blan­ dus of the equestrian order, who was succeeded by others; some of whose lives are yet extant, written by Suetonius, as many of the Grecians are by Philo­ ratus and Eunapius. Quintilian likewise gives us the names of those among the Romans, who wrote upon the art. "The first (says he), as far as I can learn, who composed anything upon this subject, was M. Cato the censor. After him Anthony the orator began upon this subject, which is the only work he has left, and that imperfect. Then followed some of less note. But he who carried eloquence to his height in this pitch among us, was Cicero; who has likewise by his rules given the best plan both to practice and teach the art. After whom modesty would require us to mention no more, had he not told us himself, that his books of rhetoric slip out of his hands whilst he was but a youth. And those better things, which many persons want, he has purposely omitted in his discourses of oratory. Cornificius wrote largely upon the same subject; Stertinius and Gallo the father, each of them something. But Celfius and Lennas were more accurate than Gallo; and in our times Virginius, Pliny, and Rutilius. And there are at this day some celebrated authors of the same kind, who, if they had taken in every thing, might have saved my pains." Time has since deprived us of most of the writers mentioned here by Quintilian. But we have the lefs reason to regret this loss, since it has preferred to us Cicero's treatises upon this subject; which we may well suppose to have been chiefly owing to their own excellence, and the great esteem they have always had in the world. Besides his Two Books of Invention, which Quintilian here calls his Books of Rhetoric, there are extant of his, Three Books of an Orator; one of famous Orators; and another, which is called The Orator; as also his Topics, a preface Concerning the chief art of Ora­ torit, and a treatise Of the parts of Oratory. Each of which treatises, whether we regard the judiciousness and delicacy of the thoughts, the usefulness of the rules, or the elegance and beauty of the style, deserves to be frequently perused by all who are lovers of eloquence. For who can be thought so well qualified to give the rules of any art, as he who excelled all mankind in the practice of it? But those Four books to Herennius, which are published among Cicero's works, seem with good reason to be attributed to Cornificius, whom Quin-
Quintilian here mentions, and Cælius is by some affirmed to have taught oratory, whom he also places among the rhetoricians, and whose Eight Books of Oratory are yet extant, written in so beautiful a style as plainly shows him to be a master of eloquence. But Quintilian himself outdid all who went before him in diligence and accuracy as a writer. His Institutes are so comprehensive, and written with such great exactness and judgment, that they are generally allowed to be the most perfect work of the kind. With this excellent author we shall finish the account of the Latin rhetoricians.

There were indeed some others in the following ages, whose works are yet extant; but as they contain nothing of moment which is not to be found in those already mentioned, we shall forbear to name them. Much less shall we defend to that numerous body of writers, who since the revival of learning have treated upon this subject, for the same reason. And a very good judge* has not long since given it as his opinion, that the method of forming the best style of oratory, is to collect it from the chief precepts of Aristotle, Cicero, Quintilian, Longinus, and other celebrated authors: with proper examples taken from the choicest parts of the purest antiquity. And this is the method attempted to be purposed in the following treatise.

§ 2. Of the Nature of Oratory.

The terms rhetoric and oratory, having no other difference but that one is taken from the Greek language and the other from the Latin, may be used promiscuously; but the cæle is not the same with respect to the words rhetoric and orator. For although the Grecians used the former, both to express those who taught the art, and those who practised it, yet the Romans afterward, when they took that word into their language, confined it to the teachers of the art, and called the rest orators. And there seems to be a sufficient reason for this distinction, since the art was the same in both, and might therefore go by either name: but the different province of rhetoricians and orators made it not improper that they should be called by different names. Besides, anciently, before rhetoric was made a separate and distinct art from philosophy, the fame persons taught both. And then they were called not only rhetoricians but sophists. But because they often employed their art rather to vindicate what was false and unjust, than to support truth and virtue; this diëgenous conduct, by which they frequently impoied upon weak minds, brought a disadvantage both upon themselves and their profession. And therefore the name sophist or sophiker, has been more generally used in an ill sense, to signify one skilled rather in the arts of caviling, than qualified to speak well and accurately upon any subject.

It is not necessary to use many words, to prove that oratory is an art. For it is comprised under certain rules, agreeable to reason, delivered in a regular method, and fitted to attain the end it proposeth; which are characters sufficient to denominate it an art. Indeed the cæle is the same here as in most other things, that a good genius is of itself more serviceable than the most exact acquaintance with all the rules of art where that is wanting. But it is sufficient that art help nature, and carry it further than it can otherwise advance without it. And he who is desirous to gain the reputation of a good orator, will find the assistance of art very necessary. Some persons have thought, that many of the common systems written upon the subject of oratory have been attended with this inconvenience, that, by burdening the mind with too great a number of rules about things of less importance, they have oftentimes rather discouraged than promoted the study of eloquence. This undoubtedly is an extreme which should be always carefully avoided. But, however, an indifferent guide in a strange road is better than none at all. It may be worth while to hear Quintilian's opinion upon this head. "I would not (says he) have young persons think they are insufficiently instructed, if they have learned one of those compends which are commonly handed about, and fancy themselves safe in the decrees, as it were, of these technical writers. The art of speaking requires much labour, constant study, a variety of exercise, many trials, the greatest prudence, and readiness of thought. However, these treatises are useful, when they fix you in a plain and open way, and do not confine you to one narrow track, from which we who think it a crime to depart mult move as slowly as one that walks upon a rope." We see he is not for having us confine ourselves too closely to systems, though he thinks they are of service at first, till use and experience render them less necessary.

The business of oratory is to teach us to speak well; the object which, as Cicero explains it, is to speak justly, methodically, floridly, and copiously.

Now, in order to speak justly, or pertinently, a person must be master of his subject, that he may be able to say all that is proper, and avoid whatever appears foreign and trifling. And he must clothe his thoughts with such words and expressions as are most suited to the nature of the argument, and will give it the greatest force and evidence.

And as it teaches to speak justly, so likewise methodically. This requires, that all the parts of a discourse be placed in their proper order, and with such just connection, as to reflect a light upon each other, and thereby to render the whole both clear in itself, and easy to be retained. But the same method is not proper for all discourses. And very frequently a different manner is convenient in handling the same subject. For it is plain, that art, as well as nature, loves variety; and it discovers the speaker's judgment, when the disposition of his discourse is fo framed, as to appear easy and natural, rather than the effect of industry and labour.

To speak floridly is so peculiar a property of this art, that we have wholly confined it to the pomp and ornaments of language. But that it extends farther, and respects things as well as words, we shall have occasion to show hereafter. It contains indeed the whole subject of eloquence, but does not solely confit in it. True and bold eloquence requires not only the beauties and flowers of language, but likewise the belt fence and clearest reasoning. Besides, rhetoric give rules for the several sorts of style, and directs the use of them agreeably to the nature of the subject.

But the force of oratory appears in nothing more than
than a copiousness of expression, or a proper manner
of enlargement, suited to the nature of the subject
which is of great use in perfusion, and forms the last
property required by Cicero, of speaking well. A
short and concise account of things is often attended
with obscurity, from an omission of some necessary cir-
cumstances relating to them. Or, however, where that
is not the case, yet for want of proper embellishments
to enliven the discourse, and thereby to excite and fix
the hearers attention, it is apt to slip through their
minds without leaving any impression. But where the
images of things are drawn in their full proportion
painted in their proper colours, fit in a clear light,
and represented in different views, with all the stren-
gh and beauties of eloquence, they captivate the minds of
the audience with the highest pleasure, engage their
attention, and by an irresistible force move and bend
them to the design of the speaker.

The principal end and design of oratory is to per-
suade: for which reason it is frequently called the art
of persuasion. Indeed the orator has often other sub-
ordinate views; as when he endeavours either to de-
light his hearers with what is pleasant and agreeable,
or to convince their good opinion by a smooth and
artful address; but still both these are in order to per-
suade and excite them to action.

An objection, may, perhaps hence be formed against
elocution as an art which may be employed for per-
suading to ill as well as good, There is no doubt
that it may; and to reason may also be, and too
often is, employed for leading men into error. But
who would think of forming an argument from this
against the cultivation of our reasoning powers? Rea-
son, eloquence, and every art which ever has been stu-
died among mankind, may be abused, and may prove
dangerous in the hands of bad men: but it were
perfectly childish to contend, that upon this account they
cught to be abolished.

While the orator employs his art in pursuing only
these ends for which it was at first designed, the per-
suading men to good and virtuous actions, and dif-
quenting them from every think that is ill and viceus
nothing can be more commendable in itself, or useful
to human societie.

§ 3. Of the Division of Oratory.

Oratory consists of four parts; invention, dispo-
sition, elocution, and pronunciation. This will appear four parts
by considering the nature of each of them and what
it contributes in forming an orator. Every one who
aims to speak well and accurately upon any subject,
does naturally in the first place inquire after and pur-
tue such thoughts as may seem most proper to explain
and illustrate the thing upon which he designs to dis-
course. And if the nature of it requires that he should
bring reasons to confirm what he says, he not only
seeks the strongest, and such as are like to be best re-
ceived; but also prepares to answer any thing which
may be offered to the contrary. This is invention.—
After this he deliberates with himself what method
to dispose of those things which have occurred to his
mind, that they may appear in the plainest light, and
not lose their force by disorder and confusion. This
is the business of disposition.—His next concern is to
give his thoughts an agreeable drefs; by making
choice of the fittest words, clearest expressions, smooth
and harmonious periods, with other ornaments of style,
as may best suit the nature of his subject, brighten his
discourse, and render it most entertaining to his hear-
ers. And this is called elocution.—The last thing he
attends to, is to deliver what he has thus composed,
with a just and agreeable pronunciation. And daily
experience convinces us, how much this contributes
both to engage the attention and impress what is spo-
ken upon the mind. This then is the method to which
nature directs, in order to qualify ourselves for discur-
sing to the best advantage: Though by custom and
habit these things become so familiar to us, that we
do not always attend to them separately in their na-
tural order. However, it is the business of art to fo-
low nature, and to treat of things in that manner which
the dictates.

Part I. Of Invention.

Chap. I. Of Invention in general; and particularly

Invention, considered in general, is the discovery
of such things as are proper to persuade. And
in order to attain this end, the orator proposes to him-
self three things: To prove or illustrate the subject up-
on which he treats; to conciliate the minds of his hear-
ers; and to engage their passions in his favour.
And as these require different kinds of arguments or mo-
tives, invention furnishes him with a supply for each
of them, as will be shown in their order.

An argument, as defined, by Cicero, is a reason
which induces us to believe what before we doubted of.
And as different kinds of discourses require different
arguments, rhetoricians have considered them two
ways; in general, under certain heads, as a common
fund for all subjects; and in a more particular manner,
as they are suited to demonstrative, deliberative, or ju-
dicial discourses. At present we shall treat only upon
the former of these. And now, that one thing may
receive proof and confirmation from another, it is ne-
cessary that there be some relation between them; for
all things are not equally adapted to prove one an-
other. Thus, in measuring the quantity of two things
which we would show to be either equal or unequal,
if they are of such a nature that one cannot be applied
to the other, then we take a third thing, which may
be applied to them both; and that must be equal at
least to one of the two, which if applied to the other,
and found equal to that also, we presently conclude
that these two things are equal; but if it be unequal
to the other, we say that these two things are un-
equal. Because it is the certain any known property
of all quantities, that whatsoever two things are equal
to a third, are equal to one another; and where one
of any two things is equal to a third, and the other
unequal, those two things are unequal to one another.
What has been said of quantities, will hold true in all
other causes, that so far as any two things or ideas
agree
Part I.

Invention.

agree to a third, so far they agree to one another. So likewise, on the contrary, as far as one of any two things or ideas does agree to a third, and the other does not, so far they disagree with one another; in which respect, one of them cannot be truly affirmed of the other. Since, therefore in every proposition, one thing is spoken of another, if we would find out whether the two ideas agree to each other or not, where this is not evident of itself, we must find out some third thing, the idea of which agrees to one of them: and then that being applied to the other, as it does agree or disagree with it, so we may conclude, that the two things proposed do agree or disagree with one another. This should be made more clear by an example or two. Should it be inquired, *whether virtue is to be loved;* the agreement between virtue and love might be found by comparing them separately with happiness, as a common measure to both. For since the idea of happiness agrees to that of love, and the idea of virtue to that of happiness; it follows, that the ideas of virtue and love agree to one another; and therefore it may be affirmed, *that virtue is to be loved.* But on the contrary, because the idea of misery disagrees with that of love, but the idea of virtue agrees to that of misery, the two ideas of vice and love must consequently disagree with one another; and therefore it would be false to affirm, *that vice is to be loved.*

Now, this third thing logicians call the *medium, or middle term,* because it does as it were connect two extremes; that is both parts of a proposition. But rhetoricians call it an *argument,* because it is so applied to what was before proposed, as to become the instrument of procuring our assent to it. Thus far as is the nature and use of arguments. We shall next explain by what methods they are to be sought.

A lively imagination, and readiness of thought, are undoubtedly a very great help to invention. Some persons are naturally endued with that quickness of fancy, and penetration of mind, that they are seldom at a loss for arguments either to defend their own opinions, or to attack their adversaries. However, these things being the gift of nature, and not to be gained by art, do not properly fall under our present consideration.

It will be readily granted, that great learning and extensive knowledge are a noble fund for invention. An orator therefore should be furnished with a flock of important truths, solid maxims of reason, and a variety of knowledge, collected and treasured up both from observation and a large acquaintance with the liberal arts; that he may not only be qualified to express himself in the most agreeable manner, but likewise to support what he says with the strongest and clearest arguments.

But because all are not born with a like happy genius, and have not the same opportunity to cultivate their minds with learning and knowledge; and because nothing is more difficult than the finding out the strongest arguments, which may be offered for and against it; upon these accounts, art has prescribed a method to leaven, in some measure, these difficulties, and help every one to a supply of arguments upon any subject. And this is done by the contrivance of common places, which Cicero calls the *feits or heads of arguments,* and by a Greek name *topics.* They are of two sorts, *internal and external.*

1. Internal topics. Though things, with regard to their nature and properties, are exceedingly various, yet they have certain common relations, by means whereof the truth of what is either affirmed or denied concerning them in any respect may be evinced. The ancient Greek rhetoricians therefore reduced these relations to some general heads, which are termed *loci or common places;* because the reasons or arguments fitted to prove any proposition are repeated in them, as a common fund or receptacle. And they are called *internal heads,* because they arise from the subject upon which the orator treats; and are to, be referred distinguished from others named *external,* which he fetches from without, and applies to his present purpose, as will be shown hereafter. Cicero and Quintilian make them 16; three of which comprehended the whole thing they are brought to prove, namely, *definition, enumeration,* and *notation:* of the remaining 13, some contain a part of it, and the rest its various properties and circumstances, with other considerations relating to it; and these are, *genus species, antecedents, consequents, adjunctions, causes, effects, contrariety, opposites, simplicity, and dissimilitude, comparison.*

*Definition* explains the nature of the thing defined, and shows what it is. And to whatsoever the definition agrees, the thing defined does so likewise. If, therefore Socrates be a rational creature, he is a man; because it is the definition of a man, that he is a rational creature.

*Enumeration* takes in all the parts of a thing. And from this we prove, that what agrees to all the parts agrees to the whole; and what does not agree to any one or more parts, does not agree to the whole: As when Cicero proves to Piso that all the Romans hate him, by enumerating the several ranks and orders of Roman citizens who all did so.

*Notation,* or etymology, explains the meaning or signification of a word. From which we reason thus: "If he cannot pay his debts, he is insolvent;" for that is the meaning of the word insolvent.

*Genus* is that which contains under it two or more sorts of things, differing in nature. From this head logicians reason thus: "Because every animal is mortal, and man is an animal, therefore man is mortal." But orators make a further use of this argument, which they call *ascending from the hypothesis to the thesis;* that is, from a particular, to a general: As should a person, when speaking in praise of justice, take occasion from thence to commend and show the excellency of virtue in general, with a view to render that particular virtue more amiable. For since every species contains in it the whole nature of the genus to which it relates besides what is peculiar to itself, whereby it is distinguished from it; what is affirmed of the genus, much of excellency is applicable to the species.

*Species* is that which comprehends under it all the individuals of the same nature. From hence we may argue, "He is a man, therefore he has a rational soul." And orators sometimes take occasion from this head to descend from the thesis to the hypothesis.
that is, in treating upon what is more general, to
introduce some particular contained under it, for the
greater illustration of the general.

Antecedents are such things, as, being once allowed,
others necessarily, or very probably, follow. From this
head an insepable property is proved from its subject;
as, It is material, and therefore corruptible.

Consequent are such things as, being allowed neces-
sarily or very probably infer their antecedents. Hence
the subject is proved from an inseparable property, in
this manner: It is corruptible and therefore material.

Adjuncts are separable properties of things, or cir-
cumstances that attend them. These are very numero-
sous, and afford a great variety of arguments, some of
which usually occur in every discourse. They do
not necessarily infer their subject; but, if at once chosen,
render a thing credible, and are a sufficient ground for
belief. The way of reasoning from them we shall all
now presently.

Conjuncts are words deduced from the same origin
with that of our subject. By these the habit is proved
from its acts: He who does justly is just. He does
not act wisely, therefore he is not wise. But this infe-
ence will not hold, unless the actions appear continu-
ed and constant.

A cause is that, by the force of which a thing does
exist. There are four kinds of causes, matter, form,
efficient and end, which afford a great variety of argu-
ments. The way of reasoning from them is to infer
the effect from the cause: as, Man is endowed with
reason therefore he is capable of knowledge.

An effect is that which arises from a cause: there-
fore the cause is proved by it: as, He is endowed with
knowledge, therefore with reason.

Contraries are things, which under the same genus,
are at the utmost distance from each other; so that
what we grant to the one, we utterly deny the other:
as, Virtue ought to be embraced, therefore vice should
be avoided.

Opposites are such things, which, though repugnant
to each other; yet are not directly contradictory: as
to love and to injure, to hate and to commend. They
differ from contraries in this, that they do not abso-
lutely exclude one another. An argument is drawn
from things repugnant, thus: He will do a man a mis-
chief, therefore he does not love him. He loves a man
therefore he will not reproach him.

Similitude is an agreement of things in quality.
Thus Cicero proves, that pernicious citizens ought to
be taken out of the state; by the likeness they bear
to corrupted members, which are cut off to prevent
further damage to the body.

Diffimilitude is a disagreement of things in quality.
Cicero from this head shows the preference of his own
exile to Piso’s government of Macedonia; by the dif-
ference between their conduct, and the people’s esteem
of them.

Comparison is made three ways: for either a thing
is compared with a greater, with a less, or with its
equal. This place, therefore, differs from that of simi-
litude on this account, that the quality was con-
dered in that, but here the quantity. An argument
from the greater is thus drawn: If five legions could
not conquer the enemy, much less will two.

We shall now give one example of the manner of
reasoning from these heads, whereby the use of them
may further appear. If any one, therefore, should
have endeavoured to persuade Cicero not to accept of
his life upon the condition offered him by Antony;
That he would burn his Philippic orations which had
been spoken against him, he might be supposed to
use such arguments as these; partly taken from the
adjuncts of Cicero, partly from those of Antony, and
partly from the thing itself. And first with regard to
Cicero; it might be said, That so great a man ought
not to purchase his life at so dear a price as the loss
of that immortal honour which by so great pains and
labour he had acquired. And this might be confirmed,
by another argument. That now he was grown old,
and could not expect to live much longer. And from
the character of Antony might argue thus: That he
was very crafty and deceitful; and only designed, by
giving him hopes of life, to have the Philippi’s fire
burnt, which otherwise he knew would transmit to
posterity an eternal brand of infamy upon him; and
then he would take off the author. And this might
be shown by comparison. For since he would not
spare others, who had not so highly exasperated him,
and from whom he had not so much to fear; cer-
tainly he would not forgive Cicero, since he knew
well enough, that so long as he lived, he himself
could never be in safety. And, lastly, an argument
might also be fetched from the nature of the thing
itself, in the following manner: That Cicero by this
action would shamefully betray the state, and the
cause of liberty, which he had through his whole life
most courageously defended, with so great honour to
himself, and advantage to the public. Upon such an
account, a person might have used these or the like argu-
ments with Cicero, which arise from the foregoing
heads.

From this account of common places, it is easy to
conceive what a large field of discourses they open to
the mind upon every subject. At the same time, though
we have mentioned them from our respect for the ora-
tors of Greece and Rome, we heartily subscribe to the
opinion of a celebrated modern, who gives them the
following account.

“The Grecian sophists were the first inventors of this
artificial syllem of Oratory; and they showed a pro-
digious fulbility and fertility, in the contrivance of
their loci. Succeeding rhetoricians, dazzled by the
plan, wrought them into so regular a syllem, that
one would think they meant to teach how a person
might mechanically become an orator, without any
genius at all. They gave him receipts for making
speeches on all manner of subjects. At the same time,
it is evident, that though this study of common places
might produce very flowery and academical declama-
tions, it could never produce useful discourses on real
business. The loci indeed supplied a most exuberant
secundity of matter. One who had no other aim, but
to talk copiously and pleasurably, by confuting them on
every subject, and laying hold of all that, they figurat-
ively might discourse without end; and that, too, though
he had none but the most superficial knowledge of the
subject. But such discourse could be no other than tri-
ivial. What is truly solid and persuasive, must be
drawn from the more solid cause, from a thorough knowledge
of the subject, and profound meditation on it. They
who
I. Of external topics. When the orator reasoneth on such topics as do not arise from his subject, but from things of a different nature, these are called external. They are all taken from authorities, and are by one general name called Telfimoniæ.

Now a testimony may be exprest by writing, speech, or any other sign proper to declare a person's mind. And all testimonies may be distiguisht into two sorts, divine and human. A divine testimony, when certainly known to be such, is incontestable, and admits of no debate, but should be acquiesced in without hesitation. Indeed the ancient Greeks and Romans esteemed the pretended oracles of their deities, the answers of their augurs, and the like fallacies, divine testimonies: but with us no one can be ignorant of their true notion, though they do not so directly come under our present consideration. Human testimonies, condered as furnishing the orator with arguments, may be reduced to three heads; writings, writings, writings, and contracts.

A writing is then said to be ambiguous, when it is capable of two or more senses, which makes the writer's design uncertain. Now ambiguity may arise either from single words, or the constriction of sentences. From single words; as when either the sense of a word, or the application of it, is doubtful. As, should it be questioned, whether money ought to be included under the word has been used. The business of the defendant, on the other hand, is to refute this by showing that money is not there included. And if either side produce precedents in his favour, the other may endeavour to shew that the cases are parallel. As to the second case, arising from an ambiguity in the word, if any other invention, words or expressions in the will seem to countenance either of the claimants, he will not fail to interpret them to his advantage. So likewise, if anything left by the testator, in his lifetime, or any regard shown to either of these nephews more than the other, may help to determine which of them was intended, a proper rule may be made of it. And the same may be laid with regard to the third case. In which the legatee may reason likewise from the common use of language and show that in such expressions it is usual to make the reference to the left or next antecedent; and from thence plead that it was the design of the testator to give him the option. But in answer to this it may be said, that allowing it to be very often so, yet in this instance it seems more easy and natural to repeat the verb give after pleases, and fo to supply the sentence, which he pleases to give him, referring it to the heir, than to bring in the verb chooseth, which was not in the sentence before; and so, by supplying the sense, which he pleases to choose, to give the option to Titius. But where controversies of this kind arise from a law, recourse may be had to the laws where the same thing has been exprest with greater clearness; which may help to determine the sense of the passage in dispute.

A second controversy from writings is, when one party adheres to the words, and the other to what he afferts was the writer's intention. Now he who opposes the literal sense, either contends, that what he himself offers is the simple and plain meaning of the writing, or that it must be so understood in the particular case in dispute. An instance of this is, as we find it in Cicero. A person who died without children, but left a widow, had made this provision in his will: "If I have a son born to me, he shall be my heir." And a little after: "If my son die before he comes of age, let Curius be my heir." There is no son born: Curius therefore sues for the estate, and pleads the intention of the testator, who designed him for his heir, if he should have no son who arrived at age; and says, there can be no reason to suppose he did not intend the same person for his heir if he had no son, as if he should have one who afterwards died in his minority. But the heir at law in fits upon the words of the will: which, as he says, require, that first a son should be born, and afterwards die under age, before Curius can succeed to the inheritance; and there being no son, a substituted heir, as Curius was, can have no claim where the first heir, does not exist, from whom he derives his pretension and was to succeed by the appointment of the will. Of the latter case, ancient writers give this example: "It was forbidden by a law to open the city-gates in the night. A certain person notwithwithstanding, in time of war, did open them in the night, and let in some auxiliary troops, to prevent their being cut off by the enemy, who was posted near the town." Afterwards, when the war was over, this person is arraigned, and tried for his life on account of this action. Now, in such a case, the prosecutor founds his charge upon the express words of the law; and pleads, that no sufficient reason can be assigned for going contrary to the letter of it, which would be to make a new law, and not to execute one already made. The defendant, on the other hand alleges, That the fact is charged

VOL. X. III.
That all such exceptions as are intended by any law, are usually expressed in it; and instances may be brought of particular exceptions expressed in some laws; and if there be any such exceptions in the law under debate, it should especially be mentioned. He may further add, That to admit of exceptions not expressed in the law itself, is to enervate the force of all laws, by explaining them away, and in effect to render them useless. And this he may further corroborate, by comparing the law under debate with others, and considering its nature and importance, and how far the public interest of the state is concerned in the due and regular execution of it; from whence he may infer, that should exceptions be admitted in other laws of less consequence, yet however, they ought not in this. Lastly, he may consider the reason alleged by the defendant, on which he founds his plea, and show there was not that necessity of violating the law in the present case, as is pretended. And this is often the more requisite, because the party who disputes against the words of the law, always endeavours to support his allegations from the equity of the case. If, therefore, this plea can be enervated, the main support of the defendant’s cause is removed. For as the former arguments are designed to prevail with the judge, to determine the matter on this side the question from the nature of the case; so the intention of this argument is to induce him to it, from the weakness of the defence made by the opposite party. But the defendant will on the contrary, use such arguments as may best demonstrate the equity of his cause, and endeavour to vindicate the fact from his good design and intention in doing it. He will say, That the laws have allotted punishments for the commission of such facts as are evil in themselves, or prejudicial to others: neither of which can be charged upon the action for which he is accused: That no law can be rightly executed, if more regard be had to the words and syllables of the writing, than to the intention of the legislator. To which purpose, he may allege that direction of the law itself, which says, “The law ought not to be too rigorously interpreted, nor the words of it strained; but the true intention and design of each part of it duly considered.” As also that saying of Cicero, “That law which might not be weakened and destroyed, if we bend the sense to the words, and do not regard the design and view of the legislator.” Hence he may take occasion to complain of the hardship of such a procedure, that no difference should be made between an audacious and wilful crime, and an honest or necessary action, which might happen to disapprove with the letter of the law, though not with the intent of it. And as it was observed before to be of considerable service to the accuser, if he could remove the defendant’s plea of equity, so it will be of equal advantage to the defendant, if he can fix upon any words in the law, which may in the least seem to countenance his case since this will take off the main force of the charge.

The third controversy of this kind is, when two writings happen to clash with each other, or at least seem to do so. Of this Hermogenes gives the following instance. One law enjoins: “He who continues alone in a ship during a tempest, shall have the property of the ship.” Another law says, “A disinherited son shall enjoy no part of his father’s estate.” Now a son, who had been disinherited by his father, happens to be in his father’s ship in a tempest, and continues there alone when every one else had deserted it. He claims the ship by the former of those laws and his brother tries his right with him by the latter. In such cases, therefore, it may first be considered, “Whether the two laws can be reconciled. And if that cannot be done, then, Which of them appears more equitable. Also, Whether one be positive and the other negative: because prohibitions are a sort of exceptions to positive injunctions. Or, If one be a general law, and the other more particular and come nearer to the matter in question. Likewise, Which was last made: since former laws are often abrogated either wholly or in part, by subsequent laws; or at least were designed to be so. Lastly, it may be observed, Whether one of the laws be not plain and express; and the other more dubious, or has any ambiguity in it. All or any of which things, that party will not omit to improve for his advantage whose interest is concerned in it.

The fourth controversy is respecting, As when something, not expressly provided for by a law, is inferred by a similitude, or parity of reason, from what is contained in it. Quintilian mentions this instance of it. “There was a law made at Tarentum, to prohibit the exportation of wool; but a certain person exports sheep.” In this case, the prosecutor may first compare the thing which occasions the charge, with the words of the law, and show their agreement, and how unnecessary it was that particular thing, should have been expressly mentioned in the law since it is plainly contained in it, or at least an evident consequence from it. He may then plead that many things of a like nature are omitted in other laws for the same reason. And lastly, he may urge the reasonableness and equity of the procedure. The defendant, on the other hand, will endeavour to shew the deficiency of the reasoning, and the difference between the two cases. He will infilt upon the plain and express words of the law, and set forth the ill tendency of such inferences and conclusions drawn from similitudes and comparisons, since there is scarce any thing but in some respect may bear a resemblance to another.

The last controversy under this head is interpretation, in which the dispute turns upon the true meaning and explication of the law in reference to that particular case. We have the following instance of this in the Pander’s; “A man who had two sons, both under age, substitutés Titius as heir to him who should die last, provided both of them died in their minority. They both perished together at sea before they came to age. Here arises a doubt whether the substitution can take place, or whether the inheritance devolves to the heir at law.” The latter pleads, That as neither of them can be said to have died last, the substitution cannot take place: which was fulminated, upon the condition that one died after the other. But to this it may be said, It was the intention of the testator, that if both died in their infancy, Titius should
makes no difference whether they died together, or one after the other: and so the law determines it.

2. The second head of external arguments are Wite-nesses. These may either give their evidence, when absent, in writing subscribed with their name; or present, by word of mouth. And what both of them testify, may either be from hearsay; or what they saw themselves, and were present at the time it was done. As the weight of the evidence may be thought greater or less on each of these accounts, either party will make such use of it as he finds for his advantage. The characters of the witnesses are also to be considered; and if any thing be found in their lives or behaviour that is justly exceptionable, to invalidate their evidence it ought not to be omitted. And how they are affected to the contending parties, or either of them, may deferve consideration; for some allowances may be judged reasonable in cases of friendship, or enmity, where there is no room for any other exception. But regard should chiefly be had to what they testify; and how far the cause is affected by it. Cicero is very large upon most of these heads in his defence of Marcus Fonteius, with a design to weaken the evidence of the Gauls against him. And where witnesses are produced on one side only, as orators sometimes attempt to lessen the credit of this kind of proof, by pleading that witnesses are liable to be corrupted, or baffled by some prevailing interest or passion, to which arguments taken from the nature and circumstances of things are not subject; it may be answered on the other hand, that sophistical arguments and false colourings are not exposed to infamy or punishment, whereas witnesses are restrained by shame and penalties, nor would the law require them if they were not necessary.

3. The third and last head of external arguments are Contracts; which may be either public or private. By public are meant the transactions between different states, as leagues, alliances, and the like, which depend on the laws of nations, and come more properly under deliberative discourses, to which we shall refer them. Those are called private, which relate to civil bodies or societies of men, and single persons; and may be either written or oral. And it is not so much the true meaning and purpose of them that is here considered, as their force and obligation. And, as the Roman law declares, "Nothing can be more agreeable to human faith, than that persons should stand to their agreements." Therefore, in controversies of this kind, the party whose interest it is that the contract should be maintained, will plead, that such covenants have the force of private laws, and ought religiously to be observed, since the common affairs of mankind are transacted in that manner: and therefore to violate them, is to destroy all commerce and society among men. On the other side it may be said, that justice and equity are chiefly to be regarded, which are immutable; and besides, that the public laws are the common rule to determine such differences, which are designed to redress those which are aggrieved. And, indeed, where a compact has been obtained by force or fraud, it is in itself void, and has no effect either in law or reason. But on the other hand, the Roman lawyers seem to have very rightly determined, that all such obligations as are founded on natural equity, though not binding by national laws, are there, invention, or custom, to be observed. Such contracts, therefore called melius partes, ought, however, in honour and confidence to be performed.

III. Of the State of a Controversy. The ancients observing that the principal question or point of dispute in all controversies might be referred to some particular head, reduced those heads to a certain number, that both the nature of the quizzion might by that means be better known, and the argument fitted to it be discovered with greater ease. And these heads, they call flutes. By the futes of a controversy, then we are to understand the principal point in dispute between contending parties, upon the proof of which the whole cause or controversy depends. We find it expressed by several other names in ancient writers: as, the constitution of the cause, the general head, and the chief question. And as this is the principal thing to be attended to in every such discourse; so it is what first requires the consideration of the speaker, and should be well fixed and digested in his mind, before he proceeds to look for arguments proper to support it. Thus Anthony, the Roman orator, speaking of his own method in his pleading, says: "When I understand the nature of the cause, and begin to consider it, the first thing I endeavour to do is, to settle with myself what is to which all my discourse relating to the matter in dispute ought to be referred: then I diligently attend to these other two things, How to recommend myself, or those for whom I plead, to the good esteem of my hearers and how to influence their minds, as may best suit my design." This way of proceeding appears very agreeable to reason and prudence. For what can be more absurd, than for a person to attempt the proof of any thing, before he has well fettled in his own mind a clear and distinct notion what the thing is which he would endeavour to prove? Quintilian describes it to be, 'That kind of question which arises from the first conflict of causes.' In judicial cases, it immediately follows upon the charge of the plaintiff, and plea of the defendant. Our common law expresses it by one word, namely the issue. Which interpreters explain, by describing it to be, "That point of matter depending in suit, whereupon the parties join, and put their cause to the trial." Examples will further help to illustrate this, and render it more evident. In the cause of Milo, the charge of the Clodian party is, Milo killed Clodius. Milo's plea or defence, I killed him, but justly. From hence a like this grand question, or state of the cause, Where is it your lawful for Milo to kill Clodius? And that Clodius was lawfully killed by Milo, is what Cicero in his defence of Milo principally endeavours to prove. This is the main subject of that fine and beautiful oration. The whole of his discourse is to be considered as centering at last in this one point. Whatever different matters are occasionally mentioned, will, if closely attended to, be found to have been introduced some way or other the better to support and carry on this design. Now in such cases, where the fact is not denied, but something is offered in its defence, the state of the cause is taken from the defendant's plea, who is obliged to make it good: As in the instance here given, the chief point in dispute was the lawfulness of Milo's action, which it was Cicero's business to demonstrate.
ORATORY.

Invention. But when the defendant denies the fact, the state of the cause arises from the accusation; the proof of which lies upon the plaintiff, and not, as in the former cafe, upon the defendant. So in the cause of Roscius the charge brought against him is, That he killed his father. But he denies the fact. The grand question therefore to be argued is, Whether or not he killed his father? The proof of this lay upon his accusers. And Cicero's design in his defence of him is to show, that they had not made good their charge. But it sometimes happens that the defendant neither absolutely denies the fact, nor attempts to justify it; but only endeavours to qualify it, by denying that it is a crime of that nature, or deserves itself which is a crime of that nature, or deserves itself.

Thus, in the cause of Milo's killing Clodius, which was a crime of that nature, or deserves itself which is a crime of that nature, or deserves itself, Cicero endeavours to prove, that Roscius did not kill his father from two reasons or arguments: Because he had neither any cause to move him to such barbarous action nor any opportunity for it.

Moreover, besides these subordinate questions, there are also incidental ones often introduced, which have some reference to the principal question, and contribute towards the proof of it, though they are not necessarily connected with it, or dependent upon it. And each of these also has its state though different from that of the cause. For every question or point of controversy, must be flated, before it can be made the subject of disputation. And it is for this reason, that every new argument advanced by an orator is called a question because it is considered as a fresh matter of controversy. In Cicero's defence of Milo, we meet with several of this sort of questions, occasioned by some aspersions which had been thrown out by the Clodian party to the prejudice of Milo. As, "That he was unworthy to see the light, who owned he had killed a man?" For Milo before his trial had openly confessed he killed Clodius. So likewise, "That the senate had declared the killing of Clodius was an illegal action." And further, "That Pompey, by making a new law to settle the manner of Milo's trial, had given his judgment against Milo." Now to each of these Cicero replies before he proceeds to the principal question. And therefore though the question, in which the state of a controversy consists, it is said by Quintilian to arise from "the first conflict of causes," yet we find by this influence of Cicero that it is not always the first question in order, upon which the orator treats.

But it sometimes happens, that the same cause or controversy contains in it more than one state. Thus, in judicial causes, every distinct charge occasions a new state. All Cicero's orations against Verres relate to one cause, founded upon a law of the Romans again unjust exactions made by their governors of provinces upon the inhabitants: but as that prosecution is made up of as many charges as there are orations, every charge or indictment has its different state. So likewise his oration in defence of Ceolus has two states, in answer to a double charge, made against him by his adheraries: one, for borrowing money of Clodia, in order to bribe certain slaves to kill a foreign ambassador; and the other, for an attempt afterward to poison Clodia herself. Besides which, there were several other matters of a less heinous nature, which it was been thrown upon him by his accusers, with a design very likely, to render the two principal charges more credible; to which Cicero first replies, in the same manner as in his defence of Milo.

Though all the examples we have hitherto brought to illustrate this subject have been taken from judicial cases;
Part I.

**Oratory.**

Invention of the orator: the art of arranging and managing the device of the deliberative kind, and sometimes those of the demonstrative, are managed in a controversal way. And all controversies have their rate. And therefore Quintilian very justly observes, that "Ratae longe both to general and particular questions; and to all sorts of cases, demonstrative, deliberative, and judicial." In Cicero's oration for the Munisian law, this is the main point in dispute between him and those who opposed that law: "Whether Pompey was the fittest person to be intrusted with the management of the war against Mithridates?" This is a subject of the deliberative kind. And of the same nature was that debate in the senate concerning the demolition of Carthage. For the matter in dispute between Cato, who argued for it, and those who were of the contrary opinion, seems to have been this: "Whether it was for the interest of the Romans to demolish Carthage?" And so likewise those two fine orations of Cato and Cæsar, given us by Sallust, relating to the controversies with Catiline, who were then in custody, the controversy turns upon this: "Whether those prisoners should be punished with death, or perpetual imprisonment?" The examples of the demonstrative kind are not so common; but Cicero's oration concerning the "Answers of the soothsayers," may afford us an instance of it. Several prodiges had lately happened at Rome; upon which the soothsayers being consulted, answered this as the reason of them: Because some places consecrated to the gods had been afterwards converted to civil uses. Cæsar charged this upon Cato, whose house was rebuilt at the public expense, after it had been demolished by Clodius, and the ground consecrated to the goddes Liberty. Cicero in this oration retorts the charge, and shows that the prodigies did not respect him but Clodius. So that the question in dispute was, "To which of the two thesoe prodi-""gies related?" This oration does not appear to have been spoken in a judicial way, and must therefore belong to the demonstrative kind. His invective against Piso is likewise much of the same nature, wherein he compares his own behaviour and conduct with that of Piso.

As to the number of these rates, both Cicero and Quintilian reduce them to three. "We must (says Quintilian) agree with those; whose authority Cicero follows, who tells us, that three things may be inquired into in all disputes: Whether a thing is; what it is; and how it is. And this is the method which nature prefers. For in the first place, it is necessary the thing should exist about which the dispute is: because no judgment can be made either of its nature or quality till its evidence be manifest; which is therefore the first question. But though it be manifest that a thing is, it does not presently appear what it is: and when this is known, the quality yet remains: and after this are settled, no further inquiry is necessary." Now the first of these three rates is called the conjectural rate; as if it were inquired, "Whether one person killed another?" This always follows upon the denial of a fact, by one of the parties; as was the case of Roscius. And it receives its name from hence, that the judge is left, as it were, to conjecture, whether the fact was really committed or not, from the evidence produced on the other side. The second is called the definitive rate, when the fact is not denied: but the dispute turns upon the nature of it, and what name it is proper to give it: as in that example of Cicero, "Whether to take a sacred thing out of a private house be theft or suicide?" For in this case it is necessary to settle the distinct notion of those two crimes, and how the one differs from the other. The third is called the quality rate; when the disputing parties are agreed both as to the fact, and the nature of it, but the dispute is, "Whether it be just or unjust, profitable or unprofitable, and the like?" as in the case of Milo.

From what has been said upon this subject, the use of it may in a good measure appear. For whoever engages in a controversy, ought in the first place to consider with himself the main question in dispute, to fix it well in his mind, and keep it constantly in his view; without which he will be very liable to ramble from the point, and bewildered both himself and his hearers. And it is no less the business of the hearers principally to attend to this; by which means they will be helped to distinguish and separate from the principal question what is only incidental, and to observe how far the principal question is affected by it; to perceive what is offered in proof, and what is only brought in for illustration; not to be misled by digressions, but to discern when the speaker goes off from his subject and, when he returns to it again; and, in a word, to accompany him through the whole discourse, and carry with them the principal chain of reasoning upon which the cause depends. So as to judge upon the whole, whether he has made out his point, and the conclusion follows from the premises.

**Chapter II.**

Of Arguments suited to Demonstrative Disputes.

These consist either in praise or dispraise; and, of arguments agreeably to the nature of all contraries, one of them must be the other. When we either praise persons or things.

1. In praising or dispraising persons, rhetoricians prefer two methods. One is, to follow the order in which every thing happened that is mentioned in the discourse; the other is, to reduce what is said under certain general heads, without a strict regard to the order of time.

2. In pursuing the former method, the discourse may be more conveniently divided into three periods. The first of which will contain what preceded the person's birth; the second, the whole course of his life; and the third what followed upon his death.

Under the first of these may be comprehended what is proper to be said concerning his country or family. And therefore, if these were honourable, it may be said to his advantage, that he no wise disgraced them, but acted suitably to such a descent. But if they were not so, they may be either wholly omitted; or it may be said, that instead of deriving thence any advantage to his character, he has conferred a lasting honour upon them; and that it is not of so much moment where, or from whom, a person derives, his birth as how he lives.

In the second period, which is that of his life, the qualities both of his mind and body, with his circumstances in the world, may be separately considered. Though,
Though, as Quintilian rightly observes, "All external advantages are not praises for themselves, but according to the use that is made of them. For riches, and power, and interest, as they have great influence, and may be applied either to good or bad purposes, are a proof of the temper of our minds; and therefore we are either made better or worse by them." But these things are a just ground for commendation, when they are the reward of virtue or industry. Bodily endowments are health, strength, beauty, activity, and the like; which are more or less commendable, according as they are employed. And where these, or any of them, are wanting, it may be shown, that they are abundantly compensated by the more valuable endowments of the mind. Nay, sometimes a defect in these may give an advantageous turn to a person's character; for any virtue appears greater, in proportion to the disadvantages the person laboured under in exerting it. But the chief topics of praise are taken from the virtues, and qualifications of the mind. And here the orator may consider the disposition, education, learning, and several virtues, which shine through the whole course of the person's life. In doing which, the preference should always be given to virtue knowledge and any other accomplishment. And in actions, those are most considerable, and will be heard with greater approbation, which a person either did alone, or first, or wherein he had fewest associates; as likewise those which exceeded expectation, or were done for the advantage of others rather than his own. And further, as the last scene of a man's life generally commands the greatest regard, if any thing remarkable at that time was either said or done, it ought particularly to be mentioned. Nor should the manner of his death, or cause of it, if accompanied with any commendable circumstances, be omitted; as if he died in the service of his country, or in the pursuit of any other laudable design.

The third and last period relates to what followed after the death of the person. And here the public toasts, and public honours conferred upon the deceased, are proper to be mentioned. Sepulchres, statues, and other monuments to perpetuate the memory of the dead, at the expense of the public, were in common use both among the Greeks and Romans. But in the earliest times, as those honours were more rare, so they were less costly. For as in one age it was thought a sufficient reward for him who died in the defence of his country, to have his name cut in a marble inscription, with the cause of his death; so in others it was very common to see the statues of gadiators, and persons of the meanest rank, ered in public places. And therefore a judgment is to be formed of these things from the time, custom, and circumstances, of different nations; since the frequency of them renders them less honourable, and takes off from their evidence as the rewards of virtue. But, as Quintilian says, "Children are an honour to their parents, cities to their founders, laws to those who compiled them, arts to their inventors, and useful customs to the authors of them."

And this may suffice for the method of praising persons, when we propose to follow the order of time, as Iocrates has done in his funeral oration upon Evagoras king of Samos, and Pliny in his panegyric upon the emperor Trajan. But as this method is invention very plain and obvious, so it requires the more agreeable drefs to render it delightful; left otherwise it seem rather, like an history than an oration: For which reason, we find, that epic poets, as Homer, Virgil, and others, begin with the middle of their story, and afterwards take a proper occasion to introduce what preceded, to diversify the subject, and give the greater pleasure and entertainment to their readers.

2. The other method above hinted was, to reduce the discourse to certain general heads without regarding the order of time. As if any one, in praising the elder Cato, should propose to do it, by showing that he was a most prudent senator, an excellent orator, and most valiant general; all which commendations are given him by Pliny. In like manner, the character of a good general may be comprised under four heads; skill in military affairs, courage, authority, and success; from all which Cicero commends Pompey. And agreeably to this method Suetonius has written the lives of the first twelve Caesars.

But in the praising of persons, care should always be taken to say nothing that may reflect on the character, which may call the orator's judgment or integrity in question. It was not without cause, therefore, that Lyfippus the statuary, as Plutarch tells us, blamed Appelles for painting Alexander the Great with thunder in his hand; which could never suit his character as a man, however he might boast of his divine defect; for which reason Lyfippus himself made an image of him holding a spear, as the sign of a warrior. Light and trivial things in commendations are likewise to be avoided, and nothing mentioned but what may carry in it the idea of something truly valuable, and which the hearers may be supposed to with for, and is proper to excite their emulation. These are the principal heads of praise with relation to men. In diffpraise, the heads contrary to these are requisite; which being sufficiently clear from what has been said, need not particularly be insisted on.

IV. We proceed therefore to the other part of the division, which respects tinging, as distinguished from persons. By which we are to understand all being inferior to man, whether animate or inanimate; as likewise the habits and dispositions of men, either good or bad, when considered separately, and apart from their subjects, as arts and sciences, virtues and vices, with whatever else may be a proper subject for praise or diffpraise. Some writers, indeed, have, for their own amusement and the diversion of others, displayed their eloquence in a jocose manner upon subjects of this kind. So Lucian has written in praise of a fly, and Sthenus an elegant encomium upon baldness. Others, on the contrary, have done the like in a fictitious way. Such is Seneca's apotheosis or consecration of the emperor Claudius; and Myrtopogon or beard-hater, written by Julian the emperor. Not to mention several modern authors, who have imitated them in such ludicrous compositions. But as to these things, and all of the like nature, the observation of Antony in Cicero's orations very just: "That it is not necessary to reduce every subject we discourse upon to rules of art." For many are so trivial, as not to deserve it; and others so plain and evident of themselves,
Part I. INVENTION. as not to require it. But since it frequently comes in
the way both of orators and historians to describe
countries, cities, and facts, we shall briefly mention the
principal heads of invention proper to illustrate each of
these.

Countries, then, may be celebrated from the plea-
santness of their situation, the clemency and whole-
omenemies of the air, and goodness of the soil; to which
last may be referred the springs, rivers, woods, plains,
mountains and minerals. And to all these may be
added their extent, cities, the number and antiquity
of the inhabitants; their policy, laws, custom, wealth,
character for cultivating the arts both of peace and
war; their princes, and other eminent men they have
produced. Thus Pacatus has given us a very elegant
description of Spain, in his panegyric upon the
emperor Theodosius, who was born there.

Cities are praised from much the same topics as
countries. And here, whatever contributes either to
their defence or ornament ought particularly to be
mentioned; as the strength of the walls and fortifica-
tions, the beauty and splendor of the buildings, whe-
deraced or civil, public or private. We have in
Herodotus a very fine description of Babylon, which
was once the strongest, largest, and most regular city
in the world. And Cicero has accurately described
the city of Syracuse, in the island Sicily in one of his
orations against Verres.

But facts come much oftener under the cognizance
of an orator. And these receive their commendation
from their honour, justice, or advantage. But in de-
scribing them, all the circumstances should be related
in their proper order; and that in the most lively and
affecting manner, suited to their different nature.

Livy has represented the demolition of Alba by the
Roman army, which was sent thither to destroy it, thro'
the whole course of that melancholy scene, in a style so
moving and pathetic, that one can hardly forbear
condoling with the inhabitants upon reading his ac-
count.

But in discourses of this kind, whether of praise or
dispraise, the orator should (as he ought indeed upon
all occasions) well consider where, and to whom, he
speaks. For wise men often think very indifferently
both of persons and things from the common people.
And we find that learned and judicious men are fre-
quently divided in their sentiments, from the several
ways of thinking to which they have been acclimated.

Euphrates, different opinions prevail, and gain the
ascendancy, at different times. While the Romans
continued a free nation, love of their country, liberty,
and public spirit, were principles in the highest esteem
among them. And therefore, when Catilina killed him-
self, that he might not fall into the hands of Cæsar,
and survive the liberty of his country, it was thought
an inauspicious of the greatest heroic virtue; but after-
wards, when they had been accustomed to an arbitrary
government, and spirit of liberty was now lost, the poet
Martial could venture to say,

Death to avoid 'tis madroof's title to die.

A prudent orator therefore will be cautious of oppo-
sing any settled and prevailing notions of those to
whom he addresses; unless it be necessary, and then he will
do it in the softest and most gentle manner.

CHAP. III. OF ARGUMENTS SUITED TO DELIBERATIVE DISCOURSES.

This kind of discourses most certainly have been
very ancient; since, doubtless, from the first beginning
of men conversing together, they deliberated upon
their common interest, and offered their advice to each
other. But neither those of the laudatory nor judi-
cial kind could have been introduced, till mankind
were settled in communities, and found it necessary
to encourage virtue by public rewards, and bring vice
under the restraint of laws. The early practice of
laudatory discourses appears from sacred writ, where we
find, that when Moses was ordered upon an embassy
into Egypt, he would have excused himself for want
of eloquence. And Homer represents the Greeks at
the siege of Troy, as flocking like a swarm of bees
to hear their generals harangue them. Nor is this part
of oratory less conspicuous for its usefulness to man-
kind, than for its antiquity; being highly beneficial ei-
er in councils, camps, or any sortie, of men. How
many instances have we upon record, where the fury
of an enraged multitude has been checked and appea-
red by the prudent and artful persuasion of some par-
ticular person? The story of Agrippa Menenius, when
the commons of Rome withdrew from the senators,
and retired out of the city, is too well known to need
reciting. And how often have armies been animated
and fired to the most dangerous exploits, or recalled to
their duty, when ready to mutiny, by a moving speec-
h of their general? many instances of which we find in
history.

All deliberation expects something future, for it is
in vain to consult about what is already past. The
subject matter of it is, either things public or private,
faced or civil; indeed all the valuable concerns of
mankind, both present and future, come under its re-
gard. And the end proposed by this kind of dis-
courses is chiefly profit or interest. But since nothing
is truly profitable, but what is in some respect good;
and every thing which is good in itself may not in
all circumstances be for our advantage; properly speak-
ing, what is both good and profitable, or beneficial
good, is the end here designed. And therefore, as it
sometimes happens, that what appears profitable may
meet to interfere with that which is truly just and
honourable; in such cases it is certainly most advis-
able to determine on the safer side of honour and ju-
stice, notwithstanding some plausible things may be of-
f ered to the contrary. But where the dispute lies ap-
parently between what is truly honest, and some ex-
ternal advantage proposed in opposition to it, all good
men cannot but agree in favour of honesty. Such was
the case of Regulus, who, being taken prisoner by the
Carthaginians, was permitted to go to Rome upon giv-
ing his oath, that unless he could persuade the senate
to let at liberty some young Carthaginian noblemen,
then prisoners at Rome, in exchange for him, he should
return again to Carthage. But Regulus, when he
 came to Rome, was so far from endeavouring to pre-
vail with the senate to comply with the desire of the
Carthaginians, that he used all his interest to dissuade
them from hearkening to the proposal. Nor could
the most earnest intreaties of his earnest relations and
friends, nor any arguments they were able to offer,
engage him to continue at Rome, and not return again
to;
The argument here made use of to persuade Æneas to leave Troy immediately, is, that he had done all that could be expected from him, either as a good subject or brave soldier, both for his king and country; which were sufficient to secure his honour; and now there was nothing more to be expected from him when the city was falling, and impossible to be saved; which could it have been preferred by human power, he himself had done it.

But although a thing considered in itself appear beneficial if it could be attained, yet the expediency of undertaking it may still be questionable; in which case the following heads, taken from the circumstances which attend it, will afford proper argument to engage in it.

(1.) The possibility of succeeding may sometimes be argued, as one motive to this end. So Hannibal endeavoured to convince king Antiochus that it was possible for him to conquer the Romans if he made Italy the seat of the war; by observing to him, not only that the Gauls had formerly destroyed their city, but that he had himself defeated them in every battle he fought with them in that country.

(2.) But an argument founded upon probability will be much more likely to prevail. For in many affairs of human life, men are determined either to prosecute them or not, as the prospect of success appears more or less probable. Hence Cicero, after the fatal battle at Pharsalia, dissuades those of Pompey’s party, with whom he was engaged, from continuing the war any longer against Caesar; because it was highly improbable, after such a defeat, by which their main strength was broken, that they should be able to stand their ground, or meet with better success than they had before.

(3.) But further, since probability is not a motive strong enough with many persons to engage in the prosecution of a thing which is attended with considerable difficulties, it is often necessary to represent the facility of doing it, as a further reason to induce them to it. And therefore Cicero makes use of this argument to encourage the Roman citizens in opposing Mark Anthony (who upon the death of Caesar had assumed an arbitrary power), by representing to them, that his circumstances were then desperate, and that he might easily be vanquished.

(4.) Again, if the thing he advised can be shown to be in any respect necessary, this will render the motive still much stronger for undertaking it. And therefore Cicero joins this argument with the former, to prevail with the Roman citizens to oppose Anthony, by telling them, that “The consideration before them was, not in what circumstances they should live, but whether they should live at all, or die with ignominy and disgrace.” This way of reasoning will sometimes prevail when all others prove ineffectual. For some persons are not to be moved, till things are brought to an extremity, and they find themselves reduced to the utmost danger.

(5.) To these heads may be added the consideration of one side, case, security, alliance, honours, and the enjoyment of his friends; and on the other, certain death, attended with cruel torments. However, thinking the former not consistent with truth and justice, he chose the latter. And he certainly acted as became an honest and brave man, in choosing death, rather than to violate his oath. Though whether he did prudently in perfusing the Senate not to make the exchange, or they in complying with him, we shall leave others to determine. Now, when it proves to be a matter of debate, whether a thing upon the whole be really beneficial or not; as here are two parts, advice and dissuasion, they will each require proper heads of argument. But as they are contrary to each other, he who is acquainted with one, cannot well be ignorant of the other. We shall therefore chiefly mention those proper for advice, from whence such as are suited to dissuade will easily be perceived. Now the principal heads of this kind are these following, which are taken from the nature and properties of the thing itself under consideration.

1. Pleasure often affords a very cogent argument in discourses of this nature. Every one knows what an influence this has upon the generality of mankind. Though, as Quintilian remarks, pleasure ought not of itself to be proposed as a fit motive for action in serious discourses, but when it is designed to recommend something useful, which is the case here. So would any one advise another to the pursuit of polite literature, Cicero has furnished him with a very strong inducement to it from the pleasure which attends that study, when he says, “If pleasure only was proposed by these studies, you would think them an entertainment becoming a man of sense and a gentleman. For other pursuits neither agree with all times, all ages, nor all places; but these studies improve youth, delight old age, adorn prosperity, afford a refuge and comfort in adversity, divert us at home, are no hindrance abroad, sleep, travel, and retire with us into the country.”

2. Profit, or advantage. This has no less influence upon many persons than the former; and when it respects things truly valuable, it is a very just and laudable motive. Thus Cicero, when he sends his books of Homer to his son, which he wrote in Latin for his use, advises him to make the best advantage both of his tutor’s instructions, and the conversation at Athens, where he then was; but withal to peruse his philosophical treatises, which would be doubly useful to him, not only upon account of the subjects, but likewise of the language, as they would enable him to express himself upon those arguments in Latin, which before had only been treated of in Greek.

3. Honour; than which no argument will sooner prevail with generous minds, or inspire them with greater ardour. Virgil has very beautifully described Hector’s ghost appearing to Æneas the night Troy was taken, and advising him to depart, from this motive of honour:

O goddes-born, escape by timely flight
The flames and horrors of this fatal night.
The fates already have pofled the wall;
Troy noks from, high, and hotter to her fall.

Enough is paid to Priam’s royal name;
More than enough to duty and to fame.
If by a mortal hand my father’s throne.
Could be defended, ’twas by mine alone.
Part I. **ORATORY**

Invention. Invention of the \textit{event}, which, in some cases carries great weight with it. As when we advise to the doing of a thing from this motive, that whether it succeed or no, it will yet be of service to undertake it. So after the great victory gained by Themistocles over the Persian fleet at the straits of Salamis, Mardonius advised Xerxes to return into Asia himself, lest the report of his defeat should occasion an insurrection in his absence; but to leave behind him an army of 300,000 men under his command; with which, if he should conquer Greece, the chief glory of the conquest would redound to Xerxes; but if the design miscarried, the disgrace would fall upon his generals.

These are the principal heads which furnish the orator with proper arguments in giving advice. Cicero, in his oration for the Manilian law, where he endeavours to persuade the Roman people to choose Pompey for their general in the Mithridatic war, reasons from these three topics, into which he divides his whole discourse; namely, the necessity of the war, the greatness of it, and the choice of a proper general.

Under the first of these he shows, that the war was necessary, from four considerations: the honour of the Roman state, the safety of their allies, their own revenues, and the fortunes of many of their fellow-citizens, which were all highly concerned in it, and called upon them to put a stop to the growing power of king Mithridates, by which they were all greatly endangered. So that this argument is taken from the head of necessity. The second, in which he treats of the greatness of the war, is founded upon the topic of possibility. For though he shows the power of Mithridates to be very great, yet not so formidable, that he might be subdued; as was evident from the many advantages Lucullus had gained over him and his associates. In the third head, he endeavours to prevail with them to intrust the management of the war in the hands of Pompey, whom he describes as a consummate general, for his skill in military affairs, courage, authority in success; in all which qualities he represents him as superior to any other of their generals whom they could at that time make choice of. The design of all which was, to persuade them, that they had very good reason to hope for success, and a happy event of the war, under his conduct. So that the whole force of his reasoning under this head is drawn from probability. These are the three general topics which make up that fine discourse. Each of which is indeed supported by divers other arguments and considerations, which will be obvious in perusing the oration itself, and therefore need not be here commented on.

On the contrary, in another oration he endeavours to dissuade the senate from confenting to a peace with Mark Antony, because it was base, dangerous, and impracticable.

But no small skill and address are required in giving advice. For since the tempers and sentiments of mankind, as well as their circumstances, are very different and various; it is often necessary to accommodate the discourse to their inclinations and opinions of things. And therefore the weightier arguments are not always the most proper and fittest to be used on all occasions. Cicero, who was an admirable master of this art, and knew perfectly well how to suit what he said to the taste and relish of his hearers, in treating upon this subject, distinguishes mankind into two sorts; the ignorant and unphilosophical, who always prefer profit to honour; and such as are more civilized and polite, who prefer honour and reputation to all other things.

Wherefore they are to be moved by these different views: Præst, glory, and virtue, influence the one; while the other is only to be engaged by a prospect of gain and pleasure. Besides, it is plain, that the generality are much more inclined to avoid evils than to pursue what is good; and to keep clear of scandal and disgrace, than to practice what is truly generous and noble. Persius likewise of a different age acted from different principles; young men for the most part things in another light from those who are older and have had more experience, and consequently are not to be influenced by the same motives.

Chap. IV. Of Arguments suited to Judicial Causes.

In judicial controversies there are two parties; the plaintiff or prosecutor, and the defendant or party charged. The subjects of them are always something in passing. And the end proposed by them Cicero calls \textit{equity}, or \textit{right} and \textit{equity}; the former of which arises from the laws of the country, and the latter from reason and the nature of things. For at Rome the prosecutors had a court of equity, and were empowered, in many cases, relating to property, to relax the rigour of the written laws. But as this subject is very copious, and causes may arise from a great variety of things, writers have reduced them to three heads, which they call \textit{flates}, to some one of which all judicial proceedings may be referred; namely, \textit{whether a thing is}, what \textit{it is}, or \textit{how it is}. By the \textit{flate} of a cause therefore is meant the principal question in dispute, upon which the whole affair depends. Which, if it crops in the first inquiry, and the defendant denies the fact, the \textit{flate} is called \textit{conjunctural}; but if the fact be acknowledged, and yet denied to be what the adversary calls \textit{definitive}; but if there is no dispute either about the fact or its name, but only the justice of it, it is called the \textit{flate of quality}; as was shown more largely before (See no. 15). But we there considered these \textit{flates} only in a general view, and deferred the particular heads of argument proper for each of them to this judicial kind of discourses; where they most frequently occur, and from which examples may easily be accommodated to other subjects.

All judicial causes are either \textit{private} or \textit{public}. Those are called \textit{private}, which relate to the right of particular persons; and they are likewise called \textit{civil} causes, as they are conversant about matters of property. Public causes are those which relate to public justice and the government of the \textit{flate}; which are also called \textit{criminal}, because by them crimes are prosecuted, whether capital, or those of a less heinous nature. We shall take the heads of the arguments only from this latter kind, because they are more copious, and easy to be illustrated by examples; from which such as agree to the former, namely, \textit{civil} causes, will sufficiently appear.

1. \textbf{The conjunctural flate}. When the accused person denies

Vol. XIII

3 C

\addtolength{\parindent}{2em}
Invention.

The definition of action comprehends three things which the prosecutor has to consider; whether he would have done it, whether he could, and whether he did it. And hence arise three topics: from the will, the power, and the signs or circumstances which attended the action. The affections of the mind discover the will; a, passion, an old grudge, a desire of revenge, a resentment of an injury, and the like. Therefore Cicero argues from Clodius's hatred of Milo, that he designed his death; and from thence infers, that he executed it in his own defence. So that in regard to this point, Which of them owned that he was killed. This is what he principally endeavours to prove, and comes properly under this head; for Milo owned that he killed him, but alleged that he did it in his own defence. Thus Cicero represents Clodius hardened in vice, and above all the restraint of laws, from having so often escaped punishment upon committing the highest crimes. On the contrary, such a confidence is sometimes raised from the condition of the injured party, if he is indigent, obscure, timorous, or delinquent of friends; much more if he has an ill reputation, or is loaded with popular hatred and reformation. It was this presumption of the obscurity of Roscius, who lived in the country, and his want of interest at Rome, which encouraged his accusers to charge him with killing his father, as Cicero shows in his defence of him. Lastly, the temper of a person, his views, and manner of life, are considerations of great moment in this matter. For persons of bad morals, and such as are addicted to vice, are easily thought capable of committing any wickedness. Hence Salluit argues from the evil disposition and vicious life of Catiline, that he affected to raise himself upon the ruins of his country. The second head is the power of doing a thing; and there are three things which relate to this, the place, the time, and opportunity. As if a crime is said to have been committed in a private place where no other person was present; or in the night; or when the injured person was unable to provide for his defence. Under this head may likewise be brought in the circumstances of the persons; as if the accursed person was stronger, and so able to overpower the other; or more active, and so could easily make his escape. Cicero makes great use of this topic in the case of Milo, and shows, that Clodius had all the advantages of place, time, and opportunity, to execute his design of killing him. The third head comprehends the signs and circumstances which either preceded, accompanied, or followed, the commission of the fact. So threats, or the accused person being seen at or near the place before the fact was committed, are circumstances that may probably precede murder; fighting, crying out, bloodshed, are such as accompany it; paleness, trembling, inconstant answers, hesitation, or faltering of the speech, something found upon the person accused which belonged to the deceased, are such as follow it. Thus Cicero proves, that Clodius had threatened the death of Milo, and given out that he should not live above three days at the farthest. These arguments, taken from conjectures, are called presumptions, which though they do not directly prove that the accused person committed the fact with which he is charged; yet when laid together, they appeared very strong, sentence by the Roman law might sometimes be given upon them, to convict him.

These are the topics from which the prosecutor takes his arguments. Now the business of the defendant is to invalidate these. Therefore such as are brought from the will, he either endeavours to show are not true, or so weak as to merit very little regard. And he refutes those taken from the power, by proving that he wanted either opportunity or ability; as, if he can shew, that neither the place nor time informed on was at all proper; or that he was then in another place. In like manner he will endeavour to confute the circumstances, if they cannot be directly denied, by shewing that they are not such as do necessarily accompany the fact, but might have proceeded from other causes, though nothing of what is alleged had been committed; and it will be of great service to assign some other probable cause. But sometimes the defendant does not only deny that he did the fact, but charges it upon another. Thus Cicero, in his oration for Roscius, not only defends him from each of these three heads, but likewise charges the fact upon his accusers.

2. The definitive state, which is principally concerned in defining and fixing the name proper to the fact; though orators seldom make use of exact definitions, but commonly choose larger descriptions, taken from various properties of the subject or thing described. The heads of argument in this state are much the same to both parties. For each of them defines the fact in its own way, and endeavours to refute the other's definition. We may illustrate this by an example from Quintilian; “A person is accused of sacrilege, for stealing money out of a temple, which belonged to a private person.” The fact is owned; but the question is, whether it be proper sacrilege? The prosecutor calls it so, because it was taken out of a temple, but charges it upon another. Thus Cicero in this case argues, that the fact is sacrilege, and says it is only an instance of theft. Now the reason why the defendant refutes this plea, and infuits upon the distinction, is, because by the Roman law the penalty of theft was only four times the value of the stolen goods, whereas sacrilege was punished with death. The prosecutor then forms his definition agreeable to his charge, and says, “To steal anything out of a sacred place is sacrilege.” But the defendant excepts against this definition,
Part I.

O R A T O R Y.

Invention.

A league between the Romans and

definition, as defective; and urges, that it does not
amount to sacrilege, unless the thing itself was likewise
lacered. And this case might once, perhaps, have been a
matter of controversy, since we know it is expressly
determined in the Pandects, that "An action of sac-

62

rilege should not lie, but only of that, against any
one who should steal the goods of private persons de-
poited in a temple."

The second thing is the proof brought by each
party to support his definition; as in the example
given us by Cicero, of one "who carried his cause
by bribery, and was afterwards prosecuted again up-
on an action of praecrivation." Now, if the defen-
dant was cast upon this action, he was, by the Ro-
man law, subjected to the penalty of the former pro-
secution Here the prosecutor defines praecrivation
to be, Any bribery or corruption in the defendant, with
a design to prevent justice. The defendant, therefore,
on the other hand, refists it to bribery only the pro-
ject or.

And if this latter sense agrees better with the com-
mon acceptation of the word, the prosecutor in the
third place pleads the intention of the law, which was
to comprehend all bribery in judicial matters
under the term of praecrivation. In answer to which
the defendant endeavours to show, either from the
head of contraries, that a real prosecutor and a pre-
scrator are used as opposite terms in the law; or
from the etymology of the word, that the praecrinator
denotes one who pretends to appear in the pros-
ezuction of a cause, while in reality he favours the con-
trary side; and consequently, that money given for this
end only can, in the sense of the law, be called pre-
scrination.

Lastly, the prosecutor pleads, that it is unreasonable
that he who does not deny the fact should escape by a
civil about a word. But the defendant insists upon
his explication as agreeable to the law; and says, the
fact is misrepresented and blackened, by affixing to it a
wrong name.

3. The third flate is that of quality, in which the
dispute turns upon the justice of an action. And here
the defendant does not deny he did the thing he is
charged with; but avers it to be right and equitable
from the circumstances of the case, and the motives
which induced him to it.

And, finally, he sometimes alleges the reason of doing
it was in order to prevent some other thing of worse
consequence, which would otherwise have happened.
We have an instance of this in the life of Epamin-
donas, who, with two other generals joined in the com-
mand with him, marched the Theban army into Pelo-
donus against the Lacedemonians; but by the in-
fluence of a contrary faction at home, their combina-
tions were superseded, and other generals sent to com-
mand the army. But Epaminodas, being sensible
that, if he obeyed this order at that time, it would be
attended with the loss of the whole army, and conse-
quently the ruin of the state, refused to do it; and
having persuaded the other generals to do the like,
they happily fulfilled the war in which they were en-
gaged; and upon their return home Epaminodas
taking the whole matter upon himself, on his trial
was acquitted. The arguments proper in this case
are taken from the justice, usefulness, or necessity, of
the action. The accuser therefore will plead, that the
fact was not just, profitable, or necessary, considered
either in itself or comparatively with that for the
fake of which it is said to have been done: and he
will endeavour to show, that what the defendant af-
signs for the reason of what he did might not have
happened as he pretends. Besides, he will represent
of what ill consequence it must be, if such crimes go
unpunished. The defendant, on the other hand, will
argue from the same heads, and endeavour to prove
the fact was just, useful, or necessary. And he will
further urge, that no just estimate can be made of
any action, but from the circumstances which attend
it; as the design, occasion, and motives for doing it:
which he will represent in the most favourable light
to his own cause, and endeavour to set them in
such a view as to induce others to think they could
not but have done the same in the like circumstances.

Again, the cause of an action is sometimes charged
by the defendant upon the party who received the
damage, or some other person, who either made it
necessary, or inoined him to do it. The first of these
was Milo's plea for killing Clodius, because he af-
faulted him with a design to take away his life. Here
the fact is not denied, as in the case of Roscius above
mentioned, under the conjectural state; but justified
from the reason of doing it. For that an affilia might
be judicially killed, Cicero shows both from law and
reason. The accuser, therefore, in such a case, will, if
there be room for it, deny the truth of this allega-
tion. So the friends of Clodius affirmed that Milo
was the aggressor, and not Clodius; which Cicero,
in his defence of Milo, principally labours to refute.
In the second case, the prosecutor will say, No one
ought to offend because another has offended first;
which defeats the course of public justice, renders the
laws useless, and destroys the authority of the magis-
tate. The defendant on the other hand, will en-
devour to represent the danger and necessity of the
case, which required an immediate remedy, and in
that manner, and urges, that it was vain and imprac-
ticable to wait for redress in the ordinary way, and
therefore no ill consequence can arise to the public.
Thus Cicero, in defending Sextus, who was prose-
cuted for a riot in bringing armed men into the forum,
shows that his design was only to repel force with
force; which was then necessary, there being no other
means left for the people to assemble, who were ex-
cluded by a mob of the contrary party. Of the third
case we have also an example in Cicero, who tells us,
that, "in making a league between the Romans and
Samnites, a certain young nobleman was ordered by
the Roman general to hold the feste (designed for a
sacrifice) ; but the senate afterwards disapproving
the terms, and delivering up their general to the Sam-
nites, it was moved, Whether this young man ought
not likewise to be given up." Those who were for it
might say, that to allege the command of another,
is not a sufficient plea for doing an ill action; and
this is what the Roman law now expressly declares.
But in answer to that, it might be replied, that it
was his duty to obey the command of his general,
who was answerable for his own orders, and not those
who were obliged to execute them; and therefore to

3 C 2
give
give up this young nobleman would be to punish one  

person for the fault of another.  

Lastly, a fact is sometimes rather excused than  
defended, by pleading that it was not done designedly,  
or with any ill intent. This is called *conceision*;  
and consists of two parts, *apologia* and *intreaty*. The former  
represents the matter as the effect of inadvertency,  
chance, or necessity. Aristotle gives us an example  
of inadvertency or imprudence in a woman at Athens,  
who gave a young man a love-potion, which killed  
him; for which she was tried, but acquitted: though  
afterwards this was made criminal by the Roman  
law. The case of Alphaius, as related by Herodotus,  
is an instance of chance; who being inducted by  
Craetus with the care of his fon, as they were hunting,  
killed him accidentally with a javelin which he threw  
at a boar. It is necessity, when a perfon excuses his  
making a default from rises of weather, sickness, or  
the like. Thus Cicero pleaded his illness contrasted  
by the fatigue of a long journey, as an excuse for not  
appearing in the senate upon the summons of Mark  
Antony, who threatened to oblige him to it by pulling  
his house down. But what the defendant here attributes  
to inadvertency, chance, or necessity, the opposite  
party will attribute to design, negligence, or some  
other culpable reason; and represent it as a matter in-  
jurious to the public to introduce such precedents;  
and also produce inferences, if that can be done,  
where the like excuses have not been admitted. On  
the other hand, the defendant will infilt on his innocence,  
and fow the hardship and severity of judging mens  
actions rather by the event, than from the intention:  
that such a procedure makes no difference between  
the innocent and the guilty; but must necetarily  
involves many honest men in ruin and destruction,  
discourage all virtuous and generous disfines, and turn  
greatly to the prejudice of human society. He will  
also consider the inferences alleged by the accuser, and  
show the difference between them and his own cafe.  
And, lastly, he will have recourse to intreaty, or a  
submissive address to the equity and clemency of the  
court, or party offended, for pardon; as Cicero has  
done in his oration to Caesar, in favour of Ligarius.  

**Chapter V. Of the Character and address of an Orator.**

**Having considered and explained the first part of  
 invention, which furnishes the orator with such arguments as are necessary for the proof of his subject,**  
we are next to show what are the proper means to  
collate the minds of his hearers; to gain their affection;  
and to recommend both himself and what he says,  
to their good opinion and esteem. For the parts  
of invention are commonly thus distinguished; that it  
the first respects the subject of the discourse, the  
following the orator, and the third the manner.  
Now the second of these, which we have at present to explain, is by Quinctilian called a *propriety of manners*. And in order to express this, it is necessary, as he tells us, "that  
every thing appear easy and natural, and the disposition of the orator be discovered by his words." We  
may form an idea of this from the conduct of such persons as are most nearly concerned in each others welfare. As when relations or friends converse together upon any affairs of importance, the temper of  
the speaker plainly shows itself by his words and manner of address. And what nature directs to without colouring or disguising, the orator is to endeavour to perform by his art. Though  
indeed, if what a person says be inconsistent with his usual conduct and behaviour at other times, he cannot expect it should gain much credit, or make any  
deep impression upon his hearers; which may be one reason why the ancient rhetoricians make it so necessary a qualification in an orator, that he be a good man; since he should always be consistent with himself, and, as we say, talk in character. And therefore it is highly requisite, that he should not only gain  
the skill of assuming those qualities which the nature and circumstances of his discourse require him to express; but likewise that he should use his utmost endeavours to get the real habits implanted in his mind. For as by this means they will be always expressed  
with greater ease and facility; so by appearing constantly in the course of his life, they will have more  
weight and influence upon particular occasions.

Now there are four qualities, more especially suited to  
the character of an orator, which should always appear in his discourses, in order to render what he says  
acceptable to his hearers; and these are, *Wifdom, Integrity, Benevolence, and Modesty*.  

1. *Wisdom* is necessary; because we easily give into  
the hands of those whom we esteem wiser and more knowing than ourselves. Knowledge is very agreeable and pleasant  
to all, but few make very great improvements in it; either by reason they are employed in other necessary  
affairs, and the mind of man cannot attend to many things at once; or because the way to knowledge at  
first is hard and difficult, so that persons either do not care to enter upon the pursuit of it, or, if they do, they  
are many times soon discouraged, and drop it, for want of sufficient resolution to surmount its difficulties.  
Such, therefore as either cannot, or do not care to  
give themselves the trouble of examining into things  
themselves, must take up with the representation of  
others; and it is an ease to them to hear the opinion of  
persons whom they esteem wiser than themselves.  
No one loves to be deceived; and those who are  
fearful of being misled, are pleased to meet with a  
perfon, in whose wisdom, as they think they can safely  
trust. The character of wisdom therefore is of great service  
to an orator, since the greater part of mankind are  
swayed by authority rather than arguments.  

2. But this of itself is not sufficient, unless the opinion of *integrity* be joined with it. Nay, so far from it, that the greater knowledge and understanding a  
man is supposed to have, unless he likewise have  
the character of an honest man, he is often the more  
supplied. For knowledge without honesty, is generally thought to dispoit a perfon, as well as qualify him, to  
deceive.  

3. And to both these qualities the appearance of  
kindness and benevolence should likewise be added. For  
though a perfon have the reputation of wisdom and honesty, yet if we apprehend he is either not well affected to us, or at least regardless of our incend, we  
are in many cases apt to be jealous of him. Munificence are naturally swayed by their affections, and much influenced
But, as has been said already, great care is to be taken that these characters do not appear feigned and counterfeit. For what is fictitious can seldom be long concealed. And if this be once discovered, it makes all that is said suspected, how specious soever it may otherwise appear.

It is further necessary, that the orator should know the world, and be well acquainted with the different tempers and dispositions of mankind. No one indeed can any one, reasonably hope to succeed in this province, without well considering the circumstances of time and place, with the sentiments and disposition of those to whom he speaks: which, according to Aristotle, may be distinguished four ways, as they discover themselves by the several affection, habits, ages, and fortunes of mankind. And each of these require a different conduct and manner of addressing.

The affection denote certain emotions of the mind, which, during their continuance, give a great turn to the disposition. For love prompts to one thing, and hatred to another. The like may be said of anger, lenity, and the rest of them.

Persons differ likewise according to the various habits of their minds. So a just man is inclined one way, and an unjust man another; a temperate man to this, and an intemperate man to the contrary.

And as to the several ages of men, Aristotle has described them very accurately; and how persons are differently affected in each of them. He divides the lives of men, considered as hearers, into three stages; youth, middle age, and old age.—Young men, he says, have generally strong passions, and are very eager to obtain what they desire; but are likewise very mutable, so that the same thing does not please them long. They are ambitious of praise, and quick in their sentiments; lavish of their money, as not having experienced the want of it; frank and open, because they have not often been deceived: and credulous for the same reason. They readily hope the best, because they have not suffered much, and are therefore not sensible of the uncertainty of human affairs: for which reason they are likewise more easily deceived. They are modest, from their little acquaintance with the world. They love company and cheerfulness: from the brilliancy of their spirits. In a word, they generally exceed in what they do; love violent, hate violence, and act in the same manner through the rest of their conduct.—The disposition of old men is generally contrary to the former. They are cautious, and enter upon nothing hurriedly: having in the course of many years been often imposed upon; having often erred, and experienced the prevailing corruption of human affairs; for which reason they are likewise fopacious, and moderate in their affections either of love or hatred. They pursue nothing great or noble, and regard only the necessaries of life. They love money; having learned by experience the difficulty of getting it, and how easily it is lost. They are fearful, which makes them provident. Commonly full of complaints, from bodily infirmities, and a deficiency of spirits. They please themselves rather with the memory of what is past, than with any further prospect; having a short review of life before them, in comparison of what is already gone: for which reason, also, they love to talk of things past; and prefer
them to what is present, of which they have but little relish, and know they must shortly leave them. They are soon angry, but not to excess. Lastly, they are compassionate, from a sense of their own infirmities, which makes them think themselves of all persons most exposed.—Persons of a middle age, beset with these two extremes, as they are freed from the raffines and tenuity of youth, fo they have not yet suffered the decay of old age. Hence in every thing they generally observe a better conduct. They are neither so halfly in their affections, nor so minutely scrupulous as the other, but weigh their reasons of things. They regard a decency in their actions; are careful and industrious; and as they undertake what appears just and laudable upon better and more deliberate consideration than young persons, so they pursue them with more vigour and resolution than those who are older.

As to the different fortunes of mankind, they may be considered as noble, rich, or powerful: and the contrary to these. Those of high birth, and noble extraction, are generally very tender of their honour, and ambitious to increase it: it being natural for all persons to desire an addition to those advantages of which they find themselves already possessed. And they are apt to consider all others as much inferior to themselves, and therefore except great regard and deference should be shown them.—Riches, when accompanied with a generous temper, command respect from the opportunities they give of being useful to others; but they usually elate the mind, and occasion pride. For as money is commonly said to command all things, those who are possessed of a large share of it, expect others should be at their beck; since they enjoy that which all desire, and which most persons make the main pursuit of their lives to obtain.—But nothing is more apt to swell the mind than power. This is what all men naturally covet, even when perhaps they would not use it. But the views of such persons are generally more noble and generous than those who only pursue riches and the hoarding up of money. A state contrary to these gives a contrary turn of mind; and in lower life, persons dispositions usually differ according to their station and circumstances. A citizen and a courtier, a merchant and a soldier, a scholar and a peasant, as their pursuits are different, so is generally their turn and disposition of mind.

It is the orator’s business, therefore, to consider these several characters and circumstances of life, with the different bias and way of thinking they give to the mind; that he may so conduct himself in his behaviour and manner of speaking, as will render him most acceptable, and gain him the good esteem of those whom he addresses.

Chap. VI. Of the Passions.

As it is often highly necessary for the orator, so it requires his greatest skill, to engage the passions in his interest. Quintilian calls this the soul and spirit of his art. And, doubtless, nothing more discovers its empire over the minds of men, than this power to excite, appease, and sway their passions, agreeably to the design of the speaker. Hence we meet with the characters of admirable, divine, and other splendid titles, ascribed to eloquence by ancient writers. It has indeed been objected by some, that whatever high encomiums may be given of this art by the admirers of it, it is however diilenious to deceive and impose upon mankind, as those seem to do, who, by engaging their passions, give a bias to their minds, and take them off from the consideration of the truth; whereas every thing should be judged of from the reasons brought to support it, by the evidence of which it ought to stand or fall. But in answer to this, it may be considered that all fallacy is not culpable. We often deceive children for their good; and physicians sometimes impose on their patients, to come at a cure. And why, therefore, when persons will not be prevailed with by reason and argument, may not an orator endeavour, by engaging their passions, to persuade them to that which is for their advantage? Besides, Quintilian makes it a necessary qualification of an orator, that he be an honest man, and one who shall not abuse his art. But since those of a contrary character will leave no methods untried in order to carry their point, it is requisite for those who design well to be acquainted with all their arts, without which they will not be a match for them; as in military affairs it is highly advantageous for the general of an army to get himself informed of all the devices and stratagems of the enemy, in order to counteract them. Indeed this part of oratory is not necessary at all times, nor in all places. The better prepared persons are to consider truth, and act upon the evidence of it, the less occasion there appears for it. But the greater part of mankind, either do not duly weigh the force of arguments, or refuse to act agreeably to their evidence. And where this is the case, the orators will neither be convinced by reason, nor moved by the authority of the speaker, the only way left to put them upon action, is to engage their passions. For the passions are to the mind, what the wind is to a ship; they move, and carry it forward; he who is without them, is in a manner without action, dull and lifeless. There is nothing great or noble to be performed in life, wherein the passions are not concerned. The Stoics, therefore, who were for eradicating the passions, both maintained a thing in itself impossible, and which, if it was possible, would be of the greatest prejudice to mankind. For while they appeared such zealous assertors of the government of reason, they scarce left it any thing to govern; for the authority of reason is principally exercised in ruling and moderating the passions, which, when kept in a due regulation, are the springs and motives to virtue. Thus hope produces patience, and fear industry; and the like might be shown of the rest. The passions therefore are not to be extirpated, as the Stoics assert, but put under the direction and conduct of reason. Indeed where they are ungovernable and resist the control of reason, they are, as some have fitly called them, dispojis of the mind; and frequently hurry men into vice, and the greatest misfortunes of life: just as the wind, when it blows moderately, carries on the ship; but if it be too boisterous and violent may overrile her. The charge therefore brought against this art, for giving rules to influence the passions appears groundless and unjust; since the proper use of the passions is, not to hinder the exercise
ORATORY.

Part I.

Invention.

exercise of reason, but to engage men to act agreeably to reason. And if an ill use be sometimes made of this, it is not the fault of the art, but of the artist.

We shall here consider the passages, as they may be separately referred, either to demonstrative, deductive, or judicial discourses; though they are not wholly confined to any of them.

Of the passages which may be referred to demonstrative discourses.

1. To the demonstrative kind, we may refer joy and sorrow, love and hate, envy and content.

Joy is an elevation of the mind, arising from a sense of some present good. Such a religion naturally creates a pleasant and agreeable sensation, which ends in a delightful calm and composure. This is heightened by a description of former evils, and a comparison between them and the present felicity. Thus Cicero endeavours to excite in the minds of his fellow-citizens the highest sense of joy and delight at Callistus's departure from Rome, by representing to them the imminent danger which threatened both them and the city while he continued among them.

Sorrow, on the contrary, is an uneasiness of mind arising from a sense of some present evil. This passion has generally a place in moral discourses. And it may be heightened, like the former, by comparison, when any present happiness is lost, in opposition to a present calamity. Hence Cicero, in his Essay on Fortune, at Rome occasioned by the death of Metellus, from his character, and great services to the public, while living.

Love excites us to esteem any person for some excellency, and to do him all the good in our power. It is distinguished from friendship, which is mutual; and therefore love may continue, where friendship is lost; that is, the affection may remain on one side. And when we affinit from no other motive but to do him a kindness, Aristotle calls this good-will. Love takes its rise from a variety of causes. Geniality, benevolence, integrity, gratitude, courtesy, and other social virtues, are great incitements to love any one endowed with such qualities. And persons generally love those who are of a like disposition with themselves and pursue the same views. It is therefore the chief art of a flatterer to suit himself in every thing to the inclination of the person whose good graces he courts. When the orator would excite this affection towards any person, it is proper to shew, that he is prejudiced of at least some, if not all, of these agreeable qualities. When the conspiicators with Catiline were to be brought to justice, Cicero was very sensible of the envy he should excite on that account, and how necessary it was for him to secure the love of the Roman senate for his support and protection in that critical juncture. And this he endeavoured to do in his first oration against Catiline, by representing to them in the most pathetic manner, that all the labours he used in the senate, the dissipation he incurred with, and the dangers to which he was exposed on that account, were not for his own sake, but for their safety, quiet, and happiness.

Hate is opposed to love, and produced by the contrary dispositions. And therefore persons hate those who never did them any injury, from the ill opinion they have of their base and vicious inclinations. So that the way to excite this passion is, by showing that any one has committed some heinous act with an ill intent. And the more nearly affected persons are by such actions, in what they account of the greatest concern, the higher in proportion their hatred rises. Since life therefore is esteemed the most valuable good, Cicero endeavours to render Mark Antony odious to the citizens of Rome, by describing his cruelty.

Envy is a disquiet, occasioned by the felicity of another, not because he enjoys it, but because we define the like for ourselves. So that this passion is itself good and laudable, as it engages men to pursue those things which are so. For the proper objects of envy are any advantages of mind, body, or fortune, acquired by study or labour.

Envy therefore is excited by a lively representation of any desirable advantages which appear to be attainable, from the example of others who are or have been possessed of them. But where the felicity of another occasions an uneasiness, not from the want of it, but because he enjoys it, this passion is called envy, which the ancients describe as an hidous monster, feeding upon itself, and being its own tormentor. Aristotle judiciously observes, that it most usually affects such persons as were once upon a level with those they envy. For most men naturally think so well of themselves, that they are uneasy to see those who were formerly their equals advanced above them. But as this is a base and vicious passion, the orator is not to inform how to excite it, but how to lessen or remove it. And the meed prescribed by Cicero for this purpose is, to show that the things which occasioned it are not happened to the envied person unfavourably, but are the just reward of his industry or virtue; that he does not too much convert them to his own present or permanent advantage, as to the benefit of others; and that the same pains and difficulties are necessary to preserve him with which they were at first acquired.

Contempt is opposed to emulation, and arises from misconduct in things, not of themselves vicious: As where a person performs acts below his station and character, or affects to do that for which he is not qualified. Thus Cicero endeavours to expose Catullus, and bring him into contempt of the court, for pretending to rival him in the accusation of Verres, for which he was altogether unfit.

2. To deductive discourses may be referred fear, hope, and shame.

Fear arises from the apprehension of some great and impending evil. For the greatest evils, while they appear at a distance, do not much affect us. Such pernicious occasion fear, who are possessed of power, especially if they have been injured, or apprehended; likewise those who are addicted to do injuries, or who see an evil will. And the examples of others, who have suffered in a like case, or from the same pernicious, help to excite fear. From the circumstance therefore either of the thing or person, it will not be difficult for the orator to offer such arguments as may be proper to awaken this passion. So Demosthenes, when he would persuade the Athenians to put themselves in a condition of defence against king Philip, enumerates the several acts of hostility already committed by him against the neighbouring states. And because men private concerns generally more affect them than what relates to the public, it is proper sometimes
ORATORY.

3. To judicial discourses, may be referred anger and lenity, pity, and indignation. 

Anger is a renovation, occasioned by some affront, or injury, done without any just reason. Now men are more inclined to resent such a conduct, as they think they less deserve it. Therefore persons of distinction and figure, who expect a regard should be paid to their character, can the less bear any indications of contempt. And those who are eminent in any profession or faculty, are apt to be offended if reflections are cast either upon their reputation or art. Magistrates also, and persons in public situations, sometimes think it incumbent on them to resent indignities, for the support of their office. But nothing farther inflames this passion, than if good services are rewarded with flight and neglect. The infame of Narves, the Roman general, is remarkable in this kind; who, after he had been successful in his wars with the Goths, falling under the displeasure of the emperor Justin, was removed from the government of Italy, and received by the empress with this taunt, That he must be sent to weave away the girl's; which so provoked him, that he said he would weave such a web as they never should be able to unravel. And accordingly, he soon after brought down the Longobards, a people of Germany, into Italy; where they settled themselves in that part of the country, which from them is now called Lombardy. (See Naress.) The time and place in which an injury was done, and other circumstances that attended it, may likewise contribute very much to heighten the fact. Hence Demosthenes, in his oration against Midias, endeavored to aggravate the injury of being struck by him, both as he was then a magistrate, and because it was done at a public festival. From hence it appears, that the persons who most usually occasion this passion are such as neglect the rules of decency, conform and inflame others, or oppose their inclinations; as likewise the ungrateful, and those who violate the ties of friendship, or requite favours with injuries. But when the orator endeavors to excite anger, he should be careful not to exceed due bounds in aggravating the charge, left what he says appear rather to proceed from prejudice, than a strict regard to the demerit of the action.

Lenity is the remission of anger. The defigns of men's actions are principally to be regarded; and therefore what is done ignorantly, or through inadvertency; is sooner forgiven. Also to acknowledge a fault, submit, and ask pardon, are the ready means to take off resentment. For a generous mind is soon cooled by submission. Besides, he who repents of his fault, does really give the injured party some satisfaction, by punishing himself; as all repentance is attended with grief and uneasiness of mind, and this is apt very much to abate the desire of revenge. As, on the contrary, nothing is more provoking, than when the offender either audaciously justifies the fact, or confidently denies it. Men are likewise wont to lay aside their resentment, when their adversaries happen by some other means to suffer what they think a sufficient satisfaction. Lately, easy circumstances, a lucky inci-
O R A T O R Y.

Part I.

Invention. -- The orator, therefore, in order to allure and pacify the minds of his auditors, will endeavour to leaven their opinion of the fault, and by that means to take off the edge of their resentment. And to this purpose, it will be proper either to represent that the thing was not designed, or that the party is sorry for it; or to mention his former services; as also to show the credit and reputation which will be gained by a generous forgiveness. And this last topic is very artfully wrought up by Cicero, in his address to Cæsar, in favour of Ligarius.

Pity arises from the calamities of others, by reflecting, that we ourselves are liable to the like misfortunes. So that evils, considered as the common lot of human nature, are principally the cause of pity. And this makes the difference between pity and good-will, which arises merely from a regard to the circumstances of those who want our assistance. But considering the uncertainty of everything about us, he must seem in a manner divested of humanity, who has no compassion for the calamities of others; since there is no affection which happens to any man, but either that, or some other as great, may fall upon himself. But those persons are generally soonest touched with this passion, who have met with misfortunes themselves. And by how much greater the distress is, or by how much the person appears least deserving it, the higher pity does it excite: for which reason, persons are generally most moved at the misfortunes of their relations and friends, or those of the best figure and character. The orator, therefore, in order to excite the greater pity, will endeavour to heighten the idea of the calamity, from the several circumstances both of the thing itself and the person who labours under it. A fine example of this may be seen in Cicero's defence of Muræna, cap. 40, 41.

Indignation, as opposed to pity, is an uneasiness at the felicity of another who does not seem to deserve it. But this respects only external advantages, such as riches, honours, and the like; for virtues cannot be the object of this passion. Aristotle therefore says, "that pity and indignation are generally to be found in the same persons, and are both evidences of a good disposition." Now the orator excites this passion, by showing the person to be unworthy of that felicity which he enjoys. And as, in order to move compassion, it is sometimes of use to compare the former happy state of the person with his present calamity, so here, the greater indignation is raised, by comparing his former mean circumstances with his present advancement: as Cicero does in the case of Vatinianus.

These are the passions with which an orator is principally concerned. In addressing which, not only the greatest warmth and force of expression is often necessary; but he must likewise first endeavour to impress his own mind with the same passion he would excite in others.

A man may convince, and even persuade others to act, by mere reason and argument. But that degree of eloquence which gains the admiration of mankind, and properly denominates one an orator, is never found without warmth or passion. Passion, when in such a degree as to move and kindle the mind, without throwing it out of the possession of itself, is universally found to exalt all the human powers. It renders the mind infinitely more enlightened, more penetrating, more vigorous and masterly, than it is in its calm moments. A man, actuated by a strong passion, becomes much greater than he is at other times. He is conscious of more strength and force; he utters greater sentiments, conceives higher designs, and executes them with a boldness and a felicity of which on other occasions he could not think himself capable. But chiefly with respect to persuasion, is the power of passion felt. Almost every man in passion is eloquent. Then he is at no loss for words and arguments. He transmits to others, by a sort of contagious sympathy, the warm sentiments which he feels; his looks and gestures are all persuasive; and nature here shows herself infinitely more powerful than art. This is the foundation of that just and noted rule, Si vis me fieris, doldenum efl primum ipsi tibi.

The warmth, however, which we express, must be suited to the occasion and the subject; for nothing can be more preposterous than an attempt to introduce great vehemence into a subject, which is either of slight importance, or which, by its nature, requires to be treated of calmly. A temperate tone of speech is that for which there is most frequent occasion, and who he who is on every subject passionate and vehement, will be considered as a blusterer, and meet with little regard.

Part II. Of DISPOSITION.

AS Invention supplies the orator with necessary materials, so Disposition directs him how to place them in the most proper and suitable order. Disposition therefore, considered as a part of oratory, naturally follows invention. And what is here chiefly intended by it is, the placing the several parts of a discourse in a just method and dependence upon one another.

Writers are not all agreed in determining the parts of an oration: though the difference is rather in the manner of considering them, than in the things themselves. But Cicero, whom we shall here follow, mentions six, namely, Introduction, Narration, Proposition, Confirmation, Conspicuation, and Conclusion.

CHAP. I. of the Introduction.

The design of this is to prepare the minds of the hearers for a suitable reception of the remaining parts that are to follow. And for this end, three things are requisite; that the orator gain the good opinion of the hearers, that he secure their attention, and give them some general notion of his subject.

1. Good opinion. When the orator introduces his general subject.
orator with his own person, he will be careful to do it with modesty, and seem rather to extenuate his virtues and abilities, than to magnify them. And where the nature of the subject may seem to require it, he will endeavour to show, that some just and good reason induced him to engage in it. We have a very fine example of this in Cicero's oration for the poet Aulus Licinius Archias, which begins this: "If I have any natural genius, which I am sensible is very small, or any ability in speaking wherein I own I have been very conversant; or any skill acquired from the study and precepts of the best arts, to which my whole life has been devoted; this Aulus Licinius has, in a particular manner, a right to demand of me the fruit of all these things. For as far back as I can remember and call to mind what passed in my youth to the present time, he has been my adviser and encourager both to undertake and pursue this course of studies." When the orator sets out with the perils of those to whom the discourse is made, it is not unusual to commend them for their virtues, and those especially which have a more immediate relation to the present subject. Thus Cicero begins his oration of thanks for the pardon of Masceius, with an encomium upon the mildness, clemency, and wisdom of Caesar, to whom it was addressed. But sometimes the orator expresses his gratitude for past favours; as Cicero has done in his orations, both to the people and senate of Rome, after his return from banishment.—And at other times he declares his concern for them and their interest; in which manner Cicero begins his fourth oration against Catiline, which was made in the senate. "I perceive (says he) that all your countenances and eyes are turned on me; I perceive that you are solicitous, not only for your own danger, and that of the state but for mine likewise, if that should be removed. Your affection for me is pleasant in myself, and grateful in my sorrow; but I adjure you to lay it aside, and forgetting my safety consider yourselves and your children." But in judicial cafes, both the character of the orator whose cause he espouses, and that of the adverse party likewise, furnish the orator with arguments for exciting the good-will of his hearers; the former, by commemorating his virtues, dignity, or merits, and sometimes his misfortunes and calamities. So Cicero, in his defence of Flaccus, begins his oration in commending him on the account of his services done to the public, the dignity of his family, and his love to his country. And Demosthenes, in his oration against Midias, sets out with a recital of his virtues in order to recommend his own cause to the favourable opinion of the court.

2. Attention. On this head, Cicero says, "We shall be heard attentively on one of these three things: if we propose what is great, necessary, or to the interest of those to whom the discourse is addressed." So that, according to him, the topics of attention are much the same with those of good opinion, when taken from the subject. And indeed, people are naturally led to attend either to those things or perons of which they have entertained a favourable opinion. But in order to gain this point, the orator sometimes thinks it proper to request the attention of his audience. Thus Cicero, in his defence of Cuenitus, after having shown the heinousness of the charge against him concludes his introduction in the following manner, speaking to the judges; "Wherefore I intreat that while I briefly and clearly reply to a charge of many years standing, you will, according to your usual custom, give me a kind and attentive hearing." And again, in his second Philippic, addressing himself to the senate: "But as I must say something for myself and many things against Mark Antony; one of these I beg of you, that you will hear me kindly, while I speak for myself; and the other I will undertake for, that when I speak against him, you shall hear me with attention." But though the introduction be the most usual and proper place for gaining attention, yet the orator finds it convenient sometimes to quicken and excite his hearers in other parts of his discourse, when he observes they flag, or has something of moment to offer.

3. Some general account of the subject of the discourse. This is always necessary, which the two others are not. And therefore it must be left to the prudence of the orator when to use or omit them as he shall judge proper, from the nature of his discourse, the circumstances of his hearers, and how he stands with them. But some account of the subject is what cannot be neglected. For every one expects to be fully informed of the design of the speaker, and what he propounds to treat of. Nor when they are all made use of, is it necessary they should always stand in the order we have here placed them. Cicero sometimes enters immediately upon his subject, and introduces the other heads afterwards. As in his third oration against Catiline, made to the body of the Roman people, which begins thus: "You see that the fate, all your lives, estates, fortunes, wives and children, and this great of the greatest empire, the most flourishing and beautiful city, having by the favour of heaven towards you, and my labours, counsels, and dangers, been this day rescued from fire and sword and the very jaws of destruction, are preserved and afforded to you." And then he proceeds to recommend himself to their esteem and benevolence, from the consideration of these benefits.

These are the heads which commonly furnish matter for this part of a discourse. But orators often take occasion from the time, place largeness of the assembly or some other proper circumstance, to compliment their hearers, recommend themselves, or to introduce the subject upon which they are about to treat. Instances of each of these may be met with in several of Cicero's orations. And sometimes they set out with some comparison, similitude or other ornament, which they accommodate to the occasion and their discourse. Thus Cicero enters upon his celebrated panegyric in praise of his countrymen the Athenians with the following comparison: "I have often wondered what could be their design who brought together these assemblies, and instituted the gymnastic sports, to propose so great rewards for bodily strength; and to vouchsafe the honour to those who applied their private labours to serve the public, and so cultivated their minds as to be serviceable to others, to whom they ought to have been more regard. For although the strength of a champion was doubled, no benefit would from hence accrue to others: but all enjoy the prudence of one man, who will hearken to his advice." In some cafes, orators
ORATORY.

Part II.

Oration. Orationers have recourse to a more covert and artful way of opening their subject, endearing to remove jaded affections, apologize for what they are about to say, and seem to refer it to the censure of the hearers to judge of it as they please. Cicero appears to have been a perfect master of this art, and used it with great success. Thus in his seventh Philippic, where he seems to express the greatest concern, but what he was about to say should give any offence to the senate to whom he was speaking: "I (says he) who always declared for peace, and to whom peace among ourselves, as it is wished for by all good men, was in a particular manner desirable; who have employed all my industry in the forum, in the senate, and in the defence of my friends, whence I have arrived to the highest honours, a moderate fortune, and what reputation I enjoy: I therefore who owe what I am to peace, and without it could not have been the person I am, be that what it will, for I would arrogate nothing to myself; I speak with concern and fear, how you will receive what I am going to say; but I beg and interest you, from the great regard I have always expressed for the support and advancement of your honour, that if anything said by me should at first appear harsh or unfit to be received, you will not withstanding please to hear it without offence, and not reject it till I have explained myself: I then, for I must repeat it again, who have always approved of peace, and promoted it in a peace with Mark Antony. This is called information; and may be necessary, where a cause is in itself doubtful, or may be thought so from the received notions of the hearers, or the impressions already made upon them by the contrary side. An honest man would not knowingly engage in a bad cause; and yet through the prevailing prejudice, that may be so esteemed which is not so in itself. In these cases, therefore, great caution and prudence are necessary to give such a turn to things, and place them in that view as may be least liable to offence. And because it sometimes happens that the hearers are not so much displeased at the subject as the person, Quintilian's rule seems very proper, when he says, "it the subject displeases, the character of the person, should support it; and when the person gives offence, he should be helped by the cause."

CHAP. II. Of Narration.

The orator having prepared his hearers to receive his discourses with favour and attention, and acquainted them with his general design in the introduction, before he proceeds directly to his subject, often finds it necessary to give some account of what proceeded, accompanied, or followed upon it. And this he does in order to enlarge the view of the particular point in dispute, and place it in a clearer light. This is called narration; which is a recital of something done, in the order and manner in which it was done. Hence it is easy to perceive what those things are which properly enter into a narration. And such are the cause, a manner, time, place, and circumstances of an action; with the temper, fortune, views, ability, associates, and other circumstances of those concerned in it. Not that each of these particulars is necessary in every narration; but for many of them at least are requisite to set the matter in a just light, and make it appear credible. Besides in relating a Disputation, the orator does not content himself with filling an account of it as it is barely sufficient to render what he says intelligible to his hearers; but describes it in strong and lively a manner as may give the greatest evidence to his relation, and make the deepest impression upon their minds. And if any part of it appears at present less probable, he promises to clear up and remove any remaining doubts in the progress of his discourse. For the foundation of his reasoning afterwards is laid in the narration, from whence he takes his arguments for the confirmation. And therefore it is a matter of no small importance that this part be well managed, since the success of the whole discourse so much depends upon it. See NARRATION.

There are four properties required in a good narration; that it be short, clear, probable and pleasant.

1. The brevity of a narration is not to be judged of barely from its length: for that may be too long, which contains but a little; and that too short, which comprehends a great deal. Wherefore he depends upon the nature of the subject, since some things require more words to give a just representation of them, and others fewer. That may properly therefore be called a short narration, which contains nothing that could well have been omitted, nor omits any thing which was necessary to be said. Now in order to avoid both these extremes, care should be taken not to go farther back in the account of things, nor to trace them down lower, than the subject requires; to say that only in general, which does not need a more particular explication; not to affign the causes of things, when it is enough to show they were done; and to omit such things as are sufficiently understood, from what either preceded, or was consequent upon them. But the orator should be careful, lest, while he endeavours to avoid prolixity, he run into obscurity. Horace was very fensible of this danger, when he said:

By striving to be short, I grow obscure.

2. Perfection. This may justly be esteemed the Narration chief excellency of language. For as the design of a man's discourse is to communicate our thoughts to others, that must be its greatest excellence which contributes most assistance to this end; and that, doubles, is perfection. As of a cause, perfection therefore is requisite in all discourse, or it is particularly servicable in a narration which contains the substance of all that is to be said afterward. Wherefore, if this be not sufficiently understood, much less the general and particular things which are to be described in the course of it. Now the following things render a narration clear and to set it in its plain; Proper and significative words, whose meaning a just or a is well known and determined; short sentences, though full and explicit, whose parts are not perplexed but light, placed in their just order; proper particles to join the sentences, and show their connection and dependence on each other; a due regard to the order of time, and other circumstances necessary to be expressed; and, lastly, suitable transitions.

3. Probability. Things appear probable when the cause assigned for them appear natural; the manner in which they are described is easy to be conceived; the confessions are such as might be expected; the character of the perfons are justly represented;
and the whole account is well attested, consistent with itself, and agreeable to the general opinion. Simplicity likewise in the manner of relating a fact, as well as in the style, without any reserve or appearance of art, contributes very much to its credibility. For truth loves to appear naked and open, stripped of all colouring or disguise. The conspiracy of Catiline was so daring and extravagant, that no one but such a desperado could ever have undertaken it with any hopes of success. However, Cicero's account of it to the Senate was so full and exact, and so well suited to the character of the person, that it presently gained credit. And therefore, when, upon the conclusion of Cicero's speech, Catiline, who was present, immediately stood up, and declared they would not entertain such hard thoughts of him, but consider how much his family had always been attached to the public interest, and the great services they had done the State; their refsentments rose to high, that he could not be heard: upon which he immediately left the city, and went to his associates.

4. The last thing required in a narration is, that it be pleasant and entertaining. And this is more difficult, because it does not admit of that accurate composition and pompous drefs which delight the ear, and recommend some other parts of a discourse. For it certainly requires no small skill in the speaker, while he endeavours to express every thing in the most natural, plain, and easy manner, not to grow flat and tiresome. For Quintilian's remark is very just, that "the most experienced orators find nothing in eloquence more difficult, than what all who hear it fancy they could have said themselves." And the reason of this seems very obvious. For as all art is an imitation of nature, the nearer it resembles that, the more perfect it is in its kind. Hence unexperienced persons often imagine that to be easiest which suits best with those natural ideas to which they have been accustomed; till, upon trial, they are convinced of their mistake. Wherefore, to render this part of a discourse pleasant and agreeable, recourse must be had to variety both in the choice of words and turns of the expression. And therefore questions, interlocutions, imagery, and other familiar figures, help very much to diversify and enliven a narration, and prevent it from becoming dull and tedious, especially when it is carried on to any considerable length.

Having given a brief account of the nature and properties of a narration, we shall now proceed to consider the uses of it.

Laudatory orations are usually as it were a sort of continued narration, set off and adorned with florid language and fine images proper to grace the subject, which is naturally so well fitted to afford pleasure and entertainment. Wherefore a separate narration is more suited to deliberative and judicial discourses. In Cicero's oration for the Manilian law (which is of the former kind), the design of the narration is to show the Roman people the necessity of giving Pompey the command of the army against king Mithridates, by representing the nature of that war, which is done in the following manner: "A great and dangerous war (says he) threatens your revenues and allies from two very powerful kings, Mithridates and Tigranes; one of whom not being pursed after his defeat, and the other provoked, they think they have an opportunity to seize Asia. Letters are daily brought from those parts to worthy gentlemen of the equestrian order, who have large concerns there in farming your revenues; they acquaint me, as friends, with the state of the public affairs, and danger of their own; that many villages in Bithynia, which is now your province, are burnt down, that the kingdom of Ariobarzanes, which borders upon your revenues, is entirely in the enemy's power; that Lucullus, after several great victories, is withdrawn from the war; that he who succeeds him is not able to manage it: that all the allies and Roman citizens will and desire the command of that war may be given to one particular person; and that he alone, and no other, is dreaded by the enemies. You see the state of the case; now consider what ought to be done." Here is an unhappy scene of affairs, which seemed to call for immediate redress. The causes and reasons of it are assigned in a very probable manner, and the account well attested by persons of character and figure. And what the consequences would be, if not timely prevented, no one could well be ignorant. The only probable remedy suggested in general is, the committing that affair to one certain person, which he afterwards shows at large could be no other than Pompey. But in Cicero's defence of Milo (which is of the judicial kind), the design of the narration, which is greatly commended by Quintilian, is to prove that, in the combat between Clodius and Milo, the former was the aggressor. And in order to make this appear he gives a summary account of the conduct of Clodius the preceding year; and from the course of his actions and behaviour, shows the inveterate hatred he bore to Milo, who obstructed him in his wicked designs. For which cause he had often threatened to kill him, and given out that he should not live beyond such a time; and accordingly he went from Rome without any other apparent reason, but that he might have an opportunity to attack him in a convenient place near his own house, by which he knew Milo was then obliged to pass. Milo was in the Senate that day, where he said till they broke up, then went home, and afterwards set forward on his journey. When he came to the place in which he was to be assaulted, Clodius appeared every way prepared for such a design, being on horseback, and attended with a company of desperate ruffians ready to execute his commands: whereas Milo was with his wife in a chariot, wrapped up in his cloak, and attended with servants of both sexes. These were all circumstances which preceded the fact. And as to the action itself, with the event of it, the attack, as Cicero says, was begun by the attendants of Clodius from an higher ground, who killed Milo's coachman: upon which Millo, throwing of his cloak, leaped out, and made a brave defence against Clodius's men, who were got about the chariot. But Clodius, in the heat of the skirmish, giving out that Milo was killed, was himself slain by the servants of Milo, to avenge, as they thought, the death of their master. Here seems to be all the requisites proper to make this account credible. Clodius's open and avowed hatred of Milo, which proceeded so far as to threaten his life; the time of his leaving Rome; the convenience of the place; his habit and company fo different from those of

mention one inllance 'of this from Cicero, where

Cicerofe's speech to the fenate, the day after

of their difcourfes. Sometimes they do it in one ge-

oration. We have an infance of this in
Cicerof's speech to the fenate, the day after Cefar was
killed (as it is given us by Dion Caihus), in which
his defign was to perfuade them to peace and unani-
" This (fays he) being the state of our
affairs, I think it necessary that we lay aside all the
difcord and enmity which have been among us, and
return again to our former peace and agreement,

And then he proceeds to offer his reasons for this
advice.

At other times, to give a clearer and more difinct
view of their difcourfe, they subjoin to the propofition
the
the general heads of argument by which they endeavour to support it. This method Cicero uses in his seventh Philippic, where he says, "A man has always commented and advised to peace, and against a peace with Mark Antony. Why am I to persuade peace? Because it is safe, because it is dangerous, and because it is impracticable. And I beseech you to hear me with your usual candour, while I make out these three things."

But when the subject relates to several different things, which require each of them to be separately laid down in a distinct proposition, it is called a partition; though some have made two kinds of partition, one of which they call separation, and the other enumeration. By the former of these, the orator shows in what he agrees with his adversary, and wherein he differs from him. In the caufé formerly mentioned, of a person accused of sacrilege for spending private money out of a temple, he who pleads for the defendant says, "He owns the fact; but it being private money the point in question is, Whether this be sacrilege?" And in the cause of Milo, Cicero speaking of Clodius, says, "The point which now comes before the court, is not, Whether he was killed or not; that we confess: but, Whether justly or unjustly." Now in reality here is no partition, since the former branch of the proposition is what is agreed upon, and given up: and consequently it is only the latter that remains to be disputed. It is called enumeration, when the orator acquaints his hearers with the several parts of his discourse upon which he designs to treat. And this alone properly speaking, is a partition. Thus Cicero states his plea in his defence of Mumæna: "I perceive the accusation concerns of three parts: the first respects the conduct of his life; the second his dignity and the third contains a charge of bribery."

There are three things requisite in a good partition: that it be short, complete, and consist but of a few members.

A partition is said to be short, when each proposition contains in it nothing more than what is necessary, so that the brevity here required is different from that of a narration; for that consists chiefly in things, this in words. And, as Quintilian judiciously observes, brevity seems very proper here, where the orator does not show what he is then speaking of, but what he designs to discourse upon.

Again it ought to be complete and perfect. And for this end, care must be taken to omit no necessary part in the enumeration.

But, however there should be as few heads as is consistent with the nature of the subject. The ancient rhetoricians prescribe three or four at the most. And we do not remember that Cicero ever exceeds that number. But it is certain, the fewer they are, the better, provided nothing necessary be omitted. For too large a number is both difficult of retention, and apt to introduce that confusion which partition is designed to prevent.

Hitherto we have been speaking only of these heads into which the subject or general arguments of the discourse is first divided. For it is sometimes convenient to divide them again, or at least some of them, into several parts or members. And when this happens, it is best done, as the speaker comes to each of them in the order at first laid down; by which means Diffusion, the memory of the hearers will be less burdened than by a multitude of particulars at one and the same time. Thus Cicero, in his oration for the Manilian law, compiles what he designs to say under three general heads. "First (says he) I shall speak of the nature of the war, then of its greatness; and lastly about the choice of a general." And when he comes to the first of these, he divides it again into four branches; and shows, "How much the glory of the Romans, the safety of their allies; their greatest revenues, and the fortunes of many of their citizens, were all concerned in this war." The second head, in which he considers the greatness of the war, has no division. But when he comes to the third head, concerning the choice of a general, he divides that likewise into four parts; and shows, that so many virtues are necessary in a consummate general, such as one as was proper to have the management of that war, namely, skill in military affairs, courage, authority, and justice; all which he attributes to Pompey. And this is the scheme of that celebrated oration.

This subdividing, however, should never have place but when it is absolutely necessary. To split a subject into a great many minute parts by divisions and sub-divisions without end, has always a bad effect in speaking. It may be proper in a logical treatise: but it makes an oration appear hard and dry, and unnecessarily fatigues the memory. In a sermon, there may be from three to five, or six heads, including subdivisions: seldom should there be more.

Further, some divide their subject into two parts, Negative and Positive, by showing first what it is not, and then what it is. But while they are employed to prove what it is not, they are not properly treating upon that, but something else, which seems as irregular as it is unnecessary. For he who proves what a thing is, does at the same time show what it is not. However in fact, there is a fort of division by affirmation and negation, which may sometimes be conveniently used. As if a person, charged with killing another, should thus state his defence: I had done right if I had killed him, but I did not kill him. Here indeed, if the latter can be plainly made to appear, it may seem needful to insist upon the former. But if that cannot be so fully proved but there may be room left for suspicion, it may be proper to make use of both: for all persons do not see things in the same light, and he who believes the fact, may likewise think it just; while he who thinks it unjust, may not believe it, but rather suppose, had it really been committed by the party, he would not have denied it, since he looked upon it as defensible. And this method of proceeding, Quintilian compares to a custom often used in traffic, when persons make a large demand at first, in order to gain a reasonable price. Cicero uses this way of reasoning in his defence of Milo; but in the contrary order: that is, he first answers the charge; and then justifies the fact, upon the supposition that the charge was true. For he proves, first, that Clodius was the aggressor; and not Milo, as the contrary party had asserted; and then to give the greater advantage to his cause, he proceeds to show, that if Milo had been the aggressor, it would however have been a glorious ac-
The orator having acquainted his hearers in the propo- 
"fit n with the subject on which he designs to 
discourse, usually proceeds either to prove or illustrate 
what he has there laid down. For some discourses 
require nothing more than an enlargement or illus- 
tration, to set them in a proper light, and recommend 
them to the hearers; for which reason, likewise, 
they have often no distinct proposition. But where 
arguments are brought in defence of the subject, 
this is properly confirmation. For, as Cicero defines it 
"confirmation is that which gives proof, authority, 
and support to a cause, by reasoning." And, or this 
end, if any thing in the proposition seems obscure, or 
liable to be misunderstood, the orator first takes care 
to explain it, and then goes on to offer such arguments 
for the proof of it, and represent them in such a 
light, as may be most proper to gain the assent of his 
hearers.

But here it is proper to observe, that there are 
different ways of reasoning suited to dissimilar 
subjects. The mathematician treats his subject after another 
manner than the logician, and the orator in a me-
ORATORY.

Disposition. Which he proves in this manner: "The rising and setting of the heavenly bodies keep a certain determined order; and the several seasons of the year do not only necessarily return in the same manner, but are fitted to the advantage of the whole; nor did the vicissitudes of night and day ever yet become prejudicial, by altering their course." From all which he concludes, "That the world must be under the direction of a wise governor." In both these examples, the regular order of the parts is observed. We shall therefore proceed another, in which the order is directly contrary; for beginning with the conclusion, he proceeds next to the minor proposition, and so ends with the major. In his defence of Cælius, his design is to prove that Cælius had not led a loose and vicious life, with which his enemies had charged him. And this he does, by showing he had closely followed his studies, and was a good orator. This may probably at first sight appear but a weak argument, though he who considers what Cicero everywhere declares necessary to gain that character, it may perhaps be thought otherwise. The sense of what he says here may be reduced to this syllogism.

Those who have pursued the study of oratory, so as to excel in it, cannot have led a loose and vicious life.

But Cælius has done this.

Therefore his enemies charge him wrongly.

But let us hear Cicero himself. He begins with the conclusion, thus: "Cælius is not chargeable with profuence, extravagancy, contracting of debts, or, intemperance, a vice which age is so far from abating that it rather increases it. Nay, he never engaged in amours, and those pleasures of youth, as they are called, which are soon thrown off, as reason prevails." Then he proceeds to the minor, and shows from the effects, that Cælius had closely applied himself to the best arts, by which he means those necessary for an orator: "You have now heard him make his own defence, and you formerly heard him engaged in profession. I speak this to vindicate, not to applaud him; you could not but perceive his manner of speaking, his ability, his good sense and command of language. Nor did he only discover a good genius, which will oftentimes do much of itself when it is not improved by industry; but what he said (if my affection for him did not bias my judgment) appeared to be the effect of learning, application, and study." And then he comes to the major: "But be assured, that those who are engaged in defending Cælius, and the studies upon which I am now discoursing, cannot meet in the same person. For it is not possible thata mind, disturbed by such irregular passions, should be able to go through what we orators do, I do not mean only in speaking, but even in thinking." And this he proves by an argument taken from the scarcity of good orators, "Can any other reason be imagined, why so few, both now, and at all times have engaged in this province, when the reward of eloquence is so magnificent, and it is attended with so great delight, applause, glory and honour? All pleasures must be neglected; diversions, recreations, and entertainments omitted; and even the conversation of all our friends must in a manner be laid aside. This it is which dete

pers persons from the labour and study of oratory; not their want of genius or education."

2. By Enthymem. But orators do not often use complete syllogisms, but most commonly enthymems. An enthymem, as is shown elsewhere, is an imperfect syllogism, consisting of two parts, the conclusion, and one of the premises. And this kind of syllogism, that proposition is omitted, whether it be the major or minor, which is sufficiently manifest of itself, and may easily be supplied by the hearers. But since the proposition that is expressed is usually called the antecedent and the conclusion the consequent. So if the major of that syllogism be omitted, by which Cicero endeavours to prove that Cælius assaulted Milo, it will make this enthymem:

The death of Milo would have been an advantage to Cælius.

Therefore Cælius was the aggressor; or, therefore he assaulted Milo.

In like manner that other syllogism above-mentioned by which he shows that the Carthaginians ought not to be trusted, by omitting the minor, may be reduced to the following enthymem.

Those who have often broken their faith ought not to be trusted.

For which reason the Carthaginians ought not to be trusted.

Every one would readily supply the minor, since the perfidiousness of the Carthaginians was known by a proverb. But it is reckoned a beauty in enthymemes when they consist of contrary parts: because the turn of them is most acute, and pungent. Such is that of Micles in Sallust: "What stranger will be faithful to you who are an enemy to your friends?" And so likewise that of Cicero for Milo, speaking of Cælius: "You fit as avengers of his death; whole life you would not restore, did you think it in your power." Orators manage enthymemes in the same manner they do syllogisms; that is, they invert the order of the parts, and confirm the proposition by one or more reasons; and therefore a rhetorical enthymem frequently consists of three parts, as a syllogism does of five. Though, strictly speaking, a syllogism can consist of no more than three parts, and an enthymem but of two: and the arguments brought to support either of the propositions constitute so many new enthymemes, of which the part they are designed to prove is the conclusion. To illustrate this by an example:

An honest man thinks himself under the highest obligation to his country.

Therefore he should shun no danger to serve it.

In this enthymem the major is wanting, which would run thus: "He who is under the highest obligations to another, should shun no danger in order to serve him." This last proposition is founded upon the common principle of gratitude; which requires that, to the utmost of our power, a return should be made in proportion to the kindness received. And this being a maxim generally allowed, it is omitted by the orator. But now this enthymem, consisting of the minor and conclusion, might be managed in some such manner as..."

Vol. XIII.
ORATORY.

Disposition

So in the famous cause of Epaminondas, general of the Thebans, who was accused for refusing to surrender his command to his successor appointed by the state, till after he had engaged the enemy, and given them a total defeat, Cicero thus represents his accuser pleading for the words of the law against Epaminondas, who alleged the intention of it in his defence: "Should Epaminondas add that exception to the law, which he says, was the intention of the writer, namely, Except any one refuse to give up his command when it is for the interest of the public he should not; would you admit of it? I believe not. Should you yourselves, which is a thing most remote from your justice and wisdom, in order to screen him, order this exception to be added to the law, without the command of the people; would the Thebans suffer it to be done? No certainly. Can it be right then to come into that, as if it was written, which it would be a crime to write? I know it cannot be agreeable to your wisdom to think fo."

Under the analytic method may be comprehended reasoning by example. Rhetoricians use this word in a different sense from the common acceptation. For it is usually called an example, which is brought either to prove or illustrate some general assertion: As if 'any one should say, that humane bodies may be brought to sustain the greatest labours by use and exercise; and in order to prove this should relate what is said of Milo of Croton, that by the constant practice of carrying a calf several furlongs every day, he could carry it as far after it has grown to a calf several furlongs every day, he could carry it as far after it has grown, which it would be a crime to write? I know it cannot be agreeable to your wisdom to think so." But in oratory the word example, is used for any kind of similitude; or, as Vellius defines it, "When one thing is inferred from another, by reason of the likenesses which appears between them." Hence it is called an imperfect induction, which infers something from several others of a like nature, and has always the greatest force when the examples are taken from facts. Now facts may be compared with respect to some agreement or similitude between them, which in themselves are either equal or unequal. Of the former kind this is an instance: "Cato acted as became a patriot and a lover of his country's liberty, in opposing the arms of Caesar; and therefore so did Ciceron." The reason of the inference is founded in the parity of the cause, which equally concerned all good subjects of the Roman government at that time. For all were alike obliged to oppose a common enemy, who endeavoured to subvert the constitution, and subject them to his own arbitrary power. But though an example consists in the comparison of two single facts, yet several persons may be concerned in each fact. Of this kind is that which follows: "As Pompey, Caesar, and Cassius, acted illegally in the first triumvirate, by engrossing the sole power into their own hands, and by that means violating the public liberty; so likewise did Augustus, Mark Antony, and Lepidus, in the second triumvirate by pursuing the same measures." But when Cicero defends M. for killing Clodius, from the like instances of Ahala Servilius, Scepio Nafeus, Lucius Opimius, and others; that is not an example, but an induction: because one thing is there inferred from its similitude to several others. But when a comparison is made between two facts that are unequal, the inference may be either from the greater to the less, or from the less to the greater. From the greater to the less in this manner: "Cesar had no just pretensions to the Roman government, and therefore much less had Antony." The reason lies in the difference between the two persons. Cesar had very much enlarged the bounds of the Roman empire by his conquests, and greatly obliged the populace by his generosity; but as he had always acted by an authority from the senate and people of Rome, these things gave him no claim to a power over them. Much less then had Antony any such pretence who always acted under Cesar, and had never performed any signal services himself. Cicero has described the difference between them in a very beautiful manner, in his second Philippic, thus speaking to Antony: "Are you in any thing to be compared to him? He had a genius, sagacity, memory, learning, care, thought, diligence; he had performed great things in war, though detrimental to the state; he had for many years designed to get the government into his hands, and obtained his end by much labour and many dangers; he gained over the ignorant multitude by public shows, buildings, consular, and other services; and the like by a show of clemency. In a word, he subjected the free states to slavery, partly through fear, and partly compliance. I can liken you to him for ambition of power; but in other things you are in no respect to be compared with him." By a comparison from the less to the greater, Cicero thus argues against Catiline: "Did the brave Scipio, when a private man, kill Tiberius Gracchus, for attempting to weaken the Roman empire by his constitution, to give those who are going out the last word by fire and sword?" The circumstances of these two cases were very different; and the comparison runs between a private man, and a confederate with the highest authority; between a design only to raise a tumult, and a plot to destroy the government: whence the orator judgst, that what was esteemed lawful in one case, was much more so in the other. The like way of reasoning is sometimes used from other similitudes, which may be taken from things of all kinds, whether animate or inanimate. Of the former fort is that of Cicero speaking of Murzena, when candidate for the consulship, after he had himself gone through that office: "If it is usual (ays he) for such persons as are safely arrived in port, to give those who are going out the best account they can with respect to the weather, pirates, and coasts; because thus nature directs us to assist those who are entering upon the same dangers which we ourselves have escaped: how ought I, who now after a great storm am brought within a near prospect of land, to be affected towards him, who, I perceive, must be exposed to the greatest tempests of the state?" He alludes to the late disturbances and tumults occasioned by the conspiracy of Catiline, which had been so happily suppried by him in the time of his confulate. Of the latter kind is that of Quintilian: "As the ground is made better and more fruitful by culture, so is the mind by instruction." There is both a beauty and justness in this simile.

But comparisons are sometimes made between facts and
Part II.  

ORATORY. 

Disposition and other things, in order to infer some difference or opposition between them. In comparing two facts, or on account of some disagreement and likeness, the inference is made from the difference between one and the other in that particular respect only. As thus:

"Though it was not esteemed cruelly in Brutus to put his two sons to death, for endeavouring to betray their country; it might be so in Manlius, who put his son to death, only for engaging the enemy without orders, though he gained the victory." The difference between the two facts lies in the different nature of the crime. The sons of Brutus entered into a conspiracy to betray their country; and though they miscarried in it, yet the intention and endeavours they used to accomplish it were criminal in the highest degree. But young Manlius could only be charged with rashness. His design was honourable, and intended for the interest of his country: only it was irregular, and might have proved ill consequence to military discipline. Now in all such cases, the force of the argument is the stronger the greater the difference appears. But the same facts which differ in one respect may agree in many others; as in the example here mentioned. Brutus and Manlius were both magistrates as well as fathers; they both killed their sons, and that for a capital crime by the Roman law. In any of which respects they may be compared in a way of similitude: as, "If Brutus might lawfully put his son to death for a capital crime, so might Manlius."

But now contrary facts do not only differ in some certain respect, but are wholly opposite to each other; so that what is affirmed of the one must be denied of the other; and if one be a virtue, the other is a vice. Thus Cicero compares the conduct of Marcellus and Verres in a way of opposition. "Marcellus (says he), who had engaged, if he took Syraeae, to erect two temples at Rome, would not beautify them with the spoils he had taken: Verres, who had made no vows to Honour and Virtue, but to Venus and Cupid, endeavoured to plunder the temple of Minerva. The former would not adorn the gods with the spoils of other deities; the latter carried the ornaments of Minerva, a virgin, into the house of a fputter." If therefore the conduct of Marcellus was laudable and virtuous, that of Verres must bear the contrary character. But this way of reasoning has likewise place in other respects. Thus Cicero, in the quarrel between Caesar and Pompey, advised to peace from the difference between a foreign and domestic war: "That the former might prove beneficial to the state; but in the latter, whichever side conquered, the public must suffer." And thus the ill effects of intemperance may be shown in a way of opposition: "That as temperance preserves the health of the body, keeps up the vigour of the mind, and prolongs life; so excess must necessarily have the contrary effects."

Thus we have given a brief account of the principal ways of reasoning commonly made use of by orators. As to the disposition of arguments, or the order of placing them, some advise to put the weaker, which cannot wholly be omitted, in the middle: and such as are stronger, partly in the beginning, to gain the eftem of the hearers and render them more attentive; and partly at the end, because what is last heard is likely to be retained longest; But if there are but two arguments, to place the stronger firft, and then the weaker; and after that to return again to the former, and inftil principally upon that. But this must be left to the prudence of the speaker, and the nature of the subject. Though to begin with the stronger, and so gradually descend to the weaker, can never be proper, for the reason last mentioned. Nor ought arguments to be crowded too clofe upon one another; for that takes off from their force, as it breaks in upon the attention of the hearers, and does not leave them sufficient time duly to consider them. Nor indeed should more be used than are necessary; because the fewer they are, the more easily they are remembered. And the observation of a great master of eloquence upon this subject is certainly very just, that arguments ought rather to be weighed than numbered.

CHAP. V. Of Confutation.  

The forms of reasoning here are the same as have been already explained under Confirmation. Confutation, however, is often the more difficult task; because he who is to prove a thing comes usually prepared; but he who is to confute it is frequently left, motion, but to a sudden answer. For which reason, in judicial or common cases, Quintilian says, "It is as much easier to accuse than defend, as it is to make a wound than to heal it." Therefore, not only a good judgment, but a readiness of thought also, seems necessary for this province. But, in all disputes, it is of the greatest consequence to observe where the facts of the controversy lies. For without attending to this, persons may cavil about different matters without understanding each other, or deciding any thing. And in confutation, what the adversary has advanced ought carefully to be considered, and in what manner he has expressed himself. As to the things themselves, whether they immediately relate to the matter in dispute, or are foreign to it. Those things that are foreign to the subject may either be past over in silence, or in a very few words shown to be insignificant. And there ought likewise to be a distinction made between such things as relate to the subject, according to their importance. Those that appear to have no great weight should be lightly remarked. For to inftil largely upon such matters is both tiresome to the hearers, and apt to bring the judgment of the speaker into question. And therefore things of that nature are generally better turned off with an air of neglect, a pungent question, or an agreeable jest, than confuted by a serious and laboured answer. But those things, which relate to the merits of the cause, may be confuted either by contradicting them, or by showing some mistake in the reasoning, or the invalidity when granted.

Things may be contradicted several ways. What is apparently false may be expressly denied. Thus Cicero in his defence of Cluentius: "When the accuser had said, that the man fell down dead after he had drunk off his cup, denies that he died that day." And things which the adversary cannot prove, may likewise be denied. Of which we have also an instance in Cicero, who first upbraids Mark Anthony as guilty of a breach not only of good breeding, but likewise of friendship, for reading publicly a private letter he had sent him.
And then adds, "But what will you say now, If I should deny that ever I sent you that letter? How will you prove it? By the hand-writing? In which I confess you have a peculiar skill, and have found the benefit of it. But how can you make out? For it is in my secretary's hand. I cannot but envy your master who had so great a reward for teaching you to understand just nothing. For what can be more unbecoming not only an orator, but even a man, than for any one to offer such things, which if the adversary denies, he has nothing more to say?" It is an handsome way of contradicting a thing, by showing that the adversary himself maintained the contrary. So when Oppius was charged with defrauding the soldiers of their provisions, Cicero refutes it, by proving, that the same persons charged Oppius with a design to corrupt the army by his liberality. An adversary is no more effectually silenced than when you can set forth contradictions upon him; for this is stabbing him with his own weapon. Sometimes a thing is not in express terms denied, but represented to be utterly incredible. And this method exposes the adversary more than a bare denial. So when some persons reproached Cicero with cowardice, and a shameful fear of death, he recites their reasons, in such a manner, that any one would be inclined to think the charge entirely false. "Was it becoming me (fays he) to expect death with that composure of mind as some have imagined? Well, and did I then avoid it? Nay, was there any thing in the world that I could apprehend more defirable? Or when I had done the greatest things in such a crowd of ill-minded persons about me, do you think banishment and death were not always in my view, and continually founding in my ears as my certain fate, while I was so employed? Was life defirable when all my friends were in such sorrow, and myself in so great distress, deprived of all the gifts both of nature and fortune? Was I so unexperienced, so ignorant, so void of reason and prudence? Had I never seen nor heard any thing in my whole life? Did I all I had read and studied avail nothing? What did not I know that life is short, but the glory of generous actions permanent? When death is appointed for all, does it not seem eligible, that life, which must be wrested from us, should rather be freely devoted to the service of our country, than referred to be worn out by the decays of nature? Was not I sensible, there has been this controversy among the wisest men, that some say, the minds of men and their confciences utterly perish at death; and others, that the minds of wise and brave men are then in their greatest strength and vigour, when they are set free from the body? The first flate is not greatly to be dreaded, to be void of fene: but the other, of enjoying larger capacities, is greatly to be desired. Therefore, since I always aimed at dignity, and thought nothing was worth living for without it; how should I, who am past the confufion, and did so great things in it, be afraid to die? Thus far Cicero. There is likewise an ironical way of contradicting a thing, by retorting that and other things of the like nature upon the adverse party. Thus Cicero, in his oration against Vatinus, fays: "You have objected to me, that I defended Cornelius, my old friend, and your acquaintance. But pray why should I not have defended him? Has Cornelius car­ried any law contrary to the omens? Has he violated any law? Has he assaulted the confult? Did he take poftellation of a temple by force of arms? Did he drive away the tribune, who opposed the passing a law? Has he thrown contempt upon religion? Has he plundered the treasury? Has he pillaged the state? No, thec, all these, are your doings." Such an unexpected return is sometimes of great service to abate the confidence of an adversary.

A second way of confutation is, by observing some flaws in the reasoning of the adverse party. We shall endeavour to illustrate this from several kinds of reasoning treated of before under confirmation. And first, as to syllogisms; they may be refuted, either by showing some mistake in the premises, or that the conclusion is not justly deduced from them. So when the Clodian party contended, that Milo ought to suffer death for this reason, Because he had confessed that he had killed Clodius; that argument, reduced to a syllogism, would stand thus:

He who confesses he has killed another, ought not to be allowed to see the light.

But Milo confesses this.

Therefore he ought not to live.

Now the force of this argument lies in the major or first proposition; which Cicero refutes, by proving, that the Roman people had already determined contrary to what is there asserted: "In what city (fays he) do these men dispute after this weak manner? In that wherein the first capital trial was in the cafe of the brave Horatius, who, before the city enjoyed perfect freedom, was faved by the suffrages of the Roman people, though he confessed that he killed his father with his own hand." But when Cicero accused Verres for mal-administration in his government of Sicily, Hortenfius, who defended him, being sensible the allegations brought against him could not be denied, had no other way left to bring him off, but by pleading his military virtues in abatement, which at the time were much wanted, and very serviceable to the flat. The form of the argument was this:

That the Romans then wanted good generals.

That Verres was such.

And consequently, that it was for the interest of the public that he should not be condemned.

But Cicero, who knew his design, flatly the argument for him in his charge; and then answers it by denying the consequence, since the crimes of Verres were of so heinous a nature, that he ought by no means to be pardoned on the account of any other qualificatons: Though indeed he afterwards refutes the minor or second proposition, and shows that he had not merited the character of a good general. Enthymems may be refuted, either by showing that the antecedent is false, or the consequent not justly inferred from it. As thus, with respect to the former cafe:

A strict adherence to virtue has often proved detrimen­tal.

Therefore virtue ought not to be collided with.
ORATORY.

Now as the certainty of that inference depends upon this general assertion, that all men love their children, which is not true, the mistake of the reasoning may be shown from the instance of Media and others, who defroyed their own children. As to induction and example, by which the truth or equity of a thing is proved from its likeness to one or more other things; the reasoning in either is invalid, if the things so compared can be shown not to have that similitude or agreement on which the inference is founded. One instance therefore may serve for both. As when Cicero, after the death of Caesar, pleaded for the continuance of his laws, but not of those which were made afterwards by Mark Antony; because, though both were in them themselves invalid, and impious upon the public liberty; yet some of Caesar’s were useful, and others could not be set aside without disturbance to the state, and injuring particular persons; but those of Antony were all detrimental to the public.

The last method of confusion before-mentioned was, when the orator does in some sense grant the adversary his argument, and at the same time shows its invalidity. And this is done by a variety of ways, according to the different nature of the subject. Sometimes he allows what was said may be true; but pleads, that what he contends for is necessary. This was the method by which Hortenius proposed to bring off Verres, as we have already shown from Cicero, whose words are these, addressing himself to the judges: “What shall I do? which way shall I bring in my accusation? where shall I turn myself? for the character of a brave general is placed like a wall against all the attacks I can make. I know the place, I perceive where Hortenius intends to display himself. He will recount the hazards of war, the necessities of the state, the scarcity of commanders; and then he will entreat you, and do your utmost to persuade you, not to suffer the Roman people to be deprived of such a commander upon the testimony of the Sicilians, nor the glory of his arms to be falsified by a charge of avarice.” At other times the orator pleads, that although the contrary opinion may seem to be attended with advantage, yet that his own is more just or honourable. Such was the case of Regulus, when his friends endeavoured to prevail with him to continue at Rome, and not return to Carthage, where he knew he must undergo a cruel death. But as this could not be done without violating his oath, he refused to hearken to their persuasions. Another way of confusion is, by retorting upon the adversary his own argument. Thus Cicero, in his defence of Ligarius, says: “You have, Tubero, that which is most desirable to an accuser, the confession of the accused party; but yet such a confession, that he was on the same side that you, Tubero, chose yourself, and your father too, a man worthy of the highest praise. Wherefore, if there was any crime in this, you ought first to confess your own before you attempt to falten any upon Ligarius.” The orator takes this advantage where an argument proves too much, that is, more than the person designed it for, who made use of it. Not much unlike this is what they call inversion, by which the orator shows, that the reasons offered by the opposite party make for him. So when Cæcilius urged, that the province of accusing Verres ought to be granted to him, and not to Cicero, because he had been his treasurer in Sicily at the time those crimes were committed with which he was charged, and consequently knew most of that affair; Cicero turns the argument upon him, and shows, for that very reason he was the most unfit of any man to be intrusted with his prosecution; since having been concerned with him in his crimes, he would certainly do all in his power to conceal or lefl'en them. Again, sometimes the charge, is acknowledged, but the crime shifted off to another. Thus, when Sextius was accused of sedition, because he had got together a body of gladiators, and brought them into the forum, where a warm engagement happened between them and Clodius’s faction; Cicero owns the fact, but charges the crime of sedition upon Clodius’s party in being the aggressors. Another method made use of for the same purpose is, to alleviate the charge, and take off the force of it, by showing, that the thing was not done with that intention which the adversary infinuates. Thus Cicero, in his defence of king Dejotarus, owns he had raised some forces, though not to invade the Roman territories, as had been alleged, but only to defend his own borders, and send aid to the Roman generals.

We have hitherto been speaking of the methods of confusion used by orators, in answering those arguments which are brought by the contrary party. But sometimes they raise such objections themselves to what they have said, as they imagine may be made by others; which they afterwards answer, the better to induce their hearers to think, that nothing considerable can be offered against what they have advanced, but what will admit of an easy reply. Thus, when Cicero, at the request of the Sicilians, had undertaken the accusation of Verres, it came under debate, whether he, or Cicero, who had been Verres’s quæstor in Sicily, should be admitted to that province. Cicero, therefore, in order to set him aside, among other arguments, shows his incapacity for such an undertaking, and that it would amount to large qualifications for an orator. Which he represents to be so many and great, that he thought it necessary to start the following objection to what he had himself said upon that subject. “But you will say perhaps, Have you all these qualifications?” To which he thus replies: “I wish I had; but it has been my constant study from my youth to gain them. And if, from their greatness and difficulty, I have not been able to attain them, who have done nothing else through my whole life; how far, do you imagine, you must be from it, who never thought of them before; and even now, when you are entering upon them, have no apprehension, what, and how great, they are?” This is an effectual way of defeating an adversary, when the objection is well founded, and clearly answered. But we shall have occasion to consider this matter more largely hereafter, under the figure prolepesis, to which it properly relates.

Chap.
Rhetoricians make the conclusion of a discourse to consist of two parts: recaptitulation, and an address to the passions.

Recaptitulation is a summary account of what the speaker has before offered in maintenance of his subject; and is designed both to refresh the memory of the hearers, and to bring the principal arguments together into a narrow compass, that they may appear in a stronger light. Now there are several things necessary to a good repetition.

And first, it must be short and concise; since it is designed to refresh the memory, and not to burden it. For this end, therefore, the chief things only are to be touched upon; those on which the cause principally depends, and which the orator is most desirous his arguments for others to judge of. But though a repetition contains only the same things which had been more fully. This method Cicero has taken in the conclusion of his third oration upon the Agrarian Law. And here sometimes the orator takes occasion to find fault with his adversary's management, in these and such like expressions: "This part he has entirely dropped. To that he has given an invidious turn, or a false colouring. He leaves arguments, and flies to intreties; and not without good reason, if we consider the weakness of his cause."

But when the discourse is very long, and the arguments infixed on have been many, to prevent the hearers growing out of patience by a more particular recital, the orator sometimes only just mentions such things, which he thinks of least consequence, by saying, that he omits or páfles over them, till he comes to what is of greater moment, which he represents more fully. This method Cicero has taken in his defence of Cluentius; where, having run over several leffer heads in the manner now described, he then alters his expression, and introduces what was of more importance, by saying, "What I first complain of, is that wickedness, which is now discovered." And so he proceeds more particularly to recite those things which immediately related to Cluentius. And this is what the writers upon this art call protection. But this much may serve for repetition or recapitulation.

2. We now proceed to the other part of the conclusion, which consists in an address to the passions. Indeed the orator sometimes endeavours occasionally to work upon the passions of his hearers in other parts of his discourse, but more especially in the conclusion, where he is warmest himself, and labours to make them so. For the main design of the introduction is to conciliate the hearers, and gain their attention; of the narration, proposition, and confirmation, to inform them; and of the conclusion, to move them. And therefore, to use Quintilian's words, "Here all the spring's of eloquence are to be opened. It is here we secure the minds of the hearers, if what went before was well managed. Now we are past the rocks and shallows, all the falls may be hofted. And as the greatest part of the conclusion consists in illustration, the most pompous language and strongest figures have place.
II. Oratory

Disposition place here." Now the passions, to which the orator more particularly addresses, differ according to the nature of the discourse. In demonstrative orations, when laudatory,—love, admiration, and emulation—are usually excited: but in invectives,—hatred, envy, and contempt.

In deliberative subjects, either the hope of gratifying one desire is set in view, or the fear of some impending evil. And in judicial discourses, all the passions have place, but more especially resentment and pity: infomuch that most of the ancient rhetoricians mention only these two. But having treated upon the nature of the passions, and the methods suited both to excite and allay them, in a former chapter, we shall at present only add a few general observations, which may not be improper in this place, where the skill of the orator in addressing to them is more especially required.

The orator will observe what circumstances either of things, or persons, or both, will furnish him with motives proper to apply to those passions he desires to excite in the minds of his hearers. Thus Cicero, in his orations for Piancus and Sylla, moves his hearers from the circumstances of the men; but in his acclamation of Verres, very frequently from the barbarity and horrid nature of his crimes; and from both, in his defence of Quintinius.

But the same passion may be excited by very different methods. This is plain from the writings of those Roman satyrians which are yet extant; for they have all the same design, and that is to engage men to a love of virtue, and hatred of vice: but their manner is very different, suited to the genius of each writer. Horace, endeavours to recommend virtue, by laughing vice out of countenance; Persius moves us to an abhorrence and detestation of vice, with the gravity and severity of a philosopher; and Juvenal, by open and vehement invectives. So orators make use of all these methods in exciting the passions; as may be seen by their discourses, and particularly those of Cicero. But it is not convenient to dwell long upon the same passion. For the image thus wrought up in the minds of the hearers does not last a great while, but they soon return to reflection. When the emotion, therefore, is once carried as high as it will can be, they should be left under its influence, and the speaker proceed to some new matter, before it declines again.

Moreover, orators, sometimes endeavour to raise contrary passions to each other, as they are concerned for opposite parties. So the accuser excites anger and resentment, but the defendant pity and compassion. At other times, one thinks it sufficient to allay and take off that passion which the other has raised, and bring the hearers to a calm and sedate consideration of the matter before them.

But this especially is to be regarded, that the orator express the same passion himself with which he endeavours to affect others; and that not only in his action and voice, but likewise in his language: and therefore his words, and manner of expression, should be suited to that perturbation and disorder of mind which he desigts to represent. However, a decency and propriety of character is always carefully to be observed; for, as Cicero very well remarks, "A neglect of this is not only very culpable in life, but like a wife in discourse. Nor do the same things equally become every speaker, or every audience; nor every time, and every place." And therefore he greatly commends that painter, who, designing to represent in a picture the sacrifice of Iphigenia, Agamemnon's daughter, drew Chalcas the priest with a fili countenance; Ulysses, her father's great friend, more dejected; and her uncle Menelaus, most disconsolate: but threw a veil over the face of Agamemnon himself, as being unable to express that excess of sorrow which he thought was proper to appear in his countenance. And this justness of character is admirably well observed by Cicero himself, in his defence of Milo; for as Milo was always known to be a man of the greatest resolution, and moft undaunted courage, it was very improper to introduce him (as the usual method then was in capital cases) moving pity, and begging for mercy. Cicero therefore takes this part upon himself; and what he could not do with any propriety in the person of Milo, he performs in his own, and thus addresses the judges: "What remains but that I treat and befiegh you, that you would show that compassion to this brave man, for which he himself does not solicit, but I, against his inclination, earnestly implore and request. Do not be left inclined to acquit him, if in this our common sorrow, you see no tear fall from Milo's eyes; but perceive in him the same countenance, voice, and language, as at other times, steady and unmoved. Nay, I know not whether for this reason you ought not much sooner to favour him: For if, in the contests of gladiators (persons of the lowest condition and fortune in life), we are wont to be displeased with the timorous and suppliant, and those who beg for their life; but interpole in favour of the brave and courageous, and such as expose themselves to death; and we shew more compassion to those who do not sue for it, than to those who do; with how much greater reason ought we to act in the same manner towards the brave and our fellow-citizens?" And as these words were agreeable to his own character, while soliciting in behalf of another; so, immediately after, he introduces Milo speaking like himself, with a generous and undaunted air: "These words of Milo (says he) quite sink and take off that which the other has raised, and the speaker proceed to some new matter, before it declines again.

Moreover, orators, sometimes endeavour to raise contrary passions to each other, as they are concerned for opposite parties. So the accuser excites anger and resentment, but the defendant pity and compassion. At other times, one thinks it sufficient to allay and take off that passion which the other has raised, and bring the hearers to a calm and sedate consideration of the matter before them.

But this especially is to be regarded, that the orator expresses the same passion himself with which he endeavours to affect others; and that not only in his action and voice, but likewise in his language: and therefore his words, and manner of expression, should be suited to that perturbation and disorder of mind which he designs to represent. However, a decency and propriety of character is always carefully to be observed; for, as Cicero very well remarks, "A neglect of this is not only very culpable in life, but like a wife in discourse. Nor do the same things equally become every speaker, or every audience; nor every time, and every place." And therefore he greatly commends that painter, who, designing to represent in a picture the sacrifice of Iphigenia, Agamemnon's daughter, drew Chalcas the priest with a fili countenance; Ulysses, her father's great friend, more dejected; and her uncle Menelaus, most disconsolate: but threw a veil over the face of Agamemnon himself, as being unable to express that excess of sorrow which he thought was proper to appear in his countenance. And this justness of character is admirably well observed by Cicero himself, in his defence of Milo; for as Milo was always known to be a man of the greatest resolution, and most undaunted courage, it was very improper to introduce him (as the usual method then was in capital cases) moving pity, and begging for mercy. Cicero therefore takes this part upon himself; and what he could not do with any propriety in the person of Milo, he performs in his own, and thus addresses the judges: "What remains but that I treat and besiegh you, that you would show that compassion to this brave man, for which he himself does not solicit, but I, against his inclination, earnestly implore and request. Do not be left inclined to acquit him, if in this our common sorrow, you see no tear fall from Milo's eyes; but perceive in him the same countenance, voice, and language, as at other times, steady and unmoved. Nay, I know not whether for this reason you ought not much sooner to favour him: For if, in the contests of gladiators (persons of the lowest condition and fortune in life), we are wont to be displeased with the timorous and suppliant, and those who beg for their life; but interpose in favour of the brave and courageous, and such as expose themselves to death; and we shew more compassion to those who do not sue for it, than to those who do; with how much greater reason ought we to act in the same manner towards the brave and our fellow-citizens?" And as these words were agreeable to his own character, while soliciting in behalf of another; so, immediately after, he introduces Milo speaking like himself, with a generous and undaunted air: "These words of Milo (says he) quite sink and take off that which the other has raised, and the speaker proceed to some new matter, before it declines again.

But as persons are commonly more affected with what they see than with what they hear, orators sometimes call in the assistance of that sense in moving the passions. For this reason it was usual among the Romans, in judicial cases, for accused persons to appear with a dejected air and a forlorn garb, attended by their parents, children, or other relations and friends, with the like efts and aspect; as likewise to shew their scars, wounds, bloody garments, and other things of the like nature, in open court. So when, upon the death of Caesar, Mark Antony harangued the populace, he at the same time exposed to their view the garment
O R A T O R Y.

Part II:

disputed. He was flung upon a pole, and the flames that Matthew and the city, and the Senate, were threatened by fire. The people, in the forum, were in the flower of their age, and prime of their strength and vigour. At which time, when he was about to expire, and his mind had lost the feme of other things, still retaining a concern for the public, and he was all in tears, and intimidated in broken and dying words, how great a form hung over the city and threatened the whole state; often striking the wall which separated his house from that of Quintus Catulus, and frequently calling both upon him and me, and seeming to grieve not so much at the approach of his own death, as that both his country and I should be deprived of his assistance. Had he not been wickedly taken off on a sudden, how would he after his consuls have withstood the fury of his kindman Publius Clodius, who, while in that office, threatened in the hearing of the Senate, to kill him with his own hand, when he first began to break out? And will this woman dare to come out of those doors, and talk of the force of poison? will not the fear left the house itself should speak the villainy? will not the dread the conscious walls, nor that sad and mournful night? But I return to the accusation.” And then he proceeds to confer and refute the several circumstances of the accusation. All this was no part of his argument; but having mentioned the charge of poison, he immediately takes occasion to introduce it, in order to excite the indignation of the hearers against Clodia, and invalidate the prosecution as coming from a person of her character. Digression cannot properly be said to be a necessary part of a discourse; but it may sometimes be very convenient, and that upon several accounts. As first, where a subject is of itself flat and dry, or requires close attention, it is of use to relieve and unbend the mind by something agreeable and entertaining. For which reason Quintilian observes, that the orators of his time generally made an excursion in their harangues upon some pleasing topic, between the narration and the proof. But he condemns the practice, as too general; for while they seemed to think it necessary, it obliged them sometimes to bring in things trifling and foreign to the purpose. Besides, a digression is confined to no one part of a discourse, but may come in anywhere, as occasion offers; provided it fall in naturally with the subject, and be made some way subservient to it. We never meet with it in Cicero, without some evident and good reason. So in his prosecution of Verres for his barbarous and inhuman outrage against the Sicilians, he takes an occasion to launch out in a beautiful description of the island, and to recount the advantages which accrued from it to the Romans. His subject did not necessarily lead him to this, but his view in it was to heighten and aggravate the charge against Verres.

Again, as a digression ought not to be made without sufficient reason, so neither should it be too frequent. And he who never does it but where it is proper and useful, will not often see occasion for it. Frequently to leave the subject, and go off to other things, breaks the thread of the discourse, and is apt to introduce confusion. Indeed some kinds of writing admit of a more frequent use of digressions than others. In history they are often very serviceable. For as
II. Transition are often used not only after a digression, but likewise upon other occasions. A transition is, "A form of speech, by which the speaker in a few words tells his hearers both what he has said already, and what he next designs to say." Where a discourse consists of several parts, this is often very proper in passing from one to another, especially when the parts are of a considerable length; for it affords the hearers to carry on the series of the discourse in their mind, which is a great advantage to the memory. It is likewise a great relief to the attention, to be told when an argument is finished, and what is to be expected next. And therefore we meet with it very frequently in history. But we consider it at present only as made use of by orators. Cicero, in his second oration against Catiline, who had then left Rome, having at large described his conduct and designs, he adds: "But why do I talk so long concerning one enemy, and such an one?" who owns himself an enemy, and whom I do not fear, since, what I always desired, there is now a wall between us; and say nothing of those, who conceal themselves, who remain at Rome, and among us." And then he proceeds to give an account of the other conspirators.

But sometimes, in passing from one thing to another, a general hint of it is thought sufficient to prepare the hearers, without particularly specifying what has been said, or is next to follow. Thus Cicero in his second Philippic says, "But those things are old, this is yet fresh." And again: "But I have infilled too long upon trifles, let us come to things of greater moment." And at other times, for greater brevity, the transition is imperfect, and mention made only of the following lead, without any intimation of what has been said already. As in Cicero's defence of Murzena, where he says: "I must now proceed to the third part of my oration concerning the charge of bribery." And soon after: "I come now to Cato, who is the support and strengh of this charge."

III. The third and last head is, Amplification. Now Amplification by amplification is meant, not barely a method of expanding upon a thing; but so to represent it in the fixed and full and most comprehensive view, as that it may be explained, the liveliest manner strike the mind, and influence the passions. Cicero, speaking of this, calls it the greatest commendation of eloquence; and observes, "that it consists not only in magnifying and heightening a thing, but likewise in extenuating and lessening it." But though it consists of these two parts, and may be applied either way; yet to amplify, is not to fet things in a false light, but to paint them in their just proportions and proper colours, suitable to their nature and qualities. Rhetoricians have observed several ways of doing this.

One is to ascend from a particular thing to a general. Thus Cicero, in his defence of Archias, having commended him as an excellent poet, and likewise observed, that all the liberal arts have a connexion with each other, and a mutual relation between them, in order to raise a just esteem of him in the minds of his hearers, takes occasion to say many things in praise of polite literature in general, and the great advantages that may be received from it. "You will ask me, (says he), why we are so delighted with this man? Because he supplies us with those things, which both refresh our minds after the noise of the forum, and delight our ears when wearied with contention. Do you think we could either be furnished with matter for such a variety of subjects, if we did not cultivate our minds with learning? or hear such a constant fatigue, without affording them that refreshment? I own I have always pursued these studies; but those are all that have given up themselves to learning, as neither to be able to convert it to any common benefit, nor discover it in public. But why should it shame me, who have so lived for many years, that no advantage or ease has ever diverted me, no pleasure allured me, nor sleep retarded me, from this pursuit. Who then can blame me, or who can justly be displeased with me, if I have employed that time in reviewing these studies, which has been spent by others in managing their affairs, in the celebration of festivals, or other diversions, in refreshments of mind and body, Vol. XIII.
And this ought the rather to be allowed me, because my ability as an orator has been improved by these pursuits, which, such as it is, was never wanting to allit my friends. And if it be esteemed but small, yet I am sensible from what spring I must draw those things which are of the greatest importance." With more of the same purport, from which he draws this inference: "Shall I not therefore love this man? Shall I not admire him? Shall I not by all means defend him?"

A contrary method to the former is, to defend from a general to a particular. As if any one, while speaking in commendation of eloquence, should illustrate what he says from the example of Cicero, and show the great services he did his country, and the honours he gained to himself, by his admirable skill in oratorical. Our common way of judging of the nature of things is from what we observe in particular instances, by which we form general notions concerning them. When therefore we consider the character of Cicero, and the figure he made in the world, it leads us to conclude, there must be something very admirable in that art by which he became so celebrated. And this method he has taken himself in his oration for the Macedonian war, where having first intimated the scarcity of good generals at that time among the Romans, he then describes the virtues of a complete commander as a proof of it, and shows how many and great qualifications are necessary to form such a character, as courage, prudence, experience, and success: all which he afterwards applies to Pompey.

A third method is by an enumeration of parts. So when Cicero, upon the defeat of Mark Antony before Mutina, proposed that a funeral monument should be erected in honour of the soldiers who were killed in that battle, as a comfort to their surviving relations; he does it in this way, to give it the greater weight: "Since (says he) the tribute of glory is paid to the valiant citizens by the honour of a monument, let us thus comfort their relations, who will receive the greatest consolation in this manner: their parents, who produced such brave defenders of the state; their children, who will enjoy these domestic examples of fortitude; their wives, for the loss of such husbands, whom it will be more fitting to extoll than lament; their bretheren, who will hope to resemble them no lefs in their virtues than their apex. And I wish we may be able to remove the grief of all these by our resolutions." Such representations greatly enlarge the image of a thing, and afford the mind a much clearer view of it than if it were contradicted into one single proposition.

Again, another method not much unlike the former is, when any thing is illustrated from a variety of causes. Thus Cicero justifies his behaviour in retiring, and not opposing his enemies, when they spirited up the mob in order to band him, from the following reasons, which at that time determined him to such a conduct: "When (says he) laws I was given up, so many armed fleets seemed ready to attack this single ship of the state; tossed with the tempests of seditions and discords, and the senate was now removed from the helm; when banishment, murder, and outrage, were threatened; when some, from an apprehension of their own danger, would not defend me; others were excited by an invertebrate hatred to all good men, others thought I should have opposed them (I will not say to my own certain destruction, but) to the dangerous both of you and your children, than alone to submit to and undergo what threatened us all in common?"

Such a number of reasons brought together, must fet a thing in a very strong and clear light.

The like may be said of a number and variety of effects. Thus Cicero describes the force and excellence of oratory from its great and surprising effects, when he says, "Nothing seems to be more excellent, than by discourse to draw the attention of a whole assembly, delight them, and sway their inclinations different ways at pleasure. This, in every free state, and especially in times of peace and tranquillity, has been always in the highest esteem and reputation. For what is either so admirable, as for one only, or a very few, out of a vast multitude, to be able to do that which all have a natural power of doing; or so delightful to hear, as a judicious and solid discourse in florid and polite language? or so powerful and grand, as to influence the populace, the judges, the senate, by the charms of eloquence? Nay, what is so noble, so generous, so munificent, as to afford aid yourself, affet your right, or repel injuries? And, not to confine our thoughts wholly to the courts of justice or the senate, what is there in the arts of peace more agreeable and entertaining than good language and a fine way of speaking? For it is this especially wherein we excel other animals, that we can discourse together, and convey our thoughts to each other by words. Who therefore would not esteem, and in a particular manner endeavour to surpass others in that wherein mankind principally excels brute beasts? But to proceed to its chief advantages: What else would have drawn men into societies, or taken them off from a wild and savage life, and foster them into a polite and civilized behaviour? or, when settled in communities, have restrained them by laws? Who but, after such a description, could conceive the strongest passion for an art attended with so many great and good effects?

A thing may likewise be illustrated by its opposite. So the blessings and advantages of peace may be recommended from the miseries and calamities of war; and thus Cicero endeavours to throw contempt upon Catiline and his party, by comparing them with the contrary side: "But if, omitting all these things which we abound, and they want, the senate, the knights, the populace, the city, treasury, revenues, all Italy, the provinces, and foreign nations; if, I say, omitting these things, we compare the causes themselves in which each side is engaged, we may learn from thence how deplorable they are.—For on this side modesty is engaged, on that impudence; on this charity, on that avarice; on this integrity, on that fraud; on this piety, on that profaneness; on this
**ORATORY.**

**Elocution.**

By this we are to be understood, that fury; on this occasion, on that baseless; on this moderation, on that unbridled passion: in a word, equity, temperance, fortitude, prudence, and all virtues, contend with injustice, luxury, cowardice, rashness, and all vices; plenty with want; reason with folly; sobriety with madness; and, lastly, good hope with despair. In such a contest, did men defeat us, would not heaven ordain that so many and so great vices should be defeated by these most excellent virtues?

Gradation is another beautiful way of doing this. So when Cicero would aggravate the cruelty and barbarity of Verres for crucifying a Roman citizen, which was a sort of punishment only inflicted upon slaves, he chooses this way of doing it. "It is a crime (says he) to bind a Roman citizen, wickedness to whip him, and a sort of barbarism to kill him; what then must I call it to crucify him? No name can sufficiently express such a villain." And the images of things may be thus heightened, either by ascending, as in this instance; or descending, as in that which follows, relating to the same action of Verres: "Was I not to complain of or bewail these things to Roman citizens, nor the friends of our state, nor those who had heard of the Roman name? nay, if not to men, but beasts; or, to go yet further, if in the most desert wilderness, to felines and rocks; even all mute and inanimate creatures would be moved by so great and heinous cruelty."

And, to name no more, facts may be amplified from their circumstances; as time, place, manner, event, and the like. But instances of this would carry us too far; and therefore we shall only add, that, as the designation of amplification is not barely to prove or evince the truth of things, but also to adorn and illustrate them, it requires a florid and beautiful style, consisting of strong and emphatical words, flowing periods, harmonious numbers, lively tropes, and bright figures. But the consideration of these things come under the third part of oratory, upon which we are now to enter.

**PART III. OF ELOCUTION.**

Elocution directs us to suit both the words and expressions of a discourse to the nature of the subject, or to speak with propriety and decency. This faculty is in one word called eloquence; and those persons who are possessed of it are therefore styled eloquent.

Elocution is twofold, general and particular. The former treats of the several properties and ornaments of language in common; the latter considers them as they are made use of to form different sorts of style.

**I. GENERAL ELOCUTION.**

Thus, according to rhetoricians, consists of three parts: Elegance, Composition, and Dignity. A discourse which has all these properties suitably adjusted, must, with respect to the language, be perfect in its kind, and delightful to the hearers.

**CHAP. I. OF ELEGANCE.**

Elegance consists in two things, Purity and Perspicuity: And both these, as well with respect to single words, as their construction in sentences. These properties in language give it the name of elegant, for a like reason that we call other things so which are clean and neat in their kind. But in the common use of our tongue, we are apt to confound elegance with eloquence; and, say, a discourse is elegant, when we mean by the expression, that it has all the properties of the fine language.

§ 1. Purity.

By this we are to understand the choice of such words and phrases as are suited and agreeable to the use of the language in which we speak: and so grammarians reduce the faults they oppose to it to two sorts, which they call barbarism and solecism; the former of which rejects single words, and the latter their construction. But we shall consider them jointly, and in a manner different from grammarians; for with them all words are esteemed pure which are once adopted into a language, and authorized by use. And as to phrases, or forms of expression, they allow them all the same claim, which are agreeable to the analogy of the tongue. But in oratory, neither all words nor all expressions are so called which occur in language; but such only as are recommended by the authority of those who speak or write with accuracy and politeness. Indeed it is a common saying, that we should think with the learned, and speak with the vulgar. But the meaning of that expression is no more than that we should speak agreeably to the common usage of the tongue, that every one may understand us; and not choose such words or expressions as are either difficult to be understood, or may carry in them an appearance of affectation and singularity. But in order to set this matter in a clearer light, we shall here recount the principal things which vitiate the purity of language.

And first, it often happens, that such words and forms of speaking as were introduced by the learned are afterwards dropped by them as mean and forfidd, from a seeming barbarism contrasted by vulgar use. For polite and elegant speakers distinguish themselves by their discourse, as persons of figure do by their garb; one being the dress of the mind, as the other is of the body. And hence it comes to pass, that both have their different fashions, which are often changed; and as the vulgar affect to imitate those above them in both, this frequently occasions an alteration when either becomes too trite and common. But beside these forfidd words and expressions, which are rendered so by the use of the vulgar, there is another sort first introduced by them, which is carefully to be avoided by all those who are dextrous in speech. For the vulgar have their peculiar words and phrases, suited to their circumstances, and taken from such things as usually occur in their way of life. Thus in the old comedians, many things are spoken by servants, agreeable to their character, which would be
Elocution. very unbecoming from the mouth of a gentleman.
And we cannot but daily observe the like instances among ourselves.

Again, this is common to language with all other human productions, that it is in its own nature liable to a constant change and alteration. For, as Horace has juelly observed,

All human works shall wane;
Then how can feeble words pretend to last.

Nothing could ever please all persons, or at least for any length of time. And there is nothing from which this can least be expected than language. For as the thoughts of men are exceedingly various, and words are the signs of their thoughts, they will be constantly inventing new signs to express them by, in order to convey their ideas with more clearness or greater beauty. If we look into the different ages of the Latin writers, what great alterations and changes do we find in their language? How few now understand the remaining fragments of the twelve tables? Nay, how many words do we meet with even in Plautus, the meaning of which has not yet been fixed with certainty by the skill of the best critics? And if we consider our own language, it will appear to have been in a living language, and therefore the greater liberty not be supplied from them, our own language, it will appear to have been in a very unbecoming to a constant change and alteration. For, as Horace has justly observed,

Some words that have or else will feel decay
Shall be retor'd, and come again in play;
And words now fam'd shall not be fancied long;
They shall not please the ear, nor move the tongue:
As ufe shall there approve, and those condemn;
Ufe, the sole rule of speech, and judge supreme.

We must therefore no less abstain from antiquated or obsolete words and phrases, than from forc'd ones. Though all old words are not to be thought antiquated. By the former we mean such as, though of an ancient standing, are not yet entirely diffused nor their signification lost. And from the use of these we are not to be wholly debarred, especially when they appear more significant than any others we can fix upon. But as to phrases or expressions, greater caution seems still necessary: and such as are old should doubtless, if at all, be used more sparingly. The Latin tongue was brought to its greatest perfection in the reign of Augustus, or somewhat sooner; and he himself studied it very carefully. For, as Suetonius tells us, "He applied himself to eloquence, and the study of the liberal arts, from his childhood, with great diligence and labour. He chose a manner of speaking which was smooth and elegant: he avoided the ill favour, as he used to call it, of antiquated words; and he was wont to blame Tiberius for his affectation of them." In our own language, such words are to be esteemed antiquated, which the most polite persons have dropped, both in their discourse and writings: whole example we should follow, unless we would be thought to converse rather with the dead than the living.

But further: As on the one hand we must avoid obsolete words and phrases; so, on the other, we should refrain from new ones, or such whose use has not yet been sufficiently established, at least among those of the best taste. Words may be considered as new in two respects: either when they are first brought into a language, or when they are used in a new sense. As the former of these may sometimes leave us in the dark by not being understood, so the latter are most apt to mislead us; for when we hear a word that has been familiar to us, we are presently led to fix that word to it with which it has usually been attended. And therefore, in both cases, some previous intimations may be necessary. Cicero, who perhaps enlarged the furniture of the Roman tongue more than any one person besides, appears always very cautious how he introduces any thing new, and generally gives notice of it when he attempts it, as appears in many instances scattered through his works. What bounds we are now to fix to the purity of the Latin tongue in the use of it, the learned are not well agreed. It is certain, our furniture is much less than when it was a living language, and therefore the greater liberty must of necessity be sometimes taken. So that their opinion seems not unadvisable, who direct us to make choice principally of what we are furnished with from the writers of the Augustan age; and, where we cannot be supplied from them, to make use of such authors as lived nearest to them, either before or since. And as to our own tongue, it is certainly prudent to be as careful how we admit any thing into it that is uncouth or disagreeable to its genius, as the ancient Romans were into theirs; for the perfection of a language does in a great measure consist in a certain analogy and harmony running through the whole, by which it may be capable of being brought to a standard.

But besides those things already mentioned, any misuse in the filing of words, or their construction, is opposed to purity. For to speak purely, is to speak correctly. And such is the nature of those faults in elocution, that they are often not so easy to be observed by hearing as by reading. Whence it is, that many persons are thought to speak better than they write; for while they are speaking, many slips and inaccuracies escape disregarded, which in reading would presently appear. And this is more especially the case of persons unacquainted with arts and literature; who, by the affinities of a lively fancy and flow of words, often speak with great ease and freedom, and by that means please the ear; when, at the same time, what they say, would not so well bear reading.

We shall only add, that a distinction ought likewise to be made between a poetic diction and that of prose writers. For poets in all languages have a sort of peculiar dialect, and take greater liberties, not only in their figures, but also in their choice and disposition of words; so that what is a beauty in them would often appear unnatural and affectless in prose.

§ 2. Of Perspicuity.

Perspicuity, as well as purity, consists partly in explained single words, and partly in their construction.

I. As explained.
Oratory.

Part III.

I. As to single words, those are generally clearer, and best understood which are used in their proper sense. But it requires no small attention and skill to be well acquainted with the force and propriety of words; which ought to be duly regarded, since the perfection of a discourse depends so much upon it. Cesar seems plainly to have been of this mind, when he tells us, "The foundation of eloquence consists in the choice of words." It may not be amiss, therefore, to lay down some few observations, by which the different notions of words and their peculiar force may more easily be perceived. All words may be divided into proper words and tropes. Those are called proper words, which are expressed in their proper and usual sense. And tropes are such words as are applied to other things than what they properly denote, by reason of some similitude, relation, or contrariety between the two things. So, when a subtle artful man is called a fox, the reason of the name is founded in a similitude of qualities. If we say, Cicero will always live, meaning his works, the cause is transferred to the effect. And when we are told, Cesar conquered the Gauls, we understand that he did it with the assistance of his army, where a part is put for the whole, from the relation between them. And when Cicero calls Antony a fine guardian of the state, every one perceives he means the contrary. But the nature and use of tropes will be explained more fully hereafter in their proper place. All words must at first have had one original and primary signification, which, strictly speaking, may be called their proper sense. But it sometimes happens through length of time, that words lose their original signification, and assume a new one, which then becomes their proper sense. So ho fists in the Latin tongue at first signified a stranger; but afterwards that sense of the word was entirely laid aside, and it was used to denote a public enemy. And in our language, it is well known, that the word knowes anciently signified a foeman. The reason of the change seems to be much the same, as in that of the Latin word latro; which first signified a soldier, but afterwards a robber. Besides, in all languages it has frequently happened, that many words have gradually varied from their first sense to others somewhat different; which may, notwithstanding, all of them, when rightly applied, be looked upon as proper. Nay, in process of time, it is often difficult to say which is the original, or most proper sense. Again, sometimes two or more words may appear to have the same signification with each other, and may therefore be used indifferently; unless the beauty of the period, or some other particular reason, determine to the choice of one rather than another. Of this kind are the words enuia and gladius in the Latin tongue; and in ours, pity and compassion. And there are other words of so near an affinity to each other, or at least appear so from vulgar use, that they are commonly thought to be synonymous. Such are the words mercy and pity; though mercy in its strict sense is exercised towards an offender, and pity respects one in distress. As this peculiar force and distinction of words is carefully to be attended to, so it may be known several ways. Thus the proper signification of substantives may be seen by their application to other substantives. As in the instance just now given, a person is said to show mercy to a criminal, and pity to one in distress. And in the like manner, verbs are distinguished, by being joined to some certain nouns, and not to others. So a person is said to command an inferior, to treat a superior, and to define an equal. Adjectives also, which denote the properties of things, have their signification determined by those subjects to which they most properly relate. Thus we say, an honest mind, and a healthy body; a wise man, and a fine horse. Another way of distinguishing the propriety of words, is by their use in gradations. As if one should say, Hatreds, grudges, quarrels, tumults, seditions, wars, spring from unbridled passions. The proper sense of words may likewise be known by observing to what other words they are either opposed, or used as equivalent. So in that passage of Cicero, where he says, "I cannot perceive why you should be angry with me: If he because I defend him whom you accuse, why may not I be displeased with you for accusing him whom I defend? You say, I accuse my enemy; and I say, I defend my friend." Here the words accuse and defend, friend and enemy, are opposed; and to be angry and displeased, are used as terms equivalent. And thus the definition of words contributes very much to determine their meaning. Thus because the word manners comes from the word man, it may properly be applied either to that or any other put for it. And therefore we say, the manners of men, and the manners of the age, because the word age is there used for the men of the age. But if we apply the word manners to any other animal, it is a trope. By these and such like observations we may perceive the proper sense and peculiar force of words, either by their connection with other words, distinction from them, opposition to them, equivalency with them, or derivation. And by thus fixing their true and genuine signification, we shall easily see when they become tropes. But though words, when taken in their proper signification, generally convey the plainest and clearest sense; yet some are more forcible, impressive, or beautiful, than others. And by these considerations we must often be determined in our choice of them. So whether we say, be get, or be obtained, the victory, the sense is the same; but the latter is more full and forcible. In Latin, timor signifies I fear; peri meus more full and significant; and permissione more forcible than either of the former. The Latin and Greek languages have much the advantage of ours in this respect, by reason of their compositions; by the help of which they can often express that in one word for which we are obliged to put two words, and sometimes more. So permission cannot be fully expressed in our language by one word; but we are forced to join one or two particles to the verb, to convey its just idea, and say, I greatly, or very much fear: and yet even then we scarce seem to reach its full force. As to tropes, though generally speaking they are not to be chosen where plainness and perspicuity of expression is only desired, and proper words may be found; yet through the penury of all languages, the use of them is often made necessary. And some of them, especially metaphors, which are taken from the similitude of things, may, when custom has rendered them familiar, be considered as proper words, and used in their stead. Thus, whether we say, I see your meaning, or, I understand your meaning, the sense is equally clear, though
As to the construction of sentences.

But perspicuity arises not only from a choice of simple words, but likewise from the conjunction of them in sentences. For the meaning of all the words in a sentence, considered by themselves, may be very plain and evident; and yet by reason of a disorderly placing them, or confusion of the parts the sense of the whole may be very dark and obscure. Now it is certain, that the most natural order is the plainest; that is, when both the words and parts of a sentence are so disposed, as both agree with their mutual relation and dependance upon each other. And where this is changed, as is usually done, especially in the ancient languages, for the greater beauty and harmony of the periods; yet due regard is had by the best writers to the evidence and perspicuity of the expression.

But to set this subject in a clearer light, on which the peristion of language so much depends, we shall mention some few things which chiefly occasion obscurity; and that either with respect to simple words, or their construction.

And first, all ambiguity of expression is one cause of obscurity. This sometimes arises from the different senses in which a word is capable of being taken. So we are told, that upon Cicero’s addressing himself to Octavius Caesar, when he thought himself in danger from his retentment, and reminding him of the many services he had done him, Octavius replied, “He came the last of his friends.” But there was a designed ambiguity in the word last, as it might either refer to the time of his coming, or the opinion he had of his friendship. And this use of ambiguous words we sometimes meet with. not only in poetry, where the turn and wit of an epigram often rolls upon it; but likewise in prose, either for pleasantry or ridicule. Thus Cicero calls Sextus Clodius the light of the senate; which is a compliment he pays to several great men, who had distinguished themselves by their public services to their country. But Sextus, who had a contrary character, was a relation of P. Clodius, whose death Boils, after he had been killed by Milo, he carried in a tumultuous manner into the senate-houfe, and there burnt it with the senators benches, in order to inflame the populace against Milo. And it is in allusion to that riotous act, that Cicero, using this ambiguous expression, calls him the light of the senate. In such instances, therefore, it is a beauty, and not the fault we are cautious against: as the same thing may either be good or bad as it is differently applied.

Though even in such designed ambiguities, where one sense is aimed at, it ought to be sufficiently plain, otherwise they lose their intention. And in all serious discourses they ought carefully to be avoided. But obscurity more frequently arises from the ambiguous construction of words, which renders it difficult to determine in what sense they are to be taken. Quintilian gives us this example of it: “A certain man ordered in his will, that his heir should erect for him a statue holding a spear made of gold.” A question arises here, of great consequence to the heir from the ambiguity of the expression, whether the words made of gold are to be applied to the statue or the spear; that is, whether it was the design of the testator by this appointment, that the whole statue, or only the spear, should be made of gold. A small note of distinction, differently placed between the parts of this sentence, would clear up the doubt, and determine the sense either way. For if one comma be put after the word statue, and another after spear, the words made of gold must be referred to the statue, as if it had been said, a statue made of gold, holding a spear. But if there be only the first comma placed after statue, it will limit the words made of gold to the spear only; in the same sense as if it had been said, A statue holding a golden spear. And either of these ways of expression would in this case have been preferable, for avoiding the ambiguity, according to the intention of the testator. The ancient heathen oracles were generally delivered in such ambiguous terms. Which, without doubt, were so contrived on purpose, that those who gave out the answers might have room left for an evasion. See Octavius.

Again, obscurity is occasioned either by too short and concise a manner of speaking, or by sentences too long and prolix; either of these extremes have sometimes this bad consequence. We find an instance of the former in Pliny the elder, where speaking of helbore, he says, “They forbid it to be given to aged persons and children, and less to women than men.” The verb is wanting in the latter part of the sentence, and left to women than men: which in such cases being usually supplied from what went before, would here stand thus; and they forbid it to be given left to women than men. But this is directly contrary to the sense of the writer, whose meaning is, either that it is ordered to be given in a less quantity to women than men, or not so frequently to women as men. And therefore the word order is here to be supplied, which being of a contrary signification to forbid, expressed in the former part of the sentence, occasions the obscurity. That long periods are often attended with the same ill effect, must be so obvious to every one’s experience, that it would be entirely needless to produce any examples in order to evince the truth of it. And therefore we shall only observe, that the best way of preventing this seems to be by dividing such sentences as exceed a proper length into two or more; which may generally be done without much trouble.

Another cause of obscurity, not inferior to any yet mentioned, is parenthesis, when it is either too long or too frequent. This of Cicero, in his oration for Sulla, is longer than we usually find in him: “O immortal gods! (for I must attribute to you what is your own; nor indeed can I claim so much to my own abilities as to have been able of myself to go through so many, so great, so different affairs, with that expedition, in that boisterous tempest of the state), you inflamed my mind with a desire to save my country.” But where any obscurity arises from such sentences, they may frequently be remedied by much the same means as was just now hinted concerning long and prolix periods; that is by separating the parenthesis from the rest of the sentence, and placing it either before or after. So in this sentence of Cicero, the parenthesis may stand last, in the following manner:—

“O immortal gods! you inflamed my mind with a desire to save my country: for I must attribute to you what is your own; nor indeed can I claim so much to
my own abilities, as to have been able of myself to go through so many, so great, such different affairs, with that expedition, in that boisterous tempest of the state." This order of the sentence is very plain, and less involved than the former.

**Chap. II. Of Composition.**

Composition, in the sense it is here used, gives rules for the structure of sentences, with the several members, words, and syllables, of which they consist, in such a manner as may best contribute to the force, beauty, and evidence of the whole.

Composition consists of four parts, which rhetoricians call period, order, juncture, and number. The first of these treats of the structure of sentences; the second, of the parts of sentences, which are words and members; and the two last, of the parts of words, which are letters and syllables. For all articulate sounds, and even the most minute parts of language, come under the cognizance of oratory.

§ 1. Of Period.

In every sentence or proposition, something is said of something. That of which something is said, logicians call the subject, and that which is said of it, the predicate; but in grammatical terms, the former is a noun substantive, or the nominative case, and the latter a finite verb, denoting affirmation, and some state of being, acting, or suffering. These two parts may of themselves constitute a sentence: As when we say, *The sun shines,* or *The clock strikes,* the word *sun* and *clock* are the subject of these expressions, *shines* and *strikes* imply each the copula and predicate. Most commonly, however, the noun and the verb are accompanied with other words, which in grammatical construction are said either to be connected with or to depend upon them; but in a logical consideration they denote some property or circumstance relating to them. As in the following sentence: *A good man loves virtue for itself.* The subject of this sentence is a good man; and the predicate, or thing affirmed of him, that he loves virtue for itself. But the two principal or necessary words, on which all the rest depend, are *man* and *loves.* Now a simple sentence consists of one such noun and verb, with whatever else is joined to either or both of them. And a compound sentence contains two or more of them; and may be divided into many different propositions, as there are such nouns and verbs, either expressed or understood. So in the following sentence, *Compliance gains friends, but truth procures hatred,* there are two members, each of which contains in it an entire proposition. For, *Compliance gains friends* is one complete sentence, and *truth procures hatred* is another; which are connected into one compound sentence by the particle *but.* Moreover, it frequently happens, that compound sentences are made up of such parts or members, some if not all of which are themselves compounded, and contain in them two or more simple members. Such is that of Sallust: "Ambition has betrayed many perjons into deceit; to say one thing, and to mean another; to found friendship and enmity, not upon reason, but interest; and to be more careful to appear honest, than really to be so." This sentence consists of four members; the last of which three, consisting of opposite parts, are all compounded, as will appear by expressing them at length in the following manner: *Ambition has betrayed many persons into deceit; that is, ambition has betrayed them to say one thing, and to mean another; it has betrayed them to found friendship and enmity, not upon reason, but in erro; and it has betrayed them to be more careful to appear honest, than really to be so.* The three last of these members, beginning with the words *it betrays,* are all of them compounded, and consist of two opposite members; which might each of them be expressed at length in the same manner, by supplying the ellipsis. As, *Ambition has betrayed many persons to say one thing, and it has betrayed them to mean another.* And so of the rest. From this instance we see how much is left to be supplied by the mind in all discourse, which it expressed would both destroy its harmony and render it exceedingly tedious. But still regard must be had to that which is omitted, so as to render what is said consistent with it: otherwise there can be no propriety in what is spoken. Nor can the members of a sentence be distinguished and duly ranged in their proper order, without this. But to proceed: Some sentences consist either wholly, or in part, of such members as contain in them two or more compound ones, which may therefore for distinction's sake, be called compound members. Of this kind is that of Cicero, in his defence of Milo: "Great is the force of conscience, great either way; that those persons are not afraid who have committed no offence; and those who have offended always think punishment prefent before their eyes." The latter member of this sentence, which begins with the word *that,* contains in it two compound members, which represent the different state of mind between innocent and guilty persons. And it is in the proper distinction and separation of the members in such complex sentences, that the art of pointing chiefly consists. For the principal use of a comma is to divide the simple members, a semicolon the compound ones, a colon such as are compounded, and a period the whole from the following sentence. We mention this the rather, to shew the different acception of these terms by grammarians, from that of the ancient writers upon oratory. For these latter apply them to the sense, and not to any points of distinction. A very short member, whether simple or compound, with them is a comma, and a longer a colon; for they have no such terms as a semicolon. Besides, they call a very short sentence, whether simple or compound, a comma, and one of somewhat a greater length, a *col.* And therefore, if a person expressed himself either of these ways in any considerable number of sentences together, he was said to speak by *comas* or *colon.* But a sentence containing more words than will consist with either of these terms, they call a *simple period,* the least compound period with them requiring the length of two comons. However, this way of denominating sentences, and the parts of them, rather from their length than the nature of them, appearing not so suitable, we have chosen rather to make use of the terms *simple* and *compound members;* and to call all those *compound periods,* which contain two or more members, whether simple or compound.

But to proceed: Sentences, with respect to their form or composition, are distinguished into two sorts, called:
called by Cicero \textit{tractus}, "straight or direct," and \textit{contorta}, "bent or winding." By the former are meant those whose members follow each other in a direct order, without any inflection; and by the latter, those which stiffly speaking are called \textit{periods}. For \textit{σχηματικά}, in Greek signifies a \textit{circuit} or \textit{circle}. And in the Latinus call it \textit{circulus} and \textit{ambitus}. By which both of them mean a sentence consisting of correspondent parts, so framed, that the voice in pronouncing them may have a proper elevation and cadency, and distinguish them by its inflection; and as the latter part returns back, and unites with the former, the period, like a circle, surrounds and incloses the whole sense. This elevation of the voice in the former part of the period, is by the Greeks called \textit{ἐπίφανες} and by the Latins \textit{propoſitis}; and the depression of it in the latter part, by the one \textit{ἀνώτατος}, and by the other \textit{reduction}.

Now as simple sentences have not these correspondent parts, which require any inflection of the voice; nor a circular form, by reason of their brevity; they are not properly periods, in the strict sense of the word: though in common speech, the words \textit{sentence} and \textit{period} are often used as equivalent terms. Thus, if we say, \textit{Gracious minds are incited to the performance of noble exploits from motives of glory}; here is no division of parts, nor inflection of the voice in this sentence. And indeed there is not any thing which relates to the structure of these sentences, but what will more properly be taken notice of in the second part of \textit{composition}, which is \textit{order}.

And as to those compound sentences, whose members follow each other in a direct order, without any inflection, there is little art required in their composition. We shall produce one example of this kind from Cicero: "Natural reason inclines men to mutual converse and society; and implants in them a strong affection for those who spring from them; and excites them to form communities, and join in public assemblies; and, for these ends, to endeavour to procure both the necessaries and conveniences of life; and that not for themselves only, but likewise for their wives, children, and others who are dear to them, and have a right to their affiance." Here are five short members in this sentence, placed in a series, without any inflection of the parts, or orbit of the whole. And as such sentences have no other boundary but the conclusion of the sense, suited to the breath of the speaker, he may either contrariwise or lengthen them at pleasure, without offending the ear. So, should the sentence last mentioned conclude with the first member in this manner: \textit{Natural reason inclines men to mutual converse and society}; the sense would be perfect, and the ear satisfied. The cafe would be the same at the end of the second member, thus: \textit{Natural reason inclines men to mutual converse and society, and implants in them a strong affection for those who spring from them.} And the like may be said of the rest. Since such sentences therefore may be thus limited at pleasure, it seems more convenient both for the speaker and hearers to confine them to a moderate length.

But because the principal art relating to this part of composition lies in the frame and structure of such compound sentences as are properly called \textit{periods}, we shall treat upon them somewhat more largely. In the formation of these periods, two things are chiefly to be regarded, their \textit{length}, and \textit{cadency}. As the length ought to be fitted to the breadth of the speaker, the ancient rhetoricians scarce admit of more than four colons; by which we may here understand compound members of a moderate size, which will be generally found a suitable and proportionate length. For to extend them farther than the voice can well manage must be painful to the speaker, and of consequence unpleasant to the hearers. As to the cadency, what Cicero has observed, is found true by experience, that the ears judge what is full, and what is deficient; and direct us to fill up our periods, that nothing be wanting of what they expect. When the voice is raised at the beginning of a sentence, they are in suspense till it be finished: and are pleased with a full and just cadency, but are sensible of any defect, and are displeased with redundancy. Therefore care must be taken that periods be neither deficient, and as it were maimed, that is, that they do not drop before their time, and defraud the ears of what seemed to be promised them; nor, on the other hand, offend them by too long and imminent excursions. This rise and cadency of the voice in pronunciation, depend on the nature and situation of the members, as we shall endeavour to shew by particular instances; in the explanation of which, by the word \textit{members}, are to be understood such as are uncompounded. In a period of two members, the turn of the voice begins with the latter member. Of this kind is the following sentence of Cicero: "If impudence prevailed as much in the forum and courts of justice, as insolence does in the country and places of last resort; Aulus Cæcina would submit as much to the impudence of Sextus Eburnius in this cause, as he did before to his insolence when faulced by him." Here the cadency begins at the words \textit{Aulus Cæcina}. If a sentence consist of three members, the inflection is best made at the end of the second member: for if it begin immediately after the first, the voice will be either apt to sink too low, and not to be heard, before it reach the end; or else be precipitated, in order to prevent it. Cicero begins his oration for Milo with a sentence of this form: "Although I fear, it may be a blame to be dismayed at the entrance of my discourse in defence of a most valiant man; and that it nowise becomes me, while Milo is more concerned for the safety of the state than for himself, not to show the fame greatneſs of mind in his behalf: yet this new form of prosecution terrifies my eyes, which, whatever way they turn, want the ancient cultum of the forum, and former manner of trials." Here the cadency beginning at the third member with the word \textit{yet}, makes a proper division of the sentence, and easy for the speaker. But a period of four members is reckoned the most complete and perfect, where the inflection begins at the middle, that is, with the third member. Nor is it the same case here, as if, in a sentence of three members, the cadency be made at the second. For in proportion to the time of raising the voice may the space be allowed for its sinking. The following sentence of Cicero gives us an instance of this, where he speaks to his son: "Although, son Mark, having now been an hearer of Craippus for a year, and this at Athens, you ought to abound in the precepts and doctrines of philosophy,
Of Socrates, contain the subject of this sentence, with what relates to it; and all those which follow, excited. Artifice to the profession of oratory, make up the predicate and its dependants. And in both parts each word grammatically considered stands in its proper order of construction. And this seems agreeable to the natural way of conveying our thoughts, which leads us first to express the subject or thing of which some other thing is said, before the predicate or that which is said concerning it; and with respect to both, as every idea succeeds another in the order of our conceptions, to range it in the same order when we communicate them to others. Our language in the general keeps pretty much to this method. But in one thing particularly it recedes from it; and that is, in placing adjectives, which denote the properties of things, before their substantives or subject, whose properties they are. As when it is said, Evil communication corrupts good manners. But in one this always do, except something follows which depends upon the adjective. So we say, He was a man eminent for his virtue; not an eminent man.

Artificial order, as it respects simple sentences, has little or no regard to the natural construction of words; but disposes them in such a manner as will be most agreeable to the ear, and best answer the design of the speaker. The Latins take a much greater liberty in this respect than we do, or than the nature of our language will permit. Quintilian says, it is best for the verb to stand last, when there is no particular reason to the contrary. And he gives this reason for it, because the force of the sentence lies in the verb. So that, according to him, they seem to have had this view in putting the verb at the end; that as the whole sentence is imperfect without the verb, the mind being thus held in suspense might receive the deeper impression from it at last. They likewise separate such words as have an immediate relation between them or dependence upon one another, and place another word, either first or last as they please. In short, their order there is in a manner arbitrary, if it does not break in upon perspicuity, to which they usually attend. But most of these things are unsuitable to the genius of our language. One might say indeed, Convince him you cannot; instead of saying, You cannot convince him: Or, With my own eyes I saw it; for, I saw it with my own eyes. And again: In proportion to the increase of luxury the Roman state declined; for, The Roman state declined in proportion to the increase of luxury. But this inversion of words is proper in English composition only when it gives force to the expression; as in the higher style it often does. It serves to impress known truths upon the mind, but is unfit for communicating the first principles of knowledge.

As to compound sentences, that is, such as consist of two or more members, either simple or compound sentences. As to simple sentences, we may call that order natural, when all the words in a sentence are so placed, as they are connected with or follow each other in a grammatical construction; and may properly enough a part of this name, as it is founded in the nature of a proposition, and the relation of the several words of which it consists to each other. This we explained in the last chapter, and illustrated by proper examples; and shall therefore only give one instance of it here, to introduce the subject we are now upon.

And it is this: The fame of Socrates excites Artifice to the profession of oratory. Here these words, the fame

Part III.

O R A T O R Y.

Of Artifices, containing the subject of this sentence, with what relates to it; and all those which follow, excited. Artifice to the profession of oratory, make up the predicate and its dependants. And in both parts each word grammatically considered stands in its proper order of construction. And this seems agreeable to the natural way of conveying our thoughts, which leads us first to express the subject or thing of which some other thing is said, before the predicate or that which is said concerning it; and with respect to both, as every idea succeeds another in the order of our conceptions, to range it in the same order when we communicate them to others. Our language in the general keeps pretty much to this method. But in one thing particularly it recedes from it; and that is, in placing adjectives, which denote the properties of things, before their substantives or subject, whose properties they are. As when it is said, Evil communication corrupts good manners. But in one this always do, except something follows which depends upon the adjective. So we say, He was a man eminent for his virtue; not an eminent man.

Artificial order, as it respects simple sentences, has little or no regard to the natural construction of words; but disposes them in such a manner as will be most agreeable to the ear, and best answer the design of the speaker. The Latins take a much greater liberty in this respect than we do, or than the nature of our language will permit. Quintilian says, it is best for the verb to stand last, when there is no particular reason to the contrary. And he gives this reason for it, because the force of the sentence lies in the verb. So that, according to him, they seem to have had this view in putting the verb at the end; that as the whole sentence is imperfect without the verb, the mind being thus held in suspense might receive the deeper impression from it at last. They likewise separate such words as have an immediate relation between them or dependence upon one another, and place another word, either first or last as they please. In short, their order there is in a manner arbitrary, if it does not break in upon perspicuity, to which they usually attend. But most of these things are unsuitable to the genius of our language. One might say indeed, Convince him you cannot; instead of saying, You cannot convince him: Or, With my own eyes I saw it; for, I saw it with my own eyes. And again: In proportion to the increase of luxury the Roman state declined; for, The Roman state declined in proportion to the increase of luxury. But this inversion of words is proper in English composition only when it gives force to the expression; as in the higher style it often does. It serves to impress known truths upon the mind, but is unfit for communicating the first principles of knowledge.

As to compound sentences, that is, such as consist of two or more members, either simple or compound sentences. As to simple sentences, we may call that order natural, when all the words in a sentence are so placed, as they are connected with or follow each other in a grammatical construction; and may properly enough a part of this name, as it is founded in the nature of a proposition, and the relation of the several words of which it consists to each other. This we explained in the last chapter, and illustrated by proper examples; and shall therefore only give one instance of it here, to introduce the subject we are now upon.

And it is this: The fame of Socrates excites Artifice to the profession of oratory. Here these words, the fame

Vol. XIII.

48 Order defined and illustrated.

§ 2. Of Order.

By order, rhetoricians mean the placing each word and member of a sentence in such a manner as will most contribute to the force, beauty, or evidence of the whole.

Order is of two kinds, natural and artificial. And each of these may be considered with respect to the parts either of simple or compound sentences.

As to simple sentences, we may call that order natural, when all the words in a sentence are so placed, as they are connected with or follow each other in a grammatical construction.

And it may properly enough a part of this name, as it is founded in the nature of a proposition, and the relation of the several words of which it consists to each other. This we explained in the last chapter, and illustrated by proper examples; and shall therefore only give one instance of it here, to introduce the subject we are now upon.

And it is this: The fame of Socrates excites Artifice to the profession of oratory. Here these words, the same

Vol. XIII.

3 G member
member which expresses the effect of an action naturally comes last; as, Though you offer ever so good reasons, you will not prevail with him. The like may be said of time, with regard to things done in it; as The Roman eloquence soon declined, when Cicero was dead. And to name no more, the reason of a thing naturally follows that of which it is the reason; as thus: All the pleasures of life must be uncertain, since life itself is not secure.

When this order is inverted, it may be styled artificial. To keep to the instances already given, the two members in the first sentence may be thus inverted: What they blame in others are apt to forgive themselves. In the second, in this manner: Socrates is a man, if he be a rational creature. In the third, thus: Thou wilt not prevail with him, though you offer ever so good reasons. And so in the right: As, When Cicero was dead, the Roman eloquence soon declined; and, since life itself is not secure, all the pleasures of life must be uncertain.

The variety of inversions in a sentence may generally be greater or less in proportion to the number of its members. In the following sentence of Cicero, the natural order seems to be this: If that greatness of mind be void of justice, which flows itself in dangers and labours, it is blameable. Which may be varied by changing the place of the first and third member, in the following manner: That greatness of mind is blameable which flows itself in dangers and labours, if it want justice. Or by altering the place of all the three members thus: That greatness of mind is blameable, if it want justice, which flows itself in dangers and labours.

But oftentimes one member may be included in another, as in the instance here given: If that greatness of mind which flows itself in dangers and labours, be void of justice, it is blameable. Here the relative member is included in the conditional, which is placed first, and the antecedent member follows both. But in Cicero it stands thus: That greatness of mind, which flows itself in dangers and labours, if it want justice, is blameable; where the relative and conditional members are both included in the antecedent member. The Latin tongue commonly admits of a much greater variety in the transposition of members, as well as in that of single words, than fuits with our idiom. In the following sentence the natural order is much preferable, as it best suits with the proper elevation and cadence of the voice in its pronunciation: I am willing to revert all that is past, provided it may be done with safety. But should we invert the members, and say, Provided it may be done with safety, I am willing to revert all that is past; the harmony of the cadence would be lost. And if the latter member be included in the former, the alteration will still be worse; as, I am willing, provided it may be done with safety, to forgive all that is past. Here the inflexion of the voice falls upon the same member as before, and destroys the beauty of the period by its elevation afterwards. Some sentences admit of no inversion of their members. Such are those whose members are connected by conjunctive or disjunctive particles. As, Virtue furnishes the mind with the truest pleasure in prosperity, and affords it the greatest comfort in adversity. And, A wise man is neither elated by prosperity, nor despaired by adversity. And the like may be laid of those where the latter member begins with some illative or redutive particle.

As in these instances: The chief thing to be regarded in life is virtue, for all other things are vain and uncertain. And, Though fortune is always inconsistent, yet she has many votaries. Neither of the members in any of these ways of expression, and some others which might be named, can be included one in the other. In all the examples hitherto given, the sentences consist only of simple members; and indeed compound members are not so often inverted, nor included one in another, by reason of their length. However, we shall here produce one instance of each: Whoever considers the uncertainty of human affairs, and how frequently the greatest hopes are frustrated; he will for just reason be always on his guard, and not place too much dependence upon things so precarious. This sentence consists of two compound members, which here stand in their natural order, but may be thus inverted: He will for just reason to be always on his guard, and not place too much dependence upon things so precarious; whoever considers the uncertainty of human affairs and how often the greatest hopes are frustrated.

In the following sentence one compound member is included in another: Let us not conclude while dangers are at a distance, and do not immediately approach us, that we are secure; unless we use all necessary precaution to prevent them. Here the natural order would be: While dangers are at a distance, and do not immediately approach us; let us not conclude, that we are secure, unless we use all necessary precaution to prevent them.

But there are some other considerations relating to order, which, being taken from the nature of things, equally suit all languages. So, in amplifying, there should be a constant gradation from a less to a greater; as when Cicero says, Ambition creates hatred, feuds, disorders, seditions, and wars. On the contrary, in extenuating we should descend from a greater to a less; as, if speaking of the ancient laws of Rome, one should say, They were so far from suffering a Roman citizen to be put to death, that they would not allow him to be whip?, or even to be bound. In constituting any whole, we put the parts first; as, Invention, disposition, elocution, and pronunciation, make up the art of oratory. But in separating any whole, the parts follow: as, The art of oratory may be divided into the four parts; invention, disposition, elocution, and pronunciation. In every enumeration care must be taken not to mix the whole with the parts; but if it be mentioned at all, it must either be put first or last. So it would be wrong to say, He was a man of the greatest prudence, virtue, justice, and modesty: for the word virtue here contains in it the other three, and therefore should not be inverted among them. See Language, no. 17.

§ 5. Of Juncture and Number.

Quintilian, speaking of composition, represents a discourse as very happy in that respect, when the order, juncture, and number, are all just and proper. The first of these which gives rules for the due placing of the words and members of a sentence, has been already explained. We now proceed to the other two, which relate to letters and syllables; the former treating of their connection, and the latter of their quantity.
As to the nature of the vowels, consonants, and syllables in the connection of words, with regard to the found.

As to the language when a word ends with a vowel, and the next begins either with a different vowel, or a word begins with a consonant, it usually renders the pronunciation hollow and unpleasant. For, as Quintilian has justly observed, "This makes a chasm in the sentence, and stops the course of it." For there must be some pause, in order to pronounce them both, or otherwise the found of one will be lost. So, for instance, in pronouncing these words, the other day, unless you stop a little after the word the, the sound of e will not be heard; and if it is dropped, it will occasion a rougher found, from the aspiration of th twice repeated so near together, as th' other day. Therefore to prevent both these inconveniences, we usually say, the other day. But the different consonants, which together with the vowels make up these syllables, often cause a considerable difference in the pronunciation, so as to render it more or less agreeable. As, if we say, the word that, which is joined twice repeated, it usually renders the pronunciation hollow and unpleasant.

As to the nature of the vowels, consonants, and syllables in the connection of words, with regard to the found.

As to the life of As to the nature and life of juncture explained and illustrated.

The pronunciation of the same syllable, at the end and beginning of words, is the last thing to be considered. And a little observation will convince us, that where this happens, it generally renders the found either confused or unpleasant. Cicero was often raised on account of this verse:

O fortunatam natam me confule Romam.

Every one will easily perceive a disagreeable found in the following expression: "A man many times does that unadvisedly, of which he afterwards repents." The chime of the words man many both seems affected, and displeases the ear. But this will soon be remedied, if we separate those two words, and say, "A man does that many times unadvisedly."

From the short account here given of this part of composition, it is easy to perceive what things are necessary to render it most complete and accurate, which are these following: If a word end with a vowel, the next ought to begin with a consonant, or such a vowel whose sound may agree well with the found. But if a word conclude with a consonant, either a vowel should follow, or such a consonant whose pronunciation will suit with it. And lastly, the same syllable ought not to be repeated, at the end of one word, and the beginning of the next. It has been observed by some critics, that the following verse at the beginning of Virgil's Æneid has all these properties:

Arma virumque cano, Troja qui primus ab oris.

Where any word in this verse ends with a vowel, the next begins with a consonant; and where any one ends with a consonant, the next begins with a vowel; and there is no repetition of the same sound throughout the whole. But this is what rarely happens, especially in our language, which abounds with consonants. And what Quintilian says of the composition of vowels, in treating upon this subject, seems applicable to the whole. "This (says he) is a thing not much to be dreaded; and I know not whether the neglect of it, or too great a concern about it, be worse. It necessarily checks the vigour of the mind, and diverts it from matters of greater importance. And therefore, as it shows negligence to permit it, so to be in constant fear of it discovers a low genius." This was the opinion of that judicious writer. And as these things cannot always be attended to, it may be sufficient to avoid them, where they prove very offensive to the ear, and it may be done without some greater inconvenience. So in this sentence, Haec est the best policy, the coalition of t and p in the two last words best policy produces a roughness in their pronunciation; but as the expression is strong, and cannot perhaps be well altered for the better, the found here ought to give way to the fenfe."

II. Number. This respects the quantity of syllables, as juncture does its quality. In the Greek and Roman languages every syllable has its distinct use of quantity; and if either long, short, or common: two number, or more of which joined together in a certain order make a foot; and a determinate number of these in a different order constitute their several f或者s of metre. This variety of sounds gives much greater harmony to their poetry, than what can arise only from the

guilt. Nor are very long words well fuited either
to the beginning or conclufion of a period; for they
retard the pronunciation at firft, and fall too heavy at
the end.

Chap. IV. Of Dignity.

Dignity consists in the right ufe of tropes and The neces-

fury of digni-

ties. It is not sufficient for an orator to expres

himself with propriety and clearnefs, or in smooth and

harmonious periods; but his language muft likewise

be fuited to the nature and importance of the subject.

And therefore, as elegance gives rules for the firft

of thefe, and composition for the fecond; fo does dignity

for the laft of them. It is very evident, that different

themes require a different fyle and manner of ex-

preffion; fince, as Quintilian fays, “ What is magni-

ficent in one difcourfe would be turgid in another;

and thofe expreffions which appear low upon a fu-

blime subject, would fuit lefser matters: and as in a

florid harangue a mean word is remarkable, and like a

blemih; fo any thing lofty and bright upon a tri-

ivial argument is disproportionate, and like a tumour

upon an even surface.” Now this variety in the man-

ner of expreffion arises in a great measure from tropes

and figures, which not only enliven and beautify a dif-

courfe, but give it likewife force and grandeur; for

which reafon this part of elocution feems to have been
called dignity.

Tropes and figures are diftinguished from each other

in feveral repects. Tropes mostly affect single words,

but figures whole fentences. A trope conveys two

ideas to the mind by means of one word; but a figure
threws the fentence into a different form from the com-

mon and ufnal manner of expreffion. Befides, tropes

are chiefly designed to represent our thoughts, but

figures our passions.

§ 1. Tropes.

A trope, which is a figure of words, has been ufnally

defined to be the change of a word from its proper figni-

fication to fome other with advantage, either as to bea-

uty or ftrength. The words, with advantage, are added in

the definition, because a trope ought not to be cho-

fen, unlefs there is some good reafon for ufnng it ra-

ther than the proper word. But in what manner, or

how far, it can be dife of all tropes in general, that

they change the proper fignification of words, will

beft appear by confidering the nature of each kind of

them feparately. Now in every trope a reference is

had to two things, which occasions two ideas; one of

the thing expreied, and another of that thing to which

it has a refept, and is supplied by the mind. For all

tropes are taken either from things internally related,

as the whole and a part; or externally, as cause and

effect, subject and adjunct; or from some fimilitude

that is found between them; or from a contrariness. The

firft of thefe is called fneecode, the second metonymy,
Part III.

THE MIND IS NOT BURDENED WITH A NUMBERLESS FLOCK OF DIFFERENT WORDS, AND YET NOTHING FEELS TO WANT A NAME. THIS SOMETIMES, WHEN A WORD IS WANTING TO EXPRESS ANY PARTICULAR THING, IT IS CLEARLY ENOUGH REPRESENTED BY THE NAME OF SOME OTHER THING, BY REASON OF THE SIMILITUDE BETWEEN THEM. AT OTHER TIMES, THE CAUSE IS SIGNIFIED BY THE EFFECT; THE SUBJECT BY THE ADJUNCT; OR THE CONTRARY. AND THE WHOLE IS OFTEN UNDERSTOOD BY A PART, OR A PART BY THE WHOLE. AND IN THIS USE OF TROPS, THE MIND IS HELPED TO CONCEIVE OF SOMETHING NOT EXPRESSED, FROM THAT WHICH IS EXPRESSED. IT IS OUR SAME CASE, AS WHEN WE HAVE OCCASION TO SPEAK OF A PERIOD, WHOM WE ARE EITHER UNACQUainted WITH, OR HAVE FORGOTT; FOR BY DESCRIBING HIS PERSON, ABODE, OR SOME OTHER CIRCUMSTANCES RELATIVE TO HIM, THOSE WE CONVERT WITH AS WELL UNDERSTAND WHAT WE MEAN, AS IF WE MENTIONED HIS NAME. SO THE SHEPHERD IN VIRGIL, WHEN HE COULD NOT THINK OF THE NAME OF ARCHIMEDES, DESCRIBES HIM BY HIS WORKS:

AND WHAT'S HIS NAME WHO FORM' D THE SPHERE,
AND HOW'D THE FAUNS OF THE FLYING YEAR?

BESIDES, IT SOMETIMES HAPPENS IN A DICTIONARY, THAT THOSE THINGS ARE NECESSARY TO BE SAID, WHICH, IF EXPRESSED IN THEIR PROPER TERMS, WOULD BE OFFENSIVE; BUT BEING CLOthed WITH TROPES, MAY BE CONVEYED TO THE MIND WITH DECENCY. THEREFORE THE IMAGINATION NEVER CONTEMPLATES ANY IDEA SINGLY AND ALONE, BUT ALWAYS TOGETHER WITH OTHER IDEAS, WHICH MAY BE CALLED ITS ACCESSORIES; THOUGH OFTEN OPERATE MORE FORCIBLY UPON THE MIND THAN THE PRINCIPAL IDEA ITSELF DOES. IN THEIR NATURE, THEY ARE OFTEN MORE AGREEABLE, AND FREQUENTLY ALSO MORE FAMILIAR, TO OUR CONCEPTIONS; OR PERHAPS THEY REMIND US OF A GREATER VARIETY OF IMPORTANT CIRCUMSTANCES. HENCE THE NAME OF THE ACCESSORY IS OFTEN PREFERRED, AS, E.G., WHEN WE WANT TO POINT OUT THE TIME IN WHICH A STATE ENJOYED ITS CHIEF REPUTATION, &C., THE PROPER WORDS MIGHT DO, BUT THE IMAGINATION SUGGESTS THE FLOURISHING PERIOD OF A PLANT OR TREE; AND WE SAY "THE ROMAN EMPIRE FLOURISHED MOST UNDER AUGUSTUS!" CATULLUS, WE SAY, WAS THE HEAD INSTEAD OF THE LEADER OF HIS PARTY, BECAUSE THE HEAD IS THE PRINCIPAL PART OF THE HUMAN FIGURE.

I. TROPS WERE FIRST INTRODUCED FROM NEECESSITY, DERIVING THEIR ORIGIN UNQUESTIONABLY IN A CONSIDERABLE DEGREE FROM THE BARENESS OF LANGUAGE, BECAUSE NO LANGUAGE WHICH WE KNOW CONTAINS A SUFFICIENT NUMBER OF PROPER WORDS TO EXPRESS ALL THE DIFFERENT CONCEPTIONS OF OUR MINDS; BUT THE PRINCIPAL CAUSE OF THEIR INTRODUCTION IS TO BE THAT EXTENSIVE INFLUENCE WHICH IMAGINATION POSSESS OVER EVERY KIND OF SPEECH. THE MIND CONSIDERS THE SAME THING UNDER VARIOUS VIEWS; IT SEES IT IN DIFFERENT LIGHTS; IT COMPARES IT WITH OTHER THINGS; AND OBSERVES ITS SEVERAL RELATIONS AND AFFECTIONS; WHEREIN THEY AGREE, AND IN WHAT THEY DIFFER. FROM ALL WHICH REFLECTIONS, IT IS FURNISHED WITH ALMOST AN INFINITE NUMBER OF IDEAS; WHICH CANNOT ALL OF THEM BE DISTINGUISHED AND EXPRESSED BY PROPER WORDS, SINEe NEW ONES OCCUR DAILY. AND WHEN THE MIND IS IMPOSSIBLE, YET WOULD IT BE IMPRUDENT; BECAUSE THE MULTITUDE OF WORDS MUST BE SO WARY, THAT THE MEMORY COULD NOT RETAIN THEM, NOR BE ABLE TO RECALL THEM AS OCCASION REQUIRED. TROPS HAVE IN A GOOD MEASURE REDDICTED BOTH THESE INCONVENIENCES; FOR BY MEANS OF THEM THE MIND IS NOT BURDENED WITH A NUMBERLESS FLOCK OF DIFFERENT WORDS, AND YET NOTHING FEELS TO WANT A NAME. THIS SOMETIMES, WHEN A WORD IS WANTING TO EXPRESS ANY PARTICULAR THING, IT IS CLEARLY ENOUGH REPRESENTED BY THE NAME OF SOME OTHER THING, BY REASON OF THE SIMILITUDE BETWEEN THEM. AT OTHER TIMES, THE CAUSE IS SIGNIFIED BY THE EFFECT; THE SUBJECT BY THE ADJUNCT; OR THE CONTRARY. AND THE WHOLE IS OFTEN UNDERSTOOD BY A PART, OR A PART BY THE WHOLE. AND IN THIS USE OF TROPS, THE MIND IS HELPED TO CONCEIVE OF SOMETHING NOT EXPRESSED, FROM THAT WHICH IS EXPRESSED. IT IS OUR SAME CASE, AS WHEN WE HAVE OCCASION TO SPEAK OF A PERIOD, WHOSE NAME WE ARE EITHER UNACQUAINTED WITH, OR HAVE FORGOTT; FOR BY DESCRIBING HIS PERSON, ABODE, OR SOME OTHER CIRCUMSTANCES RELATIVE TO HIM, THOSE WE CONVERT WITH AS WELL UNDERSTAND WHAT WE MEAN, AS IF WE MENTIONED HIS NAME. SO THE SHEPHERD IN VIRGIL, WHEN HE COULD NOT THINK OF THE NAME OF ARCHIMEDES, DESCRIBES HIM BY HIS WORKS:

AND WHAT'S HIS NAME WHO FORM'D THE SPHERE,
AND HOW'D THE FAUNS OF THE FLYING YEAR?

BESIDES, IT SOMETIMES HAPPENS IN A DICTIONARY, THAT THOSE THINGS ARE NECESSARY TO BE SAID, WHICH, IF EXPRESSED IN THEIR PROPER TERMS, WOULD BE OFFENSIVE; BUT BEING CLOTHEd WITH TROPES, MAY BE CONVEYED TO THE MIND WITH DECENCY. THEREFORE THE IMAGINATION NEVER CONTEMPLATES ANY IDEA SINGLY AND ALONE, BUT ALWAYS TOGETHER WITH OTHER IDEAS, WHICH MAY BE CALLED ITS ACCESSORIES; THOUGH OFTEN OPERATE MORE FORCIBLY UPON THE MIND THAN THE PRINCIPAL IDEA ITSELF DOES. IN THEIR NATURE, THEY ARE OFTEN MORE AGREEABLE, AND FREQUENTLY ALSO MORE FAMILIAR, TO OUR CONCEPTIONS; OR PERHAPS THEY REMIND US OF A GREATER VARIETY OF IMPORTANT CIRCUMSTANCES. HENCE THE NAME OF THE ACCESSORY IS OFTEN PREFERRED, AS, E.G., WHEN WE WANT TO POINT OUT THE TIME IN WHICH A STATE ENJOYED ITS CHIEF REPUTATION, &C., THE PROPER WORDS MIGHT DO, BUT THE IMAGINATION SUGGESTS THE FLOURISHING PERIOD OF A PLANT OR TREE; AND WE SAY "THE ROMAN EMPIRE FLOURISHED MOST UNDER AUGUSTUS!" CATULLUS, WE SAY, WAS THE HEAD INSTEAD OF THE LEADER OF HIS PARTY, BECAUSE THE HEAD IS THE PRINCIPAL PART OF THE HUMAN FIGURE.

WE NOW PROCEED TO CONSIDER THE REASONS WHICH HAVE OCCASIONED THE INTRODUCTION OF TROPS. AND THOSE, AS QUINTILLIAN OBSERVES, ARE THREE: NECES5SITY, EMPHASIS, AND BEAUTY.

1. TROPS WERE FIRST INTRODUCED FROM NECESSITY, DERIVING THEIR ORIGIN UNQUESTIONABLY IN A CONSIDERABLE DEGREE FROM THE BARENESS OF LANGUAGE, BECAUSE NO LANGUAGE WHICH WE KNOW CONTAINS A SUFFICIENT NUMBER OF PROPER WORDS TO EXPRESS ALL THE DIFFERENT CONCEPTIONS OF OUR MINDS; BUT THE PRINCIPAL CAUSE OF THEIR INTRODUCTION IS TO BE THAT EXTENSIVE INFLUENCE WHICH IMAGINATION POSSESS OVER EVERY KIND OF SPEECH. THE MIND CONSIDERS THE SAME THING UNDER VARIOUS VIEWS; IT SEES IT IN DIFFERENT LIGHTS; IT COMPARES IT WITH OTHER THINGS; AND OBSERVES ITS SEVERAL RELATIONS AND AFFECTIONS; WHEREIN THEY AGREE, AND IN WHAT THEY DIFFER. FROM ALL WHICH REFLECTIONS, IT IS FURNISHED WITH ALMOST AN INFINITE NUMBER OF IDEAS; WHICH CANNOT ALL OF THEM BE DISTINGUISHED AND EXPRESSED BY PROPER WORDS, SINCE NEW ONES OCCUR DAILY. AND WHEN THE MIND IS IMPOSSIBLE, YET WOULD IT BE IMPRUDENT; BECAUSE THE MULTITUDE OF WORDS MUST BE SO WARY, THAT THE MEMORY COULD NOT RETAIN THEM, NOR BE ABLE TO RECALL THEM AS OCCASION REQUIRED. TROPS HAVE IN A GOOD MEASURE REDDICTED BOTH THESE INCONVENIENCES; FOR BY MEANS OF THEM
Elocution: With all metaphorical expressions, used in a way of similitude; and yet perhaps no proper words can be made use of, which will convey a more lively image of the thing we design to represent by them.

But beauty and ornament, as was observed before, have been another cause of the use of tropes. Some subjects require a more florid and elegant dres than others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others. When we describe or applaud, ornaments of heighten nor the others.

"I have often wondered (says he) why tropes should give greater pleasure than proper words. I imagine the reason must be, either that there is an appearance of wit in neglecting what is at hand, and making choice of something at a distance; or that the hearer is furnished with a different thought, without being led into a mistake, which affords a very agreeable pleasure; or that a whole similitude is conveyed to the mind by a single word; or that, particularly in the most and most lively metaphor, the image is preferred to our fight, which is the quickness of our fenses." And therefore he supposes, that "as garments were first invented from necessity, to secure us from the injuries of the weather, but improved afterwards for ornament and divifion; so the poverty of language first introduced tropes, which were afterwards increased for delight." Befides, a variety of expression is pleasing in a discourse. It is many times necessary that the same thing should be repeated; and if this be done in the same words, it will grow tiresome to the hearers, and shew their ignorance of the speaker's ability. Therefore, to prevent this, it is proper the expression should be varied, that although the fene be the same, it may give the mind a new pleasure by its different drees.

We come now, in the last place, to lay down some directions proper to be observed in the choice of tropes.

And first, as every trope gives us two ideas; one, of the word expressed; and another, which, by means of that, the mind connects with it; it is necessary, that the relation between these two appear very plain and evident. For an obscure trope is always faulty, unless where some particular reason makes it necessary. And therefore tropes ought not to be too far-fetched, lest that should render them dark. For which reason Cicero says, he should not choose to call any thing degradative to a person's character, the Syrtis of his patria, but rather the rock of it; nor the Charybdis of his state, but the gulf of it. For those who either did not know that the Syrtes were two quicksands upon the coast of Africa, or that Charybdis was a gulf in the strait of Sicily, both of them very degradative to mariners, would be at a loss to understand the meaning of the metaphor. Befides, metaphors taken from things we have seen, affect the mind more forcibly than those which are taken from such things as we have only heard of. Now there is scarce any one who has not seen a rock or a gulf; but there are very few persons, comparatively, who have been either at Charybdis or the Syrtes. It is necessary therefore in a good trope, not only that there be a near affinity between the two ideas, but likewise that this affinity be very obvious and generally known, so that the word be no sooner pronounced but both images do immediately present themselves to the mind.

Again, as a trope ought to be very plain and evident, so likewise should it bear a due proportion to the thing it is designed to represent, so neither to heighten nor diminish the just idea of it. Indeed, sometimes when we speak of things indefinitely, we say too much, left we should seem to say too little. And this manner of speaking is called an hyperbole, which is not uncommon in the sacred writings. So, for instance, Saul and Jonathan are said to be faster than eagles, and stronger than lions. But even in this way of expression a proportion is to be observed. For some very considerable and unusual excess of the thing in its kind is at least designed by it; which, perhaps, cannot; or however is not necessary to be defined. And therefore Quintilian blames Cato for calling the top of an hill a war; because the proportion between the two ideas is nowise adequate. And so, on the contrary, Aristotle censures Euripides for calling rowing the empire of the oar. Poets indeed are allowed a greater liberty in this respect; but an orator should be modest in his expressions, and take care that he neither so heighten nor diminish the natural ideas of things by tropes, as to lead his hearers into mistakes.

But further: As a moderate use of tropes, justly applied, beautifies and enlivens a discourse; so an excess of them causes obscurity, by running it into abstruse allegories and riddles. Tropes are not the common and ordinary drees of our thoughts, but a foreign habitation; and therefore he who fills his discourse with tropes, it is supposed, beautifies and enlivens a discourse; so that the tropes should seem to come by permission, and not by force. And therefore, when he thought it harsh to say, The death of Cato made the Senate an orphan; he guards the expression by saying, The death of Cato has (If I may be allowed to say so) rendered the Senate an orphan.

And, to add no more, care should be taken how we transfer tropes from one language into another. For as they are frequently taken not only from natural things, or such notions as are common to the generality of mankind, but likewise from the manners, customs, and occurrences of particular nations; so they may be very plain and obvious to those among whom they took their rise, but altogether unintelligible to others who are unacquainted with the reason of them. It was customary for the Roman soldiers to carry their money in their girdles; hence it was the same thing with them to say, a person bad left his girdle, as that he had left his money. And because the Romans wore the inga, which was a long g-wn, in time of peace, and a different garb when engaged in war, their wri
Part III.

O R A T O R Y.

Metaphor. A metaphor, as usually defined, is, a trope, which changes words from their proper signification to another different from it, by reason of some similitude between them. But that a word, when used metaphorically, does not alter its signification, but retains its proper sense, was shewn above. However, it may not be amiss to explain this matter more fully, and set it in a clearer light. Every metaphor, then, is nothing else but a short similitude. Cicero calls it a similitude reduced to a single word. And Quintilian to the same purpose says, that "a metaphor is a short similitude, and differs from it only in this, that the former is compared to the thing we design to express, and the latter is put for it. It is a similitude, when I say of a man, he has acted like a lion; and a metaphor, when I say, he is a lion." Thus far Quintilian. Now in every similitude three things are requisite: two things that are compared together; and a third, in which the similitude or likeness between them consists. And therefore, to keep to this example, when Horace calls a Roman soldier a lion, if the word lion did not retain its proper sense, there could be no similitude; because there would not be two things to be compared together with respect to a third, which is necessary in every similitude, and was designed by this expression. The sense of which is plainly this: This as a lion feines his prey with the greatest ferocity, so a Roman soldi er acts with rage and fury against his enemies. In the same manner, when Cicero calls Pid the vulture of the provinces, his meaning is, that he was like a vulture, or acted in such a manner as a vulture acts, that is, rapaciously. So that the real difference between a metaphor and a similitude consists in this; that a metaphor has not those signs of comparison which are expressed in a similitude. But some persons have run into mistakes in reasoning from tropes of this kind. For they have so argued from metaphorical words, as if all the affections and properties of the things expressed by them might be attributed to those other things to which they are applied, and by that means have strained the comparison (which has usually but one particular view), in order to make it tally in other respects, where there is not that similitude of ideas. We will endeavour to make this evident by another example from Cicero, where he calls M. Antony the torch of the flute. The similitude between Antony and a torch lay in this: That as a torch burns and disperses every thing within its reach, so M. Antony brought destruction and ruin wherever he came. Now a torch has not only a property to burn, but also to give light; but the similitude would not hold in this respect, nor was it at all designed. For Cicero never calls a wicked profligate man, as Antony was, the light of the flute; though he often gives that character to good and virtuous men, who by their examples do as it were enlighten others, and show them the way to be happy themselves and useful to others. But though metaphors are usually taken from a similitude between two things, as in the inferences here mentioned; yet sometimes they are founded in the similitude which two things bear to two others in some particular respect, by means wherein what properly belongs to one of them is transferred to the other: the former of which are called simple metaphors, and the latter analogues. Hence the rudder of a ship may be called its reins; for what the reins are to a horse, that the rudder is to a ship in guiding and directing it. So that here is a double similitude, one between a ship and a horse, and another between the rudder of the former and the reins of the latter; and from the analogy between the use of the rudder to the one and reins to the other, the reins, which belong properly to the horse, are applied to the ship. Again, some metaphors are reciprocal, in which the similitude holds either way. Thus to steer and to govern are used reciprocally both of a ship and a state: the proper expressions being, to steer a ship, and govern a state; and the contrary metaphorical. But though we say, the foot of a mountain, borrowing the similitude from animals; yet we do not say, on the contrary, the bottom of an animal, meaning his feet; and therefore that metaphor is not reciprocal. From this account therefore of the nature of a metaphor, it may be said to be, The application of a word by way of similitude to some other thing than what it properly signifies. And the plainer this similitude appears, the greater beauty there is in the trope.

The use of metaphors is very extensive, as large as universal nature. For there are scarce any two things which have not some similitude between them. However, they may all be reduced to four kinds; which was the second thing proposed to be considered.

The first kind of metaphors therefore may be taken from similitudes between animate beings. As where those things which properly relate to brutes, are accommodated to men; or those which belong to men are applied to brutes. Of the former fort is that joke of Cicero: My brother being asked by Philip, why he
A second kind of metaphors lies between inanimate things, whether natural or artificial, which bear some similitude to each other. And this head is very extensive. Thus we say, "flames of fire," and "clouds of smoke," for large quantities. And to signify, "to inflame an account," that is, to heighten or increase it; with innumerable others of the like sort. In the two first of these instances, the terms proper to one element are applied to another; and as the elements of fire and water are opposite to each other, they show the extensiveness of this trope, that there are no things in nature so contrary, but may come within the limits of it, and be accommodated to each other in a way of similitude. In the last example, a natural action is applied to what is artificial.

A third sort of metaphors is, when inanimate things are applied to animals, on account of some like properties between them. Thus Homer calls Ajax, the bulwark of the Greeks, on account of his valour, which like a wall defended them from the Trojans. And nothing is more common with Cicero, than to brand ill bid high enough; and therefore put him off from reflection, unless perhaps on some particular occasion. And yet, on the other hand, metaphors ought not to sink below the dignity of what they are designed to express; but the idea they convey should at least be equal to the proper word in the place of which they are substituted. But there is a very great difference in the choice of metaphors, as they are designed either to praise or dispraise. One thing may be compared to another in a great variety of respects. And the same thing may be made to appear either noble or base, virtuous or vicious, by considering it in a different light. Such metaphors, therefore, as are chosen to commend, must be taken from great and laudable things; and on the contrary, those which are designed to discommend, from things vile and contemptible. Aristotle gives us a very pleasant example of this in the poet Simonides. A certain person, who had carried the prize at a race of males, offered him a reward to write a poem in honour of that action. Simonides thought he did not bid high enough; and therefore put him off with saying, the subject was too mean to write in praise of the males, which were the offspring of asses. But upon his being offered a larger sum, he undertook the task; and, as Aristotle observes, when he has occasion to speak of the males in that poem, he does not mention them by that name, but calls them "the daughters of fleet and generous horses," though he might wish as much propriety have called them "the daughters of dull asses." But it was the poet's business, in praising, to take the most advantageous part of the character. Where things are capable of such different turns, metaphorical expressions are generally most beautiful. And sometimes the same metaphor may be applied contrary ways, both in praise and dispraise, as it will suit different properties of the thing to which it refers. Thus, a "dove," in a metaphorical sense, may represent either innocence or fear; and an iron heart may denote either courage or cruelty; as an "hurt head" signifies the weakness of thought. And this ambiguity in the application of metaphorical words often affords occasion for
jests and comic wit. We observed before, that Cicero never calls ill men, lights of the state. But he once in this manner calls Sextius Clodius the light of the Senate. For when his kinsman Publius Clodius had been killed by Milo, and his corpse was brought to Rome, Sextius railed at the mob, and in a tumultuous manner carried it into the senate house, where they burnt it, and by that means set the building on fire: For which feditious action Cicero paffes that joke upon him, under the metaphor of light, which elsewhere he always uses in a good sense.

But to proceed: All forced and harsh metaphors should be avoided; the one being no less disagreeable to the mind than the other to the ear. Nor should they come too thick in a discourse. In a word, they ought not to be used, but either where a proper word is wanting, or where they are more significant or beautiful than the proper word.

II. Metonymy. This, as defined by Quintilian, is, the putting one word for another. But Vellius describes it more fully, when he calls it, "A trope, which changes the name of things that are naturally united, but in such a manner as that one is not of the essence of the other." That a metonymy is thus distinguished from the other tropes, has been sufficiently shown already in the two last chapters. When it is said, to put one word for another, or, to change the names of things, the meaning is, that the word is used changes its sense, and denotes something different from its proper signification. Thus, when Mars is put for war, and Ceres for corn, they lose their proper sense, and stand for the effects of which those deities were said to be the cause. So likewise, when Virgil says,

He drank the frothing bowl,

the word bowl must necessarily signify the liquor in the bowl. And when in another place, describing the temple of Juno at Carthage, in which the actions of the Trojan war were represented, and the images of the heroes, he makes Aeneas, upon discovering that of Priam among the rest, cry out,

Lo here is Priam;

it is plain the word Priam there must stand not for his person, but his image or figure. And this property of changing the sense of the word appears peculiar to metonymy. In treating upon a metaphor, we observed the mistake of those who teach, that a word used metaphorically loses its proper signification; whereas it only changes its place, but not its sense; being applied to a thing to which it does not naturally belong, by way of similitude. And as the not attending to this has run some persons into very great absurdities, in treating upon metaphorical expressions, and reasoning from them in the tropical sense; so the like has happened to others in some instances of a metonymy, where, by misapprehending their true nature, they have reasoned from them in the literal sense, as we shall show presently. A metonymy is not so extensive as a metaphor, nor altogether so necessary: because nothing is said by a metonymy, which cannot be expressed in proper words; whereas metaphors are often used for want of proper words to express some ideas. However, metonymies are very useful in language; for they enrich a discourse with an agreeable variety, and give both force and beauty to an expression. And what we observed with relation to a metaphor, is true also of this trope; that some metonymies, even in common discourse, are more frequently made use of than the proper words in whole room they are put. So, pale death, a blind way, and a happy state, are very common expressions with us. And it is more usual to say, This is such a person's hand, or I know his hand, than his writing, when we intend this latter sense of the word.

We now proceed to the division of metonymies, which are commonly distinguished into four kinds, from the different manner in which things are naturally, but externally, united to one another. Now things are thus united, or one thing depends upon another, either with respect to its productions, or in the manner of its existence when produced. In the former way the effect depends upon its cause, and in the latter the adjunct upon its subjects. And hence arise our sorts of metonymies, which receive their names from the cause and effect, the subject and the adjunct.

It is called a metonymy of the cause, when the external cause is put for the effect. The external cause is twofold, the agent and end, which are respectively called the efficient and final cause. Of the former kind are such metonymies, where the inventor or author is put for what was invented or effected by him. Thus, as we said before, Ceres is sometimes put for corn, the use of which she was said first to have introduced; and Mars for war, over which she was thought to preside. And by this way of speaking, any artificer or writer is put for his work. So Juvenal, blaming the luxury and profusion of the Romans, says, There are few tables without Mentor; that is, which were not made by him, or after his manner. And our Saviour says, in the parable of the rich man and Lazarus, They have Moses and the prophets, Meaning the books of Moses and the prophets. But under this sort of metonymy is included not only the agent, strictly so called, but also any means or instruments made use of in the doing of a thing, when put for the thing done. Thus, polite literature is called humanity, because it cultivates and improves the human mind. And in that expression of Cicero, Words move nobody but him also understand the tongue; the word tongue, which is the instrument of speech, is put for speech or language. And in the like sense, arms are sometimes put for war, and the sword for slaughter. By the same kind of metonymy likewise any affection or quality is put for its effect. As when it is said, the end of government is to maintain justice; that is, such mutual offices among men as are the effects of justice. And so likewise in that of Cicero, It is the business of magistrates to check the levity of the multitude, by which he means tumults occasioned by their levity. Moreover, as human affections are attributed to the Deity in a metaphorical sense, so several parts of the human body are likewise ascribed to him by this kind of metonymy. Thus, his hand and his arm are used to express his power, as his ear and his eye, his care and providence, these being the instruments of such effects in mankind. Metonymies of the final cause are those by which the end in doing a thing is put for the thing done. As when we say, The watch is set, meaning the watchmen, who are appointed for that purpose. And so likewise
The second kind of metonymy puts the effect for the efficient cause, whether the agent, or only the means and instrument. So Virgil calls the two Scipios the definition of Lybia, because they were the agents who effected it. And Horace compliments his patron Mæcenas with the titles of being his guard and honour; that is, his guardian, and the author of his honour. But when Cicero tells the citizens of Rome, that the death of Clodius was their safety, he means the occasion only of their safety. And elsewhere he calls that a dark hope and blind expectation, the effect of which was dubious and uncertain to those who calls that prophets, when they were eating the pottage which Elias had ordered to be set before them, cried out, There is death in the pot: that is, some deadly thing, as is presently after explained. And thus sweat, which is the effect of labour, is sometimes put for labour. As in the threat denounced against Adam, In the face of thy face shalt thou eat bread, that is, by labour in cultivating the ground. And in allusion to this way of speaking, Antony the orator tells Cæcilius, the improvement of the style by constant exercise, as he prescribed, was a thing of much sweat. And virtue is said to be gained by sweat, that is, continued care and exercise in subduing the passions, and bringing them to a proper regulation. But in these two expressions there is likewise a metaphor, the effect of bodily labour being applied to that of the mind. In all these instances, the effect is put for the efficient cause.

The third kind of metonymy is, when the subject is put for the adjunct. By subject here, in a large sense of the word, may be understood that wherein some other thing is contained, or about which it is conversant; as likewise the poëfessor with respect to the thing he poëfifies; and the thing poëfified, when put for the sign of it. Now, by the first of these ways of speaking, the feat of any faculty or affection is used for the faculty or affection itself. So it is usual to say, a man of a clear head, when we mean a clear mind or understanding; the fact of the mind being fupposed to be in the head. And a person is said to have a warm heart, because the heart has been thought the seat of the affections. In like manner, the place where any actions are performed is put for the actions done in it. As when Cicero says, "Do not always think of the forum, the benches, the rostra, and the senate;" meaning the discourses which were usually made in those places. So likewise the country, or place of residence, is put for the inhabitants, as in that passage of Cicero; And to omit Greece, which always claimed the pre-eminence for eloquence, and Athens, the inventress of all sciences, where the art of speaking was invented and perfected; in this city of ours, (meaning Rome), no studies have prevailed more than that of eloquence: where the words Greece and Athens stand to denote the inhabitants of those places. And his or her may also be referred those expressions in which the time is put for the persons living in it; as,
SYNCEDOCHE EXPLAINED.

In a word, equity, temperance, fortitude, prudence, and all virtues, engage with injustice, luxury, cowardice, rafhness, and all vices.” And to this trope those expressions are to be referred, in which any thing is put for the object about which it is conversant. As in that faying of the wife man, “Hope deferred makes the heart fick;” where hope is put for the thing hoped for. And thus Suetonius calls the emperor Titus the love and delight of mankind, whose mild and obliging temper rendered him the object of those agreeable affections to all persons under his government. A third use of this trope is by putting a thing for the time in which it was done. Thus we say of a perforn, he has served fo many campaigns, meaning fo many summers, that being the ufual time in which armies are drawn out into the field. Lastly, by this metaphor, the sign is put for the thing it signifies: as, the fpecles for the regal dignity, and the word for the authority of the magiftrate.

III. SYNCEDOCHE. This is a trope by which either the whole of a thing is put for a part of it, or a part for the whole; fo that the two things, whole ideas are presented to the mind in this trope, are internally related to each other: by which, as has been shewn already, it is diftinguished from all the other tropes. In a fynecdoche the word retains its proper fene, and the expression is elliptical, as will appear by the feveral fpecies of it, wherein the elliptis in most of the examples is very obvious, and may with no great difficulty be supplied. Now a thing may be confidered as a whole in three different refpects, which logicians call an universal, effential, and integral sene. A universal whole is any genus with regard to its feveral fpecies; as, an animal with refpect to mankind and brutes, or philosophy with refpect to the feveral arts and fciences comprifed under it. An effential whole conflits of matter and form; as, a man of body and foul. And an integral whole is any body or quantity, with refpect to the feveral parts of which the matter of it is compofed, and into which it may be divided: as, an human body with refpect to its feveral members; or a year, as diftinguible into months, weeks, and days. And thus rhetoric is an integral whole in refpect to the four parts that compofe it; namely, invention, difpofition, eloquence, and pronunciation. So likewise any aggregate body, as a civil community, which is diftinguible into thofe who govern and are governed; or any army, confifting of the general and his foldiers. As a whole therefore, in each of these acceptations of the word, is frequently put for a part, and a part for the whole; hence arise fiv fpecies or forts of fynecdoche.

The firft of these puts the genus for the fpecies.—Thus, virtue is general is fometimes used to denote fome particular fort of virtue. As when Cicero mentions virtue as one of the four qualifications neceffary in a general, he means greatness of mind. And fo perforns are often commended for perfons of virtue shown in their conduct, which refpect only fome fingle virtue, as justice, temperance, or the like: And in this fene Cicero calls Clodius a deadly animal. So when our Saviour commiffions his apoftles to preach the gospel to every creature, the meaning is, every rational creature. And thus likewise, to talk to a perforn some times denotes the fame thing as to blame him, which is an way of talking.

The second kind of fynecdoche puts the species for the genus. Thus bread denotes any kind of food: as when a perforn is faid to get his bread by his labour. In the fame fway of speaking, money is put for any kind of wealth in general. And it is an ufual expression to fay, that wine deports more than the fword; that is, than any fword armed. And the legal form of banishment among the Romans was, to prohit perforns theufe of fire and water; that is, the jufi common and ordinary necifeffities of life, in which all others were included.

The third species of this trope is, when the effential whole is put for one of its parts; that is, either for the matter or form. Thus, in the Evangelift, Mary Magdalen fays, they have taken away my Lord, and I know not where they have laid him, meaning his body. So it is ufual to fay of a deceased perforn, He was laid at fuch a time. And in the inscriptions of fepleural monuments we frequently meet with this expreffion, Here lies fuch an one; that is, his corps. Nor are infances uncommon in which the whole being is put for the form. Thus when Cicero fays, Thofe perforns live, who have fled from the confinement of the body, as from a prifon; by perforns must neceffarily be understood their fouls, which are here diftinguished from and fet in oppofition to their bodies. And fo Virgil repreffents Aneas as meeting with Dido and fome of his Trojan friends in the infernal regions; by which are meant their fouls.

The fourth kind of fynecdoche is, when either the matter or form is put for the whole being. Thus flour and gold are used to fignify money made of foths metals; as when we fay, I have fo much flour or fo much gold. And the word fowl, both in our own and other languages, is put for the whole perforn. So with us, a merry fowl, and a dull fowl; in Cicero, dear fouls and in Horace, candid fouls, are all used in this tropical fene. But this way of speaking occurs nowhere more frequently than in the sacred writings. Thus, for inftance, it is faid, All the fouls which came with Jacob into Egypt, meaning the perforns. And again, The foul that feneth it fhall die; from which expreffion, and others of the like import, fome perforns, by not attending to the nature of this trope, have been erroneously led to infer that the soul is naturally mortal. But fometimes only part of the matter fands to exprefs the whole effence or being. So we imitate the Latins in using the word caput or head to denote either a perforn or thing. For, as with them lapidem caput, fo with us a guilty head, fignifies the fame as a man of woe. And in the fame fene, fo many head of cattle means fo many entire cattle.

By the fifth fort of fynecdoche, the whole of any material thing or quantity, whether continued or discrete, is put for a part of it. So when Cicero fays, A war is kindled through the whole world, in compliment to his country, he calls the Roman empire the world. And this expression is alfo used by fcholars. Thus Cornelius Nepos, speaking of the quarrel between Mark Antony and Augustus, tells us, that each of them defired to be lord of the world. And in like manner St. Luke fays, There went out a decree from Cesar Augustus.
Elocution.  

Augur, that all the world should be taxed. So in St. Paul's shipwreck, is it said, They ran the ship a-ground, that is, the head of her, for it is plain by what follows, that the stern was loose. And as to different quantity, our Saviour, using this trope, said he should be three days and three nights in the heart of the earth. Though he did not continue three whole days and nights in the grave, but only part of the first and third day, and the whole second day, with the two whole nights between the first and third day, according to our way of reckoning. For he was buried on Friday in the afternoon, and refled in the grave that night, with the following day, which was the Jewish Sabbath, and was risen on the morning of the next day. So that we must necessarily have recourse to this synecdoche, which puts the whole for the part, to clear up that event.

By this kind of synecdoche, also, the plural number is sometimes put for the singular. Thus St. Matthew says, The thieves who were crucified with our Saviour reviled him; though it is plain from St. Luke, that only one of them did so. It may also be referred to this trope, when a certain number is put for an uncertain one. So it is an usual way of expression to say, I have seen or done such a thing an hundred or a thousand times; when perhaps so many are not really intended, but only in general some considerable number.

The sixth and last kind of synecdoche puts a part of any material thing or quantity for the whole of it. So we say of a man, He shelters himself under such an one's roof; that is, in his house. And of a fleet, that it consists of so many ships; meaning, so many ships. And by this trope, that is ascribed to a single person which was done by the affilience of others, and in conjunction with them: as when it is said, that Hannibal killed forty thousand Romans at the battle of Cannes: For an army is an aggregate body, of which the general is the head, and consequently the chief part of it. And to this kind of synecdoche may also be referred such expressions in which the singular number is put for the plural: as if one should say, A man is liable to be misled by the influence of irregular passengers; meaning all men, or mankind in general. Or when less than the real number is put for any round number: Thus some ancient writers, when they speak of the Grecian armada that came against Troy, call it a fleet of a thousand ships; though, according to Homer's life, it contained 1186. And so likewise the Greek interpreters of the Old Testament are usually called the Seventy; whereas, in reality, they were feventy-two.

IV. Iroby. This is a trope in which one contrary is signified by another: As if any one should say, Weil done; when at the same time his design is to intimate that the thing was ill done. So that, by this manner of expression, the speaker appears to mean something contrary to the sense of the word he makes use of. Not that the word is changed from its usual signification; but by the circumstances attending the expression, we perceive the contrary to what is spoken is intended. Quintilian observes, that an irony may be known of these three ways: "by the manner of pronunciation, or from the nature of the person or the thing. For (as he adds) where any of these do not suit with the words, it is plain the speaker intends the contrary." The irony is very plain from the manner of pronunciation in that passage of Terence, where Simo, speaking to his servant by way of reproof, says, "You have taken great care indeed." From the circumstances of the person, when Cicero, addressing to Catiline, says, "He went to your companion, that excellent man, Marcus Marcellus." When he calls him an excellent man, it is evident he means the contrary; because no good man would be a companion of Catiline. And when he begins his oration for Ligarius with saying, "Cæsar, this is a new crime, and never heard of till now," the thing he is speaking of shows it to be an irony; for it was not new, as all who were present very well understood.

The subjects of irony are vices and follies of all kinds. And this way of exposing them is often more effectual than serious reasoning: For many persons, who, either from temper or want of reflection, cannot be moved by the force of an argument, are not proof against the poignancy of wit and raillery. And therefore we find the most grave and serious persons have not declined the use of this trope upon proper occasions. Socrates, whom the oracle pronounced the wisest man of his age, gave so much into it, that he got the name of Socrates, that is, the droll. In the sacred writings we have a remarkable instance of it in the prophet Elijah, where he challenges the priests of Baal to prove the truth of their deity: For it is said expressly, "He mocked them, and said, Cry aloud, for he is a god; either he is talking, or he is pursuing, or he is on a journey, or peradventure he sleepeth, and must be awakened." And Solomons takes the like method to expate the follies of youth by this ironical apostrophe, "Rejoice, O young man, in thy youth," with what follows, which is all ironical. Nay, our Saviour himself thought fit thus to reprove the Jewish doctors, when he says, "Full well ye reject the commandment of God, that ye may keep your own tradition!" Where, by the words full well, or, as it is in the original, Μεσαίον, it is very evident that a severe reprimand was intended.

An irony is used on a variety of occasions, as we shall show from some instances in Cicero. Sometimes he applies it in a way of jest and banter: As when he says, "We have much reason to believe the model man would not ask him for his debt, when he pursues his life." At other times by way of insult and derision: Thus when he would represent the forces of Catiline as mean and contemptible, "O terrible war, (says he), in which this band of rakes are to march under Catiline! Draw out all your garisons against this formidable body." Again, at other times, he can give the greater force to his argument, he would seem as it were by this trope to recite and correct what he had said before; as in his oration for Milius: "But it is foolish in us to compare Drusus, Africanus, Pompey, and ourselves, with Clodius; all our calamities were tolerable, but no one can patiently bear the death of Clodius." Now the character of Clodius was so well known, that all who were present must be sensible he meant the contrary. And, to name no more, an irony is never used to greater advantage, than when it is followed immediately by something very flinging. Thus,
Thus, speaking of Pifo, he says, "You have heard this philosopher: he denies that he was ever desirous of a triumph." And then addressing himself to him, he immediately adds, "O wretch! when you destroyed the senate, sold its authority, subjected your confulate to the tribune, overturned the state, betrayed my life and liberty for the reward of a province; if you did not desire a triumph, what can you pretend you did not desire?" This must effectually condemn the false gravity at that time assumed by Pifo. Elocution.

Art. II. Secondary Tropes.

Secondary tropes are so called, because they are all of the same nature with the former, and may be referred to some or other of them, though they have received different names.

They are chiefly eight in number: _Antonomasia_, _Communis_; the word_ _Lytories_, _Euphemism_, _Catachresis_, _Hyperbole_, _Meteelongy_, and _Allergy_. The three first of these are simple tropes, and may all be referred to a _synecdoche_. But the five last are of a mixed or complex nature, and not confined to any one of the primary tropes; as will appear in treating upon them in order.

I. A common or general word is sometimes used for the proper name of some particular thing or person which upon any account is eminent and remarkable. So we say, 'He is gone to the city,' or 'He came from the city,' that is, London. And by the Scriptures we mean the Bible. So likewise, in speaking of persons, the _orator_ is used for Cicero, _the poet_ for Homer or Virgil, and the _philosopher_ for Aristotle; and it is not unusual to say the _apollis_ when we mean St. Paul. On the contrary; the proper names of things or persons are sometimes applied to any other of the same character. Thus we use the word _gospel_ for any certain and undoubted truth. And _Carthasian_ is now proverbially used for the greatest falsehood and deception among the Romans. With the Greeks, _Hercules_ signified a strong man, _Nefor a wise man_, and _Iwas a beggar_; and the names of _Samson_, _Solomon_, and _Jesh_, now answer the like characters. Both these ways of expression are often very emphatical, and heighten the idea more where than things are expressed by their own name. To call a good _orator_ Cicero, or an excellent poet a _second Virgil_, includes not only an encomium upon the arts themselves, but leads the mind to what is most perfect in them, and was peculiar to those persons. These forms of speech are called _antonomasia_, and come properly under a _synecdoche_; for in the former the whole is put for a part, and in the latter a part for the whole.

II. Nothing is more common with orators, than a change of persons. Sometimes, to avoid envy, and prevent the imputation of pride, in alluding to themselves they prefix the præfles of any laudable action, they address it to their hearers, and do not say, _see_, but _ye did so and so_. At other times, when it is necessary to remind them of something which they have done amiss, or to constrain them against some wrong step for the future; to prevent giving offence, they take it upon themselves, or at least join themselves with them, and do not say, _you have done this_, or _do not you do this_; but _we have done it, let us not do it_. And again, at other times, in compliment to their hearers, they join them as partners in the commendable actions or virtues of other persons; as when the whole body of the people is brought in to share the præifies arising from the success of wise counsels or victorious arms. Such ways of speaking often occur both in Demosthenes and Cicero. They are called _communication_, and come properly under a _synecdoche_ of the whole.

III. On the contrary, there is a mode of speech, _litotes_, in which, by denying the contrary, more is intended to be expressed than by the words expressly used. His way of speaking is called _litotes_; and is often used for sake of modesty where a person is led to say any thing in his own praise, or meant to prevent giving an expression which in direct terms might be expressed in a harsh or give offence. As if one should say, _I do not commend you for that_; meaning, _I greatly disapprove or blame you for it_: where more being underhand than the words expressly denote, it is properly a _synecdoche_ of the part. Not that this manner of speaking is always to be so interpreted; but where it is not, there is no trope; which must be judged of by the circumstances of the discourse. But that it frequently is so used, might be easily shown from many instances; though it will be sufficient to mention two or three. Cicero speaking of Cotta, calls him _no mean orator_, whom he had just called a _very great orator_. And he says of Varro, that, "he pursued his studies not without industry; and afterwards gives him the character of a _man of the greatest application._" Which passages, compared together, plainly show the import of these negative expressions. And a friend of Cicero, writing to him, begins his letter thus: "Although I am sensible the news I send you will not be very pleasant." This news was concerning the death of another friend of Cicero's; and thereby the words _not very pleasant_, mutt, surely, be _very unpleasant_ and _awfully_; but he chose that expression in the beginning of his letter, as the softest and least shocking, the better to prepare him for the following account of what the news was. And in this way interpreters explain that passage in St. Matthew: And _Bethlehem_, the land of Judah art not the least among the princes of Judah; _where_, by _not the least_, they understand _the greatest_, or _very great_, upon account of the honour it received by the birth of our Saviour, as the words immediately following plainly intimate.
by saying that he fell asleep; this is a beautiful metaphor, taken from the similitude between the death of a good man and sleep.

V. *Catachresis* signifies in general any harsh trope, though it is most commonly found in metaphors. It is principally used by poets, who make choice of it for novelty, or to enforce an expression, where the proper word does not seem strong enough. As when Milton, in describing the angel Raphael's descent from heaven, says, he

\[
\text{Sails between worlds and worlds;}
\]

where the novelty of the word enlivens the image more than if he had said *flies*. But it is sometimes found in the gravest authors, and even in the sacred writings. So we read of the *blood of the grape*. And Solomon says, *the houfe-leech hath two daughters*. In all these instances the trope is a metaphor. But when St John says in the Revelations, *I turned to see the voice that spake to me*, it is here a metonymy of the adjunction; the word *voice* being put for the person who uttereth it. In St Matthew we read of *Simon the Iper*; not that he was then a leper, but had been so, and was cured; which is a synecdoche of the part. And when a criminal is said to have had his reward, that is, his punishment, it is an irony.

VI. *Hyperbole* is the boldlest of all tropes; for it exceeds the strict bounds of truth, and represents things either greater or lesser, better or worse, than they really are. But the representation is made in such a manner as not to impose on the hearers. For an hyperbole is not used to define or describe any thing accurately, but only to magnify or depress it in a certain degree, when we either cannot or do not choose to represent it exactly. The excess in this trope is called *auxesis*; as when we say of any thing that is very high, *it reaches to the skies*. The defect, or contrary extreme, is termed *meiosis*; so we say of a very lean person, *be nothing but skin and bones*, or *a mere skeleton*. It is principally metaphorical, but sometimes taken from other tropes. When Saul and Jonathan are said to have been fatter than eagles, or stronger than lions, the expression is founded in similitude, and is therefore a metaphor. When, instead of saying Cato was a very virtuous man, the historian calls him *the image of virtue*: it is an hyperbolical metonymy of the adjunction for the subject. And when we read in the Mosiac history of *cities fenced up to heaven*, there is a synecdoche. But if a man of weak sight be said to be eagle-eyed, it is an irony. Those hyperboles which are expressed comparatively, are commonly most emphatical, because they show a peculiarity in the excess. To say a thing *is as light as a feather*, carries the idea very far; but to say it *is lighter*, not only carries it still farther, but also heightens it, by leaving the mind at an uncertainty where to fix the limits.

VII. Sometimes two or more tropes, and those of a different kind, are contained under one word; so that several gradations, or intervening steps, come between the word that is expressed, and the thing designed by it. And this is called a *metatypsis*. The contrast between Sylla and Marius proved very fatal to the Roman state. Julius Caesar was then a young man. But Sylla observing his aspiring genius, said of him, "In one Caesar there are many Marius's." Now in this expression there is a metalepsis. For the word *Marius*, by a *synecdoche*, or *autonomony*, is put for any ambitious and turbulent person; and this again, by a metonymy of the cause, for the ill effects of such a temper to the public. So that Sylla's meaning, divested of these tropes, was, that Caesar would prove the most dangerous person to the Roman state that ever was bred in it: which afterwards proved true in the event. So when Virgil, describing that part of the African coast where Aeneas arrived with his ships, says, *A dark wood hung over it*; the word *dark* by a metonymy of the effect, is put for *darkness*, and that again by the same trope for *thick*; for his meaning is, a *thick wood*. But the words of Dido, in the same poet, contain a larger gradation, when she says,

\[
\text{Happy, ah truly happy, had I been,}
\]

*If Trojan ships our coasts had never seen.*

In which expression, first by a metonymy of the adjunction, the ships are put for the *Tjans* in the ships: and these, by a *synecdoche* of the whole, for *Æneas*, who was one of them: and again his arriving on the coast, by a metonymy of the cause, for her seeing him; and lastly, her seeing him, by the same trope, for the passion she had for him. So that her meaning is, she had been happy, if she had never entertained a passion for Æneas. This trope is more frequently to be met with in poets than in orators, as they take greater liberty in using distant allusions than is suited to that perplexity of expression which is required in oratory. But as Quintilian has well observed, all the intermediate links of the chain in this trope are of no further use than to lead the mind gradually from the first to the last, the better to perceive their connection. As in the example last mentioned, relating to Dido, if we drop all the intervening steps, and connect the words expressed with what is directly intended, they will be found to contain a very remote cause put for the effect, which comes under a metonymy. On the contrary, in the second example, where dark hands for *thick*, the effect is put for a remote cause. And the first, which is founded in a similitude of temper between Caesar and Marius, belongs to a metaphor.

VIII. *Allegory*. As a *metalepsis* comprises several tropes in one word, so this is a continuation of several continuations in one or more sentences. Thus Cicero says,

\[
\text{Fortune provided you no field, in which your virtue could run and display itself; where the words}
\]

*field* and *run* are metaphors taken from corporeal things, and applied to the mind. And in another passage, speaking of himself, he says, *Nor was I so timorous, that after I had steered the ship of the state through the greatest storms and waves*, and brought her safe into port, *I should fear the cloud of your forehead, or your colleague's pernicious breath*. I saw other minds, I perceived other storms, I did not withdraw from other impending tempests, but exposed myself ignobly to them for the common safety." Here the fates is compared to a ship, and all the things said of it under that image are expressed in metaphors made use of to signify the dangers with which it had been threatened. And indeed allegories generally consist of metaphors; which being the most beautiful tropes, a number of them well chosen and put together is one of the finest and brightest ornaments in language, and exceeds
The term metaphor in literature, as a constellation does a separate sign. It is true, that allegories are sometimes found in other tropes; but this is very rare. In that known expression of Terence, the tropes are all metonymies: Without Ceres and Bacchus, Venus grows cold; that is, divested of the tropes, Without meat and drink, love dies. And Samson’s riddle is made up of synechdoch: “Out of the eater came forth meat, and out of the strong came forth sweetness.” But there is no small skill required in the right management of allegories. For care should be taken, that the same kind of trope be carried through the whole, so as to compose one uniform and consistent set of ideas: otherwise they draw up a chimera, a thing that has no existence, and of which the mind can form no perception. And, as Quintilian says very justly, “to begin with a tempell and end with a fire, would be very ridiculous and unnatural.” It is likewise very necessary that the allusions be all plain and evident, especially where the name of the thing alluded to is not exprest. These are called pure allegories. As that of Cicero: “So it happens, that I, whose business is to repel the darts, and heal the wounds, am obliged to appear before the adversaires have throw any dart; and they are allowed a time to attack us, when it will not be in our power to avoid the assault; and if they throw a perilous dart, which they seem prepared to do, we shall have no opportunity to apply a remedy.” The tropes here are all taken from military affairs, without any intimation what they are applied to. But that is plain from the context of the discurso. For he is speaking of the disadvantages he laboured under in defending his client against those of the opposite side, and so applies to the bar those terms which were proper to the field. But where the reference is not evident, it becomes a riddle: which is nothing else but an obscure allegory. To avoid this, therefore, the best writers generally use what they call mixed allegories; that is, such wherein the proper name of the thing is expressed, which the whole similitude respects. Of this kind is that in the speech of king Philip of Macedon, given us by Justin, where he says, “I perceive that cloud of a dreadful and bloody war arising in Italy, and a thunderstorm from the west, which will fill all places with a large shower of blood, whenever the tempest of victory shall carry it.” The proper words war, blood, and victors, being joined to the tropes cloud, flower, and tempest, in this sentence, render the severer parts of the similitude plain and evident. Quintilian thinks those allegories most beautiful, where the whole similitude is expressed, and those words, which in their proper sense relate to one of the two things between which the comparison is made, are allegorically applied to the other: As when Cornelius Nepos says of Atticus, “If that pilot gains the greatest reputation who prefers his ship in a boisterous and rocky sea; ought not he to be thought a man of singular prudence, who arrived in safety through my my and so great civil tempells?” These are the allegories with which orators are chiefly concerned.

§ 2. Of Figures.

This term figures to have been borrowed from the stage, where the different habits and gestures of the actors suitable to the several characters they sustained were by the Greeks called συστασεως, and by the Latins figure: And it is not unusual with us to say of a person, both with respect to his dress and action, that he makes a very but or a very graceful figure. And a language is the dress, as it were, of our thoughts, in which they appear and are represented to others; so any particular manner of speaking may, in a large tenet of the word, be called its figure, in which language writers sometimes use it. But rhetoricians have restrained the tenet of the word to such forms of speech as differ from the more common and ordinary ways of expression; as the theatrical habits of actors, and their deportment on the stage, are different from their usual garb and behaviour at other times. A figure therefore, in the sense it is used by rhetoricians, is, A mode of speaking different from, and more beautiful and emphatical than, the ordinary and usual way of expressing the same idea; or in other words, That language which is jogged either by the imagination or the passions. Now as the habits and gestures of our bodies are in a manner infinitely variable, so it is plain that the different forms of speech are almost innumerable. But every alteration from the common manner ought not to be esteemed a figure, nor deserves that character. It must contain some beauty, or express some passion, to merit a place among rhetorical figures, and be marked out for imitation.

The subject of figures seems to have been one of the last things which was brought into the art of oratory, in order to complete it. Aristotle, who teaches so accurately upon other parts, says very little of this. But the Greek writers who came after him have abundantly supplied that deficiency. It is to them we owe the chief observations that have been made on this subject. They took notice of the several modes and turns of expression, observed their force and beauty, and gave them particular names by which they might be known and distinguished from each other. And indeed they have treated the matter with such minuteness and subtlety, that Quintilian seems, not without reason, to think they have multiplied figures to an excess. But though it was so late before they were taken notice of, and introduced into the art of speaking, yet the use of them in discourse was doubtless very ancient. The ancients, and our own Homer’s life, which some have ascribed to Plutarch, has shown, by examples taken out of him, that there is scarce a figure mentioned by rhetoricians, but is to be met with in the most ancient poet. And, if we consider the nature of speech, we shall easily perceive that mankind must have been under a necessity very early to introduce the use of tropes for supplying the want of proper words to express their simple ideas: so the like necessity must have put them upon the use of figures to represent their different passions. Though both of them were afterwards increased, and improved in such a manner as to become the chief ornaments of language. The passions of men have been always the same; they are implanted in us by nature, and we are all taught to discover them by the same means. When the mind is disturbed, we show it by our countenance, by our actions, and by our words. Fear, joy, anger, alter the countenance, and excite different emotions and gestures of the whole body. And we know with what

Part III.

O R A T O R Y.
what passion a man is affected, by hearing his words, though we do not see him. He does not express himself as he usually does at other times when cool and sedate. Objects appear to him in a different view, and therefore he cannot but speak of them in a different way. He interrogates, he exclaims, he admires, he appeals, he invokes, he threatens, he recalls his professions, and therefore he cannot but speak of them in a different way. He interrogates, he exclaims, he appeals, he invokes, he threatens, he recalls his professions, and therefore he cannot but speak of them in a different way.

And therefore Cicero very handsomely compares the conduct of an orator to the exercises of the palestra: in which, as each combatant endeavours not only to defend himself, and attack his adversary, but likewise to do both with decency; so the principal weapons of an orator, as he represents them, are figures, which being no less the ornaments of language than images of our passions, answer all these purposes. Besides, figures chiefly distinguish the different kinds of style, furnish it with an agreeable variety, and often serve to represent things in a clear and forcible manner.

From this short account of the nature of figures, the advantage of them to an orator is very evident. They are a sort of natural eloquence, which every one falls into without attending to it, suitably to that temper of mind with which he is affected himself; and is careless to affect others. In a cool and sedate discourse such figures convey the sentiments with the greatest strength and evidence are most proper. And there are others, which are suited to brighten and enliven more gay and sprightly subjects. Others again are more peculiarly adapted to express the disorders and perturbations of the mind. To repeat the same thing again would many times be deemed a tautology and impertinent: but to do this when the mind is ruffled, is not only allowable, but the repetition renders it more strong and affecting. So likewise to interject, exclaim, or admire, under the influence of a passion, impress the hearers, and disposits them to attention; whereas at another time perhaps (such ways of speaking would scarce be consistent with prudence. There is a natural sympathy in men's minds, which disposes them to receive impressions from those with whom they converse. Thus one gay and pleasant companion gives a cheerfulness and vivacity to a whole company; whereas, on the contrary, one who is dull and phlegmatic damps the spirits of all about him, and disposits them with the contrary kind. Figures are peculiarly serviceable to an orator for answering these different intentions. And as he finds them in life, from thence he must copy them; as a painter does the features of the countenance, and the several parts of the body; figures being to the one what lines and colours are to the other. The design of Catiline to destroy the Roman state and burn the city, is a story well known. There was an army drawn together at a proper distance to favour the undertaking; and others were left in Rome, who had their parts assigned them for burning the city, and destroying those who should escape the flames. And in a word, every thing was ready for putting in execution this horrid and barbarous scheme. So that nothing retarded it but the taking off Cicero, who was then consul, which was thought necessary to be done first.

Cicero, upon information of the design against his life, finds means to prevent it, and the same day calls together the senate. And Catiline, who was a man of consummate boldness, had the courage to appear in that assembly. Upon their meeting, Cicero opens to them the whole affair of the conspiracy, and the design against himself, in a mild warm and pathetic harangue. In which he had two things in view; to raise the indignation of the senate against the conspirators, and particularly against Catiline; and, either by terrifying or exasperating him, to oblige him to leave the city. Now he does not begin this speech in his usual manner as at other times, by addressing his audience, bespeaking their favour and attention, or letting them gradually into the design of what he was about to say; but as Catiline was present, he immediately falls upon him with vehemence, in the following manner: "How far, Catiline, will you abuse our patience? How long will your fury insult us? What bounds will you set to your unbridled rage? Does neither the night guard of the palace, nor the city-watch, nor the peoples fear, nor the agreement of all good men, nor the meeting of this senate in this fortified place, nor the countenances and looks of this assembly, at all move you? Do not you perceive your designs are discovered, and that all who are present know of your conspiracy? Who of us, do you think, is ignorant of what you did the last night, and the night before, where you was, who were with you, and what you resolved on? O times, O manners! The senate knows this, the confult sees it; and yet this man lives!—lives! May, comes into the senate, joins in the public counsel, observes and marks out each of us for destruction!"

And in the same impetuous strain he proceeds through his whole speech, interpenetrating a great variety of the like strong and moving figures. And the discourse had its desired effect: for when Catiline stood up afterwards to make his defence, the whole senate was inflamed, and their resentments against him rose to a high pitch from what Cicero had said; that they had not patience to hear him speak; upon which he left both them and the city. Had Cicero, instead of venting his just indignation against the author of so barbarous and inhuman a design, in the manner he did, by figures suited to strike the passions of his hearers; had he, instead of this attempted to reason with him, and told the story in a cold and lifeless manner, he would have expeditiously to the same end; but by leaving the senate little or nothing moved at what he said, prevented perhaps their coming to those speedy and vigorous resolutions which were necessary at so critical a juncture. Let us suppose him to have expostulated with Catiline in much the same words as before, but thrown into a different form, and divested of those pathetic figures. As thus: "Catiline, you have really abused our patience to a great degree. You have insulted us with your furious proceedings a long while. You seem to have fixed no bounds to your
Part III. Elocution.

---

Nor the night-guard of the palace, nor the city watch, nor the people's fear, nor the agreement among good men, nor the calling together of the senate in this fortified place, nor the countenances and looks of this assembly, appear to move you in the least. I assure you we are all of us apprized of what you did last night, and the night before, where you were, and who were with you, and what resolutions you came to. These are sad times; the age is very degenerate; that the senate should know all this, is the confufion to it; and yet that this man should live, come into the senate, hear all our debates, and mark us out to destroy us.” You see the senate is entirely the same, and the words too in a great measure, so that there is little more than an alteration in the form of them. And yet who does not perceive how flat and languid such a way of talking muft have appeared at that time? and how much it loses of that spirit and energy, which flows itself in Cicero’s manner of exprefion? Had he delivered himself thus, it might indeed have made the senate look upon Catiline as an abandoned wretch,loft to all virtue and goodness, and perhaps have moved some to pity him on that account; as we are eafily induced to commiionate persons in fuch circumftances, efpccially when defended from noble and virtuous ancillaries, which was his cafe. But sure it would have been ill fent to fire their minds with that generous regard for their county, and the neceffary precautions for its security, which the circumftances of the flate then required. Nor would Catiline have been at all daftered by it, but rather encouraged in the profecution of his deeds, from the little effect a speech so managed muft probably have had upon the minds of the fenateors. But Cicero knew very well that the paflions of mankind are the springs of action: that it is many times not fufficient for an orator to convince their minds, by fetting the truth in a clear light; but he muft also rafe their hopes, alarm their fears, inflame their anger, or excite some other fuitable paflion, before they will be brought to act with that zeal and fervour which the cafe may require. And as he was admiringly well fkill’d in this art of touching the paflions, he fondly fails to fix upon the proper methods of doing it, and makes choice of fuch figures and modes of pafking as in the strongest manner repreff the emotions of his own mind. For every pafion is not to be pafped by the fame figures, any more than it is drawn by the fame lines, or painted with the fame colours. When Dido finds that Aeneas is about to leave her, the uses all her arts to detain him. And as perfons in great diftrefs are feldom at a losd to pafs their condition in the moft affeding way; she discovers her fear, anger, revenge, with the whole crowd of diforders which then poffeffed her mind, in a variety of moving figures, fuitable to rafe the counter paflions in his breaft, as is finely repreffed by Virgili in that artful speech he has made for her, which we forbear to recite for no other reafon but the length of it. But what particular figures are most accommodated to answer the feveral ends propofed by them, will beft appear when we come to treat of them separately.

We fhall therefore now proceed to lay down a few directions for the proper ufe of figures. And firft they should always be accommodated to the fentiments, and rifé in proportion to the images designed to be conveyed by them. So far as they are founded in reafon, they are fufet to impress the mind; but where the language outflies the thought, though it may please the ear, and some weak perfons may be carried away with a pomp of words, yet an intelligent hearer will foon fee through the thin and airy dress. It is the feme which gives weight to the figure, as that by striking the imagination awakens the mind, and excites it to act in conformity to reafon. Again, in the ufe of pathetic figures, it is generally better to be nervous than copious, that the images, by their clos’ union, may imprefs the mind with greater force and energy; though in fuch figures as are designed for ornament or illuftration, a more diftufive way of painting is fometimes agreeable. But farther, the too frequent ufe of figures ought to be avoided. For what was observed in relation to tropes, is as true with reft to thefe; that a great number of them is apt to darken and obfufe the figure. And besides, Cicero’s reflection in this cafe is very just. That “it is hard to fay, what fhould be the reafon, that feme things, which moft affect us with a fensible pleasure, and at firft fiooelf move us, do likewise foon elf cloy and failure us.” But that it is fo, we find by common experience. Laftly, figures fhould be fo interwoven in a difcourse, as not to render the fyle rough and uneven, fometimes high and at other times low; now dry and jejus, then pompous and florid. In a word, they fhould rather seem to arife from nature than art; to offer themfelves, than to be the effect of study; and to appear not like patches upon a face, but the agreeable beauty of a found and healthful complex ion. But of this we fhall have occafion to fpake more at large hereafter, in treating upon the different kinds or characters of fyle.

As to the division of figures, which is what remains to be confidered, they are ufually divided into two forts, figures of words, and figures of fentences. The difference between them conflicts in this; that in the former, if you alter the words, or sometimes only the fituation of them, you destroy the figure; but in the latter the figure remains, whatever words are made ufe of, or in what manner forever the order of them is changed. Thus when the name of a perfon or thing is repeated, to intimate fome known property or quality belonging thernore, it is a verbal figure called place. Cicero was a true patriot and hearty lover of his country. And therefore we fhall ufe this figure in faying, that at the time of Catiline’s confufion Cicero appeared like Cicero. The feme would remain the fame, but the figure would be loft, if we fhould alter the words, and fay, at that time Cicero appeared like himfelf. So when two or more fentences, or members of a fentence, end with the fame word, it is called appoghe; as when we fay, To lofe all reju of life, is to lose life. But if only the order of the words be changed in the latter clause thus, To lose all reju of life, is to lose life, it is called appoghe; as when we fay, To lose all reju of life, is to lose life in effect; the figure vanishes. And this is the nature of the verbal figures. But it is not fo in figures of fentences; they continue the fame, whatever alterations are made in

VOL. XIII.
the words. An orator sometimes thinks it proper to change the form of his discourse, and address himself to his audience, or an absent person, or else perhaps to introduce some other person as speaking to them whose words may be suppos'd to carry greater weight and authority with them than his own. The former of these is called apophasis, and the latter periphrasis or imagery; which require no certain words or order of expression.

**ART. I. VERBAL FIGURES.**

These may be distinguished into three sorts, as they consist in a deficiency of words, a redundancy, or a repetition.

I. Of the first sort are ellipsis and apophatic. *Ellipsis* is when one or more words are wanting in a sentence to complete the construction, and fully express the sense. This figure is often used in proverbial speeches: as when we say, *Many men, many minds;* that is, *have many minds;* and, *The more danger, the more honour;* that is, *gains more honour.* But where more is intended by such expressions than brevity, and especially when they are the effect of some passion, the figure receives another name, and is called *apo- phasis,* which is placed among the figures of sentences, where we shall consider it.

*Apophatic,* is when the particles that connect the members of a sentence one with another are left out, to represent either the celerity of an action, or the haste and eagerness of the speaker. Thus Cæsar expresses his speedy conquest of Pharnaces: *I came, I saw, I conquered.* If he had inserted the copulative, and said, *I came, and I saw, and I conquered,* it would have retarded the expression, and not given to full and just an idea of the swiftness of the action. In the last article we took notice of the vehemence and impetuous manner in which Cicero attacked Catiline in his first order, where his design was to fire the minds of the senate against him, and oblige him to leave the city, both which points he gained by that speech. The next day, therefore, when Catiline was gone, he calls together the body of the citizens, and makes a speech to them, which in a sort of raillery or transport of mind he thus begins, by acquainting them with the departure of Catiline, *He is gone, departed, escaped, broken out;* intimating at the same time both the excessive rage in which Catiline left Rome, and the great pleasure with which he was himself affected on that account. This concise way of speaking adds likewise a considerable emphasis to an expression, and by bringing the several parts of a thing nearer together affects the mind with greater force. Thus Cicero lets Cato's character in a very strong and beautiful light by the use of this figure. *"Nature itself (says he) has made you a great and excellent man for integrity, gravity, temperance, magnanimity, justice, in a word, for all virtue."*

II. The second sort of verbal figures is contrary to thefe, and consists in a redundancy or multiplicity of words; which are likewise two, *phonaphus* and *polysyneton.*

When we use more words than are necessary to express a thing, it is called phonaphus. This is done sometimes for greater emphasis, as when we say, *Where in the world is he?* At other times it is designed to affect the truth of what is said; so the servant in Terence, when the truth of what he had related was called in question, replies, *It is certainly for I saw it with these very eyes.*

When the several parts of a sentence are united by proper particles, it is called polysyneton. This adds a weight and gravity to an expression, and makes what is said to appear with an air of solemnity; and by regarding the course of the sentence, gives the mind an opportunity to consider and reflect upon every part distinctly. We often meet with this figure in Demosthenes, which very well suits with the gravity of his style. So he encourages the Athenians to prosecute the war against king Philip of Macedon, from this consideration, that now "they had ships, and men, and money, and stores, and all other things which might contribute to the strength of the city, in greater number and plenty than in former times." Every article here has its weight, and carries in it a proper motive to animate them to the war. But if you remove the copulative, the sentence will lose much of its force.

III. The third kind of verbal figures consists in a repetition. Either the same word in found or fenate, is repeated; or one of a like sound, or signification, or both.

Of the former sort there are ten, called antanaclasis, places, epizeuxis, climax, anaphora, apophasis, epanalepsis, anadiplosis, and epoanodos. The two first of these agree in sound, but differ in sense; the eight following agree in both.

When the same word in found but in fenate is repeated, it is called antanaclasis. This figure sometimes carries a poignancy in it; and when it appears natural and easy, discovers a ready turn of thought. As when a fan, to clear himself of suspicion, affurred his father *he did not wait for his death;* his father replied, *But I defire you would wait for it.* Here the word *wait* is taken in two different fenses. It is likewise used on serious occasions, as in grave and moral precepts which are apt to affect the mind with greater pleasure when delivered in an agreeable drefs.

As this, *Care for those things in your youth, which in old age may free you from care:* Where the word care in the former place signifies to provide, and in the latter anxiety of mind. And even our Saviour himself once uses this figure, when he fays to one of his disciples, who defired to be difmiffed from attending him that he might go and bury his father; *Follow me, and let the dead bury their dead:* Where dead in one place denotes a natural death, and in the other a moral or spiritual death.

Sometimes the name of some perfon or thing is repeated again, to denote some particular character or property designed to be expressed by it; and then it is called *place.* Thus Cicero says, *Young Cato wants experience,* but yet he is Cato; meaning he had the steady temper of the family. And so in the proverbial expreffion, *An ape is an ape, dres him ever so fine.*

When a word is repeated again with vehemence in the fame fenate, it is called *epizeuxis.* This figure shows the earnestness of the speaker, and his great concern of mind about what he fays; and therefore has a natural tendency to excite the attention of the audience.
Elocution. It is suited to express anger, surprise, sorrow, and several other passions. As when Cicero would express his indignation against Anthony for having been the chief instrument in bringing on the civil war, he says to him: "You, you, Anthony, pursued Caesar upon the civil war. And thus he tells Catiline in his first invective against him: You live; and live, not to lay aside, but to pursue, your wicked design. And when our Saviour would express his great concern and sorrow for the wickedness of the Jews, he does it in this pathetic manner: O Jerusalem, Jerusalem, whom killed the prophets!

Climax is a beautiful kind of repetition, when the word, which ends the first member of a period, begins the second, and so through each member, till the whole is finished. There is a great deal of strength as well as beauty in this figure, where the several parts rise naturally, and are closely connected with each other. As in this example: There is no enjoyment of property without government, no government without a magistrate, no magistrate without obedience, and no obedience where one acts as he pleases. But, as Quintilian observes, this figure lies so open, that it is apt to look too much like art; for which reason he advises not to use it often. To prevent this, therefore, orators sometimes disguise it, by not repeating the same word which flood in the former member, but some other equivalent to it. As in the following instance of Cicero for Milo: "Nor did he commit himself only to the people, but also to the senate; nor to the senate only, but likewise to the public forces; nor to these only, but also to his power with whom the senate had entrusted the whole commonwealth."

When several sentences, or members of a sentence, begin with the same word, it is called anaphora. This is a lively and elegant figure, and serves very much to engage the attention. For by the frequent return of the same word the mind of the hearer is held in an eager suspense, till the whole is finished. "You do nothing (says Cicero to Catiline), you attempt nothing, you think nothing, but what I not only hear, but also see, and plainly perceive. It is frequently used by way of question; which renders it not only beautiful, but likewise strong and nervous. As at the beginning of the same speech: "Does neither the night-guard of the palace, nor the city-watch, nor the people of fear, nor the agreement of all good men, nor the meeting of the senate, in this fortified place, nor the counsels and looks of this assembly, at all move you?" And in another of his orations: "What is so popular as peace, which seems to afford a pleasure, not only to beings endowed with sense, but even to inanimate nature? What is so popular as liberty, which even beasts as well as men seem to covet and prefer above all things? What is so popular as ease and leisure, for the enjoyment of which you and your ancestors have undergone the greatest labours?"

Epithet is contrary to the former, and makes the repetition at the end of each member or sentence. As thus: Since concord was lost; friendship was lost; fidelity was lost; liberty was lost; all was lost. And Cicero, in the charge which he brings against Mark Antony before the senate, makes use of this figure, when he says, "Do you lament the destruction of three Roman armies? the author of that destruction was Antony. Do you bewail the loss of most eminent cities? They have been taken from you by Antony. Is the authority of this order weakened? It is weakened by Antony."

Sylloge takes in both these last figures. As in that of Cicero, "You would pardon and acquit him, whom the senate hath condemned, whom the people of Rome have condemned, whom all mankind have condemned." Here the several members both begin and end with the same word. We have a beautiful instance of it in St Paul, when he says, "Are they Hebrews? so am I. Are they Israelites? so am I. Are they the seed of Abraham? so am I."

When a sentence concludes with the word with which it began, it is called epign thesis. As in that expression of Plautus, "Virtue contains all things, he wants no good thing who has virtue." The figure is the same, but the principle not so honest, in the advice which we find given by the miser in Horace, when he says, "Get money, if you can, honestly; but however, get money." This figure adds a force to an expression, when the principal thing designed to be conveyed is thus repeated, by leaving it last upon the mind. And it heightens the beauty of it, when the sentence has an agreeable turn arising from two opposite parts. As in Cicero's compliment to Caesar: "We have seen your victory terminated by the war; your drawn sword in the city we have not seen." Hermogenes calls this a circle, because the sentence returns again to the same word, as that geometrical figure is formed by the orbicular motion of a line to the same point.

When the following sentence begins with the same word with which the former concluded, it is termed anadiplosis. As in the following instance: Let us think no price too great for truth; truth cannot be bought too dear. So in that passage of St John: He came to his own, and his own received him not. This figure generally suits best with grave and solemn discourse.

Epiphros is the inversion of a sentence, or repeating it backwards, so that it takes in the two last figures; for it both begins and ends with the same word, and the same word is likewise repeated in the middle. This turn of expression has a beauty in it, and shows a readiness of thought. We have the following example in Minutius Felix, where he is exposing the folly of the Egyptian superstitition. "Ifs (says he), with Cynocephalus, and her priests, laments, laments, and seeks her lost son; her attendants beat their breasts, and imitate the grief of the unhappy mother; in a little time the son is found, upon which they all rejoice. Nor do they cease every year to love what they find, or to find what they love. And is it not ridiculous to lament what you worship, or to worship what you lament?" It serves likewise to illustrate and enforce the sense, by setting it in two opposite views. As in that expression of the prophet: "Wo unto them who call good evil, and evil good; who put darkness for light, and light for darkness!"

These figures which confit in a repetition of words of a like sound or signification, or both, are four;
paronomasia, homoeoplasia, synonymia, and derivation; the

two sorts of which respect words that are similar in
found only, the third in sense, and the last in both.

When two words very near in found, but different in
sense, respect each other in the same figure, it is
called paronomasia. As when we say, after a jest
coms a jest; and, A friend in need is a friend indeed.
We usually call it a pun, which when new, and appro-
finitely used, pleases for wit, and serves to enliven con-
versation. Nor is it wholly to be excluded from verse
and serious discourses; for a witty jest has many times
had a better effect than a solid argument, and prevailed
with those who could not be moved by close reasoning.
And therefore Cicero and the best speakers have
sometimes recourse to it upon weighty and solemn oc-
casions, as will be shewn hereafter in its proper place.

When the several parts of a sentence end with the
same cafe, or a tene of a like found, this also is con-
dered a figure, and named homoeoplasi a. As thus:
No marvel though wisdom complaint that she is either witt-fully defpifed, or carefelf neglected; either openly scorn-
ed, or secretly abhorred. This figure is esteemd most
beautiful when the parts are all of the same length, or
nearly near it; as it adds to the harmony of the
period, and renders the cadence of the several mem-
ers more musical from the juxta proportion between
them. The Greek rhetoricians were much addicted to
this figure, and Isocrates is particularly celebrated for
it. But some of the best orators seem to have indisfri-
ously avoided it, as carrying in it too much the ap-
pearance of art. And it is remarkable, that this figure
appears nowhere so much in all the works of Democ-
henes, as in an oration which he did not speak him-
self, but wrote for his friend Diodorus, a man of that
tale, who was to pronounce it as his own.

The next figure above mentioned is synonymia. New
strictly speaking, synonymous words are those which
have exactly the same sense. But there being few such,
the use of the term is so far extended as to com-
prehend words of a near affinity in their figuratia,
which in discourse are frequently put for one another.
So, to effer, and interest, are sometimes used as equi-
valent terms; whereas to deffer is no more than to
with for a thing, and to interest is to express that incli-
nation in words. In like manner, often and honour
are often taken for synonymous words, though they
have not precisely the same sense, but one is the usual
consequence of the other; for censure is the good op-
inion we entertain of a person in our mind, and ho-
nor the outward expression of that opinion. When
two or more such words come together, they consti-
tute this figure. As when Cicero, speaking of Plato,
says, “His whole countenance, which is the tacit
language of the mind, has drawn men into a mistake,
and deceived, cheated, imposed on those who did not
know him.” This figure sometimes adds force to an
expression, by enlivening the idea; and it often pro-
motes the harmony and just cadency of a sentence,
which otherwise would drop too soon, and disappoint
the ear.

When such words as spring from the same root, as
justic, jujte, injustice, unjust, and the like, come to-
tgether in the same sentence, they make the figure called
derivatio. Cicero observing the vanity of the philo-
sophers who affected praise at the same time that they
decried it, uses this figure when he says of them, “Elocution.

V The philosophers set their names to those very
books which they write for the contempt of glory;
and are defirous to be honoured and applauded even
for what they say in contempt of honour and ap-
plause.” This figure receives an additional beauty
when repeated, especially in two opposite members;
as, He wish’d rather to die a profen death, than to live a
miserable life.

II. Figures of Sentences.

Of these, none are principally adapted for reasoning,
and others to move the passions.

I. Those suited for proof. Which are six: Prothesis,
hypothese, anaconiosis, epitope, parabole, and antiethes.

Prothesis, or anticipation, is so called, when the ora-
tor first starts an objection, which he foresees may
sentence; be made either against his conduct or cause, and
then some are for
reasoning, and some
protest against
matters properly,
and to conceal any objection
which may be made against him. The occasi-
ons of this figure are various; and the manner of intro-
ducing it very different. Sometimes the orator thinks it
necessary to begin with it, in order to justify his con-
duct, and remove any exceptions which may be made
against his design. Cicero, for several years together,
after he first began to plead, had always been for the
defendant in criminal cases. And therefore, when he
was prevailed with to undertake the accusation of
Verres, he begins his oration with this apology for
himself: “If any one present should wonder, that
when for several years past I have so conducted my-
self as to defend many and accuse none, I now on a
sudden alter my custom, and undertake an accusa-
tion when he shall have heard the occasion and rea-
fon of my design, he will both approve of it, and think
no perfon so proper to manage this affair as myself.”
And then he proceeds to give an account of the rea-
sons which moved him to engage in it. At other
times the objection is admitted as an exception to
what has been said, but not so as to affect it in gen-
eral. Thus, when Cicero has represented the advan-
tages of literature and the polite arts, he starts this
objection to what himself had said. “But some one
will ask, whether those great men, the memory of
whole glorious actions is delivered down to posterity,
were acquainted with that sort of learning I so ap-
plauded?” To which he replies, “Indeed this can scarce
be said of them all. However, the answer is easy. I
have known several perfons of excellent abilities, who,
without learning, by the force of an extraordinary ge-
nius have been men of great virtue and solidity. Nay
I will add, that nature without learning, has oftener
produced these qualifications, than learning without a
genius. But yet it must still be owned, that where
both these meet, they form something very excellent
and singular.” Again, at other times, the orator arti-
fully represents the objection as something consider-
able and important, to give the greater weight to his
answer when he has confuted it. Cicero, in his cele-
brated oration for the Marian law, could not omit
Part III.  

**ORATORY.**

Eloquence.

Thus Cicero, upon his return to banishment, vindicates his conduct in withdrawing so quietly, and not opposing the faction that ejected him. "My departure (says he,) is objected to me, which charge I cannot answer without commending myself. For what must I say? That I fled from a consciousness of guilt? But what was charged upon me as a crime, was no farther from being a fault, than it is the most glorious action that the memory of man (he means his punishing the assassins of Catiline,) to be shamed being an account by the people? That was never talked of; and if it had been done, I should have come off with double honour. That I wanted the support of good and honest men? That is false. That I was afraid of death? That is a calumny. I must therefore say, what I would not, unless compelled to it, that I withdrew to preserve the city." When the objections are put by way of question, as in the example here given, they add a brusqueness and poignancy to the figure. All the parts of it are not constantly expressed. For thus Cicerone in his defence of Pansa, introduces his adversary objected, and himself answering, "The people judged ill, but they did judge; they should not have done it, but they had a power; I cannot submit to it, but many very great and wise men have."—Both the proposition and conclusion are here omitted.

The next figure in order is anathematisation, or communication; by which the speaker deliberates either with the judges, the hearers, or the adversary himself. Thus Cicero addresses the judges in his accusation of Verres: "Now I desire your opinion what you think I ought to do. And I know your advice will be, though you do not declare it, what appears to me necessary to be done." In another place we find him reasoning in this manner with the adverse party: "What could you have done in such a case and at such a time; when to have fat still, or withdrawn, would have been cowardice? When the wickedness and fury of Saturninus the tribune had called you into the capital; and the confuls, to defend the safety and liberty of your country; whose authority, whose voice, which party would you have followed, and whose command would you have chosen to obey?" The figure carries it in an air of modesty and condescension, when the speaker seems unwilling to determine in his own case, but refers it to the opinion of others. It likewise shows a persuasion of the equity of his cause that he can leave it to their arbitration; and serves very much to conciliate their minds, while he joins them, as it were, with himself, and makes them of his party. And when the appeal is made to the adverser party, it is of considerable advantage, either to extort a confession, or at least to silence him. And therefore the sacred writers sometimes very beautifully introduce God himself thus expostulating with mankind, as the prophet Malachi, A son honoureth his father, and a servant his master. If thou be a father, where is mine honour? and if I be a master, where is my fear? Another figure that comes under this head, is epistrophe or conciunction, which grants one thing, to obtain another more advantageous. It is either real or feigned; and either the whole of a thing, or a part only, is granted. We shall consider each of these separately, and illustrate them with proper examples. Nothing more confounds an adversary, than to grant him his whole argument; and at the same time either to shew that it is nothing to the purpose, or to offer something else which may invalidate it. I allow, says the claimant by will against the heir at law, that nobody was more nearly related to the deceased than you;
that he was under some obligations to you; that you were in the army together; but what is all this to the

that I overlooked.

"Pompey in the civil war between him and Caesar: "You have, Tubero, what an accuser would most desire, the accused person compelling the charge; but so as to affirm, that he was of the same party with you and your excellent father. Therefore own first that it was a crime in yourself, before you charge it as such upon Ligarius."

Sometimes the orator gives up some particular point that would well admit of a dispute, to gain something more considerable, which he thinks cannot fairly be denied him. In the affair of Roscius, where the proof depended upon circumstances, Cicero, who defended him, inquires what reason could be alleged for his committing so black a crime, as to kill his father. And after he has shewn there was no probable reason to be assigned for it, he adds, "Well, since you can offer no reason, although this might be sufficient for me, yet I will recede from my right; and upon the assurance I have of your innocence, I will grant you in this cause what I would not in another. I do not therefore insist on your telling me why he killed his father, but ask how he did it?" This appearance of candour and ingenuity in such concessions removes the suspicion of art, and gives greater credit to what is denied. We have an example of a feigned or ironical concession, in Cicero's defence of Paccius; where, interceding for him on the account of his former good services in the time of Catiline's conspiracy, he says in the way of irony, "If such things are to be overlooked, "let us appeale the ghosts of Lentulus and Cethegus; let us recall those who are in exile; these his own libertv, and the free and deliberative choice. And to these feigned concessions may be referred such ways of reasoning, by which the orator both justifies a charge brought against him upon the supposition of its being true; and also proves that the charge itself is false. Thus Cicero, in his defence of Milo, represents the taking off Clodius, with which Milo was accused, as a glorious action; after he has shewn that Milo's servants did it without the knowledge of their master.

Parable or similitude, illustrates a thing by comparing it with some other, to which it bears a resemblance. Similitudes are indeed generally but weak arguments, though often beautiful and fine ornaments. And where the design of them is not so much to prove what is doubtful, as to set things in a clear and agreeable light, they come properly under the notion of figures. They are of two sorts; simple and compound. These are called figure, in which one thing only is likened or compared to another, in this manner: 

As fowles appear in summer, but in winter retreat; so fast friends throw theiles in prosperity, but all fly away when adversity opposes. Compound similitudes are such, wherein one thing is likened or compared to several others; as thus: 

What light is in the world, phy-
III.

The second kind of figures of sentence.

Epanorthosis, or correction, is a figure, by which the speaker either recalls or amends what he had said. It is used different ways. For sometimes one or more words are recalled by him, and others subjoined in their room; at other times, without recalling what has been said, something else is substituted as more suitable. This is a very extensive figure, and made use of in addressing different passions.

We have an instance of it in Terence's Self-tormentor, where the old man, whose extraordinary concern for the absence of his son gave occasion to the name of the play, thus bewails his condition to his neighbour, "I have an only son, Chremes. Alas! did I say that I have; I had indeed; but it is now uncertain whether I have or not." Here, to aggravate his misfortune, he recalls a pleasing word, and sublites another more affecting in its place. And Cicero, in his defence of Milo, speaking to the judges concerning Cleodon, says, "Are you only ignorant what laws, if they may be called laws, and not rather torches and plagues of the state, he was about to impose and force upon us?" Again, in his defence of Plancius, he says, "What greater blow could those judges, if they are to be called judges, and not patricides of their country, have given to the state, than when they banished him, who when praetor freed the republic from a neighbouring war, and when consul from a civil one?" He is speaking there of Opimius. But in commending the moderation of Lucius Mummius, who did not enrich himself, but his country, by demolishing the wealthy city of Corinth, he thus recalls his whole exprestion, and by giving it a new turn heightens the compliment he designed him: "He chose rather (says he) to adorn Italy than his own house; though by adorning Italy his house seems to have received the greatest ornament." And sometimes the correction is made by substituting something contrary to what had been said before, as in the following passage of Cicero: "Cæsar (meaning Augustus), though but a youth, by an incredible and forspiring resolution and courage, when Antony was molt enraged, and we dreaded his cruel and pernicious return from Brundusium, at a time when we neither asked, nor expected, nor dared it (because it was thought impossible), raised a very powerful army of invincible veterans; to effect which he threw away his whole estate: Though I have used an improper word; for he did not throw it away, but employed it for the safety of the government." At other times, as has been said, the correction is made by adding a more suitable word, without any repetition of the former. Thus Cicero, after he has inveighed against the crimes of Verres, breaks out into this pathetic exclamation: "O the elements, or rather wonderful and singular patience of the Roman people! He did not think the word element strong enough, and therefore adds patience, as better answering his design. The sudden and unexpected turn of this figure gives a surprize to the mind, and by that means renders it the more pathetic. Paraphrase, or omission, is another of these figures, when the speaker pretends to omit, or passes by, what at the same time he declares. It is used either in praise or dispraise. Thus Cicero, in his defence of Sextus, introduces his character in this manner, with a design to recommend him to the favour of the court: "I might say many things of his liberality, kindnecfs to his domestics, his command in the army, and moderation during his office in the province: but the honour of the state pretends itself to my view; and calling me to it, advises me to omit these lesser matters." But in his oration to the senate against Rullus the tribune, who had proposed a law to sell the public lands, he makes use of this figure to represent the pernicious effects of such a law, particularly with respect to the lands in Italy. "I do not complain (says he) of the diminution of our revenues, and the woful effects of this loss and damage. I omit what may give every one occasion for a very grievous and just complaint, that we could not preserve the principal estate of the public, the finest possession of the Roman people, the fund of our provisions, the granary of our wants, a revenue entrufted with the state; but that we must give up those land to Rullus, which, after the power of Sylla, and the largesses of the Gracchi, are yet left us. I do not deny this is now the only revenue of the state, which continues when others cease, is an ornament in peace, fails us not in war, supports the army, and does not fear an enemy. I pass over all these things, and reserve them for my discourse to the people, and only speak at present of the danger of our peace and liberties." His view here was to raise the indignation of the senate against Rullus, and excite them to oppose the law. There is a beautiful instance of this figure in St Paul's epistle to Philemon, where, after he has earnestly intreated him to receive again Onesimus his servant, who had run from him, and promised that if he had wronged him, or owed him any thing, he would repay it, he adds, "That I may not say, you owe even yourself to us." Nothing could be a stronger motive to soften his difpleasure against his servant, from a sense of gratitude to the apostle. Hermogenes has observed, that the design of this figure is to polaris the minds of the audience with more than the words express, and that it is principally made use of on three occasions: either when things are small, but yet necessary to be mentioned.
Elocution.

83 tioned; or well known, and need not be enlarged on; or ungrateful, and therefore should be introduced with caution, and not fet in too strong a light.

The next figure abovementioned was Paresphora, or reprehenion: Not that whenever a person admonishes or reproves another, it is to be esteemed a figure; but when it is done with art and address, and in such circumstances as render it difficult not to displease.

The orator therefore sometimes prepares his hearers for this, by commending them first, urging the necessity of it, representing his great concern for them as his motive, or joining himself with them. Thus Cicero charges the senate with the death of Servius Sulpicius, for sending him to Mark Antony under a very ill state of health. And his design in it was to bring them more readily into a motion he was about to make, that both a flature and a sepulchral monument might be ered to his memory at the public expense. "You, (says he) it is a very severe express, but I cannot help saying it; you, I say, have deprived Servius Sulpicius of his life. It was not from cruelty indeed (for what is there with which this assembly is less chargeable?) but when his ditemper pleased his excuse more than his words, from the hopes you conceived that there was nothing which his authority and wisdom might not be able to effect, you vehemently oppoed his excuse, and obliged him, who always had the greatest regard for your commands, to recede from his resolution." Sometimes, indeed, the orator assumes an air of reproof, with a view only to gain a compliment with a better grace. As Cicero in his address to Caesar, when he says, "I hear that excellent and wise saying from you with concern, That you have lived long enough either in friends, or failors; how ought you not to be abolition.--

The use of this figure is an especial figure: or esp. /ion, has an affinity with the former figure: but it differs from it in this, that it consists of several equivalent expressions, or nearly such, in order to represent the same thing in a stronger manner; whereas the other enlarges the idea by an enumeration of different particulars. So that this figure has a near relation to synonomy, of which we have treated before under Verbal figures. We have an instance of it in Cicero's defence of Sextius, where he says, "Those who at any time have incited the populace to sedition, or blinded the minds of the ignorant by corruption, or have been brave and excellent men, and such as deserved well of the public, have with us always been esteemed vain, bold, haughty, and injurious citizens. But those who repressed the attempts and endeavours of such as, by their authority, integrity, constancy, resolution, and prudence, withstand their influence, have been always accounted men of solidity, the chief, the leaders, and supporters of our dignity and government." Nothing more is intended by this passage, but to let the opposite characters of fudious persons and true patriots in the strongest light, with a view to recommend the one, and create a just hatred and detestation of the other.

Another of these pathetic figures is Apothesis, or enumeration, when that which might be expressed in general by a few words, is branched out into several particulars, to enlarge the idea, and render it the more affecting. Cicero, in pleading for the Milian law, where his design is to conciliate the love and esteem of the people to Pompey, thus enlarges upon his character: "Now, what language can equal the virtue of Cneius Pompey? What can be said either worthy of him, or new to you, or which every one has not heard? For those are not the only virtues of a general which are commonly thought so; labour in affairs, courage in dangers, industry in acting, dispatch in performing, delign in contriving; which are greater in him than in all other generals we have ever seen or heard of." And to likewise, when he endeavours to difpel Pompey's apprehension that Milo designed to affiliate him: "If (says he) you fear Milo; if you imagine that either formerly, or at present, any ill design has been formed by him against your life; if the folders raised through Italy (as some of your officers give out), if these arms, if these cohorts in the Capitol, if the centres, if the watch, if the guards which defend your person and house, are armed to prevent any attempt of Milo, and all of them appointed, prepared, and stationed on his account; he must be thought a perfl of great power, and incredible resolution, above the reach and capacity of a fingle man, that the most contummate general and the whole republic are in arms against him only. But who does not perceive, that all the disfenced and flinking parts of the flate are committed to you, to rectify and support them by these forces?" This sight: have been said in a few words, that such vart preparations could never be intended for so low a purpose. But the orator's view was to expel that groundless report, and shame it out of countenance. And soon after he endeavours to raise compassion for Milo under these prejudices by the same figure: "See how various and changeable is the state of human life. How unsteady and volatile is fortune, what infidelity in friends, what disguises suited to the times, what flights, what fears, even of the nearest acquaintance, at the approach of dangers." Had no address to the passions been designed here, fewer of their reflections might: have been sufficient. The use of this figure in amplification is very evident from the nature of it, which consists in unfolding of things, and by that means enlarging the conception of them.
Part III.

ORATORY.

Elocution. So elsewhere he represents the justice of self-defence in no less different times: "If reason (says he) prescribes this to the learned, and necessity to barbarians, custom to nations, and nature itself to brutes, always to ward off all manner of violence, by all possible ways, from their body, from their head, from their life; you cannot judge this to be a criminal and wicked action, without judging at the same time that all persons who fall among robbers and assassins must either perish by their weapons, or your sentence."—He is here addressing the judges in favour of Milo. The warmth and vehemence of the speaker often runs him into this figure, when he is affected with his subject, and thinks no words, no expressions, forcible enough to convey his sentiments; and therefore repeats one after another, as his fancy suggests them. This flow of expression, under the conduct of a good judgment, is often attended with advantage; as it warms the hearers, and impresses their minds, excites their passions, and helps them to see things in a stronger light.

Hypotyposis, or imagery, is a description of things painted in such strong and bright colours, as may help the imagination of the hearers to conceive of them rather as present to their view, than described in words. It is peculiarly suited for drawing characters; and often affords the finest ornaments in poetry and history, as well as oratory. Nor is it less moving, but suited to strike different passions, according to the nature of the subject, and artful management of the speaker. Cicero has thus drawn the picture of Catiline, conflating of an unaccountable mixture of contrary qualities. "He had (says he) the appearance of the greatest virtues: he made use of many ill men to carry on his designs, and pretended to be in the interest of the best men; he had a very engaging behaviour, and did not want industry nor application; he gave into the greatest loofoens, but was a good soldier. Nor do I believe there was even the like monster in the world, made of such jarring peeces, so repugnant to each other, and inclination. Who at one time was more acceptable to the best men, and who more intimate with the worke? Who was once a better patriot, and who a greater enemy to this state? Who more devoted to pleasures, who more patient in labours? Who more rapacious, and yet more profuse? He suited himself to the humours of all he conversed with; was ferious with the referred, and pleasent with the jocose; grave with the aged, and facetious with the young; bold with the daring, and extravagant with the profligate." Such a character of a man, when accompanied with power and interest, must render him no less the object of fear than detestation, which was the design of Cicero in this description. And elsewhere, in order to prevail with the senate to direct the execution of those conspirators with Catiline who were then in prison, he paints the most dismal scene of that horrid design in the strongest colours. "Methinks (says he) I see this city, the light of the world, and citadel of all nations, sudenly falling into one fire; I perceive heaps of miserable citizens buried in their ruined country; the countenance and fury of Cethogus raging in your slaughter, presents itself to my view." This figure is very serviceable in amplification, as we have formerly shown in treating upon that subject. But no small judgment is required in the management of descriptions. Leffer circumstances should either be wholly omitted, or but slightly touched; and those which are more material drawn in their due proportion. Nature is as much the rule of the orator as of the painter, and what they both propose to imitate. And therefore, let a thought be ever so pleasing and beautiful in itself, it must not be introduced when foreign to the purpose, or out of its place, any more than a painter should attempt to alter nature, when he proposes to copy it. This figure requires likewise a vigorous and lively genius. For the images in description can rise no higher than the conception of the speaker, since the idea must first be formed in his own mind before he can convey it to others; and agreeably to the cleanliness with which he conceives it himself, he will be able to express it in words.

Apologia, or doubt, expresses the debate of the mind with itself upon a puzzling difficulty. A person in such a state is apt to hesitate, or start several things successively, without coming to any fixed resolution. The uneasiness arising from such a disorder of thought is naturally very moving. Of this kind is that of Cicero for Cluentius, when he says, "I know not which way to turn myself." Shall I deny the scandal thrown upon him of bribing the judges? Can I say the people were not told of it? that it was not talked of in the court? mentioned in the senate? Can I remove an opinion so deeply and long rooted in the minds of men? It is not in my power. You, judges, must support his innocence, and rescue him from this calamity." Orators sometimes choose to begin their discourse with this figure. A difference of mind at first is not unbecoming, but graceful. It carries in it an air of modesty, and tends very much to conciliate the affections of the hearers. Livy gives us a very elegant example of this in a speech of Scipio Africanus to his soldiers, when, calling them together after a sedition, he thus bespeaks them: "I never thought I should have been at a loss in what manner to address my army. Not that I have applied myself more to words than things; but because I have accustomed them to the genius of soldiers, having been brought up in the camp almost from my childhood. But I am in doubt what or how to speak to you, not knowing what name to give you. Shall I call you citizens, who have revolted from your country? Soldi. , who have disowned the authority of your general, and broke your military oath? Enemies? I perceive the mien, the aspect, and habit of citizens; but discerne the actions, words, designs, and dispositions of enemies." Sometimes a passion has that effect, not so much to render a person doubtful what to say, as to stop him in the midst of a sentence, and prevent his expressing the whole of what he designed; and then it is called Apologia, or concealment. It denotes different passions; as anger, which, by reason of its heat and vehemence, causes persons to break off abruptly in their discourse. So the old man in Terence, when he was jealous that his servant obstructed his designs, utes this imperfect, but threatening expression, Wenn, if I find. And Neptune, when descried by Virgil as very angry that the winds should prevent to disturb the sea without his permission, after he has called them to him to know the reason of it, threatens them in this abrupt manner:

"Whom I—but first I'll lay the storm."

But Cicero, in writing to Atticus, applies it to ex-
Elocution,

Oratory.

Part III.

pref grief, where he fays, "I know nothing of Pompey, and believe he muft be taken, if he is not got on shipboard. O incredible f Witnes! but of our friend—Though I cannot accuse him without grief, for whom I am in fo much concern and trouble." And in a letter to Caflius he ufs it to express fear, when he fays to him, "Brutus could scarce support himself at Mufina; if he is safe, we have carried the day. But it—heaven avert the omen! all muft have recourse to you." His meaning is, "If Brutus should be defeated.

The next figure is erotela, or interrogation. But every interrogation or queftion is not figurative. When we inquire about a thing that is doubtful, in order to be informed, that is no figure, but the natural form of such expressions. As if I ask a perfon, Where is he going? or What he is doing? But then it becomes figurative when the fame thing may be expreffed in a direct manner; but the putting it by way of queftion gives it a much greater life and spirit. As when Cicero fays, "Cafline, how long will you abuse our patience? do not you perceive your desigms are discovered?" He might indeed have faid, You abuse our patience a long while. You might frequent your defigns are discovered. But it is easy to perceive how much this latter way of expreffion falls short of the force and vehemence of the former. And fo when Medea fays, I could fave; and do you afk if I can defroy? Had the faid I could fave, and I can defroy, the fentence had been flat, and very unfit to express the rage and fury in which the poet there represents her. This figure is fued to express moft paflions and emotions of the mind, as anger, deflain, fear, defire, and others. It ferves also to prefs and bear down an adversary, Cicero frequently makes this ufe of it. As in his defence of Planius: "I will make you this offer (fays he), choose any tribe you please, and flay, as you ought, by whom it was bribed; and if you cannot, as I believe you will not undertake it, I will prove how he gained it. Is this a fair conteft? Will you engage on this foot? I cannot give you fairer play. Why do you feitol? Why do you defill? Why do you hefitate? I infilt upon it, urge you to it, prefs it, require, and even demand it of you." Such a way of plunging an antagonist shows the speaker has great confidence in his cafe; otherwife he would never lay himfelf fo open, if he was not affured the other party had n'thing to reply. This figure likewife verifies a discolour, and gives it a beautiful variety, by altering the form of expreffion, provided it be neither too frequent, nor continued too long at once. And besides, the warmth and eager manner in which it is expreffed, enlivens the hearers, and quickens their attention.

Epanthias, or Eclamration, is a vehement extenfion of the voice, occafioned by a commotion of mind, naturally venting itfelf by this figure, which is ufed by Cicero to exprefs a variety of paflions. It oft en denote refentment or indignation. Thus, after his return from banifhment, reflecting on thofe who had occafioned it, he breaks out into this moving explication: "O mournful day to the senate, and all good men, calamitous to the state, affliffive to me and my family, but glorious in the view of potery!" His defign was to excite an odium againft the authors of his exile, when recalled in fo honourable a manner. And again, in his defence of Catilii: "O the great force of truth; which easily supports itfelf againft the wily, craft, subtilty, and artful deigns of men!" He had been juft showing the abfurdity of the charge againft Catulus, and now endeavour to expofe his accufers to the indignation of the court. At other times it is ufed to exprefs defdain or contempt. As when speaking of Pompey's house, which was bought by Mark Antony, he fays, "O consummate impudence! dare you go within that house! dare you enter that venerable threshold, and fhew your audacious cununence to the tutelar deities which reside there?" Nor is it lefs fitting to indicate grief, as when he fays of Milo, "O that happy country, which fhall receive this man! ungrateful this, if it banifh him! miserable, if it loft him?" And fometimes it ferves to exprefs admiration; as when, in compliment to Caflus, he fays, "O admirable clemency! worthy of the greatest praise, the higheft encomiums, and molt laudable monuments! It has its ufe alfo in ridicule and irony. As in his oration for Balbus, where he derides his accufers, by faying, "O excellent interpreter of the law! master of impudence! corrector and amender of our constitution!" The fated writers fometimes ufe it by way of interject or with. As the royal psalmift: "O that I had the wings of a dove, that I might flee away, and be at reif." And at other times in triumph and exultation, as in that of St Paul: "O death, where is thy sting! O grave, where is thy victory!" It is frequently joined with the preceding figure interrogation; as appears in some of the inftrances here brought from Cicero. And it generally follows the reprefentation of the thing which occafions it. Though fometimes it is made ufe of to introduce it, and then it ferves to prepare the mind by exciting its attention. Thus Cicero, in his defence of Catius, to render the character of Clodia more odious, at whose infligation he was accufed, infinuates that he had before poisoned her husband; and to heighten the barbary of the fact, and make it appear the more shocking, he introduces the account of it, with this moving explication: "O heavens, why do you fometimes wink at the greffit crimes of mankind, or delay the punishment of them to futurity!"
The next figure in order is **apostrophe**, or address, when the speaker breaks off from the series of his discourse, and addresses himself to some particular person present or absent, living or dead; or to inanimate nature, as endowed with sense and reason. By this means he has an opportunity of saying many things with greater freedom than perhaps would be consistent with decency if immediately directed to the persons themselves. He can admonish, chide, or censure, without giving offence. Nor is there any passion, but may be very advantageously expressed by this figure. When an orator has been speaking of any particular person, on a sudden to turn upon him, and apply the discourse to that person himself, is very moving; it is like attacking an adversary by surprise, when he is off his guard, and where he least expects it. Thus Cicero: "I desire, senators, to be merciful, but not to appear negligent in great dangers of the state; tho' I think I had deferred it too long, than charge me one now, who would not approve and commend his guard, at present I cannot but condemn myself of remorse. There is a camp formed in Italy, at the entrance of Etruria, against the state; our enemies increase daily; but we see the commander of the camp, and general of the enemies, within our walls, in the very senate, contriving some intestine ruin to the state. If now, Catiline, I should order you to be seized and put to death, I have reason to fear, that all good men would rather think I had deferred it too long, than charge me with cruelty. But I am prevailed with for a certain reason not to do that yet, which ought to have been done long since." This sudden turn of the discourse to Catiline himself, and the address to him in that unexpected manner, must have touched him very sensibly. So, in his defence of Milo, expressing his concern if he should not succeed in it, he says, "And how shall I answer it to you, my brother Quintus, the partner of my misfortunes, who art now absent." And elsewhere addressing to the soldiers of the Martian legion, who had been killed in an engagement with Mark Antony, he thus bespeaks them: "O happy death, which due to nature, was paid to your country! I may esteem you truly born for your country, who likewise received your name from Mars; so that the fame deity seems to have produced this city for the world, and you for this city." And in his oration for Balbus he thus calls upon dum nature to witness to Pompey's virtues: "I invoke you, mute regions; you, most distant countries; you seas, havens, islands, and shores. For what calm, what land, what place is there, in which the marks of his courage, humanity, wisdom, and prudence, are not extant? An appeal to heaven, or any part of inanimate nature, has something very sublime and solemn in it, which we often meet with in sacred writ. So the divine prophet: "Hear, O heavens! and give ear, O earth! for the Lord hath spoken." And in like manner, the prophet Jeremy: "Be ashamed, O ye heavens, at this." See **Apostrophe**.

**Prefopoeia**, or the fiction of a person: by which, either an absent person is introduced speaking; or one who is dead, as if he was alive and present; or speech is attributed to some inanimate being. There is no figure, perhaps, which serves more or better purposes to an orator than this. For by this means he is enabled to call in all nature to his assistance, and can assign to every thing such parts as he thinks convenient. There is scarce any thing fit to be said, but may be introduced this way. When he thinks his own character is not of sufficient weight to affect his audience in the manner he desires, he substitutes a person of greater authority than himself to engage their attention. When he has severe things to say, and which may give offence as coming from himself; he avoids this, by putting them into the mouth of some other person from whom they will be better taken; or makes inanimate nature bring a charge, or expresses a resentment, to render it more affecting. And by the same method he sometimes chooses to secure himself from a fulmination of calumny, in carrying a compliment too high. We meet with several very beautiful instances of this figure in Cicero; but an example of each sort may here suffice. Beginning with that of an absent person, from his defence of Milo, whom he thus introduces as speaking to the citizens of Rome: "Should he, holding the bloody sword, cry out: Attend, I pray, hearken, O citizens, I have killed Publius Clodius; by this sword, and by this right hand, I have kept off his rage from your necks, which no laws, no courts of judicature, could restrain; it is by my means, that justice, equity, laws, liberty, shame, and modesty, remain in the city. Is it to be feared how the city would bear this action? Is there any one now, who would not approve and commend it?" And in his oration for Balbus, he introduces Marius, who was then dead, to plead in his defence: "Can Balbus (says he) be condemned, without condemning Marius for a like fact? Let him be present a little to your thoughts, since he cannot be in person; that you may view him in your minds, though you cannot with your eyes. Let him tell you, he was not acquainted with leagues, void of examples, or ignorant of war." And again, in his first invective against Catiline, he represents his country as thus expostulating with himself, and upbraiding him for suffering such a criminal as Catiline to live: "Should my country (says he), which is much nearer to me than my life, shewed all Italy, all the state, thus address me, Mark Tully what do you do? Do you suffer him, whom you have found to be an enemy, who you fee to be at the head of the war, whom you perceive your enemies wait for in their camp as their general, who has been the contriver of this wickedness, the chief of the conspiracy, the exciter of slaves and profligate citizens, to leave the city, which is rather to bring him in, than let him out? Will not you order him to be imprisoned, condemned, and executed? What prevents you? The custom of our ancestors? But private persons have often punished parricidal citizens in this state. The laws relating to the punishment of Roman citizens? But traitors never had the rights of citizens. Do you fear the censure of politerly? Truly you make a very handlime return to the people of Rome, who have advanced you from an obscure condition so early to the highest dignity; if you neglect their safety to avoid envy, or from the apprehension of any danger. And if you fear censure; which is most to be dreaded, that which may arise from justice and fertilure, or from cowardice.
ORDINARY.

Part III.

Elocution. cowardice and treachery? When Italy shall be wasted by a war, cities plundered, and houses burnt, do you think then to escape the severest cenfore? In the management of this figure, care should be taken that what is said be always consistent with the character introduced, in which both the force and beauty of it consist.

In treating upon figures, we have hitherto considered them separately: but it may not be amiss to observe, that some expressions consist of a complication of them, and may come under the denomination of several figures, as well verbal as those of sentences, differently considered. Thus when Cicero says, "What, Tubero, did your drawn sword do in the Pharsalian battle? at whose side was its point directed? what was the intention of your arms?" As he speaks to Tubero, it is an apostrophe; as the expressions have much the same import, and are designed to heighten and aggravate the fact, it is exortatio; and us they are put by question, it is interrogation. So likewise, in his second Philippic, where he says, "What can I think? that I am contemned? I see nothing in my life, interest, actions, or abilities, as moderate as they are, which Antony can despise. Did he think he could easily leaen me in the senate? But they, who have commended many for eloquence? This would be a favour indeed. For me to speak for myself their good government of the state, never thanked.

The like figures in this passage; dubt, interrogation, and subjection. And again, when he introduces Sicily thus addressing Verres in a way of complaint: "Whatever gold, whatever silver, whatever ornaments in my cities, dwellings, temples, whatever right of any kind I pollifie by the favour of the senate and people of Rome; you, Verres, have plundered and taken from me." Here is a prophetica, joined with the verbal figure anaphora, as several members of the sentence begin with the same word. The like inances of complex figures frequently occur, and therefore we need not multiply examples of them here.

PARTICULAR ELOCUTION.

Or that part of Elocution which considers the several Properties and Ornaments of Language, as they are made use of to form different sorts of Style.

CHAP. IV. Of Style, and its different Characters.

The word style, properly signifies the instrument which the ancients used in writing. For as they commonly wrote upon thin boards covered over with wax, and sometime upon the barks of trees, they made use of a long instrument like a bodkin, pointed at one end, with which they cut their letters; and broad at the other, to erase any thing they chose to alter. And this the Latins called stylo. But though this be the first sense of the word, yet afterwards it came to denote the manner of expression. In which sense we likewise use it, by the same kind of trope that we call any one's writing his hand. Style, then, in the common acceptance of the word at present, is the peculiar manner in which a man expresses his conceptions by means of language. It is a picture of the ideas which rise in his mind, and of the order in which they are there produced. As to the reasons which occasion a variety of style, they are principally these.

Since both speech and writing are only sensible expressions of our thoughts, by which we communicate them to others; as all men think more or less differently, so consequently they in some measure differ in their style. No two persons, who were to write upon one subject, would make use of all the same words. And were this possible, yet they would as certainly differ in their order and connection, as two painters, who used the same colours in painting the same picture, would necessarily vary their mixtures and disposition of them, in the several gradations of lights and shades. As every painter therefore has something peculiar in his manner, so has every writer in his style. It is from these internal characters, in a good measure that critics undertake to discover the true authors of anomalous writings; and to show that others are fpirious, and not the genuine productions of those whose names they bear; as they judge of the age of such writings from the words and manner of expression which have been in use at different times. And we may often observe in periphs a fondness for some particular words or phrases; and a peculiarity in the turn or connection of their sentences, or in their transitions from one thing to another; by which their style may be known, even when they design to conceal it. For these things, through custom and habit, will sometimes drop from them, notwithstanding the greatest caution to prevent it.

There is likewise very often a considerable difference in the style of the same person, in several parts of his life. Young persons, whose invention is quick and lively, commonly run into a pompous and luxuriant style. Their fancy represents the images of things to their mind in a gay and sprightly manner, clothed with a variety of circumstances; and while they endeavour to set off each of these in the brightest and most glittering colours, this renders their style verbose and florid, but weakens the force and strength of it. And therefore, as their imagination gradually cools, and comes under the conduct of a more mature judgment, they find it proper to cut off many superfluities; so that by omitting unnecessary words and circumstances, and by a closer connection of things placed in a stronger light, if their style becomes less swelling and pompous, it is, however, more correct and nervous. But as old age sinks the powers of the mind, chills the imagination, and weakens the judgment; the style, too, in proportion usually grows dry and languid. Critics have observed something of this difference in the writings even of Cicero himself. To be master of a good style, therefore, it seems necessary that a person should be endowed with a vigorous mind and lively fancy, a strong memory, and a good judgment. It is by the imagination that the mind conceives the images of things. If the impressions of those images be clear and distinct, the style will be fo.
Part III.

ORATORY.

Elocution too; since language is nothing but a copy of those images first conceived by the mind. But if the images are faint and imperfect, the style will accordingly be flat and languid. This is evident from the difference between such objects as are represented to our sight, and things of which we have only read or heard. For as the former generally make a deeper impression upon our minds, so we can discern them in a more forcible and lively manner. And we commonly find, that according as persons are affected themselves when they speak, they are able to affect others with what they say. Now persons are more or less affected with things in proportion to the impressions which the images of those things make upon the mind. For the same reason also, if the imagination be dull, and indisposed to receive the ideas of things, the style will be stiff and heavy; or if the images are irregular and disorderly, the style will likewise be perplexed and confused. When things lie straight (as we say) in the mind, we express them with ease, and in their just connection and dependence; but when they are warp and crooked, we deliver them with pain and difficulty, as well as disorder. A good fancy should likewise be accompanied with a happy memory. This helps us to retain the names of those things the ideas whereof are presented to the mind by the imagination, together with proper and suitable phrases to express them in their several connections and relations to each other. When the images of things offer them selves to the mind, unless the names of them present themselves at the same time, we are at a loss to express them, or at least are in danger of doing it by wrong and improper terms. Besides, variety is necessary in discourse to render it agreeable; and therefore, without a large furniture of words and phrases, the style will necessarily become insipid and redundant, by the frequent return of the same terms and manner of expression. But to both these a solid judgment is highly requisite to form a just and accurate style. A fruitful imagination willunlock the mind with plenty of ideas; and a good memory will help to clothe them in proper language; but unless they are both under the conduct of reason, they are apt to hurry persons into many inconveniences. Such are generally great talkers, but far from good orators. Fresh images continually crowd in upon them, fatter than the tongue can well express them. This runs them into long and tedious discourses, abounding with words, but void of sense. Many impertinencies, if not improprieties, necessarily mix themselves with what they say; and they are frequently carried off from their point, by not having their fancies under a proper regulation. So that such discourses, though composed perhaps of pretty expressions, rhetorical flowers, and sprightly allusions of wit, yet fall very much short of a strong and manly eloquence. But where reason presides and holds the reins, every thing is weighed before it is spoken. The properest words are made choice of which best suit the ideas they are designed to convey; rather than the moty gay and pompous. All things are not fitted which offer themselves to the mind, as fancy dictates; but such only as are fit and proper, and the rest are dropped. Some things are but slightly mentioned, and others discourse more largely and fully, according to their different importance. And every thing is placed in that order, and

clothed in such a dress, as may represent it to the electorate.

This is evident from the difference between such objects as are represented to our sight, and things of which we have only read or heard. For as the former generally make a deeper impression upon our minds, so we can discern them in a more forcible and lively manner. And we commonly find, that according as persons are affected themselves when they speak, they are able to affect others with what they say. Now persons are more or less affected with things in proportion to the impressions which the images of those things make upon the mind. For the same reason also, if the imagination be dull, and indisposed to receive the ideas of things, the style will be stiff and heavy; or if the images are irregular and disorderly, the style will likewise be perplexed and confused. When things lie straight (as we say) in the mind, we express them with ease, and in their just connection and dependence; but when they are warp and crooked, we deliver them with pain and difficulty, as well as disorder. A good fancy should likewise be accompanied with a happy memory. This helps us to retain the names of those things the ideas whereof are presented to the mind by the imagination, together with proper and suitable phrases to express them in their several connections and relations to each other. When the images of things offer them selves to the mind, unless the names of them present themselves at the same time, we are at a loss to express them, or at least are in danger of doing it by wrong and improper terms. Besides, variety is necessary in discourse to render it agreeable; and therefore, without a large furniture of words and phrases, the style will necessarily become insipid and redundant, by the frequent return of the same terms and manner of expression. But to both these a solid judgment is highly requisite to form a just and accurate style. A fruitful imagination willunlock the mind with plenty of ideas; and a good memory will help to clothe them in proper language; but unless they are both under the conduct of reason, they are apt to hurry persons into many inconveniences. Such are generally great talkers, but far from good orators. Fresh images continually crowd in upon them, fatter than the tongue can well express them. This runs them into long and tedious discourses, abounding with words, but void of sense. Many impertinencies, if not improprieties, necessarily mix themselves with what they say; and they are frequently carried off from their point, by not having their fancies under a proper regulation. So that such discourses, though composed perhaps of pretty expressions, rhetorical flowers, and sprightly allusions of wit, yet fall very much short of a strong and manly eloquence. But where reason presides and holds the reins, every thing is weighed before it is spoken. The properest words are made choice of which best suit the ideas they are designed to convey; rather than the moty gay and pompous. All things are not fitted which offer themselves to the mind, as fancy dictates; but such only as are fit and proper, and the rest are dropped. Some things are but slightly mentioned, and others discourse more largely and fully, according to their different importance. And every thing is placed in that order, and

clothed in such a dress, as may represent it to the electorate.

This is evident from the difference between such objects as are represented to our sight, and things of which we have only read or heard. For as the former generally make a deeper impression upon our minds, so we can discern them in a more forcible and lively manner. And we commonly find, that according as persons are affected themselves when they speak, they are able to affect others with what they say. Now persons are more or less affected with things in proportion to the impressions which the images of those things make upon the mind. For the same reason also, if the imagination be dull, and indisposed to receive the ideas of things, the style will be stiff and heavy; or if the images are irregular and disorderly, the style will likewise be perplexed and confused. When things lie straight (as we say) in the mind, we express them with ease, and in their just connection and dependence; but when they are warp and crooked, we deliver them with pain and difficulty, as well as disorder. A good fancy should likewise be accompanied with a happy memory. This helps us to retain the names of those things the ideas whereof are presented to the mind by the imagination, together with proper and suitable phrases to express them in their several connections and relations to each other. When the images of things offer them selves to the mind, unless the names of them present themselves at the same time, we are at a loss to express them, or at least are in danger of doing it by wrong and improper terms. Besides, variety is necessary in discourse to render it agreeable; and therefore, without a large furniture of words and phrases, the style will necessarily become insipid and redundant, by the frequent return of the same terms and manner of expression. But to both these a solid judgment is highly requisite to form a just and accurate style. A fruitful imagination willunlock the mind with plenty of ideas; and a good memory will help to clothe them in proper language; but unless they are both under the conduct of reason, they are apt to hurry persons into many inconveniences. Such are generally great talkers, but far from good orators. Fresh images continually crowd in upon them, fatter than the tongue can well express them. This runs them into long and tedious discourses, abounding with words, but void of sense. Many impertinencies, if not improprieties, necessarily mix themselves with what they say; and they are frequently carried off from their point, by not having their fancies under a proper regulation. So that such discourses, though composed perhaps of pretty expressions, rhetorical flowers, and sprightly allusions of wit, yet fall very much short of a strong and manly eloquence. But where reason presides and holds the reins, every thing is weighed before it is spoken. The properest words are made choice of which best suit the ideas they are designed to convey; rather than the moty gay and pompous. All things are not fitted which offer themselves to the mind, as fancy dictates; but such only as are fit and proper, and the rest are dropped. Some things are but slightly mentioned, and others discourse more largely and fully, according to their different importance. And every thing is placed in that order, and

clothed in such a dress, as may represent it to the electorate.
Again, people of different nations vary in their customs and manners which occasion a diversity in their style. This was very remarkable in the Atticans, Atlantics and Rhodiens, and is often taken notice of by ancient writers. The Atheniens, while they continued a free state, where an active, industrious, and frugal people; very polite indeed, and cultivated arts and sciences beyond any other nation: but as they had powerful enemies, and were exceedingly jealous of their liberties, this preferred them from wantonness and luxury. And their way of speaking was agreeable to their conduct; accurate and close, but very full and expressive. The Atlantics, on the other hand, were more gay, and loose in their manners, devoted to luxury and pleasure; and accordingly they affected a florid and swelling style, filled with redundancies and superfluities of expression. Indeed, some of the ancients have attributed who settled among them, they suppose, that, in imitating them, before they were masters of the language, they were often obliged to make use of circumlocutions, which afterwards became habitual, and very much weakened the force of their expressions, as it naturally would do. But one would think, if they were put to this necelity at first, when they found its ill-effect, they might easily have amended it afterwards, as they grew better acquainted with the Greek language, had they been inclined to do so. The Rhodian style was a medium between the other two; not so concise and expressive as the Attic, nor yet so loose and redundant as the Atlantic. Quintilian says, it had a mixture of its author, and the humour of the people; and, like plants set in a foreign soil, degenerated from the Attic purity, but not so wholly as to lose it. They first received it from Aeschines, who being workeid in his famous contest with Demosthenes, retired thither, and taught rhetoric, which put them upon the study of eloquence.

The style of the same country likewise very much alters in different ages. Cicero tells us, that the first Latin historians aimed at nothing more than barely to make themselves intelligible, and that with as much brevity as they could. Those who succeeded them advanced a step further; and gave somewhat a better turn and cadency to their sentences, though still without any dres or ornament. But afterwards, when the Greek language became fashionable at Rome, by copying after their writers, such as Herodotus, Thucydides, Xenophon, and others, they endeavoured to introduce all their beauties into their own tongue, which in Cicero's time was brought to its highest perfection. But it did not long continue in that state. A degeneracy of manners soon altered their taste, and corrupted their language, which Quintilian very much complains of in his time. The case was the same with respect to the Greek tongue; though that had the good fortune to continue its purity much longer than the Latin. Nor can any language be exempt from the common fate of all human productions; which have their beginning, perfection, and decay. Besides, their is a sort of fashion in language, as well as other things; and the generality of people are always fond of running into the mode. Perhaps some one, or a few persons, fall into a manner which happens to please. This gives them a reputation; and others immediately copy after them, till it generally prevails. Cicero tells us, that the most ancient Greek orators whose writings were extant in his time, such as Pericles, Alcibiades, and others, were subtle, acute, concise, and abounded in enepe rather than words. But another set that followed them, of which were Critias, Theramenes, and Lyfas, retained the good sense of the former, and at the same time took more care of their style; not leaving it to base as the former had done, but furnishing it with a better drefs. After these came Isocrates, who added all the flowers and beauties of eloquence. And as he had abundance of followers, they applied their ornaments and decorations according to their different genius; some for pomp and splendor; and others to invigorate their style, and give it the greater force and energy. And in this latter way Demosthenes principally excelled. Now as each of these matters had its peculiar beauties, and generally prevailed in different ages, Cicero thinks this could not have happened otherwise than from imitation. And he attributes it to the same cause, that afterwards they sunk into a softer and smoother manner, not less exact and florid, but more cold and lifeless. If we take a view of our own tongue, Chaucer seems to have been the first who made any considerable attempts to cultivate it. And whoever looks into his writings, will perceive the difference to be so great from what it is at present; that it scarce appears to be the same language. The gradual improvements it has since received, are very evident in the writers almost of every succeeding age since that time: and how much farther it may still be carried, time only can discover. See Language paffion: For the English language in particular, see n. 38. for the other European languages, as well as the Greek and Latin, see n. 27, &c.

Another cause of the variety of style arises from the different nature and properties of language. A difference in the letters, the make of the words, and the order of them, do all affect the style. So Quintilian observes, that the Latin tongue cannot equal the Greek in pronunciation, because it is harsher. The Latins want two of the four Greek letters, and the others of a very hard sound, which the Greeks have not, as θ and ρ. Again, many Latin words end in a letter of a broad and hollow sound, which never terminates any Greek word; but, does frequently, whose found is much softer and sweeter. Besides, in the combination of syllables, the letters l and d are often so situated, as to require too strong and unequal a force to be laid upon them, as in the words obversus and adjungo. Another advantage of the Greek tongue arises from the variety and different sort of the accents: for the Greeks often accent the last syllable, which both enlivens the pronunciation and renders it more musical; whereas the Latins never do this. But the greatest advantage of the Greeks lies in their plenty and variety of words; for which reason they have less occasion for tropes or circumlocutions, which, when used from necessity, have generally less force, and weaken the style. But under these disadvantages,
Part II.

Quintilian seems to give his countrymen the best advice the case will admit of: That what they cannot do in words, they should make up in style. If their expressions are not so soft and tender, they should exceed in strength; if they are less subtle, they should be more subtile, and if they have fewer proper words, they should excel in the beauty as well as number of their figures. If this account of Quintilian be just, that the Greek tongue does surpass the Latin in all these infinities, it is certain that both of them have much greater advantages over some modern languages. Their varying all their declinable words, both nouns and verbs, by terminations, and not by sign, contributes very much to the smoothness and harmony of their periods. Whereas in the modern languages, those small particles and pronouns which distinguish the cases of nouns and the tenses and persons of verbs, hinder the run of a period, and render the found much more rough and uneven. Besides, the ancient languages seem to have a better and more equal mixture of vocal- and consonants, which makes their pronunciation more easy and musical.

But the chief distinction of style arises from the different subjuncts of matter of discourse. The same way of speaking no more suits all subjuncts, than the same garment would all persons. A prince and a peasant ought not to have the same drefs; and another different from both becomes to the middle station in life. The style therefore should always be adapted to the nature of the subjunct, which rhetoricians have reduced to three ranks or degrees: the low or plain style, the middle or temperate, and the lofty or sublime: Which are likewise called characters, because they denote the quality of the subjunct, upon which they treat. This division of style into three characters, was taken notice of very early by ancient writers. Some have observed it even in Homer, who seems to affign the sublime or magnificent to Ulysses, when he represents him to cupids and vehement an orator, that his words came from him like winter snow. On the contrary, he describes Menelaus as a polite speaker, but concise and moderate. And when he mentions Nellor, he represents his manner as between these two, not so high and lofty as the one, nor yet so low and depressed as the other; but smooth, even, and pleasant, or, as he expresses it, more sweet than honey. Quintilian observes, that: although accuracy and politeness were general characters of the Attic writers; yet among their orators, Lydias excelled in the low and familiar style; Isocrates for his elegance, smoothness, and the fine turn of his periods; and Demotthenes for his flame and rapidity, by which he carried all before h.m. And Gallius tells us, that the like difference was found in the three philosophers who were sent from the Athenians to Rome (before the Romans had any relish for the polite arts) to solicit the remittance of a fine laid upon them for an injury done to a neighbouring state. Carneades, one of those orators, and the most different manner, so captivated the Roman youth, and inflamed them with a love of the Grecian arts, that old Cato, who did all he could to check it by burying away the ambassado-

dors, could not prevent their vigorous pursuit of them. Elocution.

Chap. V. Of the Low Style.

This we shall consider under two heads, thoughts and language; in each of which the several characters are distinguished from one another.

I. And with respect to the former, as the subjuncts proper for this style are either common things, or such as should be treated in a plain and familiar way; so plain thoughts are most suitable to it, and distinguish it from the other characters.

Now, by plain thoughts, are meant such as are simple and obvious, and seem to rise naturally from the subjunct, when duly considered; so that any one, upon first hearing them, would be apt to imagine they must have occurred to himself. Not that this is really the case, but because the more natural a thing is, the more easy it seems to be; though in reality it is often otherwise; and the perfection of art lies in its nearest resemblance to nature. And therefore, in order to speak plainly and clearly upon any subjunct, it must first be duly considered, well understood, and thoroughly digested in the mind; which, though it require labour and study, yet the more a person is master of what he says, the less that labour will appear in his discourse. This natural plainness and simplicity, without any digust or affectation, very much contributes to give credit to what is said. Nor is any thing more apt to impose upon, than the appearance of this, when artfully assumed. Cicero's account of the fight between Milo and Clodius, in which Clodius was killed, is a remarkable instance of this. "When Clodius knew (says he) that Milo was obliged to go to Lavinium upon a solemn and necessary occasion, he immediately hastened from Rome, the day before, to affumine him before Clodius's own house, as appeared afterwards by the event. And this he did at a time, when his turbulent mob in the city wanted his affiance; whom he would not have left, but for the advantage of that place and faction to execute his wicked design. But the next day Milo was in the senate, where he continued till they broke up; then went home; changed his dres; laid there some time till his wife was ready; and afterwards set forward to late, that if Clodius had deligned to return to Rome that day, he might have been here by that time. Clodius, prepared for his design, met him on horseback, having no chariot, no equipage, no Greek attendants as usial; and without his wife, which was scarce ever known: where as Milo was in a chariot with his wife, wraped up in a cloak, and attended by a large retinue of maid servants, pages, and other persons unfit for an engagement. He met with Clodius before his house, about five o'clock in the evening; and was presently assatt,
The former of these is justness and propriety, which is what reason dictates in all cases. 'That Cicero says of the death of Cælius the orator, seems very just, as well as natural, "It was (says he) an affliction to his friends, a loss to his country, and a concern to all good men; but such public calamities followed upon it, that heaven seemed rather to have favoured him with death, than to have deprived him of life." This thought seems very just, and agreeable to the sentiments of a good man, as Cælius was; to choose death rather than to outlive the happiness of his country, to which he himself had so much contributed. Quintilian has a reflection upon a like occasion, which is not so just and becoming. It is upon the death of his only son, a youth of very uncommon parts, as he represents him; and for whose use he had designed his Institutiones of Oratory; but he died before they were finished. The passage is this: "I have lost him of whom I had formed the greatest hopes, and in whom I had repented the greatest comfort of my old age. What can I do now? or of what farther use can I think myself to be, thus disappointed by heaven? What good parent will pardon me, if I can any longer fludy? and not condemn such resolution, if, thus surviving all my family, I can make any other use of my voice, than to accuse the gods, and declare that providence does not govern the world?" Allowance may be made for the fallacies of passion, even in wise men, upon some shocking occasions; but when it proceeds to such a degree as to become impious, it is very indecent, as well as unjust. And all indecency is unnatural, as it is disagreeable to reason, which always directs to a decorum. That seems to be a very natural as well as just thought of Pliny the Younger, when he says, "The death of those persons always appears to me highly and unaccountable, who are preparing some lofty work. For persons wholly devoted to pleasures, live, as it were, from day to day, and daily finish the end for which they live; but those who have a view to politeness, and preserve their memory by their labours, always die untimely, because they leave something unfinished." We shall mention but one more instance; and that in a comparative view, to make it the more evident. The two sons of Junius Brutus, the first Roman conful, having been convicted of treason in associating with Tarquin's party, were ordered, among others, to be put to death; and their father not only pronounced the sentence, but prefixed at the execution. This fact is mentioned by several of the Roman historians; and, as it carries in it not only the appearance of rigorous justice, but likewise of cruelty in Brutus, to have been present at the execution of his sons, they endeavour to vindicate him different ways. What Florus says, seems rather an embellishment of his father's defence of the fact. "He beheaded them (says he), that being a public parent, he might appear to have adopted the whole body of the people." Nor does Val. Maximus come up to the case, who says, "He put off the father to act the conful; and chose rather to loot the sons, than be wanting to public justice." This might be a reason for condemning them; and would have been equally true, had he not been
Elocution. But Livy, whose thoughts are generally very just and natural, aligns the belief which perhaps can be given for his vindication, when he says, “Fortune made him the executioner of the sentence, who ought not to have been a spectator.” By saying fortune made him so, he represents it not as a matter of choice, like the other historians, but of necessity, from the nature of his office, which then obliged him to see the execution of that sentence he had himself before pronounced; as is the custom at present, in some popular governments.

The other property, which thors often accompany plain and simple thoughts, is, that they be gay and sprightly. This, as has been said, is necessary to animate and enliven such discourses as require the low style. The fewer ornaments it admits of, the greater spirit and vivacity is requisite to prevent its being dry and jejune. A thought is never more brisk and lively, and at the same time appear very natural, as the effect of a ready and flowing wit. Such thoughts, attended with agreeable turns, are very suitable to this style; but care should be taken, lest, while fancy is too much indulged, the jutness of them be overlooked. We shall give one instance, in which this seems to have been the case, from a celebrated historian, which then obliged him to see the execution of the sentence he had himself before pronounced; as is the custom at present, in some popular governments.

agreement thus, but Aristides did not come. As to order, the plainest and clearest disposition, both of the words and members of sentences, and what is most agreeable to the natural construction, best suits with this character. For one of its principal beauties is perpétuity. And a proper connexion likewise of sentences, with a regular order in the dependence of things one upon another, very much contribute to this end. With regard to the collision of syllables in different words, for preventing either an hollowness or asperity of sound, greater liberty may be taken in this style than in the other characters. Here it may be allowed to say, *Virtue is amiable to all, though all do not pursue it.* But in an higher character, perhaps, in order to prevent the hollow sound of the words *though all,* a person would choose to vary the expression a little, and say, *though few pursue it.* So, *Xerxes' expedition,* may be tolerable here; but in the florid style, *the expedition of Xerxes* would found much better.

The last thing to be considered, with respect to the language, is dignity, or the use of tropes and figures. And as to tropes, they ought to be used cautiously; unless such as are very common, and by time have either come into the place of proper words, or at least are equally plain and clear. So in the instance mentioned above, Diodorus Siculus, speaking of the forces of Xerxes, calls them an *innumerable company.* Where, by a *femme claque,* he has chosen to make use of an uncertain number for a certain, as least liable perhaps to exception. Other examples might be given if necessary. And with regard to figures, as most of those which consist in words, and are therefore called *verbal figures,* serve chiefly to enliven an expression, and give an agreeable turn, they are often not improper for this character. Nor are figures of sentences wholly to be excluded, especially such as are chiefly used in reasoning or demonstration. But those which are more peculiarly adapted to touch the passions, or paint things in the strongest colours, are the more proper ornaments of the higher styles, as will be shown hereafter.

Upon the whole, therefore, pure nature, without any coining, or appearance of art, is the distinguishing mark of the low style. The design of it is to make things plain and intelligible, and to let them in an easy light. And therefore the proper subjefts of it are epistles, dialogues, philosophical dissertations, or any other discourses, that ought to be treated in a plain and familiar manner, without much ornament, or address to the passions. A freedom and ease both of thought and expression, attended with an agreeable humour and pleasantry, are its peculiar beauties that engage us. As we see person of fashion and good breeding, though in the plainest habit, have yet something in their air and manner of behaviour that is very taking and amiable. Somewhat of the like nature attends this style. It has its difficulties, which are not so easily discerned but from experience. For it requires no small skill to treat a common subject in such a manner as to make it entertaining. The fewer ornaments it admits of, the greater art is necessary to attain this end. Lofty subjefts often engage and captivate the mind by the sublimity of the ideas. And the florid style calls all the assistance of language and eloquence. But the plain style is in a great measure stripped of those advantages; and has little more to recommend it, than its own native beauty and simplicity.

*ORATORY.*

**Part III.**

*CHAPTER VI. Of the Middle Style.*

This we shall treat in the same manner as we did the former, by considering first the matter, and then the language proper for it.

I. And as the subjécts proper for this style are things of weight and importance, which require both a gravity and accuracy of expression; so fine thoughts are its distinguishing mark, as plain thoughts are of the low character, and lofty thoughts of the sublime. Now a fine thought may deserve that character from some or other of the following properties.

And the first property we shall mention is gravity and dignity. Thus Cicero, in a speech to Cæsar, says, "It has been often told me, that you have frequently said, you have lived long enough for yourself. I believe it, if you either lived, or was born for yourself only." Nothing could either be more fit and proper than this was, when it was spoken; or at the same time a finer compliment upon Cæsar. For the civil war was now over, and the whole power of the Roman government in the hands of Cæsar; so that he might venture to say, he had lived long enough for himself, there being no higher pitch of glory to which his ambition could aspire. But then there were many things in the state that wanted redressing, after those times of disorder and confusion, which he had not yet been able to effect, and of which Cicero here takes an opportunity to remind him. We shall produce another example from Curtius. Philotas, one of Alexander's captains, having formed a conspiracy against him, was convicted of it, and put to death. Aminatas, who was suspected of the same crime, by reason of his great intimacy with Philotas, when he comes to make his defence, among other things speaks thus: "I am so far from denying my intimacy with Philotas, that I own I courts his friendship. Do you wonder that we showed a regard to the son of Parmenie, whom you would have to be next to yourself, giving him the preference to all your other friends? You, Sir, if I may be allowed to speak the truth, have brought me into this danger. For to whom else is it owing, that those who endeavoured to please you, addressed themselves to Philotas? By his recommendation we have been raised to this share of your friendship. Such was his interest with you, that we courted his favour, and feared his displeasure. Did we not all in a manner engage ourselves by oath, to have the same friends, and the same enemies, which you had? Should we have seured to take this, which you as it were proposed to us? Therefore, if it be this a crime, you have few innocent persons about you; nay, indeed none. For all desired to be the friends of Philotas; though all could not be so who desired it. Therefore, if you make no difference between his friends and accomplices, neither ought you to make any between those who desired to be his friends, and those who really were so." Could anything be finer spoken, more proper, and becoming the character of a soldier,
Part III.

O R A T O R Y.

Elocution.

The next property of a fine thought which we shall mention, is delicacy. As, in the objects of our fancy, those things are said to be delicate which affect us gradually in a soft and agreeable manner; so a delicate thought is that which is not wholly discovered at once, but by degrees opening and unfolding itself to the mind, discloses more than was at first perceived. Quintilian seems to refer to this, when he says, 'Those things are grateful to the hearers, which when they apprehend, they are delighted with their own sagacity; and please themselves, as though they had not heard, but discovered them.' Such thoughts are not unlike the sketches of some pictures, which let us into the design of the artist, and help us to discern more than the lines themselves express. Of this kind is that of Sallust. 'In the greatest fortunes, there is the last liberty.' This is not often so in fact, but ought to be; both to guard against an abuse of power, and to prevent the effects of a bad example to inferiors. Pliny, speaking of the emperor Trajan's entry into Rome, says, 'Some declared, upon seeing you, they had lived long enough; others, that now they were more desirous to live.' The compliment is fine either way, since both must esteem the sight of him the greatest happiness in life; and in that confidence lies the delicacy of the thought. It was a fine character given of Grotius, when very young, on the account of his surprising genius and uncommon proficiency in learning, that he was born a man: As in nature, at his coming into the world, had at once furnished him with those endowments which others gradually acquire by study and application.

The last property of a fine thought, which we shall take notice of, is novelty. Mankind is naturally pleased with new things; and when at the same time they are set in an agreeable light, this very much heightens the pleasure. Indeed there are few subjects, but what have been so often considered, that it is not to be expected they should afford many thoughts entirely new; but the same thought set in a different light, or applied to a different occasion, has in some degree a claim of novelty. And even where a thing hath been so well said already, that it cannot easily be mended, the revival of a fine thought often affords a pleasure and entertainment to the mind though it can have no longer the claim of novelty. Cicero, in his treatise of an orator, among several other encomiums which he gives to Cato, says of him, 'Cato was always excelled by every other person, but that he excelled himself.' He means as an orator. But else where he applies the same thought to Caesar, upon another account; and with some addition to it 'You had (says he) before conquered all other conquerors by your equity and clemency, but to-day you have conquered yourself; you seem to have vanquished even victory herself, therefore you alone are truly invincible.' This thought, with a little variation of the
phrase, has since appeared in several later writers; and it is now grown common to say of a person, who excels in any way, upon his doing better than he did before, that he has outdone himself. The like has happened to another thought, which, with a little alteration, has been variously applied. It was said by Varro, That if the Muses were to talk Latin, they would talk like Plautus. The younger Pliny, applying this compliment to a friend of his, says, His letters are so finely written, that you would think the Muses themselves wanted Latin. And Cicero tells us, It was said of Xenophon, that the Muses themselves sought to speak Greek with his voice. And elsewhere that Philosophers say, if Jupiter speaks Greek, he must speak like Plato. The thought is much the same in all these instances, and has since been revived by some modern writers.

II. We shall now consider the language proper for the middle style. And in general it may be observed, that as the proper subjects of it are things of weight and importance, though not of that exalted nature as wholly to captivate the mind and divert it from attending to the diction; so all the ornaments of speech, and beauties of eloquence, have place here.

And first with regard to elegance, it is plain that a different choice of words makes a very great difference in the style, where the sense is the same. Sometimes one single word adds a grace and weight to an expression, which, if removed, the sense becomes flat and lifeless. Now such words as are most full and expressive, most become his character. Epithets also, which are proper and well chosen, serve very much to beautify and enliven it, as they enlarge the ideas of things, and set them in a fuller light.

The most accurate composition, in all the parts of it, has place here. Periods, the most beautiful and harmonious, of a due length, and wrought up with the exact order, just cadency, easy and smooth connection of the words, and flowing numbers, are the genuine ornaments, which greatly contribute to form this character.

But the principal distinction of style arises from tropes and figures. By these it is chiefly animated and raised to its different degrees or characters, as it receives a lesser or greater number of them; and those either more mild, or strong and powerful.

As to tropes, these which afford the most lively and pleasing ideas, especially metaphors, suit the middle character. It is a pretty remark, which has been made by some critics upon two verses of Virgil: one in the Eclogues, and the other in his Georgics. The former of these works is for the most part written in the low style, as the language of shepherds ought to be; but the latter in the middle style, suitable to the nature of the subject, and the persons for whom it was designed, the greatest men in Rome not thinking it below them to entertain themselves with rural affairs. Now in the Eclogue, as some copies read the verse, the shepherd complaining of the barrenness of his land, says,

In English thus:

Wild oats and dandelion grow instead of corn.

But in the Georgics, where the same sense is intended, instead of the proper word natura, grow, the author substitutes a metaphor, dominans, command, and says,

In English:

Where corn is sown, dandelion and oats command.

It was fit and natural for the shepherd to express his sense in the plaintive terms; and it would have been wrong to represent him going so far out of his way, as to fetch a metaphor from government, in talking upon his own affairs. But in the Georgics, where the poet speaks in his own person, the metaphor is much more beautiful, and agreeable to the dignity of the work. This inference may show in some measure how the style is heightened by tropes, and the same thought may be accommodated to the several characters of style by the different manner of expression.

The like may also be said of figures either of words or sentences, in reference to this character; which admits of the finest descriptions, most lively images, and bright figures, that serve either for delight, or to influence the passions without transport or ecstasy, which is the property of the sublime. This is indeed the proper seat of such embellishments, which support and make up a principal part of the middle or florid style. Having treated largely upon these in several preceding chapters, we shall here only briefly mention some of the most considerable.

Descriptions are not only a great ornament to a discourse, but represent things in a very lively and agreeable manner. In what a beautiful light has Cicero placed the polite arts and sciences, when, describing them from their effects, he thus represents to us the great advantages, as well as pleasure, which they afford to the mind? "Other studies neither suit with all times, nor all ages, nor all places; but these improve youth, delight old age; adorn prosperity, afford a refuge and solace in adversity; please at home, are no hindrance abroad; keep, travel, and retire with us." And they often affect us very powerfully, when they are addressed to the senses. Quintilian has painted the calamities of a city taken by storm, in the brightest and strongest colours, which he represents by "Flames spreading themselves over the houses and temples, the cracking of falling buildings, and a confused noise from a variety of cries and shouts; some running they know not where, others in the last embraces of their friends, the shrieks of children, women, and old men unhappily referred to such direfr; the plundering of all places civil and sacred, the hurry and confusion in carrying off the booty, captives driven before their victors, mothers endeavouring to guard their infants, and quarels among the conquerors where the plunder is largest." This seems to be a very natural, as well as moving, image of so dreadful a calamity.

Protopopia is another very strong and beautiful figure, proper for this character. Seneca has a very fine instance of it in his Confolatory letter to Marcil, upon the death of her son. After many arguments to rade the reader, he had made use of to alleviate her grief, he at last introduces her father, Cremutius Cordus, as thus addressing
ORATORY.

Part III.

Elocution.

The sublime is the most noble, as well as the most difficult, part of an orator's province. It is this principal excellence of Cicero's, which Cicero requires in his perfect orator; and whom he could not define in words, but only conceive of in his mind. And indeed, the noblest genius and greatest art are both requisite to form this character. For where nature has been most liberal in furnishing the mind with lofty thoughts, bright images, and strong expressions; yet without the affluence of art there will sometimes be found a mixture of what is low, improper, or misplaced. And a great genius, like a too rich soil, must produce flowers and weeds promiscuously, without cultivation. But the justest propriety, joined with the greatest strength and highest elevation of thought, are required to complete the true sublime. Art therefore is necessary to regulate and perfect the taste of those who are defirous to excel in this character.

In explaining the nature and properties of this character, we shall, as in the two former, consider first the thoughts, and then the language, in each of which it is distinguished from them.

§ 1. Sublime, as it relates to Thoughts.

Lofty and grand sentiments are the basis and foundation of the true sublime. Longinus therefore adds as it relates to thoughts those who aspire at this excellence, to accustom themselves to think upon the noblest subjects. A mind that always dwells upon low and common subjects, can never raise itself sufficiently to represent things great and magnificent in their full extent and proper light. But he who inures himself to conceive the highest and most elevated ideas, and renders them familiar to his thoughts, will not often be at a loss how to express them; for where proper words are wanting, by metaphors and images taken from other things he will be able to convey them in a just and adequate manner. What is more common than for two partners to conceive very differently of the same thing from the different manner of thinking to which they have been accustomed? After the great battle in Cilicia, between Alexander and Darius, in which the latter was routed, he sent ambassadors to Alexander with proposals of peace, offering him half his kingdom with his daughters in marriage. Parmenio, one of Alexander's chief captains, says to him upon this occasion, "For my part, was I Alexander, I would accept of these conditions." And so would I (replies that aspiring monarch), was I Parmenio." The half of so vast a kingdom at present, and a right of succession to the whole by marriage, was the highest ambition to which the thoughts of Parmenio could rise. But Alexander had vastly higher views; he aimed at nothing less than universal monarchy; and therefore such a proposal seems much beneath his regard. Noble and lofty thoughts are principally those which either relate to divine objects, or such things as among men are generally esteemed the greatest and most illustrious.

Of the former sort is that of Homer, when describing the goddesse discord, he says, that the

Walks on the ground, and hides her head in clouds.
This stretch of thought, says Longinus, as great as the distance between heaven and earth, does not more represent the stature of the gods, than the measure of the poet's genius and capacity. But such images, however beautiful in poetry, are not so proper for an orator, whose business it is to make choice of those which are suited to the nature of things and the common reason of mankind. When Numa the second king of Rome was settled in his government, and at peace with his neighbours, in order to soften the fierce and martial temper of his subjects, who have been always accustomed to wars during the reign of his predecessor Romulus, he endeavoured to impress their minds with an awe of the Deity; and for that end introduced a number of religious ceremonies, which he pretended to have received from the goddess Egeria. This must be esteemed an awful piece of policy at that time. But that sentiment is far more just and noble, with which Cicero endeavours to inspire the members of a community, in his treatise Of Laws, when he says, that "Citizens ought first to be persuaded, that all things are under the rule and government of the gods; that every affair is directed by their wisdom and power; that the highest regard is due to them from men, since they observe what temper and devotion he worships them; and that they make a difference between the pious and impious." Persons under the influence of such a persuasion, could not fail of behaving their wisdom and power; that the treatment of him; 2. And Valerius Maximus, speaking of Pompey's treatment of Tigranes king of Armenia after he had vanquished him, expresses it in a manner suited to the dignity and beneficence of the action, when he says, "He restored him to his former fortune, endearing it as glorious to make kings as to conquer them."

But the true sublime is consistent with the greatest plainness and simplicity of expression. And, generally speaking, the more plain and natural the images appear, the more they surprize us. How suitable, and yet how majestic, is that expression of Caesar upon his victory over Pharaces? "I came, I saw, I conquered." But there cannot be a greater or more beautiful example of this, than what Longinus has taken notice of from Moses. "The legislator of the Jews (says he), no ordinary person, having a just notion of the power and majesty of the Deity, has exprsied it in the beginning of his laws in the following words: And God said—what? Let there be light; and there was light. Let the earth be made; and it was made."

This instance from the divine writer, and the character here given of him by that excellent critic, is the more remarkable, as he was himself a Pagan. And certainly no laboured description could raise in the mind an higher conception of the infinite power of the Deity, than this plain and short narration. To command nature itself into being by a word, represents it at once altogether boundless and unlimited.

It sometimes very much contributes to heighten the image of a thing, when it is expressed in so undetermined a manner, as to leave the mind in suspense what bounds to fix to the thought. Of this kind is that of Cicero, when he first raises an objection against the necessity of an acquaintance with polite literature in order to form a great man, and then answers it. The objection is founded upon the examples of several great and excellent persons among the Romans, who had raised themselves to the highest pitch of honour and dignity, and been very serviceable to their country, by the help of a good genius, without the advantage

they came to engage, they should not be able to see the fun, for the multitude of their darts and arrows, replies. Then we shall fight in the shade. By dropping here, he gives the sentence much more life and emphasis. The next thing to be considered in composition, is the order and disposition of the several words and members of a sentence. The different placing of but one or two words will sometimes wholly destroy the grandeur of a sentence, and make it extremely flat. "This public act (says Demosthenes) dispelled the danger which at that time, like a cloud, hung over the city."

Livy says war the order a little, and read it thus: "This public act dispelled the danger, which like a cloud hung over the city at that time."

What a different turn does the expression receive for the worse! The spirit and majesty of it are entirely lost. And in placing the several parts of members, they ought to be fo disposed, that what is most weighty and important should stand last. So Tully says of Catiline, "We ought to return thanks to heaven, that we have so often escaped so odious, so frightful, so dangerous a plague of the state." A thing may be odious and frightful, and yet not dangerous; therefore he puts this in the last place, to give it the greater force, and make the deeper impression. Another thing to be attended to in composition, is the connection of the words with regard to the found; that the pronunciation, in falling from one to another, may be most agreeable to the ear, and best suited to the nature of the subject. And as this is generally something grand and magnificent; such a contexture of them as will give the greatest force and energy to the expression is most proper for the sublime. Soft and languid sounds are very unsuitable to this character. They soothe and please the ear; but rather sink and depress the mind, than excite it to things great and noble. In this respect, therefore, our tongue, by its multitude of consonants, is more suitable for sublime discourses than some other modern languages, which abound with vowels.

III. The last head to be considered, is the proper use of tropes and figures; which is here so necessary, that the title of dignity seems to have been given to this part of elocution, from the capability it more especially affords to this character. For if, as has been observed from Longinum, compositions will sometimes create a sort of sublimity; this much oftener happens from the force and efficacy of some lively tropes and strong figures.

And as to tropes, bright metaphors are particularly fitted to raise and animate the style. This is manifest from the nature of them, as they consist of contrasted terms, reduced to a single word; which, if taken from things lofty and grand, must of course give a sublimity to the style. What can suggest to us a greater idea of the valour of Ajax, than Homer's calling him the balcorth of the Greeks; or of the Scipios, than when they are flyed by Virgil, the two thunderbolts of war. A number of these, will chozen, contribute no less to the grandeur than to the beauty of discourse. Hyperbole sometimes gives the same force to an expression, if cautiously used, and so as not to exceed all appearance of truth. But the chief use of it, where proper words will not express the full idea of the thing designed to be conveyed; and it may seem rather the offspring of necessity than choice. Of this nature is that of Herodotus, when speaking of the Lacedemonians at Thermopylae, he says, "They defended themselves with the swords they had left, and even with their hands and teeth, till the barbarians buried them under their arrows."

It cannot be supposed strictly true, that so many arrows were thrown at them as to bury them; but having in the former part of the sentence represented their resolute defence in the strongest terms, by saying, that, naked and without arms, they engaged armed men with their hands and teeth, the following hyperbole seems not unnatural, and to intimate nothing more than what was necessary to quell such obstinate resolution and courage.

As to figures, whether verbal or those which consist in the senses, the nature of this character will easily direct to such as are most proper. But with respect to the latter, poets take greater liberties in the use of them than would be allowed in an orator. As their images are often formed for pleasure and delight, so they carry in them more of rapture and transport. But the orator's use of them being to set things in a stronger and clearer light, they are more sedate and moderate. Besides, an orator scarce ever has occasion for such fictitious images as we often meet with in poetry; though his ought to appear as natural, and its painting as strong and lively. We shall just mention some of the chief of these figures which seem best suited for this purpose, though they are not least suited to the middle style, as has been shown, when taken from subjects of inferior nature.

1. Description. Of this Justin gives us a fine instance, in a speech of King Philip the fifth of Macedon, wherein he represents the necessity of falling upon the Romans, who at that time were engaged in a war with Hannibal. "I behold (says he) a cloud of a most dreadful and bloody war rising in Italy. I see a form of thunder and lightning, from the west, which will overspread all places with a vast shower of blood, into whatever country the temple of victory shall drive it. Greece has undergone many violent shocks in the Persian, Gallic, and Macedonian wars; but these would all be found unworthy of regard, if the armies now engaged in Italy should march out of that country. I view the terrible and cruel wars which involve the nations through the courage of their forces, and skill of their generals. This rage and fury cannot cease by the destruction of one party, without the ruin of their neighbours. Indeed, Macedon has less reason to dread the savage conquerors than Greece; because more prepared, and better able to defend itself; but I am sensible, those who attack each other so impetuously will not confine their victories within those bounds, and that it will be our lot to engage the conquerors." So lively a picture of imminent and threatening danger must needs alarm the most timorous, and excite them to a resolution to defend their country, and all that was dear to them. Such images gives life and vigour to a discourse, and being artfully interwoven with proper arguments, influence the mind, and carry it away by an irresistible force, so that the hearer is not barely left to conclude the certainty of the thing, but moved by it, as it were, from ocular demonstration. The images therefore
fore of an orator ought to be drawn from real things, or at least such as are probable; for if they are wholly fictitious and incredible, as many poetical images are, they may give pleasure, but will not convince the mind, nor move the passions.

2. Enumeration has some affinity with the former figure; by which, if several parts have each something great in them, all the whole, when brought together, and disposed in a just order, very much contributes to the sublimity. We shall produce an example of this from an English writer, containing a description of our globe, upon a survey of it after the general conflagration, which he represents in this strong light: "Such is the vanity and transient glory of this habitual world! By the force of one element breaking loose upon the rest, all the varieties of nature, all the works of art, all the labours of man, are reduced to nothing; all that we admired and loved before, as great and magnificent, is obliterated and vanished, and another form and face of things, plain, simple, and everywhere the same, overpreads the whole earth. Where are now the great empires of the world, and their great imperial cities? their pillars, trophies, and monuments of glory? Show me where they stood, read the inscription, tell me the victor's name. What remains, what imprecations, what difference or diminution, do you see in this mass of fire? Rome itself, eternal Rome, the great city, the empress of the world, whose domination or superstition, ancient or modern, make a great part of the history of the earth, what is become of her now? She laid her foundations deep, and her palaces were strong and impregnable. She glorified herself, and lived deliciously, and said in her heart, 'I am a queen, and shall see no sorrow; but her hour is come, she is wiped away from the face of the earth, and buried in everlasting oblivion. But it is not cities only, and the work of men's hands; the everlasting hills, the mountains and rocks of the earth, are melted as wax before the sun, and their place is nowhere found. Here flood the Alps, the load of the earth, that covered many countries, and reached their arms from the ocean to the Black sea. This huge mass of stone is softened and disintegrated, as a tender cloud into rain. Here flood the African mountains, and Atlas with his top above the clouds. There was frozen Caucasus, and Taurus, and Imaus, and the mountains of Asia; and yonder, towards the north flood the Riphean hills, clothed in ice and snow; all these are vanished, dropped away, as the snow upon their heads." These particulars considered separately are all truly great and noble, and every way suited to the nature of the subject; but as they are here disposed, and in order, they both enlarge the idea, and heighten the image, of that grand catastrophe.

3. Similitude: Which serves very much for beauty and ornament; and, when taken from great and sublime objects adds a grandeur and magnificence to the things illustrated by it. We need go no farther for an example of this, than to the great critic so often mentioned already, who has treated upon the sublime in a style every way equal to the subject. He, then, comparing those two great works of Homer, his Iliad and Odyssey, thus describes them: "Homer composed his Iliad when his mind was in its full strength and vigour; the whole body of the poem is dramatic, and full of action; whereas the bulk part of the Odyssey is taken up in narrations, which seem to be the genius of old age. So that one may esteem him in the latter work to the setting sun, which still appears with the fame magnificence, but has no longer the same heat and force." And soon after, speaking of the Odyssey, he says, "That piece may be called the reflex of his genius, which like the ocean ebbs, and deferts its shores." What nobler idea could possibly have been given of that great poet, than by those two similitudes of the sun and the ocean? And elsewhere, comparing those two great orators Demosthenes and Cicero, he shows the like sublimity of thought. "Demosthenes (says he) is sublime, in that he is close and concise; Cicero, in that he is diffusive and extensive. The former, by reason of the violence, rapidity, strength, and fury, with which he rages and bears all before him, may be compared to a tempest and thunder; but the latter, like a great conflagration, devours and consumes all he meets, with a fire that is never extinguished, but wherever it advances continually gathers new strength."

4. Antithesis, or a sentence consisting of opposite parts, has often the same effect; as in the following instance of Cicero, where his view is to represent Pompey as a most consummate general. "Who," says he, "ever was, or need be more knowing, than this man? who from his childhood, and instruction at school, went into the army of his father, and learned the military art, in a very great war against the fiercest enemies: who, while yet a boy, became a soldier under the greatest general; and when but a youth was himself commander of a very great army; who has often engaged with the enemy in battle, than any other person with his adversary in private contests; has waged more wars than others have read, and conquered more provinces than others have wished to govern; whose youth has been spent in acquiring the art of war, not by the precepts of others, but his own commands; not by defeats, but victories; not by campaigns, but triumphs."
The style of an orator comprehends all the characters already explained, of low, middle, and sublime, as they are applied by him in the different parts of his province. For that the language must be suited to the nature of the subject, we have had occasion often to observe already; and the different view of the speaker or writer necessarily occasions a variety in the manner of expression. Now an orator has three things in his view; to prove what he afferts, to represent it in an agreeable light, and to move the passions. These are all necessary, we do not mean in the order wherein we have now mentioned them, but that the discourse may upon the whole have its desired effect upon the audience. For unless the mind be convinced of the truth of what is offered by solid and cogent arguments, neither will the most eloquent discourse afford a lasting pleasure, nor the most pathetic long influence the affections. Though, on the other hand, the hearers expect to be entertained at the same time they are informed; and therefore, unless the language be agreeable to their taste, they will soon call off their attention, and think but meanly of the speaker. And unless both these are warm and animated by a becoming pathos, the speaker may very probably mis of his end in bringing his audience over to his sentiments. For bare conviction is not sufficient with many persons to excite them to action. They will acquiesce in the truth of a thing which they cannot contradict, or will not give themselves the trouble to examine; and at the same time remain unconcerned to prosecute it. And the pleasure of a florid discourse will of itself soon vanish, like the harmony of muses, or the charms of a fine poem. And therefore to captivate his audience, secure them in his interest, and put them upon action, it is necessary for the orator to engage their affections; these are, as it were, the springs of the soul, which, managed by a skilful hand, move and direct it at pleasure. Now each of these parts of an orator’s province requires a different style. The low style is most proper for proof and information; because he has no other view here but to represent things to the mind in the plainest light, as they really are in themselves, without colouring or ornament. The middle style is most suited for pleasure and entertainment, because it consists of smooth and well turned periods, harmonious numbers, with florid and bright figures. But the sublime is necessary in order to sway and influence the passions. Here the orator calls in all the affiduidy both of nature and art; the most raised and lofty thoughts, clothed with the brightest and strongest colouring, enter into this character.

But as an orator has frequently each of these views in the same discourse, we shall first give a summary description of the several characters of style, which we have formerly discoursed on more at large; that by placing them together in one view, the difference between them may be more plain and obvious; and then we shall proceed to show to what particular parts of a discourse each of them is more especially to be applied.

I. First, then, as shorter periods are proper in the low style, so less care is necessary in their turn and cadency. If a sentence now and then drop unexpectedly, and disappoint the ear, or has something rough and harsh in its composition, it is no blemish in this character. For as it is suited to the manner of common discourse, an appearance of regard to the subject, rather than the form of expression, is more becoming than any beauties of art. But the words should be well chosen and proper, suited to the ideas they are designed to convey; the expressions plain and clear, and the artificial ornaments few and modest. By artificial ornaments are here meant tropes and figures; and they are called artificial, because they vary from the natural drefs of language, either in the words or manner of expression: though they are often used by those who are wholly unacquainted with the rules of art; and particularly metaphors, which person who has the least command of language frequently run into, through mere necessity, for want of a sufficient stock of proper words to convey their ideas. The low style therefore admits of these: but care should be taken to choose such as have been rendered familiar by use, or at least where the similitude is very plain and evident. Bold or lofty metaphors, or where the allusion is dark and remote, ought to be avoided. Nor is the moderate use of the other tropes wholly disagreeable to this style. And the same thing is to be said with respect to verbal figures, or such as consist in the particular disposition of the sentence, so that if the form of it be changed, the figure is lost. Of these, such as come nearest to the natural way of expression are most proper for this style; and therefore those which consist in a jingle of words, arising from the same or like found, are to be avoided, as carrying in them too much the appearance of art. Those likewise which consist in a repetition of the same word have often too great a force and vehemence for this mild and gentle character. And as to figures of sentences, which do not depend on the composition of words, but lie in the sense, many of them are too gay and
Part III.

and sprightly, and others too rapid and impetuous, for the simplicity of the low style; so that only the more moderate and sedate ones are to be allowed a place here. It is therefore no wonder if persons are often mistaken in their notions of this character; the beauty of which confiding in a certain plainness and simplicity, without any thing in it but what seems natural and common, every one is apt to imagine he can readily be matter of it; till by experience he finds the contrary. For the cafe is much the same here, as in persons of fashion and good breeding, whose behaviour and address is attended with that agreeable freedom and seeming negligence which in appearance is very easy to express, but in reality is scarce imitable by others.

As the middle style is more adapted for pleasure and delight, it admits of all those beauties and ornaments which soothe and entertain the mind. It has more force and energy than the low style, but less than the sublime. Smooth and harmonious numbers, well turned periods, of a just length, delightful cadency, and accurate disposition of the words, are suited to this style. The most beautiful and thrilling tropes, which strike the fancy, and all those verbal figures which, by a repetition, similitude, or proportion of sounds, place figures, repetitions, synonyms, gradations, contraries, &c. which the orator endeavours to enervate and overthrow that this character, or a recital of such things as either preceded, accompanied, or followed upon the subject under consideration. Now, as the qualities that recommend a narration are clearness, brevity, and probability; these sufficiently point out the style. Peripetia arises from the choice of proper words, and such tropes as have been rendered most familiar by use; brevity requires moderate periods, whose parts are but little transposed; and a plain and simple dress without ornament or colouring, is best suited to represent things probable: all which are the properties of the low style. And therefore Cicero says, "narratives come pretty near to our ordinary discourse." Indeed, sometimes it is necessary not only to relate the facts themselves, but likewise to describe the manner in which they were performed. And then a further degree of art may be requisite to represent them with all their circumstances, and paint them to the mind in their proper colours.

The next part in order is the proposition, or subject of the discourse, in which there can be no room for ornament. But as it is the basis and foundation of the orator's whole design, it ought to be laid down in the plainest and clearest terms, so as to leave no room for doubt or uncertainty what it is which he intends to discourse upon.

The next thing is confirmation, wherein the orator endeavours to maintain and defend his own cause, and to convince his hearers of the truth of it by reason and argument. Now the low style is certainly fittest for cool reasoning and debate. But the orator's method of reasoning often very much differs from that of the philosopher. The latter contents himself with the most plain and familiar manner of representing the truth, and thinks it sufficient if what he says be clearly understood. But the former, at the same time that he convinces the judgment, endeavours likewise to affect the passions, and that in a great variety of ways. So that in this part of the discourse the style is very different, according to the nature and circumstances of the cafe. Sometimes, while he is dwelling upon the proof of a thing, he talks coolly, and reasons with the sedateness of a philosopher; and where any part of his argument appears doubtful or obscure, he endeavours with the same even temper to explain and clear it up. But frequently he intermixes with his proofs all the arts of persuasion, and embellishes his reasons with the greatest ornaments and beauties of eloquence.

Confirmation is usually followed by confusion, in which the orator endeavours to enervate and overthrow all their attention, and to give them some general notion of his subject. To let out modestly is undoubtedly the most likely way to recommend himself. For to attempt to inflame an audience, before they are prepared for it, or see the reason of much warmth, is highly improper. A prudent speaker will, like Demosthenes, begin with temper, and rife gradually, till he has infensibly warmed his hearers, and in some degree engaged their affections in his favour. So that this part scarce rises above the middle style. And if it carry in it an air of pleafantry and good-humour, it is generally the more apt to engage the attention.

The introduction is usually followed by the narration, or a recital of such things as either preceded, accompanied, or followed upon the subject under consideration.

For the introduction...
of the subject, the time, place, persons, and other circumstances; by which all the style is to be regulated.

To discourse in a lofty and grand way upon a common topic, or in a low and flat manner upon a sublime argument, are both equally injudicious. Cicero refers us to some discourses of his own, as instances of each kind. His oration for Cæcina, he says, is written in the low style, that for the Manilian law in the middle style, and that for Rabirius in the sublime; and his actions against Verres, with some others, are patterns of the variety here mentioned. And he gives us a very comprehensive description of a perfect orator in very few words, when he says: “He is one who can speak upon a low subject acutely, upon a lofty subject with sublimity, and upon a moderate subject temperately.” By which he means no more, than one who is master of the three characters here described, and knows when and how to use them. But although he mentions several among the Greeks, and some few among the Romans, who excelled in one or other of these different kinds; yet one who excelled in them all, he supposes never to have existed, except in the imagination. The reason perhaps may be, because each of them seems to require a very different genius, so that it is scarce possible for the same person to succeed in them all. Since therefore it is so rare and difficult a matter to gain the command of each in any good degree, it is better perhaps for every one to pursue that which nature seems most inclined to, and to excel in it, than to strive against their genius. For every kind has its perfections; and it is more commensurable to be a master of one thing, than to do several but indifferently.

**PART IV. OF PRONUNCIATION.**

**CHAP. I. Of Pronunciation in general.**

 Pronunciation is also called *Aelion* by some of the ancients. Though, if we attend to the proper signification of each of these words, the former respects the voice, and the latter the gestures and motions of the body. But if we consider them as synonymous terms, in this large sense of pronunciation, or action may be said to be a *suitable conformity of the voice*, and the *fearful motions of the body*, in speaking to the subject matter of the discourse.

The best judges among the ancients have represented this as the principal part of an orator’s province, from whence he is chiefly to expect success in the art of persuasion. When Cicero, in the person of Cicero himself, having been long conversed upon all the other parts of oratory, coming at last to speak of this, he says: “All the former have their effect as they are pronounced. It is the action alone that governs in speaking; without which the best orator is of no value, and is often defeated by one in other respects much his inferior.” And he lets us know, that Demosthenes was of the same opinion, who, when he was asked what was the principal thing in oratory, replied, *Aelion*; and being asked again a second and a third time, what was next considerable, he still made the same answer. By which he seemed to intimate, that he thought the whole art did in a manner consist in it. And indeed, if he had not judged this highly necessary for an orator, he would have taken to much pains in correcting those natural defects, under which he laboured at first, in order to acquire it. For he had both a weak voice, and likewise an impediment in his speech, so that he could not pronounce distinctly some particular letters. The former of which defects he conquered, partly by speaking as loud as he could upon the shore, when the sea roared and was boisterous; and partly, by pronouncing long periods as he walked up hill; both of which methods contributed to the strengthening of his voice. And he found means to render his pronunciation more clear and articulate, by the help of some little stones put under his tongue. Nor was he left careful in endeavouring to gain the habit of a becoming and decent gesture; for which purpose he used to pronounce his discourses alone before a large glass. And because he had got an ill custom of drawing up his shoulders when he spoke; to amend that, he used to place them under a Arbil, which hung over him with the point downward. Such pains did this prince of the Grecian orators take to remove those difficulties, which would have
mind, was of sufficient force against the power of oratory: for the conqueror of the world became a conquering the charms of Cicero's eloquence; so that, contrary to his intention, he gave into his plot, and pardoned Ligarius. Now that oration is still extant, and appears exceedingly well calculated to touch the soft and tender passions and springs of the soul; but we believe it can scarce be discernible in any in reading it, how it should have had so surprising an effect; which must therefore have been chiefly owing to the wonderful address and conduct of the speaker.

The more natural the pronunciation is, it will of course be the more moving, since the perfection of art confits in its nearest resemblance to nature. And therefore it is not without good reason, that the ancients make it one qualification of an orator, that he be a good man; because a person of this character will make the cause he espouses his own, and the more sensibly he is touched with it himself, his action will be the more natural, and by that means the more easily affect others in the same manner. Cicero, speaking upon this subject, says, "It is certain that truth (by which he means nature) in every thing excels imitation; but it that was sufficient of itself in action, we should have no occasion for art." In his opinion therefore (and who was ever a better judge), art, in this case as well as in many others, if well managed, will affect and improve nature. But this is not all; for sometimes we find the force of it so great and powerful, that, where it is wholly counterfeit, it will for the time work the same effect as if it was founded in truth. This is well known to those who have been conversant with the representations of the theatre. In tragedies, though we are sensible that every thing we see and hear is feigned and counterfeit, yet such is the power of action, that we are sometimes affected by it in the same manner as if they were all realities. Anger and resentment at the appearance of cruelty, concern and solicitude for disaffected virtue, rise in our breasts, and tears are extorted from us for approbation innocence; though at the same time, perhaps, we are ready to laugh at ourselves for being thus decoyed. If art then has so great an influence upon us, when supported only by fancy and imagination, how powerful must be the effect of a just and lively representation of what we know to be true and real?

How agreeable it is both to nature and reason, that a warmth of expression and vehemency of motion should rise in proportion to the importance of the subject and concern of the speaker, will further appear, by looking back a little into the more early and simple ages of the world. For the higher we go, the more we shall find of both. We shall give the observation of a very great man upon this head, in his own words. "The Romans (says he) had a very great talent this way, and the Greeks a greater. The former nations excelled in it, and particularly the Hebrews. Nothing can equal the strength and vividness of the figures they employed in their discourse; and the very actions they used to express their sentiments, such as putting arms on their heads, and tearing their garments, and covering themselves with sackcloth under any deep distress and sorrow of mind. I do not speak of what the prophets did to give a more lively representation of the things they foretold, because
Such figurative actions were the effect of divine inspiration. But even in other cases we find those people understood much better than we do how to express their grief, and fear and other passions. And hence, no doubt, arose those surprising effects of eloquence, which we never experience now. Thus far this excellent writer. And what he says here with respect to the actions of the eastern nations, was in good measure customary among the Greeks and Romans; if not entirely of the same kind, yet perhaps as vehement and expressive. They did not think language of to be sufficient to express the height of their passions, unless enforced by uncommon motions and gestures. Thus, when Achilles had driven the Trojans into their city with the greatest precipitation and terror, and only Hector ventured to tarry without the gates to engage him; Homer represents both king Priam and his queen under the highest confirmation for the danger of their son. And therefore, in order to prevail with him to come into the city, and not fight with Achilles, they not only entreat him from the walls in the most tender and moving language imaginable; but he tears off his grey locks with his hands; and sheds a flood of tears exposes her breasts, and adjures him by those paps which suckled him, to comply with their request. The poet knew very well, that no words of themselves could represent those agonies of mind he endeavoured to convey, unless heightened by the idea of such actions as were expressive of the deepest sorrow. And indeed this was anciently esteemed so requisite in an orator, that in matters of importance he was scarce thought to be in earnest who wanted it. One of Cicero's orations, he does not flick to argue in that manner with his adversary. "Would you talk thus (says he) if you were serious? Would you, who are wont to display your eloquence so warmly in the danger of others, act so coldly in your own? Where is that concern, that ardour, which used to extort pity even from children? Here is no emotion of either mind or body; neither the forehead furrowed, nor the thigh, not so much as a flamp of the foot. Therefore, you have been so far from inflaming our minds, that you have scarce kept us awake."

As action therefore was judged so necessary a qualification in an orator among the ancients, so they made use of several methods and expedients for the better attaining it. The principal of which we shall briefly mention.

Decency of pronunciation is an habit. And as all habits are gained by time, so the sooner they are learned, they are generally acquired with greater ease. For while persons are young, they are not only more flexible, and capable of any particular bent, but they are likewise free from the trouble of encountering and subduing contrary habits, which doubles the labour, and increases the difficulty of attaining any laudable quality. Quintilian was very sensible of this in the case here before us; and therefore, in order to have persons trained up to it, he begins with them in their childhood, and descends so low as even to give directions how they should be taught to pronounce when they first learn to read. And he advises, that they should then be instructed where to suspend their voice, and make the proper pauses, both in distinguishing the several parts of the same sentence, and in separating one sentence from another: likewise when to raise or sink their voice, or give it a proper inflection; to be flower or fatter, more vehement or sedate, as the nature of the things may require; and that the tone of their voice be always manly and grave, but at the same time mixed with an agreeable sweetness. These things may perhaps appear in themselves small; but if duly attended to, they will be found of considerable service to bring us to a just and proper pronunciation. For in every thing that is to be attained by practice, it is a great advantage to set out right at first.

The ancients likewise had persons whom they called phonæici, whose proper business it was to teach them how to regulate and manage their voice; and others, who instructed them in the whole art of pronunciation, both as to their voice and gestures. These latter were generally taken from the theatre, being some eminent experienced actors. So Quintilian, treating of the province of these persons, says, "The comedian ought to teach them how to relate facts, with what authority to advise, with what vehemence to express anger, and with what softness compassion. And speaking of gestures, he says, "He should admonish them to raise their countenance, not distort their lips, or stretch their mouths." With several other directions of the like kind. And we are told concerning the emperor M. Antoninus, usually called the philosopher, that his first masters were Euphorbo the grammarian, and Gemini the comedian.

But though they made use of actors to instruct their youth in forming their speech and gestures, yet the action of an orator was much different from that of the theatre. Cicero very plainly represents this distinction, in the words of Caius, when speaking of orators, he says, "The motions of the body ought to be suited to the expressions, not in a theatrical way, mimicking the words by particular gesticulations, but in a manner expressive of the general sense, with a moderate and manly inflection of the sides; not taken from the stage and actors, but from the exercise of arms and the palestra." And Quintilian says to the same purpose, "Every gesture and motion of the comedians is not to be imitated, nor to the same degree." They thought the action of the theatre too light and extravagant for the imitation of an orator; and therefore, though they employed actors to inform young persons in the first rudiments, yet they were afterwards sent to the palestra, or schools designed on purpose to teach them a decent and graceful management of their bodies. And such schools, as Quintilian informs us, were in use both among the Greeks and Romans: Juft as of later ages children learn to dance, in some measure with the same intention.

Being thus far prepared, they were afterwards sent to the schools of the rhetoricians. And here, as their business was to cultivate their style, and gain the whole art of eloquence; so particularly to acquire a just and accurate pronunciation by these exercises, in which for that end they were constantly employed. And as the Greeks were most celebrated for their skill in all the polite arts, and especially oratory; the Roman gentry and nobility generally sent their sons abroad, and placed them under the tuition of some Grecian master, to instruct them in the art of speaking.
Part IV. ORATORY.

Pronunciation.

ing, and by that means to fit them for the service of their country, either in the courts of judicature or the Senate. Thus Cicero was sent to Rhodes, to study under the famous Molo, and Brutus under Pamphilus; Caesar was going to the same place when taken by pirates; and Augustus afterwards studied there under Apolloidas.

Nor, after all this pains and industry, did they yet think themselves sufficiently qualified to take upon them the character of orators. But it was their constant custom to get together some of their friends and acquaintance who were proper judges of such performances, and declaim before them in private. The business of these persons was to make observations both on their language and pronunciation. And they were allowed the greatest freedom to take notice of any thing they thought amiss, either as to inaccuracy of method, impurity of style, or indecency of their voice or actions. This gave them an opportunity to correct any such defects at first, before they became habitual. What effects might not justly be expected from such an institution? Persons trained up in this manner, with all those advantages, joined to a good natural genius, could not fail of making very complete orators. Though even after they came to appear in public, they did not lay aside the custom of declaiming, as Quintilian tells us, that C. Carbo used to practice it daily in his tent. And Augustus is reported to have continued it during the war of Mutina against M. Anthony. Nor is it to be supposed, that so constant an attendance to this practice was only serviceable to them in their public performances; but it must necessarily affect their whole conduct, give them a freedom of speech, an ease of addresses and behaviour, and render them in all respects fine gentlemen, as well as excellent orators. And from hence perhaps we may see less reason to wonder at the surprising effects of some of their discourses, when we consider what pains they took to arrive at those abilities.

Having thus far treated on pronunciation in general, we shall now proceed to consider the parts of it separately; which are voice and gesture.

CHAP. II. Of the Voice.

Voice is one kind of sound. Now the influence of sounds, either to raise or allay our passions, is evident from music. And certainly the harmony of a fine discourse, well and gracefully pronounced, is as capable to move us, if not in a way so violent and affecting, as the body is relieved by the voice. For the harmony of voice lies in the proper temperament of the voice between the extremes. In order to fix this matter in a just light, it will be necessary to consider the principal affections or properties of the voice, and how they are to be regulated by an orator. Now these may all be referred either to quantity or quality.

The quantity of the voice consists in its brevity, or the intervals between the sounds; and the intermediate degrees between them.

Every person who speaks in public, should endeavour, if he can, to fill the place where he speaks. But till he ought to be careful not to exceed the natural key of his voice. If he does, it will neither be soft nor agreeable; but either harsh and rough, or too high and squeaking. Besides, he will not be able to give every syllable its full and distinct sound; which will render what he says obscure, and difficult to be understood. He should therefore take care to keep his voice within reach, so as to have it understood. Some persons, however, use to raise and sink their voice, and to alter it at pleasure, without regard to the subject or the occasion. This is unpardonable negligence, and is to be avoided at all times.

The quality of the voice consists in the variations of the voice, that it may not be gradual to render them pleasing. Such sudden and great changes at once are rather to be esteemed chains in speaking, than variations. Besides, as they often prevent the auditors from taking in the sense of what is said, it gives them no small uneasiness that they are obliged to stretch their attention. Many persons are too apt to be guilty of this, especially at the end of a sentence, by dropping the last word; which ought in a particular manner to be expressed distinctly, because the meaning of the whole sentence often depends upon it.

The medium between these two is a moderate and even voice. But this is not the same in all; that which is moderate in one would be high in another. Every person therefore must regulate it by the nature of his own voice. A calm and sedate voice is generally best; as a moderate sound is most pleasing to the ear, if it be clear and distinct. But this equality of the voice must also be accompanied with a variety, otherwise there can be no harmony; since all harmony consists in variety. Nothing is less pleasing than a discourse pronounced throughout in one continued tone of the voice, without any change or alteration. Besides, a variation of the voice is an ease to the speaker; as the body is relieved by shifting its posture. This equality therefore we are here speaking of admits a variety of inflections and changes within the same pitch.
pitch. And when that is altered, the gradations, whether higher or lower, should be so gentle and regular as to preserve a due proportion of the parts and harmony of the whole; which cannot be done, when the voice is suddenly varied too great a distinction. And therefore it should move from one key to another, so as rather to glide like a gentle stream, than pour down like a rapid torrent, as an ingenious writer has well expressed it. An even voice is best fitted to keep the mind to close attention. And therefore, in subjects designed only for instruction, without any address to the passions, there is little room for a variety of voice. For the voice ought to agree with the style; and as upon such subjects this should be equal, moderate, and smooth, so should the other. Every thing, as we say, is beautiful in its season; and there is a certain propriety in things which ought always to be regarded. And therefore, an affected variety, ill placed, is as disagreeable to a judicious audience, as the want of it, where the subject requires it. We may find some persons, in pronouncing a grave and plain discourse, affect as many different tones, changes, and variations of their voice, as if they were acting a comedy; which is doubtless a very great impropriety. But the orator’s province is not barely to apply to the mind, but likewise to the passions; which require a great variety of the voice, high or low, vehement or languid, according to the nature of the passions he designs to affect. So that for an orator always to use the same tone or degree of his voice, and expect to answer all his views by it, would be much the same thing as if a physician should propound to cure all diseases by one medicine. From hence it is evident, that although various inflections and tones of the voice are requisite to make it harmonious and pleasing to the ear; yet the degree of it should differ according to the nature of the subject and design of the speaker. And, as a perfect monotony is always unpleasant, so it can never be necessary in any discourse.

The next property of the voice abovementioned was {

}pitch. And when that is altered, the gradations, whether higher or lower, should be so gentle and regular as to preserve a due proportion of the parts and harmony of the whole; which cannot be done, when the voice is suddenly varied too great a distinction. And therefore it should move from one key to another, so as rather to glide like a gentle stream, than pour down like a rapid torrent, as an ingenious writer has well expressed it. An even voice is best fitted to keep the mind to close attention. And therefore, in subjects designed only for instruction, without any address to the passions, there is little room for a variety of voice. For the voice ought to agree with the style; and as upon such subjects this should be equal, moderate, and smooth, so should the other. Every thing, as we say, is beautiful in its season; and there is a certain propriety in things which ought always to be regarded. And therefore, an affected variety, ill placed, is as disagreeable to a judicious audience, as the want of it, where the subject requires it. We may find some persons, in pronouncing a grave and plain discourse, affect as many different tones, changes, and variations of their voice, as if they were acting a comedy; which is doubtless a very great impropriety. But the orator’s province is not barely to apply to the mind, but likewise to the passions; which require a great variety of the voice, high or low, vehement or languid, according to the nature of the passions he designs to affect. So that for an orator always to use the same tone or degree of his voice, and expect to answer all his views by it, would be much the same thing as if a physician should propound to cure all diseases by one medicine. From hence it is evident, that although various inflections and tones of the voice are requisite to make it harmonious and pleasing to the ear; yet the degree of it should differ according to the nature of the subject and design of the speaker. And, as a perfect monotony is always unpleasant, so it can never be necessary in any discourse.

The next property of the voice abovementioned was {pronunciation}. That some expressions ought to be pronounced faster and swifter than others, is very manifest. Gay and sprightly ideas should not only be expressed louder, but also faster, than such as are sad and melancholy. And when we prefer an adversary, the voice should be brisk and quick. But to hurry on in a precipitant manner without pausing, till it wants of breath, is certainly a very great fault. This destroys not only the necessary distinction between sentence and sentence, but likewise between the several words of the same sentence; nay, and often occasions us to express our words by halves, while one is thrown so fast upon another, that we are not able to give each its full and just sound. By this means all the grace of speaking is lost, and in a great measure the advantage of hearing. For when the ears of the hearers cannot keep pace with the volubility of the speaker’s tongue, they will be little the better for what he says. Defides, by not commanding his voice, and exciting his breath at the proper pauses and points of distinction, he is often obliged to stop in the middle of a sentence; and so divides what should be continued, and joins what should be separated; which must necessarily destroy the sense, and confound his discourse. Young persons are very liable to this, especially at first setting out. And it often arises from difference. They are jealous of their performances, and the success they may have in speaking, which gives them a pain till it is over; and this puts them into a hurry of mind, which incapacitates them from governing their voice, and keeping it under that due regulation which perhaps they proposed to themselves before they began to speak. And the greater degree such persons have of a native and ingenious modesty, accompanied with a laudable ambition to excel, they are commonly more exposed to this. For while on the one hand they are fired with an ardent desire to recommend themselves, and on the other are fearful of the event, this ddbious state of mind is very apt to throw them off their guard, and run them into this excess. From which we may see the great advantage of having the voice well formed betimes; for when once it is become habitual to speak with jiltiness and propriety, persons readily practice it without much attention or concern.

And as a precipitant and hasty pronunciation is culpable, so likewise on the other hand, it is a fault to speak too slow. This seems to argue a heaviness in the speaker. And as he appears cool himself, he can never expect to warm his hearers, and excite their affections. When not only every word, but every syllable is drawn out to too great a length, the ideas do not come fast enough to keep up the attention without much uneasiness. For till the sense is completed, the mind is in suspense; and, if it be held long in that situation, it will of course flag and grow tired. Indeed, in some cases, it is requisite the pronunciation should be slower than in others; as in representing things great and difficult; or in expressing some particular passions, as admiration or grief. But the extreme we are now speaking of, is a slowness equally continued throughout a whole discourse, which must necessarily render it flat and lifeless.

Now, to avoid either of the two extremes last mentioned, the voice ought to be distinct and distinct. And in order to render it so, it is necessary, not only that each word and syllable should have its just and full sound, both as to time and accent; but likewise that every sentence, and part of a sentence, should be separated by its proper pause and interval. This is more easy to be done in reading, from the assistance of the points; but it is no less to be attended to in speaking, if we would pronounce in a distinct and graceful manner. For every one should speak in the same manner as he ought to read, if he could arrive at that exactness. Now the common rule given in pausing is, that we stop our voice at a comma till we can tell one, at a semicolon two, at a colon three, and at a full period four. And as these points are either accommodated to the several parts of the same sentence, as the first three; or different sentences, as the last; this occasions the different length of the pause, by which either the dependence of what precedes upon that which follows, or its distinction from it, is represented. And therefore, in the first three stops, the voice is rather to be suspended in different degrees or measures of time, than entirely dropped, to show that the sense is not yet completed. But between sentence and sentence we respire, and begin anew. So that
that in long periods, the voice should be favoured by beginning low and sedately, that it may hold to the end without respiration; or if it will not, the breath ought to be recovered without finching the voice. For if once the voice drop for want of breath before the period be finished, not only the beauty, but likewise, the senile of it will be lost. Quintilian lays a great stress upon a due attention to these pauses; and says, "Though it may appear not to be considerable in itself, yea, all the other virtues of a good pronunciation are deficient without it." Hitherto we have considered such properties of the voice as respect quantity, we come to speak of its qualities. And the chief of these are strength or weakness, clearness or obscurity, fulness or smallness, smoothness or roughness. Now, one half of these is what every one would willingly choose, as he would wish to be free from the others. But it is not in our power to give ourselves what qualities of the voice we please; but only to make the best use we can of what nature has bestowed upon us. However, several defects of the voice are capable of being helped by care and proper means; as, on the other hand, the best voice may be greatly hurt by ill management and indiscretion. Temperance is a great preservative of the voice, and all excess is highly prejudicial to it. The voice must necessarily suffer, if the organs of speech have not their proper tone. And in order to their having this, they must be kept in a due temperature; that is, they must neither be too moist nor too dry. If they abound with fluids, these will obstruct the clearness of the voice, and render it obscure and confused; and if they are parched with drought, the voice will be harsh and rough. Now all excesses, as well as some bodily indispositions, are apt to affect the organs one or other of these ways.

A strong voice is very serviceable to an orator, because, if it want some other advantages, he is however, capable to make himself heard. And if at any time he is forced to strain it, he is in less danger of its failing him before he has finished his discourse. But he who has a weak voice, should be very careful not to strain it, especially at first. He ought to begin low, and rise gradually to such a pitch as the key of the voice will well carry him, without being obliged to sink again afterwards. Frequent inflections of the voice will likewise be some assistance to him. But especially he should take care to speak deliberately, and equal his voice, by allowing due time for respiration at all the proper pauses. It is an extreme much less inconvenient for such a person rather to speak too slowly, than too fast. But this defect of a weak voice is sometimes capable of being helped by the use of proper methods; as is evident from the instance of Demosthenes, before-mentioned.

A voice is said to be clear, when the organs of speech are fitted to give every single letter, and all the combinations of them in syllables and words, their proper and distinct sound. Such a voice is very pleasing and agreeable to the hearers; and no less an happiness to the speaker, as it saves him a great expenditure of spirit. For a moderate voice, if clear, will be as distinctly heard, as one much louder, if thick and obscure. Which is a great advantage to the speaker, because he can better keep his voice under command, and modulate it at pleasure, as the several parts and circumstances of his discourse may require. On the contrary an obscure and confused voice is not always occasioned from a deficiency in the organ; but many times is the effect of custom and a bad habit. Some persons, either from want of due care in their education at first, or from inadvertency and negligence afterwards, run into a very irregular and confused manner of expressing their words; either by misplacing the accent, confounding the sound of the letters, or huddling the syllables one upon another, so as to render what they say often unintelligible. Indeed, from times this arises from a natural defect, as in the case of Demosthenes; who found a method to rectify that, as well as the weaknesses of his voice. But in faults of this kind, which proceed from habit, double it the most likely way to mend them is to speak deliberately.

A full voice is not the same as a strong or a loud voice. It fills the ear, but it is not pleasant. And therefore to render it so, as well as audible, it should be frequently varied. However this seems better suited to the character of an orator, than a small and shrill voice; because it has something in it more grave and manly. And those who have the misfortune of a very small voice, should be cautious of raising it to too high a pitch, especially at once; because the sudden comprefsure of the organ is apt to occasion a squeaking and very disagreeable sound.

A soft and smooth voice is of all the most musical, especially if it be flexible. And on the contrary, nothing is less harmonious than a voice that is harsh and rough. For the one grates as some bodily indisposition, are apt to affect the organs one or other of these ways.

From the consideration of these several properties of the voice, we may conclude that to be the best, and fittest for an orator, which is moderate, distinct, firm, clear, and smooth, and withal easily flexible to the several degrees and variations of sound which every part of the discourse may require.

CHAP. III. Of Gesticulation.

By this is meant, a suitable conformity of the motions of the countenance, and several parts of the body to the subject-matter of the discourse. The word gesticulation is here used in a larger sense than is the motion of the countenance, &c. ordinarily done in common language. For we rarely make use of that word to denote the motions of the countenance, or any parts of it; but as these make the considerable part of our present subject, they must discourse here be comprehended under this term.

It is not agreed among the learned, whether voice or gesticulation has the greater influence upon us. But as the latter affects us by the eye, as the former does by the ear, gesticulation in the nature of it seems to have this advantage, that it conveys the impression more speedily to the mind; for the sight is the quickest of all our senses. Nor is its influence less upon our passions; nay, in some instances it appears to act more powerfully. A caft of the eye shall express defiance in as moving a manner as the fullest language; and a different motion of it, repentment. To wring the hands, tear the hair, or strike the breast, are all strong indications...
tion. And who he claps his hand to his sword, throws us into a greater panic than one who only threatens to kill us. Nor is it in some respects less various and extensive than language. Cicero tells us, he often diverted himself by trying this with Roscius the comedian; who could express a sentence as many ways by his gestures, as he himself by words. And some dramas, called pantomimes, have been carried on wholly by mutes, who have performed every part by gestures only, without words, in a way very intelligible, as well as entertaining to the spectators. Well therefore might Cicero call *aman* (or gesture) *the language of the body*, since it is capable of so lively a manner to convey both our ideas and passions. But with respect to oratory, gesture may very properly be called the *second part of pronunciation*; in which, as the voice should be suited to the impressions it receives from the mind, so the several motions of the body ought to be accommodated to the various tones and inflections of the voice. When the voice is even and moderate, little gesture is required; and nothing is more unnatural than violent motion, in disfiguring upon ordinary and familiar subjects. The motions of the body should rise therefore in proportion to the vehemence and energy of the expression, as the natural and genuine effect of it.

But as gesture is very different and various as to the manner of it, which depends upon the scene, conduct of several parts of the body; it will not be amiss to consider more particularly the proper management of each of those parts. Now all gesture is either natural, or from imitation. By natural gesture we mean such actions and motions of the body, as naturally accompany our words, as these do the impressions of our mind. And these either respect the whole body, or some particular part of it. But before we enter upon this, we shall observe, that it has been customary in all ages and countries, in making a speech before an assembly, to do it standing. Thus we read, that *Abraham stood up, and spake unto the children of Heth.* And it seems as if he sat down, when he had ended his speech; because, immediately after the account of his answer, it is said again that *Abraham stood up and bowed himself to the people of the land, the children of Heth.* In like manner Homer represents the Grecian princes, as standing up, when they made a speech, either to the army, or in their councils. So when Achilles has assembled the army, to inquire into the reason of the great plague which at that time raged among them, he rises up before he begins to speak, and sits down again when he has done. After him the prophet Calchas rises, and charges it upon Agamemnon: who rising up in a passion, does not refuse to comply with what Calchas proposed, but expresses his resentment at him for saying it. And upon another occasion, both Agamemnon and Nestor do the same in council. And Cicero acquaints us, that when Lentulus had been charged in the senate as an associate with Catiline, he stood up to make his defence. Nor does the advantage of being better heard, seem to have been the only reason for so general an agreement in this posture; but it appears likewise to have been chosen, as the most decent and respectful. Sitting carries in it an air of authority, and is therefore a posture scarce used upon such occasions, unless perhaps where that is designed to be expressed by it. Wherefore it was a thing very much repected, that when Cesar, after he had got the power into his hands, once addressed the senate, either refused to rise, as some say, or as others, one of his friends held him down by his gown.

But though standing appears to be the most proper posture for speaking in public, yet it is very unbecoming for the body to be entirely without any motion like a statue. It should not long continue in the same position, but be constantly changing, though the motion be very moderate. There ought to be no appearance of stiffness, or a certain cafe and pliability, naturally suiting itself to every expression; by which means, when a greater degree of motion is necessary, it will appear less sudden and vehement: For as the raising, sinking, and various inflections of the voice must be gradual; so likewise should the motions of the body. It is only on some particular occasions that an haughty vehemence and impetuosity is proper in either case.

As to the several parts of the body, the head is the most considerable. To lift it up too high has the air of arrogance and pride; to stretch it out too far, or throw it back, looks clownish and unmanly; to hang it downwards on the breast, shows an unmanly bashfulness and want of spirit: and to suffer it to lean on either shoulder, argues both sloth and indolence. Wherefore in calm and sedate discourse it ought to keep its natural slant, an upright posture. However, it should not be long without motion, nor yet always moving; but gently turn sometimes on one side, and sometimes on the other, as occasion requires, that the voice may be heard by all who are present; and then return again to its natural position. It should always accompany the other actions of the body, and turn on the same side with them; except when aversion to any thing is expressed, which is done by stretching out the right hand, and turning the head to the left. The ancients erected a statue of Venus in this posture, who was called by the Greeks *Euphrosyne*, and by the Latins *Verticordia*, and in English may be termed the *forbidding Venus*. But nothing is more indelicate than violent motions and agitations of the head. And therefore, when a witty writer, who is well known among us, would convey the most ridiculous idea of a pretendor to knowledge, he expresses it thus:

> For having three times shook his head
> To stir his wit up, thus he said. — Hudibras.

But it is the countenance, that chiefly represents both the passions and dispositions of the mind. By this we express love, hatred, joy, sorrow, modesty, and confidence; by this we supplicate, threaten, footh, invite, forbear, content, or refuse; and all this without speaking. Nay, from hence we form a judgment not only of a person's present temper, but of his capacity and natural disposition. And therefore it is common to say, *such an one has a promiseful countenance,* or that *be promises little by his countenance.* It is true, this is no certain rule of judging; nor is it in the power of any one to alter the natural make of his countenance: however, it may put us upon endeavouring to gain the most pleasing aspect we can; since it is so natural, for
for mankind to draw such conclusions from it; and some persons are so unhappy, as to render their countenance more disagreeable than otherwise it would be, by ill habits.

But the several parts of the face bear their part, and contribute to the proper and decent motion of the whole. In a calm and sedate discourse, all the features retain their natural state and situation. In sorrow, the forehead and eyebrows lower, and the cheeks hang down. But in expressions of joy and cheerfulness, the forehead and eyebrows are expanded, the cheeks contracted, and the corners of the mouth drawn upwards. Anger and resentment contract the forehead, draw the brows together, and thrust out the lips. And terror elevates both the brows and forehead. As these are the natural signs of such passions, the orator should endeavour to conform to them.

But as the eyes are most active and significant, it is the advice of Cicero that the greatest care should be taken in their management. And he gives this reason for it, "Because other parts of the countenance have but few motions; whereas all the passions of the soul are expressed in the eyes, by so many different actions, which cannot possibly be represented by any gestures of the body, if the eyes are kept in a fixed posture." Common experience does in a great measure confirm the truth of this observation. We readily guess at a person's intention, or how he is affected to us, by his eyes. And any sudden change or emotion of the mind is presently followed by an alteration in the look. In speaking therefore upon pleasant and delightful subjects, the eyes are bright and cheerful; as, on the contrary, they sink and are languid in delivering any thing melancholy and sorrowful. This is so agreeable to nature, that before a person speaks, we are prepared with the expectation of one or the other from his different aspect. So likewise in anger, a certain vehemence and intensity appears in the eyes, which, for want of proper words to express it by, we endeavour to represent it by metaphors taken from fire, the most violent and rapid element, and say in such cases, the eyes "sparkle, burn, or are inflamed." In expressions of hatred or detestation, it is natural to alter the look, either by turning the eyes aside, or downwards. Virgil has very justly observed this: for when he describes Zenas meeting with Dido in the Egyptian shades, and addressing her, he represents her disregard of him, by saying,

Did disdainfully the look he; then turning round,  
Still fix'd her eyes unmoved on the ground.

She showed her resentment for his former treatment of her, by not vouchsafing to look on him. Indeed, the eyes are sometimes turned downwards upon other occasions, as to express modesty. And if at any time a particular object be addreseed to, whatever it be, the eyes should be turned that way. And therefore Philostratus very deferently ridicules a certain rhetorician as guilty of a folesism in gesture, who, upon saying, "O Jupiter!" turned his eyes downward; and when he said, "O Earth!" looked upward. A flattering look has the appearance of giddiness and want of thought; and to contract the eyes gives suffusion of craft and design. A fixed look may be occasioned from intensities of thought, but at the same time shows a disagreeable air; and a too quick and wandering motion of the eyes denotes levity and wantonness. A gentle and moderate motion of the eyes is therefore in common most suitable, always directed to some of the audience, and gradually turning from side to side with an air of respect and modesty, and looking them decently in the face, as in common discourse. Such a behaviour will of course draw an attention. As in conversation, when a person addresses us in an handsome and becoming manner, we presently put ourselves in a posture to give what he says a proper reception. But as all the passions are in the most lovely manner expressed in the eyes, their motions ought to vary according to the different nature of those passions as they are suited both to discover in a speaker and convey to his hearers; since, as the quickest access to the mind is by the light, a proper well-timed look will sometimes sooner effect this than it can be done by words; as in discharging a cannon, we are struck with the light before we hear the sound.

As to the other parts of the body distant from the head, the shoulders ought not to be elevated; for this is not only in itself indecent, but it likewise contracts the neck, and hinders the proper motion of the head. Nor, on the other hand, should they be drawn down and deprest; because this occasions a stiffness both to the neck and the whole body. Their natural posture therefore is bent, as being most easy and graceful. To thrug the shoulders has an abrupt and fervile air; and frequently to heave them upwards and downwards is a very disagreeable fashion.

A continued motion of the arms any way, is by all means to be avoided. Their action should generally be very moderate, and follow that of the hands, unless in very pathetic expressions, where it may be proper to give them a more lively spring.

The hands need never be idle. Quintilian seems to think them as necessary and powerful in action, as Cicero does the eyes. "The hands (says he), without which all gesture is lame and weak, have a greater variety of motions than can well be expressed; for they are almost equal to our words. Do not we direct with them, promise, call, dismis, threaten, b.speech, detest, fear, inquire, deny? Do not they express joy, sorrow, doubt, confession, petition, measure, plenty, number, and time? Do not they excite, restrain, prove, admire, and shame? That in so great a variety of speech among all nations and countries, this seems to me the common language of all mankind." Thus far Quintilian. Now, all bodily motion is either upward or downward, to the right or left, forward or backward, or else circular. The hands are employed by the orator in all these except the last. And as they ought to correspond with our expressions, to they ought to begin and end with them. In admiration, and addresses to heaven, they must be elevated but never raised above the eyes; and in speaking of things below us, they are directed downwards. Side motion should generally begin from the left, and terminate gently on the right. In demonstrating, addressing, and on several other occasions, they are moved forward; and in threatening, sometimes thrown back. But when the orator speaks of himself, his right hand should be gently laid on his breast. When no other motion is necessary, the hands should be kept about as high as

Part IV.

1 Pronunciation.

The subject of pronunciation is of so great importance to an orator, that it cannot be too clearly the voice laid down, nor too strongly inculcated. If we inquire, in what causes of that surprising power it has over us, and by what means it so strongly affects us, this may in some measure appear by referring to the frame and constitution of human nature. For our infinitely great and wise Maker has so formed us, that not only the actions of the body are subject to the direction of the mind, but we are likewise endowed with various passions and affections, that excite us to pursue those things which make for our happiness, and avoid others which are hurtful to us. And as we are made for society; we are also furnished with speech, which enables us to converse one with another. And such is the contrivance of our make, and influence of our minds upon the mechanism of our bodies, that we can not only communicate our thoughts to each others but likewise our passions. For, as Cicero well observes, “Every motion of the mind has naturally its peculiar countenance, voice and gesture; and the whole body, every position of the face, and sound of the voice, like the signals of an instrument, act agreeably to the impression they receive from the mind.”

Nor is this all: but as every one is differently affected himself, he is capable to make the like impressions upon others, and excite them to the same motions which he feels in himself. As when two instruments are set to the same pitch, the signals of one being touched, produce in the other the like found. This common sympathy in the human frame shows how necessary it is that an orator should not only in general be well acquainted with the rules of pronunciation, but likewise know how to use them as occasion requires.

For a general knowledge of the rules of art is not of itself sufficient to perfect an artifll, without a further acquaintance with the particular application of them to their several cafes and circumstances. Thus, for instance, it is not enough for an orator to understand all the beauties and ornaments of language, and of which of them are suited to form the several kinds of style, unless he can likewise accommodate each of these characters to their proper subject. And so likewise is the use of signals in pronunciation, he ought not only to know the several qualities of the voice, and proper gestures of the body, but also when and where to make use of them. For not only different subjects, but also different parts of the same discourse, and even particular expressions, often require a difference in the manner of pronunciation, both as to the voice and gesture. Having therefore treated on both these parts of pronunciation in general, it may not be amiss now to consider how they are to be applied in each of the two respects last mentioned.

We shall begin with the parts of a discourse, and treat...
The confirmation admits of great variety both of the voice and gestures. In reasoning, the voice is quick and pungent, and should be enforced with suitable actions. And as descriptions likewise have often a place here, in pointing out the images of things, the orator should endeavour to adapt both his voice, and the motions of his body, particularly the turn of his eyes, and action of his hands, as may best help the imagination of his hearers. Where he introduces another person speaking, or addressing himself in an abrupt person, it should be with some degree of imitation. And in dialogue the voice should alter with the parts. When he diverts from his subject by any digression, his voice should be lively and cheerful; since that is rather designed for entertainment than instruction.

In confutation, the arguments of the adverse party ought first to be repeated in a plain and distinct manner, that the speaker may not seem to conceal, or avoid the force of them. Unless they appear trifling and unworthy of a serious answer; and then a faceious manner, both of expression and gesture, may be the proper way to confute them. For to attempt to answer in a grave and serious manner, what is in itself empty and ludicrous, is apt to create a fulcution of its having more in it than it really has. So when Tubero in his accusation of Ligarius before Caesar, had made it part of his charge, that Ligarius was in Africa during some part of the civil war between Caesar and Pompey; Cicero in his answer, not thinking it deserved a serious reply, contents himself with bare defence of Ligarius. The confirmation admits of great variety both of the voice and gestures. In reasoning, the voice is quick and pungent, and should be enforced with suitable actions. And as descriptions likewise have often a place here, in pointing out the images of things, the orator should endeavour to adapt both his voice, and the motions of his body, particularly the turn of his eyes, and action of his hands, as may best help the imagination of his hearers. Where he introduces another person speaking, or addressing himself in an abrupt person, it should be with some degree of imitation. And in dialogue the voice should alter with the parts. When he diverts from his subject by any digression, his voice should be lively and cheerful; since that is rather designed for entertainment than instruction.

In dialogue the voice should alter with the parts. When he diverts from his subject by any digression, his voice should be lively and cheerful; since that is rather designed for entertainment than instruction.

In conclusion both the voice and gesture should be brisk and sprightly, which may seem to arise from a sense of the speaker's opinion of the goodness of his cause, and that he has offered nothing but what is agreeable to reason and truth; as likewise from his assurance that the audience agree with him in the same sentiment. In every undertaking that requires care and thought, persons are apt at first to be sedate and moderate; but when it is drawn to an end, and is near finished, it is very natural to appear more gay. If an enumeration of the principal arguments of the discourse be convenient, as it sometimes is, where they are preternumerous, or the discourse is long, they ought to be expressed in the most clear and forcible manner. And if there be an address to the passions, both the voice and gesture must be suited to the nature of them, of which more will be said presently.

We proceed now to the consideration of particular expressions. And what we shall offer here, will be first in relation to single words, then sentences, and lastly the passions.

II. Even in those sentences which are expressed in
the most even and sedate manner, there is often one
or more words which require an emphasis and distinc-
tion of the voice. Pronouns are often of this kind:
as, This is the man. And such are many words
that denote the circumstances and qualities of things.
Such as heighten or magnify the idea of the thing to
which they are joined, elevate the voice, as unalius,
admirabilis, majestas, gravis, and the like. On the con-
trary, those which lessen the idea, or debase it, depress
the voice, or at least protract the tone: of which fort
are the words little, maen, poorly, contemptible, with
many others. Some tropes likewise, as metaphor and
verbal figures, which consist in the repetition of a
single word, should have a particular emphasis. As
when Virgil says of the river Araxes, It disjoined a
bridge. And Nicias of himself, in the same poet, I, I
am the man; where the repeated word is loudest. This
distinction of words, and giving them their proper
emphasis, does not only render the expression more clear
and intelligible, but very much contributes to the va-
riation of the voice, and the preventing a monotony.
And the different pronunciation of these words will
also require a peculiar gesture.

II. In sentences, regard should be had to their
length, and the number of their parts, in order to di-
finguish them by proper pauses. The frame and struc-
ture of the period ought likewise to be considered, that
the voice may be so managed as to give it the most
musical accent. Unless there be some especial reason for
the contrary, it should end louder than it begins. And
this difference of tone between the end of the former
sentence and the beginning of the next, not only helps
to distinguish the sense, but adds to the harmony of
the voice. And that the last syllables of a sentence
might become more audible and distinct, was doubtless
one reason why the ancient rhetoricians disliked short
feats at the end of a period. In an antithesis, or a sen-
tence confounding of opposite parts, one contrary
must be louder than the other. As, “He is gone, but by a
gainful remove, from painful labour to quiet rest; from
unequited desires to happy contentment; from forrow to
joy; and from tranitory time to immortality.” In a
climax or gradation, the voice should rise with it. So,
“There is no enjoyment of property without govern-
ment; no government without a magistrate; no magis-
trate without obedience; no obedience where every one
all as he pleases.” And so in other gradations of a dif-
ferent form. As, “Since comes aus, liberty; aus,友谊;
trans ist, all aus left.” And again, “You would pardon
him whom the senate hath condemned, whom the people of
Rome have con-

man, and it may appear very indecent, when Milo dislo-
ces more concern for the public safety than for his
own, not to show a greatnes of mind equal to his cause,
yet this new form of the court terrifies my eyes, which
cannot discern the ancient manner of the forum, and
former custom of trials, whatever way they look: your
bench is not surrounded with its usual attendants.”
This sentence contains four moods; and Quintilius
fupposes, that though these words are the begin-
ing of a speech, and were accordingly expressed
in a calm and submissive manner, yet that the orator
used a great deal of variety in the pronunciation of
the several parts. In the first member (as he imag-
ines) his voice was more elevated in expressing the
words, a most courageous man, than in those other parts
of it, I am apprehensive it may seem base, and, to dis-
fear. In the second member no role higher, in saying
when Milo discovers more concern for the public safety than
for his own; and then again, as it were, checked him-
self in what follows, not to show a greatnes of mind equal
to his cause. The beginning of the third member, car-
rying a reflection in it, was spoke with a different
tone of the voice, this new form of the court terrifies
my eyes; and the other part of it more loud and dis-
dainfully, which cannot discern the ancient manner of the
forum, and former custom of trials. And the last mem-
er was still more railed and audible, your bench is not
surrounded with its usual attendants. And it must be
supposed, that while he was saying this, he cast his
eyes round the assembly, and viewed the soldiers whom
Pompey had placed there, which renders the expres-
Sion still more grave and solemn. If this was the man-
er of the ancient orators, and they were so exact and
accurate in expressing their periods, and the several
parts of them, as we have reason to believe they were,
it must have given a very great force, as well as bea-
ty, to their pronunciation.

III. That the passions have each of them both a
different voice and action, is evident from hence; that
we know in what manner a person is affected, by the
tone of his voice, though we do not understand the
sense of what he says, or many times so much as see
him; and we can often make the same judgment from
his countenance and gestures. Love and eafe are
expressed in a smooth and cheerful tone; but anger
and resentment, with a rough, harsh, and interrupted
voice, for when the spirits are distrusted and ruffled;
the organs are moved unequally. Joy railes and di-
lates the voice, as forrow sinks and contracts it. Ci-
cero takes notice of a passage in an oration of Gra-
clus, wherein he bewails the death of his brother,
who was killed by Scipio which in his time was
thought very moving: “Unhappy man (says he,) whi-
ther shall I betake myself? Where shall I go? Into the
capitol? that flows with my brother’s blood. Shall I go
home? and behold my unhappy mother all in tears and
depair?” Though Gracchus had a very ill design in
that speech, and his view was to excite the populace
against his governors, yet (as Cicero tells us) when
he came to this passage, he expressed himself in such
moving accents and gestures, that he excited tears
even from his enemies. Fear occasions a tremor and
hilarity of the voice, and assurance gives it strength
and firmness. Admiration elevates the voice, and
should be expressed with pomp and magnificence; O
This is Cicero's compliment to Caesar, when he thought it for his purpose. And oftentimes this passion is accompanied with an elevation both of the eyes and hands. On the contrary, contempt sinks and protracts the voice. In the dispute between Cicero and Cælius, which of them should accuse Verres, Cicero puts this contemptuous question to him: "How are you qualified, Cælius, for such an undertaking? I will not ask, when you ever gave a proof of it; but when you so much as attempted it? Do you consider the difficulty of managing a public cause?" with much more to the same purpose. Though such kind of expressions require little gesture, yet sometimes a motion of the hand may not be improper, to signify disdain or aversion. We may suppose Cicero to have asked thus in his defence of Rabirius. For to show his assurance of his client's cause, having used this expression in a very audible manner, "I wish I had it to say, that Rabirius had with his own hand killed Saturninus, who was an enemy to the Roman state," some persons in the crowd began to raise a clamour, just as of later times hissing has been practised on like occasions. Upon which Cicero immediately replies, "This noise does not disturb me, but please me, since it shows, though there are some weak persons, yet they are but few." Then prefently after follows the expression we refer to: "Why do not you cease your clamour, since it only discovers your folly, and the finallness of your number?" All exclamations should be violent. When we address to inanimate things, the voice should be higher than when to animated beings; and appeals to heaven must be made in a loftier tone than those to men.

These few hints for expressing the principal passions may, if duly attended to, suffice to direct our practice in others. Though after all, it is impossible to gain a just and decent pronunciation of voice and gesture merely from rules, without practice and an imitation of the best examples. Which shows the wisdom of the ancients, in training up their youth to it, by the affimilation of manners, to form both their speech and actions.

But there is one thing which ought always to be attended to; namely, that persons should well consider their own make and genius, especially with respect to the passions. We seldom find, that any actor can excel in all characters; but if he performs one well, he is deficient in another: And therefore they are commonly so prudent as to confine themselves to such as suit them. The cafe is the same in an orator; who should therefore keep within those bounds which nature seems to have prescribed for him. Some are better fitted for action than others, and most for some particular actions rather than others; and what suits well upon one would appear very awkward in another. Every one, therefore, should first endeavour to know himself, and manage accordingly. Though in many cafes, nature may be much assisted and improved by art and exercise. See Professor Ward's Syllen of Oratory.
The utility of a general orchard, both for private use and profit, draw'd with the various sorts of fruit-trees, must be very great, as well as afford infinite pleasure from the delightful appearance it makes from early spring till late in autumn: In spring the various trees in blossom are highly ornamental; in summer, the pleasure is heightened by observing the various fruits advancing to perfection; and as the season advances, the mature growth of the different species arriving to perfection in regular succession, from May or June, until the end of October, must afford exceeding delight, as well as great profit.

Of the proper Extent, Situation, and Soil for this Department. As to the proper extent of ground for an orchard, this must be proportioned, in some measure, to the extent of land you have to work on, and the quantity of fruit required either for private use or for public supply? so that an orchard may be from half an acre to 20 or more in extent.

With respect to the situation and aspect for an orchard, we may observe very thriving orchards both in low and high situations, and on declivities and plains, in various aspects or exposures, provided the natural soil is good; we should, however, avoid very low damp situations as much as the nature of the place will admit; for in very wet soils no fruit trees will prosper, nor the fruit be fine: but a moderately low situation, free from copious wet, may be more eligible than an elevated ground, as being less exposed to tempestuous winds; though a situation having a small declivity is very desirable, especially if its aspect incline towards the east, south-east, or southerly, which are rather more eligible than a westerly aspect; but a north aspect is the worst of all for an orchard, unless particularly compensated by the peculiar temperament or good quality of the soil.

And as for soil, any common field or pasture that produces good crops of corn, grass or kitchen-garden vegetables, is suitable for an orchard; if it should prove of a loamy nature, it will be a particular advantage: any soil, however, of a good quality, not too light and dry, or too heavy, stubbom, or wet, but of a medium nature, of a foil, plant temperature, not less than one foot deep of good flipple, will be proper for this purpose.

Preparation of the Ground. The preparation of the ground for the reception of trees, is by trenching; or, if for very considerable orchards, by deep ploughing: but trench-digging, one or two spades, as the soil will admit, is the most eligible, either wholly or only for the present in the places where the lines of trees are to stand, a space of six or eight feet wide, all the way in each row, especially if it be grass-ground, and intended to be kept in the sward: or if any under-crooks are designed to be raised, the ground may be wholly trenched at first: in either case trench the ground in the usual way to the depth of the natural soil; and if in grass, turn the sward clean to the bottom of each trench, which, when rotted, will prove an excellent manure.

In planting orchards, however, on grass-grounds, some only dig pits for each tree, capacious enough for the reception of the roots, loosening the bottom well without the labour of digging any other part of the ground.

The ground must be fenced securely against cattle, &c either with a good ditch and hedge, or with a palings fence, as may be most convenient. See Hedges.

Method of planting the Trees. The best season for planting all the kinds of fruit-trees is autumn, soon after the fall of the leaf, from about the latter end of October until December; or indeed it might be performed any time in open weather from October until March.

Choose principally full standards, with straight clean stems, six feet high; each with a branchy well-formed head, or from two or three to four or five years growth, and let several varieties of each particular species be chosen, that ripen their fruit at different times, from the earliest to the latest, according to the nature of the different sorts, that there may be a proper supply of every sort regularly during their proper season. Of apples and pears in particular, choose a much greater quantity of the autumnal and late ripening kinds than of the early sorts; but most of all of apples: for the summer ripening fruit is but of short duration, only proper for temporary service; but the latter ripening kinds keep found some considerable time for autumnal use; and the latest kinds that ripen in October, continue in perfection for various uses all winter, and several sorts until the season of apples come again.

Having made choice of the proper sorts, and marked them, let them be taken up with the utmost care, so as to preserve all their roots as entire as possible; and when taken up, prune off any broken or bruised parts of the roots, and just tip the ends of the principal roots, in general, with the knife on the under side, with a kind of lope outward.

If the trees have been already headed, or fo trained as to have branched out into regular shoots to form each a proper head, they must be planted with the faid heads entire, only retrenching or shortening any irregular or ill-placed shoot that takes an awkward direction, or grows across its neighbours, or such as may run considerably longer than all the rest, &c.

The arrangement of the trees in the orchard must be in rows, each kind separate, at distances according to the nature of the growth of the different sorts; but for the larger growing kinds, such as apples, pears, plums, cherries, &c. they should stand from 25 to 30, or 40 feet every way aunder, though 25 or 30 feet at molt is a reasonable distance for all these kinds.

Each species and its varieties should generally be in rows by themselves, the better to suit their respective modes of growth; though for variety there may be some rows of apples and pears arranged alternately, as also of plums and cherries; and towards the boundaries there may be ranges of lesfer growth, as quinces, medlars, filberts, &c. and the outer row of all may be walnut trees and some chestnuts, set pretty close to defend the other trees from violent winds.

According to the above distances, proceed to stake out the ground for making the holes for the reception of the trees; which if made to range every way, will have a very agreeable effect, and admit the currency of air, and the sun's influence more effectually.

But in planting very extensive orchards, some di-
Orchord, (Orchelton) Vide the ground into large squares or quarters, of different dimensions with intervals of fifty feet wide between; serving both as walks, and for admitting a greater currency of air; in different quarters planting different sorts of fruit, as the same in one, pears in another, and plums and cherries in others, &c. and thus it may be repeated as many quarters for each species and its varieties as may be convenient.

As to the mode of planting the trees: A wide hole must be dug for each tree, capable enough to receive all the roots freely every way without touching the sides. When the holes are all ready, proceed to planting, one tree in each hole, a person holding the stem erect, whilst another trims in the earth, previously breaking it small, and packing it into the hole, that the crown of the roots may be but two or three inches below the general surface; and when the hole is filled up, tread it gently, first round the outside, then near the stem of the tree, forming the surface a little hollow; and then if on the top of all is laid some inverted turf to the width of the holes, forming it with a fort of circular bank, three or four inches high, it will support the tree, and guard the roots from drying winds and the farmer's drought; observing that each tree stand perfectly upright, and that they range exactly in their proper rows.

ORCHESTON St Mary, on Salisbury plain in Wiltshire, about nine miles from Salisbury. There is a curious species of grass found at this place in a meadow belonging to Lord Rivers, at present in the possession of a farmer.

The meadow is situated on a small brook, is frequently overflowed, and sometimes continues so a great part of the winter. It bears the greatest burden in a wet season.

We have the following account of this peculiar species of grass in Letters and Papers in Agriculture, &c. The farmer in whose possession these meadows are, informs us, "That it generally grows to the height of about 18 inches, and then falls and runs along the ground in knots, the length of 16 or 18 feet, but that he has known instances of its running to the length of 25 feet."

"The meadow contains about two acres and a half. It is mowed twice in a season and the average quantity is generally about twenty loads (tons) of hay the first mowing, and fix the second; though sometimes considerably more. The title of the meadow has been compounded for at pl. a year. The grass is..." the farmer says, "the horses will eat it in preference to corn mixed with chaff, when both are free before them together."

"This account, came to us so singular, and the crop of grass so extraordinary, that our secretary went to Orchelton to examine more particularly into it. The farmer, and divers other persons in the village, confirmed the account contained in this letter, of its amazing produce in hummers when the meadows had been overflowed in the preceding winter and spring; but when the winter had been dry, and the meadow not overflowed, the crop of grass was not Orchelton near so large. There did not appear to be any thing peculiar in the soil; nor were the other plants or weeds growing on it more luxuriant than in many other similar situations. Some of this grass was sent to the society at Norwich: some ingenious members of which informed us, that they think it is a species of the Agrostis polymorpha, mentioned by Hudson in his Flora Anglicana, of which there are several varieties."

"Camden mentions, in his Britannia, a grass growing near the place where this is found, which he calls..." the farmer says, that 'hogs were fed with it.'

"From all the inquiry made, we have not found this species of grass growing in any other part of the kingdom: hence it is possible that there may be something in the soil of this meadow peculiarly favourable to its growth. We shall not, however, determine on this point, but recommend trials to be made of propagating it, by sowing the seed in other places subject to be overflowed in the same manner. If it can be propagated generally, it must turn out the most profitable to the farmer of any grass yet discovered, and be of great benefit to the community."

We have this further account of it in the Gentleman's Magazine for March 1782: "The first notice of the Orchelton or Maddinton grass, as far as I can find, are to be met with in Dr How's Phyllogia Britannica, printed in 1650, where it is called..." the farmer says, "Dr How's..."

"We have not, however, determined on this point, but recommend trials to be made of propagating it, by sowing the seed in other places subject to be overflowed in the same manner. If it can be propagated generally, it must turn out the most profitable to the farmer of any grass yet discovered, and be of great benefit to the community."

We have this further account of it in the Gentleman's Magazine for March 1782: "The first notice of the Orchelton or Maddinton grass, as far as I can find, are to be met with in Dr How's Phyllogia Britannica, printed in 1650, where it is called..." the farmer says, "Dr How's..."
up, I procured in July last, from the farmer himself at Maddington, a bundle of this grass as it was in spikes; and by this means, I found it to be no other than the *tritium repens*, Hudson p. 57, or common *d'or gras*, quick-grass, or cowherd-grass, in a most luxuriant state of growth. The length of this culm is greatly influenced by the nature of the feaons. Its place of growth is in a meadow that is covered with water during the greatest part of the winter and spring. In this inundated field it acquires a length of half a yard, and every year it seems to grow much higher. In some places, this bundle of grasses, when it was in the height of its growth, was found to be seven feet long, and many of the spikes or ears contained 33 glumes, or flower-bearing husks; whereas the plant in common does not contain more than half that number; and it was said by the people of that neighbourhood to have been a very unfavourable season for this grass.

"That the above-mentioned species is the grass which at this time constitutes the bulk of that all-devouring crop which we read of, is to me sufficiently ascertained; but whether, even since the first notice of this grass, this species alone has been the cultured one in this situation, I do not decide, but think it a matter worthy of further investigation; since it should seem that the soil and situation are in a peculiar manner adapted to certain plants of the graminous tribe. I observed that a plant or two of the *phalaris arundinacea*, or red Canary grass, Hudson, p. 23, which by accident were sent with the above-mentioned grass, exceeded in the thickness and succulence of the stalk the ordinary size, and were also equal to the dogs' grasses in length."

These extracts we thought it our duty to lay before our readers; and we have done it without any observation or comment of our own; because we wish to give them every information which is either curious or useful; and with which we are satisfied, not willing to obtrude our remarks, where, from the scantiness of information or the doubtfulness of the facts, they cannot be made with confidence.

**ORCHESTRA**, in the Greek theatres, was that part of the *proscenium* or stage where the chorus used to dance. In the middle of it was placed the *archon* or *pulpit*. The orchestra was semicircular, and surrounded with seats. In the Roman theatres it made no part of the *scena*, but answered pretty nearly to the pit in our playhouses, being taken up with seats for spectators, magistrates, veils, and other perfections of the scene. The actors never went down into it. See *Theatre*.

**ORCHIS LEX**, instituted by Orchius the tribune in the year of Rome 566. Its intention was to limit the number of gifts that were to be admitted at an entertainment; and it also enforced, that during supper, which was the chief meal among the Romans, the doors of every house should be left open.

**ORCHIS, FOOL-STONES**; A genus of the diandia order, belonging to the gynandra class of plants; and in the natural method giving name to the seventh order, *Orchidae*. Its characters are these: It has a single stalk, with a vague sheath, and no emplacement; the flower hath five petals, three without and two within; the nectarium is of one leaf, fixed to the side of the receptacle, between the division of the petals; the upper lip is short and erect, the under large, broad, and spreading; the tube is pendulous, corniform, or like a horn, and prominent behind; it hath two short slender stamens, fitting upon the point, with oval erect stamens, fixed to the upper lip of the nectarium; it hath an oblong contorted germen, under the flower, with a short style, fastened to the upper lip of the nectarium; the germens afterwast turns to an oblong capsule, with one cell, having three keel-shaped valves, opening on the three sides, but joined at top and bottom, filled with small seeds like dust. Miller enumerates 10, and Linnaeus 33 species.

All those sorts of orchis described by Miller grow wild in several parts of England; but on account of the extreme oddness and beauty of their flowers, deserve a place in every good garden; and the reason of their not being cultivated in gardens, proceeds from the difficulty of transplanting them: though this may be easily overcome, where a person has an opportunity of marking their roots, in their time of flowering, and letting them remain until their leaves are decayed, when they may be allowed to be transplanted with safety; for it is from the fame with most sorts of bulbous or flesh-rooted plants, which, if transplanted before their leaves decay, seldom live, notwithstanding you preserve a large ball of earth about them; for the extreme parts of their fibres extend to a great depth in the ground, from whence they receive their nourishment, which if broken or damaged by taking up their roots, seldom thrive after; for though they may sometimes remain alive a year or two, yet they grow weaker until they quite decay; which is also the case with the cafe of tulips, fritillarias, and other bulbous roots. But if their soil and situation be adapted to their various sorts, they will thrive and continue several years, and during their season of flowering will afford as great varieties as any flowers which are at present cultivated.

The most remarkable species are the following:

1. The *macula*, or male foot-foones, hath a root composed of two bulbs, crowned with oblong, broad, spotted leaves; upright stalks; a foot-high; garnished with one or two narrow amplexicaule leaves; and terminated by a long spike of reddish-purple flowers having the petals reflexed backward; a quadri-nerved create lip to the nectarium, and an obtuse horn. The flowers of this species possess a very agreeable odour. The orchis *macula*, Lin. fp. pl. is the most valuable; although the roots of *maclae* of the palmated sorts particularly of the orchis *littetia*, are found to answer almost equally well.

2. The *morio*, or female orchis, hath a double bulbous root, crowned with oblong, ribbed, spreading leaves; erect flower-stalks, eight or ten inches high; garnished with a few amplexicaule leaves; and terminated by a short loose spike of flowers, having conicent petals, a quadrifid create lip to the nectarium, and an obtuse horn.

3. The *militaris*, or man-orchis, hath a double bulbous root, crowned with oblong amplexicaule leaves; erect flower-stalks, eight or ten inches high; terminated by a loose spike of all-coloured and reddish flowers, having conicent petals; a quinqued, rough, spotted lip to the nectarium, and an obtuse horn. The structure
The structure of the flowers exhibit the figure of a naked man; and are often of different colours in the same flower, as ash colour, red, brown, and dark tipped.

Culture and Properties. All the orchis are very hardy perennials, with bulbous fleshy roots. The flowers appear in May, June, and July, but principally in June: their mode of flowering is universally in spikes; many flowers in each spike; and each flower is composed of five petals in two series, and a stamen. The season for removing them is in summer, after they have done flowering, when their leaves and flanks decay: plant them three inches deep, and let them remain undisturbed several years, for the less they are removed, the stronger they will flower.

The roots of all the species have a remarkable resemblance to the fecrotum of animals, whence the name. This plant prospers in various parts of Europe and Asia, and grows in our country spontaneously, and in great abundance. It is affiguously cultivated in the East; and the root of it forms a considerable part of the diet of the inhabitants of Turkey, Persia, and Syria. From it is made the alimentary powder called **Sala**p; which prepared from foreign roots, is sold at five or six shillings per pound, though it might be furnished by ourselves at the sixth part of that price, if we chose to pay any attention to the culture of this plant. The orchis malacca is the most valued for this purpose. A dry and not very fertile soil is best adapted to its growth.

The properest time for gathering the roots, is when the soil is formed, and the flanks is ready to fall; because the new buds, of which the false is made, is then arrived to its full maturity, and may be distinguished from the old one, by a white bud rising from the top of it, which is the germ of the orchis of the succeeding year.

The culture of the orchis is an object highly deserving of encouragement from all the lovers of agriculture. And as the root, if introduced into common use, would furnish a cheap, wholesome, and most nutritious article of diet, the growth of it would be sufficiently profitable to the farmer. See **Sala**p.

**ORCUS**, god of the infernal regions, the name with Pluto, 'from which the name to all the divinities of the infernal regions, even to Cerberus. There was a river of the same name in Thessaly, which took its rise from the marshes of the Styx, and the waters of which were so thick that they floated like oil upon the surface of the river Peneus, into which they discharged themselves. This river probably suggested to the poets the idea of the infernal abodes, which they denominated Orcus. This deity was conformed with Charon: he had a temple at Rome.

**ORDEAL**, an ancient form of trial. See **TRIAL**.

—I was an appeal to the immediate interposition of divine power, and was peculiarly distinguished by the appellation of juridicum Diis; and sometimes sulbritus purgati, to distinguish it from the canonical purgation, which was by the oath of the party. There were two sorts of it more common than the rest, at least in Europe, fire- ordeal, and water- ordeal. The former was confined to persons of higher rank, the latter to the common people. Both these might be performed by deputy; but the principal was to answer for the success of the trial; the deputy only venturing some corporal pain, for hire or perhaps for friendship.

That the purgation by ordeal, of some one kind or other, is very ancient, admits not of a doubt; and that it was very universal in the times of superstitious barbarity, is equally certain. It forms even to have been known to the ancient Greeks; for in the Argonate of Sophocles, a peron suspected by Creon of a misdeemour, declares himself ready "to handle hot iron and to walk over fire" in order to manifest his innocence; which the philosopher tells us was then a very usual purgation. And Orctius gives us many instances of water-ordeal in Bithynia, Sardinia, and other places. It seems however to have been carried to a greater height among the Hindoos, than ever it has been in any nation among any people however rude or barbarous; for in a paper of the Asiatic Researches published by the celebrated Warren Haltins, Esq; we find that the trial by ordeal among them is conducted in nine different ways: first, by the balance; secondly, by fire: thirdly, by water: fourthly, by poisons; fifthly, by the Cola, or water in which an idol has been washed: sixthly, by rice; seventhly, by boiling oil: eighthly, by red hot iron; ninthly, by image.
III. Water ordeal is performed by causing the person accused to stand in a sufficient depth of water, either flowing or stagnant, to reach his navel; but care should be taken that a ravenous animal be in it, and that it be not moved by much air: a brahman is then directed to go into the water, holding a flail in his hand; and a soldier shoots three arrows on dry ground from a bow of cane: a man is next dispatched to bring the arrow which has been shot farther; and, after he has taken it up, another is ordered to run from the edge of the water; at which instant the person accused is told to grasp the foot or the flail of the brahman, who stands near him in the water, and immediately to dive into it. He must remain under water, till the two men who went to fetch the arrows, are returned; for, if he raise his head or body above the surface, before the arrows are brought back, his guilt is considered as fully proved. In the villages near Benares, it is the practice: for the person who is to be tried by this kind of ordeal, to stand in water up to his navel, and then holding the foot of a brahman, to dive under it as long as a man can walk 50 paces very gently; if, before the man has walked thus far, the accused rises above the water, he is condemned; if not, acquitted (8).

IV. There are two sorts of trial by poison; first the Pandits having performed their homa, and the person accused his ablution, two rettis and a half, or seven barley corns, of bijamana, a poisonous root, or of farnchyas, that is, white arsenic, are mixed in eight najkar, or 64 rettis, of clarified butter, which the accused must eat from the hand of a brahman: if the poison produce no visible effect, he is acquitted; otherwise, condemned. Secondly the hooded snake, called naga, is thrown into a deep earthen pot, into which is dropped a ring, a seal or a coin: this the person accused is ordered to take out with his hand; and, if the serpent bite him, he is pronounced guilty; if not, innocent.

V. Trial by the cofha is as follows: the accused is made to drink three draughts of the water, in which the images of the sun, of devi, and other deities, have been washed for that purpose; and if, within 14 days, he has any sickness or indisposition, his crime is considered as proved.

VI. When several persons are suspected of theft, some dry rice is weighed with the sacred stone called falgram, or certain looses are read over it; after which the suspected persons are severally ordered to chew a quantity of it; as soon as they have chewed it, they are to throw it on some leaves of pipal, or, if none be at hand, on some bhuba, or bark of a tree from Nepal or Cashmir. The man from whose mouth the rice comes dry or stained with blood, is held guilty; the rest are acquitted.

VII. The ordeal by hot oil is very simple: when it is heated sufficiently, the accused thrusts his hands into it; and, if he be not burned, is held innocent (c).

VIII.

ed her character when suspected of familiarity with Alwyn bishop of Wincheller. The first account we have of Christians appealing to the fire-ordeal, as a proof of their innocence, is that of Simplicius, bishop of Autun, who lived in the fourth century. This prelate, as the story is related, before his promotion to the episcopal order, had married a wife, who loved him tenderly, and who unwilling to quit him after his advancement, continued to dwell in the same chamber with him. The fidelity of Simplicius suffered, at least in the voice of fame, by the constancy of his wife's affection; and it was rumoured about, that the holy man, though a bishop, perished, in opposition to the ecclesiastical canons, to taste the sweets of matrimony: upon which his wife in the presence of a great concourse of people, took up a considerable quantity of burning coals, which she held in her clothes, and applied to her breasts, without the least hurt to her person or her garments, as the legend says; and her example being followed by her husband with the like success, the filly multitude admired the miracle, and proclaimed the innocence of the loving pair. A similar trick was played by St Brice, in the fifth century. Moleb. Eccl. Hist. v. 2.

(a) A very peculiar species of water-ordeal is said to prevail among the Indians on the coast of Malabar. A person accused of an enormous crime is obliged to swim over a river abounding with large crocodiles; and if he escapes unhurt, he is esteemed innocent.

At Siam, besides the usual methods of fire and water ordeal, both parties are sometimes exposed to the fury of a tyger let loose for that purpose; and if the beast sakes either, that person is accounted innocent; if neither, both are held to be guilty; but if he sakes both, the trial is incomplete, and they proceed to a more certain criterion.

In Europe water-ordeal was performed, either by plunging the bare arm up to the elbow in boiling water and escaping unhurt thereby, or by casting the person suspected into a river or pond of cold water; and if he floated therein without any action of swimming, it was deemed an evidence of his guilt; but if he sunk he was acquitted. It is easy to trace out the traditional relics of this water-ordeal, in the ignorant barbarity still practised in many countries; different witches, by calling them into a pool of water, and drowning them to prove their innocence. And in the Eastern empire the fire-ordeal was used for the same purpose by the emperor Theodore Lascaris; who, attributing his sickness to magic, caused all those whom he suspected to handle the hot iron; thus joining (as has been well remarked) to the most dubious crime in the world, the most dubious proof of innocence.

(c) This species of trial by ordeal is thus performed: The ground appointed for the trial is cleared and rubbed with cow-dung; and the next day at fun-rise the Pandits worships Ganésa or the Hindu Janus, presents his oblations, and pays adoration to other deities, conformably to the Sûtras: then having read the incantation prescribed, he places a round pan of gold, silver, copper, iron, orclay, with a diameter of sixteen fingers, and four fingers deep; and throws into it one sör, or eighty 400s weight of clarified butter or oil of safanum. After this a ring of gold,
ORD

VIII. In the same manner, they make an iron-ball, or the head of a lance, red-hot, and place it in the hands of the person accused; who, if it burn him not, is judged guiltless.

IX. To perform the ordeal by dharma, which is the name of the fire appropriated to this mode of trial, either an image, named Dharma, or the genius of justice, in made of silver; and another, called Adharma, of clay or iron, both of which are thrown into a large earthen jar; and the accused having thrust his hand into it, is acquitted if he bring out the silver image, but convicted if he draw forth the iron; or, the figure of a deity is painted on white stone, and another on black; the first of which they name dharma, and the second adharma: these are severally rolled up in cow-dung, and thrown into a large jar without having ever been shown to the accused; who must put his hand into the jar, and is acquitted or convicted as he draws out the figure on white or on black cloth.

Though we have preceded thus far, we have not exhausted Mr Haftings communications. He goes on to shew (to greater extent than our limits permit us to follow him,) the manner in which each ordeal abovementioned was executed, giving examples, and unfolding other particulars of some importance in developing the nature of these barbarous customs. For these particulars, however, we must refer to the book itself. But as this subject unquestionably occupies an important department in the history of human superition, we shall give the Indian law of ordeal from the same paper; when we shall introduce some further particulars concerning this extraordinary custom, which are not to be found in the above accounts, but which deserve to be noticed.

1. The balance, fire, water, poison, the idol—these are the ordeals used here below for the proof of innocence, when the accusations are heavy, and when the accuser offers to hazard a mulct (if he should fail): 2. Or one party may be tried if he pleases, by ordeal, and the other mulct then fixed; but the trial may take place even without any wager, if the crime committed be injurious to the prince.

3. The sovereign, having summoned the accused while his clothes are yet moist from bathing, at sun-rise, before he has broken his fast, shall cause all trials by ordeal to be conducted in the presence of Brahmins.

4. The balance is for women, children, old men, the blind, the lame, Brahmins, and the sick; for the Sudra, fire or water, or seven barley-corns of poison.

5. Unless the lot of the accuser amount to a thousand pieces of silver, the accused must not be tried by the red-hot ball, nor by poison, nor by the scales; but if the offence be against the king, or if the crime be heinous, he must acquit himself by one of those trials in all cases.

6. He who has recourse to the balance must be attended by persons experienced in weighing, and go down into one scale, with an equal weight placed in the other, and a grove (with water in it) marked on the beam.

7. 'Thou, O balance, art the mansion of truth: thine heart is increased by the scale,' declare the truth, therefore, O giver of successes, and clear me from all suspicion.

8. 'If I am guilty, O venerable as my own mother, then sink me down; but if innocent, raise me aloft.' Thus shall he address the balance.

9. If he sink he is convicted; if the scales be broken; but if the fire be not broken, and he rise aloft, he must be acquitted.

10. On the trial by fire, let both hands of the accused be rubbed with rice in the huft, and well examined: then let seven leaves of the Ajuwatta (the religious fig-tree) be placed on them, and bound with seven threads.

11. 'Thou, O fire, prevail on all beings; O cause of purity, who givest evidence of virtue and of six, declare the truth in this my hand.'

12. When he has pronounced this, the priest shall place in both his hands an iron ball, red-hot, and weighing fifty (p) palas.

13. Having taken it, he shall step gradually into seven circles, each with a diameter of sixteen fingers, and separated from the next by the same space.

14. If, having cast away the hot ball, he shall again have his hands rubbed with rice in the huft, and shall show them unburned, he will prove his innocence. Should the iron fall during the trial, or should a doubt arise (on the regularity of the proceedings), he must be tried again.

15. 'Preserve me, O Varuna, by declaring the truth.' Thus having invoked the god of waters, the accused shall plunge his head into the river or pool, and hold both thighs of a man, who shall stand in it up to his navel.

16. A swift runner shall then hasten to fetch an arrow shot at the moment of his plunging; and if, while the runner is gone the priest shall see the head of gold, or silver, or iron is cleaned and washed with water, and cast into the oil; which they proceed to heat, and when it is very hot put into it a fresh leaf of pippala, or of bilva: when the leaf is burned, the oil is known to be sufficiently hot. Then, having pronounced a mantra over the oil, they order the party accused to take the ring out of the pan; and if he take it out without being burned, or without a blister on his hand, his innocence is considered as proved; if not, his guilt is.

(b) A pal is four carajis, and a carajh eighty radichus, or seeds of the Gungá creeper, each weighing above a grain and a quarter, or, correctly, 1, 67 gr.

It is reported, that this custom, with some slight variations, still prevails among the Indians on the coast of Malabar. The procès there is said to begin after the accused person has been thoroughly washed in the presence of the prince of the country, the priests, &c.; the pot is filled with boiling lead; and the accused must take the ring out three times successively. On the Malabar coast, this ordeal seems only to be used when the person is accused of a capital crime; or after the procès the arm is bound with cloth and leaved; and after several days, being brought out publicly, and the arm impaled, if it is found burned he is instantly put to death; if not, his accuser undergoes the same trial, and being burned, forfeits his life.
Ordal. [ 478 ]

17. ‘Thou, O poison, art the child of Brahmin, fled from justice and in truth; clear me then from this heavy charge, and, if I have spoken truly, become nectar to me.’

18. Saying this, he shall swallow the poison "Suraga from the tree, which grows on the mountain "Hypholaya; and if he digests it without any inflammations the prince shall pronounce him guiltless.

16. Or the priest shall perform rites to the image of the tree, a tremendous deity; and, having touched the idol, shall make the accused to drink three handfuls of the water that has dropped from it:

20. If in fourteen days after he suffer no dreadful calamity from the same of the deity or of the king, he shall inductably be acquitted.

The superstitious was a sign of mankind, when left to themselves, is astonishing. There is indeed nothing so absurd but they may be made most firmly to believe, no so impious but they will do. Nor can a more frivolous influence of the mind be thought to be possibly given than that of the trial by ordeal. The gross absurdity as well as impiety of pronouncing a man guilty unless he was cleared by a miracle, and of expecting that all the powers of nature should be suspended by an immediate interpolation of providence to save the innocent, whenever it was presumptuously required, is self-evident. Yet the origin of it may be traced as well to necessity as to superstition. At the time in which it originated in England, as well as in other countries of Europe, it was no easy matter for an innocent person, when accused of guilt, to get himself cleared by the then established mode of trial (See TRIAL). It was therefore natural for superstitious fly to heaven for those testimonies of innocence which the adulterity of human laws often prevented men from obtaining in the ordinary way; and in this way doublets did the trial by ordeal commence; and thus begun by nescientious superstitious, it was fostered by impious priestcraft and unjust litigation.

The powers of nature were adduced, and there can be no question but it was often practised; it could not therefore on any account, or in any case, be a sign of innocence or of guilt.

Besides those particular methods of trial which we have already mentioned there were some few more common in European countries; as the judicial combat—the ordeal of the crofs—the ordeal of the confined.

The judicial combat was well suited to the genius and spirit of fierce and warlike nations, and was, as we may reasonably expect, one of the most ancient and universal modes of trial. We know that it was exceedingly common in Germany in very remote ages. It was also used in some countries on the continent at pretty early periods; it is not, however, mentioned in any of the Anglo-Saxon laws; and it does not appear to have been much used in England till after the Conquest. There are, however, two remarkable instances of it upon record, which we shall give in the words of Dr. Henry: 'Henry de Eves, hereditary standard bearer of England, fled from a battle in Wales A.D. 1158, threw from him the royal standard, and cried out, with others, that the king was slain. Some time after he was accused of having done this with a treacherous intention, by Robert de Montfort, another great baron, who offered to prove the truth of his accusation by combat. Henry de Eves denied the charge, and accepted the challenge. When all preliminaries were adjusted, this combat was accordingly fought in the presence of Henry II. and all his court. Eves was defeated, and expected to give himself with confecting his elate, and making himself a monk in the abbey of Reading.'

The priory of Tintern, in Northumberland, was a cell of the abbey of St Alban's. One Simon of Tintern claimed a right to two crosies, the possession of which he did not believe, and to which he was not entitled. The same was brought before the abbot of St Alban's, and his court, who appointed it to be tried by combat on a certain day before him and his barons. Ralf Gubion, prior of Tintern, appeared at the time and place appointed, accompanied by his champion, one William Pegman, a man of gigantic stature. The combat was fought, Pegman was defeated, and the prior lost his cause; at which he was so much chagrined, that he immediately resigned his office. This judicial combat is the more remarkable, that it was fought in the court of a spiritual baron, and that one of the parties was a priest.

We need scarcely add, that this detestable form of trial was the foundation of the no less detestable crime of duelling, which so much disgraces our age and nation; which is defended only by ignorance, false honour, and injustice; which is a relic of barbarous superstition; and which was absolutely unknown to those brave and generous nations, the Greeks and Romans, which it is so much the fashion to admire, and who in this particular so well merit or imitation. See DUEL.

It was so much the custom in the middle ages of Christianty, to respect the cros even to superstitious, that it would have been indeed wonderful if the same ignorant bigotry had not converted it into an ordeal; accordingly we find it used for this purpose, in so many different ways as almost to preclude description. We shall however transcribe, for the satisfaction of our readers, Dr Henry's account of it, and of the confined: "In criminal trials, the judgment of the crofs was commonly thus conducted. When the prisoner had declared his innocence upon oath, and appealed to the judgment of the crofs, two ficks were prepared exactly like one another; the figure of the crofs was cut on one of these ficks, and nothing on the other; each of them was then wrapped up in a quantity of fine white wool, and laid on the altar, or on the relics of the saints; after which a solemn prayer was put up to God, that he would be pleased to discover, by evident signs, whether the prisoner was innocent or guilty. These solemnities being finished, a priest approached the altar, and took up one of the ficks, which was uncovered with much anxiety. If it was the fick marked with the crofs, the prisoner was pronounced innocent; if it was the other, he was declared guilty. When the judgment of the crofs was appealed to in civil cases, the trial was conducted in this manner: The judges, parties, and all concerned, being assembled in a church, each of the parties chose a priest,
The ordeal, or the confecrated bread and cheese, was the ordeal to which the clergy commonly appealed when they were accused of any crimes; in which they acted a very prudent part, as it was attended with no danger or inconvenience. This ordeal was performed in this manner: A piece of barley-bread, and a piece of cheese, were laid upon the altar, over which a priest pronounced certain conjurations, and prayed with great fervency that if the person accused was guilty, God would send him an angel to stop his throat, that he might not be able to swallow that bread and cheese. These prayers being ended, the culprit approached the altar, took up the bread and cheese, and began to eat it. If he swalloved freely, he was declared innocent; but if it stuck in his throat, and he could not swallow, (which we may presume seldom or never happened,) he was pronounced guilty."

"There were besides these a variety of other ordeals practised in Christian countries, of which we retain the same names as among Pagans, and differ only in the mode of execution. In all nations of Christians where these trials were used, we find the clergy engaged in them. Indeed, in England, so late as King John’s time, we find grants to the bishop and clergy to use the judicium foris, aques, et ignis. And, both in England and Sweden, the clergy presided at this trial, and it was only performed in the churches or in other consecrated ground: for which Stierhoek gives the reason, Non defuit illis operae et laboris precium: semper enim ab eiusmodi judicio aliquid luci faceretur donec velut. But, to give it its due praise, we find the canon law very early declaring against trial by ordeal, or pulvinar purgation, as being the fabric of the devil, cum fiet contra praecipum Dominii, Non intellebat Dominum Deum tuum. Upon this authority, though the canons themselves were of no validity in England, it was thought proper (as had been done in Denmark above a century before) to diffuse and abolish this trial entirely in the courts of justice, by an act of parliament in 3 Hen. III. according to Sir Edward Coke, or rather by an order of the king in council.

It may fill perhaps be a polliatium with some of our readers how the effects of these trials were equalled, and how it was possible to appear to do what we know could not be done really, without material injury to the persons concerned; and here we find the subject so well handled by the learned historian, whom we have already quoted, as far as concerns the ordeals in ancient Britain, which mutatis mutandis will answer for others, that we shall finish the article, which has already extended we fear too great a length, in his words: "If we suppose that few or none escaped conviction who exposed themselves to such fiery trials, we shall be very much mistaken. For the histories of those times contain innumerable examples of persons plunging their naked arms into boiling water, handling red-hot balls of iron, and walking upon burning plough-shares, without receiving the least injury. Many learned men have been much puzzled to account for this, and disposed to think that Providence graciously interposed, in a miraculous manner, for the preservation of injured innocence. But if we examine every circumstance of those fiery ordeals with due attention, we shall see sufficient reason to suspect that the whole was a gross imposition on the credulity of mankind. The accused person was committed wholly to the priest who was to perform the ceremony three days before the trial, in which he had time enough to bargain with him for his deliverance, and give him instructions how to act his part. On the day of trial, no person was permitted to enter the church but the priest and the accused till after the iron was heated, when twelve friends of the accuser, and twelve of the accused, and no more, were admitted, and ranged along the wall on each side of the church, at a respectful distance. After the iron was taken out of the fire, several prayers were said; the accused drank a cup of holy water, and sprinkled his hand with it, which might take a considerable time, if the priest was indulgent. The space of nine feet was measured by the accused himself with his own feet, and he would probably give but scanty measure. He was obliged only to touch one of the marks with the toe of the right foot, and allowed to stretch the other foot as far toward the other mark as he could, so that the conveyance was almost instantaneous. His hand was not immediately examined, but wrapped in a cloth prepared for that purpose three days. May we not then, from all these precautions, suspect that these trials were in possession of some secret that secured the hand from the impressions of such a momentary touch of hot iron, or removed all appearances of those impressions in three days; and that they made use of this secret when they saw reason? Such readers as are curious in matters of this kind may find two different directions for making ointments that will have this effect, in the work here quoted. What greatly strengthens these is the tradition of pagans, as is, that we meet with no example of any gloss, t. 5, chap. 24, p. 393, from the touch of hot iron in this ordeal; but when any one was too fool-hardy as to appeal to it, or to that of hot water with a view to deprive the church of any of her pollutions, he never failed to burn his fingers, and lose his caudex."

ORDER, in architecture, is a system of the several members, ornaments, and proportions of columns and pilasters, or a regular arrangement of the projecting parts of a building, especially the columns, so as to form one beautiful whole. See Architecture, Chap. 1. Part 1. page 339, &c.

ORDER is also used for a division or class of any thing; thus the tribe of animals called birds, is subdivided into six orders. See Ornithology, Zoology, &c.

ORDER, in rhetoric, is the placing of each word and member of a sentence, in such a manner, as will most contribute to the force, beauty or evidence of the whole; according to the genius and custom of different languages. With regard to order, we may observe in general, that in English, the nearer we keep to the natural or grammatical order, it is generally
Order. rally the best; but in Latin, we are to follow the use of the best writers; a joint regard being always had to the judgement of the ear, and the peripæticity of the fens, in both languages. 

Order is also used for a class or division of the members of the body of a state; with regard to assemblies, precedence, &c. 

In this sense, order is a kind of dignity, which, under the same name, is common to several persons; and which, of itself, does not give any particular public authority, but only rank, and a capacity of arriving at honours and employments.

To abridge this definition, order may be said to be a dignity attended with an aptitude for public employment. By which it is distinguished from an office which is the exercise of a public trust. 

In this sense, nobility is an order, &c. The clericate is also an order, &c. 

Order is also the title of certain ancient books, containing the divine office, with the order and manner of its performance. 

Roman order is that wherein are laid down the ceremonies which obtain in the Roman church. See Ritual. 

Order, in botany, is a name given to a subdivision of plants in the Linnaean system. See Botany, p. 431. &c. 

Order, by way of eminency, or holy order, denotes a character peculiar to ecclesiastics, whereby they are set apart for the ministry. See Ordination. 

This the Romanists make their sixth sacrament. 

In no reformed church are there more than three orders; viz. bishops, priests, and deacons. In the Roman church there are seven, exclusive of the episcopate: all which the council of Trent enjoins to be received, and believed, on pain of anathema. 

They are distinguished into petty or secular orders: and major, or sacred orders. 

Orders, the petty, or minor are four; viz. thosc of doorkeeper, exorcist, reader, and acolyth. 

Those in petty orders may marry without any dispensation: in effect, the petty orders are looked on as little other than formalities, and as degrees necessary to arrive at the higher orders. Yet the council of Trent is very serious about them: enjoins that none be admitted into them without understanding Latin; and recommends it to the bishops, to observe the intervals of conferring them, that the persons may have sufficient time to exercise the function of each order: but it leaves the bishops a power of dispensing with those rules; so that the four orders are usually conferred the same day, and only make the first part of the ceremony of ordination. 

The Greeks disavow these petty orders, and pass immediately to the subdiaconate; and the reformed to the diaconate. 

Their first title Flury dates in the time of the emperor Justinian. There is no call nor benefit requisite for the four petty orders, and even a bastard may enjoy them without any dispensation: nor does a second marriage disqualify. 

Orders, sacred, or major, we have already observed are three: viz. those of deacon, priest, and bishop. 

The council of Trent retrieving the ancient discipline, forbids any person being admitted to the major orders, unless he be in peaceable possession of a benefice sufficient for a decent subsistence; allowing no ordinations on patronies or penions; except where the bishop judges it for the service of the church. 

A person is said to be promoted to orders per falsum, when he has not before passed the inferior orders. The council of Constantinople forbids any bishop being ordained without passing all the degrees; yet church history furnishes us with instances of bishops consecrated, without having passed the order of priesthood; and Panormus still thinks such an ordination valid. 

Military Orders, are companies of knights, instituted by kings and princes, either for defence of the faith, or to confer marks of honour, and make distinctions among their subjects. 

Religious Orders, are congregations or societies of monastics, living under the same superior, in the same manner, and wearing the same habit.—Religious orders may be reduced to five kinds; viz monks, canons, knights, mendicants, and regular clerks. See Monks, Canons, &c. 

Father Mabillon proves, that till the ninth century almost all the monasteries in Europe followed the rule of St Benedict; and that the division of orders did not commence till upon the reunion of several monasteries into one congregation: that St Odilo, abbot of Cluny, first began this reunion, bringing several houses under the dependence of Cluny; that a little afterwards, in the 11th century, the Camaldulians arose; then by degrees the congregation of Vallombrosa; the Cistercians, Carthusians, Augustines; and at last, in the 13th century, the Mendicants. He adds that Lupus Servatus, abbot of Ferreries, in the ninth century, is the first that seems to distinguish the order of St Benedict from the rest, and to speak of it as a particular order. 

White Order denotes the order of regular canons of St Augustine. See Augustines. 

Black Order denoted the order of Benedictines. These names were first given these two orders from the colour of their habit; but are diffused since the institution of several other orders, who wear the same colours. 

Grey Order was the ancient name of the Cistercians, but since the change of the habit, the name suits them no more. 

Orders, religious military, are those instituted in defence of the faith, and privileged to say Mass; and who are prohibited marriage, &c. 

Of this kind are the knights of Malta, or of St John of Jerusalem. Such also were the knights Templars, the knights of Calatrava, knights of St Lazarus, Teutonic knights, &c. See Malta, Templars, &c. 

Father Patignani accounts those military orders where marriage is not allowed, real religious orders. Papebroch says, it is in vain to search for military orders before the 12th century. 

Orders, in a military sense, all that is lawfully commanded by superior officers. Orders are given out every day whether in camp, garrison or on a march, by the commanding officer; which orders are afterwards given to every officer in writing by their respective sergeants. 

ORDINAL,
ORDINAL, a book containing the order or manner of performing divine service. See Ritual.

ORDINAL Numbers, those which express order; as 1st, 2d, 3d, &c.

ORDINANCE, or Ordonnance, a law, statute, or command of a sovereign or superior; thus the acts of parliament are sometimes termed ordinances of parliament, as in the parliament-rolls. Though in some cases we find a difference made between the two; ordinances being only temporary things, by way of prohibition: and capable of being altered by the commons alone; whereas an act is a perpetual law, and cannot be altered but by king, lords, and commons.

Coke affirms, that an ordinance of parliament differs from an act, as the latter can only be made by the king, and the threefold content of the estates; whereas the former may be made by one or two of them.

Ordinance of the Forfe is a statute made in the 34th year of Henry 1. relating to forest matters.

In the French jurisprudence, ordonnances are such laws as are established by the king's authority alone. All ordonnances begin with, à tout présent & à venir fait.

ORDINARY, in general, signifies common, usual; thus an ambassador or envoy in ordinary, is one sent to reside flately, and for a number of years, in the court of some foreign prince or state, in order to keep up a good understanding, and watch over the interest of his own nation. This term is also applied to several officers in a king's household, who attend on common occasions. Thus we say, physician in ordinary, &c.

ORDINARY, in naval language, denotes the establishment of the persons employed by government to take charge of the ships of war, which are laid up in the several harbours adjacent to the royal dockyards. These are principally composed of the warrant-officers of the said ships, as the captain, boatswain, carpenter, deputy purser, and cook, and three servants. There is besides a crew of labourers enrolled in the list of the ordinary, who pass from ship to ship occasionally, to pump, moor, remove, or clean them, whenever it is necessary.

The term ordinary is also applied sometimes to the ships themselves: it is likewise used to distinguish the inferior sailors from the most expert and diligent. The latter are rated able on the navy books, and have 1 l. 4s. per month; whereas those who are rated ordinary have only 15s. per month.

ORDINARY, in common or canon law, means one who has ordinary or immediate jurisdiction in matters ecclesiastical, in any place. In this sense archdeacons are ordinaries, but the appellation is most frequently applied to the bishop of the diocese, who has of course the ordinary ecclesiastical jurisdiction, and the collation to benefices within such diocese. There are some chapels, chapters, abbey, &c. exclusive from the jurisdiction of the ordinary. The archdeacon is ordinary of the whole province, to visit, and receive appeals from the inferior judicatures. The Roman writers on canon law call the pope by way of eminence ordinary of ordinaries, since by the Lateran council he has usurped the right of collating, by proportion, to all benefices; in exclusion of the common ordinaries.

ORDINARY OF AFFAIRS ON SESSONS, was a deputy of the bishop of the diocese, annually appointed to give malcontents their neck-verte, and judge whether they read or not; also to perform divine service for them, and ait in preparing them for death. So the ORDINARY of NEWCASTLE is one who is attendant in ordinary upon the condemned malcontents in that prifon, to prepare them for death; and he records the behaviour of such persons.

ORDINARY, or Honorable Ordinary, in heraldry, a denomination given to certain charges properly belonging to that art. See Heraldry, Chap. III. 183. i. p. 415. &c.

ORDINATES, in geometry and conics, are lines drawn from any point of the circumference of an ellipse or other conic section, perpendicular across the axis to the other side. See Conic-section.

ORDINATION, the act of conferring holy orders, or of initiating a person into the priesthood by prayer and the laying on of hands.

Ordination has always been esteemed the principal prerogative of bishops, and they still retain the function as a mark of spiritual sovereignty in their diocese. Without ordination, no person can receive any benefice, patronage, vicarage, &c.

A person must be 23 years of age, or near it, before he can be ordained deacon, or have any share in the ministry; and full 24 before he can be ordained priest, and by that means be permitted to administer the holy communion.

A bishop, on the ordination of clergy men, is to examine them in the presence of the ministers, who, in the ordination of priests, but not of deacons, ait him at the imposition of hands; but this is only done as a mark of assent, not because it is thought necessary. In case any crime, as drunkenness, perjury, forgery, &c. be alleged against any one that is to be ordained, either priest or deacon, the bishop ought to defer from ordaining him, as it is ordered is to bring a testimonial of his life and doctrine to the bishop, and to give account of his faith in Latin; and both priests and deacons are obliged to file aite the 30 articles.

The ordination of bishops is more properly and more commonly called consecration.

In the ancient discipline there was no such thing as a vague absolute ordination; but every one was to have a church, whereof he was to be ordained clerk, or priest. In the twelfth century they grew more remiss, and ordained without any title or benefice.

The council of Trent reformed the ancient discipline, and appointed that none should be ordained but those who were provided of a benefice sufficient to subsist them, which practice still obtains in England.

The council of Rome in 744, orders, that no ordinations shall be held except on the first, fourth, seventh, and tenth months. In England, by can. 31, ordination-days are the four Sundays immediately following the Ember weeks; being the second Sunday in Lent, Trinity-Sunday, and the Sundays following the first Wednesday after September the 14th, and December the 15th. These are the flated times; but ordinations may take place at any other time, according to the discretion of the bishop or circumstances of the case.

Pope Alexander II. condemns ordination per falum.
**ORD**

ORDNANCE, as they call it; i. e. the leaping to a superior order without passing through the inferior. Ordinances are one of the sacraments of the church of Rome.

In the establishment of Scotland, where there are no bishops, the power of ordination is lodged in the presbytery and by the Independents in the suffrage of the people. See Episcopacy, Presbyterian, and Independents.

**ORDNANCE** is a general term for all sorts of great guns used in war. See Gunner.

**Boring of Ordnance.** Till within these 20 years, iron ordnance were cast with a cylindrical cavity, nearly of the dimension of the caliber of the piece, which was afterwards enlarged to the proper caliber by means of steel-cutters fixed into the dog-head of a boring-bar iron. Three side-cutters equidistant were requisite to produce the caliber straight and cylindrical; and a single cutter was used at the end of the bar to finish the breech of the piece. In boring ordnance cast hollow, the piece was fixed upon a carriage that could be moved backwards and forwards in a direct line with the centre of a water-wheel; in this centre was fixed the boring bar, of a sufficient length to reach up to the breech of the piece, or more properly to the further end of the caliber. The carriage with the piece being drawn backwards from the centre of the water-wheel to introduce the boring and finishing bars and cutters, it is then pressed forwards upon this bar by means of levers, weights, &c. and the water-wheel being set going, the bar and fullers are turned round and clean out and smooth the caliber to its proper dimensions.

Experience at last pointed out many inconveniences arising from the method of cast guns hollow, and widening the calibers by these boring bars. For the body of iron of the hollow guns, being, at casting, in contact with the core that made the caliber within side, and with the mould without side, began to constrict and to form cavities, which were too deep to be cut out fortifications in his dominions. The office of ordnance is divided into two distinct branches, the civil and the military; the latter being subordinate, and under the authority of the former. For the better understanding of the business of the different officers, they shall be distinctly treated of, beginning with the principal one, viz.

**Major General of the Ordnance** is esteemed the principal officer in the civil branch of the ordnance; yet he is always chosen from amongst the first generals in his Majesty's service. His trust is very great, as in him is vested the sole power of boring all the military magazines in the king's dominions with proper munitions of war, and likewise to supply the royal navy with what they may need in his department, the parliament granting money in the most liberal manner for this purpose. He is colonel in chief of the royal regiment of artillery, at present consisting of four battalions; and he is invested with a peculiar jurisdiction over all his Majesty's engineers employed in the several fortifications in his Majesty's dominions; and to him they are all accountable for their proceedings, and from him they receive their particular orders and instructions, according to the directions and commands given by his Majesty in Council. As major general of the ordnance, he has a salary of 1500l. per annum, and the appointment of almost all the inferior officers and warrant officers. He has a secretary, who has a salary of 220l a-year, and an under-secretary, who has a salary of 180l a-year. There is also a secretary to the board of ordnance, who has a salary of 200l a-year, and a counsel to the board who has a salary of 300l a-year.

**Lieutenant General of the Ordnance** receives all orders and warrants signed by the major general, and from the other principal officers, and he gives them duly executed, with proper orders as the occasions of the state require, and gives directions for discharging the artillery when required at coronations, birth days, signal victories, and other solemn occasions. It is also his peculiar office to see the train of artillery and all its equipage fitted for motion, when ordered to be drawn into the field, or
D Breech of the Gun.
G Drill Bar.
H Carps Tongue Cutter.
ORDNANCE [ 483 ]

Ordinance is sent upon any particular service. As lieutenant-governor of the ordnance, he has a salary of £100 per annum. He is colonel in the royal regiment of artillery, and has a secretary and several inferior officers and clerks under him.

Storekeeper of the ordnance inspects the stores and provisions of war in the custody of the storekeeper, and fees that they are ranged and placed in such order as is most proper for their preservation. He assigns all bills of debt, and keeps a check upon all labourers and artificers’ work; fees that the stores received are good and serviceable, duly proved and marked, as they ought to be, with the king’s mark, taking to his assistance the rest of the officers and proof-masters. He has a salary of £700 per annum; and, in order to assist him in the business of his office, he has under him the proof master of England, and clerks, and other inferior officers.

Clerk of the ordnance, an officer whose main function is to record all orders and instructions given for the government of the office, all patents and grants, the names of all officers, clerks, artificers, gunners, labourers, &c. who enjoy those grants, or any other fee for the same; to draw all estimates for provisions and supplies to be made, and all letters, instructions, commissions, deputations, and contracts for his Majesty’s service; to make all bills of imprest and debentures, for the payment and satisfaction of work done and provisions received in the said office; and all quarter books for the salaries and allowances of all officers, clerks, &c. belonging to the office; and to keep journals and ledgers of the receipts and returns of his Majesty’s stores, to serve as a check between the two accountants of the office, the one for money, and the other for stores. He has a salary of £100 a year, and £100 a year more for being a check on stores. In his office he has a number of clerks, under clerks, and leger-keepers, who have all fixed salaries.

Storekeeper of the ordnance takes into his custody all his Majesty’s ordnance, munitions and stores belonging thereto, and in lents and puts them in legal custody, after they have been surveyed by the surveyors-general, any part of which he must not deliver without a warrant signed by the proper officers; nor must he receive back any stores formerly issued till they have been reviewed by the surveyor, and registered by the clerk of the ordnance in the book of remains; and he must take care that whatever is under his custody be kept safe, and in such readiness as to be fit for service upon the most peremptory demand. He has a salary of £400 a year; and in this office he has several clerks at fixed salaries, for the dispatch of business.

Clerk of the deliveries of the ordnance draws all orders for delivery of any stores, and fees them duly executed; charges by indenture the particular receiver of the stores delivered; and in order to discharge the storekeeper, registers the copies of all warrants for the deliveries, as well as the proportions delivered. He has a salary of £500 per annum, and has several clerks in his office at fixed salaries, for the dispatch of business.

Treasure and Paymaster of the ordnance receives and pays all monies, both salaries and debentures, in and belonging to this office. He has a salary of £500 per annum. In his office are several clerks, ordinary and extraordinary, for the dispatch of business.
ORE [484]

ORE, in natural history, the compound mineral gable, e. rth, stone, or other sub stance, which is sufficiently rich in metallic particles to be worth the while of purification, and by this means of separating the metal from it, whether gold, silver, copper, &c. See Metallurgy, Part ii. sect. 2. p. 427, &c.; and sect. 4. p. 431, &c.; and Part i. sect. 1. &c. p. 432, &c. See also Mineralogy, Part i. sect. 2. p. 61, &c.

ORELLANA (Francis), the first European, as is commonly thought, who discovered the river of the Amazons. In 1539, he embarked near Quito, upon the river Coca, which farther down takes the name of Napo. From this he fell into another larger river; and, leaving it privately, he turned to the direction of the current, where he arrived at Cape North, on the coast of Guinea, after falling nearly 1800 leagues. Orellana perished ten years after, with three vessels which had been entrapped to him in Spain, without being able to find again the mouth of this river. In falling down the river he met with some armed men, against whom an Indian cacique had told him to be on his guard, and he thence named it the river of the Amazons.

ORENSE, an ancient town of Spain, in the kingdom of Galicia, with a bishop's see. It is famous for its hot-baths; and is seated at the foot of a mountain, on the river Minho, over which there is a handsome bridge of one arch. W. Long. 7. 27; N. Lat. 42. 16.

ORESTES, in ancient history, a son of Agamemnon and Clytemnestra. When his father was cruelly murdered by Clytemnestra and Ægisthus, young Orestes was saved from his mother's dagger by means of his father's Electra, called by Homer Laodice, having been privately conveyed to the direction of Strophius, who was king of Phocis, and who had married a sister of Agamemnon. He was tenderly treated by Strophius, who carefully educated him with his son Pyladen. The two young princes soon became acquainted, and from their familiarity arose the most inviolable attachment and friendship. W. On Orestes came to years of discretion, he visited Mycenae, and avenged his father's death by affainting his mother Clytemnestra and her adulterer Ægisthus. Various accounts are given of the way in which these murders were committed. After their commissio, however, he was acknowledged king of Mycenae; but being tormented by the furies, a punishment which the ancients always thought followed particide, he called himself toArgos, where he was still pursued by the avengeful goddess. Apollo, however, purified him, and he was acquitted by the unanimous opinion of the Areopag, &c., whom Minerva herself instituted on this occasion, according to the narration of the poet Æchylus, who figures the Athenians in his tragic history, by representing them as passing judgment even upon the gods themselves. According to Pausanias, Orestes was purified of the murder, not at Delphi, but at Truzaea, where still was seen a large stone at the entrance of Diana's temple, upon which the ceremonies of purification had been performed by nine of the principal citizens of the place. There was also at Mopsuestia, in Arcadia, a temple dedicated to the furies near which Orestes cut off one of his fingers with his teeth in a fit of frenzy. These traditions are confuted by Euripides, who says that Orestes, after the murder of his mother, consulted the oracle of Apollo at Delphi, where he was informed that nothing could deliver him from the persecutions of the furies, if he did not bring into Greece Diana's statue, which was in the Taurica Chersonesus, and which as it is reported by some, had fallen down from heaven. This was an arduous enterprise. The king of Chersonesus always sacrificed on the altars of the goddesses of Latium, which had given her birth. She even interested herself in their misfortunes, and offered to spare the life of one of them, provided he would convey letters to Greece from her hand. This was a difficult trial; never was friendship more truly displayed according to the words of Ovid, ex Pont. 3, el. 2.

At last, however, Pyladen gave way to the pressing intreaties of his friend, and consented to carry the letters of Iphigenia to Greece. These were addressed to Orestes himself; and therefore these circumstances soon led to a discovery of the connexions of the prielefs with the man whom she was going to immediate. Iphigenia was convinced that he was her brother Orestes; and when the cause of their journey had been explained, he was reconciled with the two friends to fly from Chersonesus, and to carry away the statue of Diana. Their flight was discovered, and They prepared to pursue them; but Minerva interfered, and told him that all had been done by the will and with the approbation of the gods. Some imagine that Orestes came to Capadocia from Chersonesus, and that there he left the statue of Diana at Cusiana. Others contradict this tradition; and Pausanias thinks that the statue of Diana's Orthia was the same as that which had been carried away from the Chersonesus. Some again suppose that Orestes brought it to Arcia in Italy, where Diana's worship was established. It was after this that Orestes ascended the throne of Argos, where, he reigned in perfect security, married Hermione the daughter of Menelaus, and gave his seat to his friend Pyladen. The marriage of Orestes with Hermione is also a matter of dispute among the ancients. All agree that she had been married to the son of Agamemnon; but Menelaus had married her to Neoptolemus the son of Achilles, who had shown himself to truly interested in his cause during the Trojan war. The marriage of Hermione with Neoptolemus displeased Orestes; he remembered that
she had been early promised to him; he was therefore determined to recover her by force or artifice. This he did by procuring the affinities of Neoptolemus. According to Ovid's epistle of Hermione to Orestes, Hermione had always been faithful to her first lover, and even it was by her persuasions that Orestes removed her from the house of Neoptolemus, for she was dissatisfied with the partiality of Neoptolemus for Andromache, and her attachment for Orestes was increased. There are, indeed, various opinions likewise about this; he, however, certainly had to secure her affections, and retired to his kingdom of Argos. His old age was crowned with peace and security, and he died in the 90th year of his age, leaving his throne to his son Tifamas by Hermione. Three years after the Heraclids recovered the Peloponnesus, and banished the descendants of Menelaus from the throne of Argos. Orestes died in Arcadia, as is shown by the bite of a serpent; and the Lacedaemonians, who had become his subjects at the death of Menelaus, were directed by an oracle to bring his bones to Sparta. They were some time after discovered at Teges, and his statue appeared to be seven cubits, according to the traditions mentioned by Herodotus and others. The friendship of Orestes and of Pylades became proverbial; and the two friends received divine honours among the Scythians, and were worshipped in temples.

ORFA, a considerable town of Diarbeck in Asia, very pleasantly situated, pretty large, and well fortified. It formerly belonged to Persia; but is now in the Turkish dominions, and is a place of very good trade. It has a flatlye castle standing on a hill which makes a great show at a distance. They pretend to show the well where Rachel watered her father's camels when Jacob met her, and they call it Romah's well. E. Long. 35. 45. N. Lat. 36. 40.

ORFORD, a town of Suffolk in England, 88 miles from London, situated between two channels where the river Ore, after having joined the Alde, falls into the sea. It was once a large populous town, with a castle of which, and of a nunnery near the quay, there are still some ruins. The towers of the castle and its church are a sea-mark for colliers, coalers, and ships that come from Holland. There is a light-house at Orford-Neeld, which is also of great use to seamen, and is a lighter for them when the north-east wind blows hard upon the shore. The town was incorporated by Henry III, has a mayor, 18 port­ men, 12船 barges, a recorder, a town clerk, and two Burgess' at once. Though it lent members to parliament in the 26th of Edward I., yet it had no more elections till the reign of Edward IV. It still send two members to parliament, and has the title of an ordean. There are still remaining the ruins of an knoly abbey, where the Sarum nuns used to prey for the safety of their husbands. The town is now very mean, and no one contends for an interest in it, but such as want to make themselves a merit in the choice of the two members it returns to parliament. It has indeed, by the withdrawal of the sea, been deprived of its chief advantage, nor it now deserves not the name of a harbour. It had the honour to give title of Earl to the boy a.m. 1 Raffel, who, after being many years extinct, was revived in the person of Sir Robert Walpole, whose grandson now enjoys it.

E. Long. 1. 33. 5. Lat. 52. 15.

ORGAGNA (Andrea), an excellent Italian painter, was born at Florence in 1539. In his youth he learned sculpture; he was also a poet and an architect. He had a fruitful genius and his manner resembled that of the other painters of his time. Most of his works are at Pisa. The most admired of them is his picture of the Last Judgment, in which he painted his friends among the blessed, and his foes in hell. He died in 1589.

ORGAL, among dyers, denotes the lees of wine dried.

ORGAN, in general, is an instrument or machine designed for the production of some certain action or operation, in which tend the mechanic powers, machines, and even the veins, arteries, nerves, muscles, and bones of the human body, may be called organ.

Organ, in muttie, denotes the largest and most harmonious of all wind instrum mts; on which account it received the organ appellation, the instrument by way of excellence, chiefly used for playing a thorough bass, with accompaniments.

That organs are the invention of remote antiquity has been argued and seems now to be generally allowed; but the particular time and country in which the discovery was made appears to be lost amid the ruins of time. In ancient authors there are a variety of passages where mention is made of the organ, but it is at least possible that an instrument so similar to what we now possess is much different from that which now goes by the same name. From St. Augustine's commentary on the 4th verse of the 150th Psalm we learn, that the Greeks had another name for these instruments in which bellows were employed; that the name organ was appropriated to this particular instrument merely from the usage of the Latin tongue; and that it was inartently given to all instruments used to accompany the voice in concert. We mention this, not because we doubt of the antiquity of the organ, but merely to show that the time of its invention cannot be determined by the era of the authors where its name occurs. As the following obloquy, extracted from a periodical work, Gent. Mag., which has long been in defunct esteem with the public, are intended to ascertain its early use, we omit it, without commentary, to the judgment of our readers. Calledanus has described our organ in a few words, lib. 1. Epit. 45. Praising that art, which makes Organum extrinseca mus in sinis, et organi flatus complet, as magna poëtae one scence. And the emperor Julian has given an actual description of it in an epigram, which may be found in the Anthologia b. i. ch. 86. In his time these instruments were in such request, that Annius Marcellus, b. xiv. ch. 6, complains that they occasioned the study of the sciences to be abandoned. However, those musical instruments whose melody is produced by wind, had been known at Rome long before. Witness that admirable poem of Cape, which for its elegance has been ascribed to Virgil; where we find that the museh introduces the wind into her pipes; means of a pair of bellows, which he holds under her arm and blows. In the hydraulic organ, the water moves the air contained in the bellows to a height, as Cornelius Severus, in his Ethn., has given a correct description.
Orran. description of it. And though there were two kinds of hydraulic and pneumatic instruments, the first of which played by the inspiration and action of bellows, and the others by the action of water, it is certain nevertheless, that both of them were pneumatic, being inspired by the wind. And Heron of Alexandria, in his Pneumatics, has treated of hydraulics as belonging to pneumatics. This Heron lived in the time of Ptolemy Euergetes, king of Egypt. When Suetonius says, that Nero Organum aquae novi et ignot generis circumcidit, he did not mean that they were unknown at Rome before Nero, but that those of Nero were of a new construction. Those were the hydraulics of a new fabric, which he exhibited to the people at the public games, as Suetonius relates a little after. Heliogabalus, one of the worthy successors of Nero, like him was fond of these hydraulics; and Alexander Severus, his cousin and successor, had the same inclination. Claudian, who lived some time after, has left us this elegant description of them:

Et qui magni huius dextrae murura taud
Innumerous vox societas mod natura aenea;
Intonent errantes liquidae penitentiae trabali
Vox laevantis in carmina conedit undas.

This very construction which is observed in the pipes of an organ, gradually decreasing in magnitude, has been represented in an epigram of Optatianus Porphyrius who lived in the time of Constantine. This epigram, which is quoted in Pithon’s collection of ancient epigrams, is composed of verses of an unequal length, successively increasing. This corresponds with those words of the old scholiast on Juvenal, Sat. 8. ver. 270. Tuncis Galli usitatrices in faecis in modum organi utrinque dcrefcentibus virgults purpureis.

On the whole, then, the antiquity of organs, or of instruments of a very familiar nature, can scarce be disputed; but nothing so particular respecting the time, place, or manner, of the invention can possibly be determined from those incidental observations which occur in the writings of the ancients. It appears indeed to have been borrowed by the Latins from the Greeks, but not to have been in general use till the eighth century: and it has been affirmed, that, in France, it was not known till the time of Louis the Debonair, a. d. 815, when an Italian priest taught the use and construction of it, which he himself had learned at Constantinople. By some, however, it has been carried as far back as Charlemagne, and by others as far as Pepin. Bellarmine says that the organ began to be used in the service of the church about the year 660, as Plantina relates out of the Pontificial; for when Pope Vitalian reformed the singing of the Roman church, he added to it organs in order to support and embellish it. Ammonius thinks, however, that this happened after the year 820, in the time of Louis the Pious. Perhaps the learned Bingham is our safest guide in determining this point. He positively asserts that there were no such things as organs in use in the ancient church; nee sancta and that though church music was as old as the apostles, instrumental music was not so. He also says that it was the general opinion of the learned in his days, that organs were not introduced into churches till after the time of Thomas Aquinas, A. D. 1250; and for this opinion, as far as the authority of Aquinas will go, we have a positive proof; for in his suicides we find these words: “Our church does not use musical instruments, as harps, and psalteries, to praise God withal, that she may not seem to Judaize.” From

\(\text{(a)}\) Which is thus translated by Mr Jabez Hughes:

- As in an organ*, first the rushing air
- A mass of waters does before it bear;
- And then the waters, in their turn we find
- Drive through the hollow pipes the vanquished wind;
- Which strongly from its frail confinement tent,\n- Comes loudly rattling through the narrow vent;
- Still as the waters press, the spirits sound,
- And spread the building symphony around.
- So air and water meet; &c.

It is by no means certain that Cornelius Severus was the author of this poem, though it is published under his name by Le Clerc. Seneca’s authority, on which the younger Scaliger founds his opinion, enforces no such conclusion. He only says, that “Severus was not discouraged from writing on this subject, by its having been already treated by Ovid and Virgil. Barbinius, in his aceta on Claudian, refers it to Manilius, and in his Adversaria to some Christian writer. By others it has been ascribed to Virgil, and by Scaliger, the father, to Quintilius Varus. But though it is less clear and methodical than Virgil, and though it has been much mutilated by time, it certainly was penned by a masterly and truly poetical mind.

\(\text{(b)}\) Vitruvius describes an organ in his 10th book, and St Jerome mentions one with 12 pair of bellows which might be heard a thousand paces, or a mile; and another at Jerusalem, which might be heard at the Mount of Olives.

\(\text{(c)}\) The lawfulness of using organs in churches, has, however, been ably defended by an appeal to the use which the Jews made of instruments of music in divine service; and with much reason; for were the use criminal in us, as was asserted by many well meaning men of the last century, and as it is still thought by some in this, it would unquestionably have been equally unlawful for the Jews. The Christians, in Aquinas’s time, however, acted wisely in avoiding the use of them, if by so doing they would have given offence to their weaker
From hence it has reasonably been concluded, particularly by the learned Gregory *, that they were not used in churches in his time. Mr Wharton also observed that Marcius Saturnus (who flourished A. D. 1290) first introduced wind organs into churches; from this circumstance he derived the name Terellis, the name for organ in the Italian language. About the same time Durandus in his Rationals speaks of them as generally received in the church; and he, in Mr Gregory’s opinion, is the first author who takes notice of it. These authorities are strong, and the opinions founded on them by the learned reader them still more convincing; it appears, however, from the testimony of Gervas the monk of Canterbury, who flourished A. D. 1200, that organs were introduced upwards of 100 years even before that time: for in his description of Lanfranc’s church, as it was before the fire in 1174, he has these words, “Cruix afferlis supra fornix omnina gregare solutis.” We do not say that this invalidates the reasoning of the learned Bingham; of that our readers are to judge, and forming their judgments they will be determined by the credit of the testimonies which are here opposed to each other. If we suppose that of Gervas the strongest, and in opposition to the other conclude from it, that organs where introduced into England long before 13th century, it will give some countenance to an opinion which prevails pretty generally, viz. that in Italy, Germany, and England, they became frequent about the 15th century. See Music, p. 19. But however we are disposed to determine this matter (which in itself is but of little consequence), it is certain that the use of the organ was very common in the latter ages of the church, and the propriety of it was undisputed. In the last century, however, during the civil wars, organs were removed from the churches in England; and so generally reporated, that at the Restoration, there could scarce be found either organists, organ builders, or fingers (b).

The organs in Germany (says Dr Burney in magnitude, and the organists in abilities, seem unrivalled in any other part of Europe, particularly in the use of pedals. In Marpurg’s Essay, vol. iii. there is a minute account of a variety of organs in Germany; of all which the longest pipe of the manuals is 16 feet long, and of the pedals 32. One of the largest organs in Germany, but which Marpurg has omitted in his list, is at Gorlitz in Upper Lusatia. It would be no purpose to enlarge our article with a mere minute account of the state of organic music in different parts of the world: in various parts of the article Music, observations connected with this subject will be found, and to that we must refer. We may particularly mark, for the perusal of those who wish for further information on this subject, in addition to n. 19, above referred to, several passages of the article Music, beginning at p. 492. We need scarcely refer to the life of Handel, which all our readers who are fond of music of any kind, particularly sacred, have undoubtedly perused.

The church organ consists of two parts: the main-body, called the great organ; and the positive or little organ, which form a small case or buffet, commonly placed before the great organ. The size of an organ is generally expressed by the length of its largest pipe: thus they say, an organ of 8, 16, 32, feet, &c. The organ in the cathedral church at Ulm in Germany is 93 feet high and 28 broad: its largest pipe is 15 inches in diameter, and it has 96 pairs of bellows.

The several parts of the church organ are as follow. H: H is the sound-board; which is composed of two parts, the upper board or cover HH, and the under CCCLXV. board H, which is much thicker than the other; f. t. each of these consists of several planks laid with their edges to each other, and joined very close together. Upon the under side of the upper board there are made several channels, which run in the direction LL, MM, &c. and are continued as far as there are stops in the organ, and come almost to the edge HK. These channels are covered over very close with parchment or leather all the way, except a hole that is commonly at the fore-end next HK, upon which a valve or plug is placed. These channels are called partitions. When this valve or flap is shut, it keeps out the air, and admits it when open. On the upper side of the lower board there are likewise cut several broad square channels, lying cross the former, but not so deep as to reach them; these lie in the direction LN, PQ, &c. To fit these channels, there are the same number of wooden sliders or regillers f, f, &c. running the whole length; and these may be drawn out or thrust in at pleasure. The number of these is the same as that of the stops in the organ.

IKKK is the wind-chest, which is a square box fitted close to the under side of the lower board, and made air-tight, so that no air can get out but what, goes through the valves along the partitions.

VV are the valves or plugs which open into the wind-chest: they are all included in it, and may be placed in any part of it, as occasion shall require. One of these valves, with the spring that shutts it, and the wire that opens it, is represented by fig. 2.

C, D, E, F, &c. are the keys on which the fingers are placed when the organ is played: these keys lie over the horizontal bar of wood W, in which are stuck an equal number of wire-pins x, x, on which keys are fixed: and the keys move up and down on the bar, as on a centre. There is another bar, against which the keys fall when put down, and which is here marked 3: on this also are several wires, which go through the keys, to guide them; and on this bar a lift is fastened weaker brethren. For though they are highly ornamental, and in some churches may be productive of good effects, yet the use of them is far from being essential, and may be easily dispensed with.

(b) Organs have never yet been used in the establishment of Scotland, since that became Presbyterian; but they are used in Holland, where that form of church government also obtains. Bishop Horne, in a sermon, which he preached at the opening of the new organ at Canterbury in 1784, says that he believes some Presbyterian dissenters in England have adopted it in their places of worship. See his Sermon, page 8.
The pipes are of pewter, of lead mixed with a twelfth part of tin, and of reed. Those of pewter are always open at their extremities; their diameter is very small, and their sound very clear and thrill. Those of lead mixed with tin are larger; the shortest are open, the longest quite stopped; those of a mean size are partly fig ped, and have before a little ear on each side of the mouth, to be drawn closer or set further asunder in order to raise or lower the found. The wooden pipes are square, and their extremity is stopped with a valve or tampon of leather. The found of the wooden and leaden pipes is very soft; the large ones stopped are commonly of wood, the small ones of lead. The longest pipes give the greatest found, and the shortest the mott acute; their lengths and widths are determined by a fixed proportion to their founds; and their divisions are regulated by a rule, which is called the dispars. The longest has commonly 16 feet; but in very large organs it has 32 feet. The pedal tubes are always open though made of wood and of lead. Whatever note any open pipe founds, when its mouth is stopped it will found an octave lower; and a pipe of twice its capacity will lead found an octave lower.

A reed-pipe consists of a foot AABB (fig. 4.) that carries the wind into the flue or reed CD, which is a hollow demi cylinder fixed at its extremity D, into a sort of mould, by a wooden tampon G. The flue is covered with a plate of copper KKLL, fitted at its extremity II, into the mould, by the same wooden tampon. Its other extremity KK is at liberty; so that the air entering the flue makes it tremble or shake against the reed; and the longer that part of the tongue IL, which is at liberty, is made, the deeper is the found. The mould II, that serves to fix the flue or reed, the tongue, tampon, &c. serves also to stop the foot of the pipe, and make the wind go out wholly at the reed. Lastly, in the mould is bored the tube HH, whose inward opening is a continuation of that of the reed; the form of this tube is different in different ranks of pipes. The degree of acute ness or gravity in the found of a reed pipe, depends on the length of the tongue, and that of the pipe CK, taken from the extremity of the flue to the extremity of the tube. The quantity or intention of the found depends on the width of the reed, the tongue, and the tube; as also on the thickness of the tongue, the figure of the tube, and the quantity of wind. To diversify the founds of the pipes, a valve is added to the port vent, which makes the wind go out in fits or flashes. In fig. 1. X represents a flute-pipe of wood, Z a tube pipe of metal, Y a trumpet-pipe of metal. The pipes, to prevent them from falling, pass through holes made in boards, placed upon the upper board.
communication is stopped, so that no wind can get to the pipe.

To every large organ there must be at least two pair of bellows, which are marked in fig. 1. by TU, TV, OO, are the handles, moving upon the axis n n, n n. Each of these bellows consists of two boards, the lowest of which is immovable; and in this there is a valve r, opening inwards, and a tube leading to it called the conveying tube. There is also a hole in this under board, from which a tube leads to the port-vent, which is a square tube marked s, rising upward, and entering into the under side of the wind-chest at s. In the tube leading to the port-vent, there is a valve that opens towards the port-vent, and allows the air to go up the port-vent, but not to return. Now the handle being pulled down, raises the upper board T, and the air enters through the valve r; and when the handle is let go, the weight of the upper board, which carries three or four pound to every square foot, continually descending, drives the air through the port-vent to the found board: and as the bellows work alternately, one pair is constantly descending, which occasions a continual blast through the port-vent. In chamber-organs there is but one pair of bellows; but they are formed of three boards, in the manner of a smith's bellows, and to have a continual blast. All the internal structure of the organ is concealed from the sight by the front of the instrument, which stands upon the part between the numbers 3 and 6 (fig. 1.)

In every organ the number of partitions LL, MM, &c. there are in the found-board (fig. 1.) that of the valves NN, that of the rollers ss, or of the levers yy or 8 9 and their wires, and that of the keys ABC, &c. must be always equal. Large organs have commonly four or five sets of keys, besides those that belong to the pedals or large pipes, the flue pipes which are played by the feet; and to be the invention of Bernhard, a German, about the year 1400. The command certain pipes, which, to increase the harmony, are turned below the diapason. The keys of an organ are usually divided into four octaves; the first sub-octave, second sub-octave, middle octave, and fifth octave. Each octave is divided into 12 flutes or reeds, of which seven are black and five white; the former mark the natural notes, and the latter the artificial notes, that is, flats and sharps. The number of keys, therefore, when there are four octaves, must be 48. Some organs add one or more flutes to the first and second sub-octave. The pedals have two or three, or that of the organist, so that the number of flutes is indeterminate. The keys are placed between SS (fig. 1.), but the scheme could not contain them all. There are also as many handles l, h, &c. rollers RR, &c. flules s s, f f, &c. as there are flutes upon the organ; and it must be observed, that between the flules s s, f f, &c. there are as many flutes on the right hand, and the same number of handles and rollers, and other rows of pipes placed between LN, PQ, which could not be expressed in the figure.

The lead pipes and partitions are placed toward the middle of the organ, and the greatest on the outside. The flutes of an organ have various denominations, according to the sounds they are to produce; some of which are diapason, principal, fifteenth, twelfth, treble, cornet, trumpet, French horn, vox humana, flute, bag-

When this magnificent instrument is played, the handle O of the bellows is first put down, which raises the upper board T, and gives room for the air to enter by the valve r. Then the other handle O is put down; in the mean time the board T, belonging to the first handle, descending, and fluttering the valve r drives the air through the other valve, up the port-vent, and into the wind-chest. Then drawing out any handle, as that of the flute-stop s, which draws out the slider g g, all the pipes in the set LN are ready to play, as soon as the keys C, D, E, &c. are put down; therefore if the key D be put down, it opens the corresponding valve m v, through which the air enters into the pipe X, and makes it sound. In the same manner any other pipe in the set LN, will sound when its key is put down; but no pipe, in any other set, will sound till the slider be drawn out by its corresponding handle.

Among the modern improvements of the organ, the most remarkable are the swell and the tremulant: the former, invented by an English artist, consists in a number of pipes placed in a remote part of the instrument, and inclosed in a kind of box, which, being gradually opened by the pressure of the foot, increases the found as the wind does the found of a peal of bells, or suppleys the like manner by the contrary action. The tremulant is a contrivance by means of a valve in the port-vent or passage from the wind-chest, to check the wind, and admit it only by flats; so that the notes pass to the flutes, and the whole instrument to fobs, in a manner very offensive to the ear. There is a tremulant in the organ at the German chapel in the Savoy. See Hawkin's History of Music, and Burney.

Hydraulic Organ, denotes a musical machine that plays by water instead of wind. Of these there are several in Italy, in the grottos of vineyards. Cleopatra of Alexandria, who lived in the time of Ptolemy Euergetes, is said to have invented organs that played by compressing the air with water, as is still practised. Archimedes and Vitruvius have left us descriptions of the hydraulic organ.

In the cabinet of Queen Christina is a beautiful and large medallion of Heimolan, on the reverse whereof is seen one of these hydraulic organs; with two men, one on the right, the other on the left, leaming to pump the water which plays it, and to listen to its found. It has only eight pipes, placed on a round pedestal. The inscriptions is placea spectacul, if it be not wrong copied, which is subject to be the cafe.

Orgasmus extota, denoting violence or turbulence; formed from οργή, anger, "I swell," an effusive or impetuous desire of coition, occasioned by a turbulence of the seminal vessels, which are no longer able to restrain their contents. The ancients also ex-
tend organs to the other humours, and even excrements, which being accumulated, and coming to ferment, demand excretion. Quincy uses organ for an impetuous or too quick motion of the blood or spirits; whereby the muscles are distended with an uncommon force.

ORGIA, feasts and sacrifices in honour of Bacchus, held every third year, and chiefly celebrated by wild disoriented women, called Bacche. The chief solemnities were performed in the night, to conceal, perhaps their shocking impurities; and a mountain was generally chosen as the place of celebration. They were instituted by Orpheus; and from him are sometimes called Orphica. Authors are not agreed as to the derivation of the word; but if we consider the frantic proceedings of the Bacchanalians, *ejus*, *fius* lids fair for the true etymology. See Bacchanalia.

Orgia, according to Servius, was a common name for all kinds of sacrifices among the Greeks, as ceremonies was amongst the Romans.

ORGUES, in the military art, are thick long pieces of wood, pointed at one end, and shod with iron, clear one of another; hanging each by a particular rope or cord, over the gateway of a strong place, perpendicularly, to be let fall in case of the approach of an enemy.

Orgues are preferable to hercules, or gun-cylinders, because these may be either broke by a petard, or they may be stoped in their falling down; but a petard is useless against an orgue; for if it breaks one or two of the pieces, they immediately fall down again and fill up the vacancy; or if they stop one or two of the pieces from falling, it is no hindrance to the rest; for being all separate, they have no dependence upon one another.

Orgues, is also used for a machine composed of several harquebuses or musket barrels bound together, in place of several explosions are made at the same time. It is used to defend breaches and other places attacked.

ORYX, *oryx*, an ancient Grecian measure containing six feet.

ORIBASIA, in botany: A genus of the monogynia order, belonging to the pelandria class of plants; and in the natural method ranking under the 47th order, *Stella* a. The corolla is small, tubulated, and monopetalous. The pericarp is a globular berry, grooved longitudinally; is quinquilocular, and contains one seed. Of this there are six species, all natives of the warmer parts of America, viz. 1. Oficinalis: the natives of Guiana make infusions of the leaves, and use them in cases of spasmotic affections. 2. Racemosa. 3. Violacea. 4. Lutea. 5. Paniculata. 6. Longiflora. The habit of all these plants resembles that of Physicaria.

ORIVASUS, a celebrated physician greatly esteemed by the emperor Julian, in whose reign he flourished. He abridged the words of Galen, and of all the most respectable writers on phytic. This was done at the request of the emperor. He accompanied Julian into the east, but his skill proved ineffectual in attempting to cure the fatal wound which his benefactor had received. After Julian's death he fell into the hands of the barbarians.

ORICHALCUM, or aurichalcum, a metallic substanse resembling gold in colour, but very inferior in value. It was well known to the old Romans, who often took advantage of its resemblance to gold; for some sacrilegious characters, who could not rest the temptation of taking gold from temples and other public places, chose to conceal their guilt by replacing it with orichalcum. It was thus Julius Caesar added when he robbed the capital of 5000 pound weight of gold; in which he was followed by Titellius, who defaced the temples of their gifts and ornaments, and replaced them with inferior metal. It has been a matter of dispute with philosophers and others, what this metal could be, or how it was procured or made; it is probable at least that it was a greatly analogous to our brass, if not wholly the same with it. (See Brass) The value of our brass is much less than that of gold, and the resemblance of brass to gold, in colour, is obvious at first sight. Both brass and gold, indeed, are susceptible of a variety of shades of yellow; and if very pale brass be compared with gold, mixed with much copper, such as the foreign goldsmiths, especially, use in their toys, a disparity may be seen; but the nearness of the resemblance is sufficiently ascertained in general, from observing that substances gilded with brass, or as it is commonly called Dutch leaf, are not easily distinguished from such as are gilded with gold leaf.

The Romans were not only in possession of a metallic substance, called by them orichalcum, and resembling gold in colour, but they knew also the manner of making it, and the materials from which they made it were the same from which we make brass. There are, indeed, authors of great repute who think very differently; and who consider the art of making brass as an invention wholly modern. Thus M. Cronfodt does not think it just to conclude from old coins and other antiquities, that it is evidently proved that the making of brass was known in the most ancient times; and the authors of the French *Miners* Encyclopédie assure us, that our brass is a very recent invention (a). It appears, however, from Pliny's Nat. Hist. lib. xxxiv. § 2. and from the concurring testimony of other writers, that orichalcum was not a pure or original metal; but that its basis was copper, which the Romans changed into orichalcum by means of cadmia, a species of earth which they threw upon the copper, and which is absorbed. It has indeed been contended that the cadnia of Pliny was native arsenic, an opinion which scarcely merits confutation, but which must appear extremely groundless, when we reflect that it is impossible to make either brass or copper from arsenic, and that Pliny expressly calls it a stone from which brass was made. The testimony of Ambrose

(a) Art Orichalque—"The vessels here called brazen, after ancient authors, cannot have been of the materials our present brass is composed of; the art of making it is a modern discovery." See Laugborn's Hist. of Ancient Egypt, p. 58.
The most extraordinary copper is called orichalcum, or white copper: it is white when dug out of the mine, and still more white within than without. It appears by a vast number of experiments made at Peking, that its colour is owing to no mixture; on the contrary all mixtures diminish its beauty; for, when it is rightly managed, it looks exactly like silver: and were there not a necessity of mixing a little unction, or some such metal with it, to soften it and prevent its brittleness, it would be so much the more extraordinary, as this sort of copper is perhaps to be met with nowhere but in China, and that only in the province of Tun naa.

Notwithstanding what is here said of the colour of this copper being owing to no mixture, it is certain that the Chinese white copper, as brought to us, is a mixed metal; so that the ore from which it is extracted must consist of various metallic substances, and from some such ore it is possible that the natural orichalcum, if ever it existed, may have been made. But notwithstanding that the existence of natural orichalcum cannot be shown to be impossible, yet there is some reason to doubt whether it ever had a real existence or not.

We know of no country in which it is found at present; nor was it any where found in the age of Pliny; nor does he seem to have known the country where it ever had been found. He admits, indeed, its having been formerly dug out of the earth; but it is remarkable that in the very passage where he is mentioning by name the countries most celebrated for the production of different kinds of copper, he only says in general, concerning orichalcum, that it had been found in other countries, without specifying any particular country. Pliny acknowledges, that orichalcum was a thing only talked of even in his time; it was nowhere then to be met with, though in the island of Atlantis it had been formerly extracted from its mine. The Greeks were in possession of a metallic substance, called orichalcum, before the foundation of Rome; for it is mentioned by Homer and by Hesiod, and both of them in such a manner as shows that it was then held in great esteem. Other ancient writers have expressed themselves in similar terms of commendation; and it is principally from the circumstance of the high reputed value of orichalcum that authors are induced to suppose the ancient orichalcum to have been a natural substance, and very different from the fictitious one in use at Rome, and probably in Asia, and which it has been shown was nothing different from our brass.

But this conclusion cannot be validly drawn from their encomiums upon it; for at whatever time the method of making it was first discovered, both its novelty and scarceness, joined to its utility, would enhance its value; at least there can be no absurdity in supposing, that when first introduced it was greatly prized, even though it be granted that it possessed no other properties than such as appertain to brass.

Respecting the etymology of the word there is great diversity of opinions. Those who write it auricolcnum think it is composed of the Latin word aurum, "gold," and the Greek οριχαλκος "brass or copper." The most general opinion is, however, that it is composed of ρηξ, "a mountain" and οριχαλκος, alluding perhaps to its being found in mountains or mountainous countries. The above account is chiefly extracted from a paper in the second volume of memoirs of the Literary and Philosophical Society of Manchester, written by the present Bishop of Launda, Dr. Watson, and communicated by Dr. Pervical. To this paper then we refer our readers who desire a more copious account of it. To the above two etymological meanings of the word we shall subjoin the following, mentioned by the learned bishop, and which, in our opinion is equally well founded, and certainly as ingenious as the other two.

The Hebrew word Or, Αυρ, signifies light, fire, flame: the Latin terms oro, "to burn," and aurum, "gold," are derived from it, insomuch as gold resembles the colour of flame: and hence it is not improbable, that orichalcum may be composed of an Hebrew and a Greek term, and that it is rightly rendered, flame-coloured copper. In confirmation of this it may be observed, that the Latin epithet luminis, and the Greek ωμως, are both applied to orichalcum, by the ancients.

ORIFICE, the mouth or aperture of a tube, pipe, or other cavity.

ORIGANUM, ORIGANY, or Marjoram: A genus of the gymnosophia order, belonging to the diaphania class of plants; and in the natural method ranking under the 42d order, Verticillatae. There is a fibroiliis or cone shaped the calyces together. The principal species are, two hardy perennials and an annual for the open ground, and five perennials for the green house: viz. 1. The vulgar, or wild pot marjoram; 2. The heracleoticum, or winter sweet marjoram. These are finely scented aromatics, excellent for culinary purposes, particularly for broths, soups, &c. They have likewise merit for medical uses, and for giving fragrance to ointments; so that the plants are proper both for kitchen and physic gardens, and may also be employed in the pleasure ground as plants of variety. 3. The marjorana, or annual sweet marjoram,
oriental is an aromatic of the highest fragrance, is admirable for kitchen use, and excellent for nosegays; so is proper both for the kitchen and pleasure garden, but more particularly for the former. It is often called knotted marjoram, from the flowers growing in close knotted-like heads. The following mostly assume an underfrubby growth; frequently with abiding stalks, if they have shelter here in winter. 4. The dicranus, or dittany of Crete. 5. The fyniculum or originam of mount Sipus. 6. The creticum, or Cretan origany. 7. The fynana, or Smyrna originam. 8. They Egyptian, or Egyptian origany. All these eight species of originum flower in July and August; the flowers are small, monocapetalous, ringer, universally hermaphrodite, and collected into verticilli round the stalks; succeeded by ripe seed in autumn; though in this country the annual marjoram and the three green-house sorts seldom perfect seed well unless the autumn proves remarkably fine and warm; in default, however, of seed, the propagation of all the perennial sorts, both hardy and green-house kinds, is easily affected by slips of the roots, &c. And the seed of the annual sort is imported plentifully from France or Italy by the seed dealers.

ORIENT, a harbour of France, in the province of Bretagne, in the bottom of the bay of St Lewis. Since the year 1720, a handsome town has been built here, where the East India company have large magazines. The English attempted to become masters of it in 1546, but miscarried. W. Long. 3. 22. N. Lat. 47. 45.

ORIENTAL PHILOSOPHY. See Philosophy.

ORIGEN, one of the most celebrated ecclesiastical writers, greatest geniuses, and most learned men of the primitive church during the third century, was born at Alexandria in the year 185; and was named Adamantius, either from his indefatigable application to study, or from the firmness he discovered amidst the torments he suffered for the faith. Leonidas his father trained him at home with great care, and made him apply to the study of the Holy Scriptures from his infancy, in which he made surprising progress. The son’s inclination and turn suited exactly with the father’s design; for he pursued his studies with a most extraordinary zeal and ardour; and, being ended with a quick apprehension and a strong imagination, did not content himself, with that sense which at first presented itself, but farther endeavoured to dive into mystical and allegorical explanations of the sacred books. He would sometimes even puzzle his father, by too much soliciting his father, by too much soliciting his; which obliged the good man to reprehend him a little, and wishal to advise him not to attempt to penetrate too far in the study of the holy scriptures, but to content himself with their most clear, obvious, and natural sense. Hence it appears, how early he was feign with that furor allegoricus, as a learned modern calls it, that rage of expounding the scriptures allegorically, which grew afterwards even to a dilettante, and carried him to excesses which can never be executed (A). He had afterwards in philosophy Ammonius the celebrated Chaldean philosopher, and St Clement of Alexandria for his master in divinity. At 18 years of age he succeeded that great man in the office of catechist; an important employment, which conformed in teaching divinity, and expounding the scriptures. Leonidas his father had suffered martyrdom the year before during the persecution of Severus in 202; and Origen had shown such eagerness to follow his father to martyrdom, that his mother was obliged to hide his clothes to prevent his going abroad. Origen had a great concourse of auditors who attended his school, some of whom were of the faithful, and the others pagans. He confirmed and strengthened the faith in their faith, and converted most of the others; and there were such a number of martyrs amongst his disciples, that it might be said, that he kept rather a school of martyrdom than of divinity. He taught the doctrines of Christianity to the girls and women as well as to the men; and taking in a too literal sense what Christ says of becoming voluntary eunuchs, castrated himself, to prevent his deferring or suffering scandal. He took a voyage to Rome in 211, in the beginning of Caracalla’s reign, and under the pontificate of Zepherinus. At his return he published many works, by which he acquired an extraordinary reputation, that drew to him a great number of auditors. But Demetrius, bishop of Alexandria, conceiving a jealousy of him, endeavoured by various pretences to injure him. At length Origen went to Antioch, whither the emperor Mammea had sent for him to hear him discourse on the Christian religion. He did not however stay long there, but returned to Alexandria, where he continued to teach till the year 228, when he left that city, and travelled into Achaia. In that journey he went into Palaestine, and was ordained by the bishops of that province at 42 years of age. His being ordained by foreign bishops without the permission of Demetrius, renewed that prelate’s resentment against him; on which Origen hastily returned to Alexandria, to endeavour to mollify him; but Demetrius drove him from thence in 231, and caused him to be excommunicated, and even deposed in a council held in Egypt. Origen then retired to Cæsarea.

(A) He is the first Christian (whose notions on this subject have come down to us) who believed in the restitution of all things. This is the first distinguishing tenet; to which is added this singular notion, that as Christ had been crucified in this world to save mankind, he is to be crucified in the next to save the devils. The other obnoxious tenets of Origen are these five: viz. 1. That in the Trinity the Father is greater than the Son, and the Son than the Holy Ghost. 2. The pre-existence of souls, which Origen considered as sent into mortal bodies for the punishment of sins committed in a former state of being. 3. That the soul of Christ was united to the world before the incarnation. 4. That the sun, moon, and stars, &c. were animated and endowed with rational souls. 5. That after the resurrection, all bodies will be of a round figure. It is probable that the mystic theology of the modern Quakers and other sects is derived from Origen. See Moflein. Eccl. Hist. vol. 10.
Origen, in Palestine, where he raised a celebrated school, and had St. Gregory Thaumaturgus, and a great number of other persons who were illustrious for their virtue and learning, for his discipules. He afterwards travelled to Athens; and then, at the advice of Firmianus, paid some time at Cesarea in Cappadocia, whence he was invited into Arabia, to convince and bring back to the truth Beryllus bishop of Bostra, who maintained that the Word had no existence before his incarnation. Origen had the happiness to make him sensible of his mistake; and some years after was sent for into Arabia by an assembly of bishops, to dispute against the Arabians, who maintained that the souls of the dead remained in a state of insensibility till the general resurrection. At length the seventh persecution of the Christians began in the reign of Decius, and none were used with greater severity than Origen. He supported with incredible constancy the dreadful torments which the persecutors of the Christians invented against them; torments that were the more infupportable, as they were made to continue a long time, and as they took the greatest care to prevent his expiring in the midst of his tortures: but in the midst of the most excruciating torments, he discovered an heroic courage, and suffered nothing to escape him that was unworthy a disciple of Jesus Christ. He died at Tyre, in 254, aged 69. He was the author of a great number of excellent works. The principal of those which have been handed down to us are, 1. A Treatise against Celius, of which Spencer has given a good edition in Greek and Latin, with notes: this learned treatise has been translated into French by Elias Bouhereau, a protettant minister, born at Rochelle. 2. A great number of Homilies, with Commentaries on the Holy Scriptures. 3. Philolectae, and several other treatises. 4. Fragments of his Hexaples, collected by father Montfaucnon, in two volumes folio. Of all Origen's books, the loss of the Hexaples is most to be regretted. The work was thus named from its containing six columns; in the first of which was the Hebrew text of the Bible; in the second, the same text in Greek characters; in the third, the Greek version of the Septuagint; in the fourth, that of Aquila; in the fifth, that of Symmachus; and in the sixth, Theodotion's Greek version. This admirable work gave the first hint for our Polyglot Bibles. 5. The Book of Principles; of which we have only an incorrect Latin version. In all his writings he discovers a surprising degree of modesty, candour, and humility; a noble and sublime genius, profound learning, and vast erudition. His manners were extremely pure, and he had a warm zeal for spreading the truths and morals of the gospel.

Much has been written both for and against this celebrated father, both by his cotemporaries and others: he has indeed suffered great abuse, which he did not deserve, and which we shall not retail; contenting ourselves with the following account of his character by Dupin, and some remarks on it by Dr. Jortin. "Origen (says Dupin) had very quick parts, a very strong and enlarged imagination; but he relied too much on the vivacity of his genius, and often left himself, out of too great eagerness to fatiate and subtilize every thing. He had a very happy invention, and a more happy delivery of what he invented; but he had not that exactness in his inventions, nor that gracefulness of delivery, as might be wished. He carried on his works with too great ease, that he is said to have dictated to seven or eight persons at a time; and he was so ready in expressing himself, that he made the greatest part of his homilies and treatises; upon which account his style was not very correct or coherent. He had a vail memory, but often trailed too much to it. He was a person of most profound learning: he particularly studied Plato's philosophy, and indeed was too much addicted to it for a Christian. He understood likewise the doctrines of other philosophers. He applied himself mightily to the study of human learning. He was neither ignorant of history nor mythology; and he had as great a knowledge in all the profane sciences, as those who studied nothing else. But he particularly excelled in the knowledge of the Holy Scriptures, which he learned all by heart; and that he might neglect nothing for attaining a right understanding of the letter thereof, he carefully examined all the versions of the Bible, and compared them all together with the Hebrew text, subjoining a literal commentary upon the most difficult places. He was not very well skilled in the Hebrew; yet he knew enough of it to understand it, and to observe the difference of the text and the translations. Nevertheless, he did not adhere to the literal explication of the Bible, but thought it necessary, for the sake of gaining it credit with the heathens, who despised its plainness and simplicity, and of rendering it more useful to the world, to give mythical and allegorical interpretations of every thing in it."

Dr. Jortin tells us, "That Origen was very learned Jortin's and ingenious, and indefatigably industrious. His Remarks, whole life from his early years was spent in examining, teaching, and explaining the Scriptures; to which he joined the study of philosophy and of all polite literature. He was humble, modest, and patient under great injuries and cruel tortures, which he received from Christians and Pagans: for though he ever had a considerable number of friends and admirers, on account of his amiable qualities and useful accomplishments, he was persecuted and calumniated by men, who had neither his learning nor his virtue, degraded from the order of presbyters, driven from his home, and excommunicated by one Demetrius bishop of Alexandria, who envied him, says Eusebius, for the reputation which he had gained. His inquisitive genius, and his mixing philosophy with Christianity, led him perhaps into some learned singularities and ingenious reveries; but he was too far from dogmatizing in such points, from fomenting schisms, and setting up himself for the head of a party. He lived in times when Christians were not so shackled with systems and determinations, as they were afterwards, nor so much exposed to difingenuous and illiberal objections; and had more liberty to pursue their inquiries and to speak their mind. He was ever extremely sober and exemplary, practicing what he preached to others; and he lived and died poor, and defitute even of common conveniences. The most complete edition of his works is that of Father Delarue, a Benedicite, in Greek and Latin. The celebrated Montfaucnon likewise published, in 2 vols folio, some remains and fragments of his Hexapla."
I. Bonae, a Platonic philosopher, and the disciple and friend of Porphyry, who studied philosophy under Ammonius; perhaps this Origen was the founder of the Origenians.

Origenians (Origeniani), ancient heretics, who even surpassed the abominations of the Goths.

Epicureans speak of them as subsisting in his time; but their numbers, he says, were inconsiderable. He seems to fix their rise about the time of the great Origen; but does not say that they derived their name from him. On the contrary, he distinguishes them from the Origenists, whom he derives from Origen Adalmarius; adding, indeed, that they first took their name from one Origen; by which he intimates, that it was not the great Origen. And St Augustine expressly affirms, that it was another. Their doctrines were shameful: they rejected marriage; they used several apocryphal books, as the acts of St Andrew, &c. and endeavoured to excuse their open crimes, by saying, that the Catholic did the same in private.

Origenists, in church-history, a Christian sect in the fourth century, so called from their drawing their opinions from the writings of Origen. The Origenists maintained, that the souls of men had a pre-existent state; that they were holy intelligences, and had dwelt in heaven before the body was created; that Christ is only the son of God by adoption; that he has been successively united with all the angelic natures, and has been a cherub, a seraph, and all the celestial virtues one after another; that, in future ages, he will be crucified for the salvation of the devils, as he has already been for that of men; and that their punishment, and that of the damned, will continue only for a certain limited time.

Original, a first draught or design of any thing, which serves as a model to be imitated or copied.

Original Sin, the crime of eating the forbidden fruit, of which, it is said, all mankind are guilty at their conception, by the imputation of Adam's transgression; which is accounted for by supposing, that Adam, as he was to be the father, was also the federal head and representative, of the whole human race: and that, on his sinning, all that were to spring from him partook of his crimes. See Theology, &c.

Origuela, a town of Spain in Valenia. It is seated between the mountains on the banks of the river Segura, in a place fortified by nature, and in a fertile plain, abounding in all things, especially corn. It is surrounded with pleasant gardens, and has an university and a bishop's see. It is defended by an old castle; and is the capital of a government independent of Valencia, whose jurisdiction extends 30 miles in length and 15 in breadth. W. Long. o. 56. N. Lat. 38° 22'.

Orillon, in fortification, is a small rounding of earth, faced with a wall; raised on the shoulder of those bastions which have cutmates, to cover the cannon in the retired flank, and prevent their being dismounted by the enemy. See Fortification, p. 564.

Oriolus, or Oriole, in ornithology, a genus belonging to the order of pium. The bill in this genus is slight, conic, very sharp-pointed; edges cultivated, inclining inwards; mandibles of equal length. Nipples small, placed at the base of the bill, and partly covered. Tongue divided at the end. Toes, three forward, one backward; the middle joined near the base to the others; these birds are inhabitants of America, except in a few islands; are noisy, gregarious, frugivorous, granivorous, and voracious race, very numerous, and often have penile necks. The several species (which are very numerous, for Mr Latham enumerates and describes 45) seem to be principally distinguished by their colour. We have given engravings of two of them, the sharp-tailed and Baltimore oriole.

1. The sharp-tailed oriole is about the size of a lark. The bill is dusky; the crown and brown and cinnereous; the cheeks are brown, bounded above and below with deep dull yellow. The throat is white; the breast, sides, thighs, and vent, are a dull pale yellow, spotted with brown; the belly is white; the back is varied with ochre-colour, black and white; the wing-coverts are dusky, with ferruginous edges. The quills are also dusky; the tail consists of narrow sharp-pointed feathers, of a dusky colour tinged with olives, and obscurely barred; and the legs are pale brown.

The other species which we shall describe, is called the Baltimore bird by Catesby and Latham; le Baltimore de Buffon, the oriolus Baltimore de Linnaeus, and the Baltimore oriole by Pennant, and is an inhabitant of North America; which country it quits before winter, and probably retires to Mexico, the archipel of Fernandes seeming to be of the same species. The head, throat, neck, and upper part of the back of the male, is destitute of black; the lesser coverts of the wings orange; the greater black, tinted with white; the breast, belly, lower part of the back, and covers of the tail, of a bright orange; the primaries dusky, edged with white; the two middle feathers of the tail black; the lower part of the same colour, the remaining part orange; and the legs black. The head and back of the female is orange, edged with pale brown; the coverts of the wings of the same colour, marked with a single bar of white; the under side of the body and coverts of the tail yellow; the tail dusky, edged with yellow. The length both of the male and female is eleven inches.—This bird suspends its nest to the horizontal forks of the tulip and poplar trees, formed of the filaments of some tough plants, curiously woven, mixed with wool, and lined with hair. It is of a pear shape, open at top, with a hole on the side through which the young discharget their excrements, and are fed. In some parts of North America, this species, from its brilliant colour, is called the fiery hang-nest. It is named the Baltimore bird from its colours, resembling those in the arms of the late lord Baltimore, whose family were proprietors of Maryland.

There are several other species of the oriole, all inhabitants of North America. Thefe, according to Mr Pennant's enumeration, are the white-backed, the bastard, the black, the brown-headed, the rufty, the white-headed, the Hudsonian white-headed, the olive, the yellow-throated, the unalaschka, the sharp-tailed, and the red-wing. This last species is known in America by the name of the red-winged finaking and the swamp black bird. Although they appear at New York only from April to October, they probably come through the whole year in the southern parts; at least,
Orius. Careful and Latham make no mention of their departure. They are seen at times in fuch prodigious flocks, as even to obscure the sky. They were esteemed the peft of the colonies, making most dreadful havoc among the maize and other grain, both when new fown and when ripe. They are very bold, and not to be terrified by a gun; for notwithstanding the sportsman makes slaughter in a flock, the remainder will take a foort flight, and settle again in the fame field. The farmers fometimes attempt their destruction, by leveling the maize before they faw it in a deſection of white hellebore. The birds that eat this prepared corn, are fcafed with a vertigo, and fall down; which sometimes drives the reft away. This potion is particularly aimed at the purple grackles or purple jack-daws, which conforts in myriads with this species, as if in conspiracy againft the labours of the husbandman.

The fowler feldom fires among the flocks without killing fome of each. They appear in greatest numbers in autumn, when they receive additions from the retired parts of the country, in order to prey on the ripened maize. Some of the colonies established a reward of three-pence a dozen for the extermination of the jackdaws; and in New England, the intent was almost effected at the cost of the inhabitants; who discovered, at length, that Providence had not formed these seemingly destructive birds in vain. Nowwithstanding they caused fuch havoc among the grain, they made ample recompence, by clearing the ground of the noxious worms* with which it abound. As soon as the birds were destroyed, the reptiles had full leave to multiply: and the confequence was the total loss of the grafs in 1749, when the New Englanders, too late repentants, were obliged to get their hay from Pennsylvania, and even from Great Britain.

There be besides another oriole of this fpecies, called the Boylard Baltimore: Its size is that of the true Baltimore, but it measures somewhat lefs in length; the bill is lead-coloured; the forehead and cheeks black mixed with yellow; the hind head and nape are olive grey, marked with a few spots of black; the upper part of the back is the fame, but somewhat duller; the lower part of the back, the rump, fore part of the neck, breast, belly, fides, thighs, upper and lower tail-coverts, and under the wings, are orange-yellow, but brightened on the breast and tail coverts; the latter wing-coverts are deep brown; the greater are the fame, tipped with dirty yellowish white; the quills are brown, bordered on both edges with white; the two middle tail-feathers are olive, then blackish, marked at the end with a longitudinal yellowish spot; the next on eachhide are olive and black, confufedly mixed: and the four outer ones are of yellowish olive: the legs and claws are blufh. They inhabit North America.

There seems to be great confusion and uncertainty in the true and baffard Baltimores and their females; moft likely at all they may, the whole of them, turn out mere varieties of one fingle fpecies, all of them perhaps referable to one or other fex of the true Baltimore, in the different fages of life.

It would be absurd and indeed impossible, without enlarging the article beyond all bounds, to describe each particular variety: we shall therefore refer those of our readers who wish for a more copious account, to Mr Latham's System of Birds, where the whole genus is more minutely and more accurately defcribed than any where else that we know.

Orion, in fabulous history, was the fon of Jupiter, Neptune, and Mercury. For as these gods were visiting the earth, they entered the house of Hyrieus, a native of Tanagra, in Bucotia, under the character of bemighted travellers, on account of his being famed for hospitality to strangers. Hyrieus treated them in the beft manner in his power; and even killed one of the only one he had, for their entertainment. A fuch which the gods were fo pleased, that they offered the old man whatever he would ask; who letting them know that he defired nothing fo much as a fon, they, to gratify his wish, caused the old man to be brought before them, in which, having depofited their urine, they had him keep it under ground for nine months. He then dug for the fkin, and found in it a beautiful child, whom he calld Orion ab urina. The name was afterwards changed into Orion by the corruption of one letter, as Ovid obferves; P situ antiqua litu a prima fo urn. Orion then became conspicuous; and Diana took him among her attendants, and even became deeply enamoured of him. His gigantic nature, however, displeafed Ænopius king of Chios, whofe daughter Hero or Meropen he requifited in marriage: The king, not willing to deny him openly, promifed to make him his fon-in-law as soon as he delivered his island from wild-beasts. This talk, which Ænopius fupponed to be impracticable, wasfoon performed by Orion, who eagerly demanded his reward. Ænopius, on pretence of complying, intoxicated his illufrious guest, and put out his eyes on the sea-fhore, where he had laid himfelf down to sleep. Orion found himfelf blind when he awoke. He went, directed by the found to a neighbouring forge, where he placed one of the workmen on his back, and by his directions went to a place where the rifing fun was seen with the greatest advantage. Here he turned his face towards the luminary; and, according to report, he immediately recovered his eye-light, and hated to punish the perfidious cruelty of Ænopius. Orion was reported to be an excellent workman in iron, and to have fabricated a fubterraneous palace for Vulcain.

Aurora, whom Venus had inflamed with love, carried him away into the island of Dodos, that he might enjoy his company with greater security; but Diana, who was jealous of this, destroyed him with her arrows. Some fay that Orion had provoked Diana's resentment, by offering violence to Opis, one of her female attendants: or, as others fay, because he had attempted the virtue of the godfefs herfelf. According to Ovid, Orion died of the bite of a fcorpion, which the earth produced to punish his vanity, in boiling that no animal on earth could conquer him. Some fay that Orion was fon of Neptune and Euryne, and that he had received from his father the privilege and power of walking over the sea without wetting his feet. Others affert that he was a fon of Terra, like the ref of the giants. He had married a nymph call'd Sida, before his connéction with the family of Ænopius, but Sida was the caufe of her own death, by boating herfelf fainter than June. Diodorus fays, that Orion was a celebrated hunter, superior to the rest of mankind, by his strength and uncommon fortune;
He built the port of Zancle, and fortified the coast of Sicily against the frequent inundations of the sea by heaping a mound of earth called Pelorum, on which he built a temple to the gods of the sea. After death Orion was placed in heaven, where one of the constellations still bears his name. The constellation of Orion was placed near the feet of the bull. It was composed of 17 stars in the form of a man holding a sword; for which reason the poets often speak of Orion’s sword. As the constellation of Orion, which rises about the 4th of March, and sets about the 21st of June, is generally supposed to be accompanied at its rising with great rains and storms, it has acquired the epithet of aquosus given it by Virgil. Orion was buried in the island of Deles; and the monument which the people of Tanagra in Boeotia showed as containing his remains was nothing but a Cenotaph. The daughters of Orion distinguished themselves as much as their father; and when the oracle had declared that Boeotia should not be delivered from a dreadful pestilence before two of Jupiter’s children were immolated on the altars, they joyfully accepted the offer, and voluntarily sacrificed themselves for the good of their country. Their names were Menippe and Metioche. They had been carefully educated by Diana; and Venus and Minerva had made them very rich and valuable presents. The deities of hell were struck with the patriotism of these two females; and instantly two stars were observed to arise from the earth, which still smote with their blood, and were placed in the heavens in the form of a crown. According to Ovid, their bodies were burned by the Thebans, and from their ashes arose two persons, whom the gods soon after changed into constellations.

Orion, in astronomy, one of the constellations of the southern hemisphere. The word is formed from the Greek, οριον, “to make water;” the ancients supposing that it raised temples at its rising and setting. The stars in the constellation Orion, in Ptolemy’s catalogue are 37, in Tycho’s 62, in the Britannic catalogue 80.

ORISTAGNI, an ancient town of the island of Sardinia, with an ambush’men’s house. It is pretty large and well fortified; but thinly inhabited, on account of the unhealthy air; it is seated on the western coast, in a bay of the same name, in E. Long. 8. 58. N. Lat. 39. 55.

ORIXA, a kingdom of Indoian, lying on the Gulp of Bengal. It is divided from the ancient kingdom of Colonna, by a ridge of land, at the end of which runs a little way into the sea. It is fertile in corn and cattle, and they have several good towns and harbours on the coast; there are also manufactures of different kinds carried on throughout the kingdom. The prince is a Gentoo, who pays to the Great Mogul a tribute to the amount of about 12,000 yearly.

Orissa, in botany: A genus of the monogyne order, belonging to the tetrandra class of plants; and in the natural method ranking with those that are doubtful. The calyx is quadripartite: the petals are four, plain and lanceolate; the stigma lobular: the capsule and seeds unknown. Of this there are two species, v. z. 1. The fruticose; 2. Japonica, both natives of Japan.

ORKNEY ISLANDS, called Orcades by the ancients, certain islands on the north of Scotland (a), from which they are separated by a strait 20 miles in length and 10 in breadth.

As writing seems to have been unknown in the northern islands, during those periods which the antiquarian would call the most curious and important, the

(a) The northern isles of Scotland have been often mentioned by ancient authors, and called by different names from those they now go by; so that it is sometimes difficult to know which of them are meant. The ancient name, however, of the islands, which are the subject of this article, has never been disputed. The Ebudes, it is agreed, are the modern Hebrides; and there is no doubt of the ancient Orcades being the same with the Orkneys. Of Thule, however, we are not so certain: and whether it means the Shetland islands, or Iceland, remains undetermined. Pythias, a Mafrican, pretends to have visited these islands, and particularly Thule; but he does not mention the Orcades. The geographer Mela, who was contemporary with the emperor Claudius, is the next writer who describes the northern islands. Of the Orkneys he gives a remarkably just account, and says there were thirty in number, with narrow channels between them; but he is less accurate with respect to the rest. Pliny the Elder is the third who mentions the northern islands. He makes the number of the Orkneys to be forty, and of the Hebrides to be thirty. Solinus, the suppos’d contemporary with Agricola, is the next after Pliny. In his time, and according to his account, these islands had not a single inhabitant; and were overgrown with ranky grasses. It seems on the whole to be pretty generally allowed, that Julius Agricola, who first sailed round Britain, discovered the Orcades till then unknown, and subdued them. Claudius was so far from reducing them (as is asserted by Jerome in his Chronicle), that Juvenal has these lines in Hadrian’s time:

Arma quid ultra
Littera flavae me promovit us et modo capitas
Orcades, et minima contentos modo Britannos. SAT. II. 160.

In vain, O Rome, thou dost this conquest boast
Beyond the Orcades short-nighted coast.

Dryden.

Tacitus informs us, that, before the completion of the first century the Roman fleets sailed round Scotland, and landed in the Orcades to refresh.

* The Romans, never that we know, visited these islands again but once, which was probably after Honorius had defeated the Saxons in the seas of Orkney.
Christianity had dawned on Scandinavia, and had become the established religion in the north of Norway. Its doctrines interwove themselves with the policy of the nation; its principles, so nearly interesting to human happiness, made their further publication an object of much moment to the adventurous princes, and gave a new law to their enterprises. While the power of these principles was acting with original force upon the minds of the people, and their zeal rendered them ambitious of any exploit, whereby they could diffuse their influence; Olau prince of Norway equipped a squadron defined to carry the knowledge of the gospel to other shores. On this pious adventure he was accompanied not only by numbers of all ranks, whom, as usual, a love of enterprise invited; but by many persons of distinguished knowledge and abilities, men of sincere piety, who had become particularly well acquainted with the Christian doctrines, and entertained a deep sense of their infinite importance. These entered into the fleet, joyful in the prospect of spreading the truths which they revered through yet unenlightened countries; and the squadron soon appeared off the Orkneys. Olaus got Sigurdis on board of his fleet, with his son, and but a few attendants, and, as the heir of Harold, he claimed all the provinces over which Sigurdis reigned; and at the same time he ordered him to renounce and abjure the religion of his fathers, and to embrace Christianity. Delay was not permitted; Christianity was forced upon him and his subjects; and, on the departure of Olaus, he carried the son of Sigurdis as a hostage for what he had engaged; which was to give honourable protection to all those holy men who might choose to reside in those parts for the purpose of instructing the people in the nature of the Christian doctrines; for many of the more intelligent

(A) It has been asserted, that the Orkneys, as well as the hills of Shetland, were originally peopled from Norway, in the ninth, tenth, or eleventh century. Others again imagine, with as much probability, that the Picts were the original inhabitants, and call Orkney the ancient kingdom of the Picts. Certain singular houses, now overgrown with earth, are called Pictis houes; and the Pictland frith (formerly Pightland or Pictland) is supposed to retain their name. Claudian's lines, cited by Mr Hamden, prove, that the Picts, with some other German colony, particularly the Saxons, were at that time in possession of these isles; and so Ninimus expressly says. Many of the present inhabitants use the Norfe language, which differs but little from the Teutonic or Pictish language, and was in general use to the last century; but except in Foula, where a few words are still known by the aged people, it is quite lost. The English tongue, with a Norwegian accent, is that of these isles; but the appearance of the people, in their manners and genius, evidently show their northern origin. Ninimus, c. 5, puts their arrival at Orkney not less than 900 years after the coming of Brutus into Britain, which he says was in the time of Eili the Jewish high-priest. The ancient furnaces are of German origin. Some date the first settlement of the Picts here A. M. 486; when, emigrating from their native country, they planted a colony in Orkney, and thence crossing Pictland frith, and traversing Caithnes, Rofs, Murray, Marr, and Angus, settled in Fife and Lothian; thence called by writers Pictland. Others think they did not settle here till the time of Reuther king of Scotland, when the Picts, joining with a party of the Scots, were repulsed, with the loss of their king Gethus, and many of the Picts and Scottish nobility, with great slaughter; but the invasions of the Britons, at the same time, constrained the Picts to fly to Orkney, where they chose for king Gethus their deceased sovereign's brother, till they were able to return to Lothian, and drive out the Britons. After this they flourished here, and were governed by kings of their own. There still remains a place called Cunningfmar, the dwelling place of the minifer of Sandwich, whose name and form bespeak it the residence of some of them. But no traces of their history remain, except the name of Belus, in ancient charaters, on a stone in the church of Birfa, where full is to be seen one of the principal palaces. This government probably subsisted till the subversion of the Pictish kingdom in Scotland, A. D. 839, by Kenneth II. king of Scotland. On the whole, however, the time of the discovery and population of the Orkneys is certainly unknown. Probably it was very early; for we are told that they owe their name to the Greeks:

Orcades has memorat diitas a nomine Greco. 

CLAUDIAN.
Orkney. gent and religious men who had come from Norway with Olau, remained in the Orkades and in the north of Scotland, to fulfil their pious resolution of spreading the light of the gospel there. Olau, with the rest of his followers, sailed on another expedition towards the firth of Moray. The death of Kindius his son, which happened soon after Olau's return to Norway, released Sigurdus from his engagements with him; and he entered into one with Malcolm II. one of whose daughters he had in marriage, and by whom he had a son, Torphinus. Torphinus's bravery, magnificence, generosity, and hospitality, endeared him to the inhabitants; and he ruled without control for many years, till Ronald, a grandson of Sigurdus, who had lived in Norway, and who was esteemed the rightful heir of the earldom of Orkney, made a successful descent upon it. Torphinus wished to give him battle; and in a sea-fight, with the affillence of some ships from Arminus, a man who had filled some of the chief places in Norway, he totally defeated him. By courting the friendship of that court, his dominions remained quiet but for the greater part of his life; the latter part of which was no less eminent for establishing salutary laws, and encouraging the arts of industry, than the former had been distinguished for military fame and success in the exploits of war. He lived to an advanced age, until after Malcolm III. had ascended the throne of Scotland. Torphinus had built a magnificent church in Byras, where the first bishops of Orkney reided. In the decline of life he retired to that island, and, finishing his days with exemplary piety, was with much solemnity interred in the temple which he had raised.

His country long lamented the loss of so celebrated a ruler, who had established security in it, through the influence of his laws, and had taught it to enjoy the arts and blessings of peace. He left two sons, Paul and Erland, who through the whole of their lives amicably shared both in the honours and administration of their father's extensive domain. During this period, the northern counties are said to have arrived at a very superior degree of cultivation and improvement, which became equally conspicuous in the richness of their lands, and in the mildness of their dispositions. Their sons, however, did not both inherit their father's virtues. Magnus, the son of Erland, was pious and peaceable; a great promoter of religion, and anxious in patronizing the Romish missionaries, and in protecting the establishments of Christianity: but Hacon, the heir of Paul, was vehement, wild, and impatient of restraint. He faw how Magnus was revered, and envy drove him to revenge; for, by the mod deliberate and deceitful villainy, he got Magnus into his power, and murdered him without mercy. The latter part of his life was spent in penance, and in improving his dominions.

Magnus's singular piety, and the manner of his unfortunate death, were so well represented at the court of Rome, that he was canonized. Hacon left two sons, Paul the Silent, and Harold the Orater. Caithness came to Harold, and the Orkneys were governed by Paul.

Ronald, a descendant of St Magnus, an elegant and accomplished youth, appeared at the court of Norway, and was supported in a claim upon the Orkneys, as the heir of the canonized martyr. He sent messengers to Paul, and offered to share the government with him; but this proposal was refused, and the ambassadors were treated with great contempt. They, however, found persons of power disposed to second their master's views; who soon after their return set out, and vowed, if he succeeded, to build a magnificent church, and to dedicate it to St Magnus. All seemed satisfied with the enterprise; and, full of hope, the fleet set sail. Paul in the mean time put himself in a state of defence. By very artful manceuvres, however, Ronald obtained his purpose, and willingly shared his sovereignty with Harold, the legal heir of Paul. They lived amicably together; and on the affiliation of Ronald, which was accomplished by a proud chieftain, who thought himself insulted, he was buried with great pomp. Harold now fully possessed the unrivalled sovereignty of the north, and lived long to enjoy it. We find that in 1196 he was able to bring 7000 men to the field, and a body of cavalry, against the army of William king of Scotland, but was immediately defeated. In the next year, the Caithnians rebelled again, headed by one Roderick, and Torphinus, son to Harold. The king met and defeated them near Inverness. Roderick was slain; and William, feizin on Harold in the extremity of Caithness, detained him till Torphinus surrendered himself as a hostage; but on some new treasons of the father, the king, according to the barbarity of the times, caused the eyes of the unhappy youth to be put out; and had himemasculated, of which he soon perished in prison. Harold died in the 73d year of his age; and with him ended, in itsearls, the independent sovereignty of the north of Scotland. The Norwegians seem to have been in possession of these isles as late as 1265; for then Magnus IV. king of Norway, being worsted in war with the Scots, yielded them to Alexander III. king of Scotland by treaty, and Haquin king of Norway confirmed the possession of them to king Robert Bruce in the year 1312. Lastly, in 1464, Christian I. king of Norway and Denmark, when he gave his daughter in marriage to James III. king of Scotland, transferred all his right to them to his son-in-law and his successors; to make which more binding the Pope's confirmation was obtained. We are told by some that Magnus sold them to Alexander for the sum of 4000 marks Sterling, and a yearly acknowledgment of 100 marks.

They are about 30 in number; but many of them are uninhabited, the greater part being small, and producing only pasturage for cattle. The principal islands are denominated by the names of Mainland, South Ronaldska, Swinna, Flotta, Coginsba, Strivenba, Stronsa, Sanda, &c. the terminations in a, or ha, being generally given in the Teutonic to such places as are surroundered by water. The currents and tides flowing between the islands are extremely rapid and dangerous. Near an island called Swinna are two great whirlpools, called the wells of Swinna, which are counted dangerous by mariners, especially in a calm. When sailors find themselves sucked into the vortex, it is said they throw out a barrel, or some bulky substance, which smooths the water till it is sucked down and thrown up at a considerable distance, during which time the ship paffes over in safety. But when there is a breeze of wind, these whirlpools may
may be crossed without any danger. The largest of
these islands is called Pomona, in length 33, and in
breadth 9 miles, containing 9 parish-churches, and 4
excellent harbours.

The air of these islands is moist, on account of the
neighbourhood of the sea; and frost and snow do not
continue long. In some places the soil is bare and
mountainous, and in others sandy and barren; how-
ever, many of the islands produce large crops of barley
and oats, but no wheat or other grain excepting what
is included in gardens. Those, when duly cultivated,
produce all kinds of kitchen herbs and roots, bring-
ing even fruit-trees to maturity; but out of them, in
the open country, there is scarce a tree or shrub to
be seen, except juniper, wild myrtle, and the ekur-hodon:
yet this deficiency cannot be attributed to
the poverty of the soil, or the nature
of the inhabitants frequently find, deep in the earth,
pieces of ambergris. The

The gentry of the Orkneys are civilized, polite,
and hospitable; and live like those of Scotland, from
whom they are chiefly defended. They live com-
fortably, are remarkably courteous to strangers, and
drink a great quantity of wine, with which their
cellar is generally well stored. Indeed the Inhabit-
tants of the Orkneys may be now justly deemed a
Scotch colony. They speak the language, profess
the religion, follow the fashions, and are subject to
the laws, of that people. They are frugal, sagacious,
circumspect, religious, and hospitable. Their mariners
are remarkably bold, active, dexterous, and hearty.
Many surprising incursions of longevity occur here, as
well as in Shetland, of persons living to the age of
140. The Orkney women are generally handsome
and well shaped, and bring forth children at a very
advanced age. In the Orkneys, some particular lands
are held by a tenure called Udal Right, from Ulcius,
or Olau, king of Norway, who farmed the lands,
on condition of receiving one-third of the produce;
and this right devolved in succession, without any
charter granted by the sovereign. The inhabitants
of Orkney, instead of measuring their corn, weigh
it in pilarmore or poudlers. Their alpha denomination
is a mark, consisting of 18 ounces, and 24 marks
make a longpound, which is a Danish quantity.
The poorer sort of people in the Orkneys appear very
meanly habited, with a piece of seal skin instead of
shoes; and living chiefly on salt-fish, are subject to
the scurvy. They are much addicted to superstitious
rites; in particular, interpreting dreams and omens,
and believing in the force of idle charms. The islands
of Orkney, we have already observed, produce very
bold, able, and hardy mariners. The common people,
in general, are inured to fatigue, and remarkably ad-
venturous, both in fishing during rough weather, and
in climbing the rocks for the fish, eggs, and down of
deer-fowl. Formerly, while they were exposed to
the invasions of the Norwegians, or western invaders,
every village was obliged to equip a large boat well
manned; and all the securable men appeared in arms,
when alarm was given by the beacons lighted
on the tops of the rocks and highest mountains.
These beacons, known by the name of word-bills,
are still to be seen in every island. Their corn land
they incline with mud or stone walls, to preserve it
from the ravages of their sheep, swine, and cattle,
which wander about at random, without being at-
tended by herdsmen: their ordinary manure, espe-
cially near the sea-coast, is sea-weeds, which they
carefully gather and divide into equal portions. Their
sheep are marked on the ears and nose; but so wild,
that when they have occasion to shear them in the
month of May, they are obliged to hunt every indi-
vidual, with dogs trained for that purpose. Their
manner of catching sea-fowl is curious and particular.
Under the rock where these fowls build, they row their boat, provided with a large net, to the upper corners of which are fastened two ropes, lowered down from the top of the mountain by men placed in that station. These hoisting up the net, until it be spread opposite to the cliffs in which the fowls are sitting, the boatmen below make a noise with a rattle, by which the fowl, being frightened, fly forwards into the bottom of the net, in which they are immediately enclosed and lowered down into the boat; others practise the method used in Iceland and Norway, and are lowered down by a single rope from the summit of the mountain; this is the constant way of robbing the hawk’s nest. See Brian-catching. In these island some strange effects are produced by thunder and lightning. In the year 1690, the lightning entered a cow-hutch, in which 12 cows stood in a row, and killed every second beast as the flood, and left the rest untouch’d. The delinquents that prevail mostly in the Orkneys are agues, consumptions, curvy, and itch. The agues, which abound in the spring, the natives cure with a diet drink of bitters and antiscorbutics infused in ale; for phthisical complaints they use the plant arby, and the caryophyllus marinus boiled with sweet milk.

The isles of Orkney and Shetland compose one provinity, and send one member to the British parliament. The right of superiority to the Orkneys was dismembered from the crown by the union parliament, and granted for a certain yearly consideration to the earl of Morton, by Queen Anne, who appointed him hereditary steward and judicilary. This noblemanpossesses the power of creating certain judges, called kaijfs. There is one of these established in every island and parish, with power to superintend the manners of the inhabitants, to hold courts and determine civil causes, according to the laws of Scotland, to the value of ten pounds Scots money, amounting to 16s. 8d: but all contends of higher import are referred to the decision of the steward or his deputy, who resides at Kirkwall, which is the seat of justice. Subservient to the bailiffs are fix or seven of the most reputable and intelligent inhabitants, who oversee the conduct of their fellows, acting as constables, and make report of all enormities to the bailiff; who caueth the delinquent to be apprehended and punished, if the crime be within the extent of his judicial power; otherwise he transmits him to Kirkwall, where he is tried by the steward. The Protestant religion prevails in the isles of Orkney, according to the rites and discipline of the kirk; there, and the isles of Shetland, constituting one presbytery, which assembles at Kirkwall. The country is divided into 18 parishes, containing 31 churches, and above 100 chapels.

The trade of the Orkneys is not at present very considerable, though it might be extended to great advantage. They supply with fresh provisions, for ready money, the ships and vessels that touch upon the coast in the course of northern voyages, or in their passage from the East Indies, when they go north about Ireland and Scotland, in time of war, to avoid the privates of the enemy. They are also visited by those engaged in the herring-fishery, though there is not such a retort on this account to these islands as to the isles of Shetland. Nevertheless, a good number of boats from the western parts of Scotland, as well as from Londonderry, Belfast, and other parts of Ireland, fish for herring as far north as the Ledeze, and supply the Orkneys with tobacco, wine, brandy and other spirits liquors, clothes, and divers manufactures. These they exchange for fish, and oil extracted from porpoises, seals, and other sea-animals. The people of Orkney export annually great numbers of black cattle, wine, and sheep; together with large quantities of corn, butter, tallow, salt, and fluffs made in the country, over and above the skins of seals, otters, lambs, and rabbits, down, feathers, writing- quills, hams, and wood; yet all these articles would, in point of profit fall infinitely short of their herring-fishery, were it prosecuted with industry, economy, and vigilance. As there are no merchants in the Orkneys at present who export fish on their own account, what herring are taken, they fall to the Dutch or Scotch dealers in and about Inverness. They generally fish for herring on the west side of the Orkneys; and are therefore more remote from markets than those who are employed in the same manner on the coast of Shetland. In the Orkney islands they fee to read at midnight in June and July; and during four of the summer months they have frequent communications, both for business and curiosity, with each other, and with the continent: the rest of the year, however, they are almost inaccessible, through fogs, darkens, and storms. It is a certain fact, that a Scotch fisherman is imprisoned in May, for publishing the account of the prince and princess of Orange being raised to the throne of England the preceding November; and he would probably have been hanged, had not the news been confirmed by the arrival of a ship.

We may reckon among the curiosities of the Orkneys, the Phiafof, commonly known by the name of Molucca beans, and sometimes they are called Orkney beans. They are a sort of fruit found on the shore of the Orkney islands, being thrown on them by storms of weighty wind. They are of several distinct species, and are none of them the produce of those islands, nor of any places thereabout, but are probably of American origin, many of them being plainly natives of Jamaica, and other islands of the Indies.

They are found principally on those coasts which are most exposed to the waves of the great ocean, and are on these so plentiful, that they might be gathered in large quantities, if of any value; but the only use they are put to, is the making of fine boxes out of them. Sir Robert Sibbald, and Mr Wallace, in their accounts of Scotland, have both named them Molucca Beans. Many strange fishes and curious shells are also frequently cast up by the ocean; of these last a vast variety are preferred for adorning the cabinets of modern naturalists. Sometimes exotic fowls are driven upon the Orkneys by tempestuous weather: fih, as large as whittings, have been thrown ashore to a considerable distance within the land. At Cantick head, in the island Waes, and some other places, huge fomes are often heaved up by the violence of the sea and wind, and cast over high rocks upon the land. A single Laplander has been seen more than once on this coast, in his slender canoe, covered with skins, being driven hither by adverse winds and storms. The Orkneys are
flattens than frills with hills, and to tones aole perhaps.

They have a hort of a name, handed down by Hi" to the meaning of this name, handed down by Hi" and the

Another part of the midl of a defolate heath, and is sup
pofed to have been the residence of a hermit: in the very neighborhood of this stone there is a very high and steep mountain, called the smart hill of Hoy, near the summit of which in the months of May, June, and July, something at noon-day is seen to shine and sparkle with a remarkable loiftre, supposed by the common people to be an enchanted carbuncle: many persons have clambered up the hill in quest of it, but found nothing. Perhaps this splendor is produced by the reflection of the sun on a small stream of water sliding over the face of a smooth rock. At Stennis, in the main land, there is a causeway of stones over a loch or lake, at the south end of which we observe a circle of stones rising about 20 feet above ground, each being six feet in breadth, and from one to two feet in thickness: between this circle and the causeway two stones of the same dimensions stand by themselves, and one of them is perforated in the middle. At the distance of half a mile from the other end of the causeway appears a larger circle of the same kind of stones, the diameter of which may amount to 110 paces; some of these stones are fallen; and to the east and west of the larger circle are two artificiel green mounds. Both rounds are surrounded with a ditch; and none can view them without ad
diration, considering the art that must have been used to bring such unwieldy masses together in this order. They were probably temples and places of sacrifice used in times of pagan superstition; and seem to bear a great affinity with the celebrated monument called Stonehenge, on Salisbury Plain in England. In one of the mounts, at the north end of the causeway, the natives found nine fibula, or clasps of silver, formed into a circle, and resembling a horse-shoe. In many different places of the Orkneys we find rude obelisks or single stones of a great height, set up either as mmo"rials of battles, treaties, or the decease of remarkable perfiages. In Roulay, between two high mountains, there is a place which the natives distinguish by the appellation of the camp of Jupiter Fring; but the meaning of this name, handed down by tradi
tion, is not known. At the west end of the main land, near Skel, we find a surprizing causeway, above a quarter of a mile in length, on the summit of high hills, composed of reddish stones of different magni
tudes imprinted with various figures both on the upper and under surface. Some gentlemen in the neigh
bourhood have carried off the most beautiful of these stones, to be set in their chimneys by way of ornament, like the painted tiles of Holland. This country produces many feplulchres of different nations. In the plains or links of Skel, the sand being blown away from the surface of the ground, several square catacombs appear built of stones well cemented together, containing some parcels of black earth, and each secured by a large stone at the mouth. Sepulchres of the same kind are found at Roulin in Strond; which is likewise remarkable for a different kind of monu
dent, consisting of one entire stone cylinder hollowed out, with a bottom like that of a barrel, and a round stone to fill up the entrance: above, the stone was sharpened into an edge; within were found some burned bones and red clay; and over it was placed a large flat stone for the preservation of the whole. These in all probability, were Roman catacombs. In Weltra divers Danish graves have been discovered; in one of these appeared the skeleton of a man, with a sword on one side and a damsh ax on the other. Some have been found buried with dogs, combs, knives, and other utensils. In many places of the country we find round hillocks or barrows, here known by the name of brogh, signifying in the Teutonic language, burying-place, supposed to have been the cemeteries of the ancient Saxons. In different parts of these islands we see the remains of great buildings, believed to have been fortresses erected by the Danes or Norwegians when they possessed the country. One of these in the Isle of Wyre, called the cyle of Cе

pi-eus, signifying a town of security, is surrounded by a fosse, and the first floor full remains above ground, a perfect square of stone wall, very thick, strongly built, and cemented with lime, the area within not exceeding ten feet in length. Of this coppi
rrow the common people relate many idle fables. In the chapel of Cle, in the Isle of Sands, there is a grave 19 feet long, in which was found part of a man's back bone, larger than that of a horse. Human bones, of nearly the same size, have been dug up in Weltra; and indeed this country is remarkable for producing men of a gigantic stature. Within the an
cient fabric of Lady Kirk in South Ronaldshay, there is a stone four feet long and two feet broad, on which the print of two feet are engraved, supposed to be the place where, in times of popery, penitents flocked to do public penance. The cathedral of Kirkwall, the capital of the Orkneys, is a fine Gothic building, dedicated to St Magnus; but was converted into a parifh church. Its roof is supported by 14 pillars on each side; and its steeple in which there is a good ring of bells, by four large pillars. The three gates of the church are chequered with red and white polished stones, embossed and elegantly flowered.

Campbell, in his Political Survey, suggetts two im
provements in the Orkneys: 1. The erecting an university; of which he recapitulates the probable advan
tages, arising from their centrical situation: And, 2. Allowing the East India company to erect a fraciouus magazine in one of these islands; where also a collector, and a sufficient number of king's officers, should reside, to receive the duties of such East India commodities as might be taken on the British subjects. These he propo"ses for the Orkneys in particular; and in addition to improvements proposed for the whole islands in general. We are told that the Orkneys contain 30,000 inhabitants, and are equal in extent to the county of Huntingdon.

ORLE, ORLE, or OrFe, in architecture, a fillet under
under the ovolo, or quarter round of a capital. When it is at the top or bottom of a shaft, it is called cincture. Palladio uses the word orlo for the plinth of the bases of the columns.

**ORLEANS** in heraldry. See **HERALDRY**, p. 454.

**ORLEANOIS**, a province of France, including the several districts of Orleanois-Proper, Beaute-Proper, or Chaurnois, Dunois, Vendomois, Blafois, the greatest part of Gaitinois, and Perche-Gonet. The principal rivers of it are the Loire, the Loiret, the Cher, the Loire, the Aygol, the Hyeres, the Yonne, and the Eyre. There are also some remarkable canals, particularly those of Brie and Orleans. The river Loire, and the canals drawn from thence, greatly facilitate and promote the inland trade of the kingdom, and particularly of this government, which lies entirely within the jurisdiction of the parliament of Paris; and besides the chief governor, has several subordinate ones.

Orleanois, in Latin **Aurelianum Ager**, is bounded on the south by Sologne, on the north by Upper-Beauce, on the east by Gaitinois, and on the west by Dunois and Vendomois. The Loire divides it into Upper and Lower; the former lying to the north, and the latter to the south of that river. It yields plenty of grain, wine, wood, and fruit, and abounds in cattle, game, and fish.

**ORLEANS**, the capital of the government of Orleanois. It was anciently called Genabum, or Genabum; and afterwards denominated Aurelia, Aurelie, and Aureliana, by the emperor Aurelian, who considerably enlarged it. In Julius Caesar's time it was the capital of the Carminates. It stands about 20 leagues south of Paris, on the northern bank of the Loire; across which Mr Wraall says there is an elegant bridge of nine arches, the entrance by which is exceedingly noble and striking, the street which leads from it being composed of most elegant modern buildings. In general, however, excepting this street it is very meanly built; the streets are narrow, and the inhabitants in general poor. It is surrounded with walls, and fortified with 40 towers. The streets almost all terminate at the quay for the convenience of trade. It is a place of considerable magnitude; and before the revolution it had several inferior courts of justice, and an university of no great repute. It was also a bishop's see; and the cathedral is a most superb Gothic structure, and had the finest steeple in France till it was damaged in the time of the civil wars. There were 23 parishes in it, and a great number of churches, some of which were collegiate, and religious houses. There is also a public walk, planted with several rows of trees; and there used to be some sugar-bakers; a manufacture of flax and rope of flax; a feaminity in which divinity was taught; a great trade in brandy, wine, spices, and several manufactures, which, with many other commodities, used to be conveyed to Paris by means of the Loire, and the canal which takes its name from the city. The canal begins about two miles above the city; is near 18 leagues in length; and terminates on the Loing, which falls into the Sine. The environs of Orleans, more especially in the province of Sologne, to the south of the Loire, are very agreeable. It is in general a level country, covered with corn and vines. To the north of the city is a forest, the largest in the whole kingdom. Before the revolution it belonged to the duke of Orleans; to whom the timber fell in it, one year with another, brought about 100,000 livres. Ever since the year 1344 this city has been a dukedom and peerage, and usually an appendage of some prince of the blood. The late duke, who took the name of Egiald and who has since been executed, seems to have been one of the most detestable monarchs which ever disgraced humanity. Louis XIV gave the dukedom to his own brother Philip, who began and finished the canal; which, by the duties paid by vessels going up and down, brought in, one year with another, 150,000 livres. The bishop was suffragan to the archbishop of Paris, and had a revenue of 24,000 livres, out of which his tax to Rome was 2000 florins. A new bishop it is said, on the first day of his entering, had the privilege of releasing all the prisoners in it, except those committed for treason. In the street leading from the bridge stands the celebrated monument where Charles VII. and Joan of Arc the Maid of Orleans are represented on their knees before the body of our Saviour, who lies extended on the lap of the Virgin. It was erected by order of that monarch in 1458, to perpetuate his victories over the English, and their expulsion from his dominions. All the figures are in iron. The king appears bareheaded, and by him lies his helmet surmounted with a crown. Opposite to him is the Maid her elf, in the same attitude of grateful devotion to Heaven. It is a most precious and invaluable historical monument. In the Hotel de Ville (says Wraall) is a portrait of the same immortal woman, which I studied long and attentively. Though it was not done till 1581, which was near 130 years after her decease, it is yet the oldest and best picture of her now existing. The painter seems undoubtedly to have drawn a flattering resemblance of her, and to have given her heroic imaginary charms. Her face, though long, is of exceeding beauty, heightened by an expression of intelligence and grandeur rarely united. Her hair falls looselv down her back, and she wears on her head a fort of bonnet enriched with pearls, and finished with white plumes, tied under her chin with a string. About her neck is a little collar, and lower down, upon her bosom, a necklace composed of small links. Her drics, which is that of a woman, I find it difficult exactly to describe. It fits close to the body, and is cut or flathed at the arms and elbows. Round her waist is an embroidered girdle, and in her right hand she holds the sword with which she expelled the enemies of her sovereign and her country. I am not surprised at the animated and enthusiastic attachment which the French still cherish for her memory. The critical and desperate emergency in which she appeared; her sex, youth, and even the obscurity of her birth; the unparalleled success which crowned her enterprise; the cruel and detestable sentence by which she was put to death; the ar of the marvellous spread over the whole nation, increased and strengthened by that veneration which time affixes to every great event—all these united caufes combine to place her above mortality. Rome and Athens would undoubtedly have ranked her among their tutelary deities, and have erected temples to her honour; nor can I help being amazed, that amidst the almost infinite number...
The bridge was new built this century, and opened in 1760; and the French esteem it the finest in the world. E. Long. i. 59. N. Lat. 47. 54.

The bridge was new built this century, and opened in 1760; and the French esteem it the finest in the world. E. Long. i. 59. N. Lat. 47. 54.

ORMANS, a small island of Asia, at the bottom of the gulf of the same name, at the entrance of the Gulf of Perhia. It is about two leagues from the main land, and about six leagues in circuit. They catch excellent oysters about the island; and it yields plenty of fine white salt; also a kind of shining black sand, which is used for dressing written, and is transported in considerable quantity to Europe. There is neither sweet phalrus nor grazs upon it, the soil being of a salt phalrus nature. It was taken by the Portuguese in 1507, who fortified it; and it was afterwards frequented by a vast number of merchants, who were extremely rich. In 1622 the Persians, by the alliance of the English, conquered this place, and demolished the houses, which were 4000 in number, containing 40,000 inhabitants. Some time after, the Persians rebuilt the fort, and placed a garrison in it; but they could never bring it to be a place of trade as before: however, it is the key of the Persian Gulph, as well on account of the importance of the place, as the commodiousness of the harbour. It is now almost deserted, for it produces nothing but salt, which sometimes is two inches deep upon the surface of the earth. E. Long. 56. 25. N. Lat. 27. 20.

ORNIS LAPS, a name given by some authors to the faphire of the ancients, which is a peculiar species of the laps lazuli, in which the gold-coloured matter is not disposed in veins, but in separate spots, of the form of a star. It was first called orinus and aurium, by corruption from aurinus, “golden;” and thence came at length the word erinus.

ORNITHELNE, a name given by the ancients to certain winds, which usually blew in the spring, at the time when the birds of passage came over to them. Pliny says, that these winds blew from the west, and that by some the Eolian winds were called by this name. Others suppose that they blew from the north, or north-west.

ORNITHOGALLUM, STAR OF BETHLEHEM: A genus of the monogynia order, belonging to the heptandra class of plants; and in the natural method ranking under the 10th order, Coronaria. The corolla is hexapetalous, erect, perfiling, and patent above the middle; the filaments alternated at the base. There are seven species; all of them herbaceous perennialis, rising from six inches to three feet high, having stalks terminated with long spikes of hexapetalous, star-shaped, white, and yellow flowers. Six of the species are very hardy, and will prosper in any situation; but one, named the capinc, a native of the Cape of Good Hope, requires the alliance of artificial warmth to prefer it in this country. They are all easily propagated by oil-fets from the roots. The bulbous roots of all the species are nutritious and wholesome.
ORNITHOLOGY is a science which treats of birds; describes their form, external and internal; and teaches their economy and their uses.

A bird is an animal covered with feathers; furnished with a bill; having two wings, and only two legs; with the faculty, except in a very few instances, of removing itself from place to place through the air.

But before proceeding to analyse the characteristic parts of birds, it will be proper to premise an explanation of the terms used by naturalists in describing them.

EXPLANATION of some Technical Terms in Ornithology used by Pennant and Linneus.

Fig. 1. 

1. Cere. Cera
   The naked skin that covers the base of the bill in the hawk kind.

2. Copiferum
   A word used by Linneus to express the short feathers on the forehead just above the bill. In crows these fall forwards over the nostrils.

3. Lorum
   The space between the bill and the eye, generally covered with feathers; but in some birds naked, as in the black and white grebe.

4. Oralis. Orlija
   The skin that surrounds the eye, which is generally bare; particularly in the heron and parrot.

5. Emarginatum
   A bill is called rostrum emarginatum when there is a small notch near the end; this is conspicuous in that of butcher-birds and thrushes.

6. Vibreja
   Vibreja postisnata, stiff hairs that grow on each side of the mouth, formed like a double comb, to be seen in the gnatcatcher, flycatcher, &c.

7. Booted wing
   Alula flapia
   A small joint rising at the end of the middle part of the wing, or the cubitus; on which are three or five feathers.

8. Lesser coverts of the wings
   Tetrices prince
   The small feathers that lie in several rows on the bones of the wings. The under coverts are those that line the inside of the wings.

9. Greater coverts
   Tetrices fasciade
   The feathers that lie immediately over the quill feathers and secondary feathers.

10. Quill feathers
    Primiore
    The largest feathers of the wings, or those that rise from the first bone.

11. Secondary feathers
    Secondaries
    Those that rise from the second.

12. Coverts of the tail
    Uropygium.

13. Vent feathers

14. The tail.
    Rostrum

15. Scapular feathers

16. Nucha

17. Rostrum fuligatum

18. Pes ambulatorius

19. Pes graffarius

20. Pes scopiferus

21. Finned foot. Pes cobatus

22. Scoloped foot. Pes pinnatus

23. Pes tringulatus. Pes plumatus

24. Pes dilatatus

25. Semipalmated. Pes semi-palmatus

26. Ungue pollicis fijile

27. Digits 4. omnibus palmaris Rostrum cultratum

28. Unguiculatum

29. Lingua ciliata

30. Integra

31. Limbriiformis

32. Nares Linneae

33. Emarginatum

Those that cover the base of the tail.

Those that lie from the vent to the tail. *Griffon Linnu*.

That rise from the shoulders, and cover the sides of the back.

The hind part of the head.

A term Linneus uses for a straight and slender bill.

All the toes divided to the bottom.

The outer toe more or less united to the middle one, particularly conspicuous in the feet of the kingsfisher.

The foot of the woodpecker formed for climbing. Climbing feet.

Such as those of the grebes.

The webs indented in the sides, as in the coots and scoloped-toed sandpipers.

Such as want the back toe.

In which the foot is composed of two toes, observed only in the ollarich.

When the webs reach only half way of the toes.

When the hind-claw adheres to the leg, without any toe, as in the petrels.

All the four toes connected by webs, as in the corvornants.

When the edges of the bill are very sharp, such as in that of the crow.

A bill with a nail at the end; as in those of the goosanders and ducks.

When the tongue is edged with fine bristles, as in ducks.

When plain or even.

When the tongue is long, round and slender like a worm, as that of the woodpecker.

When the legs are placed so far behind as to make the bird walk with difficulty, or as if in fetters: as is the case with the auks, grebes, and divers.

When the nostrils are very narrow, as in sea-gulls.

With a rim round the nostrils, as in the stare.
ORNITHOLOGY.

A BIRD may be divided into head, body, and limbs.

I. HEAD.

1. Bill (rostrum), is a hard horny substance, consisting of an upper and under part, extending from the head, and anwering to the mandibles in quadrupeds. Its edges generally plain and sharp, like the edge of a knife,erculated, as are the bills of crows; but sometimes serrated, as in the toucan; or jugged, as in the gannet and some herons; or perinucleus, as in the duck; or denticulated, as in the mergansers; but always de- fide of real teeth imerred in sockets.

The base in falcons is covered with a naked skin or cere (cera); in some birds with a carious appendage, as the turkey; or a calous, as the curaco.

In birds of prey, the bill is hooked at the end, and fitted for tearing: in crows, straight and strong for picking: In water-fowl, either long and pointed, for fliking: or slender and blunt, for searching in the mire; or flat and broad for gobbling. Its other uses are for building nests; feeding the young; climbing, as in parrots; or, lastly, as an instrument of defence or offence.

2. Nostriiles (nare), the nice instruments of differ- encing their food, are placed either in the middle of the upper mandible, or near the base, or at the base, as in parrots; or behind the base, as in toucans and hornbills: but some birds, as the gannet, are defide of nostrils. The nostrils are generally naked; but sometimes covered with bristles reflected over them, as in crows, or hid in the feathers, as in parrots, &c.

The fore-part of the head is called the front (capitulum); the summit (vortex), or the crown: the hind part, with the next joint of the neck (nucha), the nape: the space between the bill and the eyes, which in herons, grebes, &c. is naked (lora), the frap: the space beneath the eyes (gnea), the cheeks.

3. Orbitae (orbitae), the eye-lids; in some birds naked, in others covered with short soft feathers.

Birds have no eye-brows; but the grous kind have in lieu a scarlet naked skin above, which are called faperculas: the same word is also applied to any line of a different colour that pales from the bill over the eyes.

4. Ears. Birds are defide of auriculae or external ears, having an orifice for admission of sound; open in all but owls, whose ears are furnished with valves.

The chin, the space between the parts of the lower mandible and the neck, is generally covered with feathers; but, in the cock and some others, has carious appendages called wattles (paleria); in others, is naked, and furnished with a pouch, capable of great dilatation (jaccula), as in the pelican and conversants.

6. Neck (collum), the part that connects the head to the body is longer in birds than in any other animals; and longer in such as have long legs than in those that have short, either for gathering up their meat from the ground, or striking their prey in the water, except in web-footed fowl, which are, by reverting their bodies, defined to search for food at the bottom of waters, as沙发, and the like. Birds, especially those that have a long neck, have the power of retracting, bending, or stretching it out, in order to change their centre of gravity from their legs to their wings.

II. BODY.

1. Conuts of the Back (dorsum), which is flat, strait, and inclines; terminated by the

2. Rump (crupittum), furnished with two glands, secreting a fatty liquor from an orifice each has, which the birds express with their bills to oil or anoint the dis- composed parts of their feathers. These glands are particularly large in most web-footed water-fowl: but in the grebes, which want tails, they are smaller.

3. Breast (petrus), is ridged and very muscular, defended by a forked bone (cervicula), the merry-thought.

The short winged birds, such as grous and others, have their breasts most flabby or muscular; as they require greater powers in flying than the long-winged birds, such as gulls and herons, which are particularly lighter and have greater extent of tail.

4. Belly (abdomen), is covered with a strong skin, and contains the entrails.

5. The Vent, or vent-feathers (cristura), which lies between the thighs and the tail. The anus lies hid in those feathers.

III. LIMBS.

1. Wings (ala), adapted for flight in all birds except the dodo, ostriches, squawky, great auk, and the penguins, whose wings are too short for the use of flying; but in the dodo and ostrich, when extended, serve to accelerate their motion in running; and in the penguins perform the office of fans, in swimming or diving.

The wings have near their end an appendage covered with four or five feathers, called the tefard wings (ala nata), and alula furia.

The lesser coverts (lettrices) are the feathers which lie in the bones of the wings.

The greater coverts are those which lie beneath the former, and cover the quill-feathers and the secondaries.

The quill-feathers (primores), spring from the first bones (digiti and metacarapi) of the wings, and are 10 in number.

Quill-feathers are broader on their inner than exterior sides.

The secondaries (secundariae), are those that rise from the second part (calibus), and are about 18 in number, are equally broad on both sides. The primary and secondary wing-feathers are called renitae.

A tuft of feathers placed beyond the secondaries near the juncture of the wings with the body. This in water-fowl is generally longer than the secondaries, cuneiform, and may not unly be called the tertials.

The scapulars are a tuft of long feathers arising near the juncture of the wings (brachia) with the body, and lie along the sides of the back, but may be easily distinguished, and raised with one's finger.

The inner coverts are those that clothe the under side of the wing.

The subaxillary are peculiar to the greater Paridae.

The wings of some birds are instruments of offence.

The anhima of Marcgrave has two strong spines in the front of each wing. A species of plover, Edw. tab. 47.
2. The Tail is the director or rudder of birds in their flight; they rise, sink, or turn by its means; for when the head points one way, the tail inclines to the other side: it is, besides, an equilibrium or counterpoise to the other parts; the use is very evident in the kite and swallows.

The tail consists of strong feathers (rectrices), to in number, as in the woodpeckers, &c.; 12 in the hawk tribe, and many others; in the gallinaceous, the mergansers, and the duck kind, of more.

It is either even at the end, as in moat birds, or forked, as in swallows; or cuneated, as in magpies, &c.; or rounded, as in the purple jackdaw of Catelyb. The grebe is defitute of a tail, the rump being covered with down; and that of the caiufoary with the feathers of the back.

Immediately over the tail are certain feathers that spring from the lower part of the back, and are called the coverts of the tail (wrygypnium).

3. Thighs (femora), are covered entirely with feathers in all land-birds, except the buffalout and the plovers; the lower part of those of all waders, or cloven-footed water-fowl, are naked; that of all web-footed fowl the fame, but in a lefs degree; in raptacious birds, are very mucular.

4. Legs (crura); those of raptacious fowls very strong, furnished with large tendons, and fitted for tearing and a firm grip. The legs of some of this genus are covered with feathers down to the toes, fuch as the golden eagle; others to the very nails of their hind toes, forward while they are feeding; Owls, grebes, divers, and penguins, have their legs placed quite behind, fo are necellafiod to fix ereft: their pace is awkward and difficult, walking like men in fetters: hence Linnaeus fyles their feet pedes compedes.

The legs of all cloven-footed water-fowl are long, as they muft wade in search of food; of the pamalted, short, except thoſe of the flamingo, the avocet, and the courier.

5. Feet (pædes), in all land-birds that perch, have a large back toe: moft of them have three toes forward, and one backward. Woodpeckers, parrots, and other birds that climb much, have two forward, two backward; but parrots have the power of bringing one of their hind toes forward while they are feeding themfelves. Owls have alfo the power of turning one of their fore toes backward. All the toes of the fafli turn forwards, which is peculiar among land-birds: the tridactylous woodpecker is alfo anomalous, having only two toes forward, one backward: the oltirich is another having but two toes.

6. Toes (digi). The toes of all waders are divided; but, between the exterior and middle toe, is generally a small web, reaching as far as the first joint. The toes of birds that swim are either plain, as in the fingle inftance of the common water-hen or gallinule; or pinnated, as in the coots and grebes; or entirely webbed or palmated, as in all other swimmers. All the plover tribe, or sharadri, want the back-toe. In the swimmers the name want prevails among the albatrosses and auks. No water fowl perch, except certain herons, the corvorant and the fhang.

7. Claws (ungues). Raptacious birds have very strong, hooked, and sharp claws, vultures excepted. Thofe of all land-birds that rooff on trees have alio hooked claws, to enable them to perch in safety while alfeep.

The gallinaceous tribe have broad concave claws for fraping up the ground.

Grebes have flat nails like the human.

Among water-fowl, only the fku, Br. Zool. II. p. 529. No 243. and the black-toed gull, Br. Zool. II. p. 532. No 244, have strong hooked or aqualine claws. All land-birds perch on trees, except the frithulous and fonie of the gallinaceous tribes. Parrots climb; woodpeckers creep up the bodies and boughs of trees; swallows cling.

All water-fowl reft on the ground, except certain herons, and one species of ibis, the spoonbill, one or two species of ducks and of corvorants.

IV. FEATHERS.

Feathers are defigned for two ufe; as coverings from the incclemency of the weather, and instruments of motion through the air. They are placed in fuch a manner as to fall over one another (tégulàtim), fo as to permit the wet to run off, and to exclude the cold; and thoſe on the body are placed in a quincuncial form; molt apparent in the thick-fkinned water-fowl, particularly in the divers.

1. The parts of a feather are, the shafts; corneous, strong, light, rounded, and hollow at the lower part; at the upper, convex above, concave below, and chiefly composed of a pith.

2. On each fide the shafts are the vanes, broad on one fide, narrow on the other; each vane confifts of a multitude of thin lamines, fliff, and of the nature of a split quill. These lamines are closely braced together by the elegant contrivance of a multitude of small brijites; thoſe on one fide hooked, the other ftraight, which lock into each other, and keep the vanes smooth, compact, and strong.

The vanes near the bottom of the shafts are soft, unconnected, and downy.

3. Feathers are of three kinds: (1.) Such as compose instruments of flight; as the pen feathers, or thoſe which form the wings and tail, and have a large shaft. The vanes of the exterior fide bending downward, of the interior upward, lying clofe on each other, fo that when preval not a feather muff its impulfe on the air. The component parts of these feathers are defcribed before.

(2.) The feathers that cover the body, which may be properly called the plumage, have little shaft, and much vane; and never are exerted or relaxed unless in anger, fright, or illnefs.
Sect II.

Flight.

(3.) The Down (plume), which is dispersed over the whole body amid the plumage, is short, soft, unconnected, consists of languid vane: and is intended for excluding that air or water which may penetrate or escape through the former. This is particularly apparent in aquatic birds, and remarkably so in the anserine tribe. There are exceptions to the forms of feathers. The vanes of the subaxillary feathers of the Paradisae are unconnected, and the laminae dilatant, looking like herring-bone. Those of the tail of the ostrich, and head of a species of curassio, curled. Those of the casuary consist of two shafts, slanting from a common stem at the bottom: as do at the approach of winter (after moulting) those of the pramrgins of arctic countries. The feathers of the pingueus, particularly those of the wings, consist chiefly of thin flat shafts, and more resemble scales than feathers; those of the tail, like split whale bone.

Sect. II. Flight of Birds.

The flight of birds is various; for, had all the same, none could elude that of rapacious birds. Those which are much on wing, or flit from place to place, often owe their preservation to that cause: those in the water, to diving. Kites, and many of the falcon tribe, glide smoothly through the air, with scarce any apparent motion of the wings.

Most of the order of pies fly quick, with a frequent repetition of the motion of the wings. - The Paradies floats on the air. Woodpeckers fly awkwardly, and by jerks, and have a propensity to sink in their progress.

The gallinaceous tribe, in general, fly very strongly and swiftly; but their course is seldom long, by reason of the weight of their bodies.

The columbian race is of singular swiftness; witness the flight of the carrier-pigeon. See Carrier Pigeon. The pafferine fly with a quick repetition of strokes; their flight, except in migration, is seldom dis tant.

Among them, the swallow tribe is remarkably agile, their evolutions sudden, and their continuance on wing long.

Nature hath denied flight to the turitious; but still, in running, their short wings are of use, when erect, to collect the wind, and like tails to accelerate their motion.

Many of the greater cloven-footed water-fowl, or waders, have a slow and flapping flight: but most of the lesser fly swiftly, and most of them with extended legs, to compensate the shortness of their tails. Rails and gallinules fly with their legs hanging down.

Coots and grebes with difficulty are forced from the water; but when they rise, fly swiftly. Grebes and also divers fly with their hind parts downwards, by reason of the forwardness of their wings.

Web-footed fowl are various in their flight. Several have a falling or flapping wing, such as gulls. Pinguins, and a single auk, are denied the power of flight. Wild geese, in their migrations, do not fly pell-mell, but in a regular figure, in order to cut the air with greater ease; for example, in long lines, in the figure of a >, or some pointed form or letter, as the ancients report that the cranes assumed in their annual migrations, till their order was broken by storms.

Luceu. lib. v. 711. * TAA.

From observation it appears, that the flight of birds is much afflicted by their being endowed with the peculiar faculty of enlarging their bulk at will; and from this circumstance the animal is enabled to buoy itself up the easter in the air, its specific gravity being increased in proportion as the bulk is increased.

This arises from certain airc vessels communicating with the lungs, and dispersed over various parts of the body, even to the bones; whereby the bird, by filling or emptying these vessels, has the power of contracting or dilating itself according to the occasion it may have for the change. See Censor. Amnies, no 121—123.

Sect. III. Of the Nuptial. Notification, and Eggs of Birds.

1. Most birds are monogamous, or pair; in spring fixing on a mate, and keeping constant till the cares of incubation and educating the young brood is past. This is the case, as far as we know, with all the birds of the first, second, fourth, and fifth orders.

Birds that lose their mates early, associate with others; and birds that lose their first eggs will pair and lay again. The male, as well as the female, of several, join alternately in the trouble of incubation, and always in that of nutrition; when the young are hatched, both are busied in looking out for and bringing food to the nestlings; and, at that period, the mates of the melo-dious tribes, who, before were perched on some spire, and by their warbling alleviated the care of the females confined to the nest, now join in the common duty.

Of the gallinaceous tribe, the greatest part are polygamous, at least in a tame state; the pheasant, many of the grouses, the patridges, and bustards, are monogamous; of the grouses, the cock of the wood, and the black game, assemble the females during the season of love, by their cries.

Et resemn in sac. cap.

The males of polygamous birds neglect their young; and in some cases, would destroy them, if they met with them. The economy of the bruitious order, in this respect, is obscure. It is probable that the birds which compose it are polygamous, like the common poultry, for they lay many eggs; the dodio, however, is said to lay but one. All waders or cloven-footed fowl are monogamous; and all with pinnated feet are also monogamous, except the ruffs.

The swimmers or web-footed fowl observe the same order, as far as can be remarked with any certainty; but many of the auks assemble in the rocks in such numbers, and each individual so contiguous, that it is
not possible to determine their method in this article.

It may be remarked, that the affection of birds to their young is very violent during the whole time of nutrition, or as long as they continue in a helpless state; but as soon as the brood can fly and shift for itself, the parents neglect, and even drive it from their haunts, the affection ceasing with the necessity of it: but during that period,

The mothers nurse it, and the fires defend.
The young dismiff'd, to wander earth, or air,
There flops the infant, and there ends the care:
The link dissolves; each seeks a fresh embrace;
Another love succeeds, another race.

2. The Nest of a bird is one of those daily miracles that from its familiarity, is passed over without regard. We stare with wonder at things that rarely happen, and neglect the daily operations of nature that ought first to excite our admiration and claim our attention.

Each bird, after nuptials, prepares a place suited to its species, for the depositing its eggs and sheltering its little brood: different genera, and different species, select the same plan in the structure of its nest, and choose the same form of situation for placing this temporary habitation. The young bird of the last year, which never saw the building of a nest, directed by a heaven-born sagacity, pursues the same plan in the structure of its, and selects the same materials as its parent did before. Birds of the same species, of different and remote countries, do the same.

The Swallows of Britain, and of the remoter parts of Germany, observe the same order of architecture; and in many instances have been known to return to the same places in which they had reared their young the year before.

The nests of the larger rapacious birds are rude, made of sticks and bents, but often lined with something soft; they generally build in high rocks, ruined towers, and in defolate places: enemies to the whole feathered creation, they seem conscious of attacks, and seek solitude. A few build upon the ground.

Shrikes, allied to the rapacious birds, build their nests in bushes, with moss, wool, &c.

The order of pies is very irregular in the structure of their nests. Parrots, and in fact all birds with two toes forward and two backward, lay their eggs in the hollows of trees. And most of this order creep along the boughs of trees, and lodge their eggs also within them.

Crows build in trees: among them, the nest of the magpie, composed of rude materials, is made with much art, quite covered with thorns, and only a hole left for admittance.

The nests of the orioles are contrived with wonderful sagacity, and are hung at the end of some bough, or between the forks of extreme branches. In Europe, only three birds have penknife nests; the common oriole, the parus pendulinus or hung-neft titmouse, and one more. But in the torrid zone, where the birds fear the search of the gliding serpent and inquisitive monkey, the instancies are very frequent; a marvellous instinct implanted in them for the preservation of their young. See Oriolus.

All of the gallinaceous and struthious orders lay their eggs on the ground. The ostrich is the only exception, among birds, of the want of natural affection: "which leaveth her eggs in the earth, and warmeth them in the dust, and forgettest that the foot may crush them, or the wild beast may break them."

The columbine race makes a moss artless nest, a few sticks laid across may suffice.

Most of the pallerine order build their nests in shrubs or bushes, and some in holes of walls or banks. Several in the torrid zone are penile from the boughs of high trees; that of the taylor-bird, a wondrous instance. Some of this order, such as larks, and the &c. goat-fucker, on the ground. Some swallows make a _taccila, a_ curious plaster-nest beneath the roofs of houses; and _an Indian species, nests of a certain glutinous matter, which are collected as delicate ingredients for soups of Chinese epicures. See the article Birds Nests._

Most of the cloven-footed water-fowl, or waders, lay upon the ground. Spoonbills and the common heron build in trees, and make up large nests with sticks, &c. Storks build on churches, or the tops of houles.

Coots make a great nest near the water side.

Grebes, in the water, a floating nest, perhaps adhering to some neighbouring reeds.

Web footed fowl breed on the ground, as the avo-fet, terns, some of the gulls, merganfers, and ducks: the last pull the down from their breasts, to make a softer and warmer bed for their young. Auks and gillemots lay their eggs on the naked shelves of high rocks; pinguins, in holes under ground: among the pelicans, that which gives name to the genus, makes its nest in the defiant, on the ground. Shogs, sometimes on trees; corvorants and gannets, on high rocks, with sticks, dried algae, and other coarse materials.

3. Rapacious birds, in general, lay few eggs: eagles and the larger kinds, fewer than the less. The eggs of falcons and owls are rounder than those of most other birds; they lay more than fixed.

The order of pies vary greatly in the number of their eggs.

Parrots lay only two or three white eggs.

Crows lay fix eggs, greenish, filled with dusky. Cuckoos, as far as we can learn, two.

Woodpeckers, wryneck, and kings-fisher, lay eggs of a clear white and firm transparent colour. The woodpeckers, lay fixed, the others more.

The nuthatch lays often in the year, eight at a time, white, spotted with brown.

The hoopoe lays but two cinnerous eggs.

The creeper lays a great number of eggs.

The honey-fucker, the leaf and moss defencelefs birds, lays but two: but Providence wisely prevents the extinction of the genus, by a swiftness of flight that eludes every pursuit.

The gallinaceous order, the most useful of any to mankind, lay the most eggs, from 8 to 20. _Benigna circida hoa natura, inoica et cedentia animalia focunda genereis_, is a fine observation of Pliny. With exception to the buffard, a bird that hangs between the.
 Sect. IV. ORNITHOLOGY.

Eggs. of the gallinaceous and the waders, which lay only two.

The columbine order lays but two white eggs; but the domestick kind breeding almost every month, supports the remark of the Roman naturalist.

All of the pallerine order lay from four to six eggs; except the titmoufe and the small, which lay 15 or 16, and the goatherd, which lays only two. The thrushous order disagrees much in the number of eggs; the ostrich laying many, as far as 50; the dodo but one.

The cloven-footed water-fowl, or waders, lay, in general, four eggs: The crane and the Norfolk plower seldom more than two. All those of the Fipe and plower genus are of a dirty white, or olive spotted with black, and scarce to be distinguished in the holes they lay in. The bird called the Land Rail (an ambiguous species), lays from 15 to 20. Of birds with pinnated feet, the coot lays seven or eight eggs, and sometimes more. Grebes, from four to eight, and those white.

The web-footed, or swimmers, differ in the number of their eggs. Those which border on the order of waders, lay few eggs; the avolet two; the flamingo three; the albatross, the auks, and guillemotts, lay only one egg a-piece; the eggs of the two last are of a fize strangely large in proportion to the bulk of the birds. They are commonly of a pale green colour, spotted, and striped so variously, that not two are alike; which gives every individual the means of distinguishing its own on the naked rock where such multitudes assemble.

Divers only two.

Terns and gulls lay about three eggs, of a dirty olive, spotted with black.

Ducks lay from eight to twenty eggs; the eggs of all the genus are of a pale green, or white, and unspotted.

Penguins probably lay but one egg.

Of the pelican genus, the gannet lays but one egg; the flags or corvorants, fix or seven, all white; the last, the last of the series.

A minute account of the eggs of birds might occupy a treatise of itself. This is only meant to shew the great conformity nature observes in the shape and colours of the eggs of congenerous birds; and also, that the keeps the same uniformity of colour in the eggs as in the plumage of the birds they belong to.

Zimmant published, at Venice, in 1737, A Treatise on Eggs, illustrated with accurate figures of 106 eggs. Mr. Reyger of Dantzick published, in 1760, a polished work by Klein, with 21 plates, elegantly coloured: but much remains for future writers.

Sect. IV. System.

Considering the many systems that have been offered to the public of late years, Mr. Pennant gives the preference to that composed by Mr. Ray in 1667, and afterwards published in 1678; but observes, at the same time, that it would be unfair to conceal the writer, from whom our great countryman took the original hint of forming that system which has proved the foundation of all that has been composed since that period.

He was a Frenchman, Belon of Mans, who first attempted to range birds according to their nature; and performed great matters, confidering the unenlightened age he lived in; for his book was published in 1555. His arrangement of repacious birds is as judicious as that of the last writers. For his second chapter treats of vultures, falcon's, thrives, and owls; in the two next, he passes over to the web-footed water-fowl, and to the cloven-footed: in the fifth, he includes the gallinaceous and thrushous; but mixes them with the plowers, bunting and larks: in the sixth, the pigeons, and thrushes; and the seventh takes in the rest of the pallerine order.

Notwithstanding the great defects that every naturalist will at once fee in the arrangement of the lesser birds of this writer, yet he will observe a relitude of intention in general, and a fine notion of system, which was left to the following age to mature and bring to perfection. Accordingly Mr. Ray, and his illustrious pupil the honourable Francis Willoughby, assumed the plan; but with great judgment flung into their proper stations and proper genera those which Belon had confusedly mixed together. They formed the great division of terrestrial and aquatic birds; they made very species occupy their proper place, confulting at once exterior form and natural habit. They could not bear the affected intervention of aquatic birds in the midst of terrestrial birds. They placed the last by themselves; clear and distinct from those who's haunts and economy were so different.

The above-joined scheme of arrangement by Mr. Pennant, is introduced with the following observations.

"Mr. Ray's general plan is so judicious, that to me it seems scarce possible to make any change in it for the better: yet, notwithstanding he was in a manner the founder of systematic zoology, later discoveries have made a few improvements on his labours. My candid friend Linnaeus did not take it amiss, that I, in part, neglected his example: for I permit the land-fowl to follow one another, undivided by the water-fowl, the grallæ, and anseres of his system; but, in Mr. Pennant's generical arrangement, I most punctually attend to the order he has given in his several divisions, except in those of his anseres, and a few of his grallæ. For, after the manner of Mr Berthol, I make a distinct order of water-fowl with pinnated feet, placing them between the waders, or cloven-footed water-fowl and the web-footed. The ostrich, and land-birds with wings useless for flight, I place as a distinct order. The trumpeter (Phasianus), and the bulbul, I place at the end of the gallinaceous tribe. All are land-birds. The first multiporous, like the generality of the gallinaceous tribe; the last grannorous, swift runners, avoiders of wet places; and both have bills somewhat arched. It must be confessed, that both have legs naked above the knees; and the last, like the waders, lay but few eggs. They seem ambiguous birds that have affinity with each order; and it is hoped that each naturalist may be indulged the toleration of placing them as suits his own opinion."

In the latter arrangements of birds, although it cannot be said that the authors have lost fight of their great predecessor Linneus, yet the necessity of deviating from him must seem obvious, when the very great number of species which have come to our knowledge of late years, sufficient to justify such alteration, and satisfy the most scrupulous advocates of this great man, is considered. In his last edition of the *Systema Naturs*, Linneus enumerates about 930 birds only; but
ORNITHOMANCY, a species of divination performed by means of birds; being the same with augury. See Divination and Augury.

ORNITHOPUS, in botany: A genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, Papilionaceae. The legumen is articulated, cylindrical, and bent in the form of a bow.

ORNUS RAXINUS, is that species of the ash tree, in the Linnæan sydnum, which, according to Dr Cirollo of Naples, produces the manna. It is the ash-tree, whose smaller leaves are sawed, with flowers having petals. In order to obtain the manna, those whose business it is, in July and August, make an oblong incision, and take off from the bark of the tree about three inches in length and two in breadth: they leave the wound open, and by degrees the manna runs out, and is almost suddenly thickened to its proper confluence, and is found adhering to the bark of the tree. This is collected in baskets, and called manna graifia. When they want fine manna, they apply to the incision of the bark thin straw, or small bits of shrubs; so that the manna in coming out runs upon these bodies, and is collected in a fort of regular tubes, which gave it the name of manna in cannis.

OROBANCHE, in botany: A genus of the angiopermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, Peronaceae. The calyx is bifid; the corolla ringent; the capsule unilocular, bivalved, and polypersymous; there is a glandule under the base of the germ.

OROBOIO (Don Belchafar), a celebrated Jew of Spain. He was carefully educated in Judaism by his parents who were Jews, though they outwardly professed themselves Roman Catholics; abstaining from the practice of their religion in every thing, except only the obser- vation of the fast of expiation, in the month Tifi or September. Oroboio studied the scholastic philosophy usual in Spain, and became so skilled in it, that he was made professor of metaphysics in the university of Salamanca. Afterwards, however, applying himself to the study of phyric, he professed that art at Seville with success; till, accused of Judaism, he was thrown into the inquisition, and suffered the most dreadful cruelties, in order to force a confession. He himself tells us, that he was put into a dark dungeon, so frail that he could scarce turn himself in it; and suffered so many hardships, that his brain began to be disturbed. He talked to himself often in this way: "Am I indeed that Don Belchafar Oroboio who walked freely about in Seville, who was entirely at ease, and had the blessings of a wife and children? Sometimes, supposing that his past life was but a dream, and that the dungeon where he then lay was his true birth-place, and which to all appearance would also prove the place of his death? At other times, as he had a very metaphysical head, he first formed arguments of that kind, and then resolved them; performing thus the three different parts of opponent, respondent, and moderator, at the same time. In this whimsical way he amused himself from time to time, and constantly denied that he was a Jew. After having appeared twice or thrice before the inquisitors, he was tried as follows: At the bottom of a subterraneous vault, lighted by two or three small torches, he appeared before two persons, one of whom was judge of the inquisition, and the other secretary; who, asking him whether he would confess the truth? protested, that in case of a criminal's denial, the holy office would not be deemed the cause of his death if he should expire under the tortures, but that it must be imputed entirely to his own obstinacy. Then the executioner flipt off his clothes, tied his feet and hands with a strong cord, and set him upon a little stool, while he paased the cord through some iron buckles which were fixed in the wall; then drawing away the stool, he remained hanging by the cord, which the executioner full drew harder and harder, to make him confess, till a surgeon ascribed the court of examinants, that he could not possibly bear more without expiring. These cords put him to exquisite tortures, by cutting into the flesh, and making the blood burst from under his nails. As there was certainly danger that the cords would tear of his flesh, to prevent the world, care was taken to gird him with some bands about the breast, which however were drawn so very tight, that he would have run the risk of not being able to breathe, if he had not held his breath in while the executioner put the bands round him; by which device his lungs had room enough to perform their functions. In the severest extremity of his sufferings he was told that this was but the beginning of his torments, and that he would better confess before they proceeded to extremities. Oroboio added further, that the executioner, being on a small ladder, in order to frighten him, frequently let it fall against the hinhones of his legs; so that the flaves being sharp, cre- ated exquisite pain. At last, after three years confinement, finding themselves baffled by his perseverance in denying his religion, they ordered his wounds to be cured, and discharged him. As soon as he had got liberty, he resolved to quit the Spanish dominions; and, going to France, was made professor of physic at Thoulouze,
Thlonolus. The thieves which he made as candidate for this place were upon pursethief; and he maintained them with so much metaphysic falsity, as embarrased all his competitors. He continued in this city for some time, till outwardly profiting popery; but at last, weary of dissembling, he repaired to Amsterdam, where he was circumcised, took the name of Isaac, and professed Judaism; and continuing, however, to practice physics, in which he was much esteemed. Upon the publication of Spinoza’s book, he defaced a Tyburn the following in which he quickly discovered; and when Breendonburgh’s answer to it came to his hands, Orbelo, being persuaded that the writer, in relating Spinoza, had also admitted the same principles which tended to Atheism, took up his pen against them both, and published a piece to that purpose, intituled, *Cursus philosophicus aduersus J. B. Principia.* But the dispute which he held with the celebrated Philip Limborch against the Christian religion made the greatest noise. Here he exerted the utmost force of his metaphysical genius, and carried himself with great temper. The three papers which he wrote on the occasion were afterwards printed by his antagonist, in an account which he published of the controversy, under the title of *Antica Colalia cum Judio.* Orbelo died in 1687.

**Orobus, bitter vetch:** A genus of the decaandrid order, belonging to the chalcedapha class of plants; and in the natural method ranking under the 32d order, *Papilionaceae.* The style is linear; the calyx obtuse at the base, with the upper segments deeper and longer than the rest. There are nine species. All of them have ribbed roots, which are perennial, but are annual in flax, rising early in spring and decaying in autumn. They are very hardy plants, and proper in any common soil of a garden. Most of the flowers are very floriferous, and the flowers conspicuous and ornamental for adorning the flower compartments. The flowers are universally of the papilionaceous or butterfly kind, consisting each of four irregular petals, *i.e.* a standard, two wings, and a keel; and are all succeeded by long taper seed-pods, furnishing plenty of ripe seed in autumn; by which the plants may be propagated abundantly, as also by parting the roots.

The Scotch Highlanders have a great esteem for the tubercles of the roots of the tuberosus, or species sometimes called *Orobus.* They dry and chew them in general to give a better relish to their liquor; they also affirm that they are good against most disorders of the breath, and that by the use of them they are enabled to relish hunger and thirst for a long time. In Breadalbane and Ross-shire, they sometimes bruise and steep them in water, and make an agreeable fermented liquor with them. They have a sweet taste, something like the roots of liquorice; and, when boiled, we are told, they are nutritious and well flavoured; and in times of scarcity they have served as a substutute for bread.

**Orodes,** a prince of Parthia, who murdered his brother Mithridates, and ascended his throne. He defeated Caius the Roman triumvir, and poured melted gold down the throat of his fallen enemy, to reproach him for his avarice and ambition. He followed the interest of Caligula and Brutus at Philippi. It is said, that when Orodes became old and infirm, 50 children applied to him, and disputed in his presence their right to the succession. Pharnaces, the eldest of them, obtained the crown from his father; and, to halt him out of the world, he attempted to poison him. The poison had no effect; and Pharnaces, still determined on his father’s death, starved him with his own hands, about 35 years before the Christian era. Orodes had then reigned about 50 years.

**Orontium,** in botany; A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the second order, *Piperaceae.* The spadix is cylindrical covered with florets; the corolla hexapetalous and naked; there is no style; the follicles are monothalamous.

**Oroonoke,** a great river of terra firma, in South America, which rises in Popayan, and falls into the sea with 16 mouths.

**Orphan,** a fatherless child or minor; or one that is deprived both of father and mother.

**Orpheus,** a celebrated poet and musician of antiquity. His reputation was established as early as the time of the Argonautic expedition, in which he was himself an adventurer; and is said by Apollodorus Rhodius not only to have incited the Argonauts to row by the sound of his lyre, but to have vanquished and put to silence the sirens by the superiority of his trains. Yet, notwithstanding the great celebrity he had so long enjoyed, there is a passage in Cicero, which says, that Aristo, in the third book of his *Posters,* which is now lost, doubted if such a pofton as Orpheus ever existed. But as the work of Cicero, in which this passage occurs, is in dialogue, it is not easy to discover what was his own opinion upon the subject, the words cited being put into the mouth of Catus Cotta. And Cicero, in other parts of his writings, mentions Orpheus as a person of whole existence he had no doubts. There are several ancient authorities, among whom is Suidas, who enumerates five person of the name of Orphus, and relate some particulars of each. And it is very probable that it has fared with Orpheus as with Hercules, and that writers have attributed to one the actions of many. But, however that may have been, we shall not attempt to collect all the fables that poets and mythologists have invented concerning him; they are too well known to need mention here. We shall, therefore, in speaking of him, make use only of such materials as the most ancient historians, and the most respectable writers among the moderns, have furnished towards his history.

Dr. Cudworth, in his *Intellectual System,* after *Orodes,' mining and confounding the objections that have been Sec. 17, made to the being of an Orpheus, and with his usual learning and abilities clearly establishing his existence, proceeds in a very ample manner, to speak of the opinions and writings of our bard, whom he regards not only as the first musician and poet of antiquity, but as a great mythologist, from whom the Greeks derived the Thracian religious rites and mysteries.

"I: is the opinion (says he) of some eminent philosophers of later times, that there never was any such person as Orpheus, except in Fairy-land; and that his whole history was nothing but a mere romantic allegory, utterly devoid of truth and reality. But there..."
Orpheus was the son of Cæger, by birth a Thracian, the father or chief founder of the mythological and allegorical theology amongst the Greeks, and of all their most sacred religious rites and mysteries; who is commonly supposed to have lived before the Trojan war, that is, in the time of the Israelitish judges, or at least to have been senior both to He SECOND and Homer; and to have died a violent death, most affirming that he was torn in pieces by women, because their husbands deserted them in order to follow him. For which reason, in the vision of Herus Pamphilus, in Plato, Orpheus’s soul passing into another body, is said to have chosen that of a swan, a reputed musical animal, on account of the great hatred he had conceived for all women, from the death which they had inflicted on him. And the historic truth of Orpheus was not only acknowledged by Plato, but also by Isocrates, who lived before Arilottlo, in his oration in praise of Busiris; and confirmed by the grave historian Diodorus Siculus, who says, that Orphus diligently applied himself to literature, and when he had learned the mysteries, or the mythological part of theology, he travelled into Egypt, where he soon became the greatest proficient among the Greeks in the mysteries of religion, theology, and poetry. Neither was his history of Orphus contradicted by Origen, when so justly provoked by Celus, who had preferred him to our Saviour; and, according to Suidas, Orpheus the Thracian was the first inventor of the religious mysteries of the Greeks, and that religion was thence called Orphica Theogonia, as if a Thracian invention. On account of the great antiquity of Orpheus, there have been numberless fables intermingled with his history; yet there appears no reason that we should disbelieve the existence of such a man.”

Cudworth is also of opinion, that the poems ascribed to Orpheus were either written by him, or that they were very ancient, and contained his doctrines. He farther argues, that though Orphus was a polytheist, and affointed a multiplicity of gods, he nevertheless acknowledged one supreme unmade deity, as the original of all things; and that the Pythagoreans and Platonists not only had Orpheus in great esteem, being commonly called by them the Theologer, but were also thought in great measure to have owed their theology and philosophy to him, deriving it from his principles and traditions.

The bishop of Gloucester speaks no more doubtfully of the existence of Orpheus than of Homer and Hehid, with whom he ranks them, not only as a poet, but also as a theologian, and founder of religion.

The family of Orpheus is traced by Sir Isaac Newton for several generations: “Selæc passing over the Tyrrhenian sea, conquers Thracia; kills Lycurgus, king of that country; and gives his kingdom and one of his singing-women to Cægus, the son of Tharops, and father of Orpheus; hence Orpheus is said to have had the muse Calliope for his mother.”

He is allowed by most ancient authors to have excelled in poetry and music, particularly the latter: and that to such a degree, that he is represented as taming the most ferocious animals, changing the course of the winds by his melody, and as causing the trees of the forest to dance in concert with his lyre. This account, though we must suppose it fabulous, yet proves his excellence to have been great before it could have given rise to such fictions. He is said to have early cultivated the lyre, in preference to every other instrument: so that all those who came after him were contented to be his imitators; whereas, according to Plutarch, he adopted no model; for before his time no other music was known, except a few airs for the flute. Music was so closely connected in ancient times with the most sublime sciences, that Orpheus united it not only with philosophy, but with theology and legislation. Music, he abstained from eating animal food; and held eggs in abhorrence as aliment, being perfuaded that the egg suffered before the chicken, and was the principle of all existence: both his knowledge and prejudices, it is probable, were acquired in Egypt, as well as those of Pythagoras many ages after.

With respect to his abstaining from the flesh of oxen, Gelfner supposes it may have proceeded from the veneration shown to that animal so useful in tillage, in the Eleusinian mysteries instituted in honour of Ceres, the goddess of agriculture. He might have added, that, as these mysteries were instituted in imitation of those established in Egypt in honour of Osiris and Isis, this abstinence from animal food was of the like origin, and a particular compliment to Apis. But Abbé Praguer, in an ingenious dissertation upon the Orphic Life, gives still more importance to the prohibition; for as Orpheus was the legislator and humanizer of the wild and savage Thracians, who were carnivorous, a total abolition of eating human flesh could only be established by obliging his countrymen to abstain from every thing that had life.

With respect to theology, Diodorus Siculus tells us, that his father Cægus gave him his first instructions in religion, imparting to him the mysteries of Orphus and Bacchus, as they were then practiced in Thrace. He became afterwards a disciple of the Idae Daely in Crete, and there acquired new ideas concerning religious ceremonies. But nothing contributed so much to his skill in theological matters, as his journey into Egypt; where being initiated into the mysteries of Isis and Osiris, he acquired a knowledge concerning initiations, expiations, funeral rites, and other points of religious worship, far inferior to any one of his age and country. And being much connected with the descendants of Cadmus, the founder of Thebes in Boeotia, he resolved, in order to honour their origin, to transport into Greece the whole fable of Osiris, and apply it to the family of Cadmus. The credulous people easily received this tale, and were much flattered by the institution of the ceremonies in honour of Osiris. Thus Orpheus, who was held in great veneration at the Grecian Thebes, of which he became a citizen, admirably adapted this
this fable, and rendered it respectable, not only by his beautiful verses and manner of singing them, but by the reputation he had acquired of being profoundly skilled in all religious concerns. Diodorus Siculus also says that he was a most attentive student in all kinds of literature, whether sacred or profane.

At his return into Greece, according to Pausanias, he was held in the highest veneration by the people, as they imagined he had discovered the secret of expiating crimes, purifying criminals, curing diseases, and appeasing the angry gods. He formed and promulgated an idea of a hell, from the funeral ceremonies of the Egyptians, which was received throughout all Greece. He instituted the mysteries and worship of Hecate among the Egyptians, and that of Ceres at Sparta.

Justin Martyr says, that he introduced among the Greeks near 360 gods; Heidus and Homer purified his labours, and followed the same clue, agreeing in the like doctrines, having all drunk at the same Egyptian fountain.

Profe: authors look upon Orpheus as the inventor of that species of magic called operation of the names, or raising ghosts; and indeed the hymns which are attributed to him are mostly pieces of incantation, and real conjuration. By all accounts he was an admirable musician: he is said to have received a lyre from Apollo, or according to some from Mercury, upon which he played with such a masterly hand, that even the most rapid rivers ceased to flow, the savage beasts of the forest forgot their wildness, and the mountains came to listen to his song. All nature seemed charmed and animated, and the nymphs were his constant companions. Eurydice was the only one who made a deep impression on the melodious musician, and their meetings were celebrated. Their happiness, however, was but short: for Aritus became enamoured of her; and as she fled from her pursuer, a serpent that was lurking in the grass bit her foot, and the died of the poisoned wound. Her loss was severely felt by Orpheus, and he resolved to recover her or perish in the attempt. With his lyre in his hand, he entered the infernal regions, and gained an easy admission to the palace of Pluto. The king of hell was charmed with the melody of his strains; and according to the beautiful expressions of the poets, the wheel of Ixion stopped, the stone of Sisyphus stood still, Tantalus forgot his perpetual thirst, and even the Furies relented. Pluto and Proserpine were moved with his sorrow, and confessed to relieve him Eurydice, provided he forbore looking behind him till he had come to the extremest borders of hell. The conditions were gladly accepted, and Orpheus was already in sight of the upper regions of the air, when he forgot his promises, and turned back to look at his long lost Eurydice.

All dangers past, at length the lovely bride In safety goes, with her melodious guide; Longing the common light again to thare, And draw the vital breath of upper air: He first, and close behind him followed she; For such was Proserpine's severe decree. When strong desires th' impatient youth invade; By little caution, and much love betrayed:

A fault which easy pardon might receive, Were lovers judges, or could hell forgive. For near the confines of etherial light, Th' unwar' lover call a look behind, Forgetful of the law, nor matter of his mind. Straight all his hopes exhale'd in empty smoke; And his long toils were forfeit for a look.

Dryden's Virgil.

He saw her, but the instantly vanished from his eyes: He attempted to follow her, but he was refused admission; and the only comfort he could find was to soothe his grief at the found of his musical instrument in grottoes or on the mountains. He totally separated himself from the society of mankind; and the Thracian women whom he offended by his coldness to their amorous passion, or according to others, by his unnatural gratifications and impure indulgencies, attacked him while they celebrated the orgies of Bacchus; and after they had torn his body to pieces, they threw his head into the Hebrus, which still articulated the words Eurydice! Eurydice! as it was carried down the stream into the Aegean sea. Others think, that as he attempted to conjure his wife from the dead, which they understood by the story of his going down to hell, he thought she saw him, and when afterwards, on looking back he missed her, he died of grief. There is certainly some reason for supposing this to be the case: for there were persons and temples publicly appointed for the purpose; and Pausanias really speaks of that temple which was in Thebes, and where Orpheus went to call up the ghost of Eurydice. Poets often mention this subject; and instances of it occur in history both sacred and profane. The witch of Endor is well known to those who read the historical part of the Bible. But to particularise instances, whether sacred or profane, would be endless. Some maintain that he was killed by a thunder-bolt. He was buried at Pieria in Macedonia, according to Apollodorus. The inhabitants of Dion boasted that his tomb was in their city, and the people of Mount Libethus in Thrace claimed the fame honour; and farther observed that the nightingales which built their nests near his tomb, sang with greater melody than all other birds. Orpheus, as some report, after death received divine honours; the muses gave an honourable burial to his remains, and his lyre became one of the constellations in the heavens.

Tzetzes explains the fable of his drawing his wife Eurydice from hell, by his great skill in medicine, with which he prolonged her life, or, in other words, snatched her from the grave. Æsculapius, and other physicians, have been said to have raised from the dead those whom they had recovered from dangerous diseases.

The bishop of Gloucester, in his learned, ample, and admirable account of the Eleusinian mysteries, says, "While these mysteries were confined to Egypt their native country, and while the Grecian lawgivers went thither to be initiated, as a kind of designation to their office, the ceremony would be naturally described in terms highly allegorical. The way of speaking
The seven springs given by the poet in this passage to the lyre of Orpheus, is a circumstance somewhat historical. The first Maccenean lyre had, at most, but four strings. Others were afterwards added to it by the second Mercury, or Amphiom: but, according to several traditions preserved by Greek historians, it was Orpheus who completed the second tetrachord, which extended the scale to a heptachord, or seven sounds, implied by the form d isninae sermon.

For the assertion of many writers, that Orpheus added two new strings to the lyre, which before had seven, clashes with the claims of Pythagoras to the invention of the doachord, or addition of the sound of tisambamono to the heptachord, of which almost all antiquity allows him to have been the inventor. And it is not easy to suppose, that the lyre should have been represented in ancient sculpture with four or five strings only, if it had had nine so early as the time of Orpheus, who flourished long before sculpture was known in Greece. See the article Lyra.

With respect to the writings of Orpheus, he is mentioned by Plutarch as author of the Argonautica, and Herodotus speaks of his Orphics. His hymns, says Paulhanias, were very short, and but few in number: the Lycomides, an Athenian family, knew them by heart, and had an exclusive privilege of singing them, and those of their old poets, Melius, Onomacritus, Pamphilus, and Olen, at the celebration of the Eleusinian mysteries; that is, the priesthood was hereditary in this family.

Jamblichus tells us, that the poems under the name of Orpheus were written in the Doric dialect, but have since been transmuted, or modified. It was the common opinion in antiquity that they were genuine; but even those who doubted of it, gave them to the earliest Pythagoreans, and some of them to Pythagoras himself, who has frequently been called the follower of Orpheus, and has been supposed to have adopted many of his opinions.

Of the poems that are still subsisting under the name of Orpheus, which were collected and published at Nuremberg 1702, by And. Chrift, Eichbach, and which have been since reprinted at Leipzig 1769, under the title of ORPHEUS APHAN, several have been attributed to Onomacritus, an Athenian, who flourished under the Pythiotic, about 500 years before Christ. Their titles are, 1. The Argonautica, an epic poem. 2. Eighty-six hymns; which are full of incantations and magical evocation, that Daniel Heinian has called them serem Satana liturgiam, "the true liturgy of the devil." Paulhanias, who made no doubt that the hymns subsisting in his time were composed by Orpheus, tells us, that though less elegant, they had been preferred for religious purposes to those of Homer. 3. De lapidibus, a poem on precious stones. 4. Fragments, collected by Henry Stevens. Orpheus has been called the inventor, or at least the propagator, of many arts and doctrines among the Greeks. 1. The combination of letters, or the art of writing. 2. Music, etc.
OPR E

OPR EUS, the lyre, or cithara, of seven strings, adding three to that of Mercury, 3. Hexameter verse. 4. Mysteries and theory. 5. Mechanics. 6. Magic and divination.

7. Astrology. Servius upon the fifth Aenid, p. 459, says Oprius first instituted the harmony of the spheres.

8. He is said likewise to have been the first who imagined a plurality of worlds, or that the moon and planets were inhabited.

OPR EUS, in ichthyology, the name of a fish caught in the Archipelago. It is of a broad and flat figure, and of a fine purple colour; its eyes are large and prominent, and its teeth serrated; it has only one fin on the back, and the anterior rays of that are prickly, the others soft to the touch; its anus is small, and is said to have no passage for the semen.

This was the fish called orpies by the ancients, but the modern Greeks call another fish by that name. It is a species of the sparus, of a flat figure, but very thick, has a small mouth, and is covered with small but very rough scales, which adhere very firmly to the flesh; the tail is not forked; it has fishy lips, and very small teeth; its back and sides are black; its belly white; it has a large black spot at the root of the tail; its head is reddish, and its fins are very elegantly diversified with various colours; it has only one back-fin, and that has the anterior ray prickly, the hinder ones not at all so. It grows sometimes to 20 pounds weight, and is much esteemed among the modern Greeks.

OPR I M E N I , auripigmentum, in natural history, a bituminous mineral composed of sulphur and arsenic, sometimes artificially produced, but found also native in the earth, and constituting one of the ores of arsenic. It is of two kinds, red and yellow, the former generally found in an indurated state; though Cronstedt supposes that it may also be met with in loose fey powder, as it is sometimes met with in the ships. It is commonly found in shapelicks masses, very seldom crystallized; though Baron Borne once found it in a polyhedral form on a blue clay in Hungary. The name red opiment has been given by the more judicious to fandarch, and by the vulgar to red arsenic; but it is to be restrained only to this sulphure, which is of a fine bright red, and of the common nature of the opiments, and answering all their characters. It is a very beautiful sublimate of a fine bright red, very glossy, and a little transparent, and is found in the Turkish dominions, in the islands of the Archipelago, and even in Great Britain; Dr Hill having received some of it from Cornwall, under the name of red monxe. The yellow kind is met with commonly of thinning flexible lamellae like mica, the specific gravity about 5.515. It burns with a blue flame, and contains about one tenth of its weight of sulphur. It is found native in Hungary; and in many parts of Germany and the Turkish dominions; it is the common opiment of the flaps. Some are of opinion, that the noxious qualities of the arsenic are so much counteracted by the sulphur with which this sublimate is mixed, that it may be swallowed with safety; but Macquer positively asserts the contrary, and very seriously cautions against its use, even though we be certain that the opiment is native. There is besides a broad-flaked, gold-coloured kind, well known among the ancients, as is plain from the description of it left us by Dioscorides, and much esteemed at present by our painters. This is found in several places, as in the islands of the Archipelago, in the mines of Geoff laer in Saxony, in some parts of Turkey, and the East Indies, and in its utmost purity about Smyrna; this makes the finest of all yellows in painting. The small-flaked, yellow kind, which is the common opiment of the flaps, is also a fine colour, though greatly inferior to the former. The Indians use opiment, corrected with juice of lemons, with good success against fevers.

The red arsenic, or redger, is likewise found in an indurated state, and in regular or rhombical masses. It is either opaque or semitransparent; sometimes it is found quite transparent, and regularly crystallized in octahedral prisms or pyramids; in which form it is called rusty of arsenic. Its specific gravity is above 5.25; it contains 16 per cent. of sulphur; and its red colour is entirely derived by the nitrous acid. In order to analyse these two kinds of opiment, they ought to be digested in marline acid, adding the nitrous acid by degrees to digest the solution. The sulphur is then left on the filter, while the arsenic remains in the solution, from which it may be precipitated in its metallic form by zinc, adding spirit of wine to the solution.

OPRINE, in botany. See SADUS.

ORRERY, a curious machine for representing the motions or phases of the heavenly bodies. See ASTRONOMY, p. 13, 487, 488, and 490.

The reason of its being called an Orrery, was this: Mr Rowley, a mathematical instrument-maker, having got one from Mr George Graham, the original inventor, to be sent abroad with some of his own instruments, he copied it, and made the first for the earl of Orrery. Sir R. Chad, who knew nothing of Mr Graham's machine, thinking to do justice to the first encourager, as well as to the inventor, of such a curious instrument, called it an Orrery, and gave Mr Rowley the praise due to Mr Graham.

It would be too great an undertaking here to give an account of the mechanism of the larger fort of orreries, which represent the movements of all the heavenly bodies; nor indeed can it be done either by venography or descriptive instruments since it is impossible to the most discerning reader: but, instead of that, we shall exhibit an idea of the theory and structure of an useful, concise, and portable planetarium, which any gentleman may have made for a small expense, and will exhibit very justly the motions of all the primary planets about the sun, by wheel-work; and those that have secondaries, or moons, may have them placed about their primaries moveable by the hand, so that the whole shall be a just representation of the solar system, or true state of the heavens, for any given time of the year.

In order to this, we must compare, and find out the proportion, which the periodic times, or revolutions of the primary planets, bear to that of the earth; which, with respect to the Geographia Siderum, are not as yet sufficiently ascertained; but those of the other planets are such as are expressed in the table below, where the first column is the time of the earth's period in days and decimal parts; the second, that of the planets; the third and fourth are numbers in the same proportion to each other: as,
ORSATO (Sertorio), a celebrated antiquarian, historian, and poet, was born at Padua in 1617, and early discovered a taste for literature and the sciences. He applied himself to searching out antiquities and ancient inscriptions; for which purpose he travelled through all the different parts of Italy, and in the mean time poetry was his amusement. When advanced in age, he taught natural philosophy in the University of Padua. He was also a member of the academy of the Ricovrati. Having presented to the doge and senate of Venice the history of Padua, which he had dedicated to them, he made a long speech, during which he struggled with a natural want, and died of suffocation of urine, on the 3d of July 1678. He wrote a great number of books which are esteemed, some in Latin, and others in Italian.

He ought not to be confounded with John Bapt. Orsato, an able physician and antiquary, who was born at Padua in 1673, and wrote, 1. Difertatione ejusdem temporis; and some other works.

ORSI (John Joseph), an ingenious philologist and poet, was born at Bologna in the year 1652; and studied polite literature, philosophy, the civil law, and mathematics. His house was a kind of academy, where many per sons of literature regularly assembled. He wrote many ingenious sonnets, pastoral, and other works in Italian, and died in 1733.

ORTEGAL CAPE, the most northern promontory of Spain, where there is also a castle of the same name. W. Long. 8° 20' N. Lat. 44° 0'.

ORTELIUS (Abraham), a celebrated geographer, born at Antwerp, in 1527, was well skilled in the languages and the mathematices, and acquired such reputation by his skill in geography, that he was furnaced the Ptolemy of his time. Julius Lipius, and most of the great men of the 16th century, were Ortelius's friends. He resided at Oxford in the reign of Edward VI. and came a second time into England in 1577. His Theatrum Orbis was the completest work of the kind that had ever been published, and gained him a reputation equal to his immense labour in compiling it. He also wrote several other excellent geographical works; the principal of which are his Thesaurus, and his Synonyma Geographica. The world is likewise obliged to him for the Britannia, which he persuaded Camden to undertake. He died at Antwerp in 1598.

ORTHEZ, a city in the province of Bearn, and perhaps the meanest in all France. It was, however, till the Revolution, a bishop's see. The cathedral is a wretched edifice, very ancient, built in a barbarous style, and almost in ruins. The remains of the castle of Orthez are very noble, and its situation is fine, on a hill, which commands the town and a great extent of country. The people call it Le Chateau de la Reine Joanna, because that queen resided in it during many years, in preference to the castle of Pau. Some of the apartments, though in ruins, may yet be entered. The princes Blanche, daughter to John king of Arragon and Navarre, was shut up, and died here, in 1464. Her brother being dead, she became heiress to the crown of Navarre; but her father having delivered her into the hands of her younger sister Leonora countess of...

Ortygia.

ORTHODOX, in church history, an appellation given to those who are found in all the articles of the Christian faith.

ORTHOPNEA, in medicine, the difficulty of breathing that the relief of Raphael da Monte Lupo. Here is also a chapel, which was begun to be painted by P. Angelo, a dominican, and finished by Luke Signorelli, where you see a very beautiful representation of the last judgment. Orvieto was once a potent and populous city, but is now much upon the decline.

ORYZA, rice, in botany: A genus of the digynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 4th order, Gramina. The calyx is a bivalved uniflorous glume; the corolla bivalved, nearly equal, and adhering to the seed. There is but one species, namely the fativa or common rice. This plant is greatly cultivated in most of the eastern countries, where it is the chief support of the inhabitants; and great quantities of it are brought into England and other European countries every year, where it is much esteemed for puddings, &c. it being too tender to be produced in these northern countries without the assistance of artificial heat; but from some seeds which were formerly sent to Carolina there have been great quantities produced, and it is found to succeed as well there as in the eastern countries.

This plant grows upon moist soils, where the ground can be flowed over with water after it is come up. So that whoever would cultivate it in this country should sow the seeds upon a hot-bed; and when the plants are come up, they should be removed into pots filled with light rich earth, and placed in pans of water, which should be plunged into a hot-bed; and, as the water wanes, it must from time to time be renewed again. In July these plants may be set abroad in a warm situation, still preferring the water in the pans, otherwise they will not thrive; and, toward the latter end
of August, they will produce their grain, which will ripen tolerably well, provided the autumn proves favourable. The leaves of rice are long, like the reed, and fleshy; the flowers blow on the top like barley; but the seed which follows is disposed in clusters, each of which is included in a yellow hulk, ending in a spiral thread. The seed is oblong, or rather oval, and white.

Rice is the chief commodity and riches of Damietta in Egypt. Dr Haifelguit gives the following description of the manner in which they dress and separate it from the hulls. "It is pounded by hollow iron pestles of a cylindrical form, lifted up by a wheel worked by oxen. A person fitting between the two pestles, pushes forward the rice when the pestles are riling; another lifts, winnows, and lays it under the pestles. In this manner they continue working it until it is entirely free from chaff and hulls. When clean, they add a goth part of salt, and pound them together; by which the rice, formerly grey, becomes white. After this purification, it is passed through a fine sieve to part the salt from the rice; and then it is ready for sale." Damietta sells every year 60,000 sacks of rice, the greatest part of which goes to Turkey, Rome to Leghorn, Marseilles, and Venice.

Rice, according to Dr Cullen, is preferable to all other kinds of grain, both for largeness of produce, quantity of nourishment, and goodness. This, he says, is plain from macerating the different grains in water; for, as the rice swells to the largest size, its parts are more intimately divided. Rice is said to affect the eyes; but this is purely prejudice. Thus it is alleged a particular people of Asia, who live on this grain, are blind-eyed; but if the soil be sandy, and not much covered with herbage, and as these people are much employed in the field, this affection of their eyes may be owing to the strong reflection of the rays of light from this sandy soil; and our author is the more inclined to this opinion, because no such effect is observed in Carolina, where rice is very commonly used.

Dr Percival informs us, that as a wholesome nourishment rice is much inferior to wheat. He digested several alimentary mixtures prepared of mutton and water, beef with bread, fish with fish, ale and rice flour, fago powder, potato, old cheese, &c. in a heat equal to that of the human body. In 48 hours they had all acquired a vinous finess, and were in brisk fermentation, except the mixture with rice, which did not emit many air-bubbles, and was but little changed. The third day several of the mixtures were sweet, and continued to ferment; others had lost their innate motion, and were sour; but the one which contained the rice was become putrid. From this experiment it appears that rice, as an aliment, is flow of fermentation, and a very weak corrector of putrefaction. It is therefore an improper diet for hospital patients, but more particularly for invalids, in long voyage, because it is incapable of preventing, and will not contribute much to check the progress of, that fatal dis ease the sea fevers. Under certain circumstances, rice seems disposed of itself, without mixture, to become putrid. For by long keeping it sometimes acquires an offensive factor. Nor, according to our author, can it be considered as a very nutritive kind of food, on account of its difficult solubility in the stomach. Experience confirms the truth of this conclusion; for it is observed by the planters in the West Indies, that the negroes grow thin, and are left able to work, whilst they subsist upon rice.

ORYZIVERA, called the rice-bird of Cateby. It is about the size of a sparrow, being six inches three quarters long, with the head, and whole under side of the body, black; hind part of the neck in some pale yellow, in others white; coverts of the wings and primaries black; the last edge with white; part of the tail, leaft, covert of the wings, and rump, white; back black, edged with dull yellow; tail of the same colours, and each feather sharply pointed; the legs are red. The head, upper part of the neck, and back, of the female is yellowish brown, spotted with black; under part of a dull yellow; feathers finely streaked with black. These birds inhabit in wait numbers the island of Cuba, where they commit great ravages among the early crops of rice, which precede those of Carolina. As soon as the crops of that province are to their palates, they quit Cuba, and pass over the sea, in numerous flights, directly north, and are very oftentimes heard in their passage by sailors frequenting that course. Their appearance is in September, while the rice is yet milky; and they commit such devastations, that forty acres of that grain have been totally ruined by them in a small time. They arrive very lean, but soon grow so fat as to fly with difficulty; and when shot often burst with the fall. They continue in Carolina not much above three weeks, and retire by the time the rice begins to harden, going on to other parts, and sitting in each only so long as the rice continues green. They come into Rhode Island and New York at the end of April, or the second week in May, frequenting the borders of fields, and live on insects, &c. till the maize is fit for their palate, when they begin by pecking holes in the sides of the hulks, and after fasting themselves go on to another, which leaves room for the rain to get in, and effectually spoils the plants. They continue there during the summer, and breed, returning as autumn approaches to the southward. The males and females do not arrive together; the females come first. They are esteemed to be the most delicate birds of those parts, and the male is said to have a fine note. This species is known in the country by the names of Bob linnaeus and Canquistil; likewise called by some the White-backed Mazarth.

OSBORN (Francis), an eminent English writer in the 17th century. He was educated in a private manner; and at ripe years frequented the court, and was master of the horſe to William earl of Pembroke. Upon the breaking out of the civil wars, he adhered to the parliament party, and had several public employments conferred upon him. In the latter part of his life he lived at Oxford, in order to print several books, and to look after his son, for whom, by the favour of the parliament, he procured a fellowship in All Souls's college. His Advice to a son, so form as it was published, being complained of to Dr John Tenant, vice chancellor of Oxford, as of irreligious tendency, there was a proposal made to have it publicly burnt; but that taking no effect, it was ordered that no bookseller or others should sell it, which only made it fell the fater. He wrote also historical Memoirs of the
OSCHOPHORIA, a festival observed by the Athenians. It receives its name from carrying boughs hung up with grapes," called "sple. Its original institution is thus mentioned by "Plut. in Thes. Thæsus, on returning from Crete, forgot to hang out the white sail, by which his father was to be apprized of his success. This neglect proved fatal to Ægeus, for he threw himself into the sea, and perished. Thæsus no sooner reached the land, than he sent a herald to inform his father of his safe return, and in the mean time he began to make the sacrifices which he had vowed to make when he first set sail from Crete. The herald, on his entrance into the city, found the people in great agitation. Some lamented the king's death, while others, elated because they returned in Autumn, when the fruits and perfumes of women, as well as the "cup calleid chophoria, not the sacrifice, and that the philosophers and priests of ancient Egypt worshipped the sun by the name of Osiris, may be proved by numberless testimonies from the most authentic records of antiquity. Diogenes Laërtius affirms, that they held the sun and moon for deities, and that they called the latter "sple; and Macrobius says expressly, "Nec in occulto eft, neque alid eft Osiris quarn Solem, nec eft alid eft quam terram." The same writer informs us, that in the hieroglyphic writings of ancient Egypt, "Osiris was represented by a sceptre and an eye," to denote that this god was the "sun looking down from heaven on all things upon earth.

It must not, however, be concealed, that some of the ancients, and a few of the most learned moderns, have contended, that by Osiris the Egyptians understood the Nile or spirit of the Nile, whilst others have confounded him with the Grecian Bacchus. Scaliger and Selden have adopted the former of these opinions, and Servius on Virgil has given his countenance to the latter. But that they are all mistaken, has been evinced by Jablonski in such a manner as to enforce the fullest conviction: "When the Egyptians, in their sacred books, sometimes give the name of Osiris to the Nile and its wonderful increase during the heat of summer, they mean nothing more (says he) but to attribute to their god Osiris the gift which fertilizes their country." This they would more readily do that they believed the Nile to have its source in heaven. Hence Euæbius tells us, "Oeiros est in Nilum, eü est ìuuius in deccoltarum reliquis Baptismis, Osiris in the Nile, because they think it is sent down from heaven." — In one sense Osiris might be Bacchus, because the original Bacchus was himself the sun (see "Mysteries n° 12"); but that the Egyptian god could not be worshipped as the inventor of wine is indeed undeniable, if, as Jablonski labours to prove, the primitive religion of the country insculpted upon its votaries, that wine was the gift, not of a benevolent god, but of an evil genius, the enemy of the human race. In support of this opinion our learned author quotes a passage from Plutarch, from which it appears, that, before the era of Prommethius, the Egyptians...
Egyptians neither drank wine themselves nor offered it in libations to the gods; because they believed that the first vine sprang from the earth that was impregnated by the blood of those giants who perished in the war with the gods. It is indeed true, that the Greeks, who borrowed their religion as well as the first principles of science from Egypt, attributed to their Bacchus many of the actions of Osiris; but it is likewise true, that they gave him other attributes, which the Egyptian god could not possess consistently with the known superstitions of that country. Salmaeus, however, attempts to prove, from the import of the name, that the Osiris of Egypt must have been the Bacchus of Greece. But, or Sir, he says, signifies a son in the Egyptian language; and hence he concludes, that the god was by that people called Osiris, for the same reason that by the Greeks he was called Δίας, and by the Romans Lūnā. But this seems all to be a mistake. Siris makes a part of many Egyptian proper names, as Bu-siris, Ter-firis, Tapo-siris, &c. and is in all probability derived from the Hebrew word Sar, Sur, or Sir, which signifies a prince, potentate, or great. As the name of the god was in Egypt not Osiris, but Siris or Tiris, it was probably made up of Sir or Si, and the Hebrew prefix I or Īb, denoting strength; so that the whole word will signify the strong or mighty prince. If so, we cannot doubt, as Diodorus Siculus, Sireus, Sextus Empiricus, &c. all affirm, that the Egyptians worshipped the sun by the name of Osir, but that by this name they meant the power or governing mind of the sun, as the Greeks and Romans seem to have done by their Phoebus and Apollo.

But though the original Osiris was undoubtedly the sun, or the intelligence animating the sun, yet there is reason to believe that there was a secondary Osiris, who at a very early period reigned in Egypt, and was deified after his death for the benefits he had rendered to his country (see Polytheism). This is indeed so generally admitted, as to have occasioned great controversies among the learned respecting the time when he flourished, and whether he was the civilizer of rude barbarians or the victorious sovereign of a polished nation. The illustrious Newton, it is well known, has adopted the latter opinion; and with much plausibility endeavoured to prove, that Osiris was the name with Σωσίς or Σεφας: but it must be confessed, that his conclusion is contrary to all the most authentic records of antiquity; and that it would be evil, by the same mode of arguing, to give a shew of identity to two persons universally known to have flourished in very distant ages (a). The annals of Egypt, as may be seen in the writings of Herodotus, Diodorus Siculus, Strabo, Plutarch, and others, who copied from those annals, expressly asserted the distinct personity of Osiris and Seapis, and placed them in a series vastly distant from each other. Osiris, if any credit be due to those historians, was the founder of the Egyptian monarchy; and, as was customary in those days, having either received the name of the sun, or communicated his own to that luminary, was after his death deified for the benefits which he had rendered to his country: and being at first worshipped only as a demigod, was in process of time advanced to full divinity, and confirmed with his heavenly godfather. The Greeks, who, though original in nothing, were always prompted by their vanity to hold themselves out as the first of the nations, claimed this Osiris as their own, and pretended that he was the son of Jupiter and Niobe, He reigned, they say, over the Argives; but afterwards delivered his kingdom to his brother Algeias, and took a voyage into Egypt, of which he made himself master, and married Io or Isis. He established good laws and peace there; and they were both deified after their deaths worshipped as gods. That this is a ridiculous fiction needs no proof; since every one knows, that good laws were established in Egypt long before the Argives had any king, or indeed existed either as a tribe or nation.

OSMUNDA, Moonwort; a genus of the order of palices, belonging to the crypto gastræa class of plants. There are several species; the most remarkable of which is the regalis, osmundroyal, or flowering fern. This is a native of Britain, growing in putrid marshes. Its leaf is doubly winged, bearing bunches of flowers at the ends. The root boiled in water is very slimy; and is used in the north to stuff linen instead of flax. Some of the leaves only bear flowers.

OSNABURG, a bishopric of Germany, situated in the centre of the circle of Westphalia, between the Weser and the Elms, having Minden on the east, Munster on the west, Diepholt on the north east, and Ravensburg on the south west. It is about 45 miles long and 25 broad, producing both ripe, several sorts of turf, coals, marble, and good paffages. The inhabitants, who are a mixture of Protestants and Roman Catholics, breed a considerable number of cattle, especially hogs of which they make excellent bacon and hams: but a great part of the country consists of heaths. By the treaty concluded here in 1648, the bishopric was to be an alternative between the Roman Catholics and Lutherans; and the Lutheran bishop was to be a younger prince of the house of Brunswick Luneburg, or, on failure there of Brunswic Wolfsbuttle. In consequence of this settlement, it has been twice held by a British prince since the accession of the family of Hanover. The bishop is able to raise 25,000 men, his revenue being between 20,000 and 30,000l. The chief manufactories of the country are a coarse kind of linen cloth and yarn, which are sold to bring it into annual about 1,000,000 of six-dollars. There are also some woolen manufactories in Osnaburg and Bramic. The land-estates of the bishopric are, the chapter, the knights, and the four towns. The diets are held at Osnaburg, when called together by the bishop. The count of Bar is hereditary fœcchial or steward, and president of the college of knights. The bishop is a prince of the empire; and in the matricula is rated at 6 horse and 36 foot, or 216 florins monthly, in lieu of the

---

(a) This has been in fact done by Warburton; who employs Newton's mode of reasoning with equal plausibility, and perhaps superior force, to prove the identity of King Arthur and William the Conqueror. See Divine Legation of Moys, Vol. III. Book iv. Sect. 3.
Osnaburg. To the chamber of the empire he contributes each term 81 rix dollars, 14 krutzers and a half. The capital of this bishopric is

Osnaburg, or Osnabruce. It was formerly an imperial city, and one of the Hanse towns; but is now subject to the bishop, though it still enjoys many privileges, and a revenue of about 8000 or 9000 rix-dollars. It has its name from a bridge over the river Hafe, or Of, which divides it into the Old and New Town, and stands 75 miles west of Hanover, and 30 north east of Munster, being surrounded with walls and ditches, but commanded by a mountain within cannon shot. It stands in a fine plain, and is adorned with several good buildings, and on the mountain there is an abbey. The magnificence of this city, which is re-chosen yearly on the 29th of January, is Lutheran; and the churches belong, fome to the Luthemans, and fome to the Papists. Both parties have the full and free exercice of their religion, whether the bishop be Protestant or Papist. The bishop's palace, called Peterburg, was built by Bifhop Erneft-Auguflus, brother to King George I. It is well fortified, and separated from the town by a bridge. It is a hexagon, with a court in the middle, and at each corner a turret. In the town-house and flll preferred the pictures of the pontiffs and emperors that adorned the saloons there for the famous treaty of Welfphalia. In the treasury of the cathedral are fome fine ornaments given by Charlemagne, as also his crown, which is only of silver gilt, and his comb and baton, fix feet in length, both of ivory; together with other curiosities. Charlemagne is faid to have erected here a fchool for Latin and Greek, which the Jefuits in 1625 converted into an academy. They have the best bread and beer that is to be met with in all Welfphalia, and have a pretty good trade in bacon and linen; as also by brewing a palatable thick fort of beer called hafe. This city is noted for a treaty between the emperor and the king of Sweden in 1648, wherein the affairs of the Protestants were regulated, which was a branch of the treaty of Welfphalia. The town, with the refl of the principality, is subject to its bishop, who is a count of the empire, and by the treaty of Welfphalia must be alternately a Protestant and Papist. The Papist bishop is suffrangs to the archbishop of Cologne; but the Protestant bishop is indeed a temporal prince, and al­ ways of the house of Brunswick, in consideration of the principality of Halberflat, which was taken from this house, and conferred upon the elector of Brandenburg. Frederick duke of York, second fon of his majesty George III. is the present bishop. The cathedral is in the hands of the Roman Catholics, with the church and monastery of the Dominicans in the old city, and the collegiate church of St John in the new. The Protestants are masters of the great parochial church of St Mary in the old city; and both religions have a voice in the election of the magistrates. Of 25 canons belonging to the cathedral, 18 are Roman Catholics, and the Revenues of 4 more are enjoyed by the Jefuits for the support of the college; fo that there are but 3 Protestant canons, who have no voice in the election of the Roman Catholic bishop, when it is his turn to succeed. The bishop's palace is fortified like a castle: here it was that George I. was born on the 28th of May 1660, his Father Ernest-Auguflus being then bishop and prince of the place; and here also he died in the night of the 10th of June 1727, and, as some fay, in the very room in which he was born. The bishopric is situated in the centre of the circle; the north part of it is marily, but at the south extremity of it are fome mountains. The inhabitants have considerable manufactures of linen, and a good breed of cattle; and of their hogs, for which they are remarkable, is made the belt Welfphalia bacon. Not far from this city are to be seen the ruins of an old church and castle, called Delem, which fome fay was built by King Wittekind upon his conversion; and about two miles from it lies the monastery of Rolle, on the bank of a lake too deep, that report fays it could never yet be fathomed. This was the first town in Welfphalia which received the Lutheran doctrine.

Osnoberg Island, one of the islands in the South Sea, discovered by Captain Wallis in 1767. It is a high, round island, not above a league in circuit; in some parts covered with trees, in others a naked rock. S. Lat. 22. W. Long. 141. 34.

Osorius (Jerom), was born of a noble family at Lisbon, 1500. He was educated at the university of Salamanca, and afterwards studied at Paris and Bo­ logna. On his return to Portugal he gradually rose to the bishopric of Sylves, to which he was appointed by Catherine of Au­ stria, regent of the kingdom in the minority of Sebastian. At the request of cardinal Henry of Portugal, he wrote his history of King E­ manuel, and the expedition of Gama; which his great contemporary Camoens made at the same time the fubjeft of his immortal Luifid; a poem which has at length appeared with due fuf­ tute in our language, being translated with great spirit and elegance by Mr Mickle. It is remarkable that the history of Osorius, and the epic poem of Camoens, were published in the fame year, 1572: but the fate of thefe two great authors were very different; the poet was fuffered to perifh in poverty, under the reigne of that Henry who patronized the historian: yet allowing for the dif­ ference of their profelfions, they polifhed a fimilarity of mind. There appear many traces of that high heroic spirit even in the priet Osorius, which animated the soldier Camoens: particularly in the pleafure with which he seems to defcribe the martial manners of his country­ men under the reigne of Emanuel. In that age (fays the historian in the clofe of his manly work), poverty and fadness were banifhed from Portugal. Complaints were never heard; but every place, from the court to the cottage, was adorned with mirth and mufic. Illicit love was unknown; nor would the ladies listen to the most honourable addresses of fuch youths as had not fignalled themselves in war. No young man about court, however noble by birth, was permitted to wear the dreift of mankind till he had paffed over into A­ fia, and thence brought back with him fome animal esteem for its rarity; and fuch was the hardy edu­ cation of the nobility in that age, that many of them travelled every where in queft of adventures." This is a striking picture of the manners of chivalry, to which Portugal owed much of its glory in that splendid period. There is one particular in the character of Osorius, which, confidering his age and country, deserves the highest encomiums; and that is his toler­ rating spirit. In the firft book of his history, he

speaks of Emanuel's cruel persecution of the Jews in the following general and exalted language: "This (says he) was authorized neither by law nor by religion. Can men be compelled to believe what they reject with abhorrence? Do you take upon you to restrain the liberty of the will, or to fetter the understanding? Such an attempt must be unsuccessful; and is not acceptable to Christ, who expects from man the devotion of the heart, and not that formal worship which is the offspring of pains and penalties. He wishes them to study his religion, and adopt it from conviction, not from terror: for who does not see that forced belief is mere hypocrisy?" Orfius is said to have used many arguments to diffuse Sabianism from his unfortunate expedition into Africa, and to have felt so deeply the miseries which befel the Portuguese after that fatal event, that his grief was supposed to accelerate his death. He expired in 1580, happy, says De Thou (who celebrates his fame), who entered Portugal, and thus escaped the defolation of his country.—His various works were published at Rome in 1593, by his nephew Orfius, in four volumes folio, with a life of their author. Among these are two remarkable productions; the first, An Admonition to Queen Elizabeth, exhorting her to return into the Church of Rome; the second, An Effay on Glory, written with such classical purity, as to give birth to a report, that it was not the composition of Orfius, but the last work of Cicero on that subject.

ÖSRA. See Falco, p. 17.

ÖSSA, a lofty mountain of Thessaly, near the Peeneus, which runs between this mountain and Olympus; famous in the fabulous story of the giants (Homer, Virgil, Horace, Seneca, Ovid). The bending and unbending of its pines, on the blowing of a strong north wind, formed a clashing sound like thunder (Lucan). It was once the residence of the Centaurs, and was formerly joined to mount Olympus; but Hercules, as some report, separated them, and made between them the celebrated valley of Tempe. This separation of the two mountains was more probably effected by an earthquake which happened about 1885 years before the Christian era. Its greatest celebrity arises from its being one of those mountains which the giants in their wars against the gods heaped up one on the other to scale the heavens with more facility. A town of Macedonia.

ÖSSAT (Arnauld de), born in the diocese of Auch in 1536, of mean parentage, was taken notice of by a gentleman in the diocese, who made him study with his ward the Lord of Calleux de Magnoac. He studied the law at Dijon, under Cujas, and applied himself to the bar at Paris. He was secretary at Rome to M. de Fois, archbishop of Thoulouse; to cardinal Effe; and afterwards to cardinal de Joyeuse, by the French king's express command. After rising to the highest dignities both in church and state, in 1599 he was created a cardinal by pope Clement VIII. He died in 1604. An eminent French writer gives him the following character: "He was a man of prodigious penetration; applied himself to most closely to affairs, and especially was so judicious in forming his resolutions, that it is almost impossible to find out one false step in the many negotiations in which he was concerned." His works, and especially his letters, have been much esteemed in the learned world. OSSIANS, the son of Fingal, a celebrated Celtic poet, who flourished about the end of the second and beginning of the third century. Several incidents in his poems point out this as his era: particularly the engagement of Fingal with Carcull, or Caracalla, the son of the emperor Severus, styled by Ossian, The Son of the King of the World. M. Tellmont fixes the elevation of Caracalla to a share in the government to the year 198, and the association of his brother Geta to 208. About which time Gibbon fixes the Caledonian war, and speaks thus upon the subject: "This Caledonian war, neither marked by decisive events, nor attended with any important consequences, would ill deserve our attention; but it is suppos'd, not without a considerable degree of probability, that the invasion of Severus is connected with the most interesting period of the British history or fable. Fingal, whole fame, with that of his heroes and bards, has been revived in our language by a recent publication, is said to have commanded the Caledonians in that memorable junction, to have eluded the power of Severus, and to have obtained a signal victory on the banks of the Carun, in which the son of the King of the World, Carcull, fled from his arms along the fields of his pride." Something of a doubtful mist still hangs over these poems, Highland traditions; nor can it be entirely dispelled by the most ingenious researches of modern criticism (a): but if we could with safety indulge the pleasing supposition, that Fingal lived and that Ossian sung, the striking contrast of the situation and manners of the contending nations might amuse a philosophic mind. The parallel would be little to the advantage of the more civilized people, if we compared the unrelenting revenge of Severus with the generous clemency of Fingal; the timid and brutal cruelty of Caracalla, with the bravery, the tendernefs, the elegant genius of Ossian; the mercenary chiefs, who, from motives of fear or interest, served under the Imperial standard, with the free-born warriors who started to arms at the voice of the king of Morven: if, in a word we contemplated the untutored Caledonians glowing

(a) "That the Caracul of Ossian is the Caracalla of the Roman history, is perhaps the only point of British antiquity in which Mr Macpherson and Mr Whitaker are of the same opinion; and yet the opinion is not without difficulty. In the Caledonian war, the son of Severus was known only by the appellation of Antiminus; and it may seem strange, that the Highland bard should decribe him by a nick name, invented four years afterwards, scarcely used by the Romans till after the death of that emperor, and seldom employed by the most ancient historians. See Dion. lxxxvii. p. 1317. Hift. Auguf. p. 89. Aurel. Victor. Eufeb. in Chron. ad ann. 214."

wealth and slavery.

The date of this action, if the poems be true, is
rather confounding: for the next expedition, which is
produced to fix the time in which Ofian flourished,
was conducted by Ofiar (against the usurper Carau-
fus, the Car s of Ofian), who did not assume the
purple till late as the year 587. This account
indeed corresponds pretty well with the account gi-
ven by Irth histories, which place the death of Fin-
gal in the year 583, and that of Ofiar, (who died
many years before his father Ofian) in the year 596.
The hints are not thrown out but we think because we think
they militate against the authenticity of the poems; for
distant though these dates be, it is yet possible to re-
concile them. Old age was and is very common in
those regions; and Ofian himself, we are told, was an
instance of great longevity. Indeed at such a distance of
time it cannot be expected that we should give either
a very particular or a very exact account of Ofian and
his heroes. Were there no doubts remaining of the
truth of the facts, it is still natural to suppose that
they must have suffered obscurity through the roll
of time, and above all through the neglect of the
poem, which lately were unknown.

The first expedition on which Ofian’s father sent
him was, to raise a line on the banks of Crone, to
perpetuate the memory of a victory which the king of
Morven had obtained at that place. The Highlanders
talk of this as being emblematical of that immortality
which heroes were to receive from his future com-
positions. In this expedition he was accompanied by
Tofar, father of the beautiful Malvina, the amiable
companion of his grief, after the death of her beloved
Ofiar, his son. It appears from his poems, that, in
one of his early expeditions to Ireland, he had fallen
in love with and married Evirallin, daughter to Brann-
no, petty king of Lego. “I went in suit of the maid
of Lego’s fable surge; twelve of my people were
there, the sons of lofty Morven. We came to
Branno, friend of strangers; Branno of the founding
mail.— From whence (he said) are the arms of feet? Not
caly to win is the maid that has denied the blue-
eyed sons of Erin. But blest be thou, O son of Fin-
gal! happy is the maid that waits thee. Though
divided twelve daughters were mine, thine were the
choice, thou son of fame.”—Then he opened the hall of
the maid; the dark haired Evirallin*. This Evirallin
was the mother of his son Ofiar, whose exploits he
celebrates in many of his poems, and whose death he
laments in the first book of Temora. Evirallin died
some time before Ofiar (Fingal, B. iv.); who seems
to have been her only child; and Ofian did not marry
afterwards: so that his posterity ended in the death of
Ofiar; who seems to have died as he was about to
be married to Malvina, the daughter of Tofar. Se-
veral of her lamentations for her lover are recorded by
Ofian, which paint her grief in the strongest and most
beautiful colours. “It is the voice of my love! few
are his visits to my dreams.—But thou dwelvest in
the soul of Malvina, son of mighty Ofian My sighs arise
with the beams of the eal; my tears descend with
the drops of night. I was a lovely tree in thy pre-

cence, Ofiar, with all my branches round me: but

thy death came like a blast from the desert, and laid
my green head low; the spring returned with its
flourish, but no green leaf of mine arose.” Poem of
Cromer.

The principal residence of Ofian was in the vale of
Con, now Glencoul, in Argyleshire. See Fingal.

His poems relate many of his expeditions to Ire-
land, Scandinavia, Clyde, and Tweed or Teudla.
His exploits on these occasions, after making a large
allowance for poetical exaggeration, show him to have
been no less a warrior than a poet: (See Ofian’s
Works, in the poems Caliban and Celeph, Lathian,
Berrathon, &c. By these expeditions, which were al-
ways undertaken for the relief of the distressed,
the mind of Ofian seems to have been cultivated and
enlarged beyond what is usually to be met with in so
a rude a period of society as that in which he lived. His
poems breathe, throughout, such a spirit of generosity
and tenderness, especially towards the fair sex, as is
seldom or never to be met with in the compositions of
other poets who lived in a more advanced state of civi-

The.
The poems of Ossian, though always held in the highest esteem by those who knew them, were allowed to remain in the obscurity of their original Gaelic, till Mr Macpherson, about 30 years ago, translated a collection of them into English, which immediately attracted the attention of every person who had a true taste for poetry. Dr Blair, in particular, introduced these poems into the world with those critical remarks which do no less honour to himself than to the poet. According to that eminent critic, the two great characteristics of Ossian’s poetry are tenderness and solennity. Ossian is, perhaps, the only poet who never relaxes, or lets himself down into the light and amusing strain. He moves perpetually in the highest region of the grand and pathetic. The events which he records are all serious and grave; the scenery wild and romantic. We find not in him an imagination that sports itself, and dresses out gay trifles to pleaze the fancy. His poetry, more perhaps than that of any other, deserves to be styled the Poetry of the heart. It is a heat penetrated with noble sentiments, with sublime and tender passions; a heart that glows and kindles the fancy; a heart that is full, and pours itself forth. Of all the great poets, Homer is the one whose manner and whose times come the nearest to Ossian’s. Homer’s ideas were more enlarged, and his characters more diversified. Ossian’s ideas fewer, but of the kind suited for poetry; the bravery and generosiy of heroes, the tenderness of lovers, and the attachment of friends. Homer is diffuse; Ossian abrupt and concise. His images are a blaze of lightning, which flash and vanish. Homer has more of impropriety and fire; Ossian of a solemn and awful grandeur. In the pathetic, Homer has a great power; but Ossian exerts that power much oftener, and has the character of tenderness more deeply imprinted on his works. No poet knew better how to seize and melt the heart. With regard to dignity of sentiment, we must be surprised to find that the pre-eminence must clearly be given to the Celtic bard. This appears nowhere more remarkable than in the sentiments which he expresses towards his enemies. “Uthal fell beneath my sword, and the sons of Berrathon fled.—It was then I saw him in his beauty, and the tear hung in my eye. Thou art fallen, young tree, I said, and the fans of Ghallion.”

naturally assumed the tone of poetry; praises of their gods, or of their ancestors; commemorations of their own warlike exploits; or lamentations over their misfortunes. And before writing was invented, no other compositions, except songs or poems, could take such hold of the imagination and memory, as to be preserved by oral tradition, and handed down from one race to another.

"Hence we may expect to find poems among the antiquities of all nations. It is probable, too, that an extensive search would discover a certain degree of resemblance among all the most ancient poetical productions, from whatever country they have proceeded. In a similar state of manners, similar objects and passions operating upon the imaginations of men will stamp their productions with the same general character. Some diversity will, no doubt, be occasioned by climate and genius. But mankind never bear such refining features as they do in the beginnings of society. What we call the oriental vein of poetry, because the earliest poetical productions have come to us from the east, is probably no more oriental than accidental; it is characteristic of an age rather than a country; and belongs, in some measure, to all nations at a certain period. Of this the works of Ossian seem to furnish a remarkable proof.

"He appears clearly to have lived in a period which enjoyed all the benefit I have just now mentioned of traditionary poetry. The exploits of Thual, Trenmor, and the other ancestors of Fingal, are spoken of as familiarly known. Ancient bards are frequently alluded to. In one remarkable passage, Ossian describes himself as living in a sort of classical age, enlightened by the memorials of former times, conveyed in the fongs of bards, and points at a period of ignorance which lay beyond the reach of tradition. Ossian himself appears to have been endowed by nature with exquisite sensibility; prone to that tender affection, and where the features are so strikingly imprinted upon the imagination of men will stamp their productions with the same general character. Some diversity will, no doubt, be occasioned by climate and genius. But mankind never bear such refining features as they do in the beginnings of society. Of this the works of Ossian seem to furnish a remarkable proof.

The nations of a future state, exhibited in those poems, are likewise strongly marked with the character of antiquity. A creed so uncommon that the imagination of a modern could not be supposed to grasp to strong an idea of it from mere fancy, is uniformly supported throughout. This creed is extremely simple, but admirably suited to the times.

The language to, and the structure, of those poems, bear the most striking characters of antiquity. The language is bold, animated, and metaphorical, such as it is found to be in all infant states; where the words, as well as the ideas and object, must be few; and where the language, like the imagination, is strong and undisciplined. No abstract, and few general, terms appear in the poems of Ossian. If objects are but introduced in a simile, they are always particularized. It is "the young pine of Inihuna;" it is "the bow of the flowery Lena." This character, conspicuous in the poems of Ossian, is a striking feature in the language of all early states; where objects and ideas are few and particular, and whose ordinary conversation is of course highly figurative and poetical. A picture, therefore, marked with such striking features, could not be drawn without an original. The whole texture of the composition is also, like the language, bold, nervous, and concise; yet always plain and artless; without any thing of that modern refinement, or elaborate decoration, which attend the advancement of literature. No foreign ornaments are hunted after. The wild and grand nature which lay within the poet's view, is the only source from which he draws his ornaments. Beyond this circle, his imagination, though quick and rapid, seldom made any excursion. We perceive his language always to be that of a person who saw and felt what he describes; who bore a part in the expeditions which he celebrates,
brutes, and who fought in the battles which he sings. Such is the nature of the internal proof adduced in the present case, which, unquestionably has weight, and that not inconsiderable; but unsupported by external proof, or contrary to facts, however forcible it may be in itself, when considered in this connection, and found wanting, it will neither silence the querulous sceptic, nor, in all probability, will it ever convince those who have truth for their object, and who wish to investigate, and, if possible, discover it on firmer grounds. Internal proof is of the greatest service in a variety of excellent causes; but it comes in rather as a succedaneum than as direct evidence; and without something more to the purpose, it may excite admiration, but will seldom enforce belief. Of the customs and manners of ancient times, we know but little, and of that little we have often but a confused notion. There is therefore room for genius and ability to exert correspondence grounds. Internal proof is of the to found, or contrary to that little we have often been heard, if any appeal is necessary, it is for producing so many names in a question where the contesting silence of a whole country was, to every unprejudiced person, the strongest proof that spurious compositions, in the name of that country, had not been obtruded upon the world." It is likewise argued in support of the authenticity of the whole poems, that candid sceptics, on hearing some of them repeated by illiterate persons, who had never seen the translation, caused them to give the meaning of what they repeated, by an extemporary translation into English, and by this means had all their doubts of the authenticity of Ollian removed. They urge further, that such passages of Ollian's works as are still repeated by some old men, are among the most beautiful parts of Ollian's poems; such as the battle of Old Lorn, the most affecting parts of Carthon, Berrathon, first Poetry, the death of Offor, and Barthula, or the children of Unofith, &c. which gives a credulity to his being equal to the other parts of the collection, none of it being superior to those in merit.

To these and the like arguments advanced in support of the authenticity of the poems ascribed to Ollian, many objections have been urged. Thos of Johnson and his friend Shaw are universally known. A later writer objects to them in the following manner: No fragments of British poetry in Scotland are to be found. Many specimens of Irish poetry in Scotland have been published: but none older than a century or two. Translations have also appeared; but in general, of no fidelity. Thos of the poems ascribed to Ollian, in particular have deservedly drawn much of the public attention; but they will only mislead any reader who wishes to form an idea of Celtic poetry. He that believes Ollian to have flourished about the year 500, and his writings preferred by oral tradition for 1400 years, large is his faith, and he might move mountains! Gentlemen of the Highlands of Scotland, with whom our author conversed on the subject, assured him, that they looked upon ninthents of Mr. Macpherson's work as his own; and upon the other tenth, as so much changed by him, that all might be regarded as his own composition. There are positive evidences, he says, which convince him that not one of the poems given to Ollian, and probably not one passage of them, is older than the 15th century.
The very first author we know who mentions Fingal is Barbour, a Scotch poet, who wrote in 1375. Fingal was an Irish hero; and one Good, a schoolmaster, of Limerick, sent some account of Ireland to Camden, in 1566, in which mention is made of some strange fables, that the people amused themselves with, about the “giants Fin Mac Hayle, and Other Mac Offin,” of which we shall speak more largely presently. In the mean time, to thefe, and such like objections, it has been anfwered, That poetry has been cultivated with much fuccefs in the earfiest ages of fociety; that in Greece, Orpheus, Linus, Hefiod, and Homer, wrote their admi.ral poems fome ages before any thing had been written in prose in the Greek language; that the book of Job, written in a very early period of fociety, is highly poetical; that among the tribes of Lapland and America, there have been, in the earfiest flate, fome excellent pieces of poetry. That the Caledonians, in particular, had fome peculiar institutions, which tended to improve their minds and refine their taste. A great part of the poetry of the Caledonians, which perhaps was written in verse, has been expanded and much improved by the writers of the Highlands, and other Indians, who vied with thefe fages in the fublime, and the libidinous. The cafe of Oflian, particularly favourable. He lived in an age when manners came to a confiderable degree of refinement under the care of the bards and druids. Poetry in his day was more conftantly cultivated than now. The language, though strong and figurative, had undergone some degree of cultivation, and learned to flow in regular numbers, adapted to the harp, the favourite instrument of the times. As a prince and a warrior, his mind might have been expanded and much enlarged by his excursions to other countries. At home he had Uillin, Alpin, Carril, and Ryno, to converse with; all of them poets of eminence, who would have advanced him greatly by their example and conversation. All these advantages, meeting with a native fire and enthusiasm of genius, as in the cafe of Oflian, may well be fuppofed to have produced poems that might challenge the veneration of ages.

But it is not to their merit alone that we owe the preservation of these poems fo long by oral tradition. Other circumstances concurred; of which, the imitation of the bards deferves particular notice. In a country, the only one perhaps in the world in which there was always, from the earfiest period almost to the prefent age, a flanding order of poets, we cannot reasonably be surprized, either at finding excellent poems composed, or after being composed, carefully preferred from oblivion. A great part of the bufliness of this order was to watch over the poems of Oflian. In every family ofdiflinution there was always one principal bard, and a number of disciples, who vied with each other in having their poems in the greatest perfection. Should the imitation of the bards last for ever, the poems of Oflian could never perish.

Nor were they only the bards of great families who took an interefl in these poems; the valiant, equally fond of the song with his superior, entertained himself in the fame manner. This, with a life free from care, a spirit unbroken by labour, and a space of time unoccupied by any other employment or diversion, contributed to render the Highlanders a nation of fingers and poets. From thefe a people, the fuperior merit of Oflian’s poems would naturally procure every encouragement, which they always retained as long as the manners of the people remained unchanged.

Many other reafons conpired to preserve the poems of Oflian. The martial and intrupid spirit which they breathed, made it the intereft of the chiefs to preferve them: the ftrain of justice, generofity, and humanity, which runs through them, recommended them to the superintendents of religion, who well knew how much the morals of a people muft be tinctured with thofe fongs which they are continually repeating, and which have all the advantages of poetry and of music. In fuperflitious ages, the people revered thefe poems, from their being addreffed generally to fome, “fom of the rock,” fuppofed to be the tutelar faint of the place, or the great Irish afope St Patrick. Beside, every hill and daie which the natives of the Highlands walked over, was classic ground. Every mountain, rock, and river, was immortalized in the song. This song would naturally be fuggested by the flight of their objects, and every body would hum it as he walked along. All the proverbs and customs to which thefe poems gave life, would operate in the fame manner. The fon would ask what they meant, and the father would repeat the song from which they were taken. The difunct and unfubdufed flate in which the Highlanders remained for fo long a confufe of ages, every clan, one generation after another, inhabiting the fame valley, till towards the prefent century, contributed much to preferve their traditions and their poems; and the conftant and general custum of repeating thefe in the winter-nights, kept them always alive in their remembrance.

To these causes and customs the prefervation of Oflian’s poems, for fo many ages, has been ascribed. But thefe causes and customs have ceafed to exist; and the poems of Oflian, of confufe, have ceafed to be repeated. Within a century back, the Highlanders of Scotland have undergone a greater revolution than it had done for ten before that period. With a quicker pace the feudal fytem vanished; property fluctuated; new laws and new customs kept in, and supplanted the old; and all this with fuch sudden and fuch violent convufions, as may well account for the finking of a fabric which had stood fo long ages, and which seemed to have fidden defence to all the injuries of time. Even since Mr Macpherson gathered the poems in his collection, the amufements, employments, and taste of the Highlanders are much altered. A greater attention to commerce, agriculture, and paffage, has quite engroffed that partial attention which was paid,
even then, to the song of the bard. In twenty years hence, it manners continue to change so rapidly as they do at present, the faintest traces will scarce be found of those tales and poems. "Ossian himself is the last of his race; and he too shall soon be no more, for his grey branches are already fired on all the winds."

Among the causes which make these poems vanish so rapidly, poverty and the iron rod should come in for a large share. From the baneful thud of those murderers of the muse, the light of the song must fast retire. No other reason needs be given why the present Highlanders neglect so much the songs of their fathers.—Once, the humble, but happy vassal, fat at his ease, at the foot of his grey rock or green tree. Few were his wants, and fewer still his cares; for he beheld his herds sporting around him, on his unmeasured mountain. He hummed the careless song, and tuned his harp with joy, while his soul in silence blessed his children.—Now, we were going to draw the comparison;

sed Cynthius auren
Vellii et admonuit.

It is more agreeable to remark, as another cause for the neglect of ancient poems and traditions, the growth of industry, which fills up all the blanks of time to more advantage, and especially the increase of more useful knowledge. —But above all, the extinction of the order of the bards hastened the catastrophe of Ossian's poems. By a happy coincidence Macpherfon overtook the very last that remained of this order, (Macuvich, bard to Clanronald), and got his treasure. This fact (with the red book furnished by Mr Macdonald of Croidart, and some other MSS.) accounts for Mr Macpherson's having found these poems in greater number and perfection than they could ever since be met with. The fragments, however, which have since been gathered, give a credibility to every thing that has been said of the original grandeur of the building.

Although this disquisition has already extended to a length which readers not partial to Scotch antiquities will perhaps thing too great, we cannot dismiss it without observing, that Fingal and Ossian have been claimed by the Irish as well as by the Caledonians. On this double claim, as well as on the controversy concerning the authenticity of the poems, there is so much candour and good sense in the following remarks of T. F. Hill, published in the 53d volume of the Gentleman's Magazine, that we cannot deny ourselves the pleasure of making them conclude the article.

Mr Hill travelled through the Highlands of Scotland during the summer months of 1780. He seems to have been very ardent in his inquiries concerning Ossian, and to have concluded those inquiries with great judgement. The consequence was, that he received different accounts in different places, and picked up various songs relating to Fingal and his heroes.

"From this collection, it is evident (he says) that there are many traditional songs preferred in the Highlands relating to Fingal and his heroes, as well as to several other subjects. It is also evident, that these songs contain portions of the very poems published by Mr Macpherson and Mr Smith, under the name of Ossian. We may therefore justly conclude, that these poems are not wholly the forgery of their editors, but compiled at least from original songs. If by no means we think it worth my while to notice the various conjectures in favour of this conclusion, which the misanthropists of Ossian have of late been forced to make. I myself have given proofs of it, which need, I hope, no external confirmation. To these proofs might be added, that I met with many traditional preferers of these songs, in every different part of the Highlands; some of whom, especially in Argyleshire, Lochabar, and on the west of the western coast, were paid to recite various poems, attributed to Ossian, although I had neither leisure nor opportunity to collect copies from them.—But enough has already been said on this subject, if my testimony deferves regard.

"These principles being established, it remains to be considered how far the poems published by Macpherson and Smith deserve to be considered as the works of Ossian. The songs attributed to that bard, which contain passages of the Ossian of Macpherson and Smith, are by no means uniformly consistent with the poems in which the parallel passages are found, but frequently relate to different events, and even contain different circumstances. From hence it seems most probable, that Mr Macpherson and Mr Smith compiled their publications from those parts of the Highland songs which they most approved, combining them into such forms as according to their ideas were most excellent, and preferring the old names and the leading events. In this process they were supported and encouraged by the variety of songs preferred in the Highlands upon the same subject, and by the various modes in which the same event is related. Mr Macpherson may indeed have MSS. of all the poems he has published; which MSS. may either have been compiled by himself, or by some former collector; or they may possibly contain entire poems really ancient. But Mr Smith has honestly acknowledged, that he himself compiled his Ossian in the manner above described.

"After the materials were collected (says he), the next labour was to compare the different editions; to strike off several parts that were manifestly spurious; to bring together some episodes that appeared to have a relation to one another, though repeated separately; and restore to their proper places some incidents that seemed to have run from one poem into another;—and hence it was unavoidably necessary to throw in sometimes a few lines or sentences to join some of the episodes together. I am sensible that the form of these poems is considerable altered from what is found in any one of the editions from which they are compiled. They have assumed somewhat more of the appearance of regularity and art—than that bold and irregular manner in which they are originally delivered."

"Mr Smith also speaks of the Ossian of Mr Macpherson in a somewhat similar manner; 'That we have not the whole of the poems of Ossian, or even of the collection translated by Mr Macpherson, we allow; yet still we have many of them, and of almost all a part.
part. The building is not entire, but we have still the grand ruins of it.

What portion, therefore, of the Olifan of Macpherson and Smith is original, no man can determine except themselves. Smith indeed says, that he has mentioned all his material alterations, transpositions, and additions, in his notes; and that, for the most part, he was guided in them by the Sgeulachs, or traditionary tales accompanying the songs; but there are few such notes in his book, and perhaps as few Sgeulachs in the mouths of the Highlanders. In Macpherson and Smith also we see these poems digested of their idiomatic peculiarities and fabulous ornaments; which renders it impossible to discover what manners and opinions are really ancient, and what are of modern invention. Yet it is remarkable, that in spite of all the objections to their authenticity, necessarily produced by such a treatment of them, they still possess an internal evidence of originality which has enabled them hitherto to withstand all the torrent of opposition.

The Olifan of Macpherson and Smith appears therefore to be a mutilated work, even though we should suppose that the songs they originally compiled were the undoubted works of that celebrated bard. But this is far from being the case; for even allowing that an Olifan ever existed and wrote, yet time must have introduced such material changes in his works, if preserved merely by tradition during so long a period, that their own author would hardly know them again. I think it however doubtful, whether such a being as Olifan ever appeared in the world.

All such songs which I met with in the Highlands relative to the Feinne or Fingalian were attributed to Olifan: his name seems merely a common title, which is ascribed to all the poetic annals of his race.

From these considerations, we seem authorized finally to conclude, that the Olifan of Macpherson and Smith is a mutilated compilation from Highland songs, ascribed indeed to that bard, yet very little likely to be his composition. Out of these they selected the best parts, and rejected such as they thought might differedit the character of Highland antiquity; attributing them to later times, and the ignorant bards of the fifteenth century. Perhaps even the works of Homer himself, which had so many different editions, very considerably varying from each other, were compiled by a somewhat similar process from the ancient Greek songs.

Another question remains to be considered: Whether these songs are the compositions of the Highlanders of Ireland? and, Whether Olifan was an Irish a Caledonian Scot? It is my opinion, that the songs in this collection evidently manifest a connection with Ireland, though their traditional preservation in Scotland has sometimes introduced the name of Scotland in its stead. One of their principal personages is St Patrick, the peculiar apostle of Ireland, which alone seems sufficient to mark their origin (a). If therefore we may reason from a part to the whole, it is just to conclude, that all the other songs preserved in the Highlands relative to the Fingaliens are also Irish. They are wholly confined to the western coast of the Highlands, opposite Ireland; and the very traditions of the country themselves acknowledge the Fingaliens to be originally Irish. The genealogy of Fingal was there given me as follows: Fion Mac Coul, Mac Trathal, Mac Arthu Kioch Erin, or king of Ireland; thus attributing the origin of his race to the Irish. I am inclined to believe, that these notions about Fingal were common to the Scots in the most ancient times, and brought by them from Ireland to Scotland, the hereditary superstition of both races; for, notwithstanding it may appear most probable that Ireland should receive colonies from Scotland than the contrary, we have direct historic evidences that Scotland received them from Ireland; and no bare theoretic probability deserves to be opposed to the positive affirmations of history.

With regard to the Erse manuscripts, about which so much has been said, it becomes me to acknowledge, that I have never seen enough of them to give any decided opinion: those which I have seen induce me to think they principally owe their existence to Ireland.

I shall not repeat what others have said to prove the Fingaliens Irish; though the connection of Fingal with Ireland has been already warmly affected.

But an unnoticed though curious passage in Camden affords us the most remarkable, and perhaps the most convincing, proof that Fingal is an Irish hero, which demonstrates at least that he was indisputably claimed by the Irish 200 years ago. It is contained in an extract (already mentioned) made by Camden, from an account of the manners of the native Irish, written by one Good, a schoolmaster at Limerick, in 1566. 'They think,' says he, speaking of Ireland and its inhabitants, 'the souls of the deceased are in communion with famous men of those places, of whom they retain many stories and fonnets; as of the giants Fin-Mac-Hyule, Oker-Mac-Oishin, or Oishin-Mac-Owin; and they say, through illusion, that they often see them.'

The very material importance of this curious passage, with relation to the present subject, is unessential to urge; for every eye must see it. We also obtain from it new information in respect to the last part of the history of Fingal and his heroes; as it enables us to determine who they were, with a precision which must otherwise have been wanting, to complete their remarks on the Highland songs.

The singular agreement of this passage with the accounts of Olifan which were taught me in Scotland is worthy particular remark; it confirms them even in the most novel and peculiar instances. The Fingaliens were generally represented as giants; but the most remarkable concurrence is in the mythologic character attributed by both to Fingal, Olcar, and Olifan.

3 X 2

(a) The Scots indeed lay claim to the birth of St Patrick, and boast also his burial place. Camden, edit. Gibbon, 1693, pp. 921, 1014. And so also do the Britons, ib. p. 631, 1014; but his life and miracles all agree to attribute to Ireland. In Gough's edition of Camden, the account of St Patrick is in vol. iii. p. 612, 618. See Patrick (St).
In proof of this, I have to observe, that Mac Nab described Fingal as the Odin of the Scots, and that a song called *Urigh Offian* evidently speaks of him as such. This curious passage represents him exactly in the same character; a hero with whom the spirits of the deceased are in communion, who is their chief-tain, and the lord of their feasts. The gods of all the northern nations seem to have been of this class; mighty heroes, esteemed once to have been invincible on earth, though perhaps not ever strictly men, nor yet constantly regarded as giants. Such are Odin, Thor, and the other Teutonic gods; such are Fingal, Ósfar, and the rest of the Fingalian among the ancient Scots; such also are Hercules, Bacchus, and even Jupiter himself, with all his sons and daughters, among the ancient Greeks, a people who agreed in many particulars with our own.

The notions entertained about him were intermediate order of beings between Europe. The notions entertained about their own race; and from this cause the poems ascribed to their Edda: Aristians had it. The bardical language, would undertake to afford me. I was attributed by the religious subjects treated upon the various ages through which they have descended to us, and would probably afford much new information on subjects at present very ill understood. I own, however, that I should rather choose to seek for them in Ireland than in Scotland; but neither country should be unexplored.

After having thus freely, though I hope not uncandidly, delivered my sentiments on the Offian of Mr Macpherson, it becomes me to acknowledge myself deeply indebted to it for the pleasure in perusing it, which it has frequently afforded me. I am willing, and indeed happy, thus publicly to declare myself a warm admirer of it as a literary composition. The novelty of its manner, of its ideas, and of the objects it describes, added to the strength and brilliancy of genius which frequently appear in it, have enabled me to read it with more delight, and to return to it more frequently, than almost any other work of modern times. And let it be regarded in what light it may, the praise of elegant selection and composition certainly belongs to its editor. If I had not entertained these opinions of its merit, I should never have taken so much pains to investigate its authenticity; nor indeed can I believe, if the general opinion had not concurred with mine, that the world would ever have waited so much time in disputing about it.

OSSIFICATION, in the animal economy, the formation of the bones, but more particularly the conversion of parts naturally lost to the hardness and consistence of bones. Bones, Dr Drake contends, are formed out of the most comminuted broken parts of the blood; since we see that the blood of old men, which by a long course of circulation becomes in a manner united for the common office of nutrition, will however ossify, and convert into bones, many of the tendons and ligaments, and even the coats of the vessels themselves, whose substance being next to the bones the most compact, admits only of the smallest particles of the blood, which therefore sooner become ossious, as they are frequently found. Dr Nefit's opinion of ossification is, that in the blood, or a fluid secreted from it, there is an ossifying juice, having particles which are not apparent; that whenever nature designates an ossification between membranes, or within a cartilage, the occasions a more than usual afflux of this fluid; which so much diffuses the vessels which were before invisible, as to make them capable of receiving the red globules of blood, which is always to be seen near to the place where ossification is begun. In this blood, gritty bony particles may be felt by the point of a knife, which have been formed by the attraction and cohesion of the particles of the ossifying juice obstructed, along with the other grosser fluids, in the beginning of the vessels prepared to receive resultant juices. The blood being capable of forming fine membranes, the membraneous parts of a bone, which act as a glutten to keep these particles and fibres together, if there be any such, that do not arise from the coats of its vessels, are produced by a cohesion round the cretaceous particles of a part of the fluid, in which they were generated and contained. Thus the membranes of cartilages serve as a bed between or within which the bony particles are deposited, or shoot; but without any intermixture of the particles of the bone and cartilage, or continuation of the fibres of the one substance to those of the other, as is evident in cartilages containing bones kept long enough in water, and then flat; for the bone will, as soon as the large vessels that enter its substance are divided, slip as easily, and perhaps easier, from it than an acorn does out of its cup: and there is a smoothness and polish of the parts of both cartilage and bone, which show there is no conjunction of the fibres of the two substances. While the bones are increasing within cartilages, the cartilages are extended and spread out; by which, with the pressure which they suffer, and the great influx of various fluids, and the nutritious matter being hindered to flow freely into them, they decrease continually, and at last may truly be said to be entirely destroyed. Dr Buddens endeavours to prove,
prove, that the preternatural affections, which are commonly said to be formed in different parts of the body, do not deserve that name; for that these hard substancess have scarce or any other properties of bone except whitens and hardness.

OSSIPERUGUM, in botany, a name given by Bartholomew and other writers, to a kind of grass which grows in some parts of Norway. It comes up early in the spring, before any other grass, and the cattle are tempted to eat it; but it emaciates them, and renders them sickly: their back bones become protubant if they feed on it for any time; and their legs so weak that they can hardly go. The remedy among the country people, which is a very curious one, is this: They collect the bones of different animals, and break them into small pieces. The cattle greedily devour this sort of food when offered them in this disease, and there follows a sort of drizzling at the mouth for a considerable time, after which they become perfectly well. It is possible there may be much absurdity in this story. The kingdom of Norway is full of mines, and the effuvia of these may have occasioned the cattle's illness, and the eating of these effuvia their cure; for it is not probable that either of these effects should be owing to the grass or the bones.

OSSORY, the west division of Queen's-county in Ireland.

OSSUNA (Bale bishop of). See BALE.

OSTADE (Adrian Van), an eminent Dutch painter born at Lubeck in 1610. He was a disciple of Francis Hals, in whose school Brouwer was contemporary with him, where they contracted an intimate friendship. The subjects of his pencil were always of a low kind, he having nearly the fame ideas as Teniers; diverting himself with clowns and drunken in stables, alleys, and kitchens. His pictures are so transparent and highly finished, that they have the polish and lustre of enamel: they have frequently a force superior to Teniers; yet it were to be wished that he had not designed his figures so short. He is perhaps one of the Dutch masters who best understood the chiaro oscuro; and he was often employed to paint figures for the best landscape-painters of his countrymen. He died in 1685. His works, especially those of his chief time and manner, are very scarce; so that when they are to be purchased, no price is thought too much for them. His prints etched by himself, large and small, consist of 54 pieces.

OSTALRIC, a town of Spain, in Catalonia. It had a strong castle, but was taken by the French and demolished in 1695. It is seated on the river Tordera, in E. Long. 2. 45: N. Lat. 24. 44.

OSTEND, a very strong sea port town of the Netherland, in Austrian Flanders, with a good harbour and a magnificent town-house. It is not very large, but it is well fortified. It was much more considerable before the long siege of the Spaniards, which continued from 1609 to 1604, when it was almost entirely reduced to ashes. The Dutch lost 50,000 men, and the Spaniards 80,000. Isabella Eugenia, governess of the Netherlands, made a vow she would not OSTEND, shift her smock before Ostend surrendered; but before the town was taken it had greatly changed its colour. However, the ladies of the court, to keep her in countenance, had theirs dyed, that they might be like that of their mistress. This place was taken by the Dutch in 1706, but restored to the emperor in 1724, when an East India company was established here, but entirely suppressed by treaty in 1731. It was taken by the French in August 1745, after ten days siege, but rendered back by the treaty of Aix-la-Chapelle. It was lately over-run by the French Republicans, with Dumourier at their head, but was quickly recovered by the junction of the allies; it is now again in the hands of the French, and what may be its fate in the issue of the present war cannot as yet be determined. It is ten miles W. of Bruges, eight N. E. of Newport, 22 N. E. of Dunkirk, and 60 N. W. of Brussels. E. Long. 3. 1. N. Lat. 51. 14.

OSTECOLLA, sessile, in natural history, a white or ash-coloured sappy substance, in shape like bones, and by some fancied to have the quality of uniting broken bones, on which account it is ordered in some plasters; a supposition we fear which is not warranted by experience. It is found in long, thick, and irregularly cylindric pieces, which are in general hollow, but are sometimes filled up with a marly earth, and sometimes contain within them the remains of a flick, round which the osteocolla had been formed; but though it is plain from thence that many pieces of osteocolla have been formed by incrustations round ficks, yet the greater number are not so, but are irregularly tubular, and appear to be formed of a flat cake, rolled up in a cylindric shape. The crufis of which these are composed do not form regular concentric circles round the internal cavity, as might have been the case had they been formed by incrustation. On the other hand, they plainly show that they were once so many thin strata, composing a flat surface, which has afterwards been rolled up, as one might do a paper three or four times doubled, into two, three, or more spiral lines; in which case each fibre of the paper would be everywhere a regular point of a continued spiral line drawn from a given point; but they would by no means be so many detached concentric circles. The osteocolla is found of different sizes, from that of a crow-quill to the thickness of a man's arm. It is composed of sand and earth, which may be separated by washing the powdered osteocolla with water, and is found, both in digging and in several brooks, in many parts of Germany, and elsewhere. It is called hamnoles in many parts of Germany. It has this name from places where its always growing in sand, never in clay, or any flat foil, nor even in gravel. Where a piece of it anywhere appears on the surface, they dig down for it, and find the branches run ten or twelve feet deep. They usually run straight down, but sometimes they are found spreading into many parts near the surface, as if it were a subterraneous tree, whose main stem began at 12 feet depth, and thence grew into a branched manner till met by the open air. The main trunk is usually as thick as a man's leg, and the branches that grow out from it are thickest near the trunk, and thinner as they

Osteology, that part of anatomy which treats of the bones. See Anatomy, Part I.

Osterwald (John Frederick), a famous Protestant divine, was born at Neuchâtel in 1665; and made such rapid progress in his studies, that he became master of arts at Saumur before he was 16 years of age. He afterwards studied at Orleans and at Paris. At his return to Neuchâtel in 1690, he became pastor of the church there; and contrived a strict friendship with the celebrated John Alphonso Turretin of Geneva, and the illustrious Samuel Werenfels of Basli. The union of these three divines, which was called the Triumvirate of the divines of Switzerland, lasted till his death. Mr Osterwald acquired the highest reputation by his virtues, his zeal in instructing his disciples, and reforming ecclesiastical discipline. He wrote many books in French; the principal of which are, 1. A Treatise concerning the Sources of Corruption, which is a good moral piece. 2. A Catechism, or Instruction in the Christian Religion; which has been translated into German, Dutch, and English; and the Abridgment of the Sacred History, which he prefixed to it, was translated and printed in Arabic, in order to be sent to the East Indies, by the care of the Society for the Propagation of the Gospel; and that Society, established in London, paid him a high compliment, by admitting him an honorary member. 3. A treatise against Impurity. 4. An edition of the French Bible of Geneva, with Arguments and Reflections, in folio. 5. Ethica Christiana. 6. Theologiae Compendium, &c. He died in 1747, regretted by all who knew him.

OSTIA is a borough situated at the mouth of the Tiber, about 12 miles to the westward of Rome. It was built by Ancus Martius, the fourth king of Rome, and was called Oftia Tiberius, in the plural number; i.e. the two mouths of the Tiber, which were separated by the Holy Island, an equilateral triangle, whose sides were each of them computed at about two miles. The colony of Ostia was founded immediately beyond the left or southern, and the port immediately beyond the right or northern, branch of the river; and the distance between their remains measures something more than two miles on Cingolani’s map. In the time of Strabo, the sand and mud deposited by the Tyber had choked the harbour of Ostia; the progress of the same cause has added much to the size of the Holy Island, and gradually left both Ostia and the port at a considerable distance from the shore. The dry channels (fiumi moriri), and the large eddies (fagma di Ponte, di Levante), mark the changes of the river, and the efforts of sea. Its port was one of the most stupendous works of Roman magnificence, and it was a long time one of the best towns on the coast; but having been destroyed by the Saracens, and the harbour choked up, as mentioned above, it has not been able since to recover itself. Though it be an inconvenient place, and but poorly inhabited by reason of the badness of the air, yet it is the see of a bishop, who is always deacon of the cardinals, and crowns the Pope. The old Ostia, where you see the ruins of the ancient harbour, is beyond New Ostia, towards the sea; the latter is but a little cluster of houses, with a small castle. It is 12 miles S.W. of Rome. E. Long. 12. 24. N. Lat. 41. 44. There were salt works in Ostia, called Salina Ostenfia, as early as the times of Ancus Martius (Livy; from which the Via Salaria, which led to the Salines, took its name, (Varrs). It gave name to one of the gates of Rome, which was called Ostenfia (Ammian).

Ostiaacks, a people of Siberia in Asia. They live upon the banks of the rivers Obi and Jenissei, and on those of some other rivers which fall into them. These people are very poor, and very lazy, and in the summer-time live mostly upon fish. They are of a middle size, with broad faces and noses, and yellowish or red hair. All their garments from top to toe are made of fish skins, for they have neither linen nor woollen; and indeed they might almost as well go naked. Their greatest diversion is hunting: and they go together in crowds, with a weapon like a large knife fastened in a flick. In summer they take and dry the fish which serve them in winter; and when that season begins, they go into the woods, with their bows and arrows, their dogs and nets, to kill fables, ermines, bears, rein-deer, elks, martens, and foxes. Part of the furs of these is paid as a tax to the emperors
O STRATION, in zoology, a genus of the amphibious nates class. It has ten long cylindrical obtuse teeth in each jaw; the aperture is linear; the body is covered with a bony substance, and it has no bilistical. There are nine species; principally distinguished by the angles of their bodies, and number of fins near their tail.

OSTRACISM, in Grecian antiquity, denotes the banishment of such persons whose merit and influence gave umbrage to the people of Athens, left them shorn of any respect, and cut off from all public liberty. This punishment was called ostracismos, from the Greek word σταρις, which properly signifies a "bell," but when applied to this object, it is used for the bell on which the Athenians wrote the names of the citizens whom they thought to banish. The learned are divided with regard to the substance of which this bell was formed: some insist that it was a small stone, or a piece of brick;
The ancients are likewise divided with regard to the time when ostracism was instituted. But they all agree, that the person who moved the law was its first victim. But as to the name of its patron, and the time of its establishment, they differ extremely. Many are of opinion, that ostracism owes its origin to very remote times.

However that be, the punishment of ostracism was instituted by the Athenians when their liberty was in danger. If, for instance, jealousy or ambition had sowed discord among the chiefs of the republic; and if different parties were formed, which threatened some revolution in the state; the people assembled to propose measures proper to prevent the consequences of a division which in the end might be fatal to freedom. Ostracism was the remedy to which they usually had recourse on those occasions; and the consultations of the people generally terminated with a decree, in which a day was fixed for a particular assembly, when they were to proceed to the sentence of ostracism. Then they who were threatened with banishment, omitted no affumity or art which might gain them the favour of the people. They made harangues to evince their innocence, and the great injustice that would be done them if they were banished. They solicited, in person, the interest of every citizen; all their party exerted themselves in their behalf; they procured informers to vilify the chiefs of the opposite faction. Some time before the meeting of the assembly, a wooden inclosure was raised in the forum, with ten doors, into which as many as there were tribes in the republic; and when the appointed day was come, the citizens of each tribe entered through their respective door, and threw into the middle of the inclosure the small brick on which the citizen's name was written whose banishment they voted. The archons and the senate presided at this assembly, and counted the ballots. He who was condemned by 6000 of his fellow-citizens, was obliged to quit the city within ten days; for 6000 voices, at least, were requisite to banish an Athenian by ostracism.

The Athenians, without doubt, foreknew the inconveniences to which this law was subject; but they chose rather, as Cornelius Nepos hath remarked, sometimes to expose the innocent to an unjust censure, than to live in continual alarms. Yet as they were sensible that the injustice of confounding virtue and vice would have been too flagrant, they softened, as much as they could, the rigor of ostracism. It was not aggravated with the circumstances which were most dishonourable and shocking in the ordinary mode of exile. They did not confiscate the goods of those who were banished by ostracism. They enjoyed the produce of their effects in the places into which they were banished; and they were banished only for a certain time. But in the common banishment, the goods of the exiles were always confiscated, and no hopes were given them of ever returning to Athens.

The scholiast of Aristophanes informs us of a third difference between ostracism, and the common banishment. He says, that a particular piece of retirement was assigned to those who were banished by ostracism, which was not appointed to the other exiles. We suspect, however, the truth of this observation; for Themistocles was certainly not limited in his banishment. That great man as we are told by Thucydides, to whose chief residence was at Argi, travelled over all the Peloponnesus.

This punishment, far from conveying the idea of infancy, became at Athens, a proof of merit, by the objects on which it was inflicted; as Aristides the sophist judiciously observes, in his second declamation, against the Gorgias of Plato, where he says, that ostracism was not an effect of the vindictive spirit of the people against those whom it condemned; that the law, whether good or bad (for he enters not into an examination of the question), was only meant to prune the luxuriant growth of transcendent merit; that it condemned to an exile of ten years, only those illustrious men who were accused of being exalted far above other citizens by their conspicuous virtues; and that none of that public indignation was shown to the exiles by ostracism, which commonly breaks out against criminals.

Such were the mitigations with which this law was introduced among the Athenians: and by them we see that they were sensible of all the inconveniences to which it was subject. They were indeed too enlightened a people not to foresee the many instances of injustice which it might produce; that if in some respects it would be favourable to liberty, in others it would be its enemy, by condemning citizens without allowing them a previous defence, and by making a capricious and envious people arbiters of the fate of great men; that it might even become pernicious to the state, by depriving it of its best subjects, and by rendering the administration of public affairs an odious employment to men of capital talents and virtue.

However great the inconveniences of ostracism were, it would not have been impossible to avoid them; and we may add, that this law would have been of service to the state, if the people by whom it was instituted had always had sufficient enough only to give it force on such occasions as endangered liberty. But its fate was like that of almost all other laws which the wise legislators have planned for the good of communities. Defined by their institution to maintain order, to repress injustice, and to protect innocence, men have found ways to pervert their application, and have made them instruments to gratify their private passions. Thus ostracism was established to prevent the dangerous enterprises of the great, and to preserve the vigour of the democracy; but the people of Athens, naturally jealous and envious, exerted that law, to remove men of eminent merit from the state, by whose presence they were reproved and intimidated. The fear of tyranny was commonly but a specious pretext with which they veiled their malignity. The
OSTRACITES, in natural history, a name used for the toffile oysters, common in many parts of England. They are of various shapes and kinds; and the name is by some authors made to signify the shell itself, when preserved in its native state and condition; as is the case with those about Woolwich and Blackheath; and by others the flones cast or formed in those shells, or in cavities from whence they have been washed away and dissolved: in both these cases the stone carries the exact resemblance of the shell, even in its nicest lineaments; in the first case, bearing every mark of the inside, in the other of the outer surface. This flone is very great in many parts of England; and it is very famous, in some places, for its virtues in cafes of the gravel, and the like complaints.

OSTREA, the oyster, in zoology, a genus belonging to the order of vermes teaticea. The shell has two unequal valves; the cardo has no teeth, but a small hollowed one with transverse lateral fleakes. There are 31 species, principally distinguished by peculiarities in their shells. The common oyster is reckoned an excellent food; and is eaten both raw and variously prepared. The character of the genus, in the words of Barbut, is, "The animal a tethys; the shell bivalve, unequall, with something like ears; the hinge void of teeth, with a deep oval hole, and transverse streaks on the sides. There is no wumph nor anus." The genus is divided into four families, of which ophrea is the laft. See Pectens. The same author gives us the following enlarged account of the oyster.

This sea-fish occupies in the scale of nature one of the degrees the moft remote from perfection; defective of defensive weapons and progressive motion, without art or industry, it is reduced to mere vegetation in perpetual imprisonment, though it every day opens regularly to enjoy the element necessary to its preservation. The animal figure, and the springs of its organization, are scarce discernible through the course and shapeles mafs; a ligament placed at the summit of the shell serves as an arm to its operations. Oysters are reputed to be hermaphrodites; the spawn which they cast in May adheres to the rocks and other matters at the bottom of the sea; and in the space of 24 hours is provided with shells, in which are contained other oysters, that never leave the spot on which they were fixed, till the greedy fisherman tears them from the element. The green oysters eaten at Paris are commonly brought from Dieppe. Their colour is owing to the care taken to bed them in creeks, ensconced with verdure, whence they acquire their delicacy. Common oysters should be fresh, tender, and moist. The moll ecleem are those caught at the mouth of rivers, and in clear water.

Great account is made of oysters from Brittany, but still greater of those that come from Marennes in Saintonge. Preference is given to those that are edged with small brown fringe, or beard, which indicates call recurred dated oysters; but that those are females is a mistake. The want of fresh water renders oysters hard, bitter, and unpalatable. Kind and sea-weeds destroy them in their very birth; galangal root, musk, floops, sea-arts, and crabs, are formidable enemies to the oyster. There are found in Spain red and rufier coloured oysters; in Illiria, brown coloured, with the flesh black; and in the Red Sea, of the colour of the Iris. Oysters of the mangle-tree are of two sorts; those of St Domingo are delicate, adhering to the fumps of the trees that dip in the water. The negro divers cut them off with a bill, and they are served upon table with the roots.

Britain has been noted for oysters from the time of Juvenal; who, faturizing Montanus an epicure, says, "Circatia nata fores, an Lucrum ad fiamn, Refpinemos, edita fundo, Ophra, callibus primo prefendere morfa.

He, whether Circe's rock his oysters bore, Or Lucrine lake, or distant Richborough's shore, Knew at first taste.

The luxurious Romans were very fond of this fish, Pennant's had their layers or swarms for oysters as we have at prezent. Sergius Orata was the first inventor, as early as the time of L. Cadius the orator. He did not make them for the fake of indulging his appetite, but through avarice, and made great profits from them. Orata got great credit for his Lucrine oysters; for, says Pliny, the Britifh were not then known.

The ancients eat them raw, having them carried up unopened, and generally eating them at the beginning of the entertainment, but sometimes roasted. They had also a custom of flewing them with mallows and ducks, or with fish, and esteemed them very nourishing.

'British shell keeps its superiority in oysters over other countries. Most of the.coals produce them naturally; and in such places they are taken by dredging, and are become an article of commerce, both raw and pickled. The very shells, calcined, become an useful medicine as an aborbent. In common with other shells, they prove an excellent mufare.

Stews or layers of oysters are formed in places which nature never allotted as habitations for them. Those near Colchester have been long famous; at prezent there are others that at leaft rival the former, near the mouth of the Thames. The oysters, or their sprats, are brought to convenient places, where they improve in taste and size. It is an error to suppose, that the fine green observed in oysters taken from artificial beds, is owing to copperas; it being notorious how deftructive the fubfance of the solution of it is to all fish. We cannot give a better account of the caufe, or of the whole treatment of oysters, than what is preferred in the learned bishop Sprat's history of the Royal Society, from p. 307 to 309.

"In the month of May, the oysters cast their spawn, (which the dredgers call their spats); it is like to a drop of candle, and about the bigness of a half penny"
penny. The spat cleaves to stones, old oyster shells, pieces of wood, and such like things, at the bottom of the sea, which they call "culch." It is probably conjectured, that the spat in 24 hours begins to have a shell. In the month of May, the dredgers (by the law of the admiralty court) have liberty to catch all manner of oysters, of what size soever. When they have taken them, with a knife they gently raise the small brood from the culch, and then they throw the culch in again, to preserve the ground for the future, unless they be so newly spat, that they cannot be safely severed from the culch; in that case they are permitted to take the stone or shell, &c. that the spat is upon, one shell having many times 20 spat. After the month of May, it is felony to carry away the clutch, and punishable to take any other oysters, unless it be those of ize, (that is to say) about the bigness of an half-crown piece, or when the two shells being shut, a fair shilling will rattle between them.

"The places where these oysters are chiefly catched, are called the Pent-Burnham, Malden, and Coinwaters; the latter taking its name from the river of Colne, which paffeth by Colchester, gives name to that town, and runs into a creek of the sea, at a place called the Hythe, being the suburbs of the town. This brood and other oysters they carry to the creeks of the sea, at Brickellsea, Merly, Langlo, Fingrego, Wivenho, Tolebury, and Saltcoafe, and there throw them into the channel, which they call their beds or layers, where they grow and fetten; and in two or three years the smallest brood will be oysters of the size aforesaid. Thofe oysters which they would have grene, they put into pits about three feet deep in the salt marithes, which are overflowed only at spring tides, to which they have fluices, and let out the salt-water until it is about a foot and a half deep. These pits, from fame quality in the foil co-operating with the heat of the sun, will become green, and communicate their colour to the oysters that are put into them in four or five days, though they commonly let them continue there fix weeks or two months, in which time they will be of a dark green. To prove that the sun operates in the greening, Tolebury pits will green only in summer; but that the earth hath the greater power, Brickellsea pits green both winter and summer; and for a further proof, a pit within a foot of a greening pit will not green; and thofe that did green very well, will in time lose their quality. The oysters, when the tide comes in, lie with their hollow shell downwards; and when it goes out, they turn on the other side: they remove not from their place, unless in cold weather, to cover themselves in the oute. The reafon of the scarcity of oysters, and consequently of their dearnefs, is, becaufe they are of late years bought up by the Dutch.

"There are great penalties by the admiralty court laid upon thofe that fift out of thofe grounds which the court appoints, or that defroy the culch, or that take any oysters that are not of ize, or that do not tread under their feet, or throw upon the foare, a Fh which they call a free finger, reflembling a fur-prowl, becaufe that fift gets into the oysters when they gape, and fiefs them out.

"The reafon that fuch a penalty is fet upon any that shall defroy the culch, is, becaufe they find that if that be taken away, the oute will increafe, and the mufcles and cockles will breed there, and defroy the oysters, they having not whereon to flick their spat.

"The oysters are fick after they have spat; but in June and July they begin to mend, and in August they are perfectly well; the male oyster is black-fick, having a black fubftrance in the fin; the female white-fick (as they term it), having a milky fubftrance in the fin. They are falt in the pits, falter in the layers, but falt less at tea."

The oyster affords the curious in microscopic obser- vations a very pleasing entertainment. In the clear liquor many little round living animalcules have been found, whose bodies being conjoined, form spherical figures, with tails, not changing their place otherwise than by flinking to the bottom, as being heavier than the fluid; these have been seen frequently seperating, and then coming together again. In other oysters, animalcules of the fame kind were found, not conjoined, but swimming by one another, whence they seemed in a more perfect fale, and were judged by Mr Leeuwenhoek to be the animalcules in the roie or femen of the oyster.

A female oyster being opened, incredible multitudes of small embryo oysters were feen, covered with little shells, perfectly transparent, and swimming along fowly in the liquor; and in another female, the young ones were found of a browner colour, and without any appearance of life or motion.

Monsieur Joblot alfo kept the water running from oysters three days, and it appeared full of young oy- sters swimming about nimblly in it; these increafed in size daily; but a mixture of wine, or the vapour of vin- egar, killed them. In the month of August oysters are supposed to breed, becaufe young ones are then fround in them. Mr Leeuwenhoek, on the 4th of August, opened an oyster, and took out of it a prodigious number of minute oysters, all alive, and swimming nimblly about in the liquor, by means of certain exceeding small organs extending a little way beyond their fheels; and they calls their beards. In these little oysters, he could difcover the joinings of the shells; and perceived that there were fome dead ones, with their shells gapings. Thofe, tho' fo extremely minute, are feen to be as like the large oyfters in form as one egg is to another.

As to the ize of them he computes, that 120 of them in a row would extend an inch; and confequently that a globular body, whose diameter is an inch, would, if they were all roind, be equal to 1,278,000 of them. He reckons 3000 or 4000 are in one oyster, and found many of the embryo oyfters among the bairs; fome fivated thereto by fender flaments, and others lying loofe: he likewise found animalcules in the liquor 500 times lef then the embryo oyfters.

It is not very uncommon to fee on oyfter-shells, when in a dark place, a fhining matter or blush light, like a fame of brimstone, which ficks to the fingers when touched, and continues fhining and giving light for a considerable time, though without any fenfible heat. This fhining matter being examined with a mi- croscope, was found to conftitute of three forts of animal- cules;
OSWICH, in zoology. See STRUTHIO.

OSTROVIZZA, in Dalmatia (see DALMATIA), which some would have the name as ARAXZONA, and others the Stupi of the ancients, though probably it has no connection with either the one or the other. It was purchased in 1410 by the republic of Venice, for 5000 ducats, and some pieces of land besides. Its fort-works, which was seated on a rock, perpendicularly cut all round, and defervedly reckoned impregnable before the use of artillery, was taken by Soliman in 1574, but soon after returned under the dominion of Venice. At present, no traces of its fortification remain, and it is only a bare and insulted mass. There are some natural curiosities about the place.

OSTUNI, a town of Italy, in the kingdom of Naples, and in the Terra di Otranto, with a bishop's see. Its territory is well cultivated, and abounds with olives and almonds. It is seated on a mountain near the Guip of Venice, in E. Long. 17° 49'. N. Lat. 49° 59'.

OSWEGO, a port of North America, seated on the south side of the lake Ontario, in W. Long. 70° 35'. N. Lat. 45° 15'.

OSWIEZLN, a town of Poland, in the palatinate of Cracovia, with the title of a duchy. It carries on a great trade in salt, and is seated on the river Vistula. E. Long. 19° 47'. N. Lat. 50° 1.

OSWESTRY, in the county of Salop, in England, 172 miles from London, is a very old town, with a castle, a wall, and a ditch, and was anciently a borough. It is a place celebrated in Saxons history and legend. Its magnificence on this spot, August 5, 642, was fought the battle between the ChristianOfwald king of the Northumbrians and the pagan Penda king of the Mercians, in which Ofwald was defeated, and lost his life. The barbarian victor cut the body of the slain prince in pieces, and flung them on flakes dispersed over the field as so many trophies; but, according to others, his head and hands only were exposed. A prince so dear to the church as Ofwald, and so attached to the professors of the monastic life, received every posthumous honour they could bestow. He was raised to the rank of a saint, and his sanctity confirmed by numberless miracles, which are too numerous and too trifling to admit of particular description. Its church, which is of no great antiquity, was formerly a monastery, and was called Blencmister. It is, however, spacious, and has a handsome plain tower. In the years 1542 and 1567, this town suffered much by fire. It is governed by two bailiffs, burgesses, &c. and once enjoyed a great trade in Welsh cottons and flannel, which is now very much decayed. There is now scarce a tolerable house for travellers. But besides a good grammar school, it is noted for an excellent charity-school for 40 boys, besides girls, which has the best methods for exciting the emulation of the children in their learning; for 20 of the boys are set to science against 20 others for shoes, and the 20 who perform their task best have shoes first; then 10 of the boys are set against 10 others for the like premium, and so on till they are all shed: so in the girls school a shift is put up for the belt spinner, a head-dress for the best sempstress, a pair of fockings for the best knitter, a bible for the best reader, and a copy-book for the best writer. In the wall with which the town was fortified there were four gates. That called the Blackgate is demolished; the New-gate, Willow-gate, and the Belfric-gate, still remain. The last is a hand built, with a guard-room on both sides. There are only two fragments of the wall remaining. It stood on an artificial mount, surrounded by a fosse, extending to the Willow-gate.

OSYMANDES, a famous king of Egypt, was, according to some authors, the first monarch who collected a great number of books for the purpose of forming a library. To this curious collection he gave the title of Pharmacy of the Soul. Of all the monuments of the kings of Thebes, that of Osymandias is one of the most magnificent. "He appears (says an elegant author) to have been a prince of great elegance and taste in this day. Diodorus Siculus describes many sumptuous edifices erected by him; among those edifices his palace or mausoleum, whichsoever it was, has been eminently distinguished for the paintings and sculptures with which it was adorned. When we look to the subjects of those works, we shall have reason to think that no man in any age could discover a fairer and more enlightened judgment than he did in the employment of the genius around him, which was not tamely devoted to dull or contracted objects, nor lavished on scenes of savage life, nor wholly engrossed in allusions to himself, but evidently enlarged to a variety of contemplation which might become a great sovereign; and in each of those parts the subject was characterizedly great."

* In one place was represented, in a multitude of sculptures, his expedition against the Bactrian king of Asia, whom he had invaded with 400,000 foot, and 20,000 horse, and whom he conquered. In another part was displayed the variety of fruits and productions, with which Pan, the great source of all things, had enriched the fertile land over which Osymandias reigned. A third group of figures represented the monarch himself, as the high-priest of the country, offering to the gods the gold and silver which he drew every year from the mines of Egypt. In another part of the edifice was exhibited, in an infinite number of figures, an assembly of judges, in the midst of a great audience attentive to their decisions; the president, or chief of those judges, surrounded by many books, swore on his breast a picture of truth with his eyes fixed—those emphatic emblems, beyond which no age could go for the impregnation of that wisdom and impartiality which ought to prevail in administrative justice."

In short, we cannot without astonishment read the account which Diodorus Siculus gives of the almost incredible magnificence of this prince, and of the immense sums which he spent upon those grand works.
OTA

Oste-Viades

Otahitte.

Amongst a variety of other surprising curiosities, was to be seen a statue in the attitude of sitting, which was the largest in all Egypt, the length of one of the feet being seven cubits. Not only the art of the sculptor, but also the beauty of the stone which was perfect in its kind, contributed to render this a masterpiece of sculpture. It bore the following inscription:

I am OSTYMANDES, king of kings; whoever will dispute with me this title, let him surpass me in any of my works.

Indeed (to use the words of the same elegant author quoted above) "the palace or mausoleum of this accomplished prince must give us a striking assurance of the progress which had been made in the arts at that time; whether he was, as some have thought, the successor of the first Busiris, which was somewhat later than the period of Semiramis; or, as others have conceived, the successor of that monarch which has been placed, when we look back to what was done in those works in a period full as early by Semiramis in Asia."

OTACOUSTIC INSTRUMENT, or Auricular Tube, an instrument to facilitate the hearing. See Acoustics, ii. 25.

OTAHEITEE, a celebrated island of the South Sea, situated in W. Long. 149° 13', S. Lat. 17° 45'. It was discovered by Captain Wallis in 1767; afterwards Mr Bougainville touched there; and it was visited by Captain Cook in 1773 and 1774, who had in 1769 failed round the island in a boat to observe the transit of Venus.

The island consists of two distinct kingdoms, which are united by a narrow neck of land; the larger being called by the natives Tiara-bou, or O-Tahiti-Tea; the smaller one Opo-nehou, or O-Tahiti-Ete. The circumference of both islands is about 40 leagues; the larger kingdom being divided into 43 districts. The country has a delightful romantic appearance. The coast, viewed from the sea, presents a most beautiful prospect, being elevated like an amphitheatre. The island is skirted with a reef of rocks, and towards the sea is level, being covered with fruit-trees of various kinds, particularly the cocoa-nut. At the distance of about three miles from the shore, the country rises to lofty hills that are covered with wood, and terminate in peaks, from which large rivers are precipitated into the sea. The fountains everywhere appear to have been burnt, not one being found which did not give manifold signs of fire; so that there is great reason for supposing that this and the neighbouring islands are either the shattered remains of a continent, or were torn from rocks, which from the creation of the world have been the bed of the sea, and thrown up in heaps to a height which the waters never reach. What is further extraordinary, the water does not gradually grow shallow as we approach the shore, but is of immense depth close by the land; and the islands in this neighbourhood are almost everywhere surrounded by reefs, which appear to be rude and broken in the manner that some violent concussion would naturally leave the solid substance of the earth; and Mr Forster saw a rock with projecting longitudinal angles of black compact basaltes. The exterior ranges of hills are sometimes entirely barren, and contain a great quantity of yellowish clay, mixed with iron ochre; but others are covered with mould and wood like the mountains in the internal parts of the country. Pieces of quartz are sometimes met with here; but no indications of precious minerals or metals of any kind have been observed, iron only excepted.

The air is extremely healthy and pleasant; the heat is not troublesome; and fresh meat will keep very well for two days, and if one day. The winds do not blow constantly from the east, but generally a little breeze from east to south south-east. The tide rises very little; and, being governed by the winds, is very uncertain. "The climate," says M. Bougainville, "is so healthy, that notwithstanding the hard labour of the ships companies while on shore, though the men were continually in the water, and exposed to the meridian sun, though they slept upon the bare soil, and in the open air, none of them fell sick; those who were afflicted with the scurvy, and were sent on shore, regained their strength: although they were obliged to assist in the erecting of a fort, and had scarce one uninterrupted night, yet they were so far recovered in the short space of time they continued there, that they were afterwards perfectly cured on board."

Notwithstanding the great height of the inland mountains of Otahitte, none of their rocks have the appearance of barreneys, every one of them being covered with woods. "We hardly believed our eyes," says M. de Bougainville, "when he saw a peak covered with woods up to its highest summit, which rises above the level of the mountains in the interior parts of the southern quarter of this island. Its apparent size seemed to be more than 50 toises in diameter, and grew less in breadth as it rose higher. At a distance it might have been taken for a pyramid of immense height, which the hand of an able sculptor had adorned with garlands and foliage."

One of the mates of the Dolphin, with a party of marines and seamen, penetrated into the interior parts of the island; and having ascended, with great difficulty, a mountain which they supposed to be a mile high, they discovered mountains before them so much higher, that with respect to them they seemed to be in a valley: towards the sea the view was enchanting, the sides of the hills were beautifully clothed with wood, villages were everywhere interspersed, and the valleys between them afforded a rich prospect; the houses stood thicker, and the verdure was more luxuriant; and Mr Forster, with other gentlemen, ascended to the summit of one of the highest mountains in the island, from whence they had a prospect of the island of Huahine, and some others lying at the distance of 40 leagues; from which we may form some judgment of the prodigious height of that mountain. The view of the fertile plain below them, and of a river making innumerable meanders, was delightful in the highest degree. The vegetation on the upper part of the mountains was luxuriant, and the woods consisted of many unknown sorts of trees and plants.

The soil of this island is a rich fat earth, of a black-soil and sandy product.
Otaheite: its colour. It produces spontaneously, or with the slightest culture imaginable, a great variety of the most excellent fruits; such as bread-fruit, cocao-nuts, bananas of 13 sorts, plantains, potatoes, yams, a fruit known here by the name of jamis, and reckoned most delicious; sugar-canes, which the inhabitants eat raw; ginger; turmeric; a root of the falep kind, called by the natives called abé; a tree called wakara, which produces fruit something like the pine-apple, and which is known in the East Indies by the name of pandanus: a shrub called moro; the morinda, which also produces fruit; a species of fern; a plant called thebo; and the Chinese paper-melberry, of the bark of which they make their cloth; an herb which the inhabitants eat raw, its flavour somewhat resemblng that of the West India spinage called callettoon, but its leaf very different; a plant which the natives call apa or cacao, from the root of which they express a liquor, which, if drank to excess, intoxicates like wine or distilled spirits. Here are a fort of thady trees covered with a dark-green foliage, bearing golden-coloured apples, which, in juiciness and flavour, resemble the amos or pine-apple. One of the most beautiful trees in the world received here the name of Borringtonia; it had a great abundance of flowers larger than lilies, and perfectly white, excepting the tips of their numerous chives, which were of a deep crimson. Such a quantity of these flowers were seen dropped off, that the ground underneath the tree was entirely covered with them. The natives called the tree buddo; and said, that the fruit, which is a large nut, when bruised and mixed up with some shell-fish, and thrown into the sea, intoxicates the fish for some time, so that they come to the surface of the water, and suffer themselves to be taken with people's hands. Several other maritime plants in tropical climates are found to have the same quality. Mr Dalrymple describes the method of catching fish with these plants as follows: The plant is thrust under the coral rocks or hollows where the fish haunt; the effect is most infulible in still water, though it is effectual in the open sea; for the fame genleman fays, he has seen fish soon after found on the surface of the water half dead, and some totally without life; and where the effect is less violent, the fish will be seen under the water to have lost their poise, without coming up to the surface. Fifth caught in this manner are not in the least noxious or ill tailed.

Animals. In this island they have domestic poultry exactly resembling those of Europe: besides there are wild ducks; also beautiful green turtle-doves; large pigeons of a deep blue plumage and excellent tafte; a small fort of parquet, very singular on account of the various mixture of red and blue in their feathers; also another fort of a greenish colour, with a few red spots; the latter are frequently tamed, and are valued on account of their red feathers. Here is a kingfisher of a dark green, with a collar of the fame hue round his white throat; a large euckow, and a blue heron. Smal birds of various kinds dwell in the thady trees; and, contrary to the generall received opinion that birds in warm climates are not remarkable for their song, have a very agreeable note. There were no quadrupeds but dogs, hogs, and rats; and for these, the natives were said to have a scrupulous regard, infomuch that they would by no means kill them; however, Captain Cook, in 1773, turned about 14 cats on the island, which have probably reduced the number of these vermin. No frogs, toads, scorpions, centipedes, or any kind of serpent, have been found here: the ants, however, are troublesome, but not very numerous. When the Endeavour first arrived here in 1769, the flies were found excessively troublesome; but musquito nets and fly-flaps in some measure removed the inconvenience. Sydney Parkinson, in his journal, fays, that notwithstanding these flies are so great a nuisance, the natives, from a religious principle, will not kill them. But there is a strange dis-agreement in the accounts of different voyagers concerning this matter. For M. Bougainville fays, "this island is not infelted by thofe myriads of troublesome insects that are the plague of other tropical countries." And Mr Forster fays, "not a great or musquito hummed unpleafantly about us, or made us apprehensive of its bite." This inconvenience must therefore be felt at certain feasons of the year, and in certain districts of the country, more feinfully than at other times and places. There is a great variety of excellent fish; and, according to Atiuou, a native who embarked with M. de Bougainville, there are sea-flakes on the shore of Otaheite, whose bite is mortal.

The inhabitants of Otaheite are a ftrong, well-made, active, and comely people. The figure of the men, in general, is from five feet seven to five feet ten inches; the tallest man seen by Captain Wallis measured fix feet three inches and a half; and Captain Cook, in his second voyage, describes O'Too, the king of Otaheite, to be of that height. "In order to paint an Hercules or a Mars," fays M. de Bougainville, "one could nowhere find fuch beautiful models." They are of a pale brown comphexion; in general their hair is black, and finely frizzled; they have black eyes, flat noses, large mouths, and fine white teeth; the men wear their beards in many fashions, all of them plucking out a great part, and have prominent bellies. Most of them smell strong of the cocoa nut oil. The women in general are much smaller, especially thofe of the lower rank or housewives, which is attributed to their early and promiscuous intercourse with the men, whilst the better fort, who do not gratify their paflions in the fame unbridled manner, are above the middle stature of Europeans. Their skin is most delicately smooth and soft; they have no colour in their cheeks; their nose is generally somewhat flat, but their eyes are full of expreffion, and their teeth beautifully even and white. "The women," fays M. de Bougainville, "have features not lefs agreeable than the generality of Europeans, and a symmetry of body and beautiful proportion of limbs which might vie with any of them. The complexion of the men is tawny; but thofe who go up the water are much more red than thofe who live on shore. Some have their hair brown, red, or flaxen, in which they are exceptions to all the natives of Asia, Africa, and America, who have their hair black universally; here, in the children of both sexes, it is generally flaxen. The strongest expreffion is painted in the countenance of these people; their walk is graceful, and all their motions are performed."
OTA

Otaheite performed with great vigour and ease. I never beheld a delicate men, (says Sidney Parkinson.) The men of consequence on the island wear the nails of their fingers long, which they consider as a very honourable badge of distinction, since only such people as have no occasion to work can suffer them to grow to that length. This custom they have in common with the Chinese; but the nail of the middle finger on the right hand is always kept short, the meaning for which peculiarity could not be learned. Only the single cripple was met with among them, and he appeared to have been maimed by a fall. The women always cut their hair short round their heads. Both sexes have a custom of shaving their bodies, which they call tatouying; both men and women have the hinder part of their thighs and loins marked very thick with black lines in various forms; these marks are made by striking the teeth of an instrument somewhat like a comb just through the skin, and rubbing into the punctures a kind of paste made of foot and oil, which leaves an indelible stain. The boys and girls under twelve years of age are not marked; a few of the men, whose legs were marked in chequers by the same method, appeared to be persons of superior rank and authority. Mr Banks saw the operation of tatooing performed upon the backside of a girl about thirteen years old. The instrument used upon this occasion had thirty teeth: and every stroke, of which at least a hundred were made in a minute, drew an ichor or serum a little tinged with blood. The girl bore it with most tolerable resolution for about a quarter of an hour; but the pain of so many hundred punctures as she had received in that time, then became intolerable. She first complained in murmurs, then wept, and at last burst into loud lamentations, earnestly imploring the operator to desist. He was, however, inexorable; and when she began to struggle, she was held down by two women, who sometimes foothered and sometimes chid her; and now and then, when she was most unruly, gave her a smart blow. Mr Banks laid in a neighbouring house an hour, and the operation was not over when he went away; yet it was but performed upon one side, the other having been done some time before; and the arches upon the loins, in which they moil pride themselves, and which give more pain than all the rest, were still to be done. Both men and women are not only decently but gracefully clothed, in a kind of white cloth that is made of the bark of a shrub, and very much resembles coarse China paper. Their dress consists of two pieces of this cloth; one of them, having a hole made in the middle to put the head through, hangs from the shoulders to the middle leg and behind: another piece, which is between four and five yards long, and about one yard broad, they wrap round the body in a very easy manner: This cloth is not woven; but is made like paper, of the macerated fibres of the inner bark spread out and beaten together. Their ornaments are feathers, flowers, pieces of shell, and pearls; the pearls are worn chiefly by the women. In wet weather they wear matting of different kinds, as their cloth will not bear wetting. The drefs of the better sort of women consists of three or four pieces: one piece, about two yards wide and eleven long, they wrap several times round their waists, so as to hang down like a petticoat as low as the middle of the leg; and this they call parov. This simple drapery affords the sex an opportunity of displaying an elegant figure to the greatest advantage, according to the talents and taste of the wearer: no general fashions force them to disfigure instead of adorning themselves, but an innate gracefulness is the companion of simplicity. To this cloth they give a very strong perfume.

The chief use which they make of their houfes is to keep their sheep in them; for unless it rains, they eat in the open air under the shade of a tree. These houses are not other than huts, all built in the wood between the sea and the mountains; they are erected on an oblong square; their sides are nearly half of their length; there is nothing more than a roof, not quite four feet from the ground, raised on three rows of pillars, one row on each side, and one in the middle. The roof resembles the thatched huts in England, and consists of two flat sides inclining to each other. Their thatch consists of palm-leaves. The floor of their dwelling is covered with hay, over which they spread mats. Some of these erections are furnished with a roof, which is appropriated solely to the use of the master of the family: they consist of no other furniture except a few blocks of wood, which being square, one side is hollowed into a curve; and these they use as pillows, and with their apparel they cover themselves. In these open dwellings the whole family repose themselves at night. The size of the house is proportioned to the number that constitutes the family. The established order in these dormitories is for the master and his wife to sleep in the middle; round them the married people; in the next circle the unmarried women; and in the next, at the same distance, the unmarried men; and the servants at the extremity of the shed; but in fair weather the latter sleep in the open air. Some few dwellings, however, constructed for greater privacy, are entirely inclosed with walls of reeds, connected together with transverse pieces of wood, so as to appear somewhat like large bird cages closely lined; in these houfes there is commonly a hole left for the entrance, which can be closed up with a board.

Their candles are made of the kernels of a kind of oily nut, which they stick one above another on a skewer that is thrust through the middle of them; the upper one being lighted burns to the second, at the same time consuming that part of the skewer that goes through it; the second taking fire burns in the same manner down to the third, and so to the last; they burn a considerable time, and afford a pretty good light. The natives generally retire to rest about an hour after it is dark.

The food of the common people entirely consists of food, me-vegetables. These are, the bread-fruit, with bananas, plantains, yams, apples, and a four fruit, which, though cooked, is not pleasant by itself, gives an agreeable retrain to roasted bread-fruit, with which it is frequently beaten up: (See the article Bread-Tree). The flesh, which is reserved for the tables of the great, is either poultry, hogs, or dogs; the flesh of their fowls is not well-tasted, but that of dogs is esteemed by the natives beyond pork. The smaller fish are generally eaten raw, as we eat oysters; every thing that can be procured from the sea is made an article of their food; for they will eat not only sea-animals, but what the vagrant call blubbers.
They kill the animals they intend for food by suffocating them, which is done by flopping the mouth and nose with their hands; they then finge off the hair, by holding the animal over a fire, and scraping him with a shell: with this instrument they cut him up, and take out the entrails; which are washed, and put into cocoa-nut-sheaths, together with the blood. Dogs are eaten that are fed wholly upon bread-fruit, cocoa-nuts, yams, and other vegetables, and are never fattened; which is done, though some of them are so tough that they are obliged to suffer them to become putrid before they can be chewed. A very large shark being caught by the Dolphin's people was given to the natives; who soon cut it to pieces, and carried it away with great satisfaction.

They then dig a pit about half a yard in circumference; they pave the bottom with large pebble stones, which they lay down very smooth and even, and then kindle a fire in it with dry wood, leaves, and the husks of cocoa-nuts. When the stones are sufficiently heated, they take out the embers, and rake up the ashes on every side; they then cover the stones with a layer of green cocoa-nut leaves, and wrap up the animal that is to be dressed in the leaves of the plantain. If it is a small hog, they wrap it up whole; if a large one, they slit it. When it is placed in the pit, they cover it with the hot embers, and lay upon them bread-fruit and yams, which are also wrapped up in the leaves of plantain. Over these they spread the remainder of the embers, mixing among them some of the hot stones, with more cocoa-nut-tree leaves upon them, and then close up all with earth, so that the heat is kept in; the oven is kept thus cloistered a longer or shorter time according to the size of the meat that is dressed. The meat, when taken out, is said to be better dressed than any other way. They use shells for knives; and carve very dexterously with them, always cutting from themselves. One of the principal attendants on Oberea, attempting the use of the knife and fork, could not feed himself therewith; but, by the mere force of habit, his hand came to his mouth, and the virtuals at the end of his fork went away to his ear.

They are quite unacquainted with the method of boiling water, as they have no vessels among them that will bear the fire. Whilst the noble Oberea was one morning at breakfast with Captain Wallis on board the Dolphin, the Surgeon filled the tea-pot by turning the cock of a vase that stood upon the table. One of the lady's attendants observed this practice very attentively, and soon after turning the cock himself, received the water upon his hand; he no sooner felt himself caled, than he roared and danced about in an extravagant manner. The other Indians, unapprialed of the caufe of these emotions, looked gazing at him in amazement, and not without some mixture of terror: but the gentlemen in company, who soon perceived the caufe of the outcry, dispelled the apprehensions of their visitants; and some ointment being applied to the scald, good humour and confidence were again restored. The gunner of the ship, who was appointed comptroller of the market which was established on shore with the natives, used to dine on the first; the astonishment of these people was very great to see him dress his pork and poultry in a pot; at length an old man, who was extremely serviceable in bringing down provisions to be exchanged, was put into possession of an iron pot, and from that time he and his friends ate boiled meat every day. Several iron pots were likewise given to Oberea and some of the chiefs; which in constant use, and drew every body to see them; but although the particulars of two successive voyages of Captain Cook to this island are circumstantially related, we hear no more of this improvement in the culinary art, or of the further assistance which has been rendered these people in supplying them with pots for boiling, but however defirous the natives might be to eat boiled meat, it was not advisable to have such an article of barter as iron kettles, when a few spike nails, or a common hatchet, would procure one of the largest hogs.

Salt water is the usual sauce to their food; those who live near the sea have it furnished as it is wanted, others at a distance keep it in large bamboos. The kernels of the cocoa-nuts furnish them with another sauce: these made into a paste somewhat of the consistence of butter, are beat up with salt water, which has a very strong flavour; but though at first it seemed very nauseous, yet when the taste became familiar, it was much relished.

Their general drink is water, or the milk of the cocoa-nut. They showed in general an aversion to strong liquors; and whenever any one of them happened to drink it freely with any of the ship's company as to be intoxicated, he readily refused to taste any thing that was like to produce the same effect again; but they have a plant which they call ava ava, from the root of which they procure a liquor which has an inebriating quality. Their manner of preparing this strong drink is as simple as it is disgusting to an European. Several of the people take some of the root, and chew it till it is soft and pulpy; they then spit it out into a platter or other vessel, every one into the same: into this general receptacle water is poured according to the quantity prepared. The juice thus diluted, is strained through some fibrous stuff like fine shavings, after which it is fit for drinking, and it is always prepared for present use: it has a peppery taste; drunk flat, and rather inflamed; and though it intoxicates, yet Captain Cook found but one instance where it had that effect, as the natives generally drink it with great moderation, and but little at a time. Sometimes they chew this root as Europeans do tobacco, and sometimes they will eat it wholly.

They eat alone, or at least only in company with a guest that happens to call in; and the men and women never sit down together to a meal: the shade of a spreading tree serves them for a parlour; broad leaves spread in great abundance serve for a table cloth; and if a person of rank, he is attended by a number of servants who feast themselves round him: before he begins his meal, he washes his mouth and hands very clean, and repeats this several times whilst he is eating. The quantity...
quantity of food which these people eat at a meal is prodigious. Captain Cook says, he has seen one man devour two or three fishes as big as a perch; three bread-fruit; each bigger than two fists; 14 or 15 plantains, or bananas, each six or seven inches long and four or five round, and near a quart of the pounded bread-fruit. Men of rank are constantly fed by their women; and one of the chief who dined on board the ships in 1769, showed such reverence to feed himself, that one of the servants was obliged to feed him to prevent his returning without his meal. In one of the excursions which the gentlemen of the ships made into the country in 1773, they arrived at a neat house, where a very fat man, who seemed to be a chief of the district, was lolling on his wooden pillow; before him two servants were preparing his dinner by beating up with water some bread-fruit and bananas in a large wooden bowl, and mixing with it a quantity of fermented four pûte called *mahie*. While this was doing, a woman, who sat down near him, crammed down his throat *mahie* and meat. These people are extremely indolent; and sleeping and eating are almost all that they do. Those that are older are left drowsy, and the boys and girls are kept awake by the natural activity and sprightliness of the age.

Their islanders, who inhabit huts exposed to all the Difcover winds, and hardly cover the earth, which serves them for a bed, with a layer of leaves, are remarkably healthy and vigorous, and live to an old age without enduring any of its infirmities; their senses are acute, and they retain their beautiful teeth to the last. M. de Bougainville describes an old man, whom they saw on their landing, who had no other character of old age, than that respectable one which is imprinted on a fine figure. His head was adorned with white hair, and a long white beard; all his body was nervous and flexible; he had neither wrinkles, nor showed any other tokens of decrepitude. This venerable man seemed displeased at the arrival of these strangers; he even retired without making any return to the courtiers they paid to him; but he gave no signs either of fear, abomination, or curiosity; very far from taking any part in the raptures which the multitude expressed, his thoughtful and melancholy air seemed to indicate, that he feared the arrival of a new race of men would interrupt the happiness he had so long enjoyed. From whence it may be inferred, that his mind was not a whit more impaired than his body. They are, however, several sorts of leprous complaints on this island, which appear in cutaneous eruptions of the scaly kind; some were seen that had ulcers upon different parts of their bodies; yet they seemed little regarded by those who were afflicted with them, and no application whatever was used to them, not so much as to keep off the flies. But instances of them are rare, as the excellency of their climate, and the simplicity of their vegetable food, prevent almost all dangerous and deadly disorders. They are sometimes afflicted with the cholick, and coughs are not unknown among them; and the chiefs, who fare more sumptuously, as a punishment for their voluptuousness, are sometimes attacked with a disorder similar to the gout, in which the legs are swelled and excessively painful. M. de Bougainville's surgeon afflicted him, that he had seen many with marks of the small-pox.

The usual method employed here to restore the sick to health, is by pronouncing a set form of words; after which
which the exercice applies the leaves of the cocoa-tree

}
This they haul in smooth foal water; and its own weight keeps it so close to the ground, that scarcely a single fish can escape. They make harpoons of cane, and point them with hard wood; with which they can strike fish more effectually than an European can with one headed with iron.

The tools used by the Otaheiteans for all their purposes are, an adze made of stone; a chisel or gouge made of bone, generally the bone of a man's arm between the wrist and elbow; a rasp of coral, and the skin of a flying-fish; also coral and sand, as a file or polishing; and with these they fell timber, cleave and polish it, and hew stone. The stone which makes the blade of their adzes is a kind of balafotis, of a grey or blackish colour, not very hard, but of considerable toughness; they are formed of different sizes; some that are intended for felling, weigh from six to eight pounds; others that are used for carving, not more than as many ounces; but it is necessary to sharpen these rude tools almost every minute; for which purpose a cocoa-nut shell full of water and a stone are always at hand.

With such tools they generally take off a thin coat from a whole plank without any aid of tools used by the Otaheiteans for all their purposes are, an adze made of stone; a chisel or gouge made of bone, generally the bone of a man's arm between the wrist and elbow; a rasp of coral, and the skin of a flying-fish; also coral and sand, as a file or polishing; and with these they fell timber, cleave and polish it, and hew stone. They have likewise bows and arrows; but the arrows are good for nothing except to bring down a bird, being headed only with stone, and none of them pointed. They have targets of a semi-circular form, made of wicker-work, and plaited firings of the cocoa-nut fibres, covered with glossy, bluish-green feathers belonging to a kind of pigeon, and ornamented with many flark's-teeth, arranged in three concentric circles.

Their boats or canoes are of three different sorts. Some are made out of a single tree, and hold from two to six men. These are principally employed in fishing; the others are constructed of planks very dexterously sewed together; they are of different sizes, and will hold from 10 to 40 men: they generally falt two of these together, and set up two masts between them; or if they are fingly, they have an on- trigger on one side, and only one mast in the middle; and in these vesfels they will far beyond the fight of land. The third form seems to be principally diges for pleasure or fwell. These are very large, but have no falt; and in shape resemble the gondolas of Venice. The middle is covered with a large awning; and some of the people sit upon it, and some under it. The plank of which these vesfels are constructed, is made by splitting a tree, with the grain, into as many thin pieces as possible. The boards are brought to the thickness of about an inch, and are afterwards fitted to the boat with the fame exactness that might be ex- pected from an expert joiner. To fatten these planks together, holes are bored with a piece of bone, fixed into a ftick for that purpose. Through these holes a Otaheite, kind of plated cordage is paifed, so as to hold the planks strongly together. The seams are caulked with dry rushes; and the whole outside of the vesfels is painted over with a kind of gummy juice, which supplies the place of pitch.

The Otaheiteans are a very indolent people, and friendly in their dispositions; but like all other nations not fully civilized, their passions are extremely violent and they are very fickle. The manner of fting out a man here for a chozen friend is by taking off a part of your clothing and putting it upon him. Their usual manner of expressing their respect to strangers, or to their superiors, at a firft meeting, is by uncovering themselves to the middle. They have a custom of fating those who fneeze, by faying evociseta-tatoua, "May the good eatoua awaken you," or "May not the evil eatoua lull you asleep!

Their propensity to theft is very great, inomuch, that M. Bougainville fays, "even in Europe itself one cannot fee more expert flicbers than the people of this country;" and indeed it is all the voyages made by Captain Cook and others, they had abundant experience of this disposition of the natives, which often produced quarrels, and sometimes even fatal effects. In their behaviour they are extremely licentious, almost beyond credibility. A woman of diffiduction who visited Mr Banks ufed the following ceremony on her firft approach to the stranger. After laying down fveral young plantain-leaves, a man brought a large bundle of cloth; which having opened, he fpread it piece by piece on the ground, in the space between Mr Banks and his ulicants. There were in all nine pieces: having fpread three pieces one upon ano- ther, the lady, came forward, and, lepping upon them, took up her garments all around her to her wait; she then turned three times round, after which the cloth was again rolled up, and delivered to Mr Banks as a prezent from the lady, who with her attending friend came up and falted him. From the unbridled licentioufnefs of these people, the French gave this island the name of the New Cythera. Nay, to fuch a degree do they carry their libidinous excelles, that a number of the principal people, it is related, have formed themselves into a fociety, in which every woman is common to every man. This society is diftinguished by the name of Arrays, the members of which have meetings from which all others are excluded. At these meetings the paddions are excited by a fluided course of festivity, and the coarseft and moft brutal pleasures are enjoyed by the whole company. If, however, notwithstanding these excelles, any of the female members of this community fhould prove with child, unless she can procure some man to adopt the child as his own, not all the ftrong affections of a mother, if fuch are not entirely eradicated by a course of life indulusive of the feelings, as well as the modesty of nature, can save the life of the precondemned innocent; but the child as fon as born is mothered, and the mo- ther is left at liberty to renew her former course of execrable prostitution, Should any man be found to co- operate with a woman in saving the life of a child, they are
Otaheite are both excluded for ever from the array, and are considered as man and wife. The woman from that time is distinguished by the term *encepesh*, the bearer of children; which in this part of the world only is considered as a term of reproach; and so depraved are those people, that being a member of such a society is accounted of as being a privilege, instead of beingigmatized as the foulest crime. The arreoms are those people, that being sometimes made use of. But, above all, he added, that to the society is a privilege, and are greatly enjoyed by several privileges, and are greatly respected throughout the Society Islands, as well as at Otaheite: nay, they claim a great share of honour from the circumstance of being childless. Tupia, one of the most intelligent natives, when he heard that the king of England, had a numerous offspring, declared, that he thought himself much greater, because he belonged to the array. That this society indulge themselves in promiscuous embraces, and that every women is common to every man, is contradicted by Mr Forster. He says, that these arrayos choose their wives and mistresses from among the prostitutes; and from this circumstance, as well as their extreme voluptuosities, they have seldom any reason to dread the intrusion of children. He had the following circumstances related to him by Omai or Omiah, one of the natives, who was brought to England. He said that the pre-emience and advantages which a man enjoyed as arrayo were so valuable as to urge him against his own feelings to destroy his child; that the mother was never willing to consent to the murder; but that her husband and other arrayos perjured her to yield up the child; and that where entreaties were not sufficient, force was sometimes made use of. But, above all, he added, that this action was always perpetrated in secret; infomuch, that not even the *toway* or attendants of the house were present; because, if it were seen, the murderers would be put to death.

Both men and women constantly wash their whole bodies three times a-day in running water, and are remarkably clean in their clothes. They are most expert swimmers, being accustomed to the water from their infancy. Captain Cook relates the following remarkable instance of their expertness. On a part of the shore where a tremendously high surf broke, it was uncertain whether any European boat could live in it, and the best European swimmer he was persuaded would have been drowned, as the shore was covered with pebbles and large stones, yet here were 10 or 12 Indians swimming for their amusement. Whenever a swim broke near them, they dived under it, and rose again on the other side. The stern of an old canoe added much to their sport. This they took out before them, and swam with it as far as the outermost breach; when two or three getting into it, and turning the square end to the breaking wave, were driven in towards the shore with incredible rapidity, sometimes almost to the beach; but generally the wave broke over them before they got half way; in which case they dived, and rose to the other side with the canoe in their hands, and swimming out with it again, were again driven back. This amazing expertness drew the Captain's attention for more than half an hour; during which time none of the swimmers attempted to come ashore, but seemed to enjoy the sport in the highest degree. At another time, one of the officers of the quarter-deck intending to drop a bead into a canoe for a little boy of six years of age, it accidentally missed the boat, and fell into Otaheite; but the child immediately leaped overboard, dived after it, and recovered it. To reward him for this feat, some more beads were dropped to him; which excited a number of men and women to amuse the officers with their amazing feats of agility in the water, and not only fetched up several beads scattered at once, but likewise large nails, which, from their weight, descended quickly to a considerable depth. Some of these people continued a considerable time under water; and the velocity with which they were seen to go down, the water being extremely clear, was very surprising. Here a green branch of a tree is used as an emblem of peace, in exact conformity to the custom of the ancient nations. We shall add an extract here from Captain Cook's last voyage to the Pacific Ocean.

"Nothing could make a stronger impression at first sight, on our arrival here, than the remarkable contrast between the robust make and dark colour of the people of Tongataboo, and a fort of delicacy and whiteness which distinguished the inhabitants of Otaheite. It was even some time before that difference could preponderate in favour of the Otaheiteans; and then only, perhaps, because we became accustomed to them, the marks which had recommended the others began to be forgotten. Their women, however, struck us as superior in every respect; and as possessing all those delicate characters which distinguish them from the other sex in many countries. The beard which the men here wear long, and the hair, which is not cut so short as is the fashion at Tongataboo, made also a great difference; and we could not help supposing that on every occasion they showed a greater degree of timidity and fickleness. The muscular appearance, so common amongst the Friendly Islanders, and which seems a consequence of their being accustomed to much action, is lost here, where the superior fertility of their country enables the inhabitants to lead a more indolent life; and its place is supplied by a plumpness and smoothness of the skin; which though perhaps more consonant with our ideas of beauty, is no real advantage, as it seems attended with a kind of languor in all their motions, not observable in the others. This observation is fully verified in their boxing and wrestling, which may be called little better than the feeble efforts of children, if compared to the vigour with which these exercises are performed at the Friendly Islands.

"Personal endowments being in great esteem amongst them, they have recourse to several methods of improving them, according to their notions of beauty. In particular, it is a practice, especially amongst the arrayos, or unmarried men of some consequence, to undergo a kind of phisical operation to render them fair. This is done by remaining a month or two in the sea; during which time they wear a great quantity of clothes, eat nothing but bread fruit, to which they ascribe a remarkable property in whitening them. They also speck, as if their copulence and colour, at other times, depended upon their food; as they are obliged, from the change of scions, to use different forts at different times.

"The graceful air and firm step with which these people walk are not the least obvious proof of their personal accomplishments. They consider this as a thing
thing so natural, or so necessary to be acquired, that nothing used to excite their laughter sooner, than to see us frequently humming upon the roots of trees, or other inequalities of the ground.

Their countenances very remarkably express the abundant mildness or good nature which they possess, and are entirely free from that savage keneness which marks nations in a barbarous state. One would, indeed, be apt to fancy that they had been bred up under the severest restrictions to acquire an aspect so settled, and such a command of their passions, as well as steadiness in conduct. But they are at the same time frank, cheerful, and good-humoured; though headiness in times, from the friendly reception all strangers have met with openly or clandestinely, who have visited them. Instead of the contrary, like the never appeared in the game they call feejée, or commercial intercourse with the neighbouring islands, they seem to have acquired this knowledge of it by commercial intercourse with the neighbouring islands; but we were afterwards assured, that they had little or no traffic except with Feejee, from which they get the red feathers, and some few other articles which they esteem. Perhaps no nation in the world traffic with more honesty, and less difficulty. We could always fairly permit them to examine our goods, and to hand them about one to another; and they put the same confidence in us. If either party repented of the bargain, the goods were re-exchanged with mutual content and good humour. Upon the whole, they seem possessed of many of the most excellent qualities that adorn the human mind, such as industry, ingenuity, perseverance, affability, and perhaps other virtues which our short stay with them might prevent our observing.

The only defect fully their character, that we know of, is their propensity to thieving, to which we found those of all ages and both sexes addicted, and to an uncommon degree. It should, however, be considered, that this exceptional part of their conduct seemed to exist merely with respect to us; for in their general intercourse with one another, I had reason to be of opinion, that thefts do not happen more frequently (perhaps less so) than in other countries, the dishonest practices of whose worthies individuals are not supposed to authorize any indiscriminate censure on the whole body of the people. Great allowances should be made for the foibles of their poor natives of the Pacific Ocean, whose minds we overpowered with the glare of objects, equally new to them as they were captivating. Stealing, amongst the civilized and enlightened nations of the world, may well be considered as denoting a character deeply stained with moral turpitude, with avarice unrestrained by the known rules of right, and with profligacy producing extreme indignation, and neglecting the means of relieving it. But at the Friendly and other islands which we visited, their thefts so frequently committed by the natives, of what we had brought along with us, may be fairly traced to less culpable motives. They seemed to arise solely from an intense curiosity or desire to possess something which they had not been accustomed to before, and belonging to a sort of people so different from themselves. And perhaps, if it were possible that a set of beings seemingly as superior in our judgment as we are in theirs should appear amongst us, it might be doubted, whether our natural regard to justice would be able to restrain many from falling into the same error. That I have assigned the true motive for their proclivity to this practice, appears from their stealing every thing indiscriminately at first sight, before they could have the least conception of converting their prize to any one useful purpose. But I believe, with us, no person would forfeit his reputation, or expose himself to punishment, without knowing beforehand how to employ the stolen goods. Upon the whole, the pilfering disposition of these islanders, though certainly disagreeable and troublesome to strangers, was the means of affording us some information as to the quickness of their intellects. For their small thefts were committed with much dexterity; and those of greater consequence with a plan or scheme suited to the importance of the objects. An extraordinary instance of the last sort was, in their attempts to carry away one of the Discovery’s anchors at midday.

Their common diet is made up of at least nine-tenths of vegetable food; and I believe more particularly the mastes, or fermented bread-fruit, which makes part almost of every meal, has a remarkable effect upon them, preventing a coltive habit, and producing a very sensible coolness about them, which could not be perceived in us who fed on animal food. And it is, perhaps, owing to this temperate course of life that they have so few diseases among them. See no 8.

They only reckon five or six which might be called chronic, or national disorders; amongst which are the dropsy, and the feisai, or indolent swellings before mentioned, as frequent at Tongataboo. But this was before the arrival of the Europeans; for we have added to this short catalogue a disease which abundantly supplies the place of all the others, and is now almost universal. For this they seem to have no effectual remedy. The priests, indeed, sometimes give them a medley of simples, but they own that it never cures them. And yet they allow that in a few cases nature, without the assistance of a physician, exterminates the poison of this fatal disease, and a perfect recovery is produced. They say, that if a man is infected with it he will often communicate it to others in the same house, by feeding out of the same utensils, or handling them, and that, in this case, they frequently die, while he recovers; though we see no reason why this should happen. See no 9.

Their behaviour on all occasions seems to indicate a great openness and generosity of disposition. Omai, indeed, who, as their countryman, should be supposed rather willing to conceal any of their defects, has often said that they are sometimes cruel in punishing their enemies. According to his representation, they torment them very deliberately; at one time tearing out
Otahitee. small pieces of flesh from different parts; at another taking out the eyes; then cutting off the nose; and lastly, killing them by opening the belly. But this only happens on particular occasions. It cheerfulness argues a conscious innocence, one would suppose, that their life is seldom filled by crimes. This, however, I rather impute to their feelings, which, though lively, seem in no case permanent; for I never saw them in any misfortune labour under the appearance of anxiety after the critical moment was past. Neither does care ever seem to wrinkle their brow. On the contrary, even the approach of death does not appear to alter their usual vivacity. I have seen them when brought to the brink of the grave by disease, and when preparing to go to battle; but in neither case ever observed their countenances overclouded with melancholy or violent reflection. Such a disposition leads them to direct all their aims only to what can give them pleasure and ease. Their amusements all tend to excite and continue their amorous passions; and their songs, of which they are immoderately fond, answer the same purpose. But as a constant succession of sensual enjoyment and delight, they have seldom occasion to call upon the memory of their ancestors or of future events; and their occupations in peace, their travels to other islands and adventures there; and the peculiar beauties, and superior advantages of their own island over the rest, or of different parts of it over other less favourable districts, This marks that they receive great delight from music; and though they rather expressed a dislike to our complicated compositions, yet were they always delighted with the more melodious sounds produced finely on our instruments, as approaching nearer to the simplicity of their own. Neither are they strangers to the soothing effect produced by particular forts of motion, which in some cases seem to allay any perturbation of mind with much success as music. Of this I met with a remarkable instance. For, on walking one day about Mataiavit Point, where our tents were erected, I saw a man paddling in a small canoe so quickly, and looking about with such eagerness on each side, as to command all my attention. At first I imagined this might have been occasioned by his having stolen something from one of the ships, and was pursed; but on waiting patiently saw him repeat his amusements. He went out from the shore till he was near the place where the swell begins to take its rise; and, watching its first motion very attentively, paddled before it with great quickness till he found that it overtook him, and had acquired sufficient force to carry his canoe before it, without passing underneath. He then fat motionless, and was carried along at the same swift rate as the wave, till it landed him upon the shore. Then he started out, emptied his canoe, and went in search of another swell. I could not help concluding, that this man felt the most sublime pleasure, while he was driven on so fast and so smoothly by the sea; especially as, though the tent and ships were so near, he did not seem in the least to envy, or even to take any notice of, the crowds of his countrymen collected to view them as objects which were rare and curious. During my stay, two or three of the natives came up, who seemed to share his felicity, and always called out when there was an appearance of a favourable swell, as he sometimes misfired it, by his back being turned, and looking about for it. By them I understood that this exercise, which is called {chorus}, was frequent amongst them; and they have probably some amusements of this sort, which afford them at least as much pleasure as skating, which is the only one of ours with whose effects I could compare it.

The language of these islanders is soft and melodious: it abounds with vowels, and the pronunciation of it is easily acquired; but it was found exceedingly difficult to teach the natives to pronounce a single English word; probably not only from its abounding with consonants, but from some peculiarity in its structure; for Spanish and Italian words, if ending in a vowel, they pronounced with the greatest ease. A sufficient acquaintance has not been formed with it to determine whether it is copious or not; but it is certainly very imperfect, being totally without inflection either of nouns or verbs. Few of the nouns have more than one case, and few of the verbs more than one tense.

It was impossible to teach the islanders to pronounce the names of their guests. They called Captain Cook {Kote}; Mr. Hicks, the first lieutenant, Heke, &c. and in this manner they formed names for almost every man in the ship. In some, however, it was not easy to find any traces of the original; and they were perhaps not mere arbitrary sounds formed upon the occasion, but significative words in their own language; and it seems that they could perfectly remember these appellations at the distance of four years, by their inquiries after such gentlemen as were absent on the second voyage by name. Mr. Monkhouse, a midshipman, they called {Matar}, which in their language signifies dead; because he commanded a party that killed a man for stealing a musket. The nearest imitation they could reach of king George, was by calling him {Kibi}. We have the following observations on this subject, in vol. ii. of Cook's last voyage, to the Pacific Ocean: "The language of Otahitee, though doubled and mixed with that of New Zealand and the Friendly Islands, is distinct from that guttural pronunciation, and of some consonants, with which those latter dialects abound. The specimens we have already given are sufficient to mark wherein the variation chiefly consists, and to show, that, like the manners of the inhabitants, it has become soft and soothing. During the former voyage, I had collected a copious vocabulary, which enabled me the better to compare this dialect with that of the other islands; and during this voyage I took every opportunity of improving my acquaintance with it, by converting with Omai before we arrived, and by my daily intercourse with the natives while we now remained there (a). It abounds

(a) See this vocabulary at the end of the second volume of Captain Cook's second voyage. Many corrections and additions to it were now made by this indefatigable inquisitor; but the specimens of the language of Otahitee, already in the hands of the public, seem sufficient for every useful purpose.
OTA

abounds with beautiful and figurative expressions, which, were it perfectly known, would I have no doubt put it upon a level with many of the languages that are moat in esteem for their warm and bold images. For instance, the Otaheitians express their notions of death very emphatically, by saying, "that the soul goes into darkness; or rather into night." And, if you seem to entertain any doubt, in asking the question, "if such a person is their mother?" they immediately reply with surprise, "Yes, the mother that bore me." They have one expression that corresponds exactly with the phraseology of the scriptures, where we read of the "yearning of the bowels."—They use it on all occasions, when the passions give them uneasiness, as they constantly refer pain from grief, anxious desire, and other affections, to the bowels, as its seat; where they likewise suppose all operations of the mind are performed. Their language abounds with that inverted arrangement of words which so much distinguishes the Latin and Greek from most of our modern European tongues, whose imperfections require a more orderly construal, to prevent ambiguity.

It is of course, that for the bread-fruit alone, in its different states, they have above 20 names; as many for the taro root; and about 10 for the coconut. Add to this, that, besides the common dialect, they often expatiate in a kind of flowery or poetical, which is answered in the same manner."

A map of Otaheite, engraved for Captain Cook's first voyage, was taken out, and laid before Tuahow the high admiral, without informing him of what it was; however, he immediately found it out, and was overjoyed to see a representation of his own country. He pointed out all the districts of it, naming every one of them in their order.

These people have a remarkable facility in foretelling the weather, particularly the quarter from whence the wind will blow. In their long voyages they steer by the sun in the day, and in the night by the stars; all of which they distinguish by different names, and know in what part of the heavens they will appear in each of the months during which they are visible in their horizon. They also know the times of their annual appearing and disappearing, with more precision than would easily be believed by an European astronomer. Their time they seem to reckon by moons, 13 of which make a year. The day they divide into fix parts, and the night into an equal number. They judge of the time of the day by the height of the sun, but they cannot ascertain the time of the night by the stars. In numeration, the greatest length they can go is 200; that is, when they have counted each of their fingers and toes ten times over. When they take the distance from one place to another, they express it by the time which is required to pass it.

The government of the Otaheitians seems greatly to resemble the early state of the European nations under the feudal system. Their orders of dignity are caree-rabic, which answers to king; caree, baron; manahoumi, vassal; and tewtew, villein. There are two kings in the island, one being the sovereign of each of the peninsulas of which it consists. Each of them is treated with great respect by all ranks, but does not appear to be invested with so much power as is exercised by the carees in their own districts. When the king, whom they called O-Too, made a visit to Captain Cook, the chiefs who happened to be there before him, immediately stripped themselves in great haste. Captain Cook took notice of it; upon which they said caree, caree, signifying, that it was on account of O-Too being present; but this was the only outward token of respect they paid him, for they never rose from their seats, or made any other obeisance.

The caree are lords of one or more of the districts into which each of the peninsulas is divided, and of which there are 43 in the larger one. These parcel out their territories to the manahoumi, who superintend the cultivation of the ground. The lowest class, called tewtew, seem to be nearly under the same circumstances with the villeins in feudal governments. They do all the laborious work, cultivate the land, catch fish, fetch wood and water, &c. Each of the carees keeps a kind of court, and has a great number of attendants, chiefly the younger brothers of their own tribe; and among these some hold particular offices, but of which little more is known than some of their names. In this country a child succeeds to his father's titles and authority as soon as he is born; and thus the king no sooner has a son born, than his sovereignty ceases. A regent is then chosen; and the father generally retains his power under that title, until his child becomes of age. The child of the baron succeeds to the titles and honors of his father as soon as it is born, as well as the son of the king; so that a baron who was yesterdays called caree, and was approached with the ceremony of lowering their garments, so as to uncover the upper part of the body, is to-day, if his wife happens to be delivered of a child, reduced to the rank of a private man; all marks of respect being transferred to the child if it is suffered to live, though the father still continuesполнief for and administrator of his estate. But the acquiescence which the lower class of people, or tewtew, yield to the command of their chiefs, is very remarkable. They are not suffered to taste any animal food, although they are employed in feeding it for their lords. They endure patiently very severe blows, if, when collected into a large body, they in any manner press upon or annoy the king or a chief in his progress; and all this passive spirit is preferred without any power being lodged in the hands of the king to exact it; for he uses no military force, nor is even attended with bodyguards.

There are but few actions which are reckoned crimes among the Otaheitians. Adultery, however, is sometimes punished with death: but in general, the woman escapes with a severe beating, and the gallant parties unnoticced. The regulation of public justice is not confined to the magistrate; for the injured party redresses his own wrong by inflicting whatever punishment he can upon the offender; but in matters of notorious wrong, the chiefs sometimes intercede. The nobility have livery for their servants, and in proportion as the master's rank is more or less elevated, these falles are worn higher or lower, being fastened close under the arms of the servants belonging to the chiefs, and going round the loins of those belonging to the lowest class of nobility. Several parts of the island seem to be private property, which descend to the heir of
The religious language of the Otaheiteans, like that of the Gentoo Bramins, is different from what is used in common discourse; but, according to the accounts we have of their notions concerning the origin of the world, nothing can be more ridiculous. They imagine that the Supreme Deity, besides a great many female descendants, has one son named Tane; and to him they direct their worship, though they do not believe that the good or bad conduct of mankind here on earth makes them more or less acceptable to this divinity. They believe the existence of the soul after death, and of a greater or lesser degree of happiness to be then enjoyed; but they seem to have no conception of a state of punishment or of suffering hereafter. The share of happiness which they imagine every individual will enjoy in this future state, will be alligned to him according to the rank he holds on earth. We are not, however, told wherein they suppose the happiness of this future state to consist; but it is most probably a pretty exact imitation of a Mohammedan paradise, for these voluptuaries can hardly be supposed capable of imagining any pleasure independent of the intercourse of the sexes.

The priesthood seems to be hereditary in one family or tribe; and as it is said to be numerous, probably those of that order are restrained from becoming members of the Army: but whether or not any peculiar decorum is necessary to be observed, hath not yet appeared. Those priests are professedly the men of science; but their knowledge is altogether frivolous and uilees, for it consists in being conversant with the names of their different divinities, and such absurd traditions as have been handed down among them from one generation to another. Their religious notions being deposited in an unknown tongue, they are respected because they are not understood; and as the cure of the soul is no object of regard, the most important concern to these people, the cure of their bodies, is committed to the priests, and milk parade is used in their attempts to recover the sick, though their remedies consist of ridiculous ceremonies and enchantments rather than anything else.

The marriages of these people are merely secular contracts; but no one has a right to perform the operation of circumcising except the priests; and this being a custom universally adopted by the natives, it may be supposed that the performing it is a very lucrative employment. The males in general undergo a kind of circumcision, which is the only public ceremony wherein they suppose the happiness of the future state to consist. But what most establishes the credit of this order of men is their skill in astronomy and navigation.

Captain Cook, who had some reason to believe that, among the religious customs of this people, human sacrifices were sometimes offered up to their deities, went to the morai, or place of worship, accompanied by Captain Furneaux, having with them a tailor who spoke the language tolerably well, and several of the natives. In the morai was a Tupapau, a kind of bier, with a shed erected over it, on which lay a corpse Otaheitean, and some provisions. Captain Cook then asked if the plantain were for the Eatua? If they sacrificed to the Eatua hogs, dogs, fowls, &c. To all of which an intelligent native answered in the affirmative. He then asked if they sacrificed men to the Eatua? He was answered, "Eatua eno, 'bad men they did; first tipuamity, beating them till they were dead." He then asked if good men were put to death in this manner? His answer was no, only Eatua eno. The Captain then asked if any Earees were? The native replied, they had hogs to give the Eatua, and again repeated Eatua eno. He was then asked if towtowas, who had no hogs, dogs, or fowls, but yet were good men, were ever sacrificed to the Eatua? The answer was still no, only bad men. Many other questions were put to him; all his answers to which seemed to confirm the ideas that men for certain crimes were condemned to be sacrificed to the gods, provided they did not poiffe any property which they might give for their redemption. However, in pursing such inquiries as these, no certain information could be obtained, on account of the flight knowledge which had been acquired of the language of the country: but according to further accounts which Captain Cook received from Omai, it seems to reft with the high-priest to single out the victims for sacrifice; who, when the people are assembled on any solemn occasion, retires alone into the house of God, and stays there for some time; when he comes out, he informs the assembly that he has seen and conversed with the great god (the high priest alone having that privilege), and that he has asked for a human sacrifice; and tells them he has desired such a person, naming a man present, who has most probably, on some account or other, rendered himself obnoxious to this ghostly father. The words are no sooner gone out of his mouth, than the devoted wretch is put to death; but his guilt cannot be doubted, after the oracle has pronounced his doom.

On this island was seen the figure of a man constructed of basket-work, rudely made, but not ill designed: it was something more than seven feet high, and rather too bulky in proportion to its height. This wicker skeleton was completely covered with feathers, which were white when it was to appear, and black in the parts which it is their custom to paint or stain, as well upon the head, which was designed to represent hair. Upon the head also were four protruberances; three in front, and one behind, which the Indians called Tate ete, little men. The image was called Manioe; it was a representation of Manioe, one of their Eatuas, or gods of the second class, and was said to be the only one of the kind in Otaheite.

These people pray at sun-rise and sun-set. They have also a number of superstitious practices, in order to conciliate the influence of evil genii. E-Tee, a chief, who seemed to be the king's prime minister in 1774, very seriously asked Mr Forster whether they had a god (Eatua), in their country, and whether they prayed to him (epoor?) When he told them that they acknowledged a Divinity who had made every thing, and was invisible, and that they were accustomed to address their petitions to him, he seemed to be highly pleased, and repeated his words with comments of his own, to several persons who were
Their morais are used both as burying-grounds and places of worship: they are approached with the most wonderful expressions of reverence and humility; and this, it should seem, not because any thing there is esteemed sacred, but because they there worship an invisible being, for whom they entertain the most reverential respect, although not excited by the hope of reward or the dread of punishment. Though they do not appear to have any visible object of worship, yet, says Captain Cook, this island, and indeed the rest that lie near it, have a particular bird, some a heron, and others a kingsfisher, to which they pay a particular regard, and concerning which they have some superstitious notions, respecting good or bad fortune, as we have of the swallow and robin redbreast, and will on no account molest or kill them. One of these cemeteries, or places of worship, was known to Captain Cook, on his first voyage, by the name of Tootahah's moral, then the regent; but when on his second voyage, after the death of that chief, he called it by that name, Maratata, a chief that accompanied the party, interrupted him, intimating, that it was no longer for princes! daily reminding them of mortality. The chief and his wife, on midshipman who had snatched away a stone, were partly inclosed with a sort of inclosure in which their bones are deposited is called macai; these latter as has been already related, are also places of worship. As soon as a native of Otaheite is known to be dead, the house is filled with relations, who deplore their loss; some by loud lamentations, and some by wild clamours, but more genuine expressions of grief. Those who are in the nearest degree of kindred, and are really affected by the event, are silent; the rest are one moment uttering passioned exclamations in a chorus, and the next laughing and talking without the least appearance of concern. In this manner the remainder of the day on which they assemble is spent, and all the succeeding night. On the next morning the body is shrouded in their cloth, and conveyed to the sea-side on a bier, which the bearers support upon their shoulders, attended by the priest, who having prayed over the body, repeats his sentences during the procession. When it arrives at the water's edge, it is set down upon the beach; the priest repeats his prayers, and taking up some of the water in his hands, sprinkles it towards the body, but not upon it. It is then carried back 40 or 50 yards; and soon after brought again to the beach, where the prayers and sprinkling are repeated. It is thus removed backwards and forwards several times; and while these ceremonies have been performing, a house has been built, and a small space of ground railed in. In the centre of this house, or tupaou, as they term it, pots are set up to support the bier, which is at length conveyed thither, and placed upon it; and here the body remains to purify, till the flesh is wholly walked from the bones. These houses of corruption are of a fize proportioned to the rank of the person whose body they are to contain. Those allotted to the lower class are not sufficient to contain the bier, and have no railing round them. The largest that was seen was 30 yards long; and such are ornamented according to the abilities and inclination of the surviving kindred, who never fail to lay a profusion of good cloth about the body, and sometimes almost cover the outside of the house. Garlands of the fruit of the palm-nut, or pandanus, and cocoa-leaves, twisted by the priests in mysterious knots, with a plant called by them ebe no morais, which is parti-
Otaheite, particulars consecrated to funeral solemnities, are deposited about the place; provision and water are also left at a little distance. As soon as the body is deposited in the tapapow, the mourning is renewed. The women assemble, and are led to the door by the nearest relation, who strikes a thark's tooth several times into the crown of her head; the body expiency follows, and is carefully received upon pieces of linen, which are thrown under the bier. The roof of the women follow this example, and the ceremony is repeated at the interval of two or three days, as long as the zeal and sorrow of the parties hold out. The tears also which are shed upon these occasions, are received upon pieces of cloth, and offered as oblations to the dead. Some of the younger people cut off their hair, and that is thrown under the bier with the other offerings. This custom is founded on a notion, that the soul of the deceased, which they believe to exist in a separate state, is hovering about the place where the body is deposited; that it observes the actions of the survivors, and is gratified by such testimonies of their affectionate grief. While these ceremonies are carrying on by the women, the men seem to be wholly inoffensive of their loss; but two or three days after, they also begin to perform a part. The nearest relations take it in turn to assume the dres<s; and perform the offices.

The chief mourner carries in his hand a long flat stick, the edge of which is fet with thark's teeth; and in a frenzy, which his grief is supposed to have inspired, he runs at all the sentences; at the same time weaving the leaves of either clean, are buried, according to the rank of the person, Ids; for prayers are said by the priest, and offerings made at the morai. The chief mourner continues at certain intervals for five moons; but there is not a more ancient custom handed down to us than that of cutting the body to express grief and griefs of mind. In the code of laws delivered by Moses to the Israelites, 1400 years before the Christian era, this practice is expressly forbidden to that people: "Ye shall not cut yourselves, or make any baldness between the eyes for the dead," Deut. xiv. 1. Hence it may be supposed that this rite prevailed in Egypt, from whence the Jews derived most of these propensities which were inherited by their great legislator. We are told likewise in the book of Kings, of the priests of Baal wounding themselves, after they had long waited in vain for the supernational intervention of their idol. D'Arvieux informs us, that the moon- Arabs retain the same custom, and that the part they chiefly wound is their arms. The difference in the practice as now prevailing in O.Tahiti and Arabia seems to be, that in the first none but the women make use of it, and in the latter it is confined to the men, and generally used to express their desperate passion for some favourite mistresses.

The mourning which is worn here is a head-dress of feathers, the colour of which is consecrated to death, and a veil over the face. This dres<s is called *cesa*. The whole nation is said to appear thus on the death of their king. The mourning for fathers is very long. The women mourn for their husbands, but not the husbands for their wives.

We shall conclude this account of Otaheite with the history of *Omai*, or, as he is improperly called *Oo-miab*, who was brought over to England. He was a native of Uleite, or Raitee; and embarked at Hugine with Captain Furneaux, on board the Adventure, in September 1773; and the two ships separating in a florn on the coast of New Zealand a few months afterwards, the voyage of the Adventure was brought to a much earlier conclusion than that of the Resolution, for the arrived at Spithead the 14th of July following. This youth is said to have had some property in his native soil, of which he was dispossessed by the people of Bolabola; but he was not one of the eares, or gentry of that country, but of the middling class of people. He was eminent neither for figure, shape, nor complexion; his colour being of a deep hue, resembling a tow鲜花, or one of the common Vol. XIII. people.
people; and both Captain Cook and Mr Forster agree in thinking him no proper sample of the inhabitants of those islands, in respect of personal beauty. However, they are both of opinion, that the qualities of his heart and head resembled those of his countrymen in general, and that no one of the natives would have given more general satisfaction by his behaviour whilst he remained in England. He is described as possessing a good understanding, quick parts, and honest principles; not an extraordinary genius like Tupia; yet not at all deficient in intelligence, which appears from his knowledge of the game of chess, in which he made an amazing proficiency. His principal patron, whilst in England, were the Earl of Sandwich, Mr Banks, and Doctor Solander. His noble patron introduced him to his Majesty at Kew; and, during his stay in England, he was cared for by many of the principal nobility. He naturally imitated that easy and elegant politeness which is prevalent among the great, and which is one of the ornaments of civilized society. Indeed he adopted the manners, the occupations, and amusements of his companions in general, and gave many proofs of a quick perception and a lively fancy. He appears, however, to have been treated, whilst he resided here, rather as a fashionable exhibition, than as a rational being. No attention seems to have been paid to the enriching his mind with useful knowledge, such as might have rendered him a valuable acquisition to his country on his return thither; no means were used to instruct him in agriculture, or in any mechanical art or useful manufacture; and, above all, to instil into him a moral sense: to teach him the exalted ideas of virtue, and the sublime principles of revealed religion. After having been inoculated for the small pox, he embarked without taking leave of his friends here, his tears flowed for his separation: the moralist, or the divine, it may be useful. The time of his return to England, and his return to the manners, the occupations, or in the foil and appearance of the inhabitants, or in the soil and appearance of the inhabitants, there were then small traces of the chief pile, besides the gardener's lodge, wherein was the silk-worm room raised by King James I. He is now a most magnificent building, and commands a most extensive prospect, which words cannot describe. In the park there was a paddock, where Queen Elizabeth used to shoot with a cross bow. It is now the property of his royal highness the Duke of York, who purchased it for 43,000l. of the duke of Newcastle, 1789.

OIFORD, in England, in the county of Kent, by the Darent, at the bottom of a hill. In 753 there was a battle at this place between the two Saxon kings, Offa of Mercia and Alrick of Kent, who was killed by Offa; and another in 1016, wherein the Danish king Canute was routed by King Edmund Ironside. The said Offa, to avenge the blood he had shed in that battle, gave this place to Christ-church, Canterbury (as the deed says), in poenia parorum, "for the support of the archbishop's hags," and it remained in the archbishop's liberty, till exchanged with King Henry VIII. for other lands. There was a chantry founded at the Ryehouse in this parish. The church was once a chapel to Shereham I.'s queen. It is now in ruins.

OTOHLIEL, in sacred history, the son of Kenaz, of the tribe of Judah. We are told (Jos. xv. 17.), that Othniel was brother to Caleb; and Judges i. 13. it is expressly said, that he was Caleb's younger brother. There are, however, some difficulties in this; for if Caleb and Othniel had been brothers, the latter could not have married his niece Achshah the daughter of Caleb. Secondly, the scripture never assigns to Caleb and Othniel the same father: it always names Kenaz as father to Othniel, and Jephunneh as the father of Caleb. Lastly, Caleb must be much older than Othniel, since he gave Othniel his daughter Achshah in marriage. Thus it seems much better to suppose Kenaz and Jephunneh to be two brothers, and that Othniel and Caleb were cousin germans, and in this sense to be nearly related, or brothers according to the language of scripture. Thus Achshah being but second cousin in respect to Othniel, he might marry her without doing any thing contrary to the letter of the law.

Caleb having received his portion in the mountains of Judah, in the midst of a country that was possessed by giants of the race of Anak, after he had taken the city of Hebron, he advances towards Debir, otherwise called Kirjath-Sepher, and declares that he would give his daughter Achshah in marriage to him that should take Kirjath-Sepher. Othniel took it, and had Achshah to wife.

After the death of Joshua, the Israelites not giving themselves the trouble to exterminate the Canaanites that
Otho, a Roman emperor, born A. D. 32, of a family defended from the ancient kings of Etruria. He was among the number of Nero’s favourites, and accordingly was raised to the highest offices of the state, and made governor of Pannonia by the interest of Seneca, who wished to remove him from Rome, lest Nero’s love for Poppea should prove his ruin. After Nero’s death Otho conciliated the favour of Galba the new emperor; but when he did not gain his point, and when Galba refused to adopt him as his successor, he resolved to make himself absolute, without any regard to the age or dignity of his friend. The great debts which he had contracted encouraged his avarice; and he procured the assassination of Galba, and made himself emperor. He was acknowledged by the senate and the Roman people; but the sudden revolt of Vitellius in Germany rendered his situation very precarious, and it was mutually resolved that their respective right to the empire should be decided by arms. Otho obtained three victories, but in a general engagement near Brixellum his forces were defeated, and he flabb’d himself when all hopes of success had vanished. This happened about the 37th year of his age, after a reign of about three months. It has been justly observed, that the last moments of Otho’s life were those of a philosopher. He comforted his soldiers who lamented his fortune, and he expressed his concern for their safety when they earnestly solicited to pay him the last friendly offices before he flabb’d himself; and he observed, that it was better that one man should die than that all should be involved in ruin on account of his obliquity. His nephew was much favored, and feared exceedingly the anger and haughtiness of the conqueror; but Otho comforted him, and observed, that Vitellius would be kind and affectionate to the friends and relations of Otho, since Otho was not avaricious to pay, that in the time of their greatest enmity the mother of Vitellius had received every friendly treatment from his hands. He also burnt the letters which, by falling into the hands of Vitellius, might provoke his resentment against those who had favoured the cause of an unfortunate general. These noble and humane sentiments in a man who was the associate of Nero’s shameful pleasures, and who had stained his hand in the blood of his master, have appeared to some wonderful, and have palled for the features of policy, and not of a naturally virtuous and benevolent heart. His father was a favourite of Claudius.

Otho, a tribune of the people, who, in Cicero’s confulship, made a regulation to permit the Roman knights at public spectacles to have the 14 first rows after the seats of the senators. This was opposed with virulence by some, but Cicero ably defended it, &c.

Otho (Venius), a very celebrated Dutch painter.

He was descended of a considerable family in Leyden, and was born in 1556. He was carefully educated by his parents in the belles lettres, and at the same time learned to delign of Isaac Nicholas. He was but 15 when the civil wars obliged him to leave his country. He retired to Liege, finished his studies, and there gave the first proofs of the excellence of his mind. He was well known to Cardinal Groofbeck, who gave him letters of recommendation when he went to Rome, where he was entertained by Cardinal Mediccio. His genius was so active, that he applied himself to philosophy, poetry, mathematics, and painting, all at once. He became a great proficient in designing under Frederico Zuchero. He acquired an excellence in all the parts of painting, especially in the knowledge of the claro-obfcur; by which means he came to be accounted one of the most ingenious men of his age. He lived at Rome seven years, during which time he performed several rare pieces; and then passing into Germany, was received into the service of the emperor. After this the duke of Bavaria and the elector of Cologne employed him; but all the advantages he got from the courts of foreign princes could not detain him there. He had a desire to return into the Low Countries, of which Alexander Farnese, prince of Parma, was then governor. He drew the prince’s picture, armed cap-a-pée, which confirmed his reputation in the Netherlands. After the death of that prince, Venius returned to Antwerp, where he adorned the principal churches with his paintings. The archduke Albert, who succeeded the prince of Parma in the government of the Low Countries, sent for him to Brussel, and made him master of the mint; a place which occupied much of his time, yet he found some time for the exercise of his profession. He drew the archduke and the infant Isabella’s portraits at large, which were sent to James I. of Great Britain; and, to show his knowledge of polite learning likewise, he published several treatises, which he embellished with cuts of his own designing. Loui III. made him very great offers to tempt him into his service; but he would never leave his own country, satisfying himself with the character and employments he held there. He was the first, after Polydore Caravaggio, who reduced the claro-obfcur to a principle of the art of painting. Rubens perfected what he began, and the whole Flemish school learned it of him. Venius died at Brussel, 1634, in his 78th year. He had two brothers, Gilbert, who was a graver, and Peter a painter. He had also the honour of breeding up the famous Rubens in his art.

OTTHONNA, in botany: A genus of the polygama necessaria order, belonging to the fyngeena clavis of plants; and in the natural method ranking under the 49th order, Coptogia. The receptacle is naked; there is almost no pappus; the calyx is monophyllous, multifid and nearly cylindrical.

OTHYADES, one of the 300 Spartans who fought against 300 Argives, when those two nations disputed their respective right to Thyreata. Two Argives, Alcinor and Cronius, and Othyades, survived the
the battle. The Argives went home to carry the news of their victory; but Othryades, who had been reckoned among the number of the slain on account of his wounds, recovered himself, and carried some of the spoils of which he had stripped the Argives into the camp of his countrymen; and after he had raised a trophy, and had written with his own blood the word victor on his shield, he killed himself, unable or unwilling to survive the death of his countrymen.

OTIS, in ornithology, a genus of birds belonging to the order of grall. There are four species, principally distinguished by their colour. One of the species, the tord, or bustard, is the largest of the British land-fowl; the male at a medium weighing 25 pounds; there are instances of some very old ones weighing 27: The breadth nine feet; the length near 9 fath. Besides the size and difference of colour, the male is distinguished from the female by a tuft of feathers about five inches long on each side of the lower mandible. Its head and neck are ash-coloured; the back is barred transversely with black and bright rufi colour; the greater quill feathers are black; the belly white; the tail is marked with broad red and black bars, and conflits of twenty feathers: the legs dusky.

The female is about half the size of the male: the crown of the head is of a deep orange, traversed with black lines; the rest of the head is brown. The lower part of the fore-fide of the neck is ash-coloured; in other respects it resembles the male, only the colours of the back and wings are far more dull.

These birds inhabit most of the open counties of the south and east part of this island, from Dorsetshire, as far as the Wolds in Yorkshire. They are exceeding shy, and difficult to be shot; run very fast, and when on the wing can fly, though flawly, many miles without resting. It is said that they take flight with difficulty, and are sometimes run down with greyhounds. They keep near their old haunts, seldom wandering above 20 or 30 miles. Their food is corn and other vegetables, and those large earth-worms that appear in great quantities on the downs before flowering in the summer. These are replete with moisture, and enable them to live long without drinking on those extensive and dry tracts. Besides this, nature hath given the males an admirable quality for their security against drought, being a poult, whose entrance lies immediately under the tongue, and which is capable of holding near seven quarts: and this they probably fill with water, to supply the hen when sitting, or the young before they can fly. Butfards lay only two eggs, of the size of those of a goose, of a pale olive brown, marked with spots of a dark colour; they make no nest, only scrape a hole in the ground. In autumn they are (in Wiltshire) generally found in large tuftip-fields near the downs, and in flocks of 50 or more.

OTLEY, a town of England, in the West Riding of Yorkshire, under a cliff called Chevin, on the south side of the river Wherfe. The adjacent parts are reckoned the most delightful in England. Its church has lately been elegantly fitted up, in which are several good old monuments. The adjacent country is much improved, and from the Chevin is a most beautiful view of an extensive scope of undescribed mansions.

This manor was given by Athelstan to the see of York, where archbishop had a palace here, with several extensive privileges. There is a free grammar-school in this place, founded by M: Cave, 1611, called Prince Rupert's Sch. In 1673, it suffered much by an inundation; which carried away several bridges, mills, &c., as well as much corn, &c.

OTODINI, ancient Britons, seated, as some suppose, to the north east of the bigantes, in the countries now called Northumberland, Merse, and the Lothians. As the Otodini are not mentioned by any of the Roman historians, but only by Ptolemy, it is uncertain whether they formed a distinct independent state, or were united with the bigantes. They were, however, a considerable people, and possessed a long tract of the seacoast, from the river Tyne to the Firth of Forth. Their name is derived by Baxter from the old Britich words Ot a dinu, which signify a high and rocky shore; descriptive enough of their country. They were probably reduced by Agricola at the same time with their more powerful neighbours the bigantes; but as they lived without the wall of Severus, they were, like the rest of the Britons, engaged in frequent revolt. In the most perfect state of the Roman government in this island, the country of the Otodini made a part of the Roman province called Valetia; which comprehended all that large tract between the two walls. As this province was never longer together in the same period of the Romans, they had but few latrii in the country of the Otodini, except those on the line of the wall of Severus.

Various authors have derived the name of this people in various ways, and it is very differently spelled; and various opinions still seem to be entertained among the learned respecting their real situation; and it is even doubtful whether their country was in England or in Scotland. The celebrated Drummond of Hawthornend contends for the latter.

OTRANTO, or TERRA d' OTRANTO, a province of Italy in the kingdom of Naples; bounded on the north by the Terra di Bari and by the gulf of Venice, on the east by the same gulf, and on the south and west by a great bay which is between that and the Basilicata. It is a mountainous country, abounding in figs, olives, and wine. It is often visited by locusts, and by Algerine pirates, who carry off all the people they can catch into slavery. But to keep them off, there are a great many forts on the coasts.

Otranto, a city of Italy, in the kingdom of Naples, and capital of the province of the same name, with a commodious harbour, an archbishop's see, and a strong citadel where the archbishop resides. Mr. Swithinbury gives this account of it: It is (says he) small, stands on a hill, and contains only 3000 inhabitants. Its little harbour is not so bad but it might induce more people to settle here, as no part on the coast lies so convenient for traffic with Greece. The Adriatic gulf is here but 60 miles wide. I climbed to the top of a tower, to get a sight of the Acrocorinian mountains; but a vapour hanging over the sea, along the horizon, hid them from my view; in a clear morning, their snowy tops are said to be very visible. The cathedral of Otranto is Gothic, and, according to the Puglian fashion, has its subterraneous sanctuary. The columns are of beautiful marble and granite; the
the pavement, a rude species of mosaic, commonly called Saracen's: As it is to be met with in all churches founded by the Norman kings of Sicily, the artists who laid it were probably Saracens, or at least Greeks. These mosaics are composed of pieces of porphyry, serpentine, and cubes of gilt glass—dispersed in stars, circles, or chequers. The compartments of the vaults are bordered with them; and the small twisted columns, which support the pulpit and canopies, are ornamented with a spiral stripe of the same work. It is a pity so much durability, compactness, and beauty of materials, should have been lavished on such barbarous designs. Otranto was a Roman colonia, as is certified by an inscription, almost the only monument of antiquity left there (A). In the 10th century it was made an archbishop's see. In 1480, Laurence de Medici, to deliver himself from the attacks of the king of Naples, persuaded Mahomet II. to invade the realm; and Otranto was the unfortunate place where the Turks landed. It was levelled, its ramp, and pillaged. Its prelate was slain at the door of his church; 800 principal citizens dragged out of the gates and butchered; their bodies left 12 months unburied, till the duke of Calabria retook the city, and committed them to hallowed earth. About 100 years after a devout person affirmed, that the bones of St. Bartholomew, which had appeared to him in a dream: and, upon the strenth of his vision, they became, for the vulgar, objects of almost equal veneration with the relics of the primitive martyrs."

Otricoli, a small town of Italy, in the ecclesiastical state, and in the duchy of Spoleto; in E. Long. 13. 15. N. Lat. 42. 25. situated on a rising ground on the frontiers of the patrimony of St. Peter. From this town is seen a fine plain, and some of the windings of the famous river Tiber. The ruins that are scattered here and there at the entrance of the plain, descending from Otricoli, are thought to be the remains of the ancient Otriculum; they consist of some flasheful fragments of columns, cornices, and other pieces of marble. In the middle of the great street of Otricoli, there is a marble pedestal, upon which you see an inscription, showing they had erected a statue to Julia Luilla, who had built public baths at Otricoli at her own expense.

Ott, in cool 37. See Mustela.

Ott of Rome. See Rome.

Otterburn, in England, in the county of Northumberland, near Eleldon. It was the field of battle between the English and Scots in 1388, where Henry Percy, called Hotspur, was taken prisoner, and Douglas the Scotch general was killed. On this battle was founded the delightful old ballad of Chevy-chase; the village being situated by the river Rheid, on the south side of the Chevion hills. The entrenchments are still visible; and a number of tumuli strewed over the adjacent ground mark to future ages the slaughter made there.

Ottery, St. Mary's, a market town in Devonshire, situated 150 miles west of London, and 10 miles east of Exeter. Its market is on Tuesday, and it has two fairs. The church is very ancient, and somewhat resembles a cathedral. A very extensive woollen manufactory was lately established here by Sir Geo. Yonge and Sir J. Du Cane, bart. It has no corporation. It derives its name, as some suppose, from the river Otter, and that from the otters formerly found in it. This town was given by King Edward the Conqueror to the church of St. Mary at Rouen in Normandy, but was afterwards bought by Grandison bishop of Exeter; who made of it a quarter college in 10 Edward III. and therein placed secular priests, with other ministers to whom he gave the whole manor, parson, tithes, fines, spiritual profits, &c., which amounted to £304.2.10 yearly.

OTWAY (Thomas), an eminent tragic poet, was the son of Mr Humphry Otway, rector of Wolbeding in Sussex, and was born at Trottin in that county on the 3d of March 1651. He was educated at Oxford; when, leaving the university without a degree, he retired to London, where he commenced player, but with indifferent success. However, the 'prightness' of his conversation gained him the favour of Charles II. Charles Earl of Plymouth, who procured him a cornet's commission in one of the new-railed regiments sent into Flanders; but he returned from thence in very neccesitous circumstances, and applied himself again to writing for the stage. In comedy he has been deemed too licentious; which, however, was no great objection to his pieces in the profligate days of Charles II. But, in tragedy, few English poets have ever equaled him; and perhaps none ever excelled him in touching the passions, particularly the tender passion. There is generally something familiar and domestic in the fable of his tragedies, and there is amazing energy in his expression.—The heart that does not melt at the divinities of his Orphan must be hard indeed! But though Otway possessed in fo eminent a degree the rare talent of writing to the heart, yet he was not very favourably regarded by some of his contemporaries, nor was he always successful in his dramatic compositions. After experiencing many reverses of fortune in regard to his circumstances, but generally charging the world, he at last died wretchedly in a public house on Tower-hill; whither, it is supposed, he had retired, in order to avoid the pressure of his creditors. Some have said, that down, he hunger compelling him to fall too eagerly on a piece of bread, of which he had been for some time in want, the first mouthful choked him, and instantly put a period to his days. Dr Johnson gives this account of the matter: "He died in a manner which I am unwilling to mention. Having been compelled by his necessities to contract debts, and hunted as is proper, by the terriers of the law, he retired to a public house on Tower-hill, where he died of want; or, as it is related by one of his biographers, by swallowing, after a long fast, a piece of bread which charity had superseded. He went out, as is reported, almost naked, in the rage of hunger, and finding a gentleman in a neighboring coffee-house, asked him for a fil­ling. The gentleman gave him a guinea; and O­

way going away bought a roll, and was choaked with the first mouthful. All this I hope, is not true; but that indulgence, and its concomitants sorrow and desperation, brought him to the grave, has never been denied."

Johnston speaks of him in nearly these terms: "Ow said not much cultivated verification, nor much repleniished his mind with general knowledge. His principal power was in moving the passions, to which Dyrdon in his latter years left an illustrious testimony. He appears, by some of his verbes, to have been a zealous royalist; and had what was in those times the common reward of loyalty; he lived and died louous royalilt; and had what was in those times the nice works are printed in two pocket volumes. He wrote as

Of the ellipsis, being an irregular figure, narrower at one end than at another; whereas the ellipsis, or mathematical oval, is equally broad at each end: though caned e/lipjis. (See ELLIPSIS).

kingdoms have distinguished the germ en or feed-bud, wherein the ova or eggs are formed or lodged. See ANATOMY, containing the rudiments of the future grammar learning, was sent to St John's College. In 1596 he was made regius professor of divinity, when he took the degree of D. D. and about the same time was elected master of Catherine hali. In 1601 he was raised to the deanry of St Paul's London, by the recommendation of his patron Sir Fulke Greville, and Queen Elizabeth; and in the beginning of King James reign, he was chosen pro locutor of the lower house of convocation. In 1612 he was appointed one of the first governors of the Charter-house hospital, then just founded by Thomas Sutton, Esq. In April 1614 he was made bishop of Lichfield and Coventry; and in 1618 he was translated to Norwich, where he died in May 1619, aged, as it is reported, 60 years. He was buried in that cathedral, where he lay unnoticed and forgotten till some time after the reformation of Charles II. when Cofin, bishop of Durham, who had been his secretary, erected a monument in 1669, with a Latin inscription, in which he is said to be, "Vir undequeaque docutlum, etcmi encomio major." Wood observes, that he had the character of being the best scholastic divine in England; and Cofin, who perhaps may be thought to rival him in that sort of learning, calls himself his scholar, and absolutely says that he derived all his knowledge from him. He is also celebrated by Smith for his distinguished wisdom, erudition, and piety. In the controversy which in

town has a very flourishing trade in fine linen and tapestry, and is the capital of a cantilany which contains 53 villages. The French laid siege to it in 1708, which brought on an obdurate engagement, wherein they were defeated by the allies under the command of the duke of Marlborough. It was besieged by the French again in 1744, and taken in a few days; but they restored it at the last general peace.

OUDRI (Jean Baptile), a painter, was born at Paris, and died there May 1, 1755, aged about 74. He acquired the principles of his art under the celebrated Largillieres; and from this master he had those pure principles of colouring which he communicated at a meeting of the academy of painting, of which he was a member, and one of the professors. Oudri's superior talent for painting animals is well known: his compositions of this kind are full of truth, and are admirably handled. The Fables of la Fontaine have been engraved in 4 vols. folio from his etchings; but those who finished them possessed not equal abilities. He painted several hunting-pieces for the king, which adorn some of the royal castles, among others that of La Meute. Oudri was so well acquainted with the magic of his art, that he frequently pleased himself with painting white objects on white grounds; and these pictures have a good effect. He would likewise have succeeded in history-painting, as we may easily infer from several pieces which do him honor.

In grammar learning, was sent to St John's college, Cambridge, and was elected a scholar of that society: but afterwards removing to Trinity, was chosen fellow of that college. In 1596 he was made regius professor of divinity, when he took the degree of D. D. and about the same time was elected master of Catherine hali. In 1601 he was raised to the deanry of St Paul's London, by the recommendation of his patron Sir Fulke Greville, and Queen Elizabeth; and in the beginning of King James reign, he was chosen pro locutor of the lower house of convocation. In 1612 he was appointed one of the first governors of the Charter-house hospital, then just founded by Thomas Sutton, Esq. In April 1614 he was made bishop of Lichfield and Coventry; and in 1618 he was translated to Norwich, where he died in May 1619, aged, as it is reported, 60 years. He was buried in that cathedral, where he lay unnoticed and forgotten till some time after the reformation of Charles II. when Cofin, bishop of Durham, who had been his secretary, erected a monument in 1669, with a Latin inscription, in which he is said to be, "Vir undequeaque docutlum, etcmi encomio major." Wood observes, that he had the character of being the best scholastic divine in England; and Cofin, who perhaps may be thought to rival him in that sort of learning, calls himself his scholar, and absolutely says that he derived all his knowledge from him. He is also celebrated by Smith for his distinguished wisdom, erudition, and piety. In the controversy which in
in his time divided the reformed churches about pre-
definition and grace, he held a middle opinion, inclining perhaps to Armenianism. He seems indeed to have paved the way for the reception of that doctrine in England, where it was generally embraced a few years afterwards, chiefly by the authority and influence of Archbishop Laud. Overall cultivated a particular friendship with Gerard Vossius and Gresius; and was much grieved to see the love of peace, and the projects of that last great man to obtain it, fo ill repaid. He laboured heartily himself to settle the differences in Holland, upon what is known by the name of the Quinquennial conference, as appears in part by his letters to the two learned correspondents just mentioned, some of which are printed in the Epile's praefan-
tiam suraeus, &c.

The bishop is known in England chiefly by his Convocation Book, of which Bishop Burnet gives the following account: "This book was wrote on the subject of government, the divine institution of which was very positively asserted. It was read in convocation, and pulld by that body, in order to the publishing of it; in opposition to the principles laid down in the famous book of Parsons the Jesuit, published under the name of Dokeman. But King James did not like a convocation entering into such a theory of politics; so he discouraged the printing of it, especially since, in order to justify the owning of the United Provinces, who had lately thrown off the Spanish yoke, to be a lawful government, it was laid down, that when a change of government was brought to a thorough settlement, it was then to be owned and submitted to as a work of the providence of God. Here it flept, till Archbishop Sancroft, who had got the book into his own hands, and not observing the last-mentioned passage in it, resolved to publish it in the beginning of King William's reign, as an authentic declaration the church of England had made in the point of non-resistance. Accordingly it was published in 1640, as well as licenced, by him, a very few days before he was under suspicion for not taking the oaths."

OVERBURY (Sir Thomas), a learned and worthy English gentleman, was born in 1581; and studied at Queen's college, Oxford, after which he removed to the Middle-temple, London. He afterwards travelled for some time, and returned a most accomplished person; when he contracted an intimate acquaintance with Sir Robert Carr, knight of the bath, who being soon after taken into his majesty's favour, had Mr Overall knighted at Greenwich. Sir Thomas perceiving the familiarity which subsisted between his patron Carr, now made viscount Rochester, and the lady Frances, the wife of Robert earl of Exeter, was too much displeased at it, that he endeavoured to dissuade him from keeping her company, and from proceeding in the base design he had formed of having her first divorced from her husband, and then marrying her. The viscount, retentive of honest advice, told what he had said to the lady, who was as remarkable for her workmanship as for her beauty; on which they immediately resolved on his destruction. About this time, the king wanting to send an ambassador abroad, the viscount recommended Sir Thomas Overall. His majesty approving the choice, the viscount under the king's intentions to Sir Thomas; but, Overall under a treacherous flow of friendship, diffused him from accepting of that employment, as it might hinder him from a better way of advancement; promising that he would prevent his majesty from being duplipeated at his refutation. The viscount then went to the king, and artfully inciting his majesty against Sir Thomas for refusing to obey his commands, that gentleman was committed to the Tower for his contempt, on the 21st of April 1613, where he continued till he was dispatched by poison on the 15th of September following, and his body was interred in the Tower-chapel the same day. About two years after, the whole contrivance of his death was discovered. On this several persons were condemned and executed; but though Carr, earl of Somerfet, and the lady Frances his countess, were condemned to death for contriving the murder, and hiring the persons who were concerned in it, the king only banished them from court, and afterwards pardoned them. Sir Thomas Overall wrote several poems, &c. and an account of his travels.

His character is represented by an historian of those times; who, after relating the occasion and circumstances of his death, proceeds in the following terms: "In this manner fell Sir Thomas Overall, worthy of a longer life and a better fate; and, if I may compare private men with princes, like Germanicus Caesar, both by poison procured by the malice of a woman, both about the 33d year of their age, and both celebrated for their skill and judgment in poetry, their learning, and their wisdom. Overall was a gentleman of an ancient family, but had such blemishes upon his character, either through a too great ambition, or the insolence of a haughty temper. After the return from his travels, the viscount Rochester embraced him with so entire a friendship, that, exercising by his majesty's special favour the office of secretary provisionally, he not only communicated to Sir Thomas the secrets, but many times gave him the packets and letters unopened, before they had been perused by the king himself; which, as it prevailed too much upon his early years, so as to make him, in the opinion of some, thought high and ambitious; yet he was so far from violating his trust and confidence, that he remains now one example among others who have suffered in their persons or their fortunes for a freedom of advice, which none but sincere friends will give, and which many are such ill friends to themselves as not to receive."

OVEN, a kind of domestic furnace, used for baking bread, pies, tarts, &c. of a circular structure, with a very low roof, well lined, both on the top, bottom, and sides, with flone; it has a small entrance in the front, which is exactly fitted by a kind of door, which being clapped to the mouth of the oven confines the heat, while bread, pies, or puddings are baking. Over this, patry-cooks, &c. have another oven built much in the same manner, which is used for such things as require a less degree of heat. Ovens are heated by burning dry wood, brazier, &c. in them, till all the parts are equally hot.

OVER-HAULING, the act of opening and extending the several parts of a tackle, or other armament of ropes, communicating with blocks or dead eyes. It is used...
Inaugurated to remove those blocks to a sufficient distance from each other, that they may be again placed in a state of action, so as to produce the effect required.

Overture, or Overture, opening or preluding; a term used for the solemnities at the beginning of a public act or ceremony; an opera, tragedy, comedy, concert of music, &c.—The opening of the theatre or scene, is a piece of music usually ending with a fugue: the opening of a jubilee is a general procession, &c.

Oversel, from situation beyond the river Yssel, one of the Seven United Provinces; bounded on the east by the bishopric of Munster, on the north by Frieland and the territory of Groningen, on the west by the river Yssel, and on the south by the county of Zutphen and the bishopric of Munster. It is divided into three distinct parts; which are the territories of Drenze, Twente, and Salland. There are many morasses in this province, and few inhabitants, in comparison of the rest. Its greatest riches confit in turfs; which are dug up here, and sent to the neighbouring provinces, particularly Holland. It extends near 60 miles in length from north to south, and 40 in breadth from east to west. The whole country is low and marshy; but it produces a tolerable quantity of corn. It was formerly a dependence of the bishopric of Utrecht, before Henry of Bavaria, bishop of that see, transferred the sovereignty of it to the emperor Charles V.

Oviedo, in botany: A genus of the angiospermia order, belonging to the didymia class of plants; and in the natural method ranking under the 40th order, Persicaria. The calyx is quinquefoil: the tube of the corolla almost cylindrical above, and very long; the berry globose and diapherous.

Oviedo, a town of Spain, and capital of Asturias d'Oviedo, with a bishop's see, and an university; situated at the confluence of the rivers Ova and Deva, which form the Alta, 50 miles north west of Leon, and 208 north west of Madrid. W. Long. 5. 47. N. Lat. 43° 23'.

Oughtred (William), an eminent mathematician, was born at Eton in 1573, and educated in the school there, whence he was elected to King's-college in Cambridge, of which he afterwards became fellow. Being admitted to holy orders, he left the university about the year 1603, and was presented to the rectory of Aldbury, near Guildford in Surrey; and about the year 1628 was appointed by the earl of Arundel to instruct his son in the mathematics. He kept a correspondence by letters with some of the most eminent scholars of his time, upon mathematical subjects; and the most celebrated mathematicians of that age owed much of their skill to him, while he was full of young gentlemen that came from all parts to receive his instruction. It is said, that, upon hearing the news of the vote at Westminster for the restoration of King Charles II. he expired in a sudden transport of joy, aged 88. He wrote, 1 Caecilia Mathematica; which was afterwards published in English. 2. A description of the double horizontal dial. 3. Opuscula Mathematica; and several other works. He left also behind him a great number of papers upon mathematical subjects, which are now in the museum of William Jones, Esq.

Ovid, or Publius Ovidius Naso, a celebrated Latin poet of the Augustan age, was a Roman knight born at Sulmo, in the 43rd year before the Christian era. He studied rhetoric under Aurelius Pfeus, and for some time frequented the bar. His progress in the study of eloquence was great, but the father's expectations were frustrated; his son was born a poet, and nothing could deter him from pursuuing his natural inclination to write poetry, though he was often reminded that Homer lived and died in the greatest poverty. Every thing he wrote was expressed in poetical numbers, as he himself says, Epistola tertiana furiae verius eva. A lively genius and a fertile imagination soon gained him admirers: the learned became his friends; Virgil, Propertius, Tibullus, and Horace, honoured him with their correspodence, and Augustus patronised him with the most unbounded liberality. These favours, however, were but momentary; for after having obtained the esteem of Augustus, he incurred his displeasure, and was banished to Tomes, a city on the Pontus Euxinus, near the mouth of the Danube, when he was 50 years of age. The true cause of this sudden exile is unknown. Some attribute it to a shameful amour with Livia—the wife of Augustus, while others suppose it to arise from the knowledge which Ovid had of the unpardonable infidelity of the emperor with his daughter Julia. These reasons are indeed merely conjectural; the cause was of a very private and very secret nature, of which Ovid himself is afraid to speak. It was, however, something improper in the family and court of Augustus, as these lines seem to indicate:

Car aliquid vidi? Car voxia lumina secu?
Car imprudente scepsis et haec sepe?

Insensus
Ovid. 0

Ovid. | [ 561 ]
Ovid.

Injuicius Artexae vidit in se Dianam,
Precibus sui canibus non minus ille fuis.

Again,
Infracundum siderum luminis flctor,
Petchanque eali us ef ftabuife neum.

And in another place,
Perdidunt eum me due crimina, carmen & error,
Allerius fragil culpa flienda mibi ef.

In his banishment, Ovid betrayed his pusillanimity in a great degree; and however affected and distrezzed his situation was, yet the flattery and impatience which he showed in his writings are a disgrace to his pen, and lay him more to ridicule than to pity. Though he prostituted his pen and his time to adulation, yet the emperor proved deaf to all intreaties, and refused to listen to his most ardent friends who wished for his return. Ovid, who really wished for a Brutus to deliver Rome of her tyrannical Augustus, still continued his flattery even to meanerfs; and when the emperor died, he was so mercenary as to consecrate a small temple to the departed tyrant on the shore of the Euxine, where he regularly offered frankincense every morning. Tiberius proved as regardles as his predecessor to the intreaties which were made for the poet, and he died in the seventh or eighth year of his banishment, in the 57th year of his age. He was buried at Tomos. In the year 1508 of the Christian era, the following epitaph was discovered at Stain, in the modern kingdom of Austria.

His fuis eij notes quem Dici Cajus ira
Augusti patria sedere tuii buno.
Se saepe voluit patris accumbere terris,
Sed strenfa! Hanc illa fia deeder bosom.

This, however, is an imposition to render celebrated an obscure corner of the world, which never contained the bones of Ovid. The greatest part of his poems are remaining. His Metamorphofofes, in 15 books, are extremely curious, on account of the great variety of mythological facts and traditions which they contain, but they can have no claim to epic honours. In composing this poem he was more indebted to the then existing traditions, and to the theology of the ancients, than the powers of his own imagination. His Fafli were divided into 12 books, like the constellation in the zodiac, but of these fix are lost; and the learned world have reason to lament the loss of a poem which must have thrown so much light upon the religious rites and ceremonies, festivals and sacrifices, of the ancient Romans, as we may judge from the fix that have survived the ravages of time and barbarity. His Trifia, which are divided into five books, contain much elegance and softness of expression; as also his Elegies on different subjefts. The HEROIDES are nervous, spirited, and diffufe; the poetry is excellent, the language varied, but the expressions are often too wanton and indelicate, a fault which is very common with him. His three books Amorvm, and the fame number de Arte Amandi, with the other de Remedia Amoris, are written with peculiar elegance, and contain many flowery descriptions; but the doctrine which they hold forth is dangerous, and they are to be read with caution, as they seem to be calculated to corrupt the heart, and to sap the very foundations of virtue and morality. His Ilis, which is written in imitation of a poem of Callimachus of the fame name, is a fatyrical performance. Besides these, there are extant some fragments of other poems, and among them part of a tragedy called Medea. The talents of Ovid as a dramatic writer have been disputed, and some have remarked, that he who is often void of sentiment was not born to shine as a tragedian. He has attempted, perhaps, too many sorts of poetry at once. On whatever he has written, he has totally exhausted the subject. He everywhere paints nature with a masterly hand, and adds strength even to vulgar expressions. It has been judiciously observed, that his poetry after his banishment from Rome was delibite of that spirit and vivacity which we admire in those which were written before. His Fafli are perhaps the best written of all his poems; and after them we may fairly rank his love verfe, his Heroides, and after all his Metamorphofofes, which were not totally finished when Augustus banished him. His Epifles from Pontus are the language of a weak and fordid flatterer. However critics may have cause to cenfure the indelicacy and inaccuracies of Ovid, it is to be acknowledged that his poetry contains great sweetness and elegance, and, like that of Tibullus, charms the ear and captivates the mind. Another person of the name of Ovid accompanied his friend Caflionius, when banished from Rome by Nero.

OVIDEO (John Gonfalvez de), born at Madrid about the year 1476, was educated among the pages of Ferdinand king of Arragon and Isabella queen of Cadile; and happened to be at Barcelona in 1493, when Christopher Columbus returned from his first voyage to the island Haiti, which he called Hispaniola, and which now goes by the name of St Domingo. He formed an intimate acquaintance with Columbus and his companions, and was at pains to inform himself of every thing relating to the new discoveries. He rendered such essential service to Spain during the war of Naples, that Ferdinand determined to send him to the island of Haiti, as intendant and inspector general of the trade of the New World. The ravages which the venereal disease had made during that war, induced him to inquire into what were the most efficacious remedies for this malady, which was supposed to have come from the West Indies. His inquiries were extended to every thing which regards the natural history of those regions; and, on his return to Spain, he published Sumario de la Historia general y natural de las Indias Ocidentales; which he dedicated to Charles V. He afterwards made some additions to this work, which he published under the title of La Historia general y natural de las Indias Ocidentales; Salamanca, 1535, folio. It was translated into Italian, and afterwards into French; Paris, 1556, folio. In this work, Oviedo says that the French pox is endemical in the island of Haiti, and that it has passed from thence into Europe. He greatly extols the use of the wood of guiacum for the cure of this disease; but whether the disease is now become more obdinate, or the remedy does not possess that efficacy which is ascribed to it, is at present in little estimation.

OVIDILAI, or SEPTA, in ancient Rome, a place in the Campus Martius, at first railed in like a sheep-ten, whence its name. Afterwards it was marked with
OVIPAROUS, a term applied to such animals as bring forth their young from eggs; as birds, insects, &c.

OVIS, the Sheep, in zoology a genus of the mammalia class, and of the order of Pecora; the characters of which are variously interwoven with one another. This, as far as it is yet known, is a clothing peculiar to the sheep kind, no other animal having been seen to possess it. It is not, however, the clothing of all the species of sheep, some that are found in distant nations having short hair like that of the goat.

Linnaeus enumerates three species, which are perhaps only varieties, viz. 1. The ovis alpina, or ram sheep, of which the horns are shaped like a half moon, and compressed. 2. The ovis Guineensis, or Guinea sheep, which has pendulous ears, lax hairy dewlaps, and a prominence on the hind part of the head. The wool is short like that of the goat. It is, as its name imports, a native of Guinea. And 3. The ovis flaccida, or Cretan sheep, which has straight carinated horns, twisted in a spiral manner, and is a native of Mount Iola. According to Mr Pennant, the last two are to be reckoned only varieties.

The sheep, unquestionably a mild and gentle creature, is also represented by Buffon, as the most stupid, defenseless, and timid of all quadrupeds; inasmuch that, without the assistance of man, it could never, he thinks, have subsisted or continued its species in a wild state.

"The female is absolutely devoid of every art and of every mean of defence. The arms of the ram are feeble and awkward. His courage is only a kind of petulance, which is useless to himself, incommodious to his neighbours, and is totally destroyed by castration. The ewe is still more timid than the ram. It is fear alone that makes sheep so frequently assemble in troops; upon the smallest unfruitful noise, they run close together; and these alarms are always accompanied with the greatest stupidity. They know not how to fly from danger, and seem not even to be conscious of the hazard and inconvenience of their situation. Wherever they are, there they remain obstinately fixed; and neither rain nor snow can make them quit their station. To force them to move or to change their route, they must be provided with a chief, who is taught to begin the march; the motions of this chief are followed, step by step, by the rest of the flock. But the chief himself would also continue immoveable, if he were not pushed off by the shepherd, or by his dog, an animal which perpetually watches over their safety, which defends, directs, separates, females, and in a word, communicates to them every movement necessary to their preservation."

"Of all quadrupeds, therefore, sheep are the most stupid, and derive the smallest resources from instinct. The goat, who so greatly resembles the sheep in other respects, is endowed with much more sagacity. He knows how to conduct himself on every emergency; he avoids danger with dexterity, and is easily reconciled to new objects. But the sheep knows neither how to fly nor to attack; however imminent her danger, she comes not to man for assistance willingly as the goat; and, to complete the picture of timidity and want of sentiment, she allows her lamb to be carried off, without attempting to defend it, or showing any marks of resentment. Her grief is not even expressed by any cry different from that of ordinary bleating."

The annotator upon this article in the Edinburgh translation of Buffon, denies the above to be the natural character of the animal. "All tame animals (he observes) loose a portion of that sagacity, dexterity, and courage which they are obliged to employ against their enemies in a wild state; because they have been long accustomed to rely upon the protection of man. Sheep, when enslaved by men, tremble at the voice of the shepherd or his dog. But, on those extensive mountains where they are allowed to range without control, and where they seldom depend on the aid of the shepherd, they assume a very different mode of behaviour. In this situation, a ram or a wedder boldly attacks a single dog, and often comes off victorious. But when the danger is of a more alarming nature, like men, they trust not to the prowess of individuals, but have recourse to the collective strength of the whole flock. On such occasions, they draw up into one compact body; they place the young and the females in the centre; and the strongest males take the foremost ranks, keeping close by each other's sides. Thus an armed front is presented on all quarters, which cannot be attacked without the greatest hazard of destruction. In this manner, they wait, with firmness and intrepidity, the approach of the enemy. Nor does their courage fail them in the moment of attack. For, if the aggressor advances within a few yards of the line, the ram darts upon him with such impetuosity, as lays him dead at their feet, unless he saves himself by flight. Against the attacks of single dogs, or foxes, they are, when in this situation, perfectly secure. Besides, a ram, regardless of danger, often engages a bull, and never fails to conquer him; for the bull, by lowering his head, without being sensible of his defenceless condition, receives between his horns the stroke of the ram, which usually brings him to the ground."

"In the selection of food few animals discover greater sagacity than the sheep; nor does any domestic animal show more dexterity and cunning in its attempts to elude the vigilance of the shepherd, and to feal such delicacies as are agreeable to its palate. When perfectly tame, and rendered domestic, the sporting talents and troublesome tricks of the animal, are too well known to require any description."

As to the accusations contained in the latter part of the character above quoted, every person, it is observed,
In his account of sheep this is literally true, though, for the purpose of supporting a favourite hypothesis, he does mention the argali, or, as he calls it, mouffon; and afferts that it is the parent of all the domestic varieties: but this, in our opinion, only makes his observations in this place more accountable at least, if not inconsiderable. See below note (c).
This animal formerly frequented the regions about the upper Irtyth, and some other parts of Siberia, where it is no longer seen since colonies have been settled in those countries. It is common in the Mongolian, Songarian, and Tartarian mountains, where it enjoys its favourite solitude or liberty. The argali is found likewise on the banks of the Lena, up as high as 60 degrees of north latitude, and propagates its species even in Kamtschatka, as noticed before. The argali is also found in the mountains of Persia, and is said to obtain in the Kuril islands in great size and beauty. It purges itself in the spring, (like all the domestic varieties of the sheep when left at liberty to follow their inclination) with acid plants of the anemonoid kind, till milder plants spring up, and shrubs begin to sprout, which with Alpine plants constitute its usual food. It likewise frequents the salt-marshes which abound everywhere in Siberia; and even licks the salt effluence that rises on the ground, a regimen that fattens them up very quickly, and fully renews the health, vigour, and fleece, they had lost during winter, and during the purging course, which, together with the restorative, is by the Almighty so wonderfully dictated to the sheep species, whether in a wild or tame state, if left to roam at large where the necessary plants are to be found." Here, then, we have a variety of the sheep species, which by some indeed, and by Dr. Pallas among others, is thought to be the parent of all our domestic varieties, and which lives and propagates without any aid from man, and which on all occasions carefully hunts him. That the parent sheep we are not convinced; that being an opinion which requires proof, and better proof than we presume the abettors of it are able to produce.

Having given a figure of this animal (see Plate CCCLXXI.), we shall add the following description of it, taken likewise from the Bee. The argali is about the height of a small hart, but its make is much more robust and nervous. Its form is less elegant than that of the deer, and its neck and legs shorter. The male is larger than the female, and every way fatter. Its head resembles that of a ram, with long straggling hairs about the mouth; but no beard. Its ears are rather smaller than those of a ram. The horns are exactly represented in the plate: they weigh in an adult sometimes 16 pounds. The tail is very short. The summer coat consists of short hair, fleecy, and resembling that of a deer. The winter coat consists of wool like down, mixed with hair every where an inch and an half long at least, concealing at its roots a fine woolly down, generally of a white colour. The colour of its coat was in general of a dark greyish brown, with white tips to the longer hairs, and confluted of hair mixed with wool, of a dark iron grey. + accounts lately received from the Tihutki, the argali is found of a white colour on the continent of America, opposite to their country. It is likewise of a whitish colour at Kamtschatka.

But independent of its manners or its mental qualities, this animal is of the most extensive utility to man. We are clothed by its fleece. The flesh is a delicate and wholesome food. The skin, dressed, forms different parts of our apparel: and is used for covers of books. The entrails properly prepared and twisted, serve for string and musical instruments. The bones calcined (like other bones in general), form materials for tints for the refiner. The milk is thicker than that of cows, and consequently yields a greater quantity of butter and cheese; and in some places is so rich that it will not produce the cheese without a mixture of water to make it part from the whey. The dung is a remarkably rich manure; infomuch that the folding of fleece is become too useful a branch of husbandry for the farmer to neglect. Nature, in short, has given this animal nothing that does not redound to our benefit.

The ram is capable of generation at the age of 18 months; and the ewe can be impregnated when a year old. One ram is sufficient, according to Buffon, for 25 or 30 ewes: they have often been known indeed to beget 100 lambs in a single season. He ought to be large and well proportioned; his head should be thick and strong; his front wide, his eyes black, his nose flat, his neck thick, his body long and tall, his testicles small, and his tail long (b). White is the best colour for a ram. The ewes whole wool is most plentiful, bulky, long, soft, and white, are most proper for breeders, especially when at the same time they are of a large size, have a thick neck, and move nimbly.

In this climate ewes fed in good pastures admit the ram in July or August; but September or October are the months when the greatest part of the ewes, if left to nature, take the ram. They go with young about five months, and generally bring forth but one at a time, though frequently two; in warm climates, they may bring forth twice in a year: But in Britain, France, and most parts of Europe only once. They give milk plentifully for seven or eight months. They live from 10 to 12 years: they are capable of bringing forth as long as they live, when properly managed; but are generally old and useless at the age of seven or eight years. The ram, though he lives 12 or 14 years, becomes unfit for propagating when eight years old.

When

(a) Buffon says, "he should be garnished with horns; for hornless animals, of which there are some in our climates, are less vigorous and less proper for propagating." On this the annotator observes, that "there are many breeds of sheep in which both males and females want horns; yet they are as vigorous as any of the species. The largest and best sheep in England have no horns. In some counties, the inhabitants are perfectly unacquainted with horned sheep; in other places, a sheep without horns is as great a rarity as one with four or six horns."
When the male lambs are not intended to be kept for propagation, but fattened for food, they ought to be castrated at the age of five or six months. This operation is performed in two ways; in the one, an incision is made, and the testicles taken out; in the other, a ligature is tied tight round the scrotum, above the testicles, which soon destroys the vesicles which nourish them. After castration they are called widders.

The ram, ewe, and wether, when one year old, lose the two fore-teeth of the under-jaw; six months afterwards, they lose the two fore-teeth next to these; and at the age of three years, the teeth are all replaced. The age of a ram may likewise be dLife-vered by his horns, which always appear the first year, and frequently as soon as he is brought forth. These horns uniformly acquire an additional ring every year, as long as the creature lives. The ewes commonly have no horns, but a kind of long protuberances in place of them; however, some of them have two and some four horns.

"It has been remarked by the ancients (says Buffon), that all ruminating animals have suet: But this remark, strictly speaking, holds only with regard to the sheep and goat: The suet of the wether is more copious, whiter, drier, firmer, and better, than that of any other animal. Fat or grease is very different from suet; the former being always of any other animal. Fat or grease is very different from suet; the former being always of any other animal. The suet of the sheep is most valued, black or spotted lambs are generally slaughtered. In some places, however, almost all the sheep are black; and black lambs are often purchased by the commixture of white rams with white ewes. In France, there are only white, brown, black, and spotted sheep; but in Spain, there is a reddish kind; and in Scotland there are some of a yellowish colour. But all these varieties of colour are more accidental than those produced by different races; which, however, proceed from the influence of climate, and the difference of nourishment."

Repeeting the varieties, or, as some will have it, the different species of sheep, there has been a great difference of opinion amongst the learned. Buffon, we find, in the above extract, if we understand him right, regards the variety of races in Italy and in Spain as of the same species with our common sheep; but he considers the Barbary sheep as a different species (c). Dr. Pallas, the learned naturalist already quoted, in very

(c) How consistent this opinion is with that which makes the argali the parent sheep, we shall not pretend to determine. This hypothesis he brings forward in the end of the 7th volume of his natural history*, * Edin., and as much of it as concerns the present subject we shall here infer. He concludes from a strain of race. Ed. 1780. oning, strong, and pliable at least, if not absolutely convincing, that "the temperature of the climate, the quality of the food, and the evils produced by flaviery, are the three causes of the changes and degeneration of animals. The effects of each merit a separate examination; and their relations, when viewed in detail, will exhibit a picture of Nature in her present condition, and of what she was before her degradation.

"Let us now compare our pitiful sheep with the mouflon, from whom they derived their origin. The mouflon, which is the same with the argali, is a large animal. He is fleet as a fag, armed with horns and thick hoofs, covered with coarse hair, and dreads neither the inclemency of the sky nor the voracity of the wolf. He not only escapes from his enemies by the swiftness of his course, but he refits them by the strength of his body, and the solidity of the arms with which his head and feet are fortified: How different from our sheep, who subfift with difficulty in flocks, who are unable to defend themselves by their numbers, who cannot endure the cold of our winters without shelter, and who would all perih, if man withdrew his protection? In the warmest climates of Asia and Africa, the mouflon, who is the common parent of;
all the races of this species, appear to be less degenerated than in any other region. Though reduced to a domestic state, he has preferred his stature and his hair; but the size of his horns are diminished. Of all domestic sheep, those of Senegal and India are the largest, and their nature has suffered least degeneration. The sheep of Barbary, Egypt, Arabia, Persia, Culmuck, &c. have undergone greater changes. In relation to man, they are improved in some articles, and vitiated in others: But, with regard to nature, improvement and degeneration are the same thing; for they both imply an alteration of original constitution. Their coarse hair is changed into fine wool. Their tail, loaded with a mass of fat, has acquired a magnitude so incommodious, that the animals trail it with pain. While swollen with superfluous matter, and adorned with a beautiful fleece, their strength, agility, magnitude, and arms, are diminished: These long-tailed sheep are only half the size of the mouflon. They can neither fly from danger, nor reft the enemy. To preserve and multiply the species, they require the constant care and support of man.

The learned Count seems to speak with more certainty upon this subject than the circumstances of the cafe, or the nature of the facts (as yet far from being fully ascertained, or completely authenticated), will admit. The editor of the Bee, who is well known to have devoted much time and attention to this subject, thus ably exposes the futility of those arguments which are brought in support of an hypothesis, which he thinks extremely absurd, or at least premature. "Buffon (says he), who is the least scrupulous of all modern naturalists, has been the most forward to decide in this, as in many other cases. He does not so much as condescend to admit that there can be a doubt in this case; but on all occasions affumes it as a certainty, that all the varieties of one species have been derived from one parent; and boldly raises upon that supposition many practical inferences, which, if his theory should prove to be unfounded, might lead to very important errors; so that it is not a matter of idle curiosity to investigate this question." He then goes on to shew by some particular instances the gross absurdity of Buffon's opinion.

"Were (continues he) these diversities only casual, and apt to vary, it might be more easy for us to give the importance of the facts (as yet far from being fully ascertained, or completely authenticated), will admit. The editor of the Bee, who is well known to have devoted much time and attention to this subject, thus ably exposes the futility of those arguments which are brought in support of an hypothesis, which he thinks extremely absurd, or at least premature. "Buffon (says he), who is the least scrupulous of all modern naturalists, has been the most forward to decide in this, as in many other cases. He does not so much as condescend to admit that there can be a doubt in this case; but on all occasions affumes it as a certainty, that all the varieties of one species have been derived from one parent; and boldly raises upon that supposition many practical inferences, which, if his theory should prove to be unfounded, might lead to very important errors; so that it is not a matter of idle curiosity to investigate this question." He then goes on to shew by some particular instances the gross absurdity of Buffon's opinion.

"Were (continues he) these diversities only casual, and apt to vary, it might be more easy for us to give faith to the hypothesis; but this is not the case. Experience hath fully proved, that any one breed may be kept perfectly uncontaminated for any length of time, with all its distinctive peculiarities entire, merely by preventing an intermixture by copulation. Nor is this all; it is also known, that if such an intermixture be permitted, the descendants will undoubtedly be a mixed breed, evidently participating of the qualities and appearances of both their parents. Between a hound and a greyhound, a mongrel breed is obtained which poiffesses the sene of smelling, though in a lefs degree than the one, and the faculty of fleetness in a lefs degree than the other, of its parents; and its whole external appearance evidently indicates at first sight the compound of the stock whence it has descended. But let a small lap dog and a large mastiff be fed with the same foot and tended with the same care, the one discovers no symptoms of increasing in size or diminishing it more than the other. Let them be carried from one country to another, they equally preserve their original distinctive qualities, without any further change than the climate may perhaps produce; which equally seems to affect all the varieties of this animal. Never was there adopted an hypothesis more truly absurd than that of Buffon in this respect. Nor was there ever made such a barefaced attempt to try how far the credulity of mankind could lead them astray in deference to a great name, in direct contradiction to facts which fall immediately under the cognizance of every man who pleads but to open his eyes, and look right before him, as in those bold and unfounded assertions which he has been pleased to make, with regard to the transformation of dogs from one variety into another. Yet these opinions have been inadvertently transcribed many times by learned naturalists, without one symptom of doubt or hesitation. But can any thing be more contrary to reason, experience, and facts that every man has before his eyes every day in his life, than such opinions? It is indeed humiliating for the pride of man, who plumes himself on the superiority of reason, to remark this. And it is mortifying for modern philosophy, which affects to be founded on experience and accurate observation of facts alone, to point out such things; but truth ought in all cases to be adhered to." Though this note has already extended to an undue length, we cannot omit the following observations by the same patriotic writer: "In regard to sheep, the varieties of this useful class of animals seem to be considerable, and their natural proportions to discriminated as to be admirably calculated for adapting them to different situations on this globe, so as to make them a very universal inhabitant of it: and these are so diversified as to habits and instincts,
education or mode of life, climate, food, and crossing the
breed, have produced in sheepe, in other animals; and, 
in conformity to this opinion he considers, not only
those varieties found in Europe, but also those of other
quarters of the globe, as only accidental varieties of the
same species; and his opinion is confirmed, by find-
ing that they produce a prolific race though the breed be
ever so much crossed; which he thinks would not
be the case were they different species. The var-
ties which Dr Pallas examined, which, as we have
already said, are four, are as follow. The first is
named both by the Tartars and Russians, Tscherkessian
sheep, and by Pallas dolichura or long-tailed: it is the
ovis longicoda of authors.

The second is called the Ruffian sheep by the natives,
and by Pallas brachiu, or short-tailed: it seems to be
the ovis Isländicus of authors, with smaller horns.

The third has no fixed trivial name, as its appella-
tions are as various as the province, where it is reared;
Pallas has called it fleapoyga or fat-tailed: it is the
ovis latiscudata of authors.

The fourth has likewise no fixed trivial name, but
Pallas has called it buchtiarum, from finding it reared by
the Bucharian Tartars in immense flocks. The Tschere-
kessian sheep, or first variety, is a handsome animal,
with a noble air, in its native country and the south of
Rusia, resembling in its habits, horns, fleece, and length
of tail, the Spanish, but more particularly the Eng-
lish sheep. Its head is well proportioned, and of an
elegant form; ears straight; horns large, even, round-
ed in the angles, tapering to a point, and bending in-
wardly towards the back. The rams are feldom with-
out horns, and the ewes have them often bent in a lu-
nar form. The wool, though coarse, is without ad-
mixture of hair, which is perhaps but an accidental
distinction, and promises to be much mellowed by
crossing the breed, and rearing the animal with more
care and skill. It is even known to become much finer
without the assistance of art, merely from the influ-
ence of a temperate climate, as on mount Caucasus. The
tail of the ram is covered with fine long wool, like the
Indian sheep described by Buffon, which trails on the
ground, so as to efface the prints made by the animal’s
feet on sand, and it contains often 20 joints or vertebrae.
In passing from the state of nature to that of servitude, it
seems to have lost its native ferocity, together with its
coarse fleeces. Dr Pallas says it is a mild gentle animal,
and is left degenerated in form from the argali, which,
according to his system, is the parent species, than the
fleapoyga, which on the other hand has preferred
much more of its wildness than the Tscherkessian; per-
haps because it is allowed to range with little restraint
on the wide extended plains of Central Tartary. The
Tscherkessian is reared in all the European regions of
the Ruffian Empire, situated on this side the river Oca,
in the nearer Poland, and by the pastoral people of
mount Caucasus; and they are commonly of a white
colour.

The same variety, we are told by Ruffel, in its natu-
rally history of Aleppo, is reared under the name of
Bodanu, &c. by the Arabs, and in the western parts of
Mauritania, with a trifling difference in the length and
thickness of the tail. There are likewise sheep in Mor-
occo, which belong to this variety, on account of the
different character of it, a long tail, although
otherwise different, in having an ugly look, head cov-
ered entirely with hair, little hanging ears, and re-
markably long wool.

The Indian and Guinea sheep, so well described by
Buffon, resemble the Tscherkessian only in the length
of their tail, whilst in other respects they come nearer
the fleapoyga or fat-tailed sheep of Pallas in size,
form, and fleece mixed with hair. The learned natu-
ralist is of opinion, that these burning defects pro-
duce this change on the wool; but his reasoning in
this head is to us at least as little satisfactory as that by
which he endeavours to prove the argali to be the pa-
rent species. The inhabitants of Ukraine and Padoli
carry on an extensive and valuable traffic with the skins
of Tscherkessian sheep, the beauty of which they height-
en in a very curious manner.

The brachiu, short-tailed, or second variety which
Dr Pallas examined in his travels, is reared through-
out all the north of Ruffia, and resembles that of
Iceland in size, tail, and coarseness of fleece; but
though this be the cafe in these few respects, yet it
differs from it in a very essential character, that of
horns, which are much smaller, and have nothing of
that exuberance which Buffon and others attribute to
the sheep of that island. It resembles the Tscherk-
nessian sheep, in the form of its head, straight upright
ears, and in thickness of fleece; but the quality of the
two fleeces are very different, this variety having
wool almost as coarse as dog’s hair: but the great
distinguishing character between them is the tail,
which is almost a quarter of a yard shorter than that of
the Tscherkessian. The brachiu, or short-tailed
sheep, is reared not only by the northern Ruffians, but
likewise by the Fins and other neighbouring nations.
Some of this variety have been transported into Sibe-
ria, where they have supported themselves on some
paturage, though in poor condition; but through all
the southern countries they are in less estimation than
the long-tailed and fat-tailed varieties, which are much
superior to them for size, fat, and good eating. The
ewe of this short-tailed variety couples readily with
the ram of the fleapoyga or fat-tailed breed, and
produces an animal nobler and larger than its mother,
with a tail swelled at the base with fat, but meagre
towards the end like that of the mixed breed, which,
makes Dr Pallas’s fourth and last variety of domestic
sheep. The ewe also couples clandestinely with the
domestic

as to preferre the principal breeds very distinct, if left to a state of nature. The argali, strong, active,
nimble, delights to live among rocks and inaccessible places; while the large sagglish breed of sheep, such
as those that have been taken into keeping by our countryman Bakewell, could never ascend these fheeps,
but are well calculated to consume the produce of the fertile plains; there is therefore no chance that these
two breeds would ever intermingle, if left entirely to themselves. The late of thes two varieties has indeed
been long domesticated by man, as being utterly incapable of withdrawing itself from his sway, though
the first has been able to preferre its independence till the present hour in some of the mountainous and least
inhabited districts on the globe. He then goes on to mark the leffer distinctions, in which, however, we
cannot follow him.
domestic he-goat, and produces an animal much resembling the mother, but with a fleece of wool and hair. The latter is a fact of the truth of which we have some doubt. The Doctor may easily have been misled, and may have adopted his opinion, merely from the flagggy appearance of the fleece of some breeds of sheep, which much resembles the hair of a goat; but there are found as well in countries where no goats exist, as in those where they abound. The fact has not then, we think, been sufficiently ascertained. This variety supports extremely well the severity of a northern climate; and Dr Pallas doubts not but it might pass the winter in the plains of mountainous northern countries where there is not so much snow; nay, he even thinks it might augment their hardiness and strength, if we are to judge from the habits and treatment of the Iceland flocks, so well described by Anderson in his account of that island.

Dr Pallas remarked, that on mountainous pastures exposed to the sun, such as on the activity of the Ouralic chain, the Russian or short-tailed sheep were larger, fatter, and had a finer fleece.

Crofting the breed with the Tscherkessian or long-tailed sheep likewise mends both the stature and fleece of the brachiiura; whereas, in its own natural state, without admixture of other varieties of sheep, it is but small, lean, and produces, in the northern parts of Russia, a wool so extremely coarse as only to be fit for the cloth of peasants in a state of vassalage.

Whether coarseness of wool and lowness be indeed characteristic marks of this species, is, we think, extremely doubtful; we are rather inclined to consider them as mere accidental differences.

The Doctor’s third variety, or flostopgya, which has a different name in almost every country where it is reared, is both the most abundant and largest breed of sheep in the world. It is reared throughout all the temperate regions of Asia, from the frontiers of Europe to those of China, in the vast plains of Tartary. All the Nomade hordes of Asia, the Turcomans, Kirghiz, Calmucks, and Mongal Tartars, rear it; and indeed it constitutes their chief riches, the number they possess being enormous. The Persians also rear it in abundance; as likewise the Hotentouts, as we are informed by Kolbe in his Travels to the Cape of Good Hope; whilst Olbeck, in his Journey to China, affirms, that the fat-tailed sheep are reared through that whole empire. We are told also by Shaw and the Abbé Domanent, that the same breed obtains in Syria, Maukitania, and the other regions of Asia, under some modifications of form, from different causes; so that Dr Pallas thinks there is sufficient evidence that the flostopgya, or fat-rumped sheep, is the most universally reared and multiplied of any breed in the world. The flocks of all the Tartar hordes resembfe one another by a large yellowish muzzle, the upper jaw often projecting beyond the lower; by long hanging ears; by the horns of the adult ram being large spiral, wrinkled, angular, and bent in a lunar form. The body of the ram, and sometimes of the ewe, swells gradually with fat towards the polleronis; where a solid mass of fat is formed on the rump, and falls over the anus in place of a tail, divided into two hemispheres, which take the form of the hips, with a little button of a tail in the middle, to be felt with the finger.

See a fig. 16, plate CCCLXXI. The uroptigym or fat-rump, which is made up of this oily species of fat, is so very large as to incapacitate the animal in walking; but when the same sheep are carried into the interior parts of Russia, the tail loses half its size and weight, nay sometimes more, from a change in their food and mode of life. This variety, besides the characters mentioned above, have slender legs in proportion to their bodies, a high chief, large hanging testicles, a large prepuce, and tolerably fine wool mixed with hair. Such are the great characteristic marks by which the flocks of all the Tartar hordes resembfe one another; but climate, soil, &c. produce some small difference on this variety, whether reared by the Tartars or the Russians, in the western deserts of Great Tartary, from the river Volga to the Irith, and the Altai chain of mountains. In all that tract of country, the paturage is mostly arid; and it abounds in acrid and liliaceous plants in its own kind, whilst in summer it produces, at least in the open spots where sheep delight to feed, besides gramen, bitter and aromatic plants, artennia, camphorofna, and many species of fallofa, abounding in juices and salts. There is likewise found everywhere an effluence of natron, with sea or glaubers salt; nay, even the waters of the desert contain in general the same salts. Now it is almost unnecessary to inform European shepherds, that such paturage has the effect of augmenting the size of sheep, if it produces no other change upon them; so that we see, in this instance, how some kind of difference may arise amongst sheep of the same breed merely from accidental causes, without the least admixture of heterogeneous blood. This variety changes greatly in size and in other incidental circumstances, according to the method of rearing or of treating them in different places and by different people.

The fourth variety, reared by the Boucharian Tartars and Persians in great numbers, Dr Pallas regards as a mixed breed, araising, as he supposes, from the union of the first and third varieties, that is, of the long and fat-tailed sheep. The Doctor does not think that they ever attain to the size of either of their parents; though, as he never saw any full grown, he does not speak positively upon the subject. The head of this variety is like that of the Kirghiz; but the muzzle is sharper, resembling the Indian of Buffon; the body is rather smaller than that of the Kirghiz sheep; the ears are large and pendant: they have a small uropgyym, like that of the Tartar sheep on the Jenuy, especially when begotten by a Kirghiz ram; but in general they have a tail fat and broad at the base, with a long narrow appendage, which resembles the tail of the Tscherkessian sheep. The Boucharian Tartars have a very valuable traffic with the furs of the lambs of this variety, which are exquisitely fine and beautiful. This same variety is likewise reared in great numbers by the Persians; and it is more than probable, if we are to give credit to authors ancient and modern, that this very variety obtains in Syria, Palærine, and divers countries of Africa, known to them by the name of ovis macrocoeras. It differs in all these countries from the fat-tailed, or flostopgya of Pallas, in having a long tail, fat and broad above, with a long narrow appendage, which is exactly the great
great marked character of the Boucharian breed. Pliny tells us, that the Syrian sheep have long fat tails, and carry wool; and by Ruflf's account of them, in his Natural history of Aleppo, they resemble the Kirgufie sheep in the head, face, and ears hanging on the cheeks; but the tail is that of the Boucharian, fat above, with a long lean appendage. He adds, that they are covered with a soft wool, which is another trait of resemblance with our present variety; and that they weigh sometimes 150 pounds, one third of which is the weight of the tail.

Gefner, in his work on quadrupeds, tells us, that the Arab sheep of Kay have nearly the same characteristic marks, especially with regard to the tail.

Shaw relates in his Travels, that sheep with such a compound tail are common in Mauritania, and in all the East; whilst Kolbe affirms, us, that the sheep which are brought on board the ships at the Cape of Good Hope have tails weighing 25 or 30 pounds, fat above, with a bony appendage hanging from it; and, lastly, the Abbe Demantin, in his new History of Africa, says, that these are found in Africa covered with wool, and with such a tail as we have been describing; whilst at Cape Guardia, in the south of Africa, all the sheep are white, with rather small black heads, otherwise a large handsome breed, with broad fat tails, six or eight inches long.

The Doctor, however, does not entirely close his proofs here; for he quotes several passages from Moses in confirmation of what he has advanced, viz. that the Boucharian sheep obtain in Syria, Palestine, and divers countries of Africa. The passages he quotes are these: Leviticus vii. 25. ix. 19. But whether these verses prove what the Doctor has quoted as a proving, we will not determine.

There are the four varieties which Dr Pallas says and examined in his extensive travels. The account is, we think, curious; to naturalists interesting; and to farmers it may be useful. If it only excite further research and minute inquiry, it will answer some purpose. Indeed, the man of science will not rest satisfied with what our predecessors have permitted us to bring forward, but will recur to the original work of the learned author to whom we are primarily indebted for the above account. We refer such readers, then, to his Spie-lectiona Zoologica, sistulicus undulatus, printed at Berlin in 1776.

It may not be improper to describe the figures of these four varieties. They are all contained in Plate CCC.LXXI. fig. 16 of which is the argali. Fig. 17. is a side and back view; letter A of the ram of the Steppa, or fat-rump variety, in its greatest purity of breed, as obtained among the Kirgufie Tartars in the vast plains of Suthern Tartary. The position of the animal marked with a shows the uropygium or fat rump. Letter b is a representation of the head of the same animal, with a couple of noneola hanging from the neck, called by the Ruffians ears. Letter C is a drawing of another Kirgufie ram with five horns, showing at the same time the hanging position of the ears of this variety. Fig. 18. is a drawing of a degenerate breed of the Steppa variety of sheep, reared on the banks of the Jenify and Volga, without horns, and with the uropygium of fat rump greatly diminished, and one noneola. Letter d (fig. 19.) is a drawing of a ram of the same variety of sheep, from the flocks of the Jenify Kirgufie, with four horns symmetrically arranged by nature, as is frequently the case with this breed.

In a supplement to his article Sheep, Buffon has these words respecting the firepliceros: "I here give Buffon, as figures," says the Count (see Plate CCC.LXXI. above, fig. 14. and 15.) "of a ram and ewe," of which drawings were sent me by the late Mr Colinson, fellow of the Royal Society of London, under the names of the Walachian ram and ewe. As this learned naturalist died soon afterwards, I could not discover whether these sheep, whose horns are extremely different from those of the ordinary kind, be common in Walachia, or whether they are only an accidental variety (b).

In the northern parts of Europe, as Denmark and Norway, the sheep are not good; but, to improve the breed, rams are occasionally imported from England. In the islands adjacent to Norway, the sheep remain in the fields during the whole year; and they become larger and produce finer wool than those which are under the care and direction of men. It is alleged, that those sheep which enjoy perfect liberty always sleep, during the night, on that side of the island from whence the wind is to blow next day. This natural indication of the weather is carefully attended to by the mariners. *

*Ponto.

"The rams, ewes, and wethers of Iceland, differ from the chieflvs from our having larger and thicker horns, and without the pinnas of Norway. Some of them have three, four, and even five horns. But this peculiarity of having more horns than two, must not be considered as common to the whole race of Iceland sheep; for in a flock of four or five hundred, hardly three or four wethers can be found with four or five horns, and these are sent to Copenhagen as rarities. As a further proof of their being scarce, they give a higher price in Iceland than the common kind."

In Spain and the southern parts of Europe, the flocks of sheep are kept in shades or stables during the night; but in Britain, there is now no danger from wolves, they are allowed to remain without, both night and day; which makes the animals more healthy, and their flesh a more wholesome food. Dry and mountainous grounds, where thyme and sheep's fescue grows abound, are the best for the pasturing sheep.

The sheep is subject to many diseases; some arising from insects which deposit their eggs in different parts of the animal; others are caused by their being kept in wet pastures; for as the sheep requires but little drink, it is naturally fond of a dry soil. The dropfy, vertigo (the paro) the Welsh), the phthisis, jaundice, and worms in the liver, annually make great hail..."
voc among our flocks: for the first disease, the sheep
finds a remedy by turning the infected into fields
of broom; which plant has been also found to be very
efficacious in the same disorder among the human
species—The sheep is also infested by different sorts of
insects; like the horne fly, it has its peculiar vexating or gad-
fly, which deposits its eggs above the nose in the fron-
tal parts (see OXVOLO). With this oblong turn into mag-
gots, they become excessively paintful, and cause those
violent agitations that we so often see in the animal in.
The French shepherds make a common practice of
eating the sheep, by trepanning and taking out the
maggot; this practice is sometimes used by the Eng-
lish shepherds, but not always with the same success.
Beside these insects, the sheep is troubled with a kind of
rick and leucop, which magpies and starlings con-
tribute to ease it of, by lighting on its back, and picking
the insects off.

We had intended to have introduced into this article
some observations from Pennant; but it has already
extended beyond its just limits, and we dare not ven-
ture to extend it further. Under the article WOOL,
which is intimately connected with the present, we
may perhaps have an opportunity of introducing some
additional remarks not without importance. At all
events, we trust by that time to be able to give a fa-
favourable report of that truly patriotic society which
has been lately instituted in the northern part of Great
Britain, for promoting the blend of sheep, and in
consequence the nature and quality of the wool. From
the active and indefatigable exertions of Sir John
Sinclair, bart. net, the president of that society, we have
everything to hope from well conducted experiments,
and nothing to fear from groundless hypotheses.

OUNCE, a little weight, the 16th part of a pound
avoirdupois, and the 12th part of a pound Troy. The
word is derived from the Latin, uncia, "the twelfth
part of any whole," called as; particularly in geo-
metrical measures, an inch, or the 12th part of a foot.
See INCH and AS.

OUNCE, in zoology. See FELIS.

OVOLO, or OUM, in architecture, a round mould-
ing, whose profile is sweep, in the Ionic and Compo-
site capitals, is usually a quadrant of a circle; whence
it is also commonly called the quarter-round. It is
usually cut with representations of eggs and arrow-
heads or anchors placed alternately.

OU-POEY-TSE, a name given by the Chinese to a
kind of scale made by certain insects upon the leaves
and branches of the tree called yam-fou-tse. These
scales are much used in dyeing, and the physicians employ
them for curing many distempers. Some of these
scales were brought to Europe, and put into the hands
of the celebrated Mr Geoffroy. After having ex-
amined them with the utmost attention, this learned
academician thought he perceived some conformity in
them to those excreences which grow on the leaves
of the elm, and which the vulgar call elm-bladders; he
found these scales so sharp and altrigenous to the taste,
that he considered them as far superior to every other
species of gall used by the dyers. According to him,
they are the strongest altrignents exiting in the vege-
table kingdom.

It is certain that there is a great affinity between
the ou-poey-tse and the elm-bladders. The form of
both is unequal and irregular; they are covered on the
outside with a short down, which renders them
too to the touch; within they are full of a whitish
grey dust, in which may be observed the dried remains
of small insects, without discovering any aperture thro'
which they might have passed. These nefs or blad-
ders harden as they grow old: and their substance,
which appears refined, brittle and transparent; however,
the Chinese do not consider the ou-poey-tse, notwithstanding their resemblance to elm-
bladders, as excrescences of the tree yam-fou-tse, upon
which they are found. They are perforated, that in-
sects produce a kind of wax, and construct for them-
selves on the branches and leaves of this tree (tie sap
of which is proper for their nourishment) little re-
treats, where they may wait for the time of their me-
tamorphosis, or at least deposit in safety their eggs,
which compose that fine dust with which the ou-poey-
tse are filled. Some of the ou-poey-tse are as large as
one's fit; but these are rare, and are generally pro-
duced by a worm of extraordinary strength, or which
has affiliated with another, as two flilk-worms are joi-
nered, and then seen shut up in the same ball. The smallest
ou-poey-tse are of the size of a chafchet; the greater
part of them are round and o-long; but they seldom
remain one another entirely in their exterior configu-
ration. At first, they are of a dark green colour,
which afterwards changes to yellow, and the hulk,
though pretty firm, becomes then very brittle.

The Chinese peasants collect these ou-poey-tse be-
fore the first hoar frosts. They take care to kill the
worm included in the hulks, and to expose them for
some time to the steam of boiling water. Without
this precaution, the worm might soon break through
its weak prifon, which would immediately burst and
be useless. The ou-p-oey-tse are used at Pekin for
giving paper a durable and deep-black colour; in the
provinces of Kiang-nan and Tche-kiang, where a great
deal of beautiful satin is made, they are employed for
dying the flilk before it is put on the loom. The
Chinese literati also blacken their beards with them
when they become white.

The medicinal properties of the ou-poey-tse are very
numerous. The Chinese physicians introduce them into
the composition of many of their remedies. They
recommend them for stopping bleedings of every kind;
they consider them as an excellent specific for curing
inflammations and ulcers, and for counteracting the
effects of poison; and they employ them with success
in the dropsy, phthisis, epilepsy, cataracts, fick-
ness, fluxions of the eyes and ears, and in many other
disorders.

GREATER OUSE, a river which rises near Fitwell in
Oxfordshire, and proceeds to Buckingham, Stony-Strat-
ford, and Newport, Pagnel, in Buckinghamshire; from
thence it proceeds to Bedford, and turning north-eaft it
passes on to Huntingdon and Ely, till at length it ar-
ives at Lynn-Regis in Norfolk, and falls into the sea.
It is navigable to some distance above Downham, where
there is a good harbour for barges; and a considerable
trade is carried on by it to Lynn and other towns.

Smaller Ouses, rivers in Suffolk, and, separating that
county from Norfolk on the south-west, discharges itself
into the Great Ouse near Downham. There is
still another of the same name which rises in the west-
north
OUT

Outlaw

OUTER, or DISPOSITION, in law, an injury which carries with it the amotion of possession; for by means of it the wrong doer gets into the actual possession of the land or hereditament, and obliges him that hath a right to seek a legal remedy, in order to gain possession, together with damages. This outlaw may either be of the freehold by abatement, intrusion, defeasance, discontinuance, and defeasement; or of chattels real, as an estate by statute merchant, statute-flaple or elogit, or an estate for years.

Outlaw le main, amovere mainum, in law, denotes a liberty of lands out of the king's hands; or a judgment given for him that travailed, or sued, a monian le croit. When it appeared, upon the matter being discussed, that the king had no right or title to the land feized, judgment was given in chancery that the king's t.Beginning was awarded to the escheator, to remove the land, &c. All wardships, liveries, outla"ed, rest is taken away and discharged by statute 12. Ed. III.

OUTSTOUG, a town of the Russian empire, and capital of a province of the same name, with an archbishop's see and a castle; seated on the river Suchan, over-against the mouth of the Jug, in E. Long., 43. 25. N. Lat. 61. 48.

OUTSTOUG, a province of the Russian empire, bounded on the north by Dwina, on the eait by the forest of Zirani, on the south by Wologda, and on the west by Cargopol and Waga. It is divided into two parts by the river Suchana; is full of forests; and the rivers yield plenty of fish, which the inhabitants dry in the sun, and which make their principal nourishment.

OUT POSTS, in a military sense, a body of men posted beyond the grand guard; called out-posts, as being the rounds or limits of the camp.

OUTLAW, signifies one that is deprived of the benefit of the law; and therefore held to be out of the king's protection. Bracton affirms that an outlaw forfeits all he has; and that, from the time of his outlawry, he wears a wolf's head; and any body may kill him with impunity, especially if he defend himself or fly. But in Edward III's time it was reversed by the judges, that it should not be lawful for any man, but the sheriff alone (having sufficient warrant for it), to put to death a man that was outlawed.

OUTLAWRY, the punishment of a person who, being called into law, and lawfully, according to the usual forms, fought, does contemnously refuse to appear. The effect of being outlawed at the suit of another, in a civil cause, is the forfeiture of all the per son's goods and chattels to the king, and the profits of his land, while the outlawry remains in force. If in treason or felony, all the lands and tenements which he has in fee, or for life, and all his goods and chattels, are also forfeited: and besides, the law interprets his absence as a sufficient evidence of guilt; and without requiring farther proof, account the per son guilty of the fact, on which enures corruption of blood, &c. And then, according to Bracton, he may perish without law, &c. However, to avoid inhumanity, no man is intitled to kill him wantonly or wilfully; but in fo doing he is guilty of murder, unless it happens in endeavouring to apprehend him: for any body may arrest an outlaw, either of his own head, or by writ or warrant of capias ultagatum, in order to bring him to execution.

If after outlawry, in civil cases, the defendant publicly appears, he is to be arrested by a writ of capias ultagatum, and committed till the outlawry be reversed: which reversal may be had by the defendant’s appearing in court (and in the king's-bench, by sending an attorney, according to statute 4 and 5 W. and M. cap. 18.), and any plausible circumstance, however trifling, is in general sufficient to reverse it; it being considered only as a process to force appearance. The defendant must, however, pay full costs, and must put the plaintiff in the same condition as if he had appeared before the writ of capias fieri was awarded. It is appointed by magna charta, that no man shall be outlawed, but according to the law of the land. A minor or a woman cannot be outlawed.

In Scotland outlawry anciently took place in the case of refusal to fulfil a civil obligation, as well as in criminal cases. At present, however, it only takes place in the two cases of falling from a criminal profession, and of appearing in court attended by too great a number of followers. But the defender, upon appearing at any distance of time and offering to stand trial, is intitled de jure to have the outlawry reversed, and to be admitted to trial accordingly, and even to bail if the offence be bailable. See WAI.ES.

OVUM ANQUINUM. See AGOINUM.

OUTWORKS, in fortification, all those works made without the ditch of a fortified place, to cover and defend it. See FORTIFICATION.

OUZEL, in ornithology; a species of Motacilla.

OWEN (Thomas), a judge of the common-pleas, son of Richard Owen, Elq of Condovery, in Shropshire, was educated at Oxford, and, as is generally suppos'd, at Chrift-church college. Having taken a degree in arts, he left the university, and entered himself of Lincoln's-inn in London, where in a process of time he became an eminent councellor. In 1583 he was elected Lent reader to that society. In 1592 he was made ferjeant at law, and queen's serjeant soon after. He arrived at length at the dignity of judge of the common-pleas; which office he is said to have executed, during five years, with great abilities and integrity. He died in 1598; and was buried on the south side of the choir in Wellminter abbey, where a monument was erected to his memory. He had the reputation of a learned man, and a patron of literature. He was the author of " Reports in the common-pleas, wherein are many choice cates, most of them thoroughly argued by the learned serjeants, and after argued and resolved by the grave judges of those times, with many cases wherein the difference of the year-books are reconciled and explained." Lond. 1656, folio.

OWEN (Dr John), an eminent and learned difsenting minister, was born in 1616, at Hadham, in Ox fordshire, of which place his father was vicar. He made such surprising proficiency in learning, that at twelve years of age he was admitted into Queen's college, Oxford, and in 1635 was made master of arts; but soon after, disapproving the new regulations made by Archbishop Laud their chancellor, with which he refuted...
O W H

Wood, after cenfuring him in many respects, says
nevertheless, that, "to speak impartially, he was a
person well skilful in the tongues, Rabbinical learning,
and Jewish rites and customs; that he had a great
command of his English pen, and was one of the gen-
teeled and fairer writers who ever appeared against
the church of England.”

O W H Y H E E, the eastermost, and by far the larg-
est, of the Sandwich islands. Its greatest length from
north to south is 254 leagues, its breadth 24, and
its circumference nearly 900 English miles. It is di-
vided to fix large districts; two of which on the north-
east side are separated by a mountain, that rises in
three peaks, which is perpetually covered with snow,
and may be seen clearly at 40 leagues distance. To
the north of this mountain, the coast consists of high
and steep cliffs, down which fall many beautiful cal-
cades of water. The whole country is covered with
coa nut and bread-fruit trees. The peaks of the
mountain on the north-east side appear to be about
1/2 a mile in height, and entirely covered with snow.
To the south of this mountain, the coast presents a
prof. a of the most dreary kind, the whole country
appearing to have undergone a total change by means of
the dreadful convulsion. The island is every
where covered with cinders, and intersected in many
places with black streams, which seem to mark the
course of a lava that has flowed not many ages since
from the mountain to the sea. The southern pro-
monitory looks like the mere dregs of a volcano.
The projecting headland is composed of broken and
craggy rock, piled irregularly upon one another, and
terminating in sharp points; yet amidst these ruins,
there are many pieces of rich soil, which are carefully
laid out in plantations, and the neighbouring sea affords
a vast variety of excellent fish; so that this quarter is
much better inhabited than those which are more ver-
dant. The fields are inclosed with stone fences, and
are interspersed with groves of cocoa nut trees. We
are told indeed by some of Cook’s people who walked
through a considerable part of it, that they did not
observe a spot of ground that was susceptible of im-
provement yet unplanted; and indeed the country,
from their account, could scarcely be cultivated to
greater advantage for the purposes of the natives.
They were surprized at finding several fields of hay;
and upon their inquiry, to what particular use it was
applied, they were informed, that it was intended to
cover the grounds where the young taro grew, in or-
der to preserve them from being scorched by the rays
of the sun. They observed among the plantations a
few huts scattered about which afforded a seasonal
shelter to the labourers; but they did not see any vil-
lages at a greater distance from the coast than five
miles. Near one of them, which was situated
about four miles from the bay, they discovered a cave,
four fathoms in length, three in breadth, and six in
the same height. It was open at each end; its sides
were fluted as if wrought with a chisel; and the surf.
ce was glazed over, perhaps by the action of fire.
There are surmised to be on this island about 150,000 in-
habitants. So long as the name of Captain Cook shall
be
Owhyhee — [ 573 ]

be remembered, this island will not be forgotten; for he here fell a victim to a strange concatenation of events. See Cook.

We have the following account of the inhabitants of this island in Ellis's Authentic Narrative, &c. "The men are above the middle size, flour, well made, and belty, but not fat. Corpulence is not altogether fo great a mark of distinction in these as in the Society Isles; and in fact, for which the Owhyheans have great partiality, is also overlooked. Their colour is in general brown olive. The hair both of the head and beard is black; that of the head the men wear in the form of a helmet, that is, a long frizzled ridge from the forehead to the neck, the sides being much flouter. This fashioned seems to prevail only among the principal people, that of the inferior sort being of an equal length in every part. Most of them were very defirous of parting with their beards, which, they said, were disagreeable and troublesome, and were fond of being shaved by our people. Some of the priest wore their beards long, and would not on any account part with them. The women wear their hair long before, but very short behind, which is not the moft becoming mode; and, like those of the Friendly Isles, they have a way of rendering it of different colours, red, yellow, and brown. The features of both sexes are good, and we saw some of the females who might really be called fine women. Their teeth are even and perfectly white. In general, they seem to be very healthy, and we observed several of them who appeared to be of great age. As to disease, we saw none who laboured under any during our stay except the venereal complaint; coughs and colds indeed were pretty general, and one man died. From what we could learn of his disorder from the natives, it was a violent griping or colic.

"Both men and women appeared to be of a good disposition, and behaved to each other with the tenderest regard; when they did fall out, which sometimes was the case, occasioned by the upsetting of a canoe, or some such trifling accident, they only fellcd a little, and this was soon over and forgotten. We never saw them strike each other upon any occasion. They are all thieves, from the aee to the towow, but not quite so expert at it as our Owhyhee friends.

"The custom of tattooing prevails greatly among these people, but the men have a much larger share of it than the women: many (particularly some of the natives of Moorea) have one half their body, from head to foot, marked in this manner, which gives them a most striking appearance. It is done with great regularity, and looks remarkably neat: some have only an arm marked in this manner, others a leg; some again have both arm and leg, and others only the hand. The women are the full part marked upon the hand, and some upon the tip of their tongue; but of these we saw but few. Both sexes have a particular mark according to the old law in which they live; or it is rather the mark of the men, or principal man, under whose jurisdiction they may immediately be. We never saw the operation of tattooing performed, or could procure a sight of the instruments used upon this occasion; but it is likely they are much the same Owhyhee, as those of the Friendly and Society Isles.

"Both men and women are very cleanly in their persons; the latter wash their whole bodies in fresh water twice and sometimes three times a day; but the women of Owhyhee have the advantage of them in one point of cleanliness, which is eradicating the hairs from under the arm-pits. This is a custom we observed nowhere but at the Society Isles.

"There are no people in the world who indulge themselves more in their sensual appetite than these: in fact, they carry it to a most scandalous and shameful degree, and in a manner not proper to be mentioned. The ladies are very extravagant in their favours; but are far from being mercenary as those of the Friendly or Society Isles, and some of their attachments seemed purely the effect of affection. They are initiated into this way of life at a very early period; we saw some who could not be more than ten years old.

"Their clothing consists of cloth of different kinds: that worn by the men, which is called marro, is about half a yard wide, and four yards long; that of the women, three quarters of a yard wide, and of the same length as the men: this they call paho'ouwa; they both wear it round their middle, but the men pass it between their legs. This is the general dress of both sexes; but the better sort sometimes throw a large piece loosely over their shoulders. Besides the marro, they have several other kinds of cloth, which derive their names either from the different uses they are applied to, or their different texture and pattern; all, however, as far as we could learn, are made from the Chinese paper mulberry tree. The principal of these is the cappa, which is about 10 or 12 feet long, and nearly as many wide, and is thick and warm; they wrap themselves up in this when they retire to sleep. They have another kind, which is white, and much thinner; this, as has been before observed, they throw loosely over their shoulders; it is sometimes 20 or 30 yards long, and wide in proportion. The marro and paho'ouwa are curiously painted of various patterns, but the others are generally white, or dyed red, black, and yellow.

"The principal ornaments of the men are the feather-caps and cloaks; some of the latter reach down to their heels, and have a most magnificent appearance. They are made for the most part of red and yellow feathers, which are tied upon fine net-work. The caps are composed of the same kind of feathers, which are sometimes intermixed with black; they are secured upon a kind of basket-work, made in the form of a helmet. Both caps and cloaks are made of various patterns and fizes. The cloaks are not all composed of the same kind of feathers, but are sometimes varied with the long tail-feathers of the cock, with a border of yellow or red, and sometimes with those of the tropic bird. Both caps and cloaks, however, are only to be seen in the possession of the principal people. They have also a kind of fly flapp, made of a bunch of feathers fixed to the end of a thin piece of smooth and polished wood: they are generally made of the tail-feathers of the cock, but the better sort of people have them of the tropic birds feathers, or those belonging
The handle is very frequently made of one of the bones of the arm or leg of those whom they have killed in battle, curiously inlaid with tortoise-shell: these they deem very valuable, and will not part with them under a great price. This ornament is common to the women of both sexes. The women too have their share in the ornamental way; that which they value most is the oriel. This is a kind of ruff or necklace, made of red, green, black, and yellow feathers, curiously put together, and in most elegant patterns, which really do honour to the fancy of the ladies, whose business it is to make them. They never think themselves drest without one or two of these round their necks, and those who can afford it wear many. Others again are composed of small variegated shells, disposed in a very neat manner; and some consist of several rows of twisted hair, with a piece of carved wood or bone, highly polished, the bottom part forming a curve. The higher the quality of the wearer, the greater is the size of the wood or bone, and the quantity of the twisted hair. The next thing is the poer-nerah or bracelet; the most valuable are made of boar's tusks fastened together side by side with a piece of string, by means of a hole drilled through the middle; the larger the tusks, the greater the value. Sometimes two shells tied round the wrists with twisted or braided hair, serve the purpose of bracelets; but even in this case they show great nicety, being particularly careful to match them as near as possible. They were prodigiously fond of those we made of one of the bones of a young sheep, and at the sides of hedges in many parts of Britain, and is but seldom admitted into gardens. The roots are composed of many scaly joints, which propagate in great plenty. The leaves arise immediately from the roots upon single long foot-stalks, and are composed of three heart-shaped lobes. They are greatly acid, and of use in the febrile and other putrid disorders.

Oxford, the capital of a county of the same name in England, celebrated for its university, and pleasantly situated in a plain, with a fine fruitful country all around. The composition of the name is obvious. In the British times it seems to have been a place of study. The wisdom of our ancients (says Camden), as appears in our history, consecrated even in the British times this city to the muses, translating them from Greekland (now a small town in Wilts) hither, as to a more fruitful nursery. For Alexander Nechem, De Nat. writes, Italy claims superior knowledge of civil law; but the study of divinity and the liberal arts prove, that the university of Paris deserves the preference of all others. Agreeable also to Merlin's prophecy, Wil­dom has flourished at the Ford of Orien, and will in its due time pass over into Ireland. But in the following Saxon age, when so many critics were destroyed, it underwent the common fate, and for a long while was famous only for the relics of Frisefide, who was ranked among the sants for her holy life, merely because she had solemly devoted herself to God; and prince Algar, soliciting her in marriage, was miraculously, as they say, deprived of his eyesight.

Perhaps the following additional extract from Cam­den will be more to the purpose in developing the ancient state of learning in this city, than any thing which we could bring forward of our own. When the storm of the Danish war was over, the most religious prince Alfred restored their retreat to the long­exiled muses, by founding three colleges, one for grammarians, another for philosophy, and a third for divinity. This will be more fully explained by the following passage in the old annals of the New Monastery at Winchelsea. In the year of our Lord 866, the second year of the arrival of St Grymbold in England, the university of Oxford was begun; the first who presided and read divinity lectures in it being St Neoth, an abbot and able divine; and St Grymbold, a most eminent professor of the incomparable sweetness of the sacred pages; After the monk, an excellent scholar, professing grammar and rhetoric; John monk of the church of St David giving lectures in logic, music, and arithmetic; and John the monk, colleague of St Grimbold, a man of great parts, and a universal scholar, teaching geometry and astronomy before the most glo­
Glorious and invincible King Alfred, whose memory will dwell like honey in the mouths of all.” Soon after, as we find in an excellent MS. of the said Alfæ, who was at that time professor here, broke out a sharp and fatal quarrel between Grymbold and those very learned men whom he had brought thither with him, and the old scholars whom he found there, who, on his coming, unanimously refused to receive the rules, methods, and forms of lecturing, that Grymbold introduced. Three years had passed without any great difference between them; but the secret averion afterwards broke out with the utmost violence. In order to quell it, the invincible King Alfred, as soon as he heard of it by the messages and complaints from Grymbold, went in person to Oxford to put an end to the dispute, and he took the greatest pains to hear the cauæs and complaints on both sides. The foundation of the difference was this: The old scholars maintained, that before Grymbold came to Oxford learning had flourished there, though the scholars at that time were fewer than in more ancient times, the greater part being driven out by the cruelty and oppression of the Pagans. They also proved and shewed, and that by the undeniable testimony of ancient chronicles, that the ordinances and regulations of the place were established by certain religious and learned men, such as Oddæ, Melkinus, Ninnius, Kentigern, and others, who had all lived to a good old age in these studies, having settled matters there in peace and harmony; and also that St Germanus came to Oxford, and laid there half a year in his journey over Britain to preach against the Palagian heresies, and wonderfully approved their plan and institution. The king, with unheard-of condescension, gave both parties attentive hearing, and repeated his pious andearable advice to maintain mutual union and concord, and left them with the prospect that both parties would follow his advice and embrace his institutions. But Grymbold, offended at this proceeding, immediately retired to the monastery at Winchester lately funded by King Alfred. He also caused his tomb to be removed to Winchester, in which he had intended to lay his bones when his course of life was ended, in the vault under the chancel of St Peter’s church at Oxford, which church himself had built from the ground of stone polluted in the most costly manner:"

“This happy restoration of learning was followed in a few years by various calamities. The Danes in the reign of Edward plundered and burnt the place; and soon after Harold Hardfoot prattled the most inhuman barbarities here in revenge for some of his men who were killed in an affray; so that the most melancholy remove of the students ensued, and the university remained almost extinct, a lamentable spectacle till the time of William the Norman. Some have falsely supposed this prince took the city, mistress’d by a wrong reading in some copies of Oxonia for Eosonia. At that time, however, it was the seat of an university, as we learn from these words of Ingulphus, who lived at that time. ‘I Ingulphus settled first at Westminster, was afterwards sent to study at Oxford, having made greater proficiency than many of my own age in Artifox, &c.’ What we call an university, they in that age called a study.” Many are of opinion that it was deserted till about the year 1298, and that this defection was in consequence of its having been beleaguered and taken by William the Conqueror. About this year, however, Robert Palen began to read lectures in divinity, or as it is expressed in the Chronicle of Oxeney abbey) the Holy Scriptures, which had fallen into neglect in England; and such was the resort of students to it, that in the reign of King John there were not fewer than 3000. Robert d’Oilly, a Norman, to whom William the Conqueror had given the greatest part of it, built a college on the west side in 1703; and he is also supposed to have surrounded it with walls. In a palace built by Henry I. was born Richard I. commonly called curd de Lion. About the time of King John, there happened a quarrel between the citizens and students; in consequence of which many of the latter quitted it, but returned again in a few years afterwards. Here Henry III. held a parliament to settle the differences between him and his barons; when he confirmed the privileges granted to the university by his predecessors, and added others of his own. In this reign the students are said to have been 30,000, who were all excommunicated by the pope for some rudeness to his legate. In the time of Duns Scotus, we are told that 30,000 scholars attended his lectures. Matthew Paris makes the university of Oxford, ‘the second school of the church after Paris, and the very foundation of the church.’ The popes had also been this honoured it with the title of University, which they had conferred by their degrees on no other but that of Paris, this of Oxford, and those of Bologna and Salamanca. It was decreed by the council of Vienne, that ‘schools for the study of the Hebrew, Arabic, and Chaldæan languages, should be erected in the studies of Paris, Oxford, Bologna, and Salamanca (as the most considerable), that the knowledge of these languages might prevail by their being thus taught; and that Catholic prelates be chosen, sufficiently versed therein, two in each language. For though in Oxford, the bishops, monasteries, chapters, convents, colleges, exempt and not exempt; and the rectors of churches thro’out England, Scotland, Ireland, and Wales, were to provide a competent maintenance.’ In Edw. III. the time, the scholars were split into two factions, called the northern and southern men; in a division which was attended with much disorder and much violence, but in a short time concord and harmony again prevailed. As colleges began about this time to be founded and endowed, we shall here present our readers with a list of them, together with the time when, and the persons by whom, they were founded.

Oxford.  

**Colleges.**

- Corpus-Church.  
  - Richard Fox, bishop of Winchester, and lord privy seal.  
  - Henry VIII. and Cardinal Wolsey.

- Christ Church.  
  - Sir Thomas Pope.  
  - Sir Thomas White, merchant of London.  
  - James I.

- Trinity.  
  - Sir Richard Whitwell.

- St. John's.  
  - Thomas Tindal, Esq.; and Dr. James I.

- Pembroke.  
  - Sir Richard Whitwell.

- Wadham.  
  - Nicholas and Dorothy Wadham.  
  - James I.

- Oriel.  
  - Thomas Tindal, Esq.; and Dr. James I.

- New College.  
  - Sir Richard Coke, and made college.  
  - New College, 1740, that it was erected into a college by Dr. Richard Newton.

**Hartford.**  

- Hart Hall till 1740, that it was erected into a college by Dr. Richard Newton.

All these are richly endowed, and have fine gardens, libraries, chapels, &c. The halls in which the students maintain themselves, except a few that have exhibitions, are these: St. Edmund's, belonging to Queen's college; Magdalen, to Magdalen college; St. Alba's to Merton; St. Mary's to Oriel; New Inn, to New college. Several persons have been great benefactors to particular colleges, as Dr. Ratcliffe to University college; Colonel Codrington and Dr. Clarke, to All-souls; Queen Caroline, to Queen's; the bequest of Dr. Clarke and Mrs. Eaton, to Worcester; Dr. Wake, archbishop of Canterbury, to Christ-church. The most considerable of these colleges are Magdalen's and Christ-church, which are as noble foundations as any in the world. The church of the latter is the cathedral, and has a dean, eight canons, eight chaplains, eight singing men, eight choristers, a teacher of music, and an organist. Each of the colleges has its visitor appointed by its statutes, except Christ-church, which is subject to the visitation of the Sovereign alone. The other remarkable buildings belonging to the university are, first, the public schools; secondly, the Bodleian or public library; thirde, Ratcliffe's library, a model of elegance and beauty, for building and furnishing which, Dr. Ratcliffe left 40,000l.; fourthly, the theatre, built by Sheldon, archbishop of Canterbury; fifthly, the museum, in which is an elaborately and a repository for natural and artificial rarities and antiquities; sixthly, the Clarendon printing house, so called because it was built partly with the money arising to the university by the sale of Lord Clarendon's history. To the south of Magdalen college lies the physic garden, instituted by the Earl of Danby, and much improved by Dr. Sherrard. It contains five acres, in which is a complete series of such plants as grow naturally, disposed in their respective climes; together with two neat and convenient green-houses, stocked with a valuable collection of exotics, and a hot-house, where various plants brought from the warmer climates are raised. The whole body of the university, including professors, fellows, and students of all sorts, exceeds 5000. Each college has its particular statutes and rules for government. There are four terms in the year for public exercises, &c., and particular days and hours for public lectures by the several professors. The university is governed by a chancellor, high steward, vice-chancellor, two proctors; a public orator (see Public Orator); a keeper of the archives, a regent, three esquire-beadles, and three yeoman-beadles. As to the city, it has had the same privileges granted to it as London, particularly an exemption from toll all over England. It was made an episcopal see in 1541, when Robert King, the last abbot of Osnab, was erected Bishop. It is governed by a mayor, high-reward, recorder, four aldermen, eight aldermen, two bailiffs, a town-clerk, two chamberlains, all that have borne the office of bailiff and chamberlain, and twenty-four common-councilmen: but these are subject to the chancellor or vice-chancellor of the university in all affairs of moment; and not only the mayor, but the principal citizens, and sheriff of the county, take an oath to maintain the privileges of the university. The city, including the colleges, is a place of considerable magnitude, having 13 parish churches, besides the cathedral, well built, clean, and regular. At the entrance of the town from the Woodstock and Banbury roads, a new hospital has been lately erected by the trustees of Dr. Ratcliffe's benefaction, out of the surplus money remaining after defraying the expense of his library.

**Oxfordshire.** which made part of the territory of the ancient Deubon, a county of England, bounded on the west by Gloucestershire; on the south, where it is broadest, the river Isis divides it from Berkshire; on the east, it is bounded by Buckinghamshire, and on the north, where it terminates in a narrow point, it has on the one side Northamptonshire, and on the other Warwickshire. It extends 50 miles from north to south, and 35 from east to west, making about 130 in circumference: within which are contained one city, 15 market-towns, 280 parishes, 14 hundreds, 534,000 acres, and about 120,000 souls. The air is sweet and pleasant, and the soil rich and fertile. The lower parts consist of meadows and cornfields, and the higher were covered with woods till the civil wars; in which they were so entirely destroyed, that wood is now extremely scarce and dear, except in what is called the chiltern, and so is coal; of consequence fuel bears an exorbitant price. The county is extremely well watered; for besides the Isis, Tame, Cherwell, Evenlode, and Windrush, there is a great number of lesser rivers and brooks. One of the four great Roman ways passes quite thro' this county, entering at the parish of Chinner, and going out at that of Goring. There is another lesser one, that extends between Colnbrook and Wallingford, called Gremeshide. The county sends 5 members to parliament, viz., two for the city, two for the county, two for the university, two for new Woodstock, and one for Banbury.

**Oxgang,** or Oxgarth, is generally taken, in our old-law-books, for 15 acres, or as much ground as a single ox can plough in a year.

**Oxcliffe,** in natural history, the name of a genus of insects of the class of lepidegans, but of the columnar, not the rhomboidal, kind. Of this genus there are only
OXYS

1. A fine kind with thin flakes and transverse filaments, found in the clayey banks of the river Nen, near Peterborough in Northamptonshire; and, 2. A dull kind with thick plates and longitudinal filaments. This is not uncommon in Yorkshire, and lies sometimes in a yellow and sometimes in a blue clay.

OXUS, or Jhun, a large river of Asia, much taken notice of in Ancient histories, but does not rise in the north of India, as most authors affirm; for, according to the best and latest maps, made by those who have been upon the spot, it ran a course of about 260 miles from the Caspian Sea to the lake Aral, whose dimensions have lately been discovered, and is but very lately known to the Europeans; but, as it passes through a desert country, abounding with winds, the inhabitants so diverted its course, that the old channel can hardly be discovered.

OXYCROATE, in pharmacy, a mixture of vinegar and water, proper to affuage cool and refresh. The usual proportion is one spoonful of vinegar to five or six spoonfuls of water.

OXOD, is the term used in the new chemical nomenclature to express a very numerous class of bodies formed by the union of certain bases with a smaller proportion of oxygen than what is necessary for their conversion into acids. (See OXYGENE). The most remarkable of these bodies are what were formerly called metallic calces, and have for their base some metallic sulphides. It is in this state that metals are contained in their ores, from which they are extracted, and converted into the reguline or metallic form, by the process called Reduction. Metals are converted into oxides by combustion, and by solution in acids; and many of them assume this form from the action of the atmosphere alone, but more readily when this is affixed by moisture. During their conversion into oxides, metals lose their splendor, and, acquiring a considerable increase of absolute weight, put on an earthly, pulvulent appearance. It has of late been supposed that all earths are metallic oxides, and that all of them would be capable of reduction, were we possessed of any body for which oxygen had a stronger elective attraction than that by which it is kept in conjunction with the bases of these supposed oxides. But this opinion, being perfectly unsupported by experiment, cannot be admitted in a science which, like the chemistry of the present day, aspires to demonstration.

The term oxyd, however, is not confined to the combinations of metals with oxygen, but expresses that first degree of oxygenation in all bodies which, without converting them into acids, causes them to approach to the nature of salts; and of these there is a prodigious variety; as the oxyd of phosphorus, which is the white concrete substance into which that body is converted by combustion; the oxyd of azote, or nitrous air of Dr Priestley; and a great many others. Most of the oxides from the vegetable and animal kingdom have bases compounded of different simple combustible bodies. Thus, sugar, all the gums, mucus, and asphaltum, are vegetable oxides; the bases of which are hydrogen and carbon; combined in various proportions. We find accordingly, that all these bodies are, by farther additions of oxygen, convertible into acids; and it is probable that those acids differ from each other only in the proportion of the hydrogen and carbon in their bases. The bases of the animal oxides are still more complicated; all, or most of them, consisting of various combinations of azote, phosporus, hydrogen, carbon, and sulphur. See Cals, Chemistry, and Table of Chemical Nomenclature.

OXIDATION, is a term employed by the later chemists to express the process by which bodies are converted into oxides, and is allowed on all hands to be exactly similar to combustion. The nature of this process has been much disputed; and the question on this subject involves in itself great part of the controversy between the followers of the immortal Stahl and the justly celebrated Lavoir, the founders of the phlogistic and antiphlogistic theories, which have for some years divided the chemical world. A view of this question, sufficiently dilated, may be taken from the case of metals and their oxides. Metallic calces (oxyds say the phlogistians) are simple bodies, which, when united with phlogiston, form metals. The processes of reduction consist in expelling the parts of metals to an intense heat in contact with some inflammable body, most commonly charcoal. During this operation, they, the charcoal being inflamed, parts with its phlogiston, which is immediately absorbed by the cals and a metal is formed. Lavoir and his followers, on the contrary, contend that metals are simple bodies; but that in the state of oxides, that is, as they commonly exist in their ores, they are combined with oxygen. But as oxygen at a high temperature is more strongly attracted by charcoal than by most metals, during the process of reduction the oxide is decomposed, and the oxygen unites with the charcoal to form carbonic acid, leaving the regulus or metal free. On this point hinges the great question, the decision of which must materially affect almost every part of chemical theory. Without presuming to decide between these two opinions, the former of which is still supported by one or two chemists of the first rank, we agree with Dr Black in thinking that, though there still remain a few facts which have not been thoroughly explained on antiphlogistic principles, this theory is much more simple, and better supported by facts, than any that preceded it. It has this great advantage over the doctrine of Stahl, that it requires not the supposition of an arbitrary body, which does not affect our senses, and of the existence of which we have not even a shadow of proof. Perhaps we may further venture to assert, that though it may be extremely difficult, or even impossible, to refute the phlogistic theory, inhered as we have all been by a strong prejudice in its favour; yet had it been brought forward for the first time, when our knowledge had arrived at a point which it now holds, it would never have generally been received. See Calcination, Chemistry, Combustion, Inflammation.

OXIGENE, a term adopted in the new chemical nomenclature to express the modifying principle; from the Greek, "acid," and "genere," to generate. It is not found naturally in a separate state, but always combined or mixed with some other substance. In its acid form, or elastic state, it is called the French chemists oxygène, and in the same as the phlogisticated air of 4 D.
Oxycene Prießnitz and Cavendish, the empyreal air of Scheele, the vital air and pure air of other modern chemists. It was called dephlogisticated by the followers of Stahl's doctrine, who imagined it to be a dephlogisticated air. The epithet of empyreal was given to it by Mr. Scheele, who first discovered it to be the only constituent part of the atmosphere which contributes to support the flame. He made many curious experiments on inflammation, and was the first who completely unravelled common air, showing it to consist of 27 parts of empyreal, 72 parts of soul, and 1 part of fixed air. He found, that these 27 parts only were consumed by a burning body; and that these, during the act of combustion, were united and combined with the inflammable body burnt in them, so as to form a compound no longer combustible. Lavoisier extending these experiments, found that the body, thus produced by empyreal air, being combined with the matter of the inflammable body burnt in it, was, in many cases, an acid; in consequence of which property, he gave this air the name of oxygen, i.e., the generator of acidity. He was perhaps too hastily in adopting this name; for the same air is found in combination with inflammable matter, forming compounds that are by no means acid, of which we shall content ourselves with producing only one example, namely water, which is the compound resulting from the combination of this air with inflammable air. See Water.

Common atmospheric air was found by Scheele to promote animal life in a manner somewhat similar to its promoting combustion. He extended his experiments to this subject also; and he concludes, that this empyreal air is the only part of the atmosphere which is capable of supporting animal life, and that no animal can exist a minute without it. In consequence of this property it has been called vital air. Since, however, it is absolutely necessary for the support both of combustion and animal life, and since neither of these can exist without it, both the terms empyreal and vital are deficient, expressing only certain properties of this elastic fluid (which may be also said of the word oxygen); and hence some later chemists have suggested the propriety of designating it by the name of pure air. See Combustion, Inflammation, Chemistry, Air, Water.

Oxglycine, a species of drink prepared of the sweetest honey-combs macerated and boiled. The combs, from which all the honey has been expressed, are put into a pot with pure water, and boiled till they seem to have deposited all their contained honey in the water. This liquor is to be kept; and, when diluted with cold water, is to be drunk in the summer-time, in order to remove thirst.

Oxymel, in pharmacy, a composition of vinegar and honey. See Pharmacy.

Oyster, in law-books, seems to have been anciently used for what is now called oyster. See Assises.

Oysters, in zoology. See Ostrea.

Oyster Catcher. See Haematopus.

Oyster Fishery. See Oyster-Fishery and Ostrea.

Oyster. The largest that is known of oyster is that near Reading in Berkshire. They are entirely shaped, and have the same substance with the recent oyster-shells; and yet since the oldest histories that mention the place give an account of them, we must suppose they have lain there for a long time. They extend over no less than six acres of ground; and June above them is a large stratum of greenish loam, which some writers call a green earth, and others a green sand. It is composed of a crumbly phil­matar, and a large portion of sand. Under them is a thick stratum of chalk. They all lie in a level bed; and the strata above the shells are natural, and appear never to have been dug through till the time of finding the shells.

The oyster-shells, a green earth united make a stratum of about two feet thick; and over this there is a much thicker stratum of a bluish and a very brittle clay; but neither has this ever been dug through, except where the shells are found. This is vulgarly denominated piercy-clay, and is esteemed useless. This clay-bed is about a yard deep, and above it is a stratum of fuller's earth, about two feet and a half deep; it is extremely good, and is used by the clothes. Over this there lies a stratum of a fine white sand, unmixed either with the clay or fuller's earth: this is near seven feet deep, and above it is a stratum of a flifl red clay, of which tiles are made. This is again covered with a little vegetable mould; the depth however of this stratum of tile-clay cannot be ascertained, on account of the unevenness of the hill. These oysters are occasionally found whole, but most frequently in little shells. When they are in pairs, there is generally some of the green sand found within them; they seldom stick very fast together; so that unless very carefully taken up, it is not easy to preserve them in pairs.
shell. Oyster-shells being thus found by Mr. Homburg to be a very valuable medicine, and as one of the common methods of preparing them is by calcination, which, he observes, considerably impairs their virtues, he gives the following method of preparing them for taking inwardly, which he himself always used. Take the hollow shells of the oysters, throwing away the flat ones, as not sufficiently good: make them perfectly clean, and then dry them in the sun; when they appear dry, beat them to pieces in a marble mortar; they will still be found to contain a large quantity of moisture; lay them therefore again in the sun till perfectly dried, and then sift the powdering them, and sift the powder through a fine sieve. Give 20 or 30 grains of this powder every morning, and continue it three weeks or a month. See Chemistry, p. 1087.

OZELA, a foul and malignant ulcer of the nose, distinguished by its sector, and often accompanied with a carcass of the bones of the nose.

OZANAM (James), an eminent French mathematician born at Bologneux in Breuil, in 1640, of a wealthy family. His father gave him a good education, and designed him for the church: but some mathematical books falling into his hands, inspired him with a love for that science; and though he had no matter to instruct him, he made such progress in it, that, at 15 years of age, he wrote a piece in mathematics, which he thought proper to insert in the works he afterwards published. He at length taught that science at Lyons; and his mathematical lessons brought him in a considerable revenue, till the year 1701, at which period a war breaking out on the succession to the crown of Spain, he left almost all his scholars, and was reduced to a very melancholy situation; and his wife dying the same year, he was so afflicted, that he never perfectly recovered it. In 1702 he was admitted into the Royal Academy of Sciences; and died of an apoplexy in 1717.—He was of a mild and serene temper, of singular generosity, and of a cheerful disposition.—He would not allow himself to know more of religion than the common people. He used to say, that “it was the business of the doctors of the Sorbonne to dispute, of the Pope to decide, and of a mathematician to go to heaven in a perpendicular line.” His works are very numerous and have met with the approbation of the learned. The principal are, 1. Practical geometry, 12mo. 2. A mathematical dictionary. 3. A course of mathematics, 5 vols., 8vo. 4. Mathematical and philosophical recreations, the most complete edition of which is that of 1725, in 4 vols., 8vo. 5. An easy method of surveying. 6. New elements of algebra, a work much commended by Mont. Leibnitz. 7. Theoretical and practical perspective, &c.

OZELL (John), a well-known translator, educated in Christ's Hospital, was possess'd of a competent fortune, and always enjoyed good places, being auditor-general of the city and bridge accounts of St. Paul's cathedral, and of St. Thomas's hospital. Notwithstanding his attention to business, he still retained a love for polite literature; and though he did not appear as an original author, yet having made himself master of most of the living languages, he favoured the world with many translations from them, as well as from the Latin and Greek; which, if they are not the most elegant, are generally faithful and true to the originals. He died in the year 1743.

OZIAS, in sacred history, the son of Michal, of the tribe of Simeon, one of the governors of Bethulia when it was besieged by Holofernes. He vigorously supported the siege against this general, and received Achior into his house, when he had been driven from the Assyrian camp. Finding however at length that the city was reduced to great necessity for water, and that the people mutinied against him, he promised to surrender the place in five days, if in that time God did not send them relief. Judith (vi. vii. viii. ix. and x.) being informed of this resolution, sent to speak with Ozias and the other leading men of the city; made a prudent remonstrance upon their seeming to prescribe a time to the Lord in which he must succour them; encouraged them to patience; and without discovering her design, told them that she would go out in the night. Ozias being at the gate of the city when Judith departed, opened it to her and waited in the city for the success of her undertaking, praying with her people to God that he would be pleased to deliver them. See the article Judith.

OZEWORTH, in England, in Gloucestershire, about 18 miles from Gloucester. It is remarkable for nothing but that in one year, during the reign of Queen Elizabeth, there were no less than 251 foxes killed at it.

OZOLE, or OZOLL, a people who inhabited the eastern parts of Ætolia which were called Ozolea. This tract of territory lay at the north of the bay of Corinth, and extended about 12 miles. They received their name from the bad stench (εξ) of their bodies and clothes, which were the raw hides of wild beasts. Some derive it from the stench of the stagnated water in the neighbouring lakes and marshes. According to a fabulous tradition, they received their name from a very different circumstance: During the reign of a son of Deucalion, a bitch brought into the world a flock instead of whelps. The flock was planted into the ground by the king, and it grew up to a large vine, and produced grapes, from which the inhabitants of the country were called Ozoile, not from εξολοδρ, “to smell bad,” but from εξολοδρ, “a branch or shoot.” The name Ozole, on account of its indecent signification, was highly disagreeable to the inhabitants; they therefore exchanged it soon for that Ætolians.
PAC

P is the 15th letter and 11th consonant of the alphabet; the sound of which is formed by expressing the breath somewhat more suddenly than in forming the sound of $t$; in other respects these two sounds are pretty much alike, and are often confounded one with another. When $p$ (stands before $t$ or $j$, its sound is lost; as in the words *psalm*; *psychology; psalmic; psijan,* etc. When placed before $h$, they both together have the sound $f$; as in *philosophy, physics,* etc.

$P$ and $B$ are so like one another, that Quintillian declares, that in the word *obinitus*, his reason required him to put a $b$, but that his ears could hear nothing but a $p$, *obinitus*; hence in ancient inscriptions, and old glossaries, it appears that these two letters have often been confounded. Several nations still pronounce one for the other, the Welch and Germans particularly, who say, *ponum vinum*, for *bunum vinum*. Plutarch observes, it was usual for those of Delphi to say *μέθυν* for *πεθυν*; and among the Latins, as often as an $s$ followed, the $b$ was changed into a $p$, as *feribus*.

As an abbreviation, $P$ stands for *Pulcrus, Pondo,* &c. P. A. D. I. G. for *Patricia Dignitas*; P. C. for *Patriae Conspicui*; P. F. for *P. J. Filius*; P. P. for *Propostium; or Propositum publicum*; P. R. for *Papillus Romanus*; P. R. S. for *Praetoria sententia*, P. R. S. P. for *Praefiti provinciæ*.

$P$. M. among almanorners, is frequently used for *praeva meridiem*, or "after medioj"; and sometimes for *poel mane", "after the morning, i. e. after midnight." $P$ was also used among the ancients as a numeral letter, signifying the same with the G, viz. a hundred; according to the verfe of Ugo, *Pacum cum G numero nonvator habere*.

Though Baronius thinks it rather stood for seven.

When a daub was added a top of $P$, it stood for four hundred thousand.

St Jerome observes, on Daniel, that the Hebrews had no $P$; but that the $p$ served them instead thereof; adding that there is but one word in the whole Bible read with a $P$, viz. *apelaen.* The Greek signifies *σεαλε*; 'on the French coins, $P$ denotes those that were struck at Dijon.

In the Italian muse, $F$ stands for *pianet,* or "softly,* and P. P. P. for *pianifimo,* or "very softly*.

Among physicians, $P$ stands for *pugnii,* or the eighth part of an handful; P. $p$., *partes aquates,* or equal parts of the ingredients; P. P. signifies *pulvis patrum,* or Jesuit's bark in powder; and $p$., *preparatus* or prepared.

**PABULUM**, among natural philosophers, the fame with *Pulv.*

**Pace,** see *Mus., p. 467.*

**PACE,** a meafure taken from the space between the two feet of a man in walking; usually reckoned two feet and a half, and in some men a yard or three feet. The geometrical pace is five feet, and 60,000 such paces make one degree on the equator.

**PACE,** in the manage, is of three kinds, viz. walk, trot, and gallop; to which may be added an amble, because some horses have it naturally.

Horses which go fluffling, or with mixed paces between the walk and amble, are for the most part of no value; which commonly proceeds from their fiery temper, but sometimes from a weakness in their reins or legs.

**PACE** (Richard), a learned Englishman, born about the year 1482. He was educated at the charge of Thomas Langton bishop of Winchester, whom he served as an amanuensis, and afterwards entered into the service of cardinal Bainbridge. His accomplishments rendered him so acceptable to Henry VIII. that he made him secretary of state; and, entering into orders, he was admitted prebendary in the church of York, archdeacon of Dorset, and dean of St Paul's, &c. which preferments were conferred on him during his absence on foreign emissaries. In 1512 he was sent to Rome on the death of Pope Leo X. to solicit the papal chair for cardinal Wolsey; but a new pope was elected before his arrival, a circumstance that proved the epoch of his troubles. He fell under the displeasure of the disappointed cardinal; and being soon after employed as ambassador at Venice, he was neglected and hardly used, that he was seized with a frenzy; upon which the king ordered him home; and being carefully attended by the physicians at the king's command, he was in a short time restored to the use of his reason, and then applied himself to the study of the Hebrew tongue. Being now introduced to his Majesty, he renounced against the cardinal's cruelty; who being ordered to clear himself, summoned Pace before him, sitting in judgment with the duke of Norfolk and others; who condemned Pace, and sent him to the Tower; where he remained two years, till he was discharged by the king's command.—When he was enlarged, he reigned his deaneries, and died in retirement at Stepney in 1532; after having wrote several works. There is an elegant and just character of him by Leeland, written upon his return from Venice. He was much esteemed by the learned men of his time, especially Sir Thomas More and Erasmus. The latter had a great opinion of Pace on account of his candour and sweetness of temper; so that he was much afflicted at his misfortunes, and could never forgive the man that caused them. Stow gives him the character of a right worthy man, and one that gave in council faithful advice: learned he was also, says that antiquary, and endowed with many excellent parts and gifts of nature; courteous, pleafant, and delighting in music; highly in the king's favour, and
and well heard in matters of weight. There is extant a remarkable letter of his to the king, written in 1527, wherein he very honestly gives his opinion concerning the divorce; and Fides observes, that he always used a faithful liberty to the cardinal, which brought him at last to confinement and disfruction.

PACHAMAC, a valley of Peru, in South America, ten miles south of Lima; celebrated for its pleasantness and fertility, but more on account of a magnificent temple built by the Incas of Peru, to the honour of their god. When the Spaniards conquered Peru, they found immense riches therein.

PACHODECARHOMBIS, in natural history, the name of a genus of fossils, of the class of mollusca, from the name of a genus of shells, of the class of mollusca. The name is derived from the Greek σπαχοδεξιον, σπαχοδέκτης, σπαχοδήκτης, and ἄκρωτος ἀκρωτίαν, and expresses a thick rhomboidal body composed of ten planes. The characters of this genus are, that the felenitae of it consist of ten planes; but as the top and bottom in the leptodecarhombes, or most common kind of the felenite, are broader and larger planes than any of the rest, the great thickness of this genus, on the contrary, makes its four longer planes in all the bodies of it, meeting in an obtuse angle from its sides, its largest planes. There are four species of it.

PACHSU, a small island in the Mediterranean sea; near the coast of Epirus, and in European Turkey. It lies south of Crete, and is subject to Venice.

PACIFIC OCEAN, that vast ocean which separates Asia from America. It is called Pacific, from the moderate weather the first mariners who sailed in it met with between the tropics: and it was called South Sea, because the Spaniards crossed the isthmus of Darien from north to south when they first discovered it: tho' it is properly the Western ocean with regard to America.

Geographers call the South Sea Mar: Pacificum, “the Pacific Ocean,” as being less infested with storms than the Atlantic; but M. Frezier affirms it does not deserve that acclamation, and that he has seen as violent storms therein as in any other sea: but Magellan happening to have a very favourable wind, and not meeting with any thing to ruffle him when he first traversed this vast ocean in 1520, gave it the name which it has retained ever since. Many, however, adds, that the wind is so regular there, that the vessels would frequently go from Acapulco to the Philippine Islands without shifting a sail.

PACK, in commerce, denotes a quantity of goods made up in loads or bales for carriage. A pack of wool is 17 stone and 2 pounds, or a hogs's load.

PACKAGE, is a small duty of one penny in the pound, paid for all goods not particularly rated.

PACKET, or P a c k e t B a t s, a vessel appointed by the government to carry the mail of letters, packets, and expresses from one kingdom to another by sea in the most expeditious manner. Thus, the packet-boats, under the direction of the post master-general of Great Britain, carry the mails from Dover to Calais, from Falmouth to Lisbon, from Harwich to Helvetiushla, and from Parkgate to Dublin. See Post.

PACOS, in zoology, a name given to a species of camel, commonly though improperly reckoned a species of the Parcham, and known among many by the name of the Indian sheep or Persian sheep. See CAMEL, p. 60.

This creature has been accounted a sheep, because its hair is so long as to resemble wool, and it is prodigiously thick, its head and neck alone having more wool on them than the whole body of our largest sheep. Its body is clothed in the same proportion with a woody hair equally fine.

PACTOLUS (anc. geog.), a river of Lydia, called Chrysorrhitis, from its rolling down golden sand, according to Herodotus, Plutarch, Pliny, and Strabo; rising in mount Tmolus (Strabo). From this river Cyrus is thought to have had all his riches. In Strabo's time it ceased to roll down any. It ran through Sardes; after which it fell into the Hermus, and both together into the Ægean sea at Phocaea in Ionia. A river celebrated by Virgil, Ovid, Lucan, Lycophron, Horace, Apollonius.

PACUVIUS (Marcus), of Brundisium in Calabria, a tragic poet in high reputation about the year of Rome 660. He was nephew of Ennius; published several theatrical pieces, though we have only some fragments of his poetry remaining; and died at Tarquentum at above 90 years of age.

PADAN-ARAM (Bible), literally the plains of Aram, or Syria, translated by the Seventy simply Mesopotamia, or Mesopotamia of Syria; by the vulgar tongue, Syria; the Syrians on this and on the other side of the Euphrates, not differing remarkably from each other in language and manners, as Josephus allows.

PADDOC, or Paddock-Course, a piece of ground encompassed with pales or a wall, and taken out of a park, for exhibiting races with greyhounds, for plates, wagers, or the like.

A paddoc is generally a mile long, and a quarter of a mile broad: at the one end is a little house where the dogs are to be entered, and whence they are flapped; near which are pens to enclose two or three deer for the sport. Along the coasts are several pits, viz. the low pit, which is 160 yards from the dog-house and pens; the quarter of a mile pit, half-mile pit, and pinching pit: besides the ditch, which is a place made to receive the deer, and preserve them from further pursuit. And near this place are stooks for the jockeys to choose to decide the wager.

The keepers, in order to split the dogs fairly, put a falling collar upon each, flipp'd round a ring; and the deer being turned loose, and put forward by a teaser, as soon as he is arrived at the low-pit, the dog-house door is thrown open, and the dogs flapped. If now the deer swerve so much, as that his head is judged nearest the dog-house than the ditch before he arrived at the pinching-pit, it is no match, and must be run over again three days after: but if the deer runs straight beyond the pinching-pit, then that dog which is nearest when he swerves, or is blushed by any accident, wins the match; but if no such swerve happens, then the match is won by the dog who first leaps the ditch.

PADERBORN, a duchy of Germany in the circle of Westphalia, has the county of Lippe on the north and west; Hesse Caalf and Waldeck, on the south: and
PAD, [ 582 ]

PAD, and Munster, with the duchy of Weilphalia, on the west. Its greatest length from east to west is about 40 miles, and its breadth where widest 30. Some parts of it yield good pasture and breed abundance of cattle; but it is not very fruitful in corn. There is a heath called the Senne or Sende, of great extent, but very barren and sterile. There are however, good iron mines in the country, with salt and medicinal springs, plenty of deer and other game; and it is watered with several rivers abounding with fish, as the Wer, the Diemer, the Bever, the Nethe, the great Emmer, the Lippe, the Alme, and the Pader. It contains 54 parishes, in which are 25 market-towns and 16 monasteries. The Roman Catholic is the predominant religion of the country, yet there are also many Protestants in it. The bishopric was erected by Charlemagne, towards the close of the eighth century; and the cathedral was consecrated by Pope Leo in person, anno 796. The bishop is sovereign of the country, a prince of the empire, and suffragan of the archbishop of Mentz. His revenues are about 50,000 florins a year, and he is able to raise 5000 men. In the matricula, his assessment is 18 horse and 34 foot, or 352 florins monthly in lieu of them. Towards the large, Arminius, Icrerences) at merely a little. Le

Here are the limits of the town, 1604, and the inhabitants, 30,000. The bishofric are a sublunary cross or, in a field gules. For the commune, 1530 an attempt was made to introduce Catholicism; but 16 of the principal citizens, on the birth of the inhabitants, 30,000 inhabitants, whereas it formerly had 100,000, and many of the houses are gone to ruin; however, the hall where justice is administered is a superb structure. The cathedral church, and the college of the university, are in that part called the Old Town; and there are piazzas under all the houses, where perfons may walk without being exposed to the weather. The garden of the university is curious, on account of the number of plants. Here a student may take his degrees, let him be of what sect of Christianity he will; nay, though he should be a Jew or a Turk. The patron of this city is St Anthony, who lies in the cathedral; they have such a veneration for him, that the beggars do not ask charity in the name of God, but for the love of St Anthony. The Jews live in a distinct part of the city; and the neighbouring mountains produce excellent wine and oil, with delicious fruit. It was taken by the Venetians in 1706. It is situated on the rivers Brentae and BachiN, in a fine plain; and is about seven miles in circumference. E. Long. 11. 55. N. Lat. 45. 24.

PADUA, among the medals, a modern medal struck in imitation of the antique, or a new medal struck with all the marks and characters of antiquity. This name is properly applicable to those medals only that were struck in the seventh century by an Italian painter born at Padua; who succeeded so well in the imitator, that the best judges are at a loss to distinguish his medals from the genuine ones. Though it is frequently used in general for all medals of this kind.

PADUANO, a small province of Italy, in the territory of Venice, bounded on the east by the Dogado, on the south by the Polefino di Rovigio, on the west by the Veronese, and on the north by the Vicentino. Its soil is well-watered; and is one of the most fertile in Italy. The province is about 40 miles in length, and 35 in breadth. Padua is the capital town.

PADUS, anciently called Erdanus, especially by the Greeks; a river famous for the fable of Phaeton. (Ovid.) It rises in mount Vefulus, in the Alps Cothia, from three springs, dividing the Cilpine Gaul into the Transpadana and Cipadana, (Strabo); and, swelled by other rivers falling into it on each side from the
the Alps and Appenines, it discharges itself with a
course from well to east, at seven mouths, into the A-
driatic (M.1). The lake th'v which it discharges itself
into the sea, is called by the natives the Seven Seas.
Now the Po.

PADUS, in botany. See PONUS.

PEAN, among the ancient pagans, was a song of
 rejoicing sung in honour of Apollo, chiefly used on oc-
casions of victory and triumph. See Apollo.

PEAN, in ancient poetry, a foot consisting of four
yllables; of which there are four kinds, the pean pri-
um, secundus, &c.

The pean primus consists of one long yllable and three
short ones, or a trochees and pyrrhichius, as
temporeus; the pean secundus consists of a short yll-
able, a long, and two short, or an iambus and a py-
rhichius, as paenia; the pean tertius consists of two
short yllables, a long and a short one, or a pyrrhichius
and a trochees, as animatus; the pean quartus consists
of three short yllables and a long one, or a pyrrhichius
and iambus, as cecraria.

PEDEROTA, in botany: A genus of the mon-
ygynia order, belonging to the pentandria class of
plants; and in the natural method ranking under the
50th order, Contoria. The berry is empty, brittle,
and diapherous; the style bifid.

PEIO BAPTISM; infant baptism, or that conferred
on children from ten years of age, and in the
Baptism.

This has been the subject of great controversy in
the church. See ANABAPTISTS, BAPTISTS, &c.

PEONIA, Piony: A genus of the djigynia orde-
ring, belonging to the polyandria class of plants; and in
the natural method ranking under the 26th order, Mul-
tisitique. The calyx is pentaphyllous; the petals five;
there are no styles; the capsules are polypermorph.
There are two species, both of them very hardy, and
will stand in any common foil. They are large her-
baceous flowery perennials, with tuberous roots, send-
ing up strong annual stalks from one to three feet in
height; terminated by very large flowers of a beauti-
ful red color, and much larger than any rose. The
common officinal, or male piony, also is remarkable for
its capsules turning backward, opening and displaying
their red inside, together with the numerous seeds, in
a singularly agreeable order, appearing very ornamental
after the flower is past. The plants may be propaga-
gated either by parting the roots or by seed. This plant
was formerly celebrated in nervous distempers, but
the present practice pays very little regard to it.

PESTUM, called Pythium by the Greeks, a town
of Lucania, on the Sinus Pausinum; an ancient colony
prior to the first Punic war, according to Livy; but
later, according to Velleius. Pausina 1658 were
in great esteem, and produced twice a-year (Virgil,
Ovid).

PAGAN (Blaise Francois Compte de), an eminent
French mathematician, was born at Avignon in Prov-
ence March 3, 1604; and took to the profession of
a father at fourteen, having been bred to it with the
greatest care. In 1620 he was engaged at the siege
of Caen, in the battle of Pont de Ce, and the reduction
of the Navarens, and the relief of Bearn; where he
signified himself, and acquired a reputation far sur-
passing his years. He was present, in 1621, at the
siege of St John d'Angélic, as also that of Chârac and
Montauban, where he lost his left eye by a musket-
shot. At this siege he had another loss, which equally
afflicted him, viz., that of the confable of Lonjean,
who died there of a fever. The confable was
a near relation, and had been his patron at court. He
did not, however, sink under the misfortune, but on
the contrary took fresh spirits from the necessity he
was now in of trufting solely to himself. Accordingly
there happened after this time neither siege, battle,
nor any other occasion, in which he did not signalize
himself by some effort of courage and conduct. At
the passage of the Alps, and the barricade of Suse, he
put himself at the head of the forlorn hope, consisting
of the bravest youths among the guards; and under-
took to arrive the first at the attack, by a private
way which was extremely dangerous; when, having gained
the top of a very steep mountain, he cried out to his
followers, "See the way to glory!" He flung
himself down this mountain; and, his companions following
him, they came first to the attack, as they wished to
do. They immediately began a furious assault; and,
the army coming to assist, they forced the barricades.
He had afterwards the pleasure of glancing on the left
hand of the king, when his majesty related this heroic
action to the duke of Savoy with the deferred com-
mandements, in the presence of a very full court. When
the king laid siege to Nancy in 1655, our hero had
the honour to attend his sovereign, in drawing the
lines and forts of circumvallation. In 1652 his
majesty sent him to the service in Portugal, in the post of
field marshal. In this same year he unfortunately lost
his eye fight by a diemper. But though he was thus
disabled from serving his country with his conduct
and courage, he reassumed, with greater vigour than ever,
the study of the mathematics and fortification; and, in
1645, gave the public a treatise on this latter sub-
ject. It was allowed by all who understood the science,
that nothing had then appeared that was preferable to it;
and indeed whatever improvements have been made
since, they have perhaps been derived chiefly from
this treatise, as conclusions from their principles. In
1651 he published his Geometrical Theorems, which
show a perfect knowledge of all the parts of the mat-
ematics. In 1655 he printed A Paraphrase, in
French, of the Account, in Spanish, of the River of
the Amazons, by Father de Rames, a Jesuit; and,
we are assured, that, though blind, he drew the chart
of that river and the parts adjacent, which is seen in
this work. In 1657 he published The Theory of
the Planets, cleared from that multiplicity of eccentric
circles and epicycles, which the astronomers had in-
tended to explain their Motions. This work dislin-
guished him among astronomers as much as that of
fortification did among engineers; and he printed, in
1658, his Astronomical Tables, which are very
fascinating and plain. Few great men are without some
foible: Pagan's was that of a prejudice in favour of
judicial astrology; and though he is more revered than
most others, yet we cannot put what he did not in that
subject among those productions which do honour to
his understanding. He was beloved and respected by
all persons illustrious for rank as well as science; and
his house was the rendezvous of all the polite and
worthy both in city and court. He died at Paris
Nov. 18, 1665; and was never married. The long
ordered.
ordered his first physician to attend him in his illness; and gave several marks of the extraordinary esteem which he had for his merit.

He had an universal genius; and, having turned himself entirely to the art of war, and particularly to the branch of fortification, he made extraordinary progress in it. He understood mathematics not only better than is usual for a gentleman whose whole view is to put his fortune in the army, but even to a degree of perfection superior to that of the ordinary masters who teach that science. He had so particular a genius for this kind of learning, that he obtained it more readily by meditation than by reading authors upon it; and accordingly spent his time in such books as he did in those of history and geography. He had a fine manner of concealing and politics his particular study; so that he may be said to have drawn his own character in his *Homme Herouique*, and to have been one of the completest gentlemen of his time. Louis XIII. was heard to say several times, that the Count de Pagan was one of the most worthy, bold, adroit, and most valiant men in the kingdom. That branch of his family, which remained from Naples to France in 1522, became extinct in his person.

Pagan, a heathen, gentle, or idolater; one who adores false gods. See MYTHOLOGY.

PAGANALIA, certain festivals observed by the ancient Romans in the month of January. They were instituted by Servius Tullius, who appointed a certain number of villages (pagi), in each of which an altar was to be raised for annual sacrifices to their tutelar gods; at which all the inhabitants were to assist, and give presents in money according to their sex and age, by which means the number of country-people was known. The servants upon this occasion offered cakes to Ceres and Tellus, to obtain plentiful harvests.

PAGANELLUS, in ichthiologies. See GEBUS.

PAGANISM, the religious worship and discipline of pagans; or, the adoration of idols and false gods. See idolatry, mythology, and polytheism.

PAGRAINT, a triumphal car, chariot, arch, or other like pompous decoration, variously adorned with colours, flags, &c. carried about in public shows, processions, &c.

PAGI (Antony) a very famous Cordelier, and one of the ablest critics of his time, was born at Rognes in Provence in 1624. He took the habit in the convent at Arles in 1641, and was at length four years provincial of his order; but his religious duties did not prevent his vigorous application to the study of chronology and ecclesiastical history, in which he excelled. His most considerable work is, *A Critique upon the Annals of Baronius*; where following the learned cardinal year by year, he has rectified an infinite number of mistakes both in chronology and in the representation of facts. He published the first volume in 1689, dedicated to the clergy of France, who allowed him a pension; the whole was printed after his death, in 4 volsfolio, at Geneva, in 1705, by the care of his nephew Francis Pagi, of the same order. He wrote some other things before his death, which happened in 1699, and had the character of an able historian as well as of a learned and critical critic. His nephew Francis, abovementioned, wrote *A Chronological Abridgment of the History of the Popes*, in Latin, 3 vols folio. Francis had all, a nephew Anthony Pagi, who added three more volumes to the History of the Popes; of which two more were intended, if not executed.

PAGINUS (Sanctes), an Italian Dominican, eminent for his skill in oriental languages and biblical learning, was born at Lucca in 1466, and became afterwards an ecclesiastic of the order of St Dominic. He was deeply and accurately skilled in Latin, Greek, Hebrew, Chaldee, and Arabic; but he was particularly excellent in the Hebrew. He applied himself to examine the vulgar translation of the Scriptures; and believing it to be neither of Jerome, or greatly corrupted, he undertook to make a new one from the prefent Hebrew text; in which he meant to imitate St Jerome, who felt about making a new translation at a time when the church would admit no other but the Septuagint. This design of Pagninus so early after the restoration of letters, feemed a bold one; yet such was the reputation of the man, that it was approved by Pope Leo X. who promised to furnish him with all necessary expenses for carrying on the work; besides, we find at the beginning of this translation, which was printed at Lyons in 1517, two letters of the succeeding popes, Hadrian VI. and Clement VII. which licensed the printing of it. Pagninus, in his *Letters to Pope Clement*, for the printing of this translation openly declares, that the Vulgar edition, as it is at present, is not St Jerome's; yet adds, that he has retained in this translation as much of it as he could. It appears by a letter of Pius Mirandula to Pagninus, that he had spent 25 years upon this translation. It is the first modern translation of the Bible from the Hebrew text; and the Jews who read it affirmed, that it agreed exactly with the Hebrew, and was in some respects superior to the ancient translations. The great fault of Pagninus was, that he adhered with too great servility to the original text; and this scrupulous attachment made his translation, says Father Simon, "obscure, barbarous, and full of follecy." He imagined, that to make a faithful translation of the Scriptures, it was necessary to follow exactly the letter according to the strictness of grammar. This, however, is quite contrary to his pretended exaetness, because two languages seldom agree in their ways of speaking; and therefore, instead of expressing the original in its proper purity, he defaces and robs it of all its ornaments." Father Simon nevertheless allows the great abilities and learning of Pagninus; and all the later commentators and translators of the Scriptures have agreed in giving him his just praise. Huetius, though he thinks Father Simon's criticism of him just and well grounded, yet proposes his manner as a model for all translators of the sacred books: *Scriptura interpretandi ratione utile velis exemplar praeposui Senecus Pagninus*. He also translated the New Testament from the Greek, as he had done the Old from the Hebrew, laying the Vulgar all the while before him; and dedicated it to Pope Clement VII. He was author of an Hebrew Lexicon, and an Hebrew Grammar: which Buxtorf, who calls him *viri linguarum Orientalium peritissimus*, made great use of in compiling his. He died in 1538, aged 70. Luther spoke of him and his translations in terms of the highest applause.
PAGO, an island in the gulf of Venice, separated from the continent of Morlachia by a narrow channel. The ancient geographers have left us no description of it; "though (as Fortis observes) its form (a) extends, and rich produce, unquestionably deserved it." And this is the more unaccountable, as we know the Romans were well acquainted with it; and on the other islands adjoining to it are many vestiges of buildings, inscriptions, tiles, and hewn stones, all future signs of Roman habitations. Its ancient name was in all probability Portunata. This island (says Mr Fortis) is extended from north to south over against maritime Croatia, or the mountain Morlaca. It is about 50 miles long; its breadth is unequal. One particular circumstance distinguishes it from all the other islands of the Adriatic, and is a large internal salt-water lake 15 miles long from south to north, into which the sea enters by a canal not above an inch broad in some places. This lake is frequented by the tunny fish, which, when once in, cannot return again to the sea. There are also two smaller lakes on the island; one near Vlaflisch, abounding in fish, particularly eels; and one near the hamlet of Slabine.

In this island the winter is dreadfully cold, and the summer scorchingly hot. Those who have been there in the winter time speak of it as a Siberia quite covered with snow and ice, and always exposed to the cold north wind; I, who was there in the hot season, thought it equal to the most scorching parts of the world. The naked rocks, which not only form the organization, but also the superfluities of almost all the island; the narrowness of the valleys; the reverberation of the water of the lake, generally quite calm in summer; multiply the heat so prodigiously among those stones, that the vines, which are planted all round the lake, ripen the grapes by the beginning of August; and the few other products that grow there anticipate the usual time of maturity in the same manner. The meteors are exceedingly irregular in the summer time; sudden whirlwinds are frequent, and heavy showers of rain: the lake is hurtful to the inhabitants of one part of the island, and favourable to the cultivation of the opposite end.

They cultivate neither corn nor oil on this island; but it produces plenty of wine, and an immense quantity of salt. The other products are wool, honey, and a little salt fish. The quantity of wine amounts annually, on a medium, to 40,000 Venetian barrels; and from the husks they distil 2000 barrels of rakia or brandy. The salt, in 1663, amounted to 80,000 Venetian lire.

The salt-works are well contrived and well kept; they extend along a salt-pit pool, which forms the eastern extremity of the lake within for four miles in length and about half a mile in breadth. On the sides of this fen the boil part of the vine lie; but the upper part of the hills on each side is altogether naked and barren; there is not even a sufficiency of fire-wood, and the inhabitants are obliged to provide themselves elsewhere. The soil at the foot of the hills, where the vines are planted, is full of gravel and small stones; and hence the wine is of good quality. The air is not unhealthful, notwithstanding the vicinity of the salt-pits; but the frequent high winds carry off the noxious exhalations. The most considerable product of the island is the salt. The greatest part of the people of Pago live by working in the salt pits, and have a comfortable subsistence regularly paid by the government: it is therefore a very important circumstance for the inhabitants of the city to have a dry summer; and hence the ignorant vulgar look upon rain as a mischief brought upon the country by the force of witchcraft. In consequence of this idea, they elect a friar to exorcise the meteors, and keep the rain off the island. If, notwithstanding the poor friar's endeavours, the summer happens to be rainy, he loses his reputation and his bread; but if two or three dry seasons follow successively, he meets with great reverence and advantage. Part of the salt-works belongs to the government, and the rest to private proprietors; they are meliorated every year; and for that end the public lends money to those proprietors who want it, and who without that assistance could not make the requisite improvements.

Many vestiges of ancient habitations still remain on the island of Pago, as well as of walled places, which either have been destroyed by the incursions of enemies or by time. Historians say, that the island was often abandoned by its inhabitants; and indeed it is rather to be wondered at how men ever could resolve to settle in so wretched a country. The small number of inhabitants, after so many years of peace and tranquillity under the Venetian government, evidently proves how little the island is really habitable. The town of Pago was built by the Venetians about 500 years ago; and contains upwards of 2000 inhabitants, and all the rest of the island scarcely 900. The difficulty of access to the city of Pago, and the ill accommodation

(a) Its figure is indeed remarkably irregular, its breadth being in no proportion to its length; for one of the extremities, called Punta di Loni, is above ten miles long, and less than one bread. Almost all the circumference is diminutive, without trees or any kind of visible plants or grases, steep, craggy, and uninhabited. On entering the lake through the channel that communicates with the sea, nothing is to be seen either on the right or left but bare hanging rocks, so disfigured on the outside by the violent percussion of the waves, that the stratification is hardly distinguishable. In general, the stone of the island is of the same kind as the Istrian, or breccia; and, besides, there are large strata of blue and yellowish sandstone. The channel, or inward bay of Pago, is not a harbour; on the contrary, it is a very dangerous slatation, and even inaccessible in winter, when the bora wind blows with such fury, that the inhabitants of the town dare not flir out of their houses, and much less the few that are scattered over the country. The sky appears always cloudy in that season, by the thick mist that rises from the repercussion of the waves on that long chain of rough and hollow rocks.
PAGODA, or PAGODA, a name given by the East Indian to the temples where they worship their gods. We shall not in this place enter into a full detail of the several pagodas of different nations, and their peculiar circumstances. These matters seem to come in more properly under the religion, or, as others will call it, the superstitious, of the people to whom they belong. We shall therefore content ourselves in the present article with an account of a paper in the Asiatic Researches, concerning the sculptures, &c. at Mavallaparam, a few miles north of Sadras, and known to men by the name of the seven pagodas.

The monuments which Mr Chambers (who communicated the paper) describes, appear, he says, to be the ruins of some great city decayed many centuries ago. "They are situated close to the sea, between Covelong and Sadras, somewhat remote from the high road that leads to the different European settlements. And when visited in 1776, there was still a native village adjoining them which retained the ancient name, and in which a number of Brahmins resided that seemed perfectly well acquainted with the subjects of most of the sculptures to be seen there. — The rock, or rather hill of stone, on which great part of these works are executed, is one of the principal marks for mariners as they approach the coast, and to them the place is known by the name of the Seven Pagodas, possibly because the summits of the rock have presented them with that idea as they passed; but it must be confess'd, that no aspect which the hill affumes as viewed on the shore, seems at all to authorize this notion; and there are circumstances which will be mentioned in the sequel, that would lead one to suppose, that this name has arisen from some such number of pagodas that formerly stood here, and in time have been buried in the waves." The rock here mentioned, as it rifes abruptly out of a level plain of great extent, naturally engrosses the attention of the eye. It consists chiefly of a single stone; and in its shape (which is singular and romantic), in a distant view, it has the appearance of an antique and lofty edifice. Works of imagery and sculpture crowd thicker upon the eye on a nearer approach, and at first sight at least favours the idea of a petrified town, which, through the credulity of travellers*, has been believed to exist in various parts of the world. "Proceeding on by the foot of the hill on the side facing the sea, there is a pagoda rising out of the ground of one solid stone, about 16 or 18 feet high, which seems to have been cut upon the spot out of a detached rock that has been found of a proper size for that purpose. The top is arched, and the style of architecture according to which it is formed, different from any now used in those parts."

Beyond this a numerous group of human figures in bas relief, considerably larger than life, attract attention. They represent considerable persons, and their exploits, many of which are now very indistinct through the injuries of time, affisted by the corroding nature of the sea air; while others protected from that element, are as fresh as when recently finished.

The hill, which is at first of easy ascent, "is in other parts rendered more so by very excellent steps cut out in several places, where the communication would be difficult or impracticable without them. A winding stair of this sort leads to a kind of temple cut out of the solid rock, with some figures of idols in high relief upon its walls, very well finished, and perfectly fresh, as it faces the west, and is therefore sheltered from the sea air."

This temple our author conjectures to have been a place of worship appertaining to a palace; some remains of which still exist, and to which there is a passage from the temple by another flight of steps. This conjecture (for it is brought forward as merely such) is in some measure favoured by several ruins still remaining, and by the tradition of the bramins who inhabit the place. This finishes the objects "on that part of the upper surface of the hill, the ascent to which is on the north: but on descending from thence, you are led round the hill to the opposite side, in which there are steps cut from the bottom to a place near the summit, where is an excavation that seems to have been intended for a place of worship, and contains various sculptures of Hindoo deities. The most remarkable of these is a gigantic figure of Vishnou (A), asleep on a kind of bed, with a huge snake wound about in many coils by way of pillow for his head; and these figures, according to the manner of this place, are all of one piece hewn from the body of the rock." These works, however, although they are unquestionably stupendous, are, in our author's opinion, surpased by others about a mile and a half to the southward of the hill. "They consist of two pagodas of about 30 feet long by 20 feet wide, and about as many in height, cut out of the solid rock, and each consisting originally of one single stone. Near these also stands an elephant full as big as life, and

(A) See a figure of Vishnou in the Plate of Indian gods, with its description, under the article Polytheism.
and a lion much larger than the natural size, but very well executed, each hewn also out of one stone. None of the pieces that have fallen off in cutting these extraordinary sculptures are now to be found near or anywhere in the neighbourhood of them, so that there is no means of ascertaining the degree of labour and time that has been spent upon them, nor the size of the rock or rocks from which they have been hewn; a circumstance which renders their appearance the more striking and singular. And though their situation is very near the sea beach, they have not suffered at all by the correlative air of that element, which has provided them with a defence against itself, by throwing up before them a high bank that completely shelters them. There is also great symmetry in their form, though that of the pagodas is different from the style of architecture according to which idol temples are now built in that country. The latter resembles the Egyptian; for the towers are always pyramidal, and the gates and roofs flat and without arches, but these sculptures approach nearer to the Gothic style, being surmounted by arched roofs or domes, but as the solidity of the building is greater they have the air of being a temple on a solid rock, and appear to be part of the ruins, has hence been supposed, that the idol was not anciently known in this country, and that the pagoda was a name given to a monument that existed only in Hindoo romance. But it is plain that that animal was well known to the authors of these works, who in manners as well as arts seem to have differed much from the modern Hindoos.

"There are two circumstances attending these monuments which cannot but excite great curiosity, and on which future inquiries may possibly throw some light. One is, that on one of the pagodas last mentioned, there is an inscription of a single line, in a character at present unknown to the Hindoos. It resembles neither the Deyva-nigre, nor any of the various characters connected with or derived from it, which have come to the writer's knowledge from any part of Hindostan. Nor did it, at the time he viewed it, appear to correspond with any character, Asiatic or European, that is commonly known. He had not then, however, seen the alphabet of the Balic, the learned language of the Siamese, a language of which he has since raised in his mind a suspicion that there is a near affinity between them, if the character be not identically the same. But as these conjectures, after such a lapse of time, are somewhat vague, and the subject of them is perhaps yet within the reach of our researches, it is to be hoped that some method may be fallen upon of procuring an exact copy of this inscription."

"The other circumstance is, that though the outward form of the pagodas is complete, the ultimate design of them has manifestly not been accomplished, but seems to have been defeated by some extraordinary conflagration of nature. For the western side of the most northerly one is excavated to the depth of four or five feet, and a row of pillars left on the outside to support the roof; but here the work has been stopped, and an uniform rent of about four inches breadth has been made throughout the solid rock, and appears to extend to its foundations, which are probably at a prodigious depth below the surface of the ground. That this rent has happened since the work began, or while it was carrying on, cannot be doubted; for the marks of the mason's tools are perfectly visible in the excavated part on both sides of the rent, in such a manner as to show plainly that they have been divided by it. Nor is it reasonable to suppose, that such a work would ever have been designed or begun upon a rock that had previously been rent in two. Nothing less than an earthquake, and that a violent one, could apparently have produced such a fissure in the solid rock, and that this has been the case in point of fact, may be gathered from other circumstances, which it is necessary to mention in an account of this curious place. The great rock above described is at some small distance from the sea, perhaps 50 or 100 yards, and in that place the Hindoo village before mentioned stood in 1776. But close to the sea are the remains of a pagoda built of brick, and dedicated to Sib, the greatest part of which has evidently been swallowed up by that element; for the door of the innermost apartment, in which the idol is placed, and before which there are always two or three spacious courts surrounded with walls, is now washed by the waves, and the pillar used to discover the meridian at the time of founding the pagoda is seen floating at some distance in the sea. In the neighbourhood of this building there are some detached rocks, washed also by the waves, on which there appear sculptures, though now much worn and defaced. And the natives of the place declared to the writer of this account, that the more aged people among them remembered to have seen the tops of several pagodas far out in the sea, which being covered with copper (probably gilt) were particularly visible at sunrise, as their shining surface used then to reflect the sun's rays, but that now that effect was no longer produced, as the copper had since become incrusted with mould and verdigris."

From these circumstances our author conjectures, and we think reasonably, that the magnificent city of which these appear to be part of the ruins, has been destroyed partly by an earthquake by which the rock was rent, and partly by a sudden inundation of the sea occasioned by this commotion of the earth. The bramins give an account of this matter peculiar to themselves, filled with extravagance, fable, and folly; from which, however, with the aid of the inscriptions of ancient monuments, coins, and inscriptions, some probable conjectures at least, if not important discoveries, may, it is hoped, be made on those subjects, which are far from being uninteresting to us either as men, philosophers, or Christians. Our author thinks, therefore, that the inscriptions on the pagoda mentioned above is an object which merits considerable attention; and he concludes, on very reputable authorities, the conjecture which places it among the languages of Siam; but which it is unnecessary for us either to abridge or to transcribe. In the course of this
having merited it by these labours." And again he says, "For this God, above all others, they seem to have an high respect and devotion," &c.

Such is the nature of Mr Chambers's communication, as far as it respects pagodas; a subject to which the Asiatic Society will doubtless again direct their attention; and from the penetration and affluence of its members we have much to expect. Other parts of this paper shall be brought forward under other articles, to which we refer. Few researches of any service to true religion, than those which give us a correct view of the false and feeripitious modes of worship practised by men who have had no light but reason, or weak and corrupted traditions. They are useful likewise to the philosopher, as they always tend to give us a minute view of the real nature of man as he is in himself, and show with sufficient strength the imbecility of the human intellect without some supernatural aid. The external pomp of all Pagan religions seems to have been their elegance; a circumstance which alone shows the necessity of that, the intention of which is to reform the heart. See SIAM, SOMMONACDODN, TEMPLE, &c.

Pagod, or Pagoda, is also the name of a gold and silver coin, current in several parts of the East Indies.

PAIN, an uneasy sensation, arising from a sudden and violent solution of continuity, or other accident in the nerves, membranes, vesicles, muscles, &c. of the body. Pain, according to some, consists in a motion of the organs of sense; and, according to others, it is an emotion of the soul occasioned by those organs.

As the brain is the seat of sensation, so it is of pain. Boerhaave, and most other authors on this subject, assign a stretching of the nerves as the only immediate cause of pain; but as the nerves do not appear to consist of fibres, this cause of pain does not seem to be well founded; nor indeed will it be easy to treat this subject clearly, but in proportion as the means of sensation are understood.

Many kinds of pain are met with in authors; such as, A gravitational pain; in which there is a sense of weight on the part affected, which is always some fleshly one, as the liver, &c. A pulsating pain; which Galen says, always succeeds some remarkable inflammation in the containing parts, and is observed in abscesses while suppurating. A tense pain, which is also called a distending pain; it is excited by the distention of some nervous, muscular, or membranous part, either from some humour, or from inflammation. An acute pain is, when great pain is attended with quick and lively sensations: A dull pain is, when a kind of numbness is as much complained of as the pain is.

The immediate and more remote causes of pain are generally obvious; and when so, the cure will consist in the most part in removing them; for though in many instances the chief complaint is very distant from the seat of these causes, yet their removal is the proper method of relief. See MEDICINE, PAIN.

Perhaps all pains may be included, with irritation, in those that have pain or inflammation for their source. When pain is owing to inflammation, the pulse is quicker than in a natural state; it is also generally full, hard, and tense; the pain is equal, throbbing, and unremitting. If a pain is the cause, the pulse is rarely affected; at intervals the pain abates, and then returns with...
P A I N T I N G.

Painting is the art of representing to the eyes, by means of figures and colours, every object in nature that is discernible by the sight; and of sometimes expressing, according to the principles of physiognomy, and by the attitudes of the body, the various emotions of the mind. A smooth surface, by means of lines and colours, represents objects in a state of projection; and may represent them in the most pleasant dress, and in a manner most capable of enchanting the senses. Still farther the objects which delight us by their animation and lively colours, speak to the soul, by giving us the image of what we hold most dear, or by indicating an action which inspires us with a taste for innocent pleasures, with courage, and with elevated sentiments. Such is the definition, and such are the effects of painting.

By an admirable effort of human genius, painting offers to our eyes every thing which is most valuable in the universe. Its empire extends over every age and country. It presents to us the heroic deeds of ancient times as well as the facts in which we are more conversant, and distant objects as well as those which we daily see. In this respect it may be considered as a supplement to nature, which gives us only a view of present objects.

The art of painting is extremely difficult in the execution; and its merit can only be appreciated by those who profess the art.

The painter who invents, composes, and colours conceptions which are only agreeable, and which speak merely to the eye of the spectator, may be reckoned to possess the first merit in the style of embellishment and decoration.

The painter who is distinguished for noble and profound conceptions; who, by means of a perfect delineation, and colours more capable of fixing the attention than dazzling the eye, conveys to the spectator the sentiments with which he himself was inspired: who animates them with his genius, and makes a lasting impression on their minds; this artist is a poet, and worthy to share in the glories of Homer.

It is in forming this great idea of his art that the painter becomes himself great. But if he seek only to please or astonish by the illusion of colours, he must rest contented with the secondary merit of flattering the eye with the variety and opposition of tints, or of making an indistinct assemblage of a great multiplicity of objects. It is in painting as it is in poetry. The man who clothes trivial or common ideas in verse, exercises the profession of twisting syllables into a certain measure. The poet who clothes in good verse ideas and sentiments, that are merely agreeable, professes an agreeable art. But he who, by the magic of verse, of ideas, of imagery, or of colours, adds sublimity to the sublime objects of nature, is a great poet and a great painter. He defends the crown which the nations have decreed to Homer, Virgil, Milton, Raphael, and the statuary who modelled the ancient Apollo. It is reasonable to place in the same class those who have expressed the same ideas, whether it be in verse or in colours, on brass or on marble. The painter and statuary, who excel in their professions, deserve all the respect due to genius: they are of the number of those men whom nature, spars of her best gifts, grants but occasionally to the inhabitants of the earth. If they are sublime, they elevate the human race; if they are agreeable only, they excite those sweet sensations necessary to our happiness.

In laying before our readers a succinct account of this noble art, we shall, first, give the history of painting, including its rise, progress, and decline, in ancient and modern times; an account of the schools, and of the different merits of painters; and a comparison between the ancient and modern painting. Secondly, we shall lay down the principles of the art, and the order in which the artist conducts his studies. Thirdly, we shall enumerate the different classes of painting, with observations on each. And, Fourthly, we shall treat of economical or house-painting.

HISTORY.
HISTORY.

Sect. I. Rise, Progress, and Decline of Painting in Ancient and Modern Times.

It is to be imagined that men must naturally, and very early, have conceived an idea of the first principles of the art of painting; the shadow of each plant and animal, and of every object in nature, must have afforded them the means of conceiving, and pointed out the possibility of imitating, the figures of all bodies. Thus the savage nations, an emblem of what men were in the infancy of society, possessed the first rudiments of this art, even before those which are useful and almost necessary to existence; their naked bodies are covered with punctures of various forms, into which they infusion indelible colours. The next demand for this art, is to preserve the memory of war-like exploits. It is more natural to form some of the Egyptians, and the more artful hieroglyphics of Egypt.

Painting consisted of simple outlines long before the expression of relief or the application of colour. It was simply drawing; and the master-pieces of painting in that rude period were not superior to the sports of children. Although occupied about a single point, it was not brought to perfection; for constant experience instructs us that men never excel in the inferior parts of an art till they are capable of carrying the whole to perfection.

After employing for a long time those simple outlines, the next step in the art of painting was to make the imitation more complete, by applying colours; this was first accomplished by covering the different parts of the figure with different colours in the same way that we colour maps; and several nations, as the Egyptians, the Chinese, and the different nations of India, have never painted in a better manner. Other nations, more ingenious and more attentive to the arts, observing that the objects of nature have relief, have invented what is called clairobscur. The Greeks, the most ingenious, penetrating, and delicate of all, invented this part antecedent to colours; than which there cannot be a greater proof of their exquisite taste, as the glare of colours without judgment excites more admiration in the minds of the vulgar and ignorant, than the camais or drawings of one colour executed by the most skilful artists.

These general observations concerning the gradual improvement of this art, will be best illustrated by a more particular attention to the ancient nations in which it flourished.

Plato, who lived 400 years before the Christian era, informs us that painting had been practised in Egypt for ten thousand years; that some of the productions of that high antiquity were in existence; and that they bore an exact resemblance to those which the Egyptians executed in his time. Without regarding the period of ten thousand years mentioned by Plato, it is reasonable to consider it as an indeterminate period, which carries us back to very remote antiquity.
It appears that the great employment of the Egyptians was on earthen vessels, in drinking-cups, in ornamenting barges, and in covering with figures the chests of mummies. They painted also on cloth; but painting, as an indolent occupation, supposes a workman, not an artist: the decoration of temples, house-painting, and that of the figures relative to religion, are to be considered only in this point of view. The workmen in Ruffia who paint our Saviour holding the globe in one hand, and blesting the people with the other, are not members of the imperial academy of fine arts.

Pliny informs us that the Egyptian artists painted also the precious metals; that is to say, they varnished or enamelled them. It is doubtful what this art was, but most probably it consisted in covering gold or silver with a single colour.

The Egyptians are supposed to have continued this coarse style till the reign of the Ptolemies. The Persians were so far from excelling in the arts, that the paintings of Egypt were highly esteemed among them after they had conquered that country.

The carpets of Persia were of great value in Greece, even in the time of Alexander the Great, and these were adorned with various figures; but this is no proof that they were well executed, any more than a demand for several of the Egyptian productions is at present a proof of the taste of that people in the arts. It was the fabrication of the silk, and not the truth of the representation, which made the Greeks admire the carpets of Persia.

The Persians, as well as the Arabsians, had some knowledge of Mosaic work. This is only valuable when it copies, in a manner that cannot be destroyed, the works of a great master; but if the Persians had no good pictures to copy into Mosaic, it was of no consequence to be able to arrange, in a solid manner, pieces of flint one before another.

There is only one Persian painter whose name has descended to posterity; and he is preferred, not because he was a painter, but because he accommodated the ancient doctrine of the two principles to the Chirilian religion. Besides, it is doubted whether Mansa was a Persian or a Greek, and it is still left unknown whether he was a painter. He is praised in Asia for drawing straight lines without a ruler.

The modern Persians have made no kind of progress in the arts. The emperor Shab-abbas, wishing from caprice to be instructed in drawing, was obliged to have recourse to a Dutch painter who happened to be in his dominions.

The modern Persians paint on cloth, and the art of painting in India are their rivals in this branch of industry; but their paintings are purely capricious. They represent plants and flowers which have no existence in nature; and their only merit consists in the brilliancy and the strength of their colours.

Besides this, the art in India, as it was in the most remote antiquity, is confined to monstrous figures connected with their religion, animals not to be found in the world, and idols with a multitude of arms and heads, which have neither exactness in their forms nor proportion. See POLYTHEISM.

The paintings of Thibet discover great patience in the artist, and are remarkable for the fineness of their strokes. Their painters might dispute with Apelles and Protogenes for extreme tenuity of pencil; but it is in this alone, without any regard to the art, in which their merit consists.

Some of the idols in Thibet are executed in a certain style of relieve; but these productions are not only imperfect, they are also so defective of beauty as to forbid every hope of excellence in the art. The same thing may be observed with regard to many of the eastern nations; they seem to have that want of style which would ever condemn them to mediocrity, even if they should happen to arrive at it.

An obscure Italian painter, named Giovanni Ghirar. In China, disi, who travelled into China, whose judgment is more to be depended on in an art which he practised than that of other travellers, declares that the Chinese have not the least idea of the fine arts; and this opinion is confirmed by every thing which we know of that people.

The Chinese seem not to have the smallest conception of perspective. Their landscapes have no plan, no variety in the appearance of the clouds, and no diminishment of the objects in proportion to their distance.

The great object of their painting seems to consist in making their figures as unlike nature as possible: it is a serious caricature of the human figure.

To make the art flourish, it is necessary that the artist be esteemed and rewarded. In China, there is no artist so poorly paid as the painter.

The ignorant admire the brilliancy and purity of their colours; but simple colours appear always bright and pure: the difficulty of the art consists in melting them into one another in such a manner that the mixture shall not be perceived. It must at the same time be confided, that their natural colours are more brilliant than ours; but if their be any merit in this, it is to be ascribed to their climate, not to their ability.

A Jesuit millionnaire, who in his youth had been a grinder of colours, was raised to the greatest eminence as a painter in the Imperial court of China, and Raphael himself was never so much respected. The Chinese battles sent from that country to Paris to be engraved, are the works of the Jesuits; and except they were done by the Chinese themselves, it is impossible to conceive that they could be worse executed.

The Chinese, like other eastern nations, have a few simple strokes which they repeat in all their variety of figures. In the figures on the earthen ware, they discover no knowledge of forms, no expression of the most conspicuous muscles, and no idea of proportion. And in all the paintings of China, anatomy seems to bear no relation to the art. Some heads done by a Chinese painter have a sort of resemblance to nature, but they are in a low and vicious taste: the fineness of the drapery conceals the parts in such a manner that they do not seem to exist under it. Sculpture in China is in a state of no great perfection, but at the same time it is better executed than their paintings.
The ancient inhabitants of Etruria, now called Tuflany, were the first who connected the arts with the study of nature. In some of their monuments which still remain, there is to be observed a first style, which shows the art in its infancy; and a second, which, like the works of the Florentine artists, shows more of greatness and exaggeration in the character than precision or beauty.

Pliny says that painting was carried to great perfection in Italy before the foundation of Rome; perhaps he means in comparison with the infancy of the art in Greece at that period, but it appears that even in his time the painters of Etruria were held in great reputation.

The only Etrurian paintings which remain, have been found in the tombs of the Tarquins. They consist of long painted frizes, and pilasters adorned with huge figures, which occupied the whole space from the base to the cornice. These paintings are executed on a ground of thick mortar, and many of them are in a state of high preservation.

Winklemann is of opinion that the Greek colonies established at Naples and Nola, had at a very early period cultivated the imitative arts, and taught them to the Campanians, established in the middle of the country. This learned antiquarian considers as works purely Campanian, certain medals of Capua and Teanum, cities of Campania into which the Greek colonies never penetrated. The head of a young Hercules, and the head of a Jupiter, according to Winklemann, are executed in the finest manner. It is full a question, however, in the learned world, whether these medals owe their exuisite to Carthage or to Campania.

But there have been discovered (adds Winklemann) a great number of Campanian vases covered with painting. The design of the greatest part of these vases (says he) is such, that the figures might occupy a distinguished place in a work of Raphael. These vases, when we consider that this kind of work admits of no correction, and that the stroke which forms the outline must remain as it is originally traced, are wonderful proofs of the perfection of the art among the ancients. Winklemann had an opportunity of examining a very fine Campanian vase, on which was painted a burlesque representation of the loves of Jupiter and Alcmena. But as this must have been derived from some fragment of a Grecian comedy, the Count de Caylus is persuaded that the Campanian vases are of Greek origin.

Although the history of Greek painting be more fully known than that of the same art among the barbarous nations, it is nevertheless involved in much obscurity. Pliny is almost the only author who has preserved the materials of its history; and he complains, that on this occasion the Greek writers have not discovered their usual exactness. They place, says he, the first painter of whom they speak in the 90th Olympiad, 420 years before the Christian era. It is certain that painting in dry colours existed at the time of the siege of Troy, or at least when Homer wrote the account of it. The buckler of Achilles is a sufficient proof that the Greeks were then acquainted with the baffe-relieve, a kind of sculpture which bears a near affinity to painting.
of the painting among the ancients, at Rome by the command of Nero, The colours employed, seem to have mixed up with size, which they preferred to make by boiling the eggs, and genitals of bulls. This appears to have made the colours so durable and adhesive, that the ancient paintings lately found bear washing with a soft cloth and water; and sometimes even diluted aquafortis employed to clean their paintings on fresco. Pliny says that glue dissolved in vinegar and then dried, is not again soluble.

What the encaustic painting of the ancients was, has been much disputed. From the works of Vitruvius and Pliny, it appears evidently that it was of three kinds:

Firstly, where a picture painted in the common way, was covered with a varnish of wax melted, diluted with a little oil, and laid on warm with a brush.

Secondly, where the colours themselves were mixed up with melted wax, and the mixture used while warm. And,

Thirdly, where a painting was executed on ivory by means of the eugrum or varium.

Some experiments on this last method by Mr. Colebrook may be found in the Phil. Trans. vol. 51, and more particular directions in Monte's Tractatus de Encaustic Painting.

It appears from ancient writings of the best authority, that in the earliest and purest times of this art, the painters used few colours, perhaps not more than four. "The paintings of the ancients (Says Dionysius Halicarnasseus) were simple and unvaried in their colouring, but correct in their drawing and distinguished by their elegance. Those which succeeded, less correct in their drawing, were more finished, more varied in their light and shades, trusting their effect to the multitude of their colours." But no certain conclusion can be drawn, that the more early among the great painters of the ancients, such as Apollodorus, Zeuxis, Timanthes, &c. had no more colours than four to use, merely because they did not use them. On the contrary it may be conjectured with some degree of probability, from their charteis in design, and from the complaints Pliny makes of the gaudy taste of the Roman painters, that the Greeks in general were disinterested in their colouring, and not so merely from necessity, at least about the time of Zeuxis and Apelles; for the former could not have painted grapes so naturally as he is said to have done, with four colours only; and the rubake given by the latter to one of his scholars who had painted an Ilen very gaudily, is a confirmation of these observations. "Young man (say Apelles), not being able to make her beautiful, you have made her rich."
Whether the ancients painted in oil.

Of blue, the ancients had preparations similar to lamp, ivory, blue, and Frankfort black; also to Indian ink and common writing ink; and they used, what we do not, the precipitate of the black dyers vats.

The ancients poiffled a species of vermilion or fine cinnabar, a coarser cinnabar, red-led, various earths burnt and unburnt, apparently similar to our red ochre; Venetian red, Indian red, Spanish brown, burnt terra di Siena, and scarlet ochre; they had also a substance alike in colour and in name to our dragon's blood.

The yellow pigments of the ancients were generally the same with our orpiment, king's-yellow, Naples yellow, &c. They did not poiffle turb-thorium, mineral-yellow, or gamboge nor do they appear to have known of gall-flame as a pigment.

Of blue paints they had preparations from the lapis lazuli and laps lazurites. Indigo they had, and perhaps bice and smelt; for they made blue-glaze, but whether from some ore of cobalt or of wolfram must be uncertain: they had not Prussian blue, verditer, or litmus, which we have. We do not use the blue precipitate of the dyers vats, nor mountain blue, which they certainly employed.

Of green colours, they had verdigris, terra vert, and malachite or mountain green. The latter is not in use among us. Sap green, green verditer, and Scheele's green, appear to have been unknown to them: like us, they procured as many tints as they pleased from blues and yellow vegetables.

We have no original purple in use; that from gold by means of tin, though very good when well prepared, is too dear perhaps, and unnecessary. Their purple was a tinged earth. Their orange or scarlet (red orpiment) we also poiffle. Hence there does not appear to have been any great want of pigments, or any very material difference between the colours they used and such as we generally employ. Perhaps the full effect of colouring may be obtained without the use of the exceeding brilliant pigments, depending chiefly on the proportion and opposition of tints.

The ancients could not know any thing about the finest varnishes, dilution being a modern invention; but they were undoubtedly acquainted with the use of the better oil varnishes, that is with the use and effect of refined gums dissolved in boiling inspissated oils.

One of the best preserved mummies in the British museum has an astonishing brightness of colours on the outside of the coffin. Thousands of years have not impaired them; they are as fresh as if they had been laid on yesterday.

The chalk ground, and the excellency of the colours, some of which imply a good deal of chemical and metallurgical knowledge, do not sufficiently account for their splendour and freshness: it must be owing to other circumstances; either to the mixture of thinning colours, or to a hard glossy skin which visibly covers them all over.

From an accurate examination of one of those mummies belonging to the university of Cambridge, it appeared, that the varnish which covered the colours could not be dissolved, or in the least affected by common water; and that equally refle's the dissolving power of the strongest spirits: hence it is reasonable to conclude, that the coffins of the mummies were not covered with fine, whites of eggs, simple gums, or any preparation of wax, but with a fine transparent oil varnish. It was discovered at the same time, that the colours themselves were not prepared or mixed with oil; for where the external glossy skin was damaged, broken or rubbed off, even common water would wash the colours away, and affect the chalk ground under them.

Pliny has described the general and particular effects of the varnish of Apelles, under the name of at. ecol., so distinctly, that no body can mistake the thing or the mixture he is speaking of. He has mentioned the thinning glossy skin of the varnish which excites the brightness of the colours, and preserves them against durt: he observed, that this skin was laid on to thin, that it could not be disarranged at any distance: nor was he less accurate in reporting the particular effects of that mixture which Apelles made u of; it harmonized and lowered the tone of the brightest florid colours, in an imperceptible manner, and the whole appeared a shade finer than through thin glazes. The chemists and painters are fully of opinion, that no liquid substance or mixture of any kind is fit to produce these effects besides the oil varnishes; and if there are not, Apelles and the Greeks were certainly acquainted with those varnishes; a fact which might be strongly urged in behalf of their knowledge of oil colours.

The black outlines of the figures on the most ancient Greek paintings yet extant, that is, on Etruscan vases, are so sharp, so thick and drawn in so easy and matterly a manner, that one cannot help looking upon them as having been drawn in oil colours. Had they been in distemper or water colours on the red clay ground on which they are applied, they would have been imbibed and foaked into it. Our china and enamel painters prepare and apply their colours with spirit or other liquid oils; and the Greek masters seem to have done the same, unless they held appear to have burnt their vases before they painted them, or to have used a mixture of dissolved wax or gum for giving a body to their colours, which might have answered the same end as oils. And this is the more probable, as there is from reason to believe that these vases went through two different fires, that of baking them, and that of smelting or burning in their colours.

The Greek and Roman paintings that have been preferred or discovered at Rome and Herculaneum do not countenance the supposition of oil colours; at least Turnbull and the academists at Naples, who have described the royal collection at Portici, Couchin, and many other authors who have seen and described them, do not hint any thing of that nature. On the other hand, Vitruvius, who has left us so many valuable notices of the ancient arts, acquaints us, that there was a kind of painting which absolutely required a mixture of oil: And Pliny, to the same purpose, expressly says, "Sun and moon shine are inimical and obnoxious to red lead. The remedy is to apply the red wax when hot and melted with some oil on the well-dried walls, which is to be done with brushes."
From these observations, the evidence which the ancients have given us in behalf of themselves, and of their knowledge of oil painting, may be summed up in few words.

Their having been acquainted with the white chalk ground, which many modern masters have used for oil painting on boards, proves no more than that the ancients might have done the same.

The oil varnishes used by the Egyptians and by Apelles might have brought them to the discovery of oil painting; but as it appears both from mummies and from the works of Pliny, that their colours were not prepared and mixed with that varnish, and as it is plain rather that this varnish was externally laid over the finished pictures, no other conclusion can be drawn, except that they were within sight of the discovery, and that it is a matter of wonder that they should not have laid hold of it.

The outlines of the old Greek or Etruscan vases are merely fallacious appearances.

The old Greek and Roman paintings on walls and fames are either painted in distemper and fresco, or they have not been sufficiently examined.

The oil used in the covers wax and wall paintings, proves at most that experiments that had been tried with oils; but we have no direct proofs of oil painting having been understood or used by the Egyptians, Greeks, or Romans; and that, however great their skill or ingenuity, they might very well have been within sight and reach of the discovery, and neverthe\'less have missed it.

The art of painting was revived in Europe about the end of the 14th or beginning of the 15th century. The human mind, however, plunged in profound ignorance, was delirious of every principle of sound philosophy. It might enable it to determine on the objects of the arts; and of consequence the painters contended themselves with works adapted to the general taste, without beauty and without proportion. In Italy, where the first attempts were made, they were employed in representing the mysteries of the passion, and subjects of a similar nature, on the walls of chapels and churches. Their labours were directed to a vast number of figures, rather than to the beauty and perfection of each; and the art in more modern times has always preserved somewhat of this absurd fault which it contracted at that early period. The artists in our times is not, like those in Greece, at liberty to devote his talents only to men of knowledge and applause; he is constrained to please those who are rich, and very frequently those who are ignorant. Instead of proposing to himself the perfection of the art as the great object of his pursuit, he must first of all succeed, and character on the facility of his operation and the abundance of his works.

Painting did not long continue in the imperfect condition in which it was left by those who first cultivated it among the moderns. It was natural that their successors should endeavour to surpass them by joining some degree of theory to the barbarous practice they had adopted. The first thing which they discovered, or rather which they revived after the manner of the ancients, was perspective. This made the artists capable of expressing what is called foreshortening, and of giving more effect and more truth to their works.

Dominiqve Ghirlandais, a Florentine, was the first who enriched the style of his composition by grouping his figures, and who gave depth to his pictures, by diluting, by exact gradations, the spaces which his figures occupied; but his successors have far surpassed him in boldness of composition.

Leonard da Vinci, Michael Angelo, Giorgion, Titian, Bartholomew de St Marc, and Raphael, flourished about the end of the 14th century. Leonard da Vinci was the inventor of a great many details in the art: Michael Angelo, by studying the ancients and by his knowledge of anatomy, arrived at great elegance in drawing the outlines of his figures: Giorgion enriched the art in general, and gave greater brilliancy to his colours than his predecessors: Titian, by a careful imitation of nature, made great proficiency in the truth and perfection of his tones: Bartholomew de St Marc studied particularly the part of drapery, and discovered the chiaro-obscur, the best manner of giving drapery to his figures, and of making the naked to be felt even where they were covered: Raphael, endowed with a superior genius, began with studying carefully all his predecessors and all his contemporaries. He united in himself all the excellencies which they possessed; and formed a style more perfect and more universal than any painter who went before or who has succeeded him. But while he excelled in every part of the art, he was chiefly superior in that of invention and of composition. It is probable that the Greeks themselves would have been filled with admiration if they had beheld his chief pieces in the Vatican, where to the greatest abundance of paintings is joined so much perfection, and purity, and ease.

After painting had arrived at the greatest perfection among the Greeks by the exertions of Zeuxis and Parrhasius, Apelles found nothing to add to the art except grace; in the same manner among the moderns, after Raphael had appeared, grace was the only thing wanting to the art, and Correggio became the Apelles of Europe. Painting was by him carried to the highest degree among the moderns; the taste of the best critics and the eye of the vulgar were equally gratified.

After these great masters a considerable interval elapsed till the time of the Carracci. These artists, born at Bologna, by studying the works of their predecessors with great care, and particularly those of Correggio became the first and the most celebrated of their imitators. Hannibal possessed a very correct design, and united somewhat of the ancient style to that of Lewis his brother; but he neglected to inquire into the intricate principles and philosophy of the art. The pupils of the Carracci formed a school after their manner; but Guido, a painter of an easy and happy talent, formed a style altogether graceful, and rich, and easy. Guerfen formed after Caravaggio, or invented himself a particular style of the chiaro-obscur, composed of strong shades and vivid oppositions.

Peter de Cortone succeeded those great imitators of their predecessors and of nature; who finding it difficult to succeed in that kind of painting, and having besides great natural abilities, applied himself chiefly to composition or arrangement, and to what the artists call taste. He distinguished invention from composition; appeared not to have attended to the former,
but chiefly in those parts which are most prominent in the picture, and to the contriving of groups. It was then that the practice was introduced of loading pictures with a great number of figures, without examining whether or not they agreed to the subject of the history. The ancient Greeks employed a very small number of figures in their works, in order to make the perfection of those which they admitted more evident. The disciples or imitators of Cortona, on the other hand, have sought to conceal their imperfections by multiplying their figures. This school of Cortona is divided into many branches, and has changed the character of the art. The multiplication of figures, without a judicious and proper choice, carried back the art of painting to that point where the first restorers of it among the moderns had left it; while at the same time the disciples of Cortona were enabled to give to this first condition of the art a greater degree of perfection than the first artists.

About the middle of the 17th century flourished at Rome Carlo Maratti, who, aiming at the greatest perfection, carefully studied the works of the first painter, and particularly those of the school of the Caracci. Although he had already studied nature, he discovered by the works of these artists that it is always proper to imitate her with a ferupulous exactness. This principle, which he extended to every part of the art, gave to his school a certain style of carefulness, which however is considerably degenerated.

France has also produced great masters, particularly in the part of composition; in which Pouffin, after Raphael, is the best imitator of the style of the ancient Greeks. Charles Le Brun and many others distinguished themselves for great fertility of genius; and as long as the French school departed not from the principles of the Italian school, it produced masters of merit in the different branches of the art.

Mengs, from whom this account is taken, is not deceived when he declares the art of painting to have degenerated in France after Le Brun; but he seems to be mistaken in giving the imitation of the works of Rubens found at Paris as the cause of this decay. It appears from this opinion, that the recent French school was not well known to him. The French, indeed, if we may believe their own authors, were never much occupied in the imitation of Rubens; and they have for a long time despised him. But the preference of the dramatic art in France, the dress of their actors, the magnificence and manners of the court, have contributed very much to the decay of painting. Instead of forming their taste on the beautiful simplicity of nature, their painters studied the gestures and the attitudes of comedians, the fopperies of women of fashion, the affected airs of courtiers, the pageantry of Versailles, and the magnificence of the operas. Mengs says, "that the French have formed a national style, of which ingenuity and what they call spirit are the discriminating qualities; that they have ceased to introduce Greek, Egyptian, Roman, or barbarian personages into their paintings; and that, after the example of Pouffin, they content themselves with figures altogether French, as if it were their intention to hand down to posterity that such a nation once existed."

Since, according to the confession of Mengs, their figures are altogether French, there is no reason to believe that the French painters have imitated Rubens, whose works are marked more strongly than those of his master Anuex with his Flemish character. The truth is, that their painters, like Cortona and Maratti, have crowded their pictures with a great number of figures; have grouped them in a manner most calculated to strike the senses; have been more intent on agreeable figures than expression and beauty; and, finally, that they have borrowed the manners of the court and the theatre.

The first masters of the great schools of painting, with the ancients and nature for their guides, and their genius for their support, carried every part of the art to the greatest height of perfection. Those who followed them, and who had the example of their predecessors in addition to the first sources of truth and beauty, did by no means arrive at the same excellence. The Caracis in their school, Paul Veronese, and all the painters of his time, Vandyke, and all those who excelled the art in Italy, in Flanders, and in France, surpassed it with great brilliancy. But after the number of artists was multiplied; and flavishly copying men of inferior talents, they produced works of an inferior nature. Some wanting to be colourists, their pieces were exaggerated; others affecting simplicity became cold and inodiferous. At this period of the art, men of real abilities, and connoisseurs of fame, who wished to rise superior to the mediocrity of the times, seem not to have taken the road of truth and nature. They affected a style of pompous preparation, and annexed a kind of merit to the expert management of the pencil. The affected forms of Cortona and of his pupils, the fantastical attitudes and the poignant effect of Piazzetta, and in short the ingenious contrivances of the last masters of the French school, are decided proofs of this increasing bad taste.

It appears, that for some time past greater pains has been taken to form men for the art than to encourage those who possess the talent. In consequence of this ruinous practice, schools for drawing, very different from those formed by able painters, have been exceedingly multiplied; and these give the elements according to an uniform system, by which the mind is led under a regular restraint at the very threshold of the profession. This evil is productive of two inconveniences; it gives middling painters, and it multiplies them to that degree, as to half the downfalls and bring into contempt the art itself.

The particular reputation of the Italian painters furnishes another reason for the decline of the art. The first painters of that country were few in number; they were honoured, and they deserved to be honoured. Their distinguished reputation has conferred a value on the general paintings of their countrymen. The desire of possessing taste, or of being thought to possess it, has led the rich and the ignorant of all nations to give a preference to the Italian market. Necessity, in this case, would multiply the painters; and their abilities must bear a pretty exact proportion to the discrimination of those who give the price.

The decline of painting has also arisen from the delusion which for some time reigned in the academic faculties. In fact, these have often been ruled by men
men who would force every exertion of genius into their peculiar tract of operation. If they required such or such merit of execution, the first principles of the art were neglected for that peculiar excellency. In this manner the schools were absolute in behalf of design as long as flattery was held in chief estimation. The artist, whose abilities and inclinations led him to colouring, was obliged to abandon a pursuit which could be of no service to him, and devote himself to that for which he was not qualified by nature. On the other hand, if the instruction of the school be confined to colouring, a mind disposed to the choice and exquisiteness of forms will find no encouragement, and be for ever lost to the art. In this manner the ignorance of the few who wish to be connesseurs, and the narrow views of those who pretend to direct the general taste, have equally contributed to the decline of the arts.

Sect. II. Of the Schools.

A School, in the fine arts, denominates a class of artists who have learned their art from a certain master, either by receiving his instructions, or by studying his works; and who of consequence discover more or less of his manner, from the desire of imitation, or from the habit of adopting his principles.

All the painters which Europe has produced since the renovation of the arts are classed under the following schools: the School of Florence, the school of Rome, the school of Venice, the Lombard school, the French school, the German school, the Flemish school, the Dutch school, and the English school.

This school is remarkable for greatness; for attitudes seemingly in motion; for a certain dark severity; for an expression of strength; by which grace perhaps is excluded; and for a character of design approaching to the gigantic. The productions of this school may be considered as overcharged; it cannot be denied that they profess an ideal majesty, which elevates human nature above mortality. The Tuscan artists, satisfied with commanding the admiration, seem to have considered the art of pleasing as beneath their notice.

This school has an indubitable title to the veneration of all the lovers of the arts, as the first in Italy which cultivated them.

Painting, which had languished from the destruction of the Roman empire, was revived by Cimabue, born of a noble family in Florence in the year 1240. This painter translated the poor remains of the art from a Greek artist or two into his own country. His works, as may easily be imagined, were in a very ordinary style, but they received the applause and admiration of his fellow-citizens; and it Cimabue had not found admirer, Florence in all probability would not have been honoured with Michael Angelo. The number of painters became soon so considerable in Florence, that in the year 1350 they established a society under the protection of St Luke.

Michael Angelo, towards the beginning of the 16th century, gave more grandeur to his figures, adjusted their drapery better, and filled them with some kind of life and expression. He was surpassed by Donatello his pupil, who first gave life, animation, and relief to his works.

PAIN TING.

Andrew Callagana was the first Florentine who painted in oil. But Leonardo da Vinci and Michael Angelo, contemporary painters, were the glory of the School of Florence. Michael Angelo was superior to Leonardo in grandeur, in boldness of conception, and in knowledge of design; but Leonardo was superior to him in all the minute parts of the art. Leonardo, polished of a fine imagination, and full of sensibility, devoted himself in painting to express the affections of the soul; and if in this sublime branch of the art, he was afterwards surpassed by Raphael, he had at least the glory not only of exceeding all the painters who went before him, but of putting a path which none of them had attempted. His design was pure and neat, and not wholly destitute of greatness. He never went beyond nature, and he made a good choice of objects for imitation.

Michael Angelo, left to form his experience of the arts as than vehement passions, sought in nature what the strength of man might accomplish, not that which constitutes beauty. He delighted in being great and terrible, more in than graceful and pleasant attitudes. Well acquainted with anatomy, he knew more exactly than any other artist in what manner to express the joining of the bones of the body, and the sense and motion of the muscles; but too eager to display his knowledge of anatomy, he seems to have forgotten that the muscles are softened by the skin which covers them; and that they are left visible in children, in women, and in young men, than in hurried and vigorous manhood. In his figures (ays Mengs) the articulations of the muscles are so easy and free, that they appear to be made for the attitude in which he represents them. The flabby parts are too much rounded, and the muscles are in general too large and too equal strength. You never perceive in his figures a muscle at rest; and although he knew admirably well how to place them, their action is very frequently inconsistent with their situation.

He did not pose (ays Sir Joshua Reynolds) for many delightful parts of the art as Raphael; but those which he had acquired were of a more sublime nature. He saw in painting little more than what might be attained in sculpture; and he confined it to enlargements of form and the expression of passions.

He informs us, in one of his letters that he modelled in ear or wax all the figures which he intended to paint. This method was familiar to the great painters of his time, and ought never to be abandoned. It appears that in representing them in this manner in relievo, the painter can increase them much more exactly than when they are drawn with a crayon or pencil on a plane surface.

Michael Angelo (continues Sir Joshua Reynolds) never attempted the lesser elegancies and graces in the art. Valanti says, he never painted but one picture in oil; and resolved never to paint another, saying it was an employment only fit for women and children.

If any man had a right to look down upon the higher accomplishments as beneath his attention, it was certainly Michael Angelo; nor can it be thought strange, that such a mind should have flattered, or have been withheld from paying due attention to all those graces and embellishments of art which have diffused such lustre over the works of other painters."

Ancient
PAINTING.

History.

Ancient Rome, rich with the works brought from Greece, or imitated in its own bosom by Grecian artists, handed down in its ruins the remains of that glory to which it had been elevated. It was by the study of these remains that the modern artists were formed: they derived from them the knowledge of design, the beauty of exquisit forms, greatnec of style, and justness of expression, carried to that length only which did not affect the beauty of the figure. From them also they derived the principles of the art of drapery; and they followed their principles even while they made the drapery of modern paintings more grand and flowing than what was prized by the ancient sculptors. The Roman school was altogether devoted to the principal parts of the art, to those which require genius and vast conceptions; and was no farther occupied with colours than what was necessary to establish a difference between painting and sculpture, or rather between painting varied with colours and in cloro-obscuro.

Raphael Sanzio, born at Urbino in 1483, and scholar to Pietro Perugeno, was the undoubted founder of this school. His first manner was that of Perugeno his master; but he travelled twice to Florence to study the great artists who flourished in that city.

It was fortunate for Raphael, says Mengs, that he was born in what he terms the infancy of the art, and that he formed himself by copying nature before he had access to see the works of any great master. He began by imitating, with great exactness, the simple truth in his figures. He was then ignorant that any choice was necessary; but he saw the works of Leonardo da Vinci, of Maffacio, and of Michael Angelo, which gave his genius a new direction. After this he perceived that there was something more in the art of painting than a simple imitation of truth. But the works of these masters were not sufficiently perfect to point out the best choice to make; and he continued in uncertainty till he saw at Rome the works of the ancients. Then he perceived that he had found the true models which he wanted; and in imitating them he had only to follow the natural impulse of his genius.

Habituated by his first manner to imitate nature with precision, it was not difficult to carry the same exactness into the imitation of the ancients; and it was a great advantage to him that he flourished in an age wherein the artists were not arrived at facility of execution, at the expense of rigorous exactness. He never lost sight of nature; but he was instructed by the ancients in what manner the should be studied. He perceived that the Greeks had not entered into minute details, that they had foiled what was great or beautiful; and that one of the chief causes of the beauty of their works was the regularity of their proportions: he began, therefore, to carefully studying this part of the art. He saw also that the joinings of the bones, and the free play of their articulations, are the causes of all graceful movement: he therefore, after the example of the ancients, gave the greatest attention to this part, and was led by these observations not to be contented with the simple imitation of nature.

His design is excellent; but neither so perfect nor so finished as that of the Greeks. He excelled in representing the character of philosopher, apostles, and other figures of that kind; but he did not equal the Greeks in ideal figures, which ought to carry the impression of divinity. His taste for design was more Roman than Greek, because he formed it chiefly on the bas-relieves which he found at Rome. On this account he had the habit of marking strongly the bones and the articulations, and labouring the flithy parts; but as these bas-relieves are very exact with regard to the reciprocal proportions of every member, he excelled in this part, while at the same time he did not give to his figures all the elegance of the Greek artists, nor the flexibility of articulation which is admired in the Laocoon, in the Apollo of Belvidere, and in the Gladiator.

The manners and spirit of his age, and the subjects which he most commonly treated, prevented him from reaching the ideal of the ancients. Having seldom occasion to represent figures altogether ideal, he devoted himself to purity of expression. He knew that the expression of the passions of the soul is absolutely necessary in an art which represents the actions of men, since these affections the actions may be said truly to originate. To make figures act, and yet neglect the interior springs of action, is no more than a representation of automatæ. The attitude and action are evident; but they appear not to act of themselves, because these principles from which alone men are supposed to act. An artist who neglects expression, gives no just representation of character, even though he should take nature for his model.

Raphael's first care, when he wanted to compose a piece, was to weigh the expression; that is to say, to establish, according to the nature of the subject, the passions which were to animate the characters. All the figures, all the accessories, all the parts of the composition, were moulded to the general expression.

As he had not found examples in the ancient statues of cloro-obscuro, he was comparatively weak in this part; and if there was anything remarkable in his distribution of light and shade, it owed it to the works of the Florentine painters. It cannot be said, however, even with regard to the cloro-obscuro, that he imitated nature without taste. He delighted in what are called maffes of light; and disposed the great lights in the most conspicuous places of his figures, whether naked or in drapery. If this method did not produce effects highly illustrious, it gives his works that distincness which makes his figures conspicuous at a distance; and this must be allowed to be an essential part of the art of painting. He did not proceed beyond this; and content with that kind of cloro-obscuro which comprehends imitation, he never attempted that which is ideal.

The composition and the ensemble of his figures were the chief excellences of Raphael. His philosophical mind could not be affected with objects which did not expression. He had too high an idea of painting to consider it as a mute art; he made it speak to the heart and soul; and he could only do this in subjects which required expression. If Raphael did not reach the Greek excellence, if he did not perfect the art of embellishing nature in the same high degree, he saw at leaf, and imitated her in whatever was expressive and beau-
History. Painting.

beautiful. "The Greeks failed with majesty (says Mengs) between earth and heaven; Raphael walked with propriety on the earth."

"Composition is in general (says the same author) of two kinds: Raphael's is the expressive kind; the other is the theatrical or picturesque, which consists of an agreeable dispossession of the figures. Lanfranc was the inventor of this last, and after him Pietro de Cortona. I give the prefernce to Raphael; because reason prevails over all his works, or at least the greatest part of them. He never allowed himself in common ideas, and was never allured to give any thing in his accessory figures which might turn the attention from the principal object of the piece."

A history of the schools is nothing more than a history of the painter, who founded them. In those two which we have already given, Michael Angelo and Raphael, come readily forward to claim our attention; and therefore we cannot do better than conclude the account by his masterly contrast of those eminent painters given by Sir Joshua Reynolds. "If we put those great arts (says he) in a light of comparison with each other, Raphael has more taste and fancy; Michael Angelo more genius and imagination. The one excelled in beauty, the other in energy. Michael Angelo has more of the poetical in operation; his ideas are vast and sublime; his passages are a superior order of beings; there is nothing about them, nothing in the air of their actions, or their attitudes, or the style and call of their limbs or features, that puts one in mind of their belonging to our species. Raphael's imagination is not so elevated; his figures are not so much disjointed from our own diminutive race of beings, though his ideas are chaste, noble, and of great conformity to their subjects. Michael Angelo's works have a strong, peculiar, and marked character; they seem to proceed from his own mind entirely; and that mind is so rich and abundant, that he never needed, or seemed to disdain, to look abroad for foreign help. Raphael's materials, are generally borrowed, though the noble finish is his own. The excellence of this extraordinary man, lay in the propriety, beauty, and majesty of his characters: his judicious contrivance of composition, correctness of drawing, purity of taste, and the skilful accommodation of other men's conceptions to his own purpose."

This school is the child of nature. The Venetian painters, not having under their eyes the Roman remains of antiquity, were deficient of the means of forming a just idea of the beauty of forms and of expression. They copied without choice the forms of nature; but they were chiefly delighted with the beauties which presented themselves in the mixture and the variety of natural colours. Their attention not being detached from this part by any thing of greater importance, colouring was their chief object, and they succeeded in it. They did not rest contented with characterizing the objects by comparison, in making the colour proper for one or more value by the colour, more proper for another; but they endeavoured still further, by the agreement and opposition of the coloured objects, and by the contrast of light and shade, to produce a vigorous effect, to demand and fix the attention. Dominic, who was said to have perished at Florence by the jealousy of André Castagna, and who was the second Italian artist who painted in oil, had educated, before he quitted Venice, his native country, Jacques Bellin, who was remarkable for nothing but the picturesque education which he gave to Giotto and John his two sons.

Gentile, who was the eldest, painted chiefly in water-colours. John contributed much to the progress of his art in painting constantly in oil, and after nature. Although he always retained great stiffness in his manner, he had left him his father or brother. Great neatness of colouring, and an approach to harmony, are evident in his works. His taste in design is Gothic; his air of his heads is sufficiently noble, his attitudes are without judgment, and his figures without expression. He had for scholars Giorgion and Titian, who deserve to be considered as the founders of the Venetian school.

Giorgione distinguished himself by a design of a better taste than that of his master; but he chiefly excelled him in colouring. He died in his 32d year; and excited the emulation of Titian, who soon greatly excelled him.

Tiziano Vecelli, known by the name of Titian, was instructed to copy nature in the most servile manner in the school of John Bellin; but when he had seen the works of Giorgion, he began to study the ideal in colouring.

The truth of history is not to be expected in his historical paintings, or in those of the artists of the same school. He seems to have paid little attention to the confidence of scene, to the colours, to expression adapted to the subject, or, finally, to the accommodation of parts which characterize the works of those who have imitated the ancients. He was in short a great painter, and nothing more.

But although he deserves not to be placed among the most distinguished artists in point of judgment, yet he is by no means deficient of great and noble conceptions. There is often to be found among his male figures a considerable degree of grandeur: but if he has sometimes, like Michael Angelo, overcharged his design, it was more discovered in the swelling of the soft and fleshy parts, than in vigour and muscular strength.

Almost entirely devoted to simple imitation, he had a greater choice in the clairo-obscur than in design. He cannot be justly reproached at the same time for weakness in this particular; because in endeavouring to imitate the colours of nature, he was obliged to observe the degrees of light. And in proportion as he succeeded in the imitation of natural colours, he must be less defective than the clairo-obscur; but it is not in the knowledge of this part of the art that we are to seek for the beauties of his works. These are to be found in the happy dispositions of colours both proper and local, and he carries this to the highest point of perfection.

The arts in the Florentine and Roman schools painted most commonly in water-colours or in fresco; and in the exercise of their profession, instead of nature, they imitated their works from their first sketches. "Titian painted in oil, and followed from the objects in nature; and this praxis, joined to his exquisite talents, gave the greatest truth to his colours. His being a portrait painter was also of advantage to him as a colourist,
PAINTING.

Titian, History.

Schools.

a colourist. In this department he was accustomed to the colours of nature in carvations and draperies. He was a landscape-painter; and here also he took the colours from nature.

As Titian perceived (says Mengs) that the objects which are beautiful in nature have often a bad effect in painting, he found it necessary to make a choice in the objects of imitation; and he observed, that those were objects of which the local colours were extremely beautiful, which nevertheless were in a great measure destroyed by the reflection of light, by the porosity of the body, and by different luminous tints, &c. He perceived also, that in every object there was an infinite number of half tints, which conducted to the knowledge of harmony. In short, he observed in the objects of nature a particular agreement of transparency, of opacity, of ruggedness, and of polish, and that all objects differed in the degrees of their tints and their shades. It was in this diversity he sought the perfection of his art; and in the execution he moderated the effect of natural colours. For example, in a caravaggio which had many demi-tints, he confined himself to one; and he employed even less in a demi-curt, where there were few in the natural object. By this means he obtained a colouring exquisitely fine; and in this part he was a great master, and deserves to be carefully studied.

Titian has in general little expression in his pictures, and he sometimes introduces figures which augment the coldness of the piece; for it is true that the heads, even in historical painting, ought to be studied after nature, it is true also that an individual nature ought not to be presented, but one general and ideal. It is necessary that they should be men, while they resemble not men we are accustomed to see. The painter fails in the effect which he ought to produce, if, when he represents Achilles, Eleonor, and Cesar, his personages are familiar to our observation.

The colours of his paintings are so mingled together, as to give no idea of the colours on his palette; which distinguishes him from Rubens, who placed his colours one at the side of another. It is impossible to say, on the narrow inspection, with what colours he produced his tints. This practice, which enabled him to imitate so exactly the colours of nature, gives a marked distinction to his manner of painting. In the examination of his works, the critics lose an ordinary source of pleasures which arises from marking the freedom of hand; but they may confine themselves with the natural and exquisite touches of this artist.

He is of historical painters one of those who have succeeded in landscape. His situations are well chosen; his trees are varied in their forms, and their foliage well conceived. He had a custom of representing some remarkable appearances in his landscapes to render them more striking.

The distinguishing characteristics of this school are, grace, an agreeable taste for design, without great correctness, a mellowness of pencil, and a beautiful mixture of colours.

Antonio Allegri, called Correggio, was the father and greatest ornament of this school. He began like the painter of his time to imitate nature ab e o; but, as he was chiefly delighted with the graceful, he was careful to purify his design from all short turnings and unnecessary angles. He perceived that large figures contribute to grace; and therefore he not only rejected all small figures, but enlarged as much as possible the outlines, avoided acute angles and flat lines, and by this means gave an easy grandeur to his design. He made his figures elegant and large; he varied the outlines by frequent undulations; but he was not always pure and correct.

Correggio painted in oil, a kind of painting susceptible of the greatest delicacy and sweetness; and as his character led him to cultivate the agreeable, he gave a pleasing captivating tone to all his pictures. He sought transparent colours to represent shades conformable to nature, and adopted a manner of glazing which actually rendered his shadows more obscure. Obscurity in painting cannot be fully obtained without transparent colours; for these absorb the rays of light, and of consequence give less reflection. He laid his colours very thick on the brightest parts of his pictures, to make them capable of receiving, by a proper touch, the greatest degree of light. He perceived, that the reflections of light correspond with the colour of the body from which they are reflected; and on these principles he founded his theory of colours with respect to light and shade and reflection. But it is chiefly in the colour of his shades that he desires to be imitated; for his lights are too clear, and some-what heavy; and his fleshly parts are not sufficiently transparent.

Harmony and grace are connected together; and on this account Correggio excelled also in harmony. As the delicacy of his taste suffered him not to employ strong oppositions, he naturally became a great master in this part, which chiefly consists of easy gradations from one extreme to another. He was harmonics in his design, by making the lines which formed the angles of the contour arched and undulated. Both in the lights and shades, he placed always between the two extremes a space which served to unite them, and to form a passage from the one to the other. The delicacy of his organs made him perceive, better than any other artist, what relief was necessary to the eye after a violent exertion; and he was therefore careful to follow a bold and prevailing colour with a demi-tint, and to conduct the eye of the spectator, by an invisible gradation, to its ordinary state of tension. In the same manner (says Mengs) does agreeable and melting music pull one gently out of sleep, that the awakening reclaims insentiment more than the disturbing of repose. A delicate taste in colours, a perfect knowledge of the claro oburo, the art of mingling light to light, and shade to shade, together with that of detaching the objects from the ground, imitable, grave, and perfect harmony, were the qualities which distinguished Correggio from all the painters, and placed him near the head of his profession.

The Carracci, Lewis, Augustin, and Hannibal, formed what is called the second Lombard school, which is frequently distinguished by the name of the school of Bologna.

Lewis was the master of the other two; he had studied the works of Titian and Paolo Veronese at Venice, those of Andrea del Sate at Florence, those of Correggio at Parma, and those of Jules Romain at Mantua,
PAIN TING.

be acquired have been precious to the art. His force,
be debased by their considerations, have made him
the object of their imitation, without attending to the
sources from which he derived his knowledge, and
which he never could equal. The result has been,
that instead of becoming equal to Hannibal, they have
often copied his imperfections.

This school has been so different under different
Schools, that it is difficult to characterize it. Some of
its artists have been formed on the Florentine and La-
bard manner, others on the Roman, others on the
Venetian, and a few of them have distinguished them-
selves by a manner which may be called their own.
In speaking in general terms of this school, it ap-
pears to have no peculiar character; and it can only
be distinguished by its aptitude to imitate easily any
impression; and it may be added, speaking still in
general terms, that it unites, in a moderate degree,
different parts of the art, without excelling in any
one of them.

It is equally difficult to determine the progress
of painting in France. Miniature painting, and pain-
ing on glass, were early cultivated in that country; and
in these two kinds, the Italians had often recourse
to the French artists. When Francis I. encouraged
Rollo a Florentine, and Primaticcio a Bolognian, the
painters in France were not remarkable for any su-
perior talent; but they were capable of working under
these foreign artists.

Cousin, a painter on glass and portrait-painter, was
the first who established any kind of reputation in
France. He was correct, but possessed very little ele-
cance of design.

Painting, for some time encouraged by Francis I.,
fall into a state of languor, from which it was not re-
covered till the reign of Louis XIII. Jacques Blan-
chard, formed at the Venetian School, and called the
French Titian, flourished about this period. But as
he died young, and without educating any pupils to
perpetuate his manner, he must be regarded as a single
good artist, and not as a founder of the French
School.

In the same manner Poulin, one of the greatest
French painters, and whom they call the Raphael of
France, educated no pupils, nor formed any school.
His style and character of painting are described by
Sir Joshua Reynolds as simple, careful, pure, and
correct. No works of any modern (adds the same
author) have so much of the air of antique painting
as those of Poulin. His best performances have a
remarkable, dryness of manner, which though by no
means to be recommended for imitation, yet seems
perfectly correspondent to that ancient simplicity which
distinguishes his style.

In the latter part of his life he changed from this
manner to one much fitter and richer; where there is
a greater union between the figures and the ground.
His favourite subjects were ancient fables; and no paint-
er was ever better qualified to paint such subjects,
not only from his being eminently skilled in the knowledge
of the ceremonies, costumes, and habits of the ancients,
but from his being so well acquainted with the dif-
ferent characters which those who invented them gave
their allegorical figures.

If Poulin, in the imitation of the ancients, repre-
sents Apollo driving his chariot out of the sea by way

Vol. XIII.
of representing the sun rising, if he personifies lakes and rivers, it is no way offensive in him, but seems perfectly of a piece with the general air of the picture. On the contrary, if the figures which people his pictures had a modern air or countenance, if they appeared like our countrymen, if the draperies were like cloth or filk of our manufacture, if the landscape had the appearance of a modern view, how ridiculous would Apollo appear? instead of the sun, an old man; or a nymph with an urn, instead of a river or a lake.

Pouffin, however, more admired than imitated, had no manner of influence in forming the French school. Simon Vouet, his enemy and percursor, had this honour, because his pupils, in the happy age of the arts in France, conferred on it the greatest splendor. Vouet was a man of distinguished abilities; but the school which he erected would have had no countenance if his scholars had purposed his manner of painting. He had a kind of grandeur and facility; but his design was false with regard to colours, and with a want of reason, of expression, and of the sublime. He only needed to take the pencil in his hand to finish with one stroke the subject which he conceived; and on this account one is tempted to be pleased, because he is astonished. He had the merit of destroying the insipid manner which reigned in France and of pointing the way to a better taste.

If Vouet laid the foundation of the French school Le Brun finished the edifice. When Le Brun was placed under the tuition of Vouet, he astonishe his master and the rest of his pupils with the rapidity of his progress. At the age of 26 he finished his piece called the borjts of Diomede which gained a place in the palace royal (a), before those of the most eminent painters. He was afterwards recommended to Pouffin; but the young artist was more diffused by his natural inclinations to that modern part of the art which is called the great machine, than to the profound and studied manner of the Greek artist. Pouffin at the same time was of great service to him, in recommending to his study the monuments, the customs, the dress of the ancients; their architecture, their rites, their spectacles, their exercises, their combats, and their triumphs.

Le Brun had a noble conception and a fruitful imagination. He was on no occasion inferior to the vast compositions which he undertook, and he chiefly excelled in rigid costume and exact likenesses.

Few painters have united to great a number, of essential qualities and accessoires of the art; and if he had superiors, it confinced in this, that they possessed some particular quality in a more eminent degree.

He was a good drawer, but his design was far from being so elegant as that of Raphael, or so fine as that of Domenique, and it was less lively than that of Hamilton Carracci, whom he had taken for a model. In drapery he followed the Roman school; the clothes which he gave to his figures were not like those of the Venetian school, of such and such a stuff; they were draperies and nothing more, and this manner agreed with the heroic stile of his works, but in this part he was not equal to the painter of Urbino.

He had studied the expression of the affections of the soul, as is evident from his treatise on the character of the passions; but after observing the general characters, and establishing the principal strokes of expression, he thought he reached the whole extent of this subject, which is so infinitely extended. He always employed the few characters which he had once found out, and neglected to study the prodigious variety of gradations by which the interior affections are manifested in the exterior appearance. He fell then into the manner of repeating always; and possessed neither the delicacy, nor the depth, nor the extreme jufhnefs, of Raphael's expression. He loved and possessed in a high degree the grand machine of the art; he was delighted with great compositions; and he gave them life, and animation, and variety; but he wanted the vigour and inspiration of Raphael. His compositions are formed on philosophical principles, but those of Raphael are created. Le Brun thought well; Raphael, Pouffin, Le Sueur, thought most profoundly.

Le Brun had elevation, but he was not elevated like Raphael, to the sublime. In colouring, Le Brun did not imitate the painters of the Venetian school. The sweet attractions and strong and solid colours of the schools of Rome and Lombardy seem rather to have been the object of his imitation; and from them also he learned an easy, agreeable, and bold management of the pencil.

As Le Brun possessed a great share of lively imagination, he delighted in allegory, which gives the greatest scope for ingenious invention. The facility and resources of his imagination appeared still farther, in his inventing symbols for his allegorical figures, without retreating contented with those employed by the ancients. But fanciful representations of this kind are distant from the operations of true genius. Spirit and thought in the arts are very different from spirit and thought in literary productions. A painter of moderate abilities may introduce into his works a great deal of the invention which belongs to poetry without enrihing his peculiar art. The true spirit of painting confists in making the figures appear in the very circumstances and attitudes in which they are supposed to act, and penetrated with the sentiments with which they ought to be affected. By these means the spectator is more certainly interested than if the actions and thoughts were represented by allegorical symbols. Pouffin appears to have lost all spirit and imagination than Le Brun, while at the same time he gives more delight to people of spirit and imagination.

Eugene Le Sueur was the companion and rival of Le Brun; and no painter approached nearer to Raphael in the art of drapery, and disposing the folds in the most artistic and the noblest manner. His design was in general more fluent than that of Raphael, but, like his, it was formed on the model of the ancients. Like Raphael he represented with art and precision the affections of the soul; like him he varied the air of the head, according to the condition, the age, and the character of his personages; and, like him, he made the different parts of every figure contribute to the general effects. His intention in composing was to express his subject, not to make striking contrasts.

(a) Where it may now be is uncertain. Perhaps it has perished in the wreck of taste, art, science, and elegance, against which French democracy has waged a ruinous war.

Schools.

contrasts or beautiful groups of figures, not to allu­some and bewitch the spectator by the deceitful pomp of a theatrical scene, or the splendor of the great ma­chine. His tones are delicate, his tints harmonious, and his colours, though not so attractive as those of the schools of Venice and Flanders, are yet engaging. They steal peacefully on the soul, and fix it without distraction on the parts of the art, superior to that of colouring.

His preaching of St Paul, and the picture which he painted at St Germain, which the critics compare with the best productions of the Roman school, and the 22 pictures which he painted for the Carthusian monastery at Paris, and which were lately in possession of the king, are esteemed his best pieces. His contemporaries affirm, that he considered as sketches merely those excellent performances which are the glory of the French school.

If Le Sueur had lived longer, or, like Le Brun, he had been employed under a court, fond of the arts and of learning, to execute the great works of the age, the French school would have adopted a different and a better manner. The noble beauty of his heads, the simple majesty of his draperies, the lightness of his design, the propriety of his expression and attitudes, and the simplicity of his general disposition, would have formed the character of this school. The deceit­ful pomp of theatrical decoration would have been more lately introduced, or perhaps would never have appeared, and Paris might have been the second Rome. But as Le Brun, by an accidental fore­sight, invented a varnish that might prevent the sun from doing it harm, so he thought of a varnish that might preserve the memory of his works, and as works of inferior merit were by the false taste of the time preferred to his, it was impossible for him altogether to avoid the faults of his predecessors. He is blamed for stiffness and aridity in his outlines, for little taste or grandeur in his expression, for ignorance of the costume of aerial perspective and of gradations of colors; but he had carefully studied linear perspective, architecture, and fortification.

John Holbein or Holbein, nearly contemporary with Albert Durer painted in oil and water colors. He excelled chiefly in history and in portrait painting. His colours are fresh and brilliant, and his works are highly finished; but in his historical subjects, his draperies are not of so good a taste as those of Albert, Durer.

The Flemish school is recommended to the lovers of the art by the discovery, or at least the finest practice of oil painting. Van Mander gives us the account of this wonderful discovery in the following words: “John Van Eyck was so excellent a chemist, that he discovered a method of varnishing his distemper colors with a varnish, which was made of some oils, and was very pleasing on account of the gloss and lustre it gave them. Many artists in Italy had vainly attempted to find out that secret; they never hit on the true method. It happened once that John in his usual manner, having highly finished one of his pictures on boards, and having varnished it with his new invented varnish, exposed it to dry in the sun; but whether the boards were not well joined, or whether the heat of the sun was too violent, the boards split asunder and opened in the joints. John saw with concern that his work was spoiled, and resolved to contrive something against future accidents of the same kind. Being disgusted at distemper painting, and varnishing, he thought of a varnish that might dry without funshine; and having tried many oils and substances, he found that linseed and nut oil dried better than any other. He boiled them with some other drugs, and produced the best varnish in the world. Ever bent on improvement, he found after much inquiry, that colours mixed with these oils worked and dried extremely well, and when dried would...
PAINTING.

In this part, the first excites the attention, the second fixes it. The carnations of Titian resemble the blush of nature; those of Rubens are brilliant and polished like satin, and sometimes his tints are so strong and separated as to appear like spots.

"Rubens (says Sir Joshua Reynolds) is a remarkable instance of the same mind being seen in all the various parts of the arts. The whole is so much of a piece, that one can scarce be brought to believe but that if any one of them had been more correct and perfect, his works would not be so complete as they appear. If we should allow a greater purity and correctness of drawing, his want of simplicity in composition, colouring, and drapery, would appear more gross."

In his composition his art is too apparent. His figures have expression and act with energy, but without simplicity or dignity. His colouring, in which he is eminently skilled, is notwithstanding too much of what we call tinted. Throughout the whole of his works there is a proportionable want of that nicety of distinction and elegance of mind, which is required in the higher walk of painting, and to this want it may be in some degree ascribed, that those qualities which make the excellency of this subordinate style appear in him with their greatest fulness.

It is evident, therefore, that in painting there is a proportionable want of that nicety of distinction and elegance of mind, which is required in the higher walk of painting, and to this want it may be in some degree ascribed, that those qualities which make the excellency of this subordinate style appear in him with their greatest fulness. Indeed the facility with which he invented, the richness of his composition, the luxuriant harmony and brilliancy of his colouring, so dazzle the eye, that whilst his works continue before us, we cannot help thinking that all his deficiencies are fully supplied.

The Flemish school, of which Rubens is the greatest master, is remarkable for great brilliancy of colours and the magic of the claro-obscuro. To these may be joined a profound design which is yet not founded on the most beautiful forms; a composition possessed of grandeur, a certain air of nobleness in the figures, strong and natural expressions; in short a kind of national beauty, which is neither copied from the ancients nor from the Roman nor Lombard schools, but which deferves to please, and is capable of pleasing.

To speak in general terms, and without regarding a great number of exceptions, the Dutch school carries none of the above qualities to great perfection, except that of colouring. Far from excelling in the beauty of heads and forms, they seem chiefly to delight in the exact imitation of the lowest and most ignoble. Their subjects are derived from the tavern, the smith's shop, and from the vulgar amusements of the rudest peasants. The expressions are sufficiently marked; but it is the expression of passions which d bafe instead of ennobling human nature. One would think that they ridiculed the art of degrading the bodies and souls of men.

It must be acknowledged, at the same time, that the Dutch painters have succeeded in several branches of the art. If they have chosen low objects of imitation, they have represented them with great exactness; and truth must always please. If they have not succeeded in the most difficult parts of the claro-obscuro, they at least excel in the most striking, such as light in confined in a narrow space, light illuminated by the moon or by torches, and the light of a smiths forge. The Dutch understand the gradations of colours; and by their knowledge of contrast they have arrived at the art of painting light itself. They have no rivals
...in Landscape painting considered as the faithful representation or picture of a particular scene; but they are far from equaling Titian, Poussin, Claude Lorrain, &c. who have carried to the greatest perfection the ideal landscape, and whose pictures, instead of being the topographical representation of certain places, are the combined result of every thing beautiful in their imagination or in nature. The Dutch, however, distinguished themselves by their perspective, by their clouds, sea-scenes, animals, fruits, flowers, and insects; and they excel in miniature paintings. In short, every thing which requires a faithful imitation, colour, and a nice touch is well executed by Dutch painters.

Holland has also produced history painters, as Octavius Van Been, and Vander Hilt the rival of Van-dyke, and perhaps his superior: but it is not in the works of those artists that we find the character of the Dutch school.

Neither is the origin of their style to be derived from the works of Lucas of Leyden, though from the time he flourished, viz. about the end of the 15th century, he may be considered as the patriarch of the Dutch school. Lucas painted in oil, in water colours, and on gowns; and the kinds of his painting were history, landscape, and portrait. His picture of the last judgment is preserved in the Hotel de ville of Leyden; it possesses a merit in point of composition, and a great variety of figures.

If miniature painting be considered as a charac-
teristic of the Dutch school, Cornelius Polermurg may be regarded as the father of it. He possessed the colour, delicacy of touch, and disposition of the character which chiefly distinguish this school; and if any thing is to be added, it is want of correctness in his design.

But if the choice of low figures is its chief charac-
teristic, this is to be found in the greatest perfection in the works of the celebrated Rembrandt Van-rin; and it is the more offensive in this artist, as his composition frequently required an opposite choice of figures. As his father was a miller near Leyden, his education must altogether have depended on the exertion of great talents on the study of nature. He studied the grotesque figure of a Dutch peasant, or the servant of an inn with as much application as the greatest masters of Italy would have studied the Apollo of Belvidere or the Venus de Medicis. This was not the manner of elevating himself to the noble conceptions of Raphael; but it was acquiring the imitation of truth in vulgar painting.

"Rembrandt (says M. Defamps) may be com-
pared to the great artists for colour and delicacy of which and chiaro-oburo. It appears that he would have discovered the art, though he had been the first person that ever attempted it. He formed to himself rules and a method of colouring, together with the mixture of colours and the effect of the different tones. He delighted in the great oppositions of light and shade: and he seems to have been chiefly attentive to this branch of the art. His workshop was occasionally made dark, and he received the light by a hole, which fell as he chose to direct it on the place which he desired to be enlightened. On particular occasions he passed behind his model a piece of cloth of the same colour with the ground he wanted; and this piece of cloth receiving the same ray which en-
lightened the head, marked the difference in a sensible manner, and allowed the painter the power of augmenting it according to his principles.

"Rembrandt's manner of painting is a kind of magic. No artist knew better the effects of different colours mingled together, nor could better distinguish those which did not agree from those which did. He placed every tone in its place with so much exactness and harmony, that he needed not to mix them, and to destroy what may be called the flower and freshness of the colours. He made the first draught of his pictures with great perfection, and with a mixture of colours altogether particular: he proceeded on his first sketch with a vigorous application, and sometimes loaded his lights with so great a quantity of colour, that he seemed to model rather than to paint. One of his heads is said to have a nose nearly as much projected as the natural nose which he copied."

Such is the power of genius, that Rembrandt, with all his faults, and they are enormous, is placed among the greatest artists by M. Defamps, who saw his works, and was himself an artist. It is necessary to ob-
serve, that if Rembrandt was ignorant of the essential parts of his art, or neglected them, he was yet acquainted with expression, which alone was capable of giving animation to his works. His expressions are not noble, but they are just, lively, and executed with great judgment.

John de Laer, a miniature painter, and who made choice of his subjects from common life, deserves a distinguished place in the Dutch school. He painted hunting-scenes, the attacks of robbers, public festivals, landscapes, and sea views; and he ornamented his pictures with old ruins, and enriched them with figures of men and animals. He had a correct design, and employed vigorous and lively colouring.

Van-Offlade, although born at Lubeck, Gerard Dow, Metsu, Miris, Wouwerman, Berghem, and the celebrated painter of flowers Van Huyton, belong to the Dutch school.

The greater part of the schools of which we have treated have no longer any existence. Italy alone had four schools, and there only remain at present a very few Italian artists known to foreigners. The school of Rubens is in vain sought for in Flanders. If the Dutch school still exists, it is not known beyond the precincts of Holland. Mengs a German artist has made himself famous in our days; but it was in Italy that he chiefly improved his talents and exercised his art. M. Dietrich, another German, has made himself known to strangers; but two solitary artists do not form a school.

A new school is formed in our times and in The Eng-
lish school, called the English school. It is connected with the academy in London instituted in 1766 by Sir Joshua Reynolds and formed in 1769. Sir Joshua Reynolds is the undoubted founder of it. His works give him a distinguished rank among the artists of the present age, and exhibit a genius in his author which has seldom been surpassed: but the effects which he has contrived to give to them by the formation of a new school, and by the good principles which his discourses to academicians and his examples as a painter, have diffeminated, will secure his reputation as long as England shall enjoy the advantages and the worth of great abilities. The Eng-
lish taste appears to be formed on the great masters...
great admirer of Michael Angelo, and particularly

I. I

considered him to the attention of the academicians.

"I feel (says Sir Joshua) a self-congratulation in knowing myself capable of such sensations as he intended to excite. I reflect, not without vanity, that these discourses bear testimony of my admiration of that truly divine man; and I should define that the last words which I should pronounce in this academy, and from this place, might be the name of—Michael Angelo." But though he thus enthusiastically admired this very great man, yet he allows, what cannot indeed be denied, that he was capricious in his inventions; and this (says he) may make some circumstance necessary in studying his works; for though they appear to become him, an imitation of them is always dangerous, and will prove sometimes ridiculous. "In that dread circle none durst tread but he." To me, I confess, his caprice does not lower the estimation of his genius, even though it is sometimes, I acknowledge, carried to the extreme; and however those eccentric excursions are considered, we must at the same time recollect, that those faults, if they are faults, are such as never could occur to a mean and vulgar mind; that they flowed from the same source which produced his greatest beauties; and were therefore such as none but himself was capable of committing; they were the powerful impulses of a mind unfed to subjection of any kind, and too high to be controlled by cold criticism.

The effect of Sir Joshua's discourses is visible in the pictures of this school. The Death of General Wolfe, the Departure of Regulus for Carthage, the Arrival of Agrippina, and some other subjects, are decided proofs that the English school is acquainted with greatness of style, boldness of expression, and the art of managing a great number of figures. It will be fortunate for the painters of this school, if more rigid with regard to their forms than ambitious of poignant and alluring effects, they support the character which they have already acquired. But although England had not enjoyed this brilliant success in painting, she would have immortalized herself by the excellency of her engravings.

It is easy to perceive in all those schools the cause of the character which distinguishes them. In the Italian school, it is the excellent reduction of its first smallices, together with the precious remains of antiquity found in the ruins of ancient Rome. In the Venetian school, the magnificence derived from the commerce of the east, the frequency of feasts and masquerades, and the necessity of painting to the rich and luxurious, who were accustomed to behold these magnificent objects, were the causes of its gaudy taste. In the Dutch school, the peculiarity of its grilling manner may be accounted for from the habits of the artists. Accustomed to visit taverns and workshops, and having most commonly exposed to their view low and grotesque figures, they represented in their pictures the objects which were most familiar to them in life.

"Beauty (says a French writer) ought to be the characteristic of the English school, because the artists have it often exposed to their view. If this beauty is not precisely similar to that among the ancients, it is not inferior to it. The English school should also distinguish itself for truth of expression; because the liberty enjoyed in that country gives to every passion its natural and unbiassed operation." It will probably long preserve its simplicity unpolluted by the pomp of theatrical taste and the conceit of false graces, because the English manners will long preserve their simplicity.

Examining the picture of a French woman (continues he) painted by an artist of that nation and you will generally find, in place of expression, a forced grin, in which the eyes and the forehead does not partake, and which indicates no affection of the soul. Examine the picture of an English woman done by one of their painters, and you observe an elegant and simple expression, which makes you at once acquainted with the character of the person represented.

Sect. III. Comparison between the Ancient and Modern Painting.

No person of judgment or taste hesitates to give the superiority to the ancient sculpture; but the moderns comfort themselves with refusing the same superiority to the Greek artists in the art of painting. The small number of their productions which remain, and the probable conjectures which may be formed concerning those which have perished, go the length to prove that the Greek painters conducted themselves on other principles than those which have received the sanction of custom and the force of laws in our schools. But this censure might be applied with equal justice to Homer as an epic poet, and to Sophocles and Euripides as writers of tragedy.

The principal difference between the ancient and modern manner of painting consists in the complication of figures and the pompous decoration of scenery which prevails in the modern, when compared with the unity and simplicity of the ancient painters. This simplicity, however does not seem to arise from the want of capacity, but from a choice, as Polybius, one of their most ancient painters, represents in one of his pieces the siege of Troy, and in another the descent of Ulysses into hell; but they soon decided in favour of simplicity, and their pieces generally contain one or two figures, and very rarely more than three or four.

Poetry in this particular is conducted on very different principles. A poet may with great propriety multiply his characters, and enter into details of a variety of actions, because the whole of his characters and actions do not occupy the mind of his reader at the same time. The whole of his art consists in making one naturally succeed another; but every part of the poem which contains a separate transactio would make a picture capable of fixing the attention. In painting, the eye takes in the whole; and it is by no means satisfied if 20 or 30 figures are presented to it, which it cannot possibly comprehend. It is in vain to group the figures, or to call the attention to the principal object by a greater degree of light; the spectator is anxious to examine every object which is presented to him; and if they are not to be examined for what reason are they painted. An excellent piece, at the same time, combining a great number of figures, will give pleasure; but it is accompanied with that fatigue which one experiences when he runs over a gallery furnished with a great variety of excellent pictures.

These
Ancient History.

Painting.

There are two sources from which we can derive information; namely, from the antiquities of Herculaneum will be striking proofs of truth, elegance, and spirit, in a degree rarely to be met with among the moderns, and were habitual even to the common run of artists in the declining age of ancient painting.

The ancients excelled moreover not merely in the common and obvious parts of design; but they appear to have had no inconceivable degree of skill in the art of perspective. The performance of Paulus is a proof of this: Facit autem grandes tabulas ficut spicatum in Pompeii porticibus bonum immolationem. Eam enim pium rum primus inventa, quam pollet in vivi sunt auti, eum vitat. Autem omnia, cum leg信息发布 bene offendere volit, adversum cum pinxi, non transfueram, ab hacte intellegitam amplitudine. Dein cum omnes qui voluit eminentia videndi, candidantia faciunt, colorumque condant, hic totum hominem atque coloris factum, ubicumque et in quibus speculis. Num pro fundis artibus in quibus omnibus eruditionem et in confradis formam.

Nor will it be difficult to show, that the ancient painters were not inferior to the moderns in expression. The flate of sculpture alone among the ancients would almost furnish a decisive proof that the finer art of painting could not be deficient. Among the ancient statues which yet remain, expression is carried to a wonderful height; not merely the features of the face, but almost every motion of the body, combining to enforce the idea intended to be conveyed.

Mr. Webb very properly observes, that the ancients 'On Painting thought characters and manners so essential to painting and poetry, that they expressly term picture an art descriptive of manners. Aristotle in his Politics says of Polygenius, that he was a painter of the manners: and objects to Zeuxis, his weakness in this part.' We have in Philoctatus the following description of a picture: 'We may instantly (says he) distinguish Ulysses by his severity and vigilance; Menelaus by his mildness; and Agamemnon by a kind of divine majesty. In the son of Tydeus is expressed an air of freedom; Ajax is known by his fallen fierceness; and Antilochus by his alacrity. To give to these such sentiments and actions as are confessional from their peculiar characters, is the ethic of painting.'
Painting.

Another instance of excellence in expression among the ancient paintings was the Medea of Timonaeus. She was painted about to kill her infants. Autolycus, with admiration of the mingled expression of anger and maternal fondness in her face and manner.

Immaculam exsimia rerum in diversa laborem
Fingent afflita matrix ut odigiam,
Ira fulvis lachrymis, miseria non curt irda,
Al vertigine videt ut fit in alterius.

It may not be amiss, however, in this period of our inquiry, to make some observations on the testimonies of ancient authors respecting this subject.

It is certainly true, that when the works of an ancient artist are praised for any real or supposed merit, the commendations will be relative to the degree of perfection to which the art had attained at the time, and to the opportunities of information, the taste, and judgment of the perfons who bestowed them. Excellence will always be ascribed to him who leaves his contemporaries far behind; and those performances will often be considered as supremely beautiful which exceed in beauty all that have gone before.

In like manner, a person of natural sensibility, but who has been accustomed all his life to performances of an inferior stamp, will be in raptures at any which much exceed the best he has hitherto been taught to admire; and whatever opportunities of information he may have, his evidence will not be of much weight, if he do not possess a sufficient degree of taste and judgment to use them properly.

In ascertaining therefore the degree of credit due to the praises bestowed on any performance in a branch of the fine arts, we must take into consideration the general state of the art at the time, and the competence of the person who bestowed the praise.

No fit, fit degree of probability, however, may be attained on both these points, by attending to a circumstance not generally noticed, viz. that in an advanced state of the art, and when the observer is acquainted with his subject, the praise will be given in loose, general, and comprehensive expressions; but the terms in which it is conveyed will be characterizable and determinate, and often technical; they will frequently show the state of the art, by marking the subdivisions and the skill of the observer by judicious discrimination. When, added to these, the latter can refer for comparison to any distinct standard of perfection, his praise may fairly be adopted in its full extent, and regarded as evidence upon the point in question.

To apply these observations to painting, it is clear, with respect to the most difficult, the most fundamental, and the highest in rank among the departments of the art, viz. design and expression, that the ancients were fully equal to the moderns; and their expressions of praise must be allowed to imply an equal degree of absolute skill, with similar expressions, if applied to the great masters of modern art. It is also clear that painting was extremely cultivated among the ancients, and that their good painters were more esteemed than artists of equal merit in modern times; what that we should term gentlemen artists were so esteemed with them, (atque Romani quique honor virtute lacrymatae artis congruit); and that the expression of the ancient connoisseurs evince much theoretical and technical knowledge of the art, and display a distribution of its parts almost as minute, complete, and scientific, as the present state of it can boast.

With regard to colouring, the praises of the ancient authors chiefly relate to the style of it as executed upon single figures or particular tints. It may therefore be doubted whether the ancients were possessed of the art of distributing their colours through the whole of a picture, so as to produce an harmony and general tone of colouring similar to that which we admire in the Lombard and Flemish schools.

The present remains of ancient paintings do not appear to warrant any such conclusions; but being undoubtedly the works of inferior hands, their authority is very small when alleged against the general or particular merit of the ancient artists. The following extracts will be sufficient to evince, that the ancients did attend to this technical branch of colouring.

Indeed the modern technical expressions appear borrowed from the following passage of Pliny, which may be regarded as decisive on the subject.

Tamam se in vita, in arte est, lumen et umbra, differ- in in coloribus, altera se est exiguitas. Deinde adhibatur ad
plenam hanc ilum lumen; quem quae inter hoc ut
umbra est, auspiciario tamen. Consiliorum vero collo-
raun et tranquillitatem, harmonen. 

The above extracts of this passage might have been regarded as merely descriptive of the light and shade necessary to relieve single figures, if it were not for the subsequent definition of tone. The harmonen of Pliny means the bounding or skilful bounding and softening colours into one another, rather than what we now call harmony.

Lucian, in his fine description of that spirited painter, in his painting by Zenis of the male and female costours, after relating the treatment of the subject itself, proceeds to notice the technical execution of the picture; and he praises particularly the truth and delicacy of the drawing, the perfect blending of the colours, the skilful shading, the scientific preservation of size and magnitude, and the equality and harmony of the proportion throughout the whole piece.

Painters, says Plutarch, increase the effect of the light and splendid parts of a picture by the neighbourhood of dark tints and shades. And Maximus Tyrius observes, that bright and vivid colour are always pleasant to the eye; but this pleasure is always lessened if you omit to accompany them with somewhat dark and gloomy. These passages seem to imply a knowledge of the use of cold and dark tints even where a brilliancy of tone is required. The belt among the ancient painters, however, seem to have preferred a chaste and sober style of colouring to the gaudiness and flutter of the later artists.

Upon the whole, therefore, with respect to colouring as employed upon single figures, as the ancients were fully as competent to judge of excellence in the moderns, as the expressions of the ancient connoisseurs are very warm in praise of the colouring of many of their painters; as they appear also to have attended very much to the art of colouring; and, moreover as probable evidence can be adduced that they attended to miniature painting—o a considerable degree of merit may be allowed them in the use of the colours they possessed.

4
PAINTING.

Comparison between the Ancient and Modern.

Chiaro-furo, or the art of placing and proportioning light and shade in such a manner as to produce a pleasing effect, independently of any other circumstance connected with the picture, has been commonly deemed a characteristic difference between the knowledge of ancient and modern painters. On this subject the works of the ancients now remaining give little or no information; hence Sir Joshua Reynolds observes, "that this, which makes so considerable a part of the modern art, was to them totally unknown. If the great painters had possessed this excellence, some portion of it would have infallibly been diffused, and have been discovered, in the works of the inferior rank of artists which have come down to us, and which may be considered as on the same rank with the paintings that ornament our public gardens." But the accounts of the places where these paintings have been found, make it evident that they were thus ornamented at a very inconsiderable expense. The generality of them consist of single figures; some of them of two or three figures, generally relieved by an uniform ground; and except in a few instances, evidently designed as mere reliefs to a compartment, and answering, as near as may be, the stuccoed ornamens in our modern rooms; nor do any of them seem the works of artists equal in their day to those at present employed on the painted ceilings of private houses.

The Abbé du Bos maintains, on the other hand, that what Pliny and other ancient writers say concerning the chiaro-furo, and the delightful distribution of light and shade, is altogether decisive; and that their writings are full of so many probable circumstances, that it cannot be denied that the ancients at least equalled the most celebrated of the moderns in this part of the art.

On the examination of the greater part of the passages from antiquity, it is evident that they may relate to the light and shade of single figures, without involving what is now called the science of the chiaro-furo. The passage of Pliny, however, already quoted, and several others, go very near to prove that this branch of painting was understood among the ancients. The dark, the light, and mezzotint are evidently and accurately described in that passage.

Equally strong is that expression in Quintilian: *Zeuxis luminum undique, saepeque ad hominem interiusse traditur.* This cannot well be otherwise translated than by the science of light and shade.

That some technical knowledge of the effect producible by *aedes* of light and shade was possessed by the ancients, appears indubitable from the passages adduced: to what extent it was carried cannot now be ascertained. In all probability they were much inferior in this respect to the moderns; otherwise, although much science of this kind could hardly be expected from the trifling performances that remain, much more would have occurred on the subject, it would have been more largely dwelt on, and more precisely expressed among the observations of ancient authors on the best paintings of the ancient masters.

Neither is there sufficient evidence that the ancients were eminent in that important branch of the composition of a picture, which consists in distributing the figures and objects in groups or motives. There are few examples of this difficult branch of the art among the remaining antiquities; and indeed, from the passages of the figures introduced in the generality of these ancient paintings, there is little room to expect them. But what makes it still more doubtful whether the ancients attained any degree of eminence in grouping is, that among the many paintings of these great masters enumerated by Pliny, Lucian, or Philostratus, there is none of them praised for this species of excellence. This, however, it must be confessed, may as well arise from want of knowledge in the writer as of skill in the artist; for in a picture found in Heraclaneum, which represents in all probability the education of Achilles, the figure of an old man holding a child on his knees, together with that of a woman behind him, form a very agreeable group. A work of the same collection, painted in one colour on marble, consists of five figures grouped very much after the modern idea, if it were not that three of the heads are at the same height. It is extremely probable, that this morceau had been the copy of a picture finished in the purest times of the art. But although it were proved that the ancients did not attempt grouping their figures, it is still uncertain whether this might not arise from their peculiar and perhaps excellent taste in the arts.

Wishing to enjoy in the fullest manner their painted figures as they enjoyed the aspect of a statue, they took care that every figure should be detached from another in the same picture, which permitted them to give their objects more relief, and to render them more distinct to the eye of a distant spectator.

We are not therefore to conclude, that they were entirely ignorant of grouping; on the one hand; or that they declined the execution of it from want of skill, on the other. Indeed it actually appears to have been technically attended to by them, whatever might be their comparative excellence in it; for Appelles is expressly asserted by Pliny to have been inferior to Melanthius in composition (*de dispositione*); and one of their paintings, mentioned by the same author, is said to have contained one hundred figures; but this unwieldy number must have been offensive, if they were not grouped with some skill.

From the connection between the finer arts of poetry painting, and sculpture, and the admirable performances of the ancients in the other two departments of the fine arts, it is reasonable to conclude, that the ancient painters were not deficient in invention. Many instances, were it necessary, might be collected in support of their well grounded claim to this branch of the art; but it will be sufficient to observe, that as invention is rather a natural endowment than an acquired talent, and as the ancients universally seem to be at least equal to the moderns in the gifts of genius and good sense, we cannot but admit, on their part, an equality with ourselves so far as invention is concerned.

Very nearly connected with the subject of invention is that of the *eikon*; by which is meant an attention to probability with respect to times, places, objects, persons, and circumstances in the translation represented.

The ancient paintings now remaining, so far from exhibiting any proofs of attention to this important branch of the art, are full of gross violations of probability.
of the owner, and not of probability in the works of their arts; and from the breaches of probability, it is known any gross violation of the rules of perspective; and if the writers express themselves on the subject (not so much recommending the practice of it as taking it for granted), we may reasonably conclude, that their best painters were seldom guilty of any gross violation of the costume. *Sint fata similina ve is* was an apothegm generally known, and when known must have been universally admitted.

The principles of the costume are well expressed and illustrated by Horace in the first lines of his Art of Poetry; and Vitruvius, lib. vii. chap. 5. says, that no pictures can be approved of which have not a resemblance to truth and nature. Whether the ancient painters put in practice a greater share of good sense with respect to the costume than the moderns, cannot now be accurately determined; the advantage seems to be in favour of the former: for, as we shall have occasion more particularly to observe afterwards, the most celebrated of modern painters from Raphael to Sir Joshua Reynolds have been guilty of such flagrant breaches of probability, as would appear astonishing to those who are not in the habit of expecting them.

It has been doubted whether the ancients were acquainted with the science of perspective; and if the remains of ancient painting were alone to decide the question, it must be determined against them; for the works of the ancient painters now in possession of the moderns afford no proof of attention to the rules of representations of any person or transmission; and perspective equal to the performance of a modern fine-painter. The picture of the sacrifice among the Herculanean antiquities, and the fourth of the prints which Bellori has published and described, taken from the paintings in the sepulchre of the Naonii, are barely tolerable; but the other landscapes (almost the only remaining antique paintings which admit of perspective) are grossly defective in this particular; so much so indeed, that considering the late period when landscape-painting was introduced among the ancients, together with this manifest imperfection in point of perspective of such as are yet extant, we cannot help suspecting the inferiority of the ancients in this respect. In perspective, as in the chiaro-obscur, had good practice been common, some traces would have been discovered in the works of their lowest artists.

And yet some general knowledge of the principles, and some degree of attention to the practice, of perspective, cannot well be denied to the ancients. They were good mathematicians, they were excellent architects, and some of them are celebrated for their skill in scene-painting. *Geminius the Rhodian, contemporary with Cicero,* was the author of an express treatise on perspective; and Euclid, Heliodorus, Larifeus, Agatharcus, wrote also on the same subject. It is well known, besides, that the ancients practiced the art of painting in perspective on walls in the same way that it is now done by the moderns; and Pliny (Nat. Hist. lib. xxxv. c. 4.) says, that one of the walls of the theatre of Claudius Pulcher, representing a roof covered with tiles, was finished in so matterly a manner, that the rocks, birds of no small sagacity, taking it for a real roof, attempted to light upon it. We are likewise told that a dog was deceived to such a degree by certain steps in a perspective of Dantos, that expecting to find a free passage, he made up to them in full speed, and dashed his brains against them. What is still more, Vitruvius tells us in express terms by whom and at what time this art was invented. It was first practiced by Agatharcus, a contemporary of Phidias, in the theatre of Athens; and afterwards reduced to certain principles, and treated as a science, by Anaxagoras and Democritus; thus faring like other arts which existed in practice before they appeared in theory.

Portrait-painting seems to have been a principal employment of the first artists whom the ancients have to boast of, since Alexander is said to have permitted no painter but Apelles, and no sculptor but Phidias, to take his likenesses. Pliny particularizes several instances of Apelles as a portrait-painter.

In the drawing and colouring of single figures, to which the ancients paid peculiar attention, they must be allowed to be equal, if not superior, to the moderns. That spirit and animation, ease and dignity, which are common to the performances of ancient artists, the ancient statues and paintings still remaining most evidently evince; and as they possessed, therefore, all the requisites to excel in portrait-painting, a branch of the art at all times much in request among them, there is good reason to infer, in favour of the ancients, at least an equality with the moderns in this respect.

On the whole, all the principal parts of the art, as purity of design, and beauty and expression in the forms, were not only to be found in the ancient statues, but were actually the foundation of excellence in modern painting; and hence we may conclude, that their painters, formed on the same models, and very often the same men who excelled in sculpture, were not inferior in those branches of the art. But with regard to the inferior parts, the allurement of colouring, the ingenuity of the chiaro-obscur, the splendor of composition, the art of grouping figures, and the nice handling of the pencil, the moderns are superior to those ancient painters who have most deserved the notice of their contemporary writers. It is full to be observed, however, that the progress of the arts among the ancients, from the principal parts to the more splendid, was somewhat similar to that among the moderns; and as the painters of the first rank were more immediately the objects of criticism and delight to authors of genius, it is impossible at this distance of time to state any accurate comparison between the ancients and moderns in what may be termed the decay of the art. This is particularly the case with regard to colours, there being in ancient as well as in modern times two epochs; the one comprehending Polygnotus and his immediate successors, and the other the painters both of Greece and Rome after the art began to decay. The colouring of Polygnotus was hard, and his manner had something of wildness;
PAINTING.

P A R T I. Principles of the Art, and the Order of the Artist's Studies.

We have joined these together, because they are like cause and effect; and comprehend both on what parts in the execution of the art the painter is to employ his chief attention, and also the manner in which he is to employ it. We shall not therefore be confined to the dry and abstract, and as it were unembodied principles, but connect them with the useful and agreeable branches of the art, in that order in which it appears to us they should be studied.

SECT. I. Of Anatomy.

To ask if the study of anatomy is requisite to a painter, is the same thing as to ask if, in order to learn any science, a man must first make himself acquainted with the principles of it. It would be an useless waste of time to cite, in confirmation of this truth, the authorities of the ancient masters, and the most celebrated schools. A man, who is unacquainted with the form and construction of the several bones which support and govern the human frame, and does not know in what manner the muscles moving these bones are fixed to them, can make nothing of what appears of them thro' the integuments with which they are covered; and which appearance is, however, the noblest object of the pencil. It is impossible for a painter to copy faithfully what he sees, unless he thoroughly understand it. Let him employ ever so much time and study in the attempt, it cannot but be attended with many and great mistakes: just as it must happen to a man, who undertakes to copy something in a language which he does not understand; or to translate into his own, what has been written in another, upon a subject with which he is not acquainted.

It seldom happens, that nothing more is required of a painter than to copy exactly an object which he has before him. In still and very languid attitudes, in which every member is to appear motionless and dead, a living model may no doubt, yield for a long time a faithful image, and prove an useful pattern to him. But in regard to gestures any way sudden, motions any way violent, or those momentary attitudes which it is more frequently the painter's business to express, the cafe is quite different. In these a living model can hold but one instant or two; it soon grows languid, and settles into a fixed attitude, which is produced by an instantaneous concourse of the animal spirits. If, therefore, a painter postpones not so thoroughly all the principles of anatomy, as to be at all times able to have immediate recourse to them; if he know not the various manners in which the several parts of the human body play, according to their various positions; living models, far from proving an useful pattern to him, will rather tend to lead him astray, and make him lose sight of truth and nature, by exhibiting the very reverse of what is required, or at least exhibit it in a very faint and imperfect manner. In living models, we often behold those parts flow, which should be very quick; those cold and torpid, which should have the greatest share of life and spirit in them.

Nor is it, as some may be apt to imagine, merely to represent athletic and vigorous bodies, in which the parts are most bold and determined, that anatomy is requisite; it should be understood, to represent persons of the most delicate frame and condition, even women and children, whose members are smoothest and roundest, though the parts made known by it are not to be strongly expressed in such objects; just as logic is equally requisite under the polished infallations of the orator and the rough arguments of the philosopher.

But it is needless to spend much time in proving that a painter should be acquainted with anatomy; or in showing, how far his acquaintance with it should extend. For instance, it is unnecessary for him to enter into the different systems of the nerves, blood-vessels, bowels, and the like; parts which are removed from the sight, and which therefore may be left to the surgeon and the physician, as being a guide in the operations of the former and in the prescriptions of the latter. It is enough for the painter, to be acquainted with the skeleton; in other words, with the figure and connection of the bones, which are, in a manner, the pillars and props of the human body; the origin, progress, and shape, of the muscles which cover these bones; as also the different degrees in which nature has clothed the muscles with fat, for this substance lies thicker upon them in some places than in others. Above all, he should in what manner the muscles effect the various motions and gestures of the body. A muscle is composed of two tendinous and slender parts, one called the head, the other the tail, both terminating at the bones; and of an intermediate part, called the belly. The action of a muscle consists in an extraordinary swelling of this intermediate part, while the head remains at rest, so as to bring the tail nearer the head, and consequently the part, to which the tail of the muscle is fixed, nearer to that part into which the head is in¬serted.

There are many motions, to effect which several of the muscles (for this reason called operating muscles,) must swell and operate together, while those calculated to effect a contrary motion (and therefore called antagonistic muscles) appear soft and flaccid. Thus, for example, the biceps and the brachious internus labour...
improvement, to give the muscles various tints; those muscles especially which the pupil might be apt to mistake for others. For example, though the maboidees, the deltoides, the factorioes, the pudendee laxa, the gastrocnemee, are of themselves, sufficiently distinguishable, it is not so with regard to the muscles of the arm and of the back, the right muscles of the belly, and some others, which either run into the many parts into which they branch, or of their being interwoven one with another, do not so clearly and fairly present themselves to the eye. But let the cause of confusion be what it will, it may be effectually removed, by giving, as already hinted, different colours to the different muscles, and illuminating anatomical figures; in the same manner that maps are coloured, in order to enable us readily to distinguish the several provinces of every kingdom, and the several dominions of every prince.

The better to understand the general effect, and remember the number, situation, and play of the muscles, it will be proper to compare, now and then, the anatomical casts, and even the dead body itself, with the living body covered with its fat and skin; and above all things, with the Greek statues full in being. It was the peculiar happiness of the Greeks, to be able to characterize and express the several parts of the human body much better than we can pretend to do; and this, on account of their particular application to the study of naked figures, especially the fine living ones which they had continually before their eyes. It is well known, that the muscles most used are likewise the most protuberant and conspicuous; such as, in those who dance much, the muscles of the legs; and in boatmen, the muscles of the back and arms. But the bodies of the Greek youth, by means of their constant exertion of them in all the gymnastic sports, were so thoroughly exercised, as to supply the literary with much more perfect models than ours can pretend to be.

There are a great many exercises, which a young painter should go through while engaged in the study of anatomy, in order to make himself more thoroughly master of that science. For example: The thighs of any figure, a Laocoon for instance, being given, he should add to them legs suitable to that statue in which the muscles of the thighs are represented, that is, the muscles which serve to bend and extend the legs, and to effeuate in them such a precise position and no other. To the simple contours of an anatomical, or a statue, he should add the parts included by it, and give it a system of muscles conformable to the quality of that particular contour; for every contour denotes some one certain attitude, motion, exertion, and no other. Exercises of this kind would soon establish him in the most fundamental principles of painting, especially if he had an opportunity of comparing his drawings with the statues or casts from which the parts given him to work upon were taken, and thereby discovering and correcting his mistakes. This method is very like that used by those who teach the Latin tongue; when having given their scholars a passage of Livy or Caesar already translated into their mother-tongue, to translate back into Latin, they make them compare their work with the original text.
The study of perspective should go hand in hand with that of anatomy, as not less fundamental and necessary. In fact, the contour of an object drawn upon paper or canvas, represents nothing more than such an interposition of the visual rays that it is, as would arise on a glass put in the place of the paper or canvas. Now, the situation of an object at the side of a glass being given, the declination of it on the glass itself depends entirely on the situation of the eye on this side of the glass; that is to say, on the rules of perspective: a science which, contrary to the opinion of most people, extends much farther than the painting of scenes, floors, and what generally goes under the name of quadratur. Perspective, according to that great master da Vinci, is to be considered as the reins and rudder of painting. It teaches in what proportion the parts fly from, and, when they are to be marshalled upon a plain surface, and fore-shortened. It contains, in short, the whole rationale of design.

Such are the terms which the masters best grounded in their profession have employed to define and recommend perspective: so far were they from calling it a fictitious art, and an invidious guide; as some amongst the moderns have not blushed to do, inferring that it is to be followed no longer than it keeps the high road, or leads by easy and pleasant paths. But the writers plainly show, that they are equally ignorant of the nature of perspective, which, founded as it is on geometrical principles, can never lead its votaries astray; and of the nature of their art, which, without the assistance of perspective, cannot, in rigour, expect to make any progress, nay, not so much as to delineate a simple contour.

When a painter has formed a scene in his mind, and filled his imagination with it, the study should be to know, as far as possible, what he is to do. He must first consider the manner of arranging the objects of his picture, and take care that the horizontal line of the picture may be as nearly as possible, in the highest horizontal plane with that of the spectator; for this disposition has an amazing effect. When a picture is to be placed very high, as, amongst many others, that of the Purlification of Paolo Venetian, engraved by Le Fevre, it will be proper to assume the point of sight so low, that it may lie quite under the picture, no part of which is visible; for, were the point of sight to be taken above the picture, the horizontal ground of it would appear flopping to the eye, and both figures and buildings as ready to tumble head foremost. It is true, indeed; that there is seldom any necessity for such extraordinary extremities; and that, unless in some particular cases, the point of sight had better be rather high than low: the reason of which is, that, as we are more accustomed to behold people on the same plane with ourselves, than either higher or lower, the figures of a piece must strike us most when standing on a plane nearly level with that upon which we ourselves stand. To this it may be added, that by placing the eye low, and greatly shortening the plane, the feet of the, figures will seem to bear against the heads of the foreground, so as to render the distance between them far less perceptible than otherwise it would be.

The point of sight being fixed upon, according to the situation in which the picture is to be placed, the point of distance is next to be determined. In doing this, a painter should carefully attend to three things: firstly, that the spectator may be able to take in, at one glance, the whole and every part of the composition; secondly, that he may see it distinctly; and thirdly, that the degradation of the figures and other objects of the picture be sufficiently evident. It would take up too much time to lay down certain and precise rules for doing all this, considering the great variety in the sizes and shapes of pictures; for which reason we must leave a great deal to the discretion of the painter.

But there is a point still remaining, which will not admit of the least attention. This is the delineation of the picture, when once the point of sight has been fixed upon. The figures of a picture are to be considered as so many columns erected on different spots of the same plane; and the painter must not think of designing any thing, till he has laid down, in perspective, all those columns which are to enter his composition, with the most minute and exactness. By proceeding in this manner, he may not only be sure of not committing any mistake in the diminution of his figures according to their different distances, but may further himself with the thoughts of treating in the legs of the greatest masters. It is to the punctual observance of these laws that we are to attribute the grand effect of some paintings by Caravaggio and Mantegna, so careless in other respects; whereas a single fault against them is often sufficient entirely to spoil the whole of a Guido, in spite of the subtlety and beauty of his superior style.

Now, as the demonstration of the rules of perspective depends on the doctrine of proportions, on the properties of similar triangles, and on the effect of planes, it will be proper to put an abridgment of Euclid into the hands of the young painter, that he may...
may understand those rules fundamentally, and not
and confused to a blind practice of them: but then,
thing in the author relative to the art of paint-
thing, which may not easily be acquired in a few months.
For, as it would be as no use to a painter to launch
out into the anatomical depths of a Mona or an Al-
binus, it would be equally superfluous to perplex him-
self with the intricacies of the higher geometry
with a Taylor, who has handled perspective with that
rich profoundness, which we cannot help thinking
does a great deal more honour to a mathematician,
than it can possibly bring advantage to a simple
artist.

But though a much longer time were requisite to
become a perfect master of perspective, a painter, sur-
tly, ought not to grudge it; as no time can be too
long to acquire that knowledge, without which he
cannot possibly expect to succeed. Nay, we may
boldly affirm, that the shortest road in every art is
that which leads through theory to practice. From
theory arises that great facility, by means of which
a man advances the quicker, in proportion as he is
furer of not taking a wrong step; whilst those, who
are not grounded in the science, labour on in per-
petual doubt; obliged, as a certain author expresses it, to
feel out their way with a pencil, just as the blind, with
their flects, feel for the streets and turning, with
which they are not acquainted.

As practice, therefore, ought in every thing to be
built upon principle, the study of Optics, as far as it
is requisite to determine the degree in which objects
are to be illuminated or shaded, should proceed hand
in hand with that of perspective: And this, in order
that the shades, cast by figures upon the planes on
which they stand, may fall properly, and be neither
too strong nor too light; in a word, that those most
fair effects of the chiaro- scuro may run no risk
of ever receiving the lie from truth, which sooner or
later discovers itself to every eye.

Sect. III. Of Symmetry.

The study of symmetry, it is obvious, should im-
immediately follow that of anatomy; for it would avail
us little to be acquainted with the different parts of the
human body, and their several offices, were we at the
same time ignorant of the order and proportion of
those parts in regard to the whole in general, and to
each other in particular. The Greek statuaries distin-
guished themselves above all others, as much by the
just symmetry of their members, as by their skill in
anatomy; but Polygnotes surpassed them all by a statue,
called the Rod, from which, as from a most accurate
pattern, other artists might take measures for every part
of the human body. These measures, to say nothing
of the books which treat professedly of them, may now
be derived from the Apollo of Belvedere, the La-
coon, the Venus of Medicis, the Fannus, and particu-
larly the Antinous, which last was the rule of the
learned Poulin.

It is the general opinion of painters, that the an-
cients were not as happy in representing the bodies of
children, as they are allowed to have been in repre-
senting those of woman and men; especially those of
their gods; in which they excelled to such a degree,
that with these gods were often worshipp'd the artificers
Symmetry, who had car'd them. Yet the Venus of Gidus by
Praxiteles was not more famous than her Cupid, on
whose account alone people flocked to Therapia 9.
To 8 (Lic. in
children, they, the ancients knew not how to im-
part that softness and effeminacy which Flaminio
has since contrived to give them, by representing their
cheeks, hands, and feet, swelled, their heads large
and with an encircling belly. But such critics fem to Hil.
not to forget, that those first sketches of nature very seldom
come in the painter's way, and that this play and de-
licate state has not in its time even the least glimmering
of perfection. The ancients never undertook to rep-
resent children less than four or five years old; at
which age the superfluous humours of the body being
in some measure digested, their members begin
to assume such a contour and proportion as may
serve to point out what they are afterwards likely to
be. This observation is confirmed by the children
which we meet with in ancient basf-relieves and paint-
ings; for they are all doing one thing or another; like
the most beautiful little Cupids in a picture at Ve-
nice, who are playing with the arms of Mars, and lift-
ing up the ponderous sword of that deity; or that
little urchin in the Diana of Canossa, who empties
a quiver of its arrows in order to fill it with the golden
flower. Now, what can be a greater blunder in point
of costume, than to attribute actions, which require
some degree of strength and judgment, to infancy, to
that raw and tender age so totally unable to govern
and support itself?

Let a young painter consider the Greek statues ever
so often, of whatever character or age they may be
represented, it is impossible he should ever consider
them without discovering new beauties in them. It is there-
fore impossible he can copy them too often, according
to that judicious motto placed by Maratti on his
print called The school. This truth was acknowledged
by Rubens himself; for though, like one bred, as he
was in the foggy climate of the Low Countries, he
generally painted from the life; in some of his works
he copied the ancients; nay, he wrote: a treatise on the
excellency of the ancient statues, and on the duty of a
painter to study and imitate them. As to the fictitious
print, or rather paquinade, of the great Titian, in
which he has represented a parcel of young monkeys
aping the group of Laocoon and his sons; he intend-
ed nothing more by it than to lull the dullest and po-
vety of those artists, who cannot so much as draw a
figure without having a statue before them as a mo-
del.

In fact, reason requires, that an artist should be so
much master of his art, as seldom to stand in need of a
pattern. To what other purpose is he to sweat and
toil from his infancy, and spend so many days and
nights in studying and copying the best models; espe-
cially the finest faces of antiquity, which we are still
possessed of; such as the two Niobes, mother and
daughter; the Ariadne, the Alexander, the young
Nero, the Silenus, the Nile: and likewise the finest
figures; for instance, the Apollo, the Gladiator, the
Venus, and others; all which (as was said of Pietro
Fei!a), he should have, as it were, perfectly by heart?
With a flock of excellencies like these, treasured up in
his memory, he may one day hope to produce some-
thing
PART I.

PAINTING.

Symmetry: thing of his own without a model; form a right judgement of that natural beauties which fall in his way; and when occasion offers, avail himself properly of them.

It is very injudicious to send boys to an academy to draw after naked figures, before they have imbibed a proper relish for beautiful proportions, and have been well grounded in the true principles of symmetry. They should first learn, by studying the precious remains of antiquity, to improve upon life; and discern where a natural figure is faulty through negligence in the members, or the limbs in the trunk, or in any other respect; so as to be able to correct the faulty part, and reduce it to its proper bounds. Painting, in this branch, is, like medicine, the art of taking away and adding.

It must not, however, be differenced, that the methods hitherto laid down are attended with some danger; for by too flauish an attention to features, the young painter may contrive a hard and dry manner; and by studying anatomies too servilely, a habit of representing living bodies as stripped of their skin; for after all, there is nothing but what is natural, that, besides a certain peculiar grace and liveliness, possesseth that simplicity, ease, and voluntariness, which is not to be expected in the works of art, or even in those of nature when deprived of life. Poullin himself has now and then given into one of these extremes, and Michael Angelo very often into the other; but from this we can only infer, that even the greatest men are not infallible. It is, in short, to be considered as one imitance, among a thousand, of the ill use those are wont to make of the best things, who do not know how to temper and qualify them properly with their contraries.

But no such danger can arise to a young painter from confining himself for a long time to mere design, as not to attempt colouring till he has made himself master of that branch. If, according to a great master, colours in painting are in regard to the eye what numbers in poetry are in regard to the ear, so many charms to allure and captivate that sense; may we not affirm, that design is in the same art what propriety of language is in writing, and a just utterance of sounds in music? Whatever some people may think, a picture designed according to the rules of perspective and the principles of anatomy, will ever be held in higher esteem by good judges, than a picture ill designed, let it be ever so well-coloured. Hannibal Caracci set so great a value upon the art of colour, that, according to some expressions of his which have reached us, he considered almost every thing else as nothing in comparison with it. And this his judgement may be justified, by considering, that nature, though the forms men of various colours and combinations, never operates in the motions contrary to the mechanical principles of anatomy, nor, in exhibiting these motions to the eye, against the geometrical laws of perspective; a plain proof that in point of design, no mistake is to be deemed trifling. Hence we are unable to feel all the weight of those words in which Michael Angelo, after he considered a picture drawn by a prince of the Venetian school, addressed Vafari: “What a pity it is,” said he, “that this man did not set out by studying design!” As the energy of nature

flames most in the finest subjects, so the energy of imitation.

Sect. IV. Of Imitation.

When you consider art as the imitation of nature (I say Mengs), it is not to be understood that nature which is the object, is more perfect than art which imitates it. Nature, it is well agreed, offers some views of which the imitation must ever remain imperfect, as in the fulness of the clari-doctrino, but, on the other hand, in every thing relative to beauty of form, imitation may even surpass nature. Nature, in her productions, is subject to many accidents. Art, labouring on passive and obstinate materials, renders perfect the objects of its creation, chooses every thing in nature the most excellent, and collects the different parts and the different beauties of many individuals into one whole. It is seldom that we find in the same man greatness of soul and the due proportions of bodily, vigour, suppleness, firmness, and agility, joined together. Art constantly represents what is rarely or never to be met with in human nature; regularity in the outlines, grandeur in the forms, grace in the attitudes, beauty in the members, force in the breath, agility in the limbs, adds to the arms, frankness in the forehead, spirit in the eyes, and affability over the whole countenance. Let an artist give force and expression to all the parts of his subject, let him vary this force and expression as different circumstances make it necessary, and he will soon perceive that art may surpass nature. But although this be granted, the artist is not to imagine that art is actually arrived at this supreme degree of perfection, and can proceed no farther. The moderns seem never to have perceived the tract pointed out by the ancient Greeks; for, since the revival of painting, the true and the agreeable, instead of the beautiful, have been the objects of cultivation. Still, however, imitation is the first part of the art of painting, though not the most excellent or beautiful. It is a necessary step in the progress which leads forward to greater perfection.

A painter ought attentively to consider, compare together, and weigh in the balance of reason and truth, all the different styles of the great masters; but he ought likewise carefully to guard against too great a fondness for any one of them in particular that he may think proper to adopt; otherwise, to use the expression of a first-rate master, instead of the child, he would become the grand child of nature.

Besides, his imitation must be of generals, and not of particulars. Whatever a young painter's natural disposition may be, whether to paint boldly and freely like Titoreet and Rubens, or to labour his works like Titian or Da Vinci, let him follow it. This kind of imitation is very commendable. It is thus that Dante, at the same time that he carefully avoided adopting the particular expressions of Virgil, endeavoured to seize his bulk and free manner, and at last caught from him that elegance of style which has done him so much honour.

As to the rest, nothing should hinder an able master from making use now and then of any antique, or even modern figure, which he may find his account in employing. Sansio, in a St Paul at Leyther, sculpted not
not to avail himself of an ancient sacrifice in balsam-leaf; nor did Buonaroti himself disdain to use, in his paintings of the Sistine chapel, a figure taken from that famous cornelian which tradition tells us he wore on his finger, and which was lately in the possession of the most Christian king. Men like these avail themselves of the productions of others in such a manner as to make us apply to them, what La Bruyere said of Delfrere, that one would imagine the thoughts of other men had been of his own creation.

In general, a painter should have his eye constantly fixed on nature, that inexhaustible and varied source of every kind of beauty; and should study to imitate her in her most singular effects. As beauty, scattered over the whole universe, shines brighter in some objects than in others, he should never be without his little book and crayon, in order to make drawings of every beautiful or uncommon object that may happen to present itself; and take sketches of every fine building, every situation, every effect of light, every flight of clouds, every flow of drapery, every attitude, every expression of the passions, that may happen to strike him. He may afterwards employ these things as occasion offer; and in the mean time will have the advantage of acquiring a grand style.

It is by carefully studying the best masters, and imitating nature, that a painter arrives at the style of perfection which the Italians call giufts grandiosi, the French le beau idéal, and the English the great fyle.

A mind (says Sir Joshua Reynolds, enriched by an assemblage of all the treasures of ancient and modern art, will be more elevated and fruitful in resources in proportion to the number of ideas which have been carefully collected and thoroughly digested.

The addition of other mens judgment is so far from weakening, as is the opinion of many, our own, that it will fashion and consolidate those ideas of excellence which lay in their birth feeble, ill shaped, and confused; but which are finished and put in order by the authority and practice of those, whose works may be said to have been consecrated by having flood the heart of ages.

When we speak of the habitual imitation and constant study of masters, it is not to be understood that we advise any endeavour to copy the exact peculiar colour and complexion of another man's mind; the success of such an attempt must always be like his who imitates exactly the air, manners, and gesture, of him whom he admires. His model may be excellent, but he himself will be ridiculous; and this ridicule arises not from his having imitated, but from his not having chosen the right mode of imitation.

It is a necessary and warrantable rule to disdain to walk feively in his own; however elevated his rank. The true and liberal ground of imitation is an open field, where, though he who preceded him had the advantage of having g before you, yet it is enough for his course; you need not tread in his footsteps; and you certainly have a right to outstrip him if you can.

Nor, whilst I recommend studying the art from artists, can I be supposed to mean that nature is to be neglected: I take this study in aid, and not in exclusion of the other. Nature is, and must be, the foundation, which alone is inexhaustible; and from which all Colouring excellencies must originally flow.

The great use of studying our predecessors is to open the mind, to shorten our labour, and to give us the result of the efforts made by those great minds of what is grand or beautiful in nature: her rich stores are all spread out before us; but it is an art, and no easy art, to know how or what to choose, and how to attain and secure the object of our choice.

Thus the highest beauty of form must be taken from nature; but it is an art of long deduction and great experience to know how to find it. I cannot avoid mentioning here an error which students are apt to fall into.

He that is forming himself must look with great caution and wariness on those peculiarities or prominent parts which at first force themselves on view, and are the marks, or what is commonly called the manner, by which that individual artist is distinguished.

Peculiar marks I hold to be generally, if not always, defects, however difficult it may be wholly to escape them.

Peculiarities in the work of art are like those in the human figure; it is by them that we are cognizable and distinguished one from another; but they are always so many blemishes, which however, both in the one case and in the other, cease to appear deformities to those who have them continually before their eyes. In the works of art, even the most enlightened mind, when warmed by beauties of the highest kind, will by degrees find a repugnance within him to acknowledge any defects; yet his enthusiasm will carry him so far as to transform them into beauties and objects of imitation.

It must be acknowledged, that a peculiarity of style, either from its novelty, or by seeming to proceed from a peculiar turn of mind, often escapes blame; on the contrary, it is sometimes striking and pleasing; but it is vain labour to endeavour to imitate it, because novelty and peculiarity being its only merit, when it ceases to be new, it ceases to have value.

A manner, therefore, being a defect, and every painter, however excellent, having a manner, it seems to follow, that all kinds of faults as well as beauties may be learned under the influence of the greatest authorities."

"Sect. V. Of Colouring.

Colouring, though a subject greatly inferior to many others to which the painter must study, is yet of sufficient importance to employ a considerable share of his attention; and to carry in it, he must be well acquainted with that part of optics which has the nature of light and colours for its object. Light, however simple and uncompoundcd it may appear, is never without made up, as it were, of several distinct substances; and the number, and even dose, of these ingredients, has been happily discovered by the moderns. Every undivided ray, let it be ever so fine, is a little bundle of red, orange, yellow, green, azure, indigo, and violet rays, which, while combined, are not to be distinguished one from another, and form that kind of light called color;
Painting.

Part I.

Colouring.

Trattato della Pittura, c. 12.

"Cubite;" so that white is not a colour per se, as the learned Da Vinci (so far, it seems, the precursor of Newton) expressly affirms, but an allegeme of colours. Now, these colours, which compose light, although immutable in themselves, and endued with various qualities, are continually, however, separating from each other in their reflection from and passage through other substances, and thus become manifest to the eye. Grays, for example, reflect only green rays, or rather reflect green rays in greater number than it does those of any other colour; one kind of wine transmits red rays, and another yellowish rays; and from this kind of separation arises that variety of colours with which nature has diversified her various productions. Man, too, has contrived to separate the rays of light by making a portion of the sun's beams pass through a glass prism; for after passing through it, they appear divided into seven pure and primitive colours, placed in succession one by the other, like so many colours on a painter's palette.

Now, though Titian, Correggio, and Vandyke, have been excellent colourists, without knowing anything of these phyletic subtleties, that is no reason why others should neglect them. For it cannot but be of great service to a painter to be well acquainted with the nature of what he is to imitate, and of those colours with which he is to give life and perfection to his designs; not to speak of the pleasure there is in being able to account truly and solidly for the various effects and appearances of light. From a due tempering, for example, and degrading, of the tints in a picture; from making colours partake of each other, according to the reflection of light from one object to another; there arises, in some measure, that sublime harmony which may be considered as the true muse of the eye. And this harmony has its foundation in the genuine principles of optics. Now this could not happen in the system of those philosophers, who held, that colours did not originally exist in light, but were, on the contrary, nothing else than so many modifications which it underwent in being reflected from other substances, or in passing through them; thus subjected to alterations without end, and every moment liable to perils. Were that the case, bodies could no more receive any hues from another, nor this body partake of the colour of that, than scarlet, for example; because it has the power of changing into red all the rays of the sun or fire which immediately fall upon it, has the power of changing into red all the other rays reflected to it from a blue or any other colour in its neighbourhood.

Whereas, allowing that colours are in their own nature immutable one into another, and that every body reflects, more or less, every sort of coloured rays, though those rays in the greatest number which are of the colour it exhibits, there must necessarily arise, in colours placed near one another, certain particular hues or temperaments of colour: nay, this influence of one colour upon another may be so far traced, that three or four bodies of different colours, and likewise the intensities of the light falling upon each, being assigned, we may easily determine in what situations and how much they would tinge each other. We may thus too, by the same principle of optics, account for several other things practiced by painters; insomuch that a painter, who has carefully observed natural effects with an eye directed by solid learning, shall be colouring able to form general rules, where another can only distinguish particular cases.

But after all, the pictures of the best colourists are, it is universally allowed, the books in which a young painter must chiefly look for the rules of colouring; that is, of that branch of painting which contributes so much to express the beauty of objects, and is so requisite to represent them as what they really are. Correggio and Titian seem to have discovered circumstances in nature which others have entirely overlooked; and the last in particular has been happy enough to express them with a pencil as delicately as his eye was quick and piercing. In his works we behold that sweetness of colouring which is produced by union; that beauty, which is consistent with truth; and all the intangible transmutations, all the soft transitions, in a word, all the pleasing modulations, of tints and colours. When a young painter has, by close application, acquired from Titian, whom he can never sufficiently dwell upon, that art which, of all painters, he has felt contrived to hide, he would do well to turn to Baffano and Paño, on account of the beauty, boldness and elegance of their touches. That richness, softness, and freshness of colouring, for which the Lombard school is so justly cried up, may likewise be of great service to him. Nor will he reap less benefit by studying the principles and practice of the Flemish school; which, chiefly by means of her vanishes, has contrived to give a most enchanting lustre and transparency to her colours.

But whatever pictures a young painter may choose to study the art of colouring upon, he must take great care that they are well preferred. There are very few pieces which have not suffered more or less by the length, not to say the injuries, of time; and perhaps that precious patina, which years alone can impart to paintings, is in some measure akin to that other kind which ages alone impart to medals; inasmuch as, by giving testimony to their antiquity, it renders them proportionably beautiful in the superlative eyes of the learned. It must indeed be allowed, that if, on the one hand, this patina beflows, as it really does, an extraordinary degree of harmony upon the colours of a picture, and destroys, or at least greatly lefens their original rawness, it, on the other hand, equally impairs the freshness and life of them. A piece seen many years after it has been painted, appears much as it would do, immediately after painting, behind a dull glass. It is no idle opinion, that Paolo Veronese, attentive above all things to the beauty of his colours, and what is called frescito, left entirely to time the care of harmonizing them perfectly, and (as we may say) mellowing them. But most of the old masters took that talk upon themselves; and never exposed their works to the eyes of the public, until they had ripened and finihed them with their own hands. And who can say whether the Christ of Moneta, or the Nativity of Baffano, have been more improved or injured (if we may so speak) by the touchings and retouchings of time, in the course of more than two centuries? It is indeed impossible to be determined. But the studious pupil may make himself ample amends for any injuries which his originals may have received from the hand of time, by turning to truth, and to Nature which never grows old,
PAINTING. Part I.

Draper.

Drapery is one of the most important branches of the whole art, and accordingly demands the greatest attention and study. It seldom happens that a painter has nothing but naked figures to represent; nay, his subjects generally consist of figures clothed from head to foot. Now the flowing of the folds in every garment depends chiefly upon the relief of the parts that lie under it. A certain author, we forgot his name, observes, that as the inequalities of a surface are discoverable by the inequalities in the water that runs over it, so the posture and shape of the members must be discernible by the folds of the garment that covers them. Those idle windings and gatherings, with which some painters have affected to cover their figures, make the clothes made up of them look as if the body had fled from under them and left nothing in its place but a heap of empty bubbles, fit emblems of the brain that conceived them. As from the trunk of a tree there issue here and there boughs of various forms, so from one miterless fold there always flow manyelier ones: and as it is on the quality of the tree that the elegance, compactness, or openness of its branches chiefly depends; it is, in like manner, by the quality of the fluid of which a garment is made, that the number, order, and size of its folds must be determined. To sum up all in two words, the drapery ought to be natural and easy, so as to show what stuff it is, and what parts it covers. It ought, as a certain author expresses it, to cover the body, as it were merely to fit with.

It was formerly the custom with some of our masters to draw all their figures naked, and then drape them from the same principle that they first drew the skeletons of their figures, and afterwards covered them with muscles. And it was by proceeding in this manner that they attained to such a degree of truth in expressing the folds of their drapery, and the joints and directions of the principal members that lay under it, so as to exhibit in a most striking manner the attitude of the person to whom they belonged. That the ancient sculptors clothed their statues with equal truth and grace appears from many of them that are still in being; particularly a Flora lately dug up in Rome, whose drapery is executed with so much judgment, and in so grand and rich a style, that it may vie with the finest of their naked statues, even with the Venus of Medicis. The statues of the ancients had so much beauty when naked, that they retained a great deal when clothed. But here it must be considered, that it was usual with them to suppose their originals clothed with wet garments, and of an extreme fineness and delicacy, that by lying close to the parts, and in a manner clinging to them, they might the better show what these parts were. For this reason a painter is not to confine himself to the study of the ancient statues, lest he should contract a dry style, and even fall into the same faults with some great masters who accustomed to drape with such light stuffs as fit close to the body, have afterwards made the coarsest lie in the same manner, so as plainly to exhibit the muscles underneath them. It is therefore proper to study nature herself, and those modern masters who have come nearest to her in this branch; such as Paolo Veroneze, Andrea del Sarto, Rubens, and above all, Guido Reni. The flow of their drapery is soft and gentle; and the gatherings and plait is are so contrived, as not only not to hide the body but to add grace and dignity to it. There gold, silk, and woollen stuffs, are so distinguishable one from another, by the quality of their several lustres, and the peculiar light and shade belonging to each, that above all, it is by the form and flow of their folds, that the age and sex of their figures are hardly more discoverable by their faces. Albert Durer is another great master in this branch, inasmuch that Guido himself was not ashamed to study him. There are still extant several drawings made with the pen by this great man, in which he has copied whole figures from Albert, and scrupulously retained the flow of his drapery as far as his own peculiar style, left harth and sharp, but more easy and graceful, would allow. It may be said that
Part I. PAINTING.

Draperies. It was necessary that the folds should be large and few in number; for large folds produce great masses of light and shadow, while small ones multiply the objects of view and distract the attention. But if the character of the drapery or kind of stuff require small folds, they should at least be distributed in groups, in such a manner that a great number of small folds shall be subordinate to an equal mass formed by a principal fold.

It is also proper to observe, that the colour of the drapery contributes to the harmony of the whole, and produces effects which the chiaro-obscuré cannot do alone. At the same time, the principles of the chiaro-obscuré should prevail over, or at least regulate, the art of drapery. If the folds of the stuff which cover the members exposed to the light are too strongly shaded, they will appear to enter into the members, and cut them.

Drapery contributes to the life, to the character, to the expression of the figures, provided all the movements of the folds announce the lively or more tranquil movement of those figures. The colour, and the kind of stuff concur also to promote the general expression; brilliant or fine drapery cannot be properly introduced in a mournful subject, nor the opposite in a gay one.

The drapery must also agree with the age and character of the figures: And if nature in any instance is found to contradict those principles, it is because they relate to the ideal of the art; and it is this ideal which carries it to the greatest perfection.

Great attention is also necessary to the situation in which the figures are placed, and the actions about which they are employed. If they are in the act of ascending, a column of air weighs down the drapery; if, on the contrary, they are defending, the drapery is supported and spread out. The folds placed on every member, and the general play of the drapery, should indicate whether the figure is in action or about to be so; whether action be beginning or ending; and whether it be flow, or quick, or violent. All this is agreeable to nature; but it also partakes of the ideal, since nature never can be copied in such fluctuating situations. The practice of the Roman schools, first to draw after nature, and then to paint after the drawing, cannot be adopted by colourists; because nature, according to the kind of the stuffs, produces tones and lights which give more perfection and truth to the work. Meanwhile Raphael, who followed this practice, enjoys the first reputation for giving play to his drapery, and disposing the folds in the best order. In this part he has even attained the height of ideal beauty. He is the greatest painter of drapery, as the Venetians are the greatest in painting fluids.

Raphael, says Mengs, imitated at first his master PerUGIN'S manner of drapery, and he brought this manner to perfection, by studying the works of MasACCIO and of Bartholomew; but he departed entirely from the taste of the school in which he was educated when he had seen the works of the ancients. It was the baso-relievo of antiquity which pointed out to him the true flowing of drapery, and he was not backward to introduce it. He discovered, by attending to the principles of the ancients, that the naked is the principal part; that drapery is to be regarded altogether as an accessory, and that it is intended to cover, not to conceal: that it is employed from necessity, not caprice; that of consequence the clothes should not be so narrow as to constrain the members, nor so ample as to embarrass them; but that the artist should adapt them to the fize and attitude of the figures intended to wear them.

He understood that the great folds should be placed at the large places of the body; and where the nature of the drapery required small folds, that it was necessary to give them a projection, which indicates a sub-ordination to the principal parts.

He made his ample draperies without useless folds, and with bendings at the articulations. It was the form of the principal parts, and the specific weight of the air, were always the causes of his folds. It was easy to discover in his works, by the folds of his drapery, the attitude of the figure previous to the one in which it was placed: and whether, for example, the arm was extended or otherwise, immediately before the action. This was an expression which he had carefully studied on all occasions, because he found it in nature.

When the drapery was to cover the leg or arm but half, or in an imperfect manner, he made it cut obliquely the member which was partly to be covered. His folds were of a triangular form. The reason of this form is nature: for all drapery has a tendency to enlarge itself and be extended; and as at the same time its own weight obliges it to fall back on itself, it is naturally formed into triangles.

He knew perfectly, that the movements of the body and of its members are the causes of the actual situation of drapery, and of the foundation of its folds. All his practice is nothing else but the unfolding and demonstrating of this theory; and drapery executed in any other manner must be in a false and vicious taste.

Sect. VIII. Of Landscape and Architecture.

When our young painter has made a sufficient progress in those principal branches of his art, the designing, perspective, colouring, and drapery of human figures, he should turn his thoughts to landscape and architecture: for, by studying them, he will render himself universal and qualified to undertake any subject; so as not to resemble certain literalists, who, though great masters in some articles, are mere children in every thing else.

The most eminent landscape-painters are Poussin, Lorenoé, and Titian. Poussin was remarkable for his great diligence. His pieces are quite exotic and uncommon; being set off with buildings in a beautiful but singular style, and
PAINTING.

Part I.

Expression of the

Palladian.

That language which above all others a painter should carefully endeavour to learn, and from nature herself, is the language of the painter. Without it the finest works must appear lifeless and inanimate. It is not enough for a painter to be able to delineate the most exquisite forms, give them the most graceful attitudes, and compose them well together: it is not enough to draw them out with propriety, and in the most beautiful colours; it is not enough, in fine, by the powerful magic of light and shade, to make the canvas vanish. No; he must likewise know how to clothe his figures with grief, with joy, with fear, with anger; he must, in some sort, write on their faces what they think and what they feel; he must give them life and speech. It is indeed in this branch that painting truly fears, and in a manner riles superior to itself; it is in this branch the spectator apprehends much more than what the painter expresses.

The means employed in her imitations by painting, are the circumjacent forms of the chiaroscuro, and colours; all which appear solely calculated to strike the visual faculty. Now, withstanding which, the contrivings to represent hard and soft, rough and smooth surfaces, which are objects of the touch; and this by means of certain tints, and a certain chiaroscuro, which has a different look in marble, in the bark of trees, in downy and delicate substances. Nay, the contrivings to express found and motion, by means of light and shade, and certain particular configurations. In some landscapes of Diderich, we almost hear the water murmur, and see it tremble along the sides of the river and of the boats upon it. In the battle of Burgoyne, we are really apt to fancy that the trumpet sounds; and we see the horse, who has thrown his rider, scamper along the plain. But what is still more wonderful, painting, in virtue of her various colours and certain particular gestures, expresses even the sentiments and most hidden affections of the soul, and renders her visible, so as to make the eye not only touch and hear, but even kindle into passion and reason.

Many have written, and amongst the rest the famous Le Brun, on the various changes that, according to the various passions, happen in the muscles of the face, which, as it were, the dumb tongue of the soul.
Byrons, for example, that in fits of anger the face reddens, the muscles of the lips pull out, the eyes sparkle; and that, on the contrary, in fits of melancholy, the eyes grow motionless and dead, the face pale, and the lips sink in. It may be of service to a painter to read these and such other remarks; but it will be of infinitely more service to study them in nature itself, from which they have been borrowed, and which exhibits them in that lively manner which neither tongue nor pen can express.

Upon Le Brun's Treatise on the Passions, we have the following judicious, though severe, criticism by Winkelman. "Expression, though precocious in its nature (says he), has been reduced into a system, in a Treatise on the Passions by Charles Le Brun, a work generally put into the hands of young artists. The plates which accompany this treatise do not only give to the face the affections of the soul in too high a tone, but there are many of the heads in which the passions are represented in an outrageous manner. He appears to give instructions in expression, as Diogenes gave examples of morality: I act like musicians, said that cynic, who give a high tone, in order to indicate a true one. But the servior of youth has naturally more inclination to seize the extreme than the middle; and hence it is difficult for the young artist, in copying after Le Brun, to seize the true tone. Youth may be supposed to have that regard for the calm and moderate in the arts, which they have for the precepts of wisdom and virtue."

Other French writers have given instructions respecting the expression of the passions, equally exceptional with those of Le Brun. All of them whom we have consulted make so many divisions and subdivisions of passions, that a philosopher cannot follow them in metaphorical theory, nor a painter exhibit their effects upon canvas. Nature therefore must be his guide particularly in treating those very minute and almost imperceptible differences, by which, however, things very different from each other are often expressed. This is particularly the case with regard to the passions of laughing and crying; as in thele, however, contrary to the mechanic, the muscles of the face operate in the same manner. As the famous Pietro de Cortona was one day finishing the face of a crying child in a representation of the Iron Age, with which he was adorning the floor called the Hall of the Royal Palace of Pisa, Ferdinand II, who happened to be looking over him for his amusement, could not forbear expressing his approbation, by crying out, "Oh how well that child cries!" To whom the artist answered, "Has your majesty a mind to see how easy it is to make children laugh? Behold, I shall prove it in an instant." And taking up his pencil, by giving the contour of the mouth a concave turn downwards, instead of the convex upwards which it before had, and with little or no alteration in any other part of the face, he made the child, who a little before seemed ready to burst its heart with crying, appear in equal danger of bursting its sides with immoderate laughter; and then by rendering the altered features to their former position, he soon set the child a-crying again.

The different expressions of laughter and weeping are thus described by Le Brun. "The movements of laughter are expressed by the eye-brows elevated towards the middle of the eye, and lowered towards the sides of the nose; the eyes almost shut, appear sometimes moistened with tears; the mouth a little open, allows the teeth to be seen: the extremities of the mouth drawn back, make a dimple in the cheeks, which appear to be swelled; the nostrils are open; and the face becomes red. The changes which weeping occasions are equally visible. The eye-brow is lowered on the middle of the forehead; the eyes are almost shut, moistened and lowered towards the sides of the cheeks; the nostrils are swelled, and the veins of the forehead very apparent: the mouth shut, by the lowness of its sides, occasions wrinkles in the cheeks; the under lip is turned down, and presses at the same time the upper lip; the whole countenance is wrinkled and becomes red: especially the eye-brows, the eyes, the nose, and the cheeks."

According to Leonardo da Vinci, the best masters that a painter can have recourse to in this branch are those dumb men who have found out the method of expressing their sentiments by the motion of their hands, eyes, eye-brows, and in short every part of the body. If this advice be at all proper, such gestures must be imitated with great fidelity and moderation, lest they should appear too strong and exaggerated; and the piece should show nothing but pantomimes, when speaking figures alone are to be exhibited; and so become theatrical and second-hand, or at best, look like the copy of a theatrical and second hand nature.

The artist will reap greater benefit from studying such fine ancient heads as those of Mithridates, Sene­ca, Alexander dying, Cleopatra, Niobe, &c. and above all, from attentively observing such movements of nature as we daily meet with in the world. But let him chiefly consult his looking-glass, and study after his own face, what, in certain expressions, are the muscles, the linear motions, the tints, and the accidental circumstances which characterize the situation of the soul. It rarely happens that a model, which is affected with no sentiment, presents to us which we ourselves feel, and which we are capable of expressing when we are our own model. Puget executed the legs of his Milo after his own; and many ingenious artists have had recourse to a similar expedient. In short to be affected ourselves is the true secret of affecting the spectator.

We must not neglect, at the same time, to secure the fleeting charactères which nature presents to us, thousand occasions. We must distrust our memory, and all the resources which are not easily employed when we happen to flound in need of them. It is necessary to watch the circumstances from which we can derive any useful hint; to seize them when they present themselves; and to be careful never to lose, by an irreparable negligence, the fruit of a happy incident.

Let us also endeavour to posses the feeling of what we are to express; whether it be by forming the image of a thing absent as if it were present, or by being affected, with the lively idea of a situation which we have either experienced, or with which we have seen another person remarkably affected. We must never forget, that all the terrible or agreeable, the violent or flight movements, are to be treated in a natural manner; and bear a relation to the age, conditions,
P A I N T I N G.

Part I.

Expression of the Passions.

Expression of the Passions, or the beauty, grandeur, and dignity of the person. Those gradations, which art varies according to the nature of the situation, and the character of men, compose the principal ingredients of discerment, knowledge, and taste. They have been the objects of attention and inquiry to the most eminent artists of every age; and they were of the last importance in enabling them to arrive at that degree of excellence to which they have carried expression.

We are told strange things of the ancient painters of Greece in regard to expression: especially of Aristides, who in a picture of his, representing a woman wounded to death at a siege, with a child crawling to her breast, makes her appear afraid, left the child, when she was dead, should, for want of milk, suck her blood. A Medea murdering her children, by Timonachus, was likewise much cried up, as the ingenious artful contrivance to express, at once, in her countenance, both the fury that hurried her on to the commission of so great a crime, and the tenderness of a mother that found it necessary to hold her from it. Rubens attempted to express this double effect in the face of Mary of Medicis, in pain from her past labour, and at the same time full of joy at the birth of a Dauphin. And in the countenance of Sandro Bototo, painted by Tiepolo for St. Anthony's church at Padua, one may clearly read a mixture of pain from the wound given her by the executioners, and of pleasure from the prospect of paradise opened to her by her Lord.

Few, to say the truth, are the examples of strong expression afforded by the Venetian, Flemish, or Lombard schools. Deprived of that great happiness, the happiness of being able to contemplate, at leisure, the works of the ancients, the purest sources of perfection in point of design, expression, and character; and having nothing but nature constantly before their eyes; they made strength of colouring, blooming complexion, and the grand effects of chiaroscuro, their principal study; they aimed more at charming the senses than at captivating the understanding. The Venetians, in particular, seem to have placed their whole glory in setting off their pieces with all that rich variety of personages and draperies, which their capital is continually receiving by means of its extensive commerce, and which attracts so much the eyes of all those who visit it. It is much to be doubted, if in all the pictures of Paolo Veronese, there is to be found a bold and judicious expression, or one of those attitudes which, as Petrarch expresses it, speak without words; unless, perhaps, it be that remarkable one in his Marriage of Cana of Galilee. At one end of the table, and directly opposite to the bridegroom, whose eyes are fixed upon her, there appears a woman in red, holding up to him the skirt of her garment; as much as to say, we may suppose that the wine miraculously produced was exactly of the colour of the stuff on her back. And in fact it is red wine we see in the cups and pitchers. But all this while the faces and attitudes of most of the company betray not the least sign of wonder at so extraordinary a miracle. They all, in a manner, appear intent upon nothing but eating, drinking, and making merry. Such in general, is the style of the Venetian school. The Florentine, over which Michael Angelo presided, above all things curious of design, was most minute and scrupulously ex-
when defires of trying his strength this way, and producing something from his own mind. Invention is the finding out probable things, not only such as are adapted to the subject in hand, but such, besides, as by their sublimity and beauty are most capable of exciting suitable sentiments in the spectator, and of making him, when they happen to be well executed, fancy that it is the subject itself in its greatest perfection, and not a mere representation of it, that he has before him. We do not say true things, but probable things; because probability or verisimilitude is, in fact, the truth of those arts which have the fancy for their object. It is, indeed, the business and duty of both naturalists and historians to draw objects as they find them, and represent them with all those imperfections and blemishes, to which as individuals, they are subjected. But an ideal painter, and such alone is a true painter, refembles the poet: instead of copying, he imitates; that is, he works with his fancy, and represents objects endowed with all that perfection which belongs to the species, and may be conceived in the archetype.

"'Tis nature all, but nature methodized,"

says an eminent poet, speaking of poetry: And the same may be said of painting; it is nature methodized, and made perfect. In short, that the circumstances of the action, exalted and sublimed to the highest degree of beauty and sublimity, which may happen exactly such as the painter fancies and thinks proper to represent them. Thus, the piety of Aeneas, and the anger of Achilles, are things so perfect in their kind, as to be merely probable. And it is for this reason that poetry, which is only another word for invention, is more philosophical, more intructive, and more entertaining, than history.

Here it is proper to observe, what great advantages the ancient had over the modern painters. The history of the times they lived in, fraught with great and glorious events, was to them a rich mine of the facts, their sublimity and probability; as to be merely probable. And it is for this reason that poetry, which is only another word for invention, is more philosophical, more intructive, and more entertaining, than history.

Here it is proper to observe, what great advantages the ancient had over the modern painters. The history of the times they lived in, fraught with great and glorious events, was to them a rich mine of the facts, their sublimity and probability; they never happened exactly such as the painter fancyed and thought proper to represent them. Thus, the piety of Aeneas, and the anger of Achilles, are things so perfect in their kind, as to be merely probable. And it is for this reason that poetry, which is only another word for invention, is more philosophical, more instructive, and more entertaining, than history.

Here it is proper to observe, what great advantages the ancient had over the modern painters. The history of the times they lived in, fraught with great and glorious events, was to them a rich mine of the facts, their sublimity and probability: they never happened exactly such as the painter fancyed and thought proper to represent them. Thus, the piety of Aeneas, and the anger of Achilles, are things so perfect in their kind, as to be merely probable. And it is for this reason that poetry, which is only another word for invention, is more philosophical, more instructive, and more entertaining, than history.

After all, there have not been wanting able inventors in painting among the moderns. Michael Angelo, notwithstanding the depth and boldness of his own fancy, is not aftounded, in some of his compositions, to Dantiscis; as Phidias and Apeles may be said formerly to have Homerized. Raphael, too, entered by the Greeks, has found means, like Virgil, to extract the quintessence of truth; has feaoned his works with grace and nobleness, and exalted nature, in a manner above herself, by giving her an aspect more beautiful, more animating, and more sublime, than she is in reality accustomed to wear. In point of invention, Domenichino and Hennibals Carracci came very near Raphael, especially in the pieces painted by them in Rome; nor does Poussin fall very short of him in some of his pictures, particularly in his Eicher before Abasurus, and his Death of Germanicus, the richest jewel belonging to the Barberine family. Of all the painters who have acquired any extraordinary degree of reputation, no one studied less to set off his pieces by bold and beautiful circumstances, or was more a stranger to what is called poetical perfection, than Jacopo Bassano. Among the numberless instances we could produce of his carelessness this way, let it suffice to mention a Preaching of St. Paul, painted by him in a place, near that of his birth, called Murphys. Instead of representing the apostle full of a divine enthusiasm, as Raphael has done, and thundering against the superstitions of the heathen in an assembly of Athenians; instead of exhibiting one of his auditors struck to the quick, another persifledled, a third inflamed; he makes him hold forth, in a village of the Venetian state, to a parcel of poor peasants and their wives, who take not the least notice of him; the women especially, who seem to mind nothing but the country labours, in which he had found them employed.

With regard to invention, painting and poetry resemble each other so much in many other respects, besides that of combining in every action all the beauty and elegance it will admit, that they well deserve the name of fijter arts. They differ, however in one point, and that too of no small importance. It is this, the poet, in the representation of his story, relates what has already happened, prepares that which is still to come; and so proceeds, step by step, through all the circumstances of the action; and, to produce the greater effect on his hearers, avails himself of the succession of time and place. The painter, on the contrary, deprived of such helps, must be content to depend on the sublimity and beauty of his composition.
The arms forged by Vulcan for Æneas, if not better tempered, are at least better engraven, than those which the same god had forged several ages before for Achilles. Nevertheless, in the eyes of judges, both the games and the arms of Homer are more pleasing than those of Virgil, because the former are more necessary in the Iliad than the latter in the Æneid. Every part should agree with, and have a relation to, the whole. Unity should reign even in variety; for in this beauty consists. This is a fundamental maxim in all the arts whose object it is to imitate the works of nature.

Pictures often borrow no small grace and beauty from the fictions of poetry. Albani has left us, in several of his works, sufficient proofs of the great share the belles lettres had in refining his taste. But Raphael, above all others, may in this branch too be considered as a guide and master. To give but one instance out of many; what a beautiful thought was it to represent the river himself, in a Passage of Jordan, with the arms of Alexander, conquered by the beauty of Rosso and Lampi. Among the ancients, Apelles and Parthenius were those who distinguished themselves most in allegorical Life ofSubjects, in which the inventive faculty shows itself to the greatest advantage: the first by his picture of Calaminæ*, the second by that of the Genius of the Athenians†. The ancient painter called Galatius gave

of the Poet.

So much for invention. Diffusion, which may be considered as a branch of invention, consists in the proper classification of what the narrative faculty has imagined, so as to express the subject in the most lucid manner. The chief merit of diffusion may be said to consist in that disorder, which, wearing the appearance of mere chance, is in fact the most finished effect of art. A painter, therefore, is equally at a loss to save the dryness of those ancient works which always painted their figures like so many copies in a precipitation, and the affection of those moderns who jumble them together as if they were meant merely to fight and squabble. In this branch Raphael was happy enough to choose the just medium, and attain perfection. The disposition of his figures is always exactly such as the subject requires. In the Battle of Carthage, they are confusedly cluttered with as much art, as they are regularly marshalled in Chirrip's commissary of the keys to St. Peter and constituting him prince of the apostles.

Let the inferior figures of a peace be placed as they will, the principal figure should strike the eye most and stand out, as it were, from among the rest. This may be effected various ways, as by placing it on the foremost lines, or in some other conspicuous part of the piece; by exhibiting it, in a manner, by itself; by making the principal light fall upon it; by giving it the most resplendent drapery; or, indeed, by several of these methods, may, by all of them together. For, being the hero of the picturesque theme, it is but just that it should draw the eye to itself, and lord it, as it were, over all the other objects.

According to Leon Battaia Alberti, painters should follow the example of comic writers, who compose their fables of as few persons as possible. For, in fact, a crowded picture is apt to give as much pain to the spectator, as a crowded road to the traveller.

Some subjects, it must be granted, require a number, nay, a nation, as it were, of figures. On these occasions, it depends entirely on the skill of the painter to diffuse them in such a manner, that the principal one may always make the principal appearance, and contrive matters so, that the piece be not over-crowded, or want convenient reliefs and palettes. He must, in a word, take care that his piece be full, but not charged.

In this respect, the Battle of Alexander by Le Brun are master-pieces which can never be sufficiently studied; whereas nothing, on the other hand, can be more unhappy than the famous Paradise of Tintoret, which covers one entire side of the great council chamber at Venice. It appears no better than a confused heap of figures, a swarm, a cloud, a chaos, which pains and fatigues the eye. What a pity it is that he did not dispose the subject after a model of his own, now in the gallery of Bevilacqua at Verona! In this last, the several choirs of myrtys, virgins, bishops, and other saints, are judiciously thrown into so many clusters, parted here and there by a fine fleec of clouds: so as to exhibit the immeasurable host of heav
By varying the height and direction of his light, he may easily discover such accidental effects as are most likely to recommend his performance, and so establish a proper medium for the illuminating it. Nor will he afterwards find it a difficult matter to modify the quality of his shades, by softening or strengthening them, according to the situation of his image, and the quality of the light falling upon it. If it should happen to be a candle or lamp light scene, he would then have nothing to do but consider his model well, and faithfully copy it.

In the next place, to turn a group elegantly, the best pattern is that of a bunch of grapes adopted by Titian. As, of the many grains that compose a bunch of grapes, some are struck directly by the light and those opposite to them are in the shade, whilst the intermediate ones partake of both light and shade in a greater or less degree; fo, according to Titian, the figures of a group should be so disposed, that by this union of the chiaro-scuro, several things may appear as it were but one thing. And in fact it is only from his having pursued this method, that we can account for the very grand effect of his pieces this way, in which it is impossible to fludg him too much.

The mannerists, who do not follow nature in the track of the masters just mentioned, are apt to commit many faults. The reason of their figures casting their shades in this or that manner seldom appears in the picture, or at least does not appear sufficiently probable. They are, besides, wont to represent all bounds in splashing their pieces with light, that is, in enlivening those parts which we usually term the deafs of a picture. This method, no doubt, has sometimes a very fine effect; but it is, however, to be used with no small discretion, as otherwise the whole loses that union, that pace, that majestic silence, as Carracci used to call it, which affords so much pleasure. The eye is not less hurt by many lights scattered here and there over a picture, than the ear is by the confused noise of different persons speaking all together in an assembly.

Guido Reni, who has imparted to his paintings a gayety and splendour in which he lived, seems adorned with a bright and opulent light; whereas Michael Angelo da Caravagio, who was of a sullen and savage disposition, appears fond of a gloomy and clouded sky; so that neither of them were qualified to handle indifferently all objects. The chiaro scuro may likewise prove of great service to a painter in giving his composition a grand effect; but, nevertheless, the light he chooses must be adapted to the situation of the scene where the action is laid: nor would he be left faulty, who in a grotto or cavern, where the light entered by a chink, should make his shades soft and tender, than he who should represent them strong and bold in an open sky-light.

But this is by no means the only fault which mannerists are apt to be guilty of in historical pieces, and particularly in the disposition of their figures. To lay nothing of their favourite group of a woman lying on the ground with one child at her breast, and another playing about her, and the like, which they generally place on the first lines of their pieces; nor of those half figures in the back ground peeping out from the hollows contrived for them: they make a common practice...
Among the obstructions which are opposed to the perfection of this branch of the art, we shall chiefly attend to this which naturally proceeds from our habits of thinking and judging on all occasions. These, together with the experience we daily have of light on all kinds of surfaces, and of all colours, are sufficient to demonstrate the want of reality in the mere representation of any scenes.

It has been elsewhere shown, that distance, figure, and magnitude, are not naturally objects of perception by the sense of sight; that we judge of these things by the eye only, in consequence of allocations early formed between the perceptions of touch and the corresponding impressions on the retina and optic nerve by the rays of light; and that a painter makes his picture resemble the original, merely by laying his colours on a plain surface in such a manner, as that they reflect the same rays of light with the convex or concave original, when the spectator stands at the proper distance (see Metaphysics, n. 49, 50, 51, 52, and 95). But if this be admitted, illusion in painting can never be made perfect, on account of the inevitable fallacy of the shades which mark the most distant parts of the picture. The painter can only imitate those shades by obsolete colours, laid on a plane surface, and susceptible of reflecting the light with a degree of force relative to the real distance. Now our eyes give us the true plane of this surface, opposed to the idea of deepening which the painter wishes to produce, a contrariety which prevents the deception. On this account, the faults found in the works of the greatest masters, with regard to the effects produced by the whole, most frequently relate to their manner of shading, which is sufficient to prove, that the want of illusion in painting depends chiefly on the imperfection of the shades.

The defect, though it cannot be wholly avoided, may yet be rendered less perceptible. There has yet indeed, been no painter able to imitate shadow, nor is it probable that any one will ever perfectly accomplish this task. Shadow in nature is not a body, but the privation of light, which destroys colours in a greater or less degree, in proportion as it is more or less complete. Now the painter can only imitate this privation and real darkens, by colours which must from their very nature be capable of reflecting light—

The colours may be more or less obscure, but they prefer always something which gives a mixture of reflection. To carry the imitation of the shadow to the highest degree of perfection, it would be necessary to apply a colour capable of darkening all others more or less as there should be occasion, and which might have no visible trace of its existence, that is, no one part of it which reflected one coloured ray more strongly than another. Perhaps this kind of negative colour might be found in practice to be of service to the art; but it would not render the surface totally invisible, for it would be necessary, further, that it should have the property of not reflecting a single ray of light when exposed to it, which is altogether impossible, as there is no colour or body in nature without reflection in such a situation.

We shall be further convinced of the impossibility of
of painting shadow, if we attend to the pictures of the greatest masters, with regard to the imitation of truth. Every part, when taken by itself, connected with light, or with demiurges, presents a perfect imitation. Even the different degrees of light or the objects are sufficiently exact; but notwithstanding this assemblage of circumstances corresponding with truth, and of which the result should be perfect illusion, yet in considering the whole, we are never to completely deceive, as to take a picture for a reality; from which we may conclude, that the want of illusion proceeds almost entirely from the imperfection of shading.

Illusion in the strictest sense, cannot exist in painting; but there is another kind of illusion, perhaps improperly so called, which is one of the principal parts of the art, and worthy of the greatest attention: It is, that the picture shall resemble truth so much as to be capable of being mistaken for the original, if seen in a small circle of equal dimensions with the original; but it is that truth of imitation of which painting is susceptible, even in pictures containing any number of figures at any reasonable distance from each other.

But it remains to be considered whether this imitation of truth, taken by itself, be the highest attainable perfection in painting. It is generally granted, that the greatest beauty is that which not only pleases at first view, but on the nearest and most critical examination. But if illusion, such as we have described it, were the sole merit of the art, it would follow, that the person who was least acquainted with its beauties would experience the same pleasure as he who had studied them most. Further, in examining the works of the greatest masters, it is easy to perceive, that it is not their illusion which has excited the attention and admiration of the critic. Even the works of the divine Raphael do not deceive the eye in any point of view more completely than those of an ordinary painter. Raphael, pure in his character and design, is, without doubt, very deficient in this part of the art. Meanwhile the grandeur of his ideas in composition, and the choice of his forms: the beauty of his heads, wherein one does not admire simply the imitation of any known truth; his ingenious and noble manner in drapery, which yet does not resemble any known stuff, or the garb of any nation; in short, all his beauties are superior to the simple imitation of truth, and contrary to the sentiment of the greatest pleasure arising from illusion.

If we pass to those who have purified colouring, with the greatest success, we shall find them, doubtless, approach nearer to illusion than those who have neglected it; and it is also a fact, that their works have been more universally admired.

At the same time it is not the illusion occasioned by colours which has altogether excited this admiration. The exquisite demiurges, and the freethinkers of Correggio and Titian, which excite the ordinary beauties of nature, and even imitate her most perfect productions, may perhaps not be considered as destroying illusion; but it is not less a fact, that weaker and less precious colouring would carry it to greater perfection. Besides this large, easy, and exquisite manner of painting, this harmony, of which they have given us the most examples, are owing to qualities in them much more excellent than what would be sufficient to produce the simple imitation of truth. Guido, Correggio, and Titian, although the first failed in colouring and in the knowledge of the claret obscure, the second in point of correctness, and the third in the choice of noble subjects.

From this we may conclude, that the nearest resemblance to truth is not the sole object in painting; that it acquires a superior degree of elevation, by the art of adding beauty and perfection to the most exact resemblance; and that it is this art which distinguishes and characterizes extraordinary men.

If we run over the great branches of painting, we shall find a number of essential beauties different from those which are capable of carrying illusion to the greatest possible height. In composition, we principally admire the extent of genius, the choice of picturesque and graceful attitudes, the ingenious combination of groups, whether in uniting the light and shade in order to obtain the greatest effect, or in dispensing a whole in such a manner as to make no part superfluous; and finally, that kind of practical talent by which the mind takes possession of nature, and forces it to produce all the beauties of which the art is susceptible. In this enumeration of particulars it is easy to perceive that the beauties of composition are very distant from those of illusion.

To obtain illusion in design, there is no occasion for correctness nor taste beyond what is perceived in nature by the most ignorant spectator. And with regard to colouring, that is not always most admired which is most natural. What departs widely from truth, indeed, is not of consequence beautiful, but many qualities are required besides the simple imitation of truth. Freethinkers, also, and transparency in certain tones, are deemed absolutely requisite; and the most esteemed colourists have carried their beauties in all these respects beyond what they have seen in nature. If soft tones in the flesh give have approached towards vermilion, to a light blue, or a silver grey, they have made them more apparent, not only to point them out to the spectator, but to show their knowledge in the discovery and their art in painting them. This would have been going beyond the limits of perfection, if these had confided in simple illusion.

The opposition of colour, of light and of shade, would have been in this case also superfluous; for nature is always true, without any pointed attempt to make her more engaging. The suppression of certain lights, which truth would require, and which art extinguishes, in order to augment the harmony of effect, would be also worthy of censure, whatever pleasure would result from it.

Finally,
Part I.

Painting. Finally, one of the greatest beauties of the art, namely, the peculiar manner of a great master, has no relation to illusion. This is not even founded in nature, but depends on the genius or singularity of the artist. It is this manner which distinguishes the original of a great master from the most exact copy; and which characterizes the talents of the artist so well, that the smallest part of the picture, and even the least interesting, is sufficient to discover the painter. The distinction between the beautiful and illusive in painting has made Sir Joshua Reynolds, in express terms, recommend a perfection superior to the imitation of nature. The principle now laid down (says he), that the perfection of the art does not consist in mere imitation, is far from being new or singular. It is, indeed, supported by the general opinion of the enlightened part of mankind. The poets, orators, and rhetoricians of antiquity, are continually enforcing this position, that all the arts receive their perfection from an ideal beauty, superior to what is to be found in individual nature. They are ever referring to the practice of the painters and sculptors of their times, particularly Phidias the favourite artist of antiquity to illustrate their assertions. As if they could not sufficiently express their admiration of his genius by what they knew, they have recourse to poetical enthusiastic. They call it inspiration; a gift from heaven. The artist is supposed to have ascended the celestial regions to furnish his mind with this perfect idea of beauty. He (says Proclus) who takes for his model such forms as nature produces, and confines himself to an exact imitation of them, will never attain to what is perfectly beautiful. For the works of nature are full of disproportion, and fall short of the true standard of beauty. So that Phidias, when he formed his Jupiter, did not copy any object ever presented to his sight; but contemplated only that image which he had conceived in his mind from Homer's description. It is not easy to define in what this great style consists, nor to describe by words the proper means of acquiring it, if the mind of the student should be at all capable of such an acquisition. Could we teach rules or genius by rules, they would be no longer rules and genius. But though there neither are nor can be any precise invariable rules for the exercise of the acquisition of these great qualities; yet we may truly say that they always operate in proportion to our attention in observing the works of nature, to our skill in fecking, and to our care in digesting, methodizing, and comparing our observations. There are many beauties in our art that seem at first to lie without the reach of precept, and yet may easily be reduced to practical principles. Experience is all in all; but it is not every one that profits by experience; and most people err not so much from want of capacity to find their object, as from not knowing what object to pursue. This great ideal perfection and beauty are not to be sought in the heavens, but upon the earth. They are about us, and upon every side of us: But the power of discovering what is deformed in nature, or, in other words, what is particular or uncommon, can be acquired only by experience; and the whole beauty and grandeur of the art consists in being able to get above all singular forms, local customs, particularities, and details of every kind.

After these opinions, however, derived from the practice of the art, and this high authority, it may not be improper to hazard a few observations. Although illusion can be distinguished from many of the most excellent parts of the art taken separately, yet it does not follow that it shall not add in every picture to the beauty of the whole. It is impossible to state it in opposition to design, to composition, to colouring, or to the peculiar manner of a great artist; because all these may exist where there also exists the most perfect illusion. This is evident from the works of art which have real relics, and which at the same time are capable of perfection in all those branches, and of showing the peculiar manner of the artist. Again, it appears evident, that illusion, properly so called, should be a proper object of attention in painting. We may rate the ideal beauty very high, and with great justice; but it still consists in overcoming the defects in individual objects in nature, and in not departing from the truth of representation. And perhaps it may be alleged, that the impossibility of giving perfect illusion on a plain surface has pulled the greatest matters too far, and made them crowd artificial beauties into their pictures to conceal their want of power to give real ones. It is not improbable, that on this very account the art is less perfect than otherwise it might have been; For in all subjects thought to be impossible, there is not only great room for exertion, but the person carries the art to greater perfection as he comes nearer to show that it may not be impossible. And if the works of Raphael, in point of illusion, are not superior to an ordinary artist, we may be permitted to say that there is great room for improvement in this branch.

Sect. XII. Of the Costume.

The costume in painting corresponds with the unities of time, place, and action, in tragedy and in epic poetry. It is chiefly confined to history-painting; and regards the customs of different periods, the manners, the dress, and the colour, of different nations. Great exactness in the costume is scarcely practicable; but too sensitive a departure from it denotes unpardonable negligence. It frequently happens that a piece composed of picturesque figures derives considerable advantage from certain liberties which are calculated to please both the artist and the spectator; for the judges of painting are not habitually occupied with the details of ancient and modern history, or profoundly versed in all the circumstances which make a departure from the costume confusible. On the other hand, if they were so ignorant as not to understand, or so indifferent as not to regard those circumstances, this branch of the art would be altogether arbitrary. The road of the painter is between these two extremes, not to despise beauty on the one hand, nor probability on the other. But in pursuing this part of the art, it is in vain to seek for perfect models in ancient or modern painting.

When Raphael in his cartoons introduces monks and Swiss guards; when he puts into a boat more figures p. 564. &c.
Artists of the present day should be led to reject the company of common fene; or that Sir Joshua's performances should furnish examples of his own precepts.

"Mrs Siddons is represented by Sir Joshua in the character (as it is said) of the tragic muse: She is placed in an old-fashioned arm chair, this arm chair is supported by clouds, suspended in the air: on each side of her head is a figure not wont to fuffge the idea of the attendant imps of an enchantress: of these figures, one is supposed to represent Comedy, and the other Tragedy; Mrs Siddons herself is decently attired in the fashionable habiliments of 20 or 30 years ago.

"If this be a picture of the tragic muse, she ought not to appear in a modern dress, nor ought she to be seated in an old arm chair. If this be a portraiture of Mrs Siddons, she has no butinfs in the clouds, nor has she any thing to do with aerial attendants. If this be Mrs Siddons in the character of the tragic muse, the first set of objections apply; for she is placed in a situation where Mrs Siddons could never be.

"In the death of Dido, Sir Joshua Reynolds introduces her sister, lamenting over the corpse of the unfortunate queen. This is possible; but he has also introduced Atropos cutting Dido's hair with a pair of scissors, a being equally real and apparent in the painting with Dido or her sister. This (continues our author) appears to me a gross offence against mythological probability; nor is it the only offence against the costume with which that picture is chargeable.

"There is one other breach of the costume, however common among painters, more gross and offensive than any of the infinences hitherto alleged; we mean the perpetual and unnecessary display of the naked figure. We shall not lay to enquire whether more skill can be shown in painting the human body clothed or unclothed. If the personages introduced in any picture are more naked in the representation than can be justified by the probability of the times, persons, places, or circumstances, it is a breach of the costume proportionate to the deviation. This fault, however, is so common, as hardly to be noticed; so flight indeed, when compared with that general taste for voluptuous imagery and obscene representation, which has so long disgraced the art of painting in every stage of its progress, that science and morality are callous to the flight offence.

"This depravity of imagination, this prostitution of the pencil to the base purposes of licentious inclination, was a subject of much complaint among the ancients. Nor is there less reason to complain in modern times, that this delightful art, which might be employed in exciting the noblest sentiments, and become subservient to the best interests of society, should so often be exercised upon subjects solely calculated to please the eye of the voluptuary and debauche. It is hardly possible to pass through any admired collection without meeting with some of these; of which, however excellent the performance may be, the common feelings of decency and morality (if we are neither professed artists nor connoisseurs) prevent us from viewing them without a mixture of disgust."

"Et pudor averto..."

* Albè de Marty.
Part I.

PAINTING.

It is impossible to express how much a picture suffers by such looseness of fancy, and links as a bard of the art in the esteem of good judges. Some people, indeed, are of opinion, that so scrupulous an observance of the costume is apt to hurt pictures, by depriving them of a certain air of truth arising, they think, from those features and habits to which we are accustomed; and which are therefore apt to make a greater impression, than can be expected from things drawn from the remote sources of antiquity; adding, withal, that a certain degree of licence has ever been allowed those artists who in their works must make fancy their chief guide. See, say they, the Greeks, that is, the masters of Raphael and Poultin themselves. Do they ever trouble their heads about such niceties? The Rhodian flatuaries, for example, have not scrupled to represent Lucooon naked; that is, the priest of Apollo naked in the very act of sacrificing to the gods, and that too in the presence of a whole people, of the virgins and matrons of Illium. Nor, continue they, if it was allowable in the ancient flatuaries to neglect probability and decency to such a degree, to have a better opportunity of displaying their skill in the anatomy of the human body; why may it not be allowable in modern painters, the better to attain the end of their art, which is deception, to depart now and then a little from the ancient manners and the too rigorous laws of the costume? But these real men, we beg leave to observe, are more absurd than they are ingenious. What are we to draw conclusions from an example, which, far from deciding the dispute, gives occasion to another? The learned are of opinion, that those Rhodian matters would have done much better had they looked out for a subject in which, without offending so much against truth, and even probability, they might have had an equal opportunity of displaying their know ledge of the naked. And certainly no authority or example whatever should tempt us to do any thing contrary to what both decency and the reason of things require, unless we intend, like Carponi, to represent Sogni d'inferni, e fede di romanzi.

The dreams of daemons and the tales of fools.

No: a painter, the better to attain the end of his art, which is deception, ought carefully to avoid mixing the antique with the modern, the domestic with the foreign; things, in short, repugnant to each other, and therefore incapable of gaining credit. A spectator will never be brought to consider himself as actually present at the scene, the representation of which he has before him, unless the circumstances which enter into the perfect fitly agree among themselves, and the field of action, as we may use the expression, in no shape belies the action itself. For instance, the circumstances, or if you please, the accessories, in a Finding of Moses, are not, fully, to represent the borders of a canal planted with rows of poppies, and covered with country houses in the European taste; but the banks of a great river shaded with clusters of palm-trees, with a Sphinx or an Anubis in the adjacent fields, and here and there in the back ground a towering pyramid. And indeed the painter, before he takes either canvas or paper in hand, should on the wings of fancy transport himself to Egypt, to Thebes, or to Rome; and summoning to his imagination the phytogonomy, the dyes, the plants, the buildings, suitable to his subject, with the particular spot where he has chosen to lay his scenes, to manage the pencil, as by the magic of it, to make the enraptured spectators fancy themselves there along with him.

SECT. XIII. Of proper Books for a Painter.

From what has been already said it may be easily gathered, that a painter should be neither illiterate nor unprovided with books. Many are apt to imagine, that the Iconography of Ripa, or some such collection, is alone sufficient for this purpose; and that all the apparatus in hands in need of, may be reduced to a few calls of the remains of antiquity, or rather to what Rembrandt used to call his antiques, being nothing more than costs of mail, turbans, lizards of fuff, and all manner of old household trumpery and wearing apparel. Such things, no doubt, are necessary to a painter, and perhaps enough for one who wants only to paint half-lengths; or is willing to confine himself to a few low subjects. But they are by no means sufficient for him who would soar higher; for a painter who would attempt the Universe, and represent it in all its parts, on painting, such as it would appear, had not matter proved refractory to the intentions of the sovereign Artift. Such a painter alone is a true, an universal, a perfect painter — No mortal, indeed, must ever expect to rise to that sublimity; yet all should aspire to it, on the pain of otherwise ever continuing at a very mortifying distance from it: as the orator, who wishes to make a figure in his profession, should propose to himself no less a pattern than that perfect orator described by Tully; nor the courter, than that perfect courtier delineated by Caliglione. It cannot, therefore, appear surprising, if we insist on the propriety of reckoning a good collection of books as part of such a painter's implements. The Bible, the Greek and Roman historians, the works of Homer, that prince of poets, and of Virgil, are the most classical. To these let him add the Metamorphoses of Ovid, some of our best poets, the voyage of Pausanius, Vinci, Vafai, and others, upon painting.

It will also be of considerable advantage to him to have a well chosen collection of drawings by the best masters (n), in order to trace the progress and history of his art, and make himself acquainted with the various styles of painting which have been, and now are, in the greatest vogue. The prince of the Roman school, was not ashamed to hang up in his study the drawings of Albert Durer; and spared no pains or expense to acquire.

(n) We have formerly (see ANATOMY, p. 672. column 2.) mentioned a great anatomical work carried on by Andrew Bell, Esq; in Edinburgh, of the figures of which, as they are engraved under the inspection of able ananatomists as Mr Fyfe; and with the approbation of Dr Monro, we may at least form a favourable opinion; and if well executed, of which there can be but little doubt, they will unquestionably be of essential service to the painter.
II.

...to acquire all the drawings he could meet with that were taken from baso relieves; things which the art of engraving has since rendered so common as to be in every one's hands. This art of multiplying drawings by means of the graver is of the same date, and boasts the same advantages, with the art of printing, by means of which the works of the mind are multiplied, as it were, at one stroke, and dispersed over the whole world.

The sight of fine subjects treated by able masters, and the different forms which the same subjects assume in different hands, cannot fail both of enlightening and enflaming the mind of the young painter. The same may be said of the perusal of good poets and historians, with the particulars and proofs of what they advance; not to mention those ideas and flights of invention, with which the former are wont to clothe, beautify, and exalt every thing they take in hand.

Bouchardon after reading Homer, conceived, to use his own words, that men were three times greater than before, and that the world was enlarged in every respect. It is very probable, that the beautiful thought of covering Agamemnon's face with the skirt of his mantle at the sacrifice of Iphigenia, was suggested to Timantes by the tragedy of Euripides. And the sublime conceit of Raphael, who, in a Creation of his, represents God in the immeasurable space, with one hand reaching to the sun and the other to the moon, may be considered as the child of the following words of the Psalmist: The heavens declare the glory of God, and the firmament sheweth his handy-work.

This thought of Raphael has been, indeed, confured by Mr. Webb. "A God (says this gentleman), extending one hand to the sun, and another to the moon, destroys that idea of immensity which should accompany the work of creation, by reducing it to a world of a few inches." But the opinion of Count Algarotti is very different. "For my part (says that elegant critic), I cannot discover in this painting a world of a few inches, but a world on a much greater scale; a world of millions and millions of miles; and yet this so immense a world, by means of that act of the Godhead, in which with one hand he reaches to the sun, and with the other to the moon, the whole in imagination, to a mere nothing, in respect to the immensity of God himself. This invention is, though in a contrary sense, of the same kind with that of Timantes, who, to express the enormous size of a fleaping Polyphemus, placed round him some furies measuring the monster's thumb with a thyrus. Hence Piniy, who relates the fact, takes occasion to tell us, that his works always imply more than they express; and that how great a work he may be in execution, he is still greater in invention: "Utique in omnibus ejus operibus intelligitur, maior quam quam quisque ingenium, ut ingenium tanum ultra arctem est." Nat. Hist. lib. xxxv. c. 10.

The perusal of good authors cannot but be very serviceable to a painter in another respect; as, among the great number of subjects afforded by history and poetry, he may expect to meet with many on which his talents may display themselves to the greatest advantage. A painter cannot but too much in the choice of his arguments; for on the beauty of them, that of his piece will greatly depend. How much to be pitied, therefore, were our first masters, in being so often obliged to receive their subjects from the hands of simple and illiterate persons! and what is worse, to spend all the riches of their art upon barren or unworthy subjects! Such are the representations of those saints, who, though they never had the least intercourse with each other, and perhaps even lived in different ages, are notwithstanding, to be introduced, ete et eis, as it were in the same picture. The mechanic of the art may, indeed, display itself in those occasions; but by no means to the ideal. The disposition may be good and praise-worthy, as in the works of Cortoni and Lanfranc: but we are not to expect in them either invention or expression, which require for their bals the representation of some fact capable of producing such effects. Who does not, on the bare mention of this abode, immediately recollect many fine instances of it? such as the famous actions of Raphael, surrounded by St. Paul, St. Mary Magdalen, St. John, and St. Augustin; and the picture of Paolo Veronese, in the veltry of the Nuns of St. Zachary at Venice, in which St. Francis of Assisiun, St. Catherine, and St. Jerome richly habited in his cardinal's robes, form a ring round the Virgin seated on a throne with the child Jesus in her arms; perhaps the most beautiful and picturesque of all the inimitable and insignificant pieces with which Italy abounds. It is very shocking to think that young painters should be obliged to study their art from such wretched compositions.

The subjects in which the pencil triumphs most, and with which a judicious painter may lack himself by the perusal of good books, are no doubt those which are most universally known, which afford the largest field for a display of the passions, and contain the greatest variety of incidents, all concurring in the same point of time, to form one principal action. Of this the story of Coriolanus besieging Rome, as related by Livy, is a shining example. Nothing can be imagined more beautiful than the scene of action itself, which ought to take in the pretorium in the camp of the Volscians, the Tiber behind it, and the seven hills, among which the towering Capitol is, as it were to lord it over the rest. It is impossible to conceive a greater variety, than what must appear in that crowd of soldiers, women, and children, all which are to enter the composition; unless, perhaps, it be that of the different passions with which they are severally agitated; some wishing that Coriolanus may raise the siege, others fearing it, others again sulphecting it. But the principal group is the picturesque part of the piece. Coriolanus, hastily detaching from his tribunal, and hurried on by filial affection, to embrace his mother, stops short through shame, on her crying out to him, Hold! let me first know, it is a son, or a daughter. Des, an enemy, I am going to embrace! Thus a painter, ete et eis, may impart novelty to the most hackneyed subjects, by taking for his guides those authors who possess the happy talent of adding grace and dignity, by their beautiful and sublime descriptions, even to the most common and trifling transactions.
PAINTING.

Sect. XIV. Of the Painter's Balance.

The celebrated De Piles, who by his writings has thrown so much light upon painting, in order to attract young painters in forming a right judgment of the masters who hold the first rank in the profession, and to reduce such judgment to the greater precision, thought himself of a pictorial balance, by means of which a painter's merit may be weighed with the greatest exactness. This merit he divides into Composition, Design Colouring, and Expression; and in each of these branches he has assigned to every painter that share to which he thought him entitled, according as he approached more or less the highest degree of excellence and summit of perfection; so that, by summing up the numbers which, standing against each master's name, expresses his share of merit in each of these branches, we have his total merit or value in the art, and may hence gather what rank one painter holds in regard to another. Several objections, it is true, have been started to this method of calculation, by a famous mathematician of our days, who, among other things, inflicts, that it is the product of the above numbers multiplied by each other, and not the sum of them, that gives the merit of the art. But this is not a place to enter into such niceties, nor indeed would the doing of it be of any service to the art.

The only thing worth our notice is, that it is the balance, and may have the greatest dignity to the human form.

He who endeavours to copy accurately the figure before him, not only acquires a habit of exactness and precision, but is continually advancing in his knowledge of the human figure; and though he seems to superficial observers to make a flower progress, he will be found at last capable of adding (without running into capricious wildness) that grace and beauty which is necessary to be given to his more finished works, and which cannot be got by the moderns, as it was not acquired by the ancients, but by an attentive and well-directed study of the human form.

2. It is, in the next place, a matter of great importance, that the drawings on which the young artist first exercises his talents be of the most excellent kind. Let the profiles, the hands, and the feet given to him by the best masters, so as to bring his eye and his hand early acquainted with the most elegant forms and the most beautiful proportion. A painter who has early acquired a fine taste, finds it an easy matter to give dignity to the meanest features, while even the works of a Praxiteles or a Glycon are seen to suffer in the hands of another. A veil will ever retain the scent which it has first contrived.

3. It would be proper also to make the pupil copy some fine heads from the Greek and Roman medals; not so much for the reason just laid down, as to make him acquainted, if we may use the expression, with those personages which in time he may have occasion to introduce into his pieces, and, above all, to improve him early in the art of copying from relief. Hence he will learn the rationale of light and shade, and the nature of that chiaro-fueto by which it is properly speaking that the various forms of things are distinguished.

There is no danger of studying too much the works of the greatest masters, either in painting or sculpture; but how they may be studied to advantage is an inquiry of great importance. "Some [says Sir Joshua Reynolds), who have never raised their minds to the consideration of the real dignity of the art, and who rate the works of an artist in proportion as they excel or are defective in the mechanical parts, look on theory as something that may enable them to talk,
PAINTING.

You are still in the first clafs. We may regret the innumerable beauties which you may want; you may be very imperfect; but still you are an imperfect person of the highest order.

"I inculcate as frequently as I can your forming yourselves upon great principles and great models.---Your time will be much mispent in every other pursuit. Small excellencies should be viewed, not studied; they ought to be viewed, became nothing ought to escape a painter's observation, but for no other reason.

"There is another caution which I wish to give you. Be as exact in those whom you endeavour to please, as in those whom you endeavour to imitate. Without the love of fame you can never do any thing excellent: but by an excessive and unfounded thirst after it, you will come to have vulgar views: you will degrade your style; and your taste will be entirely corrupted. It is certain that the lowest style will be the most popular, as it falls within the compass of ignorance itself, and the vulgar will always be pleased with what is natural in the confined and misunderstood sense of the word."

Genius he considers as an improving talent, never to be destroyed by the most extreme, if well directed, application, and displaying the elegancies of the art in proportion to the number of ideas which have been carefully collected and digested in the mind.

He cautions painters, therefore in every flage of their progress to beware of that false opinion, but too prevalent among artists, of the imaginary power of native genius, and its sufficiency in great works.

This opinion, according to the temper of mind it meets with, almost always produces, either a vain confidence or a flagitious despair, both equally fatal to all proficiency. "Study, therefore, the great works of the greatest masters for ever: Study as nearly as you can, the order of the principles on which they studied. Study nature attentively, but always with those masters in your company; consider them as models which you are to imitate, and at the same time as rivals whom you are to combat."

PART II. Of the Different CLASSES of PAINTING.

I. HIStory Painting: which represents the principal events in history sacred and profane, real or fabulous: and to this class belongs the allegorical expression. These are the most sublime productions of the art; and in which Raphael, Guido, Rubens, Le Brun, &c. have excelled.

II. Rural History: or the representation of a country life, of villages and hamlets, and their inhabitants. This is an inferior class; and in which Teniers, Breughel, Watteau, &c. have great reputation, by rendering it at once pleasing and graceful.

III. Portrait Painting: which is an admirable branch of this art, and has engaged the attention of the greatest masters in all ages, as Apelles, Guido, Van deke, Rembrandt, Regauds, Peine, Kneller, La Tour, &c.

IV. Grotesque History; as the nocturnal meetings of witches; forgeries and enchantments; the operations of mountebanks, &c. a sort of painting in which the younger Breughel, Teniers, and others, have exercised their talents with success.

V. Battle pieces by which Huchtemberg, Wouwerman, &c. have rendered themselves famous.

VI. Landscape: charming specés of painting that has been treated by masters of the greatest genius in every nation.

VII. Landscapes diversified with waters, as rivers, lakes, cataracts, &c.; which require a peculiar talent to express the water sometimes smooth and tranquil.
P A I N T I N G.

Part II.

General Enunciation.

VIII. Sea-pieces; in which are represented the ocean, harbours, and great rivers; and the vessels, boats, barges, &c. with which they are covered; sometimes in a calm, sometimes with a fresh breeze, and at others in a storm. In this class Backhuysen, Vandervelde, Blome, and many others, have acquired great reputation.

IX. Night pieces; which represent all sorts of objects, either as illuminated by torches, by the flames of a conflagration, or by the light of the moon. Schalk, Vandenbierne, Vanderpool, &c. have here excelled.

X. Living Animals: A more difficult branch of painting than is commonly imagined; and in which Rofa, Carre, Vandervelde, and many others, have succeeded marvellously well.

XI. Birds of all kinds; a very laborious species, and which require extreme patience minutely to express the infinite variety and delicacy of their plumage.

XII. Landscape-pieces; a kind of painting in which the Italians excel all others. Under this class may be comprehended the representations of ruins, sea ports, streets, and public places; such as are seen in the works of Canaletto, and other able painters.

XIII. Flower-pieces; a charming class of painting, where art in the hands of Huysum, P. Segers, Merian, &c. becomes the rival of Nature. Plants and insects are usually referred to the painters of flowers, who with them ornament their works.

XIV. Architectural pieces; a kind of painting in which the Italians excel all others. Under this class may be comprehended the representations of ruins, sea ports, streets, and public places; such as are seen in the works of Canaletto, and other able painters.

XV. Landscape-pieces; a charming class of painting, where art in the hands of Huysum, P. Segers, Merian, &c. becomes the rival of Nature. Plants and insects are usually referred to the painters of flowers, who with them ornament their works.

XVI. Imitations of nature and invention and disposition.

In the class of landscape-pieces, wherein both these styles happily meet; and which of the two has the ascendant, will appear from what we have been just observing of their respective properties. The chief parts of landscapes are, their openings or situations, accidents, flowers, and clouds, offskips and montains, verdure or turfing, rocks, grounds, or lands, terraces, fabrics, waters, fore-grounds, plants, figures, and trees; of all which in their place.

Of Openings or Situations. The word fite, or situation, signifies the "view, prospect, or opening of a country." It is derived from the Italian word fite; and our painters have brought it into use; either because they were used to it in Italy, or because, as we think, they found it to be very expressive.

Sect. II. Of Landscape.

Landscape-painting includes every object that the country presents; and is distinguished into the heroic, and the pastoral or rural; of which indeed all other styles are but mixtures. The heroic style is a composition of objects, which in their kind draw both from art and nature; and which are but little distinguished from one another. The situations perfectly agreeable and pleasing. The only buildings are temples, pyramids, ancient places of burial, altars, confecrated to the divinities, places of a regular architecture; and if nature appear not there as we every day casually see her, she is but a representation of what we think the ought to be. This style is an agreeable illusion, and a fort of enchantment, which handled by a man of fine genius and a great understanding, as Poullin was, who has so happily expressed it. But if, in the course of this style, the painter has not talent enough to maintain the sublime, he is oft in danger of falling into the childlish manner.

The pastoral style is a representation of countries, rather abandoned to the caprice of nature, than cultivated: we there see nature simple, without ornament, and without artifice; but with all those graces with which the adorns herself much more when left to her Intelli when constrained by art.

In this style, situations bear all sorts of variety; sometimes they are very extensive and open, to contain the flocks of the shepherds; at others very wild, for the retreat of solitary persons, and a covert for wild beasts.

It rarely happens that a painter has a genius extensive enough to embrace all the parts of painting; there is commonly some one part that pre-engages our choice, and fols our mind, that we forget the pains that are due to the other parts; and we seldom fail to see, that those whose inclination leads them to the heroic style, think they have done all, when they have introduced into their compositions such noble objects as will raise the imagination, without ever giving themselves the trouble to study the effects of good colouring. Those, on the other hand, who prefer the pastoral, apply closely to colouring, in order to represent truth more lively. Both these styles have their sects and partisans. Those who follow the heroic, supply their imagination what it wants of truth, and they look no farther.

As a counterbalance to heroic landscape, it would be proper to put into the pastoral, besides a great character of truth, some affecting, extraordinary, but probable effect of nature, as was Titan's custom.

There is an infinity of objects wherein both these styles happily meet; and which of the two has the ascendancy, will appear from what we have been just observing of their respective properties. The chief parts of landscapes are, their openings or situations; accidents, flowers, and clouds, offskips and mountains, verdure or turfing, rocks, grounds, or lands, terraces, fabrics, waters, fore-grounds, plants, figures, and trees; of all which in their place.

Of Openings or Situations. The word fite, or situation, signifies the "view, prospect, or opening of a country." It is derived from the Italian word fite; and our painters have brought it into use; either because they were used to it in Italy, or because, as we think, they found it to be very expressive.

Situations ought to be well put together; and so dif
PAINTING.

Landscapes.

engaged in their making, that the conjunction of grounds may not seem to be obstructed though we should see but a part of them.

Situations are various, and represented according to the country the painter is thinking of; as either open or close, mountainous or watery, tilled and inhabited, or wild and lonely; or, in fine, variegated by a prudent mixture of some of these. But if the painter be obliged to imitate nature in a flat regular country, he must make it agreeable by a good disposition of the chiaro-obscuré, and such pleasing colouring as may make one soil unite with another.

It is certain, that extraordinary situations are very pleasing, and cheer the imagination by the novelty and beauty of their makes, even when the local pleasing, and cheer in themselves is properly to imagine some ingenious accident where common situations and appearances seem to create such wonderful effects; and such pleasing colouring as may make the painter is thinking of; as either

\[ \text{40x40} \]

and disfiguishing yellow? Who can account for the different reds seen in different clouds, at the very moment that these reds receive the light but in one place? For these colours and surprising appearances seem to have no relation to the rainbow, a phenomenon for which the philosopher pretends to give solid reasons.

These effects are all seen in the evening when the weather is inclining to change, either before a storm, or after it, when it is not quite gone, but has left some remains of it to draw our attention.

The property of clouds is to be thin and airy, both in shape and colour; their shapes, though infinite, must be studied and chosen after nature, at such times as they appear fine. To make them look thin, we ought to make their grounds unite thinly with them, especially near their extremities, as if they were transparent:

And if we would have them thick, their reflections must be managed, as, without destroying their thinness they may seem to shine and unite, if necessary, with the clouds that are near to them. Little clouds often discover a little manner, and do dom have a good effect unless when, being near each other, they seem altogether to make but one object.

In short, the character of the sky is to be luminous; and as it is even the source of it, every thing that is upon the earth must yield to it in brightness; if, however, there is any thing that comes near it in light, it must be waters, and lifted bodies which are susceptible of luminous reflections.

But whilst the painter makes the sky luminous, he must not represent it always shining throughout.

On the contrary, he must contrive his light so, that the greatest part of it may fall only upon one place: and, to make it more apparent, he must take as much care as possible to put it inopposite to some terrestrial object, that may render it more lively by its dark colour; as a tree, tower, or some other building that is a little high.

This principal light might also be heightened by a certain disposition of clouds having a superposed light, or a light ingeniously included between clouds, whose sweet obscurity spreads itself by little and little on all hands. We have a great many examples of this in the Flemish school, which best understood landscape; as Paul Brill, Brugel, Saveri: And the Sadeler's and Merian's prints give a clear idea of it, and wonderfully awaken the genius of those who have the principal of the chiaro-obscuré.

Of Offskips and Mountains. Offskips have a nearer affinity with the sky: it is the sky which determines either the force or faintness of them. They are darkest when the sky is most loaded, and brightest when it is most clear. They sometimes intermix their shapes and lights; and there are times, and countries, where the clouds pass between the mountains. Whole tops rise and appear above them. Mountains that are high, and covered with snow, are very proper to produce extraordinary effects in the offskip, which are advantageous to the painter, and pleasing to the spectator.

The disposition of offskips is arbitrary; let them only
only agree with the whole of the picture together, and the nature of the country we would represent. They are usually blue, because of the interposition of air between them and the eye; but they lose this colour by degrees, as they come nearer the eye, and take that which is natural to the objects.

In distanced mountains, we must observe them insensibly by the rounding off, which the recessions make probable; and must, among other things, avoid a certain edginess in their extremities, which makes them appear in slices, as if cut with scissors, and stuck upon the cloth.

We must further observe, that the air, at the feet of mountains, being charged with vapour, is more susceptible of light than at their tops. In this case, we suppose the main light to be set towards high, and to enlighten the mountains equally, or that the clouds deprive them of the light of the sun. But if we suppose the main light to be very low, and to strike the mountains, their tops will be strongly enlightened, as well as every thing else in the same degree of light.

Though the forms of things diminish in bigness, and colours with their strength, in proportion as they recede from the first plane of the picture, to the more remote effect, as we observe in nature and common practice; yet this does not exclude the use of the accidents. These contribute greatly to the wonderful in landscape, when they are properly introduced, and when the artist has a just idea of their good effects.

Of V's or Turfing. By turfing is meant the greenness with which the herbs colour the ground. This is done several ways; and the diversity proceeds not only from the nature of plants, which, for the most part, have their particular verdures, but also from the change of season, and the colour of the earth when the herbs are but thin sown. By this variety, a painter may choose or unite, in the same tract of land, several sorts of greens, intermixed and blended together, which are often of great service to those who know how to use them; because this diversity of greens, as it is often found in nature, gives a character of truth to those parts where it is properly used. There is a wonderful example of this part of landscape, in the view of Mechlin by Rubens.

Of Rocks. Though rocks have all sorts of shapes, and participate of all colours, yet there are, in their diversity, certain characters which cannot be well expressed without having recourse to nature. Some are in banks, and set off with beds of thistles; others in huge blocks, either projecting or falling back; others consist of large broken parts, contiguous to each other; and others, in short, of an enormous size, all in one block, either naturally, as free-stone, or else through the injuries of time, which in the course of many ages has worn away their marks of separation. But whatever their form be, they are usually set out with clefs, breaks, hollows, bulges, &c., and the slants of time; and these particulars, well managed, create a certain idea of truth.

Rocks are of themselves gloomy, and only proper for obliquities; but where accompanied with bulges, they inspire a fresh air; and, when they have waters, either proceeding from, or walking them, they give an infinite pleasure, and seem to have a soul which animates them, and makes them sociable.

Of Grounds or Lands. A ground or land, in painters terms is a certain distinct piece of land, which is neither too woody nor hilly. Grounds contribute, more than any thing, to the gradation and distancing of landscape, because they follow one another, either in shape, or in the claro-obscuro, or in their variety of colouring, or by some insensible conjunction of one with another.

Multiplicity of grounds, though it be often contrary to a grand manner, does not quite destroy it; for, besides the extent of country which it exhibits, it is susceptible of the accidents we have mentioned, and which, with good management, have a fine effect.

There is one nicety to be observed in grounds, which is, that in order to characterize them well, care must be taken, that the trees in them have a different verdure and different colours from those grounds; though this difference, withal, must not be too apparent.

Of Terraces. A terrace, in painting, is a piece of ground, either quite naked or having very little herbage, like great roads and places often frequented. They are of use chiefly in the foregrounds of a picture, where they ought to be very spacious and open, and accompanied, if we think fit, with some ancient verdure, and also with some flowers, which, if placed with judgment, give a terrace a greater air of probability.

Of Buildings. Painters mean by buildings any structures they generally represent, but chiefly such as are of a regular architecture, or at least are most conspicuous. Thus building is not to proper a name for the habitations of country-people, or the cottages of shepherds, which are introduced in the rural taste, as for regular and showy edifices, which are always brought into the heroic.

Buildings in general are a great ornament in landscapes even when they are Gothic, or appear partly inhabited and partly ruinous: they raise the imagination by the use they are thought to be designed for; as appears from ancient towers, which seem to have been the habitations of faries, and are now retreats for shepherds and owls.

Poullin has very elegantly handled the Roman manner of architecture in his works, as Bourdon has done the Gothic; which, however Gothic, fails not to give a sublime air to his landscapes. Little Bernard has introduced into his sacred history what may be called a Babylonian manner; which, extraordinary as it is, has its grandeur and magnificence. Painter ought such pieces of architecture to be quite rejected: they raise the imagination; and perhaps would succeed in the heroic style, if they were placed among half-distant objects, and if we knew how to use them properly.

Of Waters. Much of the spirit of landscape is owing to the waters which are introduced into it. They appear in divers manners; sometimes impetuous, as when a storm makes them overflow their banks; at other times rebouding, as by the fall of a rock; at other times, through unusual pressure, gushing out and dividing into an infinity of silver streams, whose motion and murmuring agreeably deceive both the eye and ear.
PAINTING.

Part II.

of the foreground to reflect on, for in this condition, which
robs them of all connection with the landscape, they
appear to be pasado out. But without obtruding the
painter’s liberty in this respect, undoubtedly the best
way to make figures valuable is, to make them do to
agree with the character of the landscape, that it may
seem to have been made purely for the figures. We
would not have them either infipid or indifferent, but
to represent some little subject to awaken the specata-
tor’s attention, or else to give the picture a name of
distinct on among the curious.

Great care must be taken to proportion the size of
the figures to the bigness of the trees, and other ob-
jects of the landscape. If they be too large, the pic-
ture will discover a little manner; and if too small,
they will have the air of pignites; which will destroy
the worth of them, and make the landscape look enor-
rous. There is, however, a greater inconvenience in
making figures too large than too small; because the
latter at least gives an air of greatness to all the ref-

But as landscape figures are generally small, they must
be touched with spirit, and such lively figures as wish
attract, and yet preserve probability, and a general
union. The artist must, in fine, remember, that as the
figures chiefly give life to a landscape, they must be
depersoned as conveniently as possible.

Of Trees. The beauty of trees is perhaps one of
the greatest ornaments of landscape; on account of the
variety of their kinds, and their freshness, but chiefly
thi r lightness, which makes them seem, as being ex-
plo ed to the air, to be always in motion.

Though diversity be pleasing in all the objects of
landscapes, it is chiefly in trees that it shows its greatest
beauty. Landscape considers both their kind and their
forms. Their kinds require the painter’s particular
study and attention, in order to distinguish them from
each other; for we must be a ale at fist fight to dis-
cover which are oaks, elms, firs, fycemores, poplars, will-
ows, pines, and other such trees, which, by a specific
colour, or touching them, are distinguishable from all other
kinds. This study is too large to be acquired in all its
extent; and indeed, few painters have attained such a
competent exactness in it as their art requires. But it
is evident, that those who come nearest to perfection in
it, will make their works infinitely pleasing, and gain
a great name.

Besides the variety which is found in each kind of
tree, there is in all trees a general variety. This is ob-
served in the different manners in which their branches
are disposed by a sport of nature; which takes delight
in making some very vigourous and thick, others more
dry and thin; some more green, others more red or
yellow. The excellence of practice lies in the mix-
ture of these various kinds; but if the artist can distinguish
the forts but indifferently, he ought at last to vary
their makes and colours; because repetition in land-
scape is as offensive to the eye, as monotony in dis-
course is to the ear.

The variety of their makes is so great, that the pain-
ter would be inexpe*nse n to put it in practice up-
on occasion, especially when it is necessary to
awaken the spectator’s attention; for, among trees,
we discover the young and the old, the open and close,
tapering and squat, bending upwards and downward,
flowing
Part II.

P A I N T I N G.

A description of the works of great masters; a little reflection on nature will be of more service than all that can be said on this head. By great masters, we mean such as have published prints; for those will give better ideas to young copyists than even the paintings themselves.

Among the many great masters of all school's, De Piles prefers Titian's wooden prints, where the trees are well shaped; and those which Cornelius Cort and Agostino Carracci have engraved. And he affirms, that beginners can do no better than consult, above all things, an habit of imitating the touches of these great masters, and of considering at the same time the perspective of the branches and foliages, and observing how they appear, either when rising and seen from below, or when sinking and seen from above, or when fronting and viewed from a point, or when they appear in profile; and, in a word, when seen in the various views in which nature presents them, without altering their characters.

After having studied and copied, with the pen or crayon, all the prints, and then the designs of Titian and Carracci, the student should imitate with the pencil those touches which they have most distinctly specified, if their paintings can be procured: but since they are scarce, others should be got which have a good character for their touching; as those of Fourquier, who is a most excellent model: Paul Bril, Breugel, and Bourdon, are also very good; their touching is neat, lively, and thin.

After having duly weighed the nature of trees, their spread and order, and the disposition of their branches, the artist must get a lively idea of them, in order to keep up the spirit of them through-out, either by making them apparent and distinct in the foregrounds, or obtuse and confused in proportion to their distance.

After having thus gained some knowledge in good manner, it will next be proper to study after nature, and to choose and rectify it according to the ideas which the afore-said great masters had of it. As to perfection, it can only be expected from long practice and perseverance. On the whole, it is proper for those who have an inclination for landscape, above all things to take the proper methods for beginning it well.

As for those who have made some advance in this part of painting, it is proper they should collect the necessary materials for their further improvement, and study those objects at least which they shall have most frequent occasion to represent.

Painters usually comprise, under the word study, any thing whatever which they either design or paint separately after the life, whether figures, heads, feet, hands, drapery, animals, mountains, trees, plants, flowers, or whatever may concern them in the just imitation of nature: the drawings of these things is what they call study whether they be for instruction in design, or only to affure them of the truth, and to perfect their work. In fact, this word study is the more properly used by painters, as in the diversity of nature they are daily making new discoveries, and confirming themselves in what they already know.

As the landscape painter needs only study such objects as are to be met with in the country, we would recommend

flopping and shooting: in short, the variety is rather to be conceived than expressed. For instance the character of young trees, is, to have long slender branches, few in number, but well set out; bushes well divided, and the foliage vigorous and well shaped: whereas, in old trees, the branches are short, flexible, thick, and numerous; the tufts blunt, and the foliage unequal and ill shaped: but a little observation and genius will make us perfectly sensible of these particulars.

In the various makes of trees, there must also be a distribution of branches, that has a just relation to, and probably connects with, the boughs or tufts, so as mutually to assist each other in giving the tree an appearance of thickness and of truth. But, whatever their natures or manners of branching be, let it be remembered, that the handling must be lively and thin, in order to preserve the spirit of their characters.

Trees likewise vary in their barks, which are commonly grey; but this grey, which in thick air, and grey; but this grey, which in thick air, and
recommend to him some order, that his drawings may be always at hand when he wants them. For instance, he should copy after nature, on separate papers, the different effects of trees in general, and the different effects of each kind in particular, with their trunks, foliage, and colours. He should also take the same method with some sorts of plants, because their variety is a great ornament to terraces on fore-grounds. He ought likewise to study the effects of the sky in the several times of the day and seasons of the year, in the various dispositions of clouds, both in serene, thundering, and stormy weather; and in the offskip, the several sorts of rocks, waters, and other principal objects.

These drawings, which may be made at different times, should be collected together; and all that relate to one matter be put into a book, to which the artist may have recourse at any time for what he wants.

Now, if the fine effects of nature, whether in shape or colour, whether for an entire picture or a part of one, be the artist's study; and if the difficulty lies in choosing those effects well, he must for this purpose be born with good sense, good taste, and a fine genius; and this genius must be cultivated by the observations which ought to be made on the works of the best masters, how they chose nature, and how, while they corrected her, according to their art, they preferred her character. With these advantages, derived from nature and perfected by art, the painter cannot fail to make a good choice; and, by distinguishing between the good and the bad, must find great instruction even from the most common things.

To improve themselves in this kind of studies, painters have taken several methods.

There are some artists who have designed after nature, and in the open fields; and have there quite finished those parts which they had chosen, but without adding any colour to them.

Others have drawn, in oil colours, in a middle-tint, on strong paper; and found this method convenient, because the coloursinking they could put colour on colour, though different from each other. For this purpose they took with them a flat box, which commodiously held their pallet, pencils, oil, and colours. This method, which indeed requires several implements, is double the best for drawing nature more particularly, and with greater exactness, especially if, after the work be dry and varnished, the artist return to the place where he drew, and retouch the principal things after nature.

Others have only drawn the outlines of objects, and slightly wash’d them in colours near the life, for the sake of their memory. Others have attentively observed such parts as they had a mind to retain, and contrasted them; by thus committing them to their memory, which upon occasion gave them a faithful account of them. Others have made drawings in palel and wash together. Others, with more curiosity and patience, have gone several times to the places where they were to their taste; the first time they only made choice of the parts, and drew them correctly; and the other times were spent in observing the variety of colouring, and its alterations through change of light.

Now these several methods are very good, and each may be practis’d as best suits the student and his temper; but they require the necessaries of painting, as colours, pencils, pastil, and lea. Nature however, at certain times, presents extraordinary but transient beauties, and such as can be of no service to the artist who has not as much time as necessary to imitate what he admires. The best way perhaps to make advantage of such momentary occasions is this:

The painter being provided with a quire of paper, and a black-lead pencil, let him quickly, but slightly, design what he sees extraordinary; and, to remember the colouring, let him mark the principal parts with characters, which he may explain at the bottom of the paper, as far as is necessary for himself to understand them: A cloud, for instance, may be marked A, another cloud B, a light C, a mountain D, a terrace E, and so on. And having repeated these letters at the bottom of the paper, let him write against each that it is of such or such a colour; or for greater brevity, only blue, red, violet, grey, &c. or any other shorter abbreviation. After this, he must go to painting as soon as possible; otherwise most of what he has observed will, in a little time, slip out of his memory. This method is the most useful, as it not only prevents our losing an infinity of sudden and transitory beauties, but also helps, by means of the aforesaid marks and characters, to perfect the other methods we have mentioned.

If it be asked, Which is the proper time for these studies? the answer is, That nature should be studi’d at all times, because she is to be represented at all seasons; but autumn yields the most plentiful harvest for her fine effects: the mildness of that season, the beauty of the sky, the richness of the earth, and the variety of objects, are powerful inducements with the painter to make the proper inquiries for improving his genius and perfecting his art.

But as we cannot see or observe every thing, it is very commendable to make use of other men’s studies, and to look upon them as if they were our own. Raphael sent some young men into Greece to design such things as he thought would be of service to him, and accordingly made use of them as good a purpose as if he himself had designed them on the spot: for this, Raphael is so far from deserving contempt, that he ought, on the contrary to be commended; as an example, that painters ought to leave no way untried for improving in their professions. The landscape-painter may, accordingly, make use of the works of all those who have excelled in any kind, in order to acquire a good manner; like the bees, which gather their variety of honey from different flowers.

**General Remarks on Landscapes.** As the general rules of painting are the bases of all the several kinds of it, we must refer the landscape-painter to them, or rather suppose him to be well acquainted with them. We shall here only make some general remarks on this kind of painting.

I. Landscape supposes the knowledge and practice of the principal rules in perspective, in order to maintain probability.

II. The接纳 of the leaves of trees are to the earth, the larger they are, and the greener; as being aptest to receive, in abundance, the sap which nourishes them: and the upper branches begin first to take the rednesses
Part II. 

Painting.

redness or yellowness which colours them in autumn.

But it is otherwise in plants; for their flocks renew all the year round, and their leaves succeed one another, at a considerable distance of time, inasmuch that nature, employed in producing new leaves to adorn the fock as it riles, does by degrees defert the under ones; which, having first performed their office, are the firft that die: but this effect is more visible in some than in others.

III. The under parts of all leaves are of a brighter green than the upper, and almost always incline to the silverish; and those which are wind-shaken are known from others by that colour: but if we view them from beneath, when penetrated by the sun's rays, they discover such a fine and lively green as is far beyond all comparison.

IV. There are five principal things which give spirit to landscape, viz. figures, animals, waters, wind-shaken trees, and thinness of pencilling; to which add smoke, when there is occasion to introduce it.

V. When one colour predominates throughout a landscape, as one green in spring, or one red in autumn, the piece will look either as one of colour, or else as unfihed. We have seen many of Bourbon's landscapes, which, by handling the corn one way throughout, have loft much of their beauty, though the situations and waters were very pleasant. The ingenious painter must endeavour to correct, and, as they say, redeem the harfth unhithly colouring of winter and spring by means of figures, waters, and buildings; for turning each subject in itself is capable of great variety.

VI. Titian and Caracce are the best models for inspiring good taste, and leading the painter into a good track, with regard to forms and colours. He must ufe all his endeavours to gain a jufh idea of the principles which those great men have left us in their works; and to have his imagination filled with them, if he would advance by degrees towards that perfection which the artist should always have in view.

VII. The landscapes of these two masters teach us a great many things, of which the difference of trees in general be determined, as we determine thefe of the human body? The tree has no settled proportions; most of its beauty lies in the contral of its branches, an unequal distribution of boughs, and, in fhort, a kind of whimsical variety, which nature delights in, and of which the painter becomes a judge when he has thoroughly relifhed the works of the two masters aforefaid. But we must fay, in Titian's praise, that the path he struck out is the fureft; because he has exactly imitated nature in its variety with an exquisite taste and fine colouring: whereas Caracce, though an able artist, has not, more than others, been free from manner in his landscapes.

VIII. One of the greatest perfections of landscape, in the variety it represents, is a faithful imitation of each particular character: as its greatestfault is a licentious practice, which brings us to do things by rote.

IX. Among thefe things which are painted practically, we ought to intermix one degree after nature, to induce the painter to believe that all are fo.

Sect. III. Of Portraiture.

If painting be an imitation of nature, it is doubly fo in a portrait; which not only represents a man in general, but fuch an one as may be distinguished from all others. And as the greateft perfection of a portrait is extreme likeness, fo the greateft of its faults is to reSmall a person for whom it was not made; since there are not in the world two persons quite like one another. But before we proceed to the particulars which let us into the knowledge of this imitation, it is neceffary, for shortening this part of our subject, to attend to fome general propofitions.

I. Imitation is the effence of painting: and good choice is to this effence what the virtues are to a man; they raife the value of it. For this reason, it is extremely the painter's interest to choose none but good heads, or favourable moments for drawing them, and fuch propofitions as may supply the want of a fine natural.

II. There are views of the natural, more or lefs advantageous: all depends upon turning it well, and taking it in the favourable moment.

III. There is not a fingle perfon in the world who has not a peculiar character both in body and face.

IV. Simple and genuine nature is more proper for imitation; and is a better choice than nature much formal, and embellished too artificially.

V. To adorn nature too much is doing it a violence; and the action which attends it can never be free when its ornaments are not easy. In fhort, in proportion as we adorn nature, we make it degenerate from itself, and bring it down to art.

VI. Some means are more advantageous than others to come at the fame end.

VII. We muft not only imitate what we do fee in nature, but also what we possibly fee that is advantageous in art.

VIII. Things are valuable by comparison; and it is only by this we are enabled to make a right judgment of them.

IX. Painters easily accustom themselves to their own tints, and the manner of their matters; and after this habit is rooted in them, they view nature not as she really is, but as they are used to paint her.

X. It is very difficult to make a piture, the figures of which are as big as the life, to have its effeet near as at a distance. A learned picture pleafes the ignorant only when it is at fome distance; but judges will
XI. Knowledge makes work pleasant and easy. The traveller who knows his road, comes to his journey's end with more speed and certainty than he who inquires and gropes it out.

XII. It is proper, before we begin a work, to meditate upon it, and to make a nice coloured sketch of it, for our own satisfaction, and an help to the memory.

We cannot too much reflect on these propositions; and it is necessary to be well acquainted with them, that they may present themselves to our mind, of their own accord, without our being at the trouble to recall them to our memory when we are at work.

There are four things necessary to make a portrait perfect; **air, colouring, attitude and dress.**

**Of Air.** The air respects the lines of the face, the head-attire, and the fize.

The lines of the face depend upon exactness of draught, and agreement of the parts; which altogether must represent the physiognomy of the person painted in such a manner, that the picture of his body may seem to be aloof that of his mind.

It is not exactness of design in portraits that gives spirit and true air, so much as the agreement of the parts at the very moment when the disposition and temper of the sitter are to be hit off. We see several portraits which, though correctly designed, have a cold, languishing, and stupid air; whilst others, less correct in design, strike us, however, at first sight with the sitter's character.

Few painters have been careful enough to put the parts well together; Sometimes the mouth is smiling, and the eyes are sad; at other times, the eyes are cheerful, and the cheeks lank: by which means their work has a false air, and looks unnatural. We ought therefore to remember, that, when the sitter puts on a smiling air, the eyes close, the corners of the mouth draw up towards the nostrils, the cheeks swell, and the eye brows widen: but in a melancholy air, these parts have a contrary effect.

The eye brows being rai"ed, give a grave and noble air; but if arched, an air of astonishment.

Of all the parts of the face, that which contributes most to likeness is the nose; it is therefore of great moment to set and draw it well.

Though the hair of the head seems to be part of the dress which is capable of various forms without altering the air of the face; yet the head-attire which one has been most accustomed to, creates such a likeness, that we scarce know a familiar acquaintance on his putting on a perriwig somewhat different from that which he used to wear. It is necessary therefore, as far as possible, to take the air of the head ornament, and make it accompany and set off that of the face, if there be no reason to the contrary.

As to the nature, it contributes so much to likeness, that we very often know people without seeing their face; It is therefore extremely proper to draw the fize after the sitter himself, and in such an attitude as we think fit; which was Van Dyke's method. Here let us remark, that, in fitting, the person appears to be of a less free make, through the heaving of the shoulders; whereas, to adjust his fize, it is proper to make him stand for a small time, swaying in the posture we would give him, and then make our observation. But here occurs a difficulty, which we shall endeavour to examine: "Whether it is proper, in portraiture, to correct the defects of nature?"

Likeness being the essence of portraiture, it would seem that we ought to imitate defects as well as beauties, since by this means the imitation will be more complete: it would be even hard to prove the contrary to one who would undertake the defence of this position. But ladies and gentlemen do not much approve of those painters who entertain such sentiments, and put them in practice. It is certain that some complaisance in this respect is due to them; and there is little doubt but their pictures may be made to resemble, without displeasing them; for the effectual likeness is a just agreement of the parts that are painted with those of nature; so that we may be at no loss to know the air of the face, and the temper of the person, whose picture is before us. All deformities, therefore, when the air and temper may be discovered without them, ought to be either corrected or omitted in women's and young men's portraits. A nose somewhat awry may be helped, or a thrivelled neck, or high shoulders, adapted to a good air, without going from one extreme to another. But this must be done with great discretion: for, by endeavouring to correct nature too much, we infensibly fall into a method of giving a general air to all our portraits; just as, by confining ourselves too much to the defects and little nesses of nature, we are in danger of falling into the low and tawdry manner.

But in the faces of heroes and men of rank, distinguished either by dignities, virtues, or great qualities, we cannot be too exact, whether the parts be beautiful or not; for portraits of such persons are to be flending monuments to posterity; in which case, every thing in a picture is precious that is faithful. But after whatever manner the painter acquires himself in this point, let him never forget good air nor grace; and that there are, in the natural, advantageous moments for hitting them off.

**Of Colouring.**—Colouring, in portraiture, is an essence of nature, discovering the true tempers of persons; and the temper being essential to likeness, it ought to be handled as exactly as the design. This part is the more valuable, as it is rare and difficult to hit. A great many painters have come to a likeness by strokes and outlines; but certainly they are few who have shown in colours the tempers of persons.

Two points are necessary in colouring; exactness of tints, and the art of setting them off. The former is acquired by practice, in examining and comparing the colours we see in life with those by which we would imitate it: and the art of those tints consists in knowing what one colour will produce when set by another, and in making good what either distance or time may abate of the glow and freshness of the colours.

A painter who does nothing more than what he sees, will never arrive at a perfect imitation; for though his work may seem, on the first, to be good to him, it may not appear so to others, and perhaps even to himself, at a distance. A tint which, near, appears disjoined, and of one colour, may look of another at a distance, and be confounded in the mass it belongs to. If you would have your work, therefore, to produce a good
PAINTING.

Part II.

Attitude. good effect in the place where it is to hang, both the colours and lights must be a little loaded; but learnedly, and with dexterity. In this point consult Titian, Rubens, Vandyke and Rembrandt's methods; for indeed their art is wonderful.

The tints usually require three times of observation. The first is at the person's first sitting down, when he has more spirit and colour than ordinary; and this is to be noted in the first hour of his sitting. The second is when, being composed, his look is as usual; which is to be observed in the second hour. And the third is when, through tiresomeness by sitting in one posture his colour alters to what weariness usually creates. On which account, it is best to keep to the sitter's usual tint, a little improved. He may also rise, and take some turns about the room, to gain fresh spirits, and shake off or prevent some tiresomeness.

In draperies, all sorts of colours do not suit all sorts of persons. In mens portraits, we need only observe great truth and great force: but in women there must also be charms; whatever beauty they have must appear in a fine light, and their blemishes must by some means or other be softened. For this reason, a white, lively, and bright tint, ought never to be set off by a fine yellow, which would make it look like plaster; but rather by colours inclining to green, blue, or grey, or such others as, by their opposition, may give the tint more fitful than usual in fair women. Vandyke often made a fillemot-coloured curtain for his ground; but that colour is soft and brown. Brown women on the other hand, who have yellow enough in their tints to support the character of fleshiness, may very well have yellowish draperies, in order to bring down the yellow of their tints, and make them look the fairer, and near very high-coloured and lively carinations linen does wonders.

In grounds, two things are observable: the tone and the colour. The colour is to be considered in the same manner as those of draperies, with respect to the head. The tone must be always different from the mass it supports, and of which it is the ground, that the objects coming upon it may not seem transparent, but solid and raised. The colour of the hair of the head usually determines the tone of the ground; and when the former is a bright chesnut, we are often embarrassed, unless helped by means of a curtain, or some accident of the clare-obfcur, supposed to be behind, or unless the ground is a sky.

We must further observe, that where a ground is neither certain nor landscape, or such like, but is plain and like a wall, it ought to be very much party-coloured, with almost imperceptible patches or stains; for besides its being so in nature, the picture will look the more grand.

Of Attitude, or Posture.—Attitudes ought to suit the ages and qualities of persons and their tempers. In old men and women, they should be grave, majestic, and sometimes bold: and generally, in women, they ought to have a noble simplicity and modest cheerfulness; for modesty ought to be the character of women; a charm infinitely beyond coquetry! and indeed coquettes themselves care not to be painted such.

Attitudes are of two kinds: one in motion, the other at rest. Those at rest may suit every person; but those in motion are proper for young people only, and are hard to be expressed; because a great part of the hair and drapery must be moved by the air; motion, in painting, being never better expressed than by such agitations. The attitudes at rest must not appear so much at rest as to seem to represent an inactive person, and one who fits for no other purpose but to be a copy. And though the figure that is represented be at rest, yet the painter, if he thinks fit, may give it a flying drapery, provided the figure or ground be not a chamber or close place.

It is above all things necessary that the figures which are not employed should appear to satisfy the spectator's curiosity; and for this purpose show themselves, in such an action as suits their tempers and conditions, as if they would inform him what they really were, and as most people pretend to sincerity, honesty, and greatness of mind, we must avoid, in attitudes, all manner of affectation; everything there must appear easy and natural, and discover more or less spirit, nobleness, and majesty, in proportion to the person's character and dignity. In a word the attitudes are the language of portraits: and the skilful painter ought to give great attention to them.

But the best attitudes are such as induce the spectator to think that the sitter took a favourable opportunity of being seen to advantage, and without affectation. There is only one thing to be observed with regard to women portraits, in whatever attitude they are placed; which is, that they sway in such a manner as to give their face but little shade; and so that the ground is at the person's elbow; because a white, to give great attention to them.

In mens portraits, in whatever attitude they are placed, to suit their manner of appearance, that the painter may have the pleasure of presenting a person, and one who is at the hour of his sitting. The colour of the hair of the head usually determines the tone of the ground, and when the former is a bright chestnut, we are often embarrassed, unless helped by means of a curtain, or some accident of the clare-obfcur, supposed to be behind, or unless the ground is a sky.

Of Practice in Portraiture.—According to De Piles, portraiture requires three different fittings and operations; to wit, dead-colouring, second-colouring, and retouching or finishing. Before the painter dead-colour, he must attentively consider what affect will befit the sitter, by putting him in different positions, if we have not any settled design before us: and when we have determined this, it is of the last consequence to put the parts well together, by comparing always one part with another; for not only the portrait acquires a greater likeness when well designed, but it is troublesome to make alterations at the second fitting, when the artist must only think of painting, that is, of disproving and uniting his colours.

Experience tells us, that the dead-colouring ought to be clean, because of the slope and transparency of the colours, especially in the shades: and when the parts are well put together and become clammy, they must be judiciously sweetened and melted into each other; yet without taking away the air of the picture, that the painter may have the pleasure of finishing it, in proportion as he draws. But if fiery geniuses do not like this method of scumbling, let them only mark the parts slightly, and so far as is necessary for giving an air.

In dead-colouring, it is proper to put in rather too little than too much hair about the forehead; that, in finishing, we may be at liberty to place it where we please, and to paint with all possible softness and delicacy. If, on the contrary, you sketch upon the forehead a lock which may appear to be of a good taste,
and becoming the work, you may be puzzled in finishing it, and not find the life exactly in the same position as you would paint it. But this observation is not meant for men of skill and confummate experience, who have nature in their heads, and make her submit to their ideas.

The business of the second setting is, to put the colours well in their places, and to paint them in a manner that is suitable to the fitter and to the effect we propose: But before they are made clammy, we ought to examine afresh whether the parts are rightly placed, and here and there to give some touches towards likeness, that, when we are affured of it, the work may go on with greater satisfaction. If the painter understands what he is about, and the portrait be justly designed, he ought as much as possible to work quick; the fitter will be better pleased, and the work will by this means have the more spirit and life. But this readiness is only the effect of long study and experience; for we may well be allowed a considerable time to find out a road that is easy, and such as we must often travel in.

Before we retouch or finish, it is proper to terminate the hair, that, on finishing the carnations, we may be able to judge of the effect of the whole head.

If, at the second setting, we cannot do all we intended, which often happens, the third makes up the loss, and gives both spirit, physiognomy, and character.

If we would paint a portrait at once, we must load the colouring; but neither sweeten, nor drive, nor very much oil it: and if we dip the pencil in the colouring; but neither sweeten, nor drive, nor right or not; and to make a fixed rule of what tended, served to him now little time he had bestowed on his business, and also to get something for the person's fitting, and worked not above the first or second day; whereupon his servant came to clean his pencils, and brought a fresh pallet, whilst he was receiving another fitter, whom he had before appointed. By this method he worked on several pictures the same day with extraordinary expedition.

After having lightly dead-coloured the face, he put the fitter into some attitude which he had before contrived: and on a grey paper, with white and black crayons, he designed, in a quarter of an hour, his shape and drapery, which he disposed in a grand manner, and an exquisite taste. After this he gave the drawing to the skilful people he had about him, to paint after the fitter's own clothes, which at Vandyke's request, were sent to him for that purpose. When his disciples had done what they could to these draperies, he lightly went over them again; and in a little time, by this great knowledge, displayed the art and truth which we at this day admire in them. As for hands, he had in his house people of both sexes, whom he paid, and who served as models.

This conduct of Vandyke, however, is mentioned rather to gratify the reader's curiosity, than to excite his imagination; he may choose as much of it as he pleases, and as suits his own genius, and leave the rest.

We must observe by the way, that there is nothing so rare as fine hands, either in the design or colouring. It is therefore convenient to cultivate, if we can, a friendship with some woman who will take pleasure in serving for a copy: The way to win them is, to praise their beauty exceedingly. But if an opportunity serves of copying hands after Vandyke, it must not be lift off: for he drew them with a surpassing delicacy, and an admirable colouring.

It is of great service to copy after the manners which come nearest to nature; as are those of Titian and Vandyke. We must, at such times, believe them, to be nature itself; and, at some distance, consider them as such, and say to ourselves.—What colour and tint shall I use for such a part? And then, coming near the picture, we ought to examine whether we are right or not; and to make a fixed rule of what we have discovered, and did not practice before without uncertainty.

It is recommended, before we begin colouring, to catch the very first moments, which are commonly the most agreeable and most advantageous, and to keep them in our memory for use when we are finishing: for the fitter, growing tired with being long in the same place, looses those spirits, which, at his first setting down, gave beauty to the parts, and conveyed the tint more lively, and a rarer colour. In short, we must join to truth a probable and advantageous possibility, which, far from abating likeness, serves rather to set it off. For this end, we ought to begin with observing the ground of a tint, as well what it is in lights as in shades; for the shades are only beautiful as they are proportioned to the light. We must observe, if the tint be very lively, whether it partake of yellowness, and where that yellowness is placed; because usually, towards the end of the setting, fatigue diffuses a general yellowness, which makes us forget what parts were of this colour, and what were not, unless we had taken due notice of it, before. For this reason, at the second setting, the colours must be everywhere readily clapped in, and such as appear at the first setting down; for these are always the fittest.

The surest way to judge of colours is by comparison; and to know a tint, nothing is better than to compare it with linen placed next it, or else placed next to the natural object, if there is occasion. We say this only to those who have little practiced nature.

The portrait being now supposed to be as much finished,
Part II.

PAINTING.

4. Painting in water-colours; that is, with colours mixed with water and gum, or paste, &c.

5. MINIATURE painting; which differs from the preceding as it represents objects in the least discernible magnitudes.

6. Painting in crayons; for which purpose colours, either simple or compounded, are mixed with gum, and made into a kind of hard paste like chalk, and with which they draw on paper or parchment.

7. Painting in enamel; which is done on copper or gold, with mineral colours that are dried by fire, and become very durable. The paintings on the porcelains of China and Europe, on Delphite ware, &c. are so many sorts of enamel.

8. Painting in wax, or encaustic painting: This is a new or rather an old invention renewed, in which only in France performances highly pleasing. It is done with wax mixed with varnish and colours.

9. Painting on glass; of which there are various kinds.

See all the articles here enumerated, explained in the order of the alphabet. Of one of them, however, some additional observations may here be subjoined.

§ 1. Of painting in fresco.

Of all kinds of painting fresco is the most ancient, the most durable, the most speedily executed, and the most proper to adorn great buildings. It appears, that the fragments of ancient painting handed down to us by the Romans are all in fresco. Nordm, quoted by Winklemann, speaks of the ruins of Egyptian palaces and temples, in which are Colossal paintings on walls 80 feet high. The description which those authors have given of these paintings, of the prepared ground, and of the manner in which the colours have been employed, &c. shows plainly that they have been executed in fresco.

The stability of fresco is demonstrated by the existence of those fragments of the highest antiquity. There are no other kinds of painting which could equally have resisted the injuries of the weather, the excessive aridity of certain elements, the moisture of subterraneous situations, and the encroachments of barbarians.

There are different opinions concerning the climate most proper to preserve this kind of painting. "It is observed (says Felibien), that the colours in fresco fade sooner in Italy and Languedoc than at Paris; perhaps from less heat in the latter mentioned place, or better time." M. Falconet contradicts this assertion in his notes on Pliny, vol. i. p. 223. of his miscellaneous works, published at Paris 1757.

Painting in fresco, according to this author, is longer preserved in dry and warm, than in northern and moist climates. However opposite the sentiments of these two authors may appear to be, it is possible to reconcile them, when we consider, that the exposure to a burning sun is capable of operating a great change of the colours on the one hand, and that the frost in a cold climate inevitably destroys the paintings of fresco on the other.

Fresco is capable of burting stones, of corroding the petrified veins of earth in the heart of coloured marble, and, in short, nothing can reftit its destructive operation.

These observations on fresco painting, lead us to conclude, that the choice of place, when they are without doors, is of the greatest importance. In countries where
where there is little or no frost, an exposure to the north is the most favourable; and in cold climates a western exposure should be made choice of, because the first rays of the rising sun have a very pernicious effect after frost. We are not, however, wholly to adopt the sentiment of M. Falconet with regard to the pernicious effects of moisture on fresco paintings: for, 1. The ancient paintings recovered from moist places, in which they were buried for many ages, have, under enormous heaps of earth, preserved all their colours. Those from the ruins of Herculanum have been observed, on the contrary, to lose their colours in a short time after they have been dried by the exterior air. 2. The mortar which composes the ground of this painting is not destroyed in our rainy climates. It is necessary frequently to use powder in removing pieces of this mortar, which are now found to obstrut some buildings in Paris. After the choice of place, the choice of materials is the next thing of importance in executing fresco. To make it durable, the ground is the object of chief attention; and to make this perfect, the mortar used by the ancients, now unknown, would be necessary.

It is easy to perceive, that a minute detail of forms, an extensive mixture and gradation of tints, and the merit of a delicate and gentle touch, can make no part of the excellencies of this kind of painting. It cannot bear a close examination like a picture in oil. There is always something dry and rough which displeases. An artist who would flatter himself with success in a fresco placed near the eye would be grossly deceived: a common spectator would find it coarse and badly finished.

Fresco is chiefly employed in palaces, temples, and public edifices. In those vast places no kind of painting can be preferred to it; large, vivid in its strokes, and constantly fresh, it enriches the architecture, animates it, and gives relief to the eye from the repetition of the same forms, and the monotony of colour in a place where coloured marbles and bronzes are not employed. Still more a fine fresco gives the greatest effect to a lofty building, since this building serves as a frame and support to this enchanting art, which fixes the attention of every person of sensibility and taste.

We shall afterwards have occasion to show the manner of executing fresco, as well as the nature and application of the colours employed in it: it is necessary to demonstrate here, that it has a freshness, splendor, and vigour not to be found in oil or water colours.

A known principle in all kind of painting is, that the colouring is more perfect in proportion as it approaches to the lights and shades in nature. As colours applied to any subject can never reach this degree of perfection, the allusion which painters produce confilts in the comparison and opposition of the tones of colours among themselves.

If the white of the finest and purest oil appears heavy and grey, compared with great lights in natural white, it follows, that, in order to copy them with fidelity, the tones which follow the finest white must be degraded in an exact proportion. Thus it is necessary that the shades of a picture be considerably deeper than those of the model; especially if, from the greatest lights to the browns, one hath proportionally followed the distance which is found between the colours on the pallet and the tones of the object copied.

Now if the white of fresco be infinitely more bright than that of oil, the same effect will be obtained in a brown tone. On the other side, if it constantly happens that the brown tones of fresco are much more vigorous than those of water colours, and equal even to the browns of oil itself, it is certain that it possesses a splendor and vigour more extensive than any other kind of painting. Thus in the hands of an artist who is well acquainted with the colours fit for fresco, it is more susceptible of the general effect, and more capable than any other kind of giving projection and the semblance of life to the figures.

If we were to inquire why painting in fresco is now feared or never practised, we should perhaps ascribe it to the great talents required to execute it. "Many of our painters (says Vafari in his treatise on painting) excel in oil and water colours, and yet fail in fresco; because of all kinds this requires the greatest strength of genius, boldness in the strokes, and resolution." If in an age abounding in great matters, it was difficult to excel in this kind, it must be much more so in ours; but we should not require the characters of sublimity and style to which men were accustomed in the time of Vafari.

We should execute in fresco as we do in oils; for Italy herself, along with Michael Angelo and Zuccharo, had Cortomi Giardano and Francichini as middling fresco-painters. And in France, Lafosse, Bon Boulogne, and Perur, performed several works in fresco which might be imitated by the painters of our times. But let us proceed to the real causes for abandoning this art. These proceed from the want of knowledge and taste in the persons who employ the artists, and from the manners of the age. As a pleasant or licentious conceit, unfurnished colouring, and bold effects of shade, are the chief objects of confidence, a very smooth painting enlivened by gentle touches completely gratifies the person who pays the price; and therefore the philosophical principles of the art, which require study, are not cultivated.

We shall now attend to the mechanical process of this useful and beautiful kind of painting. Before painting, it is necessary to apply two layers. If the wall on which you are to paint is of brick, the layer is easily applied; but if it is of freestone closely united, it is necessary to make excavations in the stone, and to drive into them nails or pegs of wood in order to hold the first layer.

The first layer is made of good lime and a cement of pounded brick, or, which is still better, river-sand; this latter forms a layer more uneven, and better fitted to retain the second smooth and polished layer applied to its surface.

There should be experiments to discover a layer still more compact, and more independent of the variations of the air; such for example, as covers the aqueducts and ancient reservoirs constructed by the Romans in the neighbourhood of Naples.

Before applying the second layer, one should be well prepared to paint, and the first should be properly dry; for there is still from the lime, when it is moist, a smell both disagreeable and pernicious to the artist.
Painting.

Part II.

Fresco. When the first layer is perfectly dry, it is wet with water in proportion to its dryness, that the second layer may be more easily incorporated with it.

The second layer is composed of lime flaked in the air and exposed for a year, and of river-loam, of an equal grain, and moderately fine.

It requires an active and intelligent mason to apply this layer, as the surface must be altogether equal. The operation is performed with a spade; and the operator requires to have a small piece of wood to take away the large grains of sand, which remaining, might render the surface uneven.

To give a fine polish to this layer, one ought to take a sheet of paper, apply it to the wall, and pass and repass the spade over the paper. By this means the little inequalities which hurt the exactness of the stroke, and which produce false appearances at a distance, are entirely smoothed.

The artificer must not lay more than the painter can finish in a day, as this kind of painting must be executed on a fresh ground.

The layer being thus prepared, the painter begins his operation; but as painting in fresco must be executed rapidly, and as there is no time to retouch any of the strokes, the painters, as we have observed under the article Fresco, takes care to provide himself with large cartoons, on which he has drawn, with exactness, and in their full size, the figures which he is to paint, which leaves him nothing to do but to copy them on the wall.

The cartoons are composed of several sheets of large paper pasted one on another, neither too thick nor too slender.

The painter traces the tracks of the figures on the plaster, by passing a steel point over the tracks in the cartoons, or in prickling them.

Having in this manner attained an exact and speedy drawing, it now remains to execute the painting.

But it is essential, when one wishes to finish any small work of this kind, in the first place to be informed of the proper colours, and of those which cannot be used.

In general the colours which are extracted from earth are the only ones which can be employed in this kind of painting.

The colours are white, made of lime, the white of egg-shells, ultramarine, the black of charcoal, yellow ochre, burnt vitriol, red earth, green of Verona, Venetian black, and burnt ochre.

There are others which require to be used with great precaution, such as enamel blue, cinnabar, and white marble dust.

When enamel blue is used, it requires to be applied instantaneously, and when the lime is very moist, otherwise it does not incorporate with the plaster; and if one retouch with this colour, it must be done an hour or more after the first application, to increase its lustre.

With regard to the white marble dust, it is subject to turn black if it be not mixed up with a convenient quantity of white lime.

Cinnabar, which has a splendor almost superior to all other colours, loses it almost entirely when mixed with lime. At the same time, it may be employed in places not exposed to the air, with a little degree of care in the preparation. Reduce a quantity of the purest cinnabar to powder, put it into an earthen vessel, and pour lime-water on it for two or three times. By this process the cinnabar receives some impression of lime-water, which makes it capable of being employed in fresco-painting.

One of the best colours, and the one most used in fresco for the gradation of tints, and for giving the requisite tone, is white of lime. This white is prepared by mixing lime flaked long before with good water. The lime deposits a sediment at the bottom of the vessel; when the water is poured off, this sediment is the white of lime.

Another kind of white might be used, the effects of which would be known by experience, namely, the white of egg-shells. To prepare this white one must take a great quantity of shells of eggs, which must be pounded and boiled in water along with a quantity of quicklime; after this they are put into a strainer, and washed repeatedly with fountain-water.

The shells are again pounded until the water employed for that purpose become pure and limpid; and when they are in this manner reduced to powder, this powder is ground in water, and formed into small pieces, and dried in the sun.

All the different kinds of ochres make excellent colours for fresco, and take different shades, being previously burned in iron chests.

With regard to the Naples yellow, it is dangerous to use it where the painting is much exposed to the air. The blacks of charcoal, of peach flowers, and of vine twigs, are good; but that extracted from bones is of no value.

Roman vitriol gathered at the furnaces, and which is called burnt vitriol, ground afterwards in spirit of wine, refills the air extremely well when employed in lime. There is also a red extracted from this preparation somewhat like that produced from lac.

This colour is very proper for preparing the layers to be coloured with cinnabar; and the draperies painted with these two colours will vie in splendor with those painted with fine lace in oil.

The ultramarine is the most faithful colour; and it not only never changes, but it communicates this precious quality to those colours with which it is mixed.

The manner of employing those colours, is to grind them in water, and to begin by arranging them into the principal tints you are to employ: these are afterwards put into pots; and it is necessary to use a great many pallets raised at the edges, to form the intermediate shades, and to have under your eye all the shades you require.

As all the tints, except burnt ochre, violet red, and blacks of all kinds, are apt to become clear, the painter must have beside him some pieces of brick or new tile very dry. A dahl of the colours is applied to one of these with the pencil before using them; and as tile instantaneously imbibles the water, one perceives what the shade will be after the fresco is dry.

§ 2. Elydoric Painting, invented by M. Vincent of Montpetit.

This new kind of painting is little known, and capable of great improvement.

R
PAINTING.

When the materials are thus prepared, the subject is lightly traced on one of the pieces of cloth above-mentioned with a lead pencil.

The tints are formed on the pallets from the heaps of colours under the water, and the pallet placed as usual on the left arm with the thumb through the aperture.

The picture is held before the thumb and fore-finger, supported by the middle, and the necessary pencils between the third and little fingers. The hand is supported on the back of a chair, that there may be full liberty of bringing the work near, or keeping it at a distance from the eye.

The pencils are cleaned with the essence of rectified turpentine.

After having made the rough draught with the colours still fresh, the circle of copper, which ought to surround the picture is fitted exactly to the surface.

The distilled water is poured within this circle to the height of one-eighth part of an inch; and the body is leaned forward till the fall fall perpendicularly on the object.

The third finger of the right hand must rest on the internal right angle of the picture.

The artist, with a fine and firm pencil, runs over the first draught, to give colour to the weak places, and to soften those which appear too strong.

As soon as the oil swims on the top, the water is poured off, and the picture is carefully covered with a watch-glass, and dried in a box with a gentle heat.

When it is sufficiently dry, to be scraped almost to a level with the knife: the above operation is renewed till the artist is satisfied with his work.

It is in this last work that the artist feels all the advantage of this new method for fining.

The water poured on the picture discovers all the faults of the pencil, gives facility in searching into the bottom of the shades, and the power of correcting the work and rendering it perfect.

When the work is finished: it is put under a crystal where there is no admixture of external air, and dried with a gentle heat.

PART III. Of Economical Painting.

SECTION III.

The object of this Part is to give an account of some mechanical proceedings in certain kinds of painting, dedicated to preserve and embellish the walls of houses and furniture. This branch of the art extends to every part of architecture. The whole building becomes the workshop of the artist: the stairs, the ballustrades, the fathes, the doors, and the railing of all kinds, occupying his first care, and then the ceilings and wainscotting.

The artist gives to all his subjects a chosen and uniform tint; but he has it in his power to vary the colours on different parts of the building in such a manner as to produce the most pleasing effect.

Among the utensils of the painter, it is needless, but for rendering the article complete, to mention the brushes and pencils of all sizes as absolutely necessary.

The brushes are made of boars bristles, or of hair with a mixture of bristles; they ought to be straight, very smooth, and of a round form. Half an hour before they are used, it is proper to soak them in water, in order to swell the wood of the handle, and prevent the hairs from falling off; after this they may be applied to all purposes, either in water colours or in oil; but it may be observed, that for the former they require less softening.

The pencils are made of badgers hair, or any fine hairs enchafted in the pipes of quills of all sizes.

The vessels wherein the pencils are cleaned is made of copper or of tin, smooth below, rounded at the ends, and divided into two parts by a thin plate in the middle. The oil, or the substance with which the pencil is cleaned, is contained in one of the divisions.

The pallet is made of the wood of the pear or apple tree, of an oval or square shape, very slender, but some
PAINTING.

and those which are newly mixed are more vivid and beautiful.

2. Hold the brush straight before you, and allow only the surface to be applied to the subject: if you hold it inclined in any other direction, you will run the hazard of painting unequally.

3. It is necessary to lay on the colours boldly, and with great strokes, taking care at the same time to spread them equally over the surface, and not filling up the moulding and carved work. If this accident should happen, you must have a little brush to clean the colours.

4. Stir them frequently in the vessel, that they may preferre always the same tint; and that no sediment may remain at the bottom.

5. Take care not to overcharge the brush with the colour.

6. Never apply a second layer till the first or preceding one be perfectly dry; which it is easily known to be when, in bearing the hand gently over it, it does not adhere.

7. In order to render this drying more speedy and uniform, make always the layers as thin as possible.

8. Before painting, it is necessary to prime the subject; that is, to give it a layer of size, or of white colouring oil, to fill up the pores, and render the surface smooth; by this means fewer layers of colour or varnish are afterwards necessary.

9. Every subject to be painted or gilded, ought to have first a white ground; this preserves the colours fresh and vivid, and repairs the damage which they occasionally receive from the air.

§ 1. Of painting in Water-colours.

To paint in water-colours, is to do it in those which are ground in water and diluted in size. There are three kinds of this painting; namely, common, the varnished, and that which is called king's white; but before entering on these, it is necessary to make some preliminary observations.

1. Take care that there be no grease on the subject; and if there be, scrape it off, or clean it with a lye, or rub the greasy part with garlic and wormwood.

2. Let all the diluted colour fall in threads from the end of the brush when you take it out of the vessel, if it adheres to it, it is a proof that it wants size.

3. Let the layers, especially at the beginning, be laid on very warm, provided that the liquid be not boiling, which would effectually spoil the subject; and on wood, expose it to crack. The last layer, given immediately before the varnish, is the only one which ought to be applied cold.

4. In very fine work, where it is necessary to have beautiful and solid colours, the subjects are prepared by size and proper whites, which serve as a ground to receive the colour, and render the surface very equal and smooth.

5. Whatever colour is to be laid on, the white ground is the best, as it affinimates most easily with the painting, which borrows always something of the ground.

6. If knots of wood are found in the subject, it is necessary to rub them with garlic, to make the size adhere.

SECT. II. Application of Colours.

1. Prepare only the quantity necessary for the work you undertake, because they do not keep long; and if you use them more than once, they may be neither too thick nor too thin.
To make the following details sufficiently plain, we shall take the measures to which the quantity of colours are applied at fathoms: that is to say, fix feet in height by fix feet in breadth. We shall afterwards fix the quantity of materials, and of liquids necessary to cover this surface. This, however, cannot be exactly defined; as some subjects imbibe the colours much more than others. The manner of employing them also makes a difference; as habit enables one to manage them to greater advantage than another. And it is also to be observed, that the first layer will consume more than the second; and that a prepared subject requires less than one which has not been so.

When we speak of a fathom, it must be understood of a smooth and equal surface; for if the wood is varied with mouldings and carving, there must be a difference in the quantity of colours. In general it requires about a pound of colours to paint a square fathom in water-colours. In making up this quantity, take three fourths of colours grinded in water, and one fourth pound, or fix ounces, of size to dilute it.

§ 2. Of Painting in Common Water-colours.

Works which require no great care or preparation, as ceilings and staircases, are generally painted in common water colours, i.e. with earths, infused in water and diluted in size.

For a common white kind of this painting, steep Spanish white moderately pounded in water for two hours. Infuse a proper quantity of the black of charcoal in water for the space of time; mix the black and white in the proportion that the tint requires; afterwards mix them up with a pretty strong size, sufficiently thick and warm, and apply them to the subject in as many layers as may be thought necessary. It requires about two pounds of white in a pint of water, and a quantity of black in proportion to the tint, together with a part of size, to cover a square fathom. If this be employed on old walls, they must be well scraped, the dust brushed off with a hair besom, and washed carefully with lime-water. If on new plaster, the colours require more size.

All kinds of colours may be grinded in water only when the tint is made; and when they have been infused in water, they must be mixed up with size.

§ 3. Walls done with the White Des Carmes.

The white des carmes, is a manner of whitening interior walls, whereby they are rendered extremely beautiful.

1. Procure a quantity of the very best lime, and pass it through fine linen; pour it into a large tub, furnished with a spigot at the height equal to that which the lime occupies; fill the tub with clear fountain-water; beat the mixture with great pieces of wood, and then allow it to sette for 24 hours.

2. Open the spigot, allow the water to run off, supply the tub with fresh water, and continue this operation for several days until the lime receives the greatest degree of whiteness.

3. When you allow the water finally to run off, the lime will be found in the consistence of paste, but with the quantity you use it is necessary to mix a little Prussian blue or indigo to relieve the brightness of the white, and a small quantity of turpentine to give it brilliancy. The size proper for it is made of glove-leather, with the addition of some alum; and the whole is applied with a strong brush in five or fix layers to new plaster.

4. The wall is strongly rubbed over with a brush of hogs bristles after the painting is dry; which gives it its lustre and value, and which makes it appear like marble or stucco.

§ 4. Of Badgeson.

Badgeson is a pale yellow colour applied to plaster to make it appear like free stones. It gives to old houses and churches the exterior of a new building, by affuming the colour of stones newly cut.

1. Take a quantity of lime newly killed.

2. Add to it the half quantity of what the French call feinte de pierre, in which you have mixed of the ochre of rus, according to the colour of the stone you intend to imitate.

3. Steep the whole in a pail of water, in which is melted a pound of rock alum. When the feinte de pierre cannot be obtained, it is necessary to use a greater quantity of ochre de rus, or of yellow ochre, or grind the scales of the stone of St Leu; pass it through a sieve, and along with the lime it will form a cement, on which the weather will scarcely make any impression.

§ 5. Of Ceilings and the Roofs of Rooms.

When the ceilings or roofs are new, and you wish to whiten them, take white of Bougival, to which add a little of the black of charcoal to prevent the white from growing reddish: infuse them separately in water; mix the whole with half water and half size of glove-leather, which being strong would make the layer come off in rolls if it were not reduced with water. Give two layers of this tint while it is lukewarm. If the roof has been formerly whitened, it is necessary to scrape to the quick all the remaining white; then give it two or three layers of lime to ground and whiten it: Brush it carefully over; and give it two or three layers of the white of Bougival prepared as before.

§ 6. Of Colouring the Backs of Chimneys with Lead Ore.

Clean them with a very strong brush, and carefully rub off the dust and rust; pour about a quarter of a pound of lead ore into a fine powder, and put it into a vessel half a pint of vinegar; then apply it to the back of the chimney with a brush: When it is made black with this liquid, take a dry brush, dip it in the same powder without vinegar, and dry and rub it with this brush till it become shining as glass.

§ 7. Of Varnished Water-colours.

The advantages of this kind of painting are, that the colours do not fade; that they reflect the light; that they give no offensive smell, but permit the places to be inhabited as soon as finished; and that the varnish preserves the wood from insects and moisture.

To make a fine varnish on water colours, seven principal operations are necessary; namely, to size the wood, to prepare the white, to soften and rub the subject, to clean the moulding, to paint, to size, and to varnish.

Seco~~
Fifth ope­ration.

Size the wood with this boiling liquor; allow it to
penetrate into the carved and smooth places of the
wood, but take care at the fame time to take it as
clean off the work as poffible, or at leat to leave it at
no place thicker than another. This first fizing forfs
fervs to fill up the pores of the wood, and to prevent
the materials afterwards from collecting in a body, which
would cause the work to fall off in fcales.

In a pint of strong parchmim fize, to which you
have added four pints of warm water, put two hands­fuls of white Bougival, and allow it to infufe for the
space of half an hour.

Stir it well, and give a fingle layer of it to the
subjed very warm but not boiling, equally and regularly
laid on, and afhed with repeated strokes of the brush
into the mouldings and carved work.

To prepare the white, take a quantity of strong
parchmim fize, and afpinkle lightly over it, with the
hand, Bougival white, till the fize be covered with
it about half an inch in thickness; allow it to fook for
half an hour as near the fire as to keep it milk
warm; and then flir it with the brush till the lumps
are broken, and it be fufficiently mixed.

Give seven, eight, or ten layers of this white, or
as many as the nature of the work or the defects in
the wood fhall render neceffary, giving more white to
the parts which require to be foftened; but in gene­
eral, the layers muft beequal both with regard to
the quantity of the white and the fhrength of the fize.

The fIaff layer of the white ought to be clearer
than the reft, which is made by adding water. It
muft be applied more flightiy, taking care with aml
brushes to cover all the difcult places in the mouldings
and carved work. It is neceffary alfo, between the
drying of the different layers, to fill up all the de­
etfes with white mafflch and fize.

To foren, is to give to the subjed after the whiten­
ing a smooth and equal surface, and to rub it over with
a pumice-flone.

The wood being dry, take little pieces of white
wood and of pumice-flone, graded for the purpofe
into all neceffary forms, either for the panels or the
moulding.

Take cold water, heat being defruftive of this kind
of work; in fummer it is common to add a little ice.
Sofen the wall with a brush, but only as much at a
time as you can eafily work, as the water might di­
fluence the white and fpoil the whole; Then smooth
and rub it with the pumice flones and with the small
pieces of wood: Wash it with a brush as you smooth
it, and rub it over with a piece of new linen, which
gives a fine luflre to the work.

The mouldings and carved work are cleaned with
an iron; and the only thing to be attended to in the
operation is not to raise the grain of the wood.

The subjed thus prepared is ready to receive the co­
lour you intend to give it. Choose your tint; fupply

Grind white cerufe and Bougival white penetrately
in water, of each an equal quantity, and mix them to­
gether.—Add a little blue of indigo and a very fmall
quantity of black of charcoal from the vine tree very
fined, alfo separately, and in water; more or
lefs of the one or other gives the tint you require.—

Dilute this tint in firing parchment ftze; pafs it
through a boiling clothe of filk very fine, and lay the
tint on your work, taking care to fpread it very
equally; and then give it two layers, and the colour
is applied.

Make a weak, beautiful, and clean fize; stir it till
Sixth ope­ration.

This derives its name from the use of it in the
apartments of the French King. It is in all respects
conducted like the former, except that there is only
a fmall quantity of indigo, to take the yellow from
the white, without any black of charcoal, and with­
out varnish.

This white anfwers extremely well for appart­
ments which are seldom used; but otherwife it fpoils easi­ly,
especially in bed-rooms. It is the beft white where
there is any kind of gilding; and in this cafe it re­
ceives a little varnish.

Sect. III. Of Painting in Oil colours.

To paint in oil is to apply to all forts of subjeds,
as walls, wood, cloths, and metals, coloured earths
grinded and diluted in oil. The ancients are thought
to have been ignorant of this art, and the honour of
the discovery is generally ascribed to John Van Eyck
a Flemifh painter. The fecret is nothing more than
fantituting oil in the place of water in grinding and
diluting colours.

By means of oil the colours are longer preferred;
and not drying so speedily, they give painters longer
time to smooth, fhine, and retoch, their works; the
colours being more marked, and mixing better to­
gether, give more dilinguifhable tints, and more vi­
vid and agreeable graduations, and the colouring is
more sweet and delicate.

The painting in oil confists of two kinds, namely,
of that in fimple oil and of that in polished oil varnish.

§ 1. Observations on painting in Oil.

1. When bright colours, as white or grey, are grinded
and diluted in oil, it is neceffary to make use of the
Painting.

1. When the colours are dark, such as chestnut, or olive, or brown, you must make use of pure linseed oil.

2. When the colours are mixed with oil, they must be laid on cold, except on a new or moist plaster, which requires them to be boiling.

3. Every colour diluted in pure oil, or in oil mixed with effence, ought to fall in threads from the end of the brush.

4. Take care to stir from time to time your colour before taking it up on the brush, that it may preserve an equal thickness, and consequently the same tone. Notwithstanding the precaution of stirring, if it is found to be thicker towards the bottom, it will be necessary to pour in from time to time a little oil.

5. In general, every subject which is painted in oil ought first to receive one or two layers of white ceruse, grinded and diluted in oil.

6. When the painting is exposed to the air, as in doors, windows, and other works, which cannot be varnished, it is necessary to make these layers with pure oil of walnuts, mixed up with about one ounce of effence to a pound of colours; more would make the colours brown, and occasion them to fall off in dust; but this quantity prevents the fun from penetrating the work.

7. In subjects on the inside of the house, or when the painting is varnished, the first layer ought to be grinded and diluted in oil, and the last diluted with pure effence.

8. If copper or iron, or other hard substances, are to be painted, it is necessary to mix a little effence with the first layers, to make the oil penetrate into them.

9. When there are many knots in the subject, as is particularly the case with fir-wood, and when the colour does not easily take imprefion on these parts, it is necessary, when you paint with simple oil, to lay on a little oil mixed with litharge on the knots. If you paint with polished oil varnished, it is necessary to apply a hard tint, which we shall have occasion to speak of afterwards. A single layer well applied is generally sufficient to give a body to the wood, and make the other layers apply easily.

10. There are colours, such as what the French call fil-de-grain, black of charcoal, and especially bone and ivory-blacks, which are difficult to dry when grinded in oil. To remedy this inconvenience, the following fixcatives are mixed with the colours, to make them dry, viz. litharge both of the silver and gold colour, vitriol or copperas, and what is called fixcative oil.

1. Do not mix the fixcatives with the colours till they are to be employed, otherwise it will thicken them.

2. Mix it only in very small quantities in oil, which in there is white lead or ceruse, because those colours are fixcative of themselves, especially when they are diluted in oil.

3. In painting which is to be varnished, give the fixcative only to the first layer, and allow the other layers, in which there is essence, to dry of themselves.

4. In dark colours in oil, give to every pound of colours in diluting them half an ounce of litharge; paint in to bright colours, a drachm of white copperas grinded in walnut oil.

5. When in place of litharge or copperas the fixcative oil is employed, it requires a quarter of this oil to every pound of colour.

The fixcative oil is prepared of one half ounce of litharge, as much of calcined ceruse, as much of terre d'ombre, a colour with which the French paint windows, and as much of tallow boiled for two hours on a flow and equal fire, with one pound of linseed oil, and stirred the whole time. It must be carefully skimmed and clarified, and the older it grows it is better.

§ 3. Observations on the Quantities of Substances and Liquids.

1. Ochres and earths require more liquids both in grinding and diluting than ceruse.

2. Different quantities of liquids are required in the grinding only on account of greater or less dryness; but in diluting, the quantity is always the same.

3. For the first layer after the priming, which has no relation to the colours laid on afterwards, to a square fathom give fourteen ounces of ceruse, about two ounces of liquid to grind, and four ounces to dilute it. If there is a second layer of the same materials, the quantities will require to be less.

4. It will require three pounds of colour for three layers of a square fathom. The first may consume eighteen ounces, the second sixteen, and the third fourteen.

5. To compose these three pounds of colour, take two or two and a half pounds of grinded colours, and dilute them in a pint or three half pints of oil, mixed with essence or pure oil. But if the first layer of ceruse is not used, there will be a necessity for a greater quantity of colours.

N. B. In the following kinds and applications of oil painting, we are to hold those proportions in our eye.

§ 4. Painting in simple Oil.

On doors and windows give a layer of ceruse grinded in oil of walnuts diluted in the same oil, together with a little fixcative; then give another layer of the same preparation; to which, if you want a greyish colour, add a little black of charcoal and Prussian blue, grinded also in oil of walnuts. If to those you incline to add a third layer, grind and dilute it in pure walnut oil; observing that the two last layers be less clear, or have less oil in them, than the first; the colour in this case is more beautiful and less apt to blister with the sun.

Walls that are to be painted must be very dry; and of walls, this being sputtered, give two or three layers of boiling linseed oil to harden the plaster; then lay on two layers of ceruse or ochre, grinded and diluted in linseed oil; and when these are dry, paint the wall.

To paint tiles of a flat colour, grind separately of Tiles ceruse and German black in linseed oil; mix them together in the proportion which the colour requires, and dilute them in linseed oil; then give the first layer very clean to prime the tiles; and make the three next layers thicker to give solidity to the work.

To paint arbours and all kinds of garden work,

36 If you wish to paint on walls not exposed to the air, or on new plaster, give one or two layers of boiling linseed oil, and continue the brush till the walls are fully soaked; then give a layer of white ceruse, grinded in oil of walnuts and diluted with three fourths of the same oil and one fourth essence; and lastly, give two layers more of white ceruse, grinded in oil of walnuts and diluted in oil mixed with essence, if it is not to be varnished; but in pure essence if it is. It is in this manner that walls are painted white. If you adopt another colour, it is necessary to grind and dilute it in the same quantities of oil and essence.

37 To paint chairs, benches, stone, or platter, give a layer of white ceruse grinded in oil of walnuts and diluted in the same oil, into which you have cast a little litharge to make it dry; then apply a layer of the tint you fix on, grinded in oil and diluted in one part oil and three parts essence; and afterwards give two more layers of the same tint grinded in oil and diluted in pure essence. This may be varnished with two layers of spirit of wine.

38 To make a dark colour, grind separately in essence, white ceruse, Prussian blue, fine lac, and verdigris. The tone which you require is procured by the proper mixture of those ingredients. When you have fixed on the tone of colour, take about the size of a walnut of the ingredients, and dilute them in a small vessel in one part of essence and three parts of white oily varnish. N.B. This colour is generally made of white ceruse, of black charcoal, and Prussian blue, grinded in thick oil, and diluted in essence, which is the cheapest method of procuring it; but the former is the most beautiful.

39 For painting ballustrades and railings, dilute lampblack with varnish of vermilion; giving two layers of it, and afterwards two layers of spirit-of-wine varnish.

40 Since the discovery of oil painting, and the knowledge that wood is preserved by it, and especially since the discovery of a varnish without smell, and which even takes away that oil, the painting of apartments in oil has been with justice preferred. In fact the oil stops up the pores of the wood; and although it does not altogether refit the impression of moisture, yet the effect is so little perceptible, that it is to be recommended as the best method of preserving wood.

To preserve wainscotting in the most effectual manner from moisture, it is necessary to paint the wall behind it with two or three layers of common red, grinded and diluted in linseed oil.

To paint the wainscotting itself, give a layer of white ceruse grinded in oil of walnuts, and diluted in the same oil mixed with essence. This layer being dry, give two more of the colour you have adopted, grinded in oil and diluted in pure essence. If you with the mouldings and sculpture to be painted in a different colour, grind and dilute it in the same manner.

Two or three days after, when the colours are fully dry, give two or three layers of your white varnish without smell, and which also prevents the offensive smell of the oil colours. N.B. Those who begin their operations in water colours, if they find it more agreeable, may finish it in oil colours as above.

When the pores of the wood are well stopped by the prepared white, a layer of white ceruse grinded in oil of walnuts, and diluted in the same oil, mixed with essence, may be applied. This will be sufficient, the wood being previously primed; and afterwards lay on your intended colour and varnish.

§ 5. Painting in Oil with the polished Varnish.

This is the best kind of oil painting, owing more to the care it requires than to the proceedings, for they are nearly the same with those of simple oil painting; the difference consisting only in the preparation and manner of finishing.

To paint wainscottings of apartments with the polished varnish, it is necessary, in the first place, that the panels be new. Then,

1. Make the surface of the subject which you mean to paint very smooth and level, which is done by a layer, which serves to receive the hard tint or polished ground and the colours.

This layer ought to be of white, whatever colour you are afterwards to apply. It consists of white ceruse grinded very fine in linseed oil, with a little litharge, and diluted in the same oil mixed with essence.

2. Make the polished ground by seven or eight layers of the hard tint. In painting equipages, a dozen is necessary.

The hard tint is made, by grinding pure white ceruse, which has not been much calcined, very finely in thick oil, and diluting it with essence. You must take care that the layers of the hard tint be not, only equal as to the application, but to the quantity of the white ceruse and the oil, and to the degree of calcination. Then,

3. Soften this ground with pumice-flour.

4. Poiñit it moderately with a piece of large foaked in a pail of water, in which you have put some powder of pumice-flour finely grinded and passed through a fine sieve. There is no occasion to spare washing, as this part of the operation will not spoil with water.

5. Choose the tint with which you intend to decorate your apartment; grind it in oil, and dilute it in essence; pass it through a piece of very fine silk, give two or three layers carefully and thinly spread over the surface, as on this part of the operation depends a great measure the beauty of the colour. All sorts of
6. Give two or three layers of a spirit of wine varnish, if it is to wainscotting; if to the body of a couch, a varnish of oil is employed. If the varnish is to be polished, it is necessary to get seven or eight layers at least, laid on equally and with great precaution, not to be thicker in one place than another, which occasions spots.

7. It is again polished with pumice-flone reduced to powder, and water and a piece of sarge. If the wainscotting has been painted before, it is necessary to rub off the colour till you come to the hard tint, which is done with pumice flone and water, or with a piece of linen dipped in essence.

There is a white painting in oil, called white varnish polish, which corresponds to the king's white in water colours, and is equal to the freshness and whiteness varnish, mix them carefully; give one layer above the white.

6. This layer being dry, put one ounce of colours into the same quantity of varnish as above, and give a second layer.

7. To the third layer give half an ounce of colour to the same quantity of varnish.

8. As each of these layers dry, be careful to rub them with a piece of new coarse cloth, in such a manner, however, as not to injure the colour. N.B. The Proportion of Colours

three layers may be given in one day.

9. If you want to give a period fuller, add a fourth layer prepared as the third.

All other colours, as blue, &c. may be applied in the same manner. This method is the only one by which orpiment can be employed in all its beauty, but not without some of its inconveniences.

Another manner of performing this kind of work, is to apply the colours and the varnish without previously using the size and the white ground. This is extremely expeditious, but it is easy to perceive it will want the polish and brilliancy of the other.

SECTION IV.

We cannot perhaps more properly conclude this article, than with an account of M. de Morveau's attempts to render more perfect the proportion of colours, and especially of white, employed in painting. These we shall extract from a memoir of his read in the academy of Dijon.

"White (says the ingenious academician) is the most important of all colours in painting. It affords to the painter the materials of light, which he distributes in such a manner as to bring his objects together, to give them relief, and that magic which is the glory of his art. For these reasons I shall confine my attention at present to this colour.

"The first white which was discovered, and indeed the only one yet known, is extracted from the calx of lead. The danger of the process, and the dreadful distemper with which those employed in it are often seized, have not yet led to the discovery of any other white. Let us anxious, indeed, about the danger of the artiff than the perfection of the art, they have varied the preparation, to render the colour less liable to change. Hence the different kinds of white, viz. white of crems in Austria, white lead in shells, and white ceruse. But every perfon conversant in colours, knows that the foundation of all these is the calx of lead, more or less pure, or more or less loaded with gas. That they all participate of this metallic sub‐flance, will indeed appear evident from the following experiment, which determines and demonstrates the alterability of colours by the phlogistic vapour.

"I poured into a large glass bottle a quantity of li‐ver of sulphur, on a basis of alkali, fixed or volatile, it makes no difference; I added some drops of distilled vinegar, and I covered the mouth of the bottle with a piece of pasteboard cut to its size, on which I disposed different samples of crems, of white lead, and of ceruse, either in oil or in water; I placed another ring of pasteboard over the flir, and tied above all a piece of bladder round the neck of the bottle with a strong pack‐thread. It is evident, that in this operation I took advantage of the means which chemistry offers to produce a great quantity of phlogistic vapour, to accomplish instantaneously the effect of many years; and, in a word, to apply to the colours the very same vapours to which the picture is necessarily exposed, only more accumulated and more concentrated. I lay the fame vapour, for it is now fully established, that the smoke of candles, animal exhalations of all kinds, alkaline effluvia, odours, the electric effluvia, and even light, furnish continually
CONTINENTAL ARTS.

The first, that it dilutes easily, and take a body both with oils and with mucilages, or at least with the one or other of these substances, a circumstance which depends on a certain degree of affinity. Where this affinity is too strong, a dissolution ensues; the colour is extinguished in the new composition, and the mass becomes more or less transparent; or else the sudden refraction absorbs the fluid, and leaves only a dry substance which can never again be softened. But if the affinity is too weak, the particles of colour are scarcely suspended in the fluid, and they appear on the canvas like sand, which nothing can fix or unite.

The second condition is, That the materials of which colours are composed do not bear too near an affinity with the phlogistic vapour. The experiments to which I submitted whites from lead, is an infallible means of ascertaining the quality of colours in this respect, without waiting for the slow impregnation of time.

A third condition equally essential is, That the colouring body be not volatile, that it be not connected with a substance of a weak texture, susceptible of a spontaneous degeneracy. This consideration excludes the greater part of substances which have received their tint from vegetable organization; at least it makes it impossible to incorporate their finer parts with a combination more solid.

After these reflections, my researches were directed, first, to the five pure earths; next, to the earthy compounds; in the third place, to the earthy falls, which can scarcely be dissolved; lastly, to the metallic earths, either pure or precipitated by Prussian alkali. M. Wenzel has discovered a sixth earth, which I call smaragd, and which, after other experiments I thought of applying to the purposes of painting; but I soon perceived that it would have the same fault with other proportion of colours. It is not analogous, but identically the same with the vapour of vitriolic acid mixed with sulphur.

"If it happens that the samples of colours are sensibly altered by the phlogistic vapour, then we may conclude with certainty, that the materials of which the colours are composed, bear a great affinity to that vapour; and since it is not possible to preserve them entirely from it in any situation, they will be more or less affected with it, according to the time and a variety of circumstances.

"After some minutes' continuance in this vapour, I examined the samples of colours submitted to its influence, and found them wholly altered. The ceruse and the white lead both in water and oil were changed into black, and the white of ceras into a brownish black; and hence these colours are bad, and ought to be abandoned. They may indeed be defended in some measure by varnish: but this only retards for a time the contact of the phlogistic vapour; for as the varnish loses its humidity, it opens an infinite number of passages to this subtle fluid.

"After having ascertained the infallibility of the whites in common use, I made several attempts to discover such as would prove more lasting; and tho' many of these attempts were without effect, I shall give a succinct account of the whole, which may save a great deal of trouble to tho' who wish to travel over the same field.

"There are three conditions essential to a good colour in painting.

"First, That it dilutes easily, and take a body both with oils and with mucilages, or at least with the one or other of these substances, a circumstance which depends on a certain degree of affinity. Where this affinity is too strong, a dissolution ensues; the colour is extinguished in the new composition, and the mass becomes more or less transparent; or else the sudden refraction absorbs the fluid, and leaves only a dry substance which can never again be softened. But if the affinity is too weak, the particles of colour are scarcely suspended in the fluid, and they appear on the canvas like sand, which nothing can fix or unite.

"The second condition is, That the materials of which colours are composed do not bear too near an affinity with the phlogistic vapour. The experiments to which I submitted whites from lead, is an infallible means of ascertaining the quality of colours in this respect, without waiting for the slow impregnation of time.

"A third condition equally essential is, That the colouring body be not volatile, that it be not connected with a substance of a weak texture, susceptible of a spontaneous degeneracy. This consideration excludes the greater part of substances which have received their tint from vegetable organization; at least it makes it impossible to incorporate their finer parts with a combination more solid.

"After these reflections, my researches were directed, first, to the five pure earths; next, to the earthy compounds; in the third place, to the earthy falls, which can scarcely be dissolved; lastly, to the metallic earths, either pure or precipitated by Prussian alkali. M. Wenzel has discovered a sixth earth, which I call smaragd, and which, after other experiments I thought of applying to the purposes of painting; but I soon perceived that it would have the same fault with other proportion of colours. It is not analogous, but identically the same with the vapour of vitriolic acid mixed with sulphur.

"If it happens that the samples of colours are sensibly altered by the phlogistic vapour, then we may conclude with certainty, that the materials of which the colours are composed, bear a great affinity to that vapour; and since it is not possible to preserve them entirely from it in any situation, they will be more or less affected with it, according to the time and a variety of circumstances.

"After some minutes' continuance in this vapour, I examined the samples of colours submitted to its influence, and found them wholly altered. The ceruse and the white lead both in water and oil were changed into black, and the white of ceras into a brownish black; and hence these colours are bad, and ought to be abandoned. They may indeed be defended in some measure by varnish: but this only retards for a time the contact of the phlogistic vapour; for as the varnish loses its humidity, it opens an infinite number of passages to this subtle fluid.

"After having ascertained the infallibility of the whites in common use, I made several attempts to discover such as would prove more lasting; and tho' many of these attempts were without effect, I shall give a succinct account of the whole, which may save a great deal of trouble to tho' who wish to travel over the same field.

"There are three conditions essential to a good colour in painting.

"First, That it dilutes easily, and take a body both with oils and with mucilages, or at least with the one or other of these substances, a circumstance which depends on a certain degree of affinity. Where this affinity is too strong, a dissolution ensues; the colour is extinguished in the new composition, and the mass becomes more or less transparent; or else the sudden refraction absorbs the fluid, and leaves only a dry substance which can never again be softened. But if the affinity is too weak, the particles of colour are scarcely suspended in the fluid, and they appear on the canvas like sand, which nothing can fix or unite.

"The second condition is, That the materials of which colours are composed do not bear too near an affinity with the phlogistic vapour. The experiments to which I submitted whites from lead, is an infallible means of ascertaining the quality of colours in this respect, without waiting for the slow impregnation of time.

"A third condition equally essential is, That the colouring body be not volatile, that it be not connected with a substance of a weak texture, susceptible of a spontaneous degeneracy. This consideration excludes the greater part of substances which have received their tint from vegetable organization; at least it makes it impossible to incorporate their finer parts with a combination more solid.

"After these reflections, my researches were directed, first, to the five pure earths; next, to the earthy compounds; in the third place, to the earthy falls, which can scarcely be dissolved; lastly, to the metallic earths, either pure or precipitated by Prussian alkali. M. Wenzel has discovered a sixth earth, which I call smaragd, and which, after other experiments I thought of applying to the purposes of painting; but I soon perceived that it would have the same fault with other proportion of colours. It is not analogous, but identically the same with the vapour of vitriolic acid mixed with sulphur.
The calx of tin is easily applied to any purpose, and experiences no change from the concentrated phlogistic vapour. These confederations induced me to endeavour to obtain the calx perfectly white; and here follows the result of my operations: The tin of calcined melale gives a pretty white calx; but whatever attention I paid to take off the red surface which the violence of the fire occasioned, it takes always a shade of grey when it is diluted. Tin calcined by nitre in fusion, gives a tarnished and gross calx, which multiplied washings could not deprive of a yellowish tint.

Having precipitated, by means of crystallized vegetable alkali, a dissolution of English tin, which had been made in the muriatic acid, after the manner of M. Bayen to extract the arsenic, I had a calx of the greatest whiteness, so light that it buoyed up to the surface of the liquor, and so thin that the greater part of it passed through the filter; but it experiences at the same time a kind of adhesion with the salts, which makes the part of it retained by the filter incapable of being pulverized, gummy, half transparent, and even a little changed into yellow. In this condition it is extinguished when diluted: it is necessary, therefore, to moisten it in boiling water, and afterwards to calcine slightly the sediment after it has had sufficient time to settle.

I have tried the calcination by means of moisture, in employing the tin of the purest melale, and a rectified nitrous acid, according to the method of Meyer. It formed a very white sparkling calx, which remained in the filter in the constancy of jelly. Meanwhile, I observed that it was always a little yellow by the mixture of a portion of that earth, which took in the operation, the colour of turrit mineral.

A very fine white calx is extracted from antimony, calcined by nitre infusion; but the earth of this semi-metal must be placed in the number of those which combine too easily with the phlogistic vapour. The diaphoretic antimony, grinded in oil, took in ten minutes in my phlogistic apparatus a colour somewhat like sulphur.

The property of bismuth to give a very fine white calx, known by the name of magister, or white sand, is generally known; it is easily prepared, since it is only necessary to dissolve the bismuth in nitrous acid, and to precipitate the dissolution by pure water: it dilutes perfectly with oil and mucilages. But, this colour ought to be rejected, as the most alterable by the phlogistic vapour. It became completely black in ten minutes in my apparatus; and this fact is also proved from what happens to women who use this colour, when they are exposed to the vapours of sulphur, of garlic, or of any purifying substances.

Zinc furnishes by all the processes of calcination and precipitation a pretty white calx, when it is pure and separated from iron; otherwise the disolutions of the vitriol of zinc will become yellow when exposed to the air. I have precipitated those disolutions by lime-water, by caustic, and effervescent alkalis; I have calcined this semi-metal alone and with nitre; and in all those operations I have obtained an earthy substance of different degrees of whiteness, which, after it was dried and prepared, mixed readily with oil and mucilages.
Part III.

PAINTING.

Proportions mucilages without losing its colour: and which experienced no sensible change when exposed to the phlogistic vapour.

These valuable properties, the chief object of my researches, engaged me to multiply my experiments, to determine at once the most economical process, and the most advantageous and infallible preparation. These attempts have convinced me, that the calcination of this semi-metal alone in a crucible, placed horizontally on the corners of a reverberatory furnace, gives the purest, the whitest, and the least reducible calx, and that to make an excellent colour, it is sufficient to separate the parts not burned with water, and grind it with a little of the earth of alum or chalk to give it a body. Zinc precipitated in Prussian alkali, even in distilled vinegar, remains always a shade of yellow, does not unite so well in oil, and takes a demi-transparent confidence like chicle.

White arsenic extinguishes much less in diluting than one would believe from its nature; it preserves its colour best in gum water: and it is remarkable, that instead of turning black in the phlogistic vapour, it takes a very distinct shade of yellow. This property is sufficiently singular and constant to furnish a new method of analysing arsenic, so as to know it. And this alteration of colour makes it of no use in painting, although its deleterious qualities did not forbid the practice.

The semi-metal known by the name of manganese gives also a white calx. I had at first great hopes from this colour, as, contrary to all the others extracted from the other metals, it became white by the phlogistic vapour. There remained, therefore, but one difficulty to overcome, viz. to separate from the manganese the portion of iron which it usually contained, and which infallibly makes the earth a little yellow. To accomplish this in the cheapest manner, I submitted the black ore of the manganese to a long calcination, to render its iron infusible: I afterwards applied vinegar to it, after the example of M. de la Peyrouse; and in precipitating the dissolution by effervescent alkali, I easily obtained a pure white precipitate. But I soon perceived that the facility with which a colouring body looses its phlogiston, is no less an inconveniency than that of attracting it, and productive of the same alterations.

The white of manganese became very soon yellow when exposed to the air; and this is not to be attributed to the iron contained in it, since neither the galls nor Prussian alkali had discovered any of it in the dissolution. This substance, therefore, can be of no use in producing a white colour for painting.

The experiment by which M. de Morveau tried the colours not alterable by the phlogistic vapour, was performed before the academy, the prince of Conde being president. "I placed (says he) in my apparatus pieces of cloth, on which were laid the white of calcareous tartar in water, different preparations of white from tin and zinc, in oil and water; and I allowed them to continue exposed to the phlogistic vapour during a sitting of the academy: if they were not altered, their superiority over the whites in use would be sufficiently established. The sitting continued for near an hour; and the bottle having been opened, all the colours continued to have the same shade which they had before. I can, therefore, recommend to painters these three whites, and particularly that of zinc, the preparation of which is exposed to less variation, the shade more lively and uniform, and moreover it is fit for all purposes, and perhaps procured at less expense.

I will add further, that it may be procured in sufficient quantities to supply the place of various in every branch of the art, even in interior house-painting. I would recommend it, less with the view of adding new splendor to this kind of ornament, than for the safety of those who are employed in it, and perhaps for the safety of those who inhabit houses ornamented in this manner.

But without being too sanguine, although the precedents in the fabrication be simplified in proportion to the demand, as it usually the case, yet there is reason to apprehend, that the low price of ceruse will always give it the preference in house-painting. With regard to those who apply colours to nobler purposes, they will not hesitate to employ the white of zinc. I am assured that four franks is paid for the pound of white of crems; and I believe the white in question, prepared in the manner which I have pointed out, might be sold for fix.

M. Courtois, connected with the laboratory of the academy, has already declared that it is used for house-painting: less, however, in regard to its unalterability, than to its solubility: and this can be the more readily believed, as the flower of zinc enters into many compositions of the apothecary. The fame M. Courtois has arrived at the art of giving more body to this white, which the painters termed defirer, and also of making it bear a comparison with white lead either in water or oil. The only fault found with it, is its drying slowly when used in oil; but some experiments which I have made, incline me to believe that this fault may be easily remedied, or at least greatly corrected, by giving it more body. At any rate, it may be rendered efficative at pleasure, by adding a little vitriol of zinc or copperas lightly calcined.

Painters already know the properties of this salt, but perhaps they do not know that it mixes with the white of zinc better than with any other colour; the reason is, they have chemically the same base. It is prepared by purging the white copperas of that small portion of iron which would render it yellow; and this is easily done in digesting its dissolution, even when cold, on the filings of zinc.

The mixture of this salt thus prepared is made on the pallet, without producing any alteration, and a small quantity will produce a great effect."

Vol. XIII. 637.

A O 4.0 8 PAIR;
PAIR; two of a fort, a couple.

PAIRING, the uniting or joining in couples.

The instinct of pairing is bestowed on every species of animals to which it is necessary for rearing their young; and on no other species. All wild birds pair; but with a remarkable difference between such as place their nests on trees and such as place them on the ground. The young of the former, being hatched blind, and without feathers, require the nursing care of both parents till they be able to fly. The male feeds his mate on the nest, and cheers her with a song. As soon as the young are hatched, fingling yields to a more necessary occupation, that of providing food for a numerous litter; a task that requires both parents.

Eagles and other birds of prey build on trees, or on other inaccessible spots. They not only pair, but continue in pairs all the year round; and the same pair procreates year after year. This at least is the case of eagles: the male and female hunt together, unites during incubation, at which time the female is fed by the male. A greater number than a single pair are never seen in company.

Gregarious birds pair, in order probably to prevent discord in a society confined to a narrow space. This is the case particularly of pigeons and rooks. The male and female sit on the eggs alternately, and divide the care of feeding their young.

Partridges, plovers, pheasants, sea-fowl, grouse, and other kinds that place their nests on the ground, have the instinct of pairing; but differ from such as build on trees in the following particular, that after the female is impregnated, she completes her task without needing any help from the male. Retiring from him, she chooses a safe spot for her nest, where she can find plenty of worms and grasses-feed at hand; and her young, as soon as hatched, take foot, and seek food for themselves. The only remaining duty incumbent on the dam is, to lead them to proper places for food, and to call them together when danger impends. Some males, provoked at the desertion of their mates, not only leave them to find eggs in the sand. The young are hatched by the sun, and immediately crawl to the sea.

Birds of prey, such as lions, tygers, wolves, pair not. The female is left to shift for herself and for her young; which is a laborious task, and often unsuccessful as to shorten the life of many of them. Pairing is essential to birds of prey, because incubation leaves the female no sufficient time to hunt for food. Pairing is not necessary to beasts of prey because their young can bear a long fast. As soon as the young are hatched, pairing yields to a more necessary occupation, that of providing food for a numerous litter; a task that requires both parents.

Among animals that pair not, males fight desperately about a female. Such a battle among horned cattle is finely described by Lucretius. Nor is it unusual for seven or eight lions to wage bloody war for a single female.

The same reason that makes pairing necessary for gregarious birds, obtains with respect to gregarious quadrupeds: those especially who feed up food for winter, and during that season live in common. Discord among such would be attended with worse consequences that even among lions and bulls, who are not confined to one place. The bears, with respect to pairing, resemble birds that place their nests on the ground. As soon as the young are produced, the males abandon their flock of food to their mates, and live at large; but return frequently to visit them while they are feeding their young.

Hedgehogs pair as well as several of the monkey-kind. We are not well acquainted with the natural history of these animals; but it would appear that the young require the nursing care of both parents.

Seals have a singular economy. Polygamy seems to be a law of nature among them, as a male associates with several females. The sea-turtle has no occasion to pair, as the female concludes her task by laying her eggs in the sand. The young are hatched by the sun, and immediately crawl to the sea.

PAISLEY, a town of Renfrewshire, in Scotland, situated about six miles and a half west of Glasgow, on the river White-Cart, over which there are two stone-bridges of two arches each, and one which consists of three arches. The town is very ancient; but was of much less consequence formerly than it is at present. No satisfactory etymology has hitherto occurred of the name Paisley. The following has been suggested by a good Gaelic scholar; A ridge of rocks that runs across the river and forms a beautiful cascade, would prior to the building of the town, be undoubtedly the most striking object that this place would present. The brow of a rock is in Gaelic Pais-lîcht. A church is front of the rock would be the church in Pais-lîcht. A church did stand here previous to 1160; it is named in the foundation charter Eclesia de Paislîch, Latinized, in the records of the monastery, Païsiam, an easy derivative from Pais-lîcht in all probability the original of the modern Paisley.

It was erected into a burgh in barony by James IV. in the year 1488, at that time probably deriving all its importance from the rich monastery, which had been established there for several ages; for George Schaw, who was then abbot of that monastery obtained this privilege from the king. Even in Mr Crawford's time, who wrote the history of the thre of Renfrew near the beginning of this century, it seems to have been but an inconsiderable place; for he describes it as consisting only of one principal street, about half a mile in length, with several lands belonging to it; whereas now
P A I

Paifley. Now the town, with its suburbs, occupies such an extent of ground, that strangers are apt to consider it as, next to Edinburgh and Glasgow, the largest and most populous town in Scotland. Its buildings of late years have been greatly improved; its streets are well paved; and the different parts of the town and suburbs, where the river intervenes, are connected with one another by three bridges at convenient distances.

The affairs of the community are managed by three bailies, of which the eldest is commonly in the commission of the peace, a treasurer, a town-clerk, and 17 councillors, who are annually elected upon the first Monday after Michaelmas. It enjoys all the powers necessary for government and police, without any of the burdens to which royal boroughs are subjected. The freedom of the place is conferred on very moderate terms.

The revenues of the town are not great, but they have been managed to the best advantage. The rapid increase of the place has not been attended with a proportional increase of revenue; therefore several necessary improvements, and intended public buildings, are not yet carried into execution. It gives the title of baron to the earls of Abercorn; the first of whom was a younger son of the Duc de Chatelherault. The black book of Paifley, frequently mentioned in Scottish history, was a chronicle of the public affairs and remarks on events, kept by the monks who resided in the monastery. It is in every material part with the Scot chronicon of Fordun; and is by many thought to be the same performance.

The old part of the town runs east to west upon the south slope of a ridge of hills, from which there is a fine prospect of the city of Glasgow and the adjacent country; but to the southward, the view terminates in a ridge of green hills, about two miles distant. Including the late buildings and suburbs, it is fully a mile long, and nearly as much in breadth. On the east side of the river Cart, stand the abbey and new town. This new town was some years ago feued off by the earl of Abercorn, and now consists of a number of handsome buildings. The streets are laid off in a regular manner, but (rather unfortunately for the convenience and elegance of some of the houses) not in right angles. Here the earl of Abercorn has built at his own expense one of the largest, most commodious, and most elegant inns in Scotland. In the vicinity of this his lordship is likewise building several convenient and necessary market-places. A little way south of the inn stands the abbey-church, the only one which Paifley formerly required. This church, when entire, has been a most noble building, and consisted of several distinct and separate places of worship: what now remains of this magnificent Gothic structure is not yet unworthy the notice of the curious in antiquities. Mr. Pennant says, the great north window is a noble ruin, the arch very lofty, the middle pillar wonderfully light, and still entire: only the chancel now remains, which is divided into a middle and two side aisles, all very lofty pillars, with Gothic arches; above these is another range of pillars much larger, being the segment of a circle, and above a row of arched niches from end to end, over which the roof ends in a sharp point. The outside of the building is decorated with a profusion of ornaments, especially the great west and north doors, than which scarce anything lighter or taller in Paisley can be imagined.

The town of Paisley continued a part of the original or abbey parish of Paisley till the year 1756; when the magistrates and council having purchased the right of patronage from the then earl of Dunmore, a new church was built, and the town was erected into a separate parish. This is called the Leigh Church, is built in the form of a Greek cross, very well laid out, and capable of containing a great number of people. In 1756 another church was built, upon a very extended plan, to accommodate its multiplied inhabitants; in which, though it is one of the largest in Scotland, yet the most distant of the congregation can hear a tolerably good speaker with ease and distinctness; and as it stands upon the highest part of the town, it was afterwards ornamented with a lofty and well-proportioned spire visible at a great distance. This is called the High Church, and is a very fine building; it is an oblong figure of 82 feet by 62 within the walls, built of free-lime well smoothed, having rustic corners and an elegant stone cornice at the top. In the construction of the roof (which is a pavilion covered with slate, having a platform covered with lead on the top), there is something very curious, and it is admired by every person of taste. In 1781, the number of the inhabitants still rapidly increasing, another church, called the Middle Church, was built, not quite so large as the former, but very handsomely and elegantly finished: and in the following year, the town was divided and erected into three separate parishes, exclusive of the Abbey parish, and named according to their respective churches.

There are two large dissenting congregations in the town; those of the Antiburgher persuasion, and the Relief. The first of these has existed there for upwards of 30 years; the other is of a late date. There is besides a small congregation of Cameronians.

The town-house is a very handsome building of cut stone, with a tall spire and a clock. The flesh-market has a gablet front of cut stone, and is one of the neatest and most commodious of the kind in Britain. Butchers-meat, butter, cheese, fish, wool, and several other articles, are sold here by what they call the town pound, of 22 English ounces and an half.

The poor-house is a large building, very well laid out; and stands opposite to the quay, in a fine free air. It is supported by a small tax laid upon the inhabitants quarterly.

Close by the Abbey church is the earl of Abercorn's burial place, the greatest curiosity in Paisley. It is a vaulted Gothic chapel, without pulpit, pew, or any other ornament, but has the finest echo perhaps in the world. When the end door (the only one it has) is shut, the noise is equal to a loud and not very distant clap of thunder. If you strike a single note of music, you hear the sound gradually ascending, with a great number of repetitions, till it dies away as if at an immense distance, and all the while diffusing itself thro' the circumambient air. If a good voice sings, or a musical instrument is well played upon, the effect is inexplicably agreeable. The deep and hollow tones are带到 reverberated, and those in regular intervals of time. When a musical instrument
is founded, it has the effect of a number of instruments of a like size and kind playing in concert. When a number of different instruments in unison founds the same note, a good ear is able to distinguish the variety of sound produced by each. A single instrument founds a particular note, and then instantly its fifth, of any other concordant note, the two sounds can be heard, as it were, running into and uniting with each other in a manner peculiarly agreeable. But the effect of a variety of instruments playing in concert is particularly charming, and must excite such emotions in the soul as it is impossible to describe. In this chapel is the monument of Marjory Bruce (A); the wife of Robert Bruce, and wife of Walter, great steward of Scotland, and mother of Robert II. In the same chapel were interred Elizabeth Muir and Euphemia Ross, both conforts to Robert II.

A particular account of the abbey of Paisley would fill many pages. It was founded as a priory for monks of the order of Cluny about the year 1169 by Walter, great steward of Scotland. It was afterwards raised to the rank of an abbey; and the lands belonging to it were by Robert II. erected into a regality, under the jurisdictiion of the abbots. After the reformation, the abbacy was secularized by the Pope in favour of Lord Claud Hamilton, third son of the Duke of Chatelherault, in reward of his steady adherence to the cause of Queen Mary; and, in 1598, it was by the king and parliament erected into a temporal lordship, and Lord Claud was created Lord Paisley. The revenues of the abbacy were very considerable: They consisted of the tythes of 28 different parishes, with the property of the lordships of Paisley, of Kilpatrick in Dunbartonshire, and of Monketoun in Ayrshire, extending each to a hundred mercant land; and the forty pound land of Glen in Lochwinnoch; with the lands of Anchengew, Grange, &c. and a considerable detached property in different parts of the kingdom. All this property, with the patronage of the several churches, fell to Lord Claud Hamilton, last abbot of Paisley. It continued in that family till 1653, when his grandson James Earl of Abergrom took the lordship of Paisley to the Earl of Angus, who next year sold it to William Lord Cochran, Kilpatrick to Sir John Hamilton of Orbiston, Monksoun to Lord Bargenny, and Glen to Lord Semple and others. Great part of the lordship of Paisley was at different times sold off by the family of Dundonald; and what remained of it was in 1764 repurchased by the late Earl of Abergrom. The fabric of the abbey owed much of its magnificence to Abbot George Schaw, who about 1484 enlarged and beautified the building, surrounding the church, the precepts of the convent, the gardens, and a small deer-park with a noble wall of bewn free-stone. The abbey was after the reformation successively the seat of the Earls of Abergrom and Dundonald. The late Earl of Dundonald demolished the ancient gateway; and, by flaving off the immediately adjoining grounds for building, entirely changed the appearance of the place. As it was thus rendered totally unfit for a family residence, it has since that time been let out into separate dwellings, and is now in a very mean and almost ruinous state. The wall stood whole till 1781, when the gardens being feued off for building upon by the late Earl of Abergrom, the wall was sold to the feuers, and the stones of it employed in their houses.

The vestiges of the Roman camp and praelium, at the west end of the town, are at present almost annihilated. It was suppos'd to be vaulted underneath.

The number of inhabitants in the town of Paisley amounted in 1693 to 2200; in 1735 they were 4950 in 1782, 11,100; and in 1792 they were 13,800. At present the number of inhabitants in the town and suburbs certainly exceeds 20,000.

Paisley is now the first manufacturing town in Scotland, and is greatly celebrated on account of some of its branches. The manufactory of silk gauze, in this respect, first claims our notice. This branch is brought here to the utmost perfection, and is wrought to an amazing variety of patterns. It has been computed, that there have been no less than 5000 weavers employed in Paisley and in the country adjacent; and the number of winders, warpers, clippers, and others necessary in other parts of the silk-manufaeture, has been likewise computed to be no less than 5000. Each loom will produce in an average value 70l. yearly; the whole will then be 350,000l.

It appears, from the best calculation that could be made, that in the year 1784, the manufactures of Paisley, in silk gauze, lawn and linen gauze, and white fewing thread (a), amounted to the value of 579,185l. 16s. 6d., and that no fewer than 26,484 persons were employed in carrying on it. It is difficult to give an exact account of the state of its manufactures at present. The silk branch has evidently declined, but the muflin has far come in its room, and the thread manufacture has considerably increased. There is, however, reason to conclude, that though it is daily advancing, it has not yet recovered its former greatness. Besides these principal manufactories, there are some others carried on there of too much importance to be overlooked; for instance, considerable tan-works, four in number, two soap and candle works, a manufacture of ribbons, and another

(a) Her story is singular: In the year 1317, when she was big with child, the broke her neck in hunting near this place; the Caledonian operation was instantly performed, and the child taken out alive, but the operator chanceing to hurt one eye with his instrument, occasioned the blemish that gave him afterwards the epithet of Blind George; and the monument is also stiled that of Queen Blurry. Elizabeth Muir died before the accession of her husband Robert.

(b) This was introduced into this town about 60 or 70 years ago. A gentleman in this place lately discovered the method of making what is called glazed white thread, to us great perfection as that made by Mr. Leland and Son, London. The value of this branch is computed at about 8000l. annually.
In 1789 the annual value of all the manufactures in Paisley of every sort amounted to £606,385 l. 16s.

In the various weaving branches there were employed at Whitunday 1791, in the suburbs of Paisley, 1108 looms, which added to 2493 employed in the town, gives 3602 in all. But it is to be observed, that the extent to which the weaving branches are carried on by the manufacturers of Paisley, is not to be judged of from the number of looms in the town and suburbs. Besides about 150 in the country part of the parish, there are great numbers employed by them in the villages of Neilston, Barhead, Beith, Dalry, Kilwinning, &c. &c. In 1744, when all the business was confined to the town and suburbs, there were 867 looms at work.—The thread making in Abbey parish employs 9 mills, which, added to 128 employed in Paisley, makes 137 in all. The number in 1744 was 25. The spinning of cotton was introduced into Abbey parish in 1783. The principal seat of that manufacture is at Johnstone, a neat and regularly built village about three miles west from Paisley, upon the estate of Mr Houton of Johnstone. The feuing of that village was begun in 1782; and it contained, at Whitunday 1792, 293 families, or 1434 souls. There are five companies established in it for cotton spinning. Two of these carry on their principal operations by water-machinery. In the two mills employed in them, there are going at present 11,672 spindles: but, when the whole machinery in both shall be completed, there will be 22,572. The number of persons, young and old, at present employed in both mills is 660. There is also in the neighbourhood of Paisley a calico printing work and a copperas work.

The bleaching business in the Abbey parish is carried on to a very considerable extent. There are 20 fields for whitening muslins and lawns, and about as many for thread, almost wholly employed by the manufacturers in Paisley. About 300 persons are at work in this branch of business, of whom about 240 are women, who are hired for the season. A soap and candle manufacturer pays about 2000 l. of duty per annum to government, and has in some years paid upwards of 3000 l. A black and hard flax manufacture, 4500 l. per annum. The flax manufacture is but lately established. The distillery business is to be mentioned under this head; it has for some time past been carried on to a great extent, and the spirit manufactured in great perfection. A considerable quantity of it is exported, but too much of it is consumed at home.

The river on which Paisley stands runs from south to north; and falls into the Clyde, after it has joined the confluent of the rivers Grief and Black-Cart at Inchman bridge, about three miles below the town. At spring-tides, vessels of 40 tons burthen come up to the quay. The communication by water is of great importance to the inhabitants: for in this way they are frequently served with salt of different kinds, and can send their goods and manufactures to ports of Glasgow and Greenock, and to Glasgow likewise; and now, by means of the great canal, they have also a communication with the frith of Forth.

The air here is moist; a necessary consequence of the prevailing southerly winds, which, coming loaded with vapour from the Atlantic, produce frequent and heavy rains. The effects of this moist atmosphere appear in rheumatism, sciatica, pneumatic ailments, and all the tribe of inflammatory disorders. Upon the whole, however, neither the town nor country adjacent can be said to be unhealthy. Contagious, indeed, at times visit this as other places, which run their usual course as epidemics; but none are remembered of any uncommon violence except a pleuro-pneumonia in summer 1771, and which, contrary to the received opinion, was truly epidemic. There are no disorders that can be said to be endemic, unless scrofula is to be excepted, which is still but too common. This has been ascribed to the water used by the inhabitants in Paisley: it more probably proceeded from, and certainly was greatly aggravated by, poor living, and by the damp workshops which were necessary for the linen manufacture; for linen filk-weaving became the general employment, and increase of trade has introduced a better living, this disease is less frequent. From the same causes probably it is that dwelling and fore-logs, once extremely common here, are now but rarely met with. Dyestuffs neglected with great violence in 1763; since that time it has been scarcely complained of. Nervous fevers at times appear; but they are neither very general nor uncommonly fatal. It is to be apprehended, that the confinement and sedentary posture of the weaver, and the laborious life of the bleacher, are frequent causes of consumptive complaints. Intermittents, which from the damp air, and adjoining moats, might be expected to be common, are not so much as known. W. Long. 4. 20. N. Lat. 55. 52.

PAIX, a town of America, in the island of Hispaniola, and on the north coast. It was built by the French, to whom it is subject, and has a pretty good harbour. W. Long. 72. 55. N. Lat. 19. 58.

PAITA, a sea-port of America, in Peru, and in the audience of Quito. The town consists of about 200 houses but one story high; and the walls are made of split cane and mud, and the roofs only a covering of leaves. The only defence of Paita is a fort without either ditch or out-work; but is surrounded by a brick wall of little or no strength, on which are mounted eight pieces of cannon. It has frequently been plundered by the buccaneers; and Commodore Anson got possession of its fort in 1741, and took and burnt the town because the governor refused to ransom it. W. Long. 81. 19. S. Lat. 6. 12.

PALACE, Palatium, a name generally given to the dwelling-houses of kings, princes, and other great personages; and taking different epithets, according to the quality of the inhabitants, as imperial palace, royal palace, pontifical palace, cardinal palace, ducal palace, episcopal palace, &c.

It is customary in China to build palaces in honour of great ancestors. Hu-pei-lay, of the Mogul empire, in the year 1263, built one for his ancestors; and he is the first who borrowed this Chinese custom. Amongst the works of the ancient Egyptians, we have an account, in the Ancient Universal History, of a most magnificent palace in the Upper Egypt, not far from Abydos, the ancient Sycene; the ruins whereof are enough to strike a spectator with astonishment. It is as large as a little city, having four avenues of columns, leading to as many porticoes. At each gate, between two pillars of porphyry, stand two gigantic figures of fine black.
black marble, armed with maces. The avenues consist of columns set three and three together, in a triangle; on one pedestal; on the chapter of each triangle is placed a sphinx and a tomb alternately. Every column is 70 feet high, all of one stone. There are in all the four avenues about 5000 or 6000 of these columns, a great many of which are fallen down.

The first hall of this palace is adorned with pieces of history, which seem as fresh as if the painting had not been long finished. In some places they have represented the hunting of antelopes; in others, feals, and a great many young children playing with all kinds of animals. From thence you go into other apartments, inclosed with marble, the roof being supported with pillars of porphyry and black marble. Notwithstanding the vast quantity of rubbish, our author made shift to get up to the top of this building, from whence he had a prospect of the ruins of the greatest city that ever had been, as he thought, in the world. He supposes it might be the ancient Thebes, but that city flood much lower.

PALÆSTRÆA, in Grecian antiquity, a public building where the youth exercised themselves in wrestling, running, playing at quoits, &c. To prevent the combatants from hurting themselves by falling, the bottom of the palestra was covered with dust or gravel. Some will have the palestra to be only a part of the gymnasion. Many authors imagine that the palestra was of two kinds; the one for the exercise of the body, the other for the cultivation of the mind; but the derivation of the word seems to confine it to bodily exercise.

We have this account of the palestra in Barthelemi's Anacharsis: "They are nearly of the same form with the gymnasion. We visited the apartments appropriated to all the species of baths; those where the wrestlers leave their clothes, where, they rub their bodies with oil to render their limbs supple, and where they roll themselves in the sand in order to give their antagonists a hold.

"Wrestling, leaping, tennis, and all the exercises of the lyceum, were here repeated before us with greater varieties, and with more strength and skill on the part of the performers. Among the different groups before us, we distinguished men of the most perfect beauty, and worthy of serving as models for artists; some with vigorous and boldly marked outlines, as Hercules is represented; and others of a more slim and elegant shape, as Achilles is described. The former devoting themselves to wrestling and boxing, had no object but to increase their bodily strength; the latter, educated to feats violent exercises, such as running, leaping, &c. confined themselves to acquisitions of agility.

"Their regimen is suited to the different exercises for which they are designed. Some of them abstain from women and wine; others lead a very abominable life; but those who make laborious exertions stand in need of a great quantity of substantial food, such as roasted beef and pork, to restore their strength. If they require only two minae a-day, with bread in proportion, they give a very favourable idea of their temperance. But several are mentioned who have made a terrible consumption of provisions. The genes of Thasos, for instance, is said to have eaten a whole ox in a day. The fame exploit is ascribed to Milo of Crotona, whose usual quantity of food for a day was twenty minae of meat, as many of bread, and three congii of wine. It is said likewise, that Atydamas of Miletus, when at the table of Ariobarzanes the Persian satrap, devoured alone the supper prepared for nine guests. These stories, no doubt exaggerated, prove at least the idea generally entertained of the voracity of this class of wrestlers. When they are not able to gratify it without danger, they acquire extraordinary strength: their stature becomes sometimes gigantic; and their adversaries, struck with terror, either decline entering the lists, or sink under the weight of their enormous bodies.

"They are so oppressed by excess of nutriment as to be obliged to pafs part of their lives in a profound sleep, and soon become so extremely corpulent as to be no longer known to be the same persons: this is succeeded by disorders which render them as wretched as they have always been unserviceable to their country; for it cannot be denied that wrestling, boxing, and
PALAMEDEA, or Palamboang, a town of Asia in the East Indies, and in the island of Java, capital of a kingdom: seated at the east end of the island, on the straits of Bally, and separated from the island of Bally by a narrow channel. E. Long. 115. 10. S. Lat. 7. 15.

PALAMEDEA, in ornithology, a genus belonging to the order of grallides. The character of this genus, according to Latham, is, the bill bends down at the point, with a horn, or with a tuft of feathers erect near the base of it; the nostrils are oval; the toes are divided almost to their origin, with a small membrane between the bottoms of each.

There are two species of it: the first of which is the palamedea cornuta, or horned screamer. It is about the size of a turkey; in length about three feet four inches. The bill is two inches and a quarter long, and black: the upper mandible is a little gibbons at the point, with a tuft of hairs, the nostrils are oval and pervious, and placed near the middle of the bill. From the crown of the head springs a slender horn of more than three inches in length, and pointed at the end: the irides are the colour of gold: the plumage on the head, neck, and upper part of the body, is black, margined with grey on the flanks, and downy: some of the feathers round the neck are like those with the same: the under parts of the wings are pale rufous, appearing on the flouchers and edges of them when cloathed; at the bend of the wing are two strong, sharp, horny, yellow spurs, one above another, the uppermost an inch and a half in length: the belly, thighs, and vent are white: the tail is eight inches and a half long, and black: the legs are stout and dusky: the fore claws are moderately bent; the hind one is nearly straight, not unlike that of a lark, and is about an inch long. — The female, we are told, is very like the male.

It is remarked, that they are always met with in pairs; and if one dies, the other mourns to death for the loss. They frequent places near the water; make a large nest of mud, in the shape of an oven, upon the ground; and lay two eggs, of the size of those of a goose. The young are brought up in the nest till able to shift for themselves. They have but one nest in a year, which is in January or February, except the first eggs are taken away, when they make a second in April or May. The young birds are frequently eaten by the natives, though the colour of the flesh is very dark; that of the old ones is tough and ill tasted. By some authors this species is said to feed on crabs and birds, such as pigeons, poultry, and even to attack sheep and goats; but this is denied by others, who say that its principal food is reptiles. In the thomach of one which M. Bajon dissected, there were only found herbs and seeds of plants; however, he adds, that the bird has no gizzard. The cornuta is a rare species. It is found in certain districts in Cayenne, Guiana, Surinam, and other parts of South America, chiefly in the marshes and wet savannas, and for the most part near the sea. Thence should seem to be the birds mentioned by Ulloa (a), which are called by the inhabitants of Quito difprendores, or "awakeners," from their giving notice to others of the approach of danger; as on hearing the least noise, or seeing any one, though at a great distance, they rise from the ground, and make a loud chattering like a magpie, continuing the noise, and hovering over the object which caused the alarm, whereby the rest of the birds, taking the hint, are able in time to escape the impending danger. This screaming noise, which some authors relate as being exceedingly loud and terrible (c), has occasioned Mr. Pennant to give the genus the name annexed to it. In Dr. Hunter's museum there is a fine specimen of this bird brought from Cayenne.

The second species of palamedea is the criptata, or crested screamer. This bird is about the size of an heron: the bill is short, bent like that of a bird of prey, and of a yellowish brown: the irides are gold-coloured: on the forehead, just above the bill, is a tuft of black feathers, variegated with ash colour: the head, neck, and body, are grey, mixed with rufous and brown, most inclined to the last on the wings and tail: the wings are not furnished with spurs: the legs pretty long; o. a dull yellow: claws brown; the hind toe placed high up, as not to touch the ground in walking.

This bird inhabits Brazil. Linnaeus makes it to belong to the screamer genus, perhaps from its cry; for it is said to be heard at a great distance, and is not unlike that of a hen turkey. None of our later writers seem to have seen it, all of them relying on Maregraves both for description and figure. It is said to feed on the same food as the heron tribe: the flesh is good, and the bird by some kept tame.

PALAMEDES, a Greek chief, son of Nauplius king
king of Ithaca, by Clemene. He was sent by the Grecian princes who were going to the Trojan war, in order to bring Ulysses to the camp, who, to avoid the expedition, pretended insanity; and the better to carry on the imposture, he often harneffed different animals to a plough, and fowed felt instead of barley. Palamedes soon discovered the cheat. He knew that regret to part with Penelope, whom Ulysses had lately married, was his only reason for pretending insanity; and to demonstrate this, Palamedes took Telemaochus, of whom Penelope had lately been delivered, and put him before his father's plough. Ulysses turned the plough a different way, not to hurt the child. He was therefore obliged to attend the Greek princes to give a different fate to Palamedes. The army, and according to some he is attributed of the latter, in the circle we are now treating, belongs to the electors of Bavaria, and belongs to the elector thereof; but the Palatinate, a province or sort of the territory of the Teutonic order in France; to the west by Alsace, the duchy of Deuxponts, the county of Sponeheim, the duchy of Simmen, and certain districts of the electorates of Mentz; to the south by the duchy of Wurttemberg and the bishopric of Speire; and to the north by a part of the archbishopric of Mentz and the county of Katzenelnobogen. It contains 41 towns, besides several boroughs; and is about 100 miles in length and 70 in breadth. The soil is fruitful in corn, potatoes, wine, tobacco, and all sorts of pulse and fruits, particularly walnuts, chestnuts, and almonds. This country also breeds abundance of cattle, and is well watered by the Neckar, the Nahe, and the Rhine. In the lathe of thieves, near Germersheim and Sels, is found gold; the exclusive right of searching for which is farmed out by the elector. The flat of religion hath varied greatly here since the Reformation, Lutheranism and Calvinism having been uppermost by turns, till the elector devilized to the Popish branches of the family, when Popery, with all its superstition and mummeries, was establishe anew: so that the Protestant religion is now on a very precarious footing in the Palatinate, though most of the natives are still of that persuasion; but the two sects of Protestants, namely, the Lutherans and Calvinists, have greatly contributed to their own ruin, by their mutual jealousy and animosity, being no less rancorous against one another than against their common adversaries the Papists. The Lutherans reckon themselves 30,000 strong, and are possessed of about 85 churches; but not one half of their preachers and schoolmasters have a competent maintenance. The number of Calvinist clergy here is estimated at 700, and that of the Roman Catholics at 400. Besides schools and Jesuits colleges in this country, there is one university, namely, that of Heidelberg; but there is very little trade in it except in wine. Authors are divided about the origin of the name Palatine, or Palatia, as the Germans call them; but it seems most likely to be derived from the palatia, or palaces, which the old Frankish and German kings and Roman emperors were possessed of in different parts of the country.
PALATINE, country, and over which they appointed supreme rewards or judges, who were called Palatines or Palatsgraves. The countries where these Palatines kept their courts, were, from them, called Palatinate; which name came at last to be appropriated, by way of eminence, to this country, as being the most considerable of them. The ancient electoral line falling in 1685, the electorate devolved to Philip-William duke of Neuburg; and upon the death of his second son Charles-Philip, to the prince of Sulzbach. This elector has the title of arch-treasurer of the empire, as well as the elector of Brunfwic-Lunenburg, and is the fifth in rank among the secular electors. He is also one of the vicars of the empire alternately with the elector of Bavaria, and enjays many other prerogatives. In his own dominions, he disposes of all vacant benefits; but allows the ecclesiastical council, composed of two clergy men and two laymen, to elect two candidates, of which he chooses one. He is also master of all the tithes in his dominions; but either grants them to the clergy, or salaries in lieu of them, out of the revenues of the church. His title is Palatgrave of the Rhine; arch-treasurer and elector of the holy Roman empire; duke in Bavaria, Juliers, Cleve, and Berg; prince of Mors; marquis of Berген-op-Zoom; count of Veldens, Sponhein, the Mark, and Ravenberg; and lord of Ravenfein. His quota to the army of the empire is 30 horse and 138 foot, or 914 florins monthly. To the Chamber of Wetzlar he contributes each term, 404 rix-dollars, 8 kruitzers. There is an order of knighthood in this country, viz. that of St Hubert; the badge of which is a quadrangular cros pendant to a red ribbon, with a star on the breast. The whole of the elector's revenue arising from the Palatinate, the duchies of Berg and Juliers, the seigniory of Ravenfein, and the duchies of Neuburg and Sulzbach, hath been estimated at about 400,000 florins per annum. The military establishment consists of several regiments of horse and foot, besides the horse and Swifs life-guards: in time of peace he isaid to maintain about 6000 men. All the different courts and councils, usual in other countries for the different departments of government, are also to be found here.

In general, the Lower Palatinate has suffered more by the preceding wars with France than all the provinces of Germany put together during the space of 30 years; for the French have plundered the country, and demolished some of its first towns more than once. In the modern part of the Universal History, we have the following account of the rise of the Palatinate, of the Rhine, under the history of Germany.

"Though Conrad the son of Everhard inherited from his father the duchy of Franconia, with the counties of HefFe and Alfaec, he could not succeed him in the dignity of count-palatine, because Otho had taken it from his father, and conferred it on Herman third son of Arnold duke of Bavaria; but as this honour was unattended with any solid advantage, the emperor began to annex to it the lands and castles situated on the Rhine, whence he acquired the title of Count Palatine of the Rhine; and, in process of time, these courts made great acquisitions by marriages, purchases, mortgages, and imperial donations, so as to form a very considerable province." The powers of counts palatine in the German empire have always been ample; we have this account of it in the same learned work.

"When the counts palatine of the Rhine began to execute their office, they neither possessed on that river lands, cities, nor castles; but having by degrees made great acquisitions by marriages, purchases, agreements, imperial donations, or otherwise, they have at length formed a very considerable principality. We are told, that under the emperors of the house of Stau-bia, their authority and power increased greatly, tho' it was a gradual increase. Under the reign of the emperor Henry IV, the credit of the counts palatine was very considerable at the court; and by the German law, the count palatine of the Rhine enjoys not only during the absence of the emperor, but likewise during a vacancy of the empire, the right of the emperor's beyond the Rhine, till within a mile of the city of Metz, and as far as the sea, as well as in Flanders. However, this right of the ban has not been granted to him by the emperors. There is likewise an ancient ordonnance, in which the office of count palatine is mentioned; it imports, that the count palatine is always by right the representative or lieutenant of the kingdom. Lastly, how great the power of the counts palatine was, may be understood from this, that in the election of Rodolphus of Hapburg, and in that of Henry VII, the other electors promised to acknowledge him as emperor whom he should name. Although, however, the power of the counts palatine had as it were secured to them the vicariate of the empire, nevertheless the emperors still referred to themselves the right of establishing vicars." See Bavaria.

PALATINATES of Poland. Previous to the Revolution in this unfortunate country, it was divided into palatinate; whether those will be now changed is at present uncertain, tho' it seems likely. A Polish palatine is thus described in the Universal History:

"A palatine may be regarded as the governor of a province, who levies and leads the troops of his own jurisdiction to join the army of the republic. His civil power is likewise considerable, as he presides at the assemblies of his palatinate, rates the prices of all commodities and merchandise in the province, regulates the weights and measures, and judges and defends the Jews within his jurisdiction. This part of his function is particularly specified, that a set of men of the most useful and industrious in Poland may not be oppressed; the king being likewise obliged, by his oath, to afford them the protection of the laws and his sovereignty. Under him is appointed a substitute or vice-palatine, who takes an oath to his superior, and must be possessed of a land-estate to a certain value."

PALATINE, or COUNT PALATINE, a title anciently given to all persons who had any office or employment in the prince's palace, but afterwards confined to those delegated by princes to hold courts of justice in the provinces; and on such among the lords as had a palace, which is, a court of justice, in their own houses.

Counties-Palatine in England.—Chester, Durham, and Lancaster, are called counties palatine. The two former are such by prescription, or immemorial cu-
of parliament, in the first year of his reign, ordaining that the duchy of Lancaster, and all other his hereditary estates, with all their royalties and franchises, should remain to him and his heirs for ever; and should remain, descend, be administered, and governed, in like manner as if he never had attained the regal dignity; and thus they descended to his son and grandson, Henry V., and Henry VI.; many new territories and privileges being annexed to the duchy by the former. Henry VI. being attained in 1 Edward IV. this duchy was declared in parliament to have become forfeited to the crown, and at the same time an act was made to incorporate the duchy of Lancaster, to continue the county-palatine (which might otherwise have determined by the attendant), and to make the same a parcel of the duchy: and, farther, to vest the whole in king Edward IV. and his heirs, kings of England, for ever; but under a separate guiding and governance from the other inheritances of the crown.

And in 1 Hen. VII. another act was made, to refuse such part of the duchy lands as had been dismembered from it in the reign of Edward IV. and to vest the inheritance of the whole in the king and his heirs for ever, as amply and largely, and in like manner, form, and condition, separate from the crown of England and possession of the same, as the three Henries and Edward IV. or any of them, had and held the same.

The isle of Ely was not a county-palatine, though sometimes erroneously called so; but only a royal franchise: the bishop having, by grant of king Henry I. jura regalia within the isle of Ely; whereby he exercises a jurisdiction over all causes, as well criminal as civil.

Palatine Games, in Roman antiquity, games instituted in honour of Augustus by his wife Livia, after he had been enrolled among the gods. They were celebrated in the palace, from whence the name, and were confirmed by the succeeding emperors.

Some authors say that these games were instituted in honour of Julius Cæsar, and others again confound them with the Ludi Augustales; but neither of these opinions seem to be well supported. See Augus­tales.

Palatine Mons, or Palatium, the first mountain of Rome, occupied by Romulus, and where he fixed his residence and kept his court, as did Tullus Hostilius, Augustus, and all the succeeding emperors; and hence it is that the residence of princes is called palatium. The reason of the name is variously aligned: some say it is derived from the goddes Pales, or from the Palatini, who originally inhabited the place, or from balore or palore, the beatings of sheep, which were frequent there; or perhaps from the word palantes, wandering, because Evander, when he came to settle in Italy, gathered all the inhabitants, and made them all one society. To the east it has the mount Celius, to the south the Aventine; to the west the Capitoline, and to the north the Forum. — Palatium, the surname of Apollo from this place; where Augustus built a temple to that god, adorned with poricaces and a library, valuable for the various collections of Greek and Latin manuscripts which it contained.

Palatium (anc. geog.), a place in the territory of Reate, distant from it 25 stadia. Dionysius Halicarnassensis.
Palatium reckons it one of the first towns of the Aborigines; and from it Varro accounts for the name of the Mons Palatinus; namely, that a colony from Palatium settled there.

Palatium (Pliny.) Palatium (Pausanias), Palatium (Livy); Palatium (Solinus). This last is the true writing: the great grandchild of Eunder, from whom it took its name, being called Palus, not Palas: a town of Arcadia, which concurred to form Megapolis (Pausanias). From it the Palatium, or Mons Palatianus, takes also its name, according to Virgilian Pliny.

Palatium Divifioni; the villa of Diocletian, near Salone, where he died (Eufebius). Afterwards called Spalatum; which refers to a confiderable city from the ruins of Salone; situated in Dalmatia on the Adriatic. Now Spalato, or Spalato.

Palatium Luculli, (Flutarch), or Vila Luculli; a place between Misenum and Baiz in Campani, of wonderful fruite. Now in ruins, and called Pftina Mirdale.

Palato-Salpingeus, [See Anatomy, Table Plaato-Stphiinis, § of the Mufcels, p. 708.]

PALE, a little pointed flake or piece of wood used in making inclosures, separations, &c. The pale was an instrument of punishment and execution among the ancient Romans, and still continues so among the Turks. Hence emulating, the paling a sharp pale up the fundament through the body.

PALE, in heraldry. See Heraldry, p. 446.

PALEARIUS (Aonius), was a man of the greatest probity, and one of the best writers of the 16th century. He gained the esteem of the men of wit and learning of his time by a noble poem on the immortality of the soul. He was appointed professor of polite literature at Sienna; where his tranquillity was disturbed by contefts with an envious colleague, and by the malicious aspersions of his enemies: against which, however, his eloquence proved always a sufficient defence. At last he left Sienna, and accepted the invitation of the magistrates of Lucca, who gave him several marks of their esteem, and fetted a considerable stipend upon him. Some years after he removed to Milan; where he was seized by order of pope Pius V. and carried to Rome. He was convinced of having spoken in favour of the Lutherans, and against the inquisition; and therefore was condemned to be burnt. This sentence was executed in 1566. He wrote several pieces in verse and prose of which the one above-mentioned is the most esteemed.

PALENCIA, a town of Spain, in the kingdom of Leon, with a rich archbishop’s see. It had an university, but it was removed to Salamanca. It is seated in a fertile foil on the river Camion on the frontiers of Caffile, in W. Long. 3°. N. Lat. 47° 10.

PALERMO, a city of Sicily, in the Val-di-Mazara, with an archbishop’s see and a large harbour. “This city (says Mr Hill)”, which is the capital of Sicily, is of great antiquity; and if a conjecture may be formed from its ancient name Panareaus, which signifies an universal harbour, it was formerly in a very flourishing condition. By whom it was founded is uncertain, nor have we any authenticated accounts of its inhabitants till it became a colony of the Phoenicians, after which it passed into the hands of the various nations that became masters of this island. The present city principally consists of two wide, uniform, and well-built streets, each about a mile in length, crossing each other at right angles in the centre, where there is a small octagon space, ornamented with four statues.” Most of the cities of Sicily have surnames: Palermo is denominated the foppy. It has gained this epithet, no doubt, on account of the advantages of its situation. It has two harbours: in the one, which is very large, and in which there is a mole 1300 paces in length, ships lie at an; horn; in the other their cargoes are laden and unladden. Both the harbours open to the west: there is also a superb quay which extends a mile from west to east, in a rectilinear direction, and is called Le maliari. The prospect is, on the one side, left in the wide expanses of the ocean, and on the other confined by the walls of the city; the walls appear adorned with pilasters, and crowned with a row of ballustrades through which the eye discovers a long range of palaces. These objects altogether form a delightful spectacle. Indeed nothing can be more picturesque than the bay of Palermo. It forms a large amphitheatre, with the capital of Sicily in the centre; surrounded for some miles by a most delightful country, and inclosed by romantic rocks and mountains. The town was formerly surrounded by a strong wall; but the fortifications are now entirely neglected, except towards the sea, where there are still a few weak works. The quay is the principal public walk here. Palermo is embellished all round with avenues of trees, and has four principal entrances, facing the four cardinal points which are at the extremities of the two fricans streets which cross each other. The most frequented of these two streets is called Coftoro. It begins where the quay ends, with the north gate called Porto Ferre, the happy gate; and terminates on the south, at the new gate, which opens on the road to Monreale. Near the last of these gates, this city, which so well merits the attention of a lover of the arts, exhibits in a large square, round which stand some extensive monasteries, the palace of the archbishop, and the palace of the viceroy. Directly opposite to the palace of the viceroy stands, on a pedestal richly ornamented with a variety of figures, a statue of Philip IV. The statue, the pedestal, and the ornaments, are all of marble.

Palermo is quite filled with public monuments, churches, monasteries, palaces, fountains, statues, and columns. These are not all eminently beautiful: for they have not been all erected under the reign of God taffe; but every one of them shows that the nation is fond of the arts, and possesses a genius for decoration. Spring waters are very copious in this city. Not a quarter in Palermo but is liberally supplied with fountains, most of which are marble, all of them adorned with pieces of sculpture, and all afford large quantities of water.

The situation of this city is truly happy: the sea, the hills, the lofty mountains, present on all sides beautiful and striking prospects, which render it one of the most favourable situations for the genius of the artist, whose object is to copy the beauty and sublimity of nature. Freed from the fetters of the Inquisition, the abolition of which was procured by the marquis of Caraccioli, and from the influence of some
other unfavourable institutions, which are rapidly declining, Palermo must become one of the finest cities in the world; and the island of which it is the capital, being all cultivated like a garden, one of the most enchanting spots on the face of the earth. Nature has denied none of her best gifts to Sicily. It was the beauteous province of antiquity, when the political circumstances of the Sicilians were not so much as to repress their genius, prompt and enabled them to erect so many illustrious monuments.

"Adjoining to the town, and near the sea, is a public garden or promenade, planted with orange and lemon-trees, formed into avenues, and now loaded with fruit; the stems of the trees stand in furrows, and are continually watered by a small stream. In the middle is a fountain on which stands a column of white marble, surrounded by four grotesque temples, in two of which are canary birds. Among the oranges is a kind called sanguinel or bloody, which are planted in the middle with red, and have usually the finest flavour. Some of the lemons are sweet, but very flat, tainting like sugar and water. The citrons grow to an immense size; the rind, which occupies at least three-fourths of the bulk of the fruit, is eaten with sugar; the juice is sharper than the fourrell lemon. Indian figs in very great abundance grow wild in the fields and hedges, to the height of twelve or fourteen feet; of these there are three kinds, one with large spines, another with smaller, and the third almost smooth. Their fruit is cooling and delicious, 10,000 l. of which is sold annually to the poor people in the neighbourhood of this city. Another plant, very common in this country, is the aloe, which usually blossoms every fifth or sixth year. Of these there are five or six species, which grow mostly in the hedges, and, together with the Indian figs, form a most impenetrable fence.

"The palace, which is an indifferent old building, is situated in a square, near the south gate of the city, and commands a delightful prospect of the adjacent country. At the top is an observatory, inhabited by an ingenious old priest, who has been in England, and brought from thence several astronomical instruments constructed by Ramden. Neither the structure, situation, nor architectural ornaments of the palace are such as to merit any extraordinary praise. It is, like many others, an assemblage of buildings erected in various ages, as need of accommodation or fancy suggested; and, of consequence, it must unavoidably be defective in architectural order and beauty. The chapel is the only part of it that merits any attention. It was founded by the Counts Roger, the Norman conquerors of Sicily. Within, it is decorated with beautiful pieces of marble and porphyry, and of Mosaic work in gold and various colours. It is in the same taste with the cathedral of Montreale. It is built on the same plan with common churches, only on a smaller scale. The nave is inclosed with pillars; on the right and the left are two narrower openings, called lateral or low passages: the choir and sanctuary are at the end of the nave. Among all the pillars which inclose the nave, it would be hard to find two exactly of the same form and workmanship. Opposite to a channelled column stands another on which the carving tool has made no such impressions; several have neither adze or file, nor scale: they are formed of various kinds of marble, and are of different orders and unequal in height. The walls, the arcades, and the arches, are covered with Mosaic work, in gold and colours, representing angels, and male and female saints.

Over the entrance into the choir, and fronting the nave, there is an Eternal Father of a huge size; the design of which has, in all probability been to impress the beholder with a sufficiently awful idea of the greatness of God. Such representations of the Deity, however improper, not to say impious, occur pretty commonly in the churches of Sicily. The cathedrals of both Montreale and Palermo display the Divine Majesty with equal dignity. Over the walls of the chapel there are many pieces of granite, porphyry, and serpentine, cut into a round, or a square, or some other form, and set like panes of glass. Their edges are inclosed with various draughts in gold and colours; decorations unquestionably expensive, as they are indeed very finely executed in their kind. But it is amazing that such irregularity of design was admitted in a building of such magnificence and raised at such an enormous expense. The pavement of the chapel has been originally laid, and still consists in part of large blocks of tin, porphyry, and serpentine. Most of these are round; ornamented with compartments of draughts, and covered over, as well as the walls, with incrustations of coloured Mosaic work. The fret designed for the viceroy is of the same kind, and highly ornamented. The candlestick intended to receive the waxlights at the festival of Easter is of white marble. All the riches of sculpture are lavished on it with such profusion as renders it a prodigy of labour; but in a fantastic unnatural taste.

In a long gallery in the palace of the viceroy, stand two figures of rams in bronze, concerning which we find the following tradition. Archimedes is said to have long ago erected in one of the public squares of Syracuse four columns with a brazen ram upon the top of each. He is said to have placed them there in such a posture, that some one of them always indicated which of the four principal winds was blowing; and it is added, that they were fabricated with such art, that the wind caused them to utter sounds exactly similar to the bleating of sheep; and whenever any one of the four bleated, it thereby was known that the wind was blowing from that quarter towards which it blew. It is certain (as travellers inform us) that the two brazen rams in this gallery are perforated with small holes in their flanks, close to their thighs, and in other places over their bodies; and that by blowing through those holes a sound is produced much like the bleating of sheep. The wind appears to pass through the holes, and to issue out at the mouth; there might, however, be other holes in the pedestal on which the ram stood, or in other parts of the body, which might contribute to produce the bleating; for travellers agree in saying, that those which they could observe, do not appear to be sufficient to produce the effect. The prince of Torre Muzza, one of the most enlightened men in Sicily, informed M. Houel, that these two rams were dug up from among the ruins of Syracuse in the fourteenth century, as they were buried under-ground, they had probably lain there for many centuries. They were bought by the Marquis Geraci, of the family of Ventimiglia, and lay long in
About the middle of the fifteenth century they were brought to Palermo and placed in the palace of the viceroy. It is not known what is become of the other two. They are probably buried in some ancient ruins, and may be one day or other discovered in digging for the foundation of some new building. The proportions of these two ruins are larger than nature. They are pieces of very fine workmanship: both the heads and the horns are formed with taste, delicacy, and truth; the wool is not so well executed; the forms all together are not absolutely the fineness that might be selected from among the whole species.

The cathedral of Palermo is dedicated to St Rosalia. The Sicilians, though so exceedingly devout, have however neglected to repair it; and it is at present in a most miserable state, as the interior parts appear to be falling into ruins. Proposals have been made for rebuilding it, and various plans have been shown.

The present church appears to have been built by the Counts Roger. The external parts are in a Gothic taste, and very heavy: within, it has been at different periods repaired and embellished. The pillars of the nave are adorned with pilasters of the Corinthian order; these are joined by arches through which you pass to the sides of the building. In some places it is overloaded with ornaments, in others but very poorly ornamented: viewed all together, it is so delusive of order or proportion as to be absolutely ridiculous.

In a chapel on one side of the cathedral are four Gothic tombs of the same period. They have been originally sarcophagi; and having escaped the fate of most of the other works of antiquity, have been spoiled by attempts to repair or improve them, and have been set up here to preserve the remains of some of the kings of Sicily. The only thing about them that can deserve attention is the beauty of the stone: they are of a fine red porphyry.

In the same chapel there is a fine large tabernacle; the whole of which, when viewed without distinction of the parts, resembles the dome and the front gate of the Val de Grace at Paris. It is of rich lapis lazuli, of the very finest colour. The whole of it is plated, and the pillars are said to be solid. All its ornaments are of gilt brays. And on the whole it is extremely beautiful.

Around the church are several statues of saints by Guagini, the celebrated sculptor. On the way from the cathedral down the Cafero there is, on the right hand, a small square, at the entrance of which stands a pedestrian statue of Charles V. in bronze. Near the place where the two great streets cross stands the fanes-house, in a small court, before which there is a fine marble fountain; there are besides about this edifice many curious fragments of antiquity. It would extend this article beyond all proportion if we were to mention all the curiosities which are to be found in Palermo. We shall now endeavor to give our readers an idea of the internal government of the place, which we shall do in the words of Mr. Hill.

"The magistrates appointed to preserve the order of society in this city are, first, the supreme judge, to whom belongs the administration of justice in criminal cases: he is the head of the nobility, and immediately follows the viceroy in all the solemn functions. Secondly, the pretor, who regulates the affairs of the city. He is the perpetual deputy of the kingdom; chief in parliament of the order to whom appertains the right of regulating the king's demesne, and possessed of the prerogative of captain general during the absence of the viceroy. Thirdly, the praetorian court, which consists of three judges, citizens of Palermo, who are chosen annually by the king. They afford the supreme judge in the decision of criminal affairs, and the pretor in the deliberations upon the finances; these two officers, however, have neither vote nor signature, except the pretor, in the bourse respecting the public bank and bank of fruits. Fourthly, the senate of Palermo, composed of the pretor and six practicioners of the law, named by the king, who wear the toga after the manner of the ancient Roman senator, and principally inspect the police which regards the grain and provisions. There are besides seven great officers of state, to each of which is assigned a peculiar employment. First, Il Maistro Perlian, to whom is committed the care of the public granaries, and who manages the sale of the corn both at home and abroad. The impost of a tax upon this commodity has nearly proved the ruin of agriculture, especially as the exportation of it is prohibited to all those who are not able to pay an exorbitant price for that privilege. The quantity of corn annually produced in the island does not at present amount to more than a tenth part of what was collected in former years. Secondly, the auditor general, who passes judgment without appeal upon all offences committed within the precincts of the palace. Thirdly, the high-admiral, whose jurisdiction extends over the marine. Fourthly, the chancellor, who overlooks all the notaries of the kingdom, prepares all official patents, reads the propositions when the parliament assembles, and at the time of a revolution tenders the oath of fidelity to the people; and also proclaims that of the monarch, who thereby binds himself to maintain and defend the privileges of the city of Palermo. The same ceremony takes place upon the installation of a viceroy. Fifthly, the prothonotary of the queen's chamber, who has the inspection of the demesnes of six cities, viz. Syracuse, Lentini, Carletti, St. Filippo, Mineo, and Virini, which were formerly appropriated to the queen of Sicily. Sixthly, the chief secretary, who presides over the officers appointed to receive the taxes and duties in the places of their respective jurisdictions. And seventhly, the lieutenant of the royal eschequer, who has the administration of all effects that have been sequestered or confiscated.

"Palermo is the principal residence of the greater part of the Sicilian nobility; and as it is not the custom for any gentleman to walk in the streets, at least 1000 carriages are said to be kept in the town. They are for the most part in the English style, very elegant, shown to the greatest advantage, with beautiful horses, richly caparisoned, and as many footmen in splendid liveries as can be crowded together behind. Every evening all the people of rank drive about in this manner on the grand public terrace by the sea side. There are also very convenient hackney-coaches, covered and open, waiting all day in their respective stations."
It is very remarkable, that the dead in Palermo are never buried. Captain Sutherland gives the following account of this circumstance in his 'Tour to Constantinople.' The dead bodies are carried to the capuchin convent, which is one of the largest in Italy; "where, after the funeral service is performed, they are dried in a stove, heated by a composition of lime, which makes the skin adhere to the bones. They are then placed erect in niches, and fastened to the wall by the back or neck. A piece of coarse drab is thrown over the shoulders and round the waists; and their hands are tied together, holding a piece of paper with their epitaphs, which are simply their names, age, and when they died. We of course (says Captain Sutherland) visited this famous repository; and it is natural to suppose, that so many corpses would impress one with reverence and awe. It was nearly dusk when we arrived at the convent. We paddled the chapel, where one of the order had just finished saying vespers, by the gloomy glimmering of a dying lamp. We were then conducted through a garden, where the yew, the cypresses, and the barren oranges, obscured the remaining light; and where melancholy fancies are darted through a minster window, where a holy father, who gives the cross, has passed, and with his finger points in a direction, invisible to the saints.

It was a sombre reposeitory; and it is natural to suppose, this circumstance from the charnel house. We were for the number of French corpses would impress one with the fearful water-fall. All these circumstances] uncared for minds for the dismal scene which we were going to behold; but we had still to defend a flight of steps impervious to the sun; and these, at last, conveyed us to the dreary mansion of the dead. But (will you believe me?) notwithstanding the chilling scene through which we had paddled, notwithstanding our being in the midst of more than a thousand lifeless bodies, neither our respect for the dead, nor for the holy fathers who conducted us, could prevent our trembling. The phrenology of the deceased are so ludicrously mutilated, and their muscules are so contracted and distorted in the drying, that no French mimic could equal their grimaces. Most of the corpses have left the lower part of the nose; their necks are generally a little twisted; their mouths drawn awry in one direction; their noses in another; their eyes, which had pointed different ways; one ear perhaps turned up, the other drawn down. The friars soon observed the marks which these unexpected visages occasioned; and one of them, as a kind of memento, pointed out to me a captain of cavalry, who had just been cut off in the pride of his youth: but three months ago, he was the minion of a king—the favourite of a princess—Alas! how changed! Even on earth there is no distinction between him and the meanest beggar. This idea in a moment restored my reflection; and I felt with full force the folly of human vanity. I turned to the holy father, who gave me this lesson. His eyes were fixed on what was once a captain of horse—I saw in them. * Read this, titled pomp, and shrink to thy original nothingness. His thee to my lady's chamber, tell her, though the paint an inch thick, to this mutilate at last—make her laugh at that. The relations of the deceased are bound to fend two wax tapers every year for the use of the convent; in default of which, the corpse is taken down and thrown into the charnel house. Were it not for the number of vacancies occasioned by the nonpayment of this stipend, the capuchins would be unable to find niches for the number of men who must die every year in so populous a city as this. Women are dried as well as the men, but are not exposed. Nobles are shut up in chells.

The number of the inhabitants is above 200,000; and the harbour, though very large, is not so commodious as might be expected, and the vessels that ride therein are not always very safe. There is a magnificent castle built near the sea-side, wherein the vicerey resides six months in the year; and his presence draws a great number of nobility to this place. This city has suffered greatly by earthquakes, particularly in 1693; and it was greatly damaged by a fire in 1730, when a magazine of powder was blown up, containing 400 tons. It stands in a pleasant fruitful country on the north-east coast of the island, and at the bottom of the gulph of the same name. E. Long. 13° 23'. N. Lat. 38° 15'.

PALES, in Pagan worship, the goddess of the shepherds; to whom they offered milk and honey, in order that she might deliver them and their flocks from wild beasts and infectious diseases. This goddess is represented as an old woman. She was worshipped with great solemnity at Rome; and her festivals called Palatine, were celebrated on the 21st of April, the very day that Romulus began to lay the foundation of the city of Rome. The ceremony of which consisted in burning heaps of straw, and in leaping over them. No sacrifices were offered, but purifications were made with the smoke of horses' blood, and with the ashes of a calf that had been taken from the belly of its mother after it had been sacrificed, and with the ashes of beans. The purifications of the flocks was also made with the smoke of sulphur, of the olive, the pine, the laurel, and the rosemary. Offerings of mild cheese, boiled wine, and cakes of millet, were afterwards made to the goddess. Some call this festival Purlina, quid a paradiso, because the sacrifices were offered to the divinity for the fecundity of the flocks.

PALESTINE, in its present state, is a part of Asiatic Turkey, situated between 32° 20' and 33° 20' north latitude; and between 35° 50' and 37° 55' east longitude. It is bounded by Mount Libanus, which divides it from Syria, on the north; by Mount Hermon, which separates it from Arabia Deserta, on the east; by the mountains of Seir and the desarts of Arabia Petraea, on the south; and by the Mediterranean sea on the west.

This once fertile and happy spot was first called the land of Canaan, or Chanaan, from Noah's grandson. In Scripture, however, it is frequently distinguished by other names: such as the Land of Promise, the Land of God, the Land of Israel, &c. It received the name ofPalestine from the Palatines or Philistines, who possessed a great part of it; and it had the name of Judea, or Judea Palestina, from Judea, the most considerable of the twelve sons of Jacob. The Christians have denominated it the Holy Land; partly on account of the many singular blessings it received from the Divine Providence, and partly on account of its metropolis being made the centre of God's worship and his peculiar habitation; but much more for its being the place of our Saviour's birth, the scene of his preaching and manifold miracles; especially the place in which he accomplished the great work of our redemption. As to the name of Judea, it did not begin to receive that till after the return of the Jews from the Babylonian
Palestine

with captivity, though it had been styled long before
the Kingdom of Judah; in opposition to that of Israel,
which revolted from it under Jeroboam, in the reign of
Rehoboam the son of Solomon. But after the return,
the tribe of Judah, the only one that made any figure,
sitting at Jerusalem, and in the countries adjacent,
quickly gave its name to the whole territory. By pro-
fligate authors it was called by many different names;
such as Syria, Palæstina Syria, Calafyrnia, Iduma, Idu-
maea, and Phenicia or Phœnicia; but these are suppos-
ed only to have been given out of contempt to the
Jewish nation, whom they looked upon as unworthy of
any other name than what distinguished the most ob-
scure parts of the neighbouring provinces.

That part of the country which was properly called
the Land of Promise, was inclosed on the west by the
Mediterranean; on the east by the lake Apameities,
the Jordan, and the sea of Tiberias or of Galilee, and
the Samachonit lake; to the north it had the moun-
tains of Libanus, or rather of Antilibanus, or the pro-
vince of Phœnicia; and to the south, that of Edom or
Idumea, from which it was likewise parted by another
ridge of high mountains. The boundaries of the other
part, which belonged to the two tribes and an half
beyond the river Jordan, are not so easily defined, as
well as those of the conquests made by the more pro-
sprous kings of the Jews. All that can be said with
any probability is, that the river Arnon was the first
northern boundary on that side; and with respect to
those on this side of the Jordan, there is a considerable
disagreement between the Hebrew and Samaritan ver-
ions of the Pentateuch.

The extent of this country is likewise variously set-
tled by geographers; some giving it no more than 170
or 180 miles from north to south, and 140 in breadth
where broadest, though not much above half that
breadth where narrowest. But from the latest and
most accurate maps, it appears to extend near 200
miles in length, and about 80 in breadth about the
middle, and about 10 or 15, more or less, where it
widens or shrinks.

The climate is certainly very happy, its situation be-
ning neither too far south nor too far north. The long-
east day is not above 14 hours 15 minutes: But the li-
mits of Palestine appear so small, considering that the
country is likewise inclosed by high ridges or moun-
tains, woods, deferts, &c. that many learned men have
been induced to question what we read of its fertility
and population in former times. It must be owned, in-
deed, that when we compare its ancient and flourishing
state, when it was cultivated with the utmost diligence
by persons well skilful in every branch of agriculture,
with what it hath been since the total extirpation of
the Jews out of it, and more especially since it fell into
the hands of the Turks, the contrast is amazingly great;
but when we consider the many evident causes which
have contributed to effect this change, and even yet
consider the nature of the country itself, we find not
the least reason to doubt the truth of what the sacred
historians have related. Moses describes the richness
of it in the strongest terms, even before the Israelites
got possession of it. It even exceeded the land of E-
gypt, so much celebrated by ancient historians; espe-
cially in the vast numbers of cattle which it produced;
in the quantity and excellence of its wine, oil, and
fruits. With respect to the oil and fruits, it is plain,
that the olives and oil of Canaan exceeded in goodness
those of Egypt, since the tribes lent them thither from
thence; and as for vines, Herodotus tells us, that the
Egyptians had none at all, but supplied the want of
them by a liquor brewed from barley. The presents
which Jacob left to his son Joseph, of honey, spices,
myrrh, almonds, and other fruits of Palestine, show
that they must have been much better in the land of
Judea than in Egypt. The wines of Gaza, Afralon,
and Sarepta, were famous among the most remote na-
tions; though it is allowed, that the wine which was
made at and in the neighbourhood of Bethlehem, in
great quantities, was equal at least, if not superior, to
any of the rest: and that of Libanus, mentioned by
the prophet Hosea, was no less celebrated for its ex-
cellent flavour.

Several circumstances contributed to this wonderful
fertility; such as, the excellent temperature of the
air, which was never subject to excessive heats or colds;
the regularity of its feaons, especially the former and
latter rain; and the natural fatness and fertility of its
soil, which required neither dunging nor manuring,
and could be ploughed with a single yoke of oxen and
a small kind of plough; for the soil was, and is still,
so shallow, that to have gone deep into it, would rather
have endangered than improved the crop. With respect
to the excellency of its corn, we are told, that the bread
of Jerusalem was preferred above all other; and the
tribe of Asher produced the belt of both, and in a greater quantity than any other tribe; and such plenty
was there of it, that, besides what sufficed the inhabi-
tants, who made it their chief sustenance, Solomon,
we read, could afford to send 20,000 tons or
measures, of it, and as many of oil, yearly, to Hiram,
king of Tyre; besides what they exported into other
countries. And we find, even to this day, that the
own of its fulness came from its hitherto.

As to their fruits, the grapes were delicious, finely
flavoured, and very large. The palm-tree and its
dates were in no less request; and the plain of Jeicho,
among other places, was famed for the great plenty
and excellence of that fruit; insomuch, that the met-
ropolis of that territory was emphatically styled the
city of palm-trees. But what both this plain, and
other parts of Palestine, were most celebrated for,
was the balsam shrub, whose balsam was esteemed so
precious a drug among the Greeks, Romans, Egyp-
tians, and other nations, and is still to this day under
the name of halm of Gilead. They had likewise the
greatest variety of other spices in the highest per-
fecHon; and which might be, in some sense, styled
perpetual, because they were not only covered with a
constant verdure, but because the new buds always
appeared on the same boughs before the old fruit was
ripe; and of those buds, which were in too great
quantities to be allowed to come to maturity, they
gathered enough to make very delightful pickles and
sweetmeats, especially of their citrons, oranges, and
apples of paradise, which last commonly hung by hun-
dreds in a cluster, and as big as hens eggs, and of an
excellent taste and flavour. Their vines yielded grapes
twice, and sometimes three times a year, great quan-
tities of which were dried up, and preserved for use, as
well
convinced nature, even those resulting from a great number of medals struck under the reigns of the kings of Syria and Judæa, and under the Romans, both by Jews and Pagans, and which all bear the symbols of a rich fertility. To these proofs are added a multitude of facts, recorded in the history of the Jews during this period; the efforts of the neighbouring kings to conquer their country: the long and bloody wars that the Jews carried on with vigour, and sometimes with success, against powerful princes and nations; the tribute and taxes they paid to the kings of Egypt and Syria, to the Romans, and to their own princes; the magnificence of their sovereigns, and among others of Herod; the troops he raised and kept on foot; the temples, fortresses, palaces and cities, which he erected and embellished, not only in his own country, but also in Syria, Asia Minor, and even in Greece; the immense sums he lavished among the Romans, the donations he made to his own people, and the vaft treasures which he left behind him: all these circumstances concur in proving the fertility and riches of Palestine during that period.

In the second memoir, the Abbé Guénée considers the state of Palestine as it was from the time of the Emperor Adrian to the caliphate of Omar, which comprehends a period of four centuries. From fundry facts he shows, that it could not then have been the barren country which it has been represented by some sceptical writers. He particularly mentions the project formed by Adrian of rebuilding and embellishing Jerusalem, of forming it into a Roman colony, and giving it its own name; a project of which he could never have entertained a thought, if Judea, which he had seen and examined with his own eyes, had appeared to him such a barren and wretched country, as it is said to be by some who have neither seen that country nor examined the matter with care and attention. Our author also produces a variety of other facts, to shew that Judea, after all that it had suffered from the devastations of war both in ancient and latter times, still remained at the period in question fertile, rich, and populous. This is the idea which the writers of the time, pagan and Christian, as well as Jewish, have given of Palestine. Antoninus Martyr, a citizen of Piaentina, who in the 6th century travelled to Palestine, and composed an account of his voyage, which is still extant, says, that the country of Nazareth was not inferior to Egypt in corn and fruits; and that though the territory of that city was not very extensive, it abounded in wine and oil, and excellent honey. The country about Jericho appeared to him still more fertile. He saw mount Tabor, which he represents as surrounded with cities: and he observed, in the neighbourhood of Jerusalem, vineyards, great plantations of fruit trees, and through the whole country a considerable number of hospitals, monasteries, and beautiful edifices. Our learned Abbé, in concluding his work, acknowledges, that the fertility and fertility of Judea might begin to diminish towards the middle of the period treated of in his second memoir: but he does not think that any argument can be drawn from hence against its having been at the commencement of this period in a flourishing state; and much less can any proof be brought from hence, that in preceding peri-
Palestine. As, under the kings, or under the administration of Moses, the country of Palestine was a barren and uncultivated district.

Besides, it ought to be considered, that it was then inhabited by an industrious people, who knew how to improve every inch of their land, and had made even the most desert and barren places to yield some kind of productions, by proper care and industry; so that the very rocks, which now appear quite bare and naked, were made to produce corn, pulse, or pasture; being, by the industry of the old inhabitants, covered with mould, which, through the laziness of the succeeding proprietors, has been since washed off with rains and storms. We may add, that the kings themselves were not above encouraging all kinds of agriculture, both by precept and example; and, above all, that they had the divine blessing promised to their honest endeavours and industry; whereas it is now, and hath been long since, inhabited by a poor, lazy, indolent people, groaning under an intolerable servitude, and all manner of discouragements; by which their aversion to labour and agriculture, farther than what barely serves to supply their present wants, is become in a manner natural and invincible. We may farther observe, after the judicious Mr Maundrell, that there is no forming an idea of its ancient flourishing state when under the influence of heaven, from what it is now under a visible curse. And, if we had not several concurring testimonies from profane authors, who have extolled the fecundity of Palestine, that figure one of Julian the apostate, a sworn enemy to Jews and Christians, as well as to all the sacred writings, would be more sufficient to prove it; who frequently makes mention, in his epistles, of the perpetuity, as well as excellence and great abundance, of its fruits and produce. The visible effects of God's anger, which this country has felt, not only under Titus Vespasian (when myriads of inhabitants were either slain, or perished by the most severe famine, pestilence, and other calamities; and the rest fold for slaves, into all lands; and new colonies sent to repeople it; who found it in such a defolate state, as quite discouraging them from resting on it to its primitive fruitfulness); but much more since that emperor's time, in the inundations of the northern barbarians, of the Saracens, and of the more cruel and destructive Christians during the holy war; and in the oppression it now feels under the Turkish yoke; may be easily owned to be more than sufficient to have wrought the diurnal change we are speaking of, and to have reduced the far greater part into a mere desert.

Nevertheless, if we may credit those who have viewed it in this dextrous condition, they will tell us, there are still such visible signs of its natural richness and fertility, as plainly show, that the bare want of culture is the main if not the only cause of its present poverty and barrenness. We shall hint, as a further proof of this, what a learned traveller hath lately written of it from his own observations.

"The Holy Land (says Dr Shaw), were it as well peopled and cultivated as in former times, would fill more fruitful than the very best part of the coasts of Syria and Phœnicia; for the soil is generally much richer, and, all things considered, yields a preferable crop. Thus the cotton that is gathered in the plains of Ramah, Esdraelon, and Zabulun, is in greater esteem than what it cultivated near Sidon and Tripoli. Neither is it possible for pulse, wheat, or any kind of grain, to be more excellent than what is sold at Jerusalem. The barrenness of Kedron valley, rather, which some authors may, either ignorantly or maliciously, complain of, doth not proceed from the incapacity or natural unfruitfulness of the country, but from the want of inhabitants, and the great avarice there is to labour and industry in those few who possess it. There are, besides, such perpetual discords and depredations among the petty princes who share this fine country, that, allowing it was better peopled, yet there would be small encouragement to sow, when it was uncertain who should gather in the harvest. Otherwise, the land is a good land, and full capable of affording its neighbours the like supplies of corn and oil which it is known to have done in the time of Solomon."

And Volney, in his Travels in Egypt and Syria, observes, that though the whole of Palestine is almost an entire level plain, without either river or rivulet in summer, and only watered by the winter torrents, the soil is yet good, and may even be termed fertile; for when the winter rains do not fail, every thing springs up in abundance; and the earth, which is black and fat, retains moisture sufficient for the growth of grain and vegetables during the summer. More doura, fe-mamum, water-melons, and beans, are now here than in any other part of the country. They also raise cotton, barley, and wheat; but though the latter be most esteemed, it is less cultivated, for fear of too much inviting the avarice of the Turkish governors and the rapacity of the Arabs.

Judea, in its largest sense, was divided into maritime and inland, as well as into mountainous and champaign; and again subdivided into Judea on this side, and Judea beyond Jordan. But the most considerable division is that which was made among the twelve tribes, by lot, to prevent all murmuring and discontent among those stubborn people; of these, two and a half were seated beyond Jordan, and the rest on this side. The next remarkable division was made by king Solomon, who divided his kingdom into twelve provinces or districts, each under a peculiar officer; and every one of these was to supply the king with provisions for his household in his turn; that is, each for one month in the year. But the most fatal division of all was, that which obtained under his imputrid son Rehoboam; when ten of the twelve tribes revolted, under the conduct of Jeroboam, who became head of this new monarchy, styled The kingdom of Israel, in opposition to that of Judah, the title which distinguished the mainéd kingdom of Rehoboam from that time downwards. Under the second temple the division lasted a considerable time, and the fame bloody hatred and hosillities continued between these two kingdoms; that of Israel taking the name of Samaria from its capitol. The inhabitants were a mixture of the old Israelites, and of new colonies sent thither by the kings of Assyria after their conquest of it, till they were subdued by the Maccabees, and their metropolis destroyed. Under the Romans it began to be divided into tetrarchies and toparchies: the larger were those of Judea, Samaria, and Galilee, Upper and Lower; the leffer, those of Gerariska, Saron, and others of less note;
lib. i. Antig. xiv.

Palestine.

PALESTRINA, a town of Italy, in the Campagna di Roma, with a bishop's fee. It is the capital of a principality of the name, and the bishop is one of the six cardinal bishops. It was anciently famous for the temple of Fortune, being then called Prænæa, and seated on the top of a mountain, the ruins of which may yet be seen. E. Long. 12. 55. N. Lat. 41. 51.

PALESTRINA, is one of the largest and most populous of the islands called the Lagunes, near Venice, and where the most considerable of the nobleman have houses of pleasure. It is 15,000 paces in length and 400 in breadth; the principal harbour has also the same name.

PALFIN (John), an eminent surgeon, anatomist, and reader in surgery at Ghent, the place of his birth; acquired great reputation by his learning and works.

The principal of these are, 1. A Treatise on Osteology, in 12mo, Paris, 1731. 2. Anatomy of the Human Body, in 2 vols 8vo, Paris, 1734, he died at Ghent at a great age, in 1730.

PALFREY, is one of the better sort of horses used by noblemen or others for haste; and sometimes of old taken for a horse fit for a woman to ride. Camden says, that William Fauconberg held the manor of Cuckeney, in the county of Nottingham, in fergeantry, by the service of shoeing the king's palfrey when the king should come to Manfield.

PALICAUD; or PALLICHERY, a fortress of considerable strength in India, which commands the passage between the two coasts of Malabar and Coromandel, by way of the Tichinopoly and Coimbettore countries: there is also a communication with it thro' the Naye country. It is in the hands of the English; and is of great importance to them, because as Coimbettore is in the hands of Tipoo, by their holding this place on the west, and Dindigul on the east of Coimbettore, the province is rendered of little use to Tipoo in time of war, unless he keeps a very large force there to protect it. See Memoir of a Map of the Peninsula of India by Major Renell.

PALICATE, a feaport town of India, on this side of the Ganges. It is seated on the coast of Coromandel in the kingdom of Carnate, 70 miles north of Fort St. George. Here the Dutch have a factory and fort called the Fort of Guelderland. E. Long. 80. 1. N. Lat. 13. 34.

PALICI, or PALISCI (fab. hist.), two deities, sons of Jupiter by Thalia, whom Εἰκής, according to Macrobius, calls Εἰνη, in a tragedy which is lost. The nymph Εἰνη, when pregnant begged Jupiter to remove her from the pursuit of Juno. Upon which he concealed her in the bowels of the earth; and when the time of her delivery arrived, the earth opened and brought into the world two children, to whom were given the name of Palici Πάλικες, because they came again into the world from the bowels of the earth. These deities were worshipped with many ceremonies by the Sicilians; and near their temple were two small lakes, which were fupposed to have sprung out of the earth when they were born. Near these pools it was usual to take the most solemn oaths when any body wished to decide controversies and quarrels. If any of the persons who took the oaths were perjured, they were immediately punished supernaturally; and those whose oath, by the deities of the place, was sincere, departed unhurt. The Palici had also an oracle, which was consulted upon some great emergencies, and which rendered the truest and most unequivocal answers. In a superstitious age, the altars of the Palici were staked with the blood of human sacrifices; but this barbarous custom did not last long, as the deities were satisfied with the usual offerings.

PALINDROMUS, a verse or sentence which runs the
the fame when read either backwards or forwards.
Such is the verse.

Roma tibi jubito multibus ibit amor.

Some people of leisure have refined upon the Palindrome, and composed verses, each word of which is the same backwards as forwards; for instance, that of Camden.

Odo tenet mulum, madidam mappam tenet Anna.
Anna tenet mappam madidam, mulum tenet Odo.

PALINGENIA, among divines, the fame with regeneration. Among chemists, it denotes the producing of a body from its principles.

PALIGENIUS (Marcellus), well known by a poem divided into 12 books, and intitled Zodiacus Vita, which he was several years of composing and dedicated to Hercules I. of Este, duke of Ferrara. Some say he was physician to the prince; others rank him among the learned Lutherans, to whom the duchess of Ferrara gave a reception in her court and honoured with her protection. His Zodiac contains good things, and is a philosophical fatire against immorality and false prejudices. Though this poem has borne a multitude of impressions, the author's life is but little known. He died some time between the years 1537 and 1543.

PALINODY, a discourse contrary to a preceding one; hence the phrase of palinodia canere was taken for a recantation.

PALINUR, promontorium (Virgil, Velleius), with a cognominal port, was situated at the south extremity of the Sinus Puteanus, on the coast of Lucania; so called from Palinurus, Æneas's seaman, who there perished (Mela Dionysius Halicarnassiacus).

PALINURUS (fab. infl.), Æneas's pilot, whose fate Virgil very particularly describes. He fell into the sea when asleep; and was three days exposed to the tempers and its agitation, and at least came safe afores, where the cruel inhabitants of the place murdered him to get his clothes. His body was left unburied on the seaside; and since, according to the religion of the old Romans, no one could cross the Stygian lake before 1000 years were elapsed, if his remains had not been decently buried, we find Æneas, when he went down to hell, speaking to Palinurus, and assuring him that though his bones were deprived of a funeral, yet the place where his body was exposed would soone be adorned with a monument, and bear his name; and accordingly the promontory was called Palinurus.

PALISADES, in fortification, flakes made of strong split wood, about nine feet long, fix or seven inches square, three feet deep in the ground, in rows about two and an half or three inches auster, placed in the covert way, three feet from, and parallel to, the parapet or side of the glacis, to secure it from surprize. They are also used to fortify the avenues of open forts, gorges, half-moons, the bottoms of ditches, and in general all poles liable to surprize. They are usually fixed perpendicularly, though some make an angle inclining towards the ground next the enemy, that the ropes cast over them to tear them up may slip off.

Turning PALISADES; an invention of Mr Cochorn.

in order to preserve the palisades of the covert way from the besiegers shot. They are so ordered, that as many of them as stand in the length of a rod, or about ten feet, turn up and down like traps, so as not to be in sight of the enemy till they just bring on their attack; and yet are always ready to do the proper service of palisades.

PALISSE, in heraldry, a bearing like a range of palisades before a fortification, reprented on a fesse, rising up a considerable height, and pointed at top, with the field appearing between them.

PALIURUS, in botany. See RHAMNUS.

PALL in heraldry, a figure like a Greek P, about the breadth of a pallet; it is by some heralds called a crof-pall on account of being looked upon as an archiepiscopal bearing.

PALLA, in Roman antiquity, a mantle which women wore over the gown called fola. It was borne on the left shoulder; whence palletting to the other side, under the right arm, the two ends were bound under the left arm, leaving the breast and arm quite bare. It had a great many folds, and derived its name from παλλας, to shake or tremble.

PALLADIO (Andrea), a celebrated Italian architect of the 16th century, was a native of Vicenza in Lombardy, and the disciple of Triffin. He made exact drawings, of the principal works of antiquity to be met with at Rome, adding comments to them which went through several impressions. But this, though a very useful work, was greatly exceeded by the Treatise of Architecture in four books, which he published in 1570. Inigo Jones wrote some excellent remarks on it; which were included in an edition of Palladio, published by Leoni, in two vols folio. 1742.

PALLADUM in antiquity, a statue of the goddef Pallas. It was about three cubits high, and represented the goddess fitting and holding a pike in her right hand and in her left a daffaf and a spindie. It fell down from heaven near the tent of Ilias, as he was building the citadel of Ilium. Some, however, suppose, that it fell at Pefinus in Phrygia, or, according to others, Dardanus got it as a present from his mother Electra. There are some who maintain, that the Palladium was made with the bones of Pelops by Abas; but Apolloforus says, that it was no more than a piece of clock-work which moved of itself. However various the opinions of ancient authors be about this celebrated statue, it is universally allowed, that on its preservation depended the safety of Troy. This fatality the Greeks, during the Trojan war, were well aware of; and therefore Ulysses and Diomedes were commissioned to steal it. This they effected; and if we can rely upon the authority of some, they did direct how to carry it away by Helenus a son of Priam, who in this betrayed his country, because his brother Deiphobus, at the death of Paris, had married Helen, of whom he was enamoured. Minerva was enraged at the violence offered to her statue; and, according to Virgil, the palladium itself seemed to have received life and motion; and by the flashes which started from its eyes, and sudden springs from the earth, it seemed to show the resentment of the goddes. The true palladium, as is observed by some, was not carried away from Troy by the Greeks, but
only a statue of similar size and shape, which was placed near it, to deceive whatever facriligious persons attempted to steal it. The palladium, therefore, as they maintain, Æneas conveyed safe from Troy to Italy, and it was afterwards preferred by the Romans with the greatest secrecy and veneration in the temple of Vesta; a circumstance which none but the vestal virgins knew. It was esteemed the deity of Rome; and there were several others made perfectly like it, to secure it from being stolen, as was that at Troy, which the oracle of Apollo declared should never be taken long as the palladium was found within its walls. A palladium was also placed by Nicias in the citadel of Athens.

PALLADIUS, bishop of Helenopolis in Bithynia, and then of Afpasia. He was a Galatian, and born at Cappadocia. He became an Anchorite in the Mountain of Nebria in 388, and was consecrated a bishop in 401. He was an intimate friend of St John Chrysostom, whom he never forsook during the time of his persecution, nor even in his exile. He went to Rome some time after Chrysostom’s death, and at the request of Lausus governor of Cappadocia, composed the history of the Anchorites or Hermits, and intitled it Lausaces, after the name of that lord, to whom he dedicated it in 420, when it was written, being then in the 20th year of his episcopacy, and 536 of his age. Palladius was accused of being an Origenist. It is true, he was an enemy to St Jerome, of whom he does not speak well, and was intimately connected with Rufinus; but perhaps no good proof can be brought of his Origenism. He had been the disciple of Evagrius of Pontus, and was even suspected of entertaining the sentiments of Pelagius.

He died in the 7th century, but in what year is not certain. His History was published in Greek by Meursius at Amsterdam in 1619; and in Latin in the Bibliotheca Patrum; but he seems not to have been the writer of the life of St John Chrysostom, in Greek and Latin by M. Bigot, printed in 1800.

Pallas, a freed man of Claudius, celebrated for the power and the riches which he obtained. He advised the emperor his master to marry Agrippina, and to adopt her son Nero for his successor. It was through him and Agrippina that the death of Claudius was hastened, and that Nero was raised to the throne. Nero, however, forgot to whom he was indebted for it. He disdained Pallas, and some time after cauited him to be put to death, that he might procure his great riches.

Pallavicini (Perrante), an Italian wit of considerable note, was defended from a branch of a noble family seated in Placentia, where he was born about the close of the 16th century. He soon gave great proofs of an extraordinary genius, and quickly acquired a masterly knowledge in the elements of classical erudition. He was afterwards sent to complete his education in the monastery of Augustin friars at Milan, where he took the habit, lived much esteemed, improved himself in piety as well as learning, and raised great expectations of future fame; but being somewhat amorously inclined, he engaged in an intrigue with a young countess of Venice, whose charms proved irresistible; and in order to enjoy them without restraint, he obtained leave from his general to make the tour of France. Accordingly, he pretended to set out for that country; but it was only a blind to cover his real design. He never left Venice, but lived there privately, enchanted in the arms of his Venus: and having too ready a talent at invention, he imposed upon his friends, by often sending them in letters feigned accounts of his travels through France; also informing them of several things respecting that court, which he learned from the advice of many considerable persons with whom he corresponded.

His money in the mean time flew with expanded wings, and he soon found his purse much drained. In this exigence he naturally had recourse to his wits for supplies. He wrote for the book-sellers; and composed several pieces, more for the sake of lucrative than out of fondness for authorship. Among other things, he wrote a collection of letters, mostly satirical, which he called the Courier robbed of his Mail. The work appeared at first in such a coach, as could not give great offence except to the Spaniards, against whom he had some grudge. The piece was accordingly licensed by the inquisitors; but falling into the hands of the secretary of the republic of Venice, who at that time was licencier of books, he would not give his imprimatur, though great interest was employed for that purpose, neither would he return the manuscript. This enraged Pallavicini so much, that had not his friends restrained him, he would have purified the affair to his ruin.

At length he found an opportunity of travelling into Germany with duke Amalfi as his chaplain. This journey, as was to be expected, had no good effect either upon his wit or his morals. On the contrary, finding himself, from the manners of the Germans, more at liberty, he indulged his genius and passions with greater ease; and after a residence there of upwards of a year with the duke, he returned to Venice, with a face marked all over with blotches like the evil, and a spirit resolved to sacrifice to his resentment at the rack of his life. He was resolved to have his full measure of revenge against the secretary of the republic for keeping his manuscript; and with him his resentment joined the family of the Barberini, pope Urban VIII. and his nephews, because they also endeavoured, at the instigation of the Jesuits, to get all his manuscripts forbid the press. In this rancorous spirit he cast his Courier into a new model, and enlarged it with many letters and discourses. Thus new modelled, he offered it to a book-seller, who undertook to get it printed; but our author was betrayed by a pretended friend, who acted the part of a spy, and informed the archbishop of Vitelli, then the Pope’s nuncio at Venice, just as the work was finisht at the press: at the same time, this treacherous friend bought the whole impreffion; and upon the nuncio’s complaint, Pallavicini was imprisoned. In this miserable condition he found a friend in one of his mistresses, who, seeing him abandoned by most of his patrons, not only supported him, but conveyed letters to him, by which she gave him such informations as enabled him to make a proper defence, and to recover his liberty.

But war having in the mean time broke out between the Barberini and the duke of Parma; Pallavicini,
Palavicini, in order to revenge himself upon the supposed instruments of his imprisonment, wrote a piece intitled "The tinkling Instrument to call together the Barberini Bees;" and dedicated it in terms of profoundest contempt to the nuncio Vitelli. The nuncio finding that little notice was taken of his complaints on the occasion, procured by bribery one Charles Morfu, a Frenchman of famous character, who pretended to pass for a gentleman, to entice Palavicini to which end, the traitor used his best endeavours to intimate himself into his friendship, and at length exhorted him to accompany him to France. He declared that his fortune would be made by the extraordinary encouragements which was given to men of letters by Cardinal Richelieu; and the better to favour the deceit, he produced forged letters from the Cardinal, inviting our author to France, and expressing a desire he had to establish in Paris an academy for the Italian tongue, under the direction of Palavicini. The share took; and now fascinated by the prospect of gain, Palavicini suffered himself to be led like an ox to the slaughter, whithersoever Morfu thought proper. He left Venice much against the advice of his friends, and went first to Bergamo, where he spent a few days with some of his relations, by way of giving some entertainment to Morfu. They then set off for Geneva, to the great satisfaction of our author, who proposed to get some of his works printed there, which he had not been able to do in Italy. Morfu, however, instead of conducting him to Paris, took the road to Avignon; where, crossing the bridge of SORaces, in the county of Venaissin, they were feized by a gang of flibi, or sheriff's officers, on pretence of carrying contraband goods, and confined. Morfu was quickly discharged and very liberally rewarded; but Palavicini, being carried to Avignon, was imprisoned; and notwithstanding, on his examination concerning some papers found upon him he made a very artful defence, it was in vain. The sentence was already brought from Rome, and he was to undergo a trial merely for form's sake. For this purpose being put into a dark dungeon, he made another effort to escape. He managed matters so well with his keeper, as to procure wax candles to be allowed him, under pretence of amusing himself with reading; and when he had got a number of those, he set fire one night to the prison-door, in order to get off by that means; but the stratagem did not succeed, and he was of course confined much cloer, and treated with great inhumanity. After a year's suffering, he was brought to trial, in which he made an excellent defence, and flattered himself with hopes of relief. He had even begun a whimsical piece on the subject of melancholy; but, contrary to his expectations, he was sentenced to die, and lost his head on a scaffold in the flower of his age.

He was of so heedless and profuse a disposition, that had he petified an immense estate he would have spent it all. He was never engaged in a virtuous passion, being inflamed to a prodigious and unnatural degree with the love of the meanest and most infamous profuities. On the other hand, no one could be more sincere and faithful in his friendships, nor was ever a man a greater prey to treachery; infomuch, that when released from prison in Venice, he was told that a wretch had betrayed him, he could not be prevailed upon to believe it, saying, "How can this be, since he declared himself my friend, and I made him privy to all my concerns!" He used, while he wore a religious habit, to study or write two or three hours in bed every morning. The rest of the day he spent either in the company of idle persons or else with the ladies; but after he had wholly left the monastic life, upon pretence of securing himself from the snares of his enemies, he lived in a very irregular manner. He was pollied of a fine genius, and had a great facility in writing; and till he was corrupted by the commerce of mean low women, he wrote pieces worthy of immortality. He did not spend much time or pains either in composition or in revision, for he frequently sent to the press the very first exertions of his genius; ye nature had given him so noble a vein of eloquence, which he had greatly improved by perusing the best authors, that his first thoughts were often equal to the most laboured compositions. He was modest, and spoke of himself with diffidence; but his works are strongly tinctured with envy, malice, and gall. He made but a poor figure in conversation; and when with persons of worth and distinction, would often retire to a corner of the room, and seem quite wrapt up in thought. He never exerted his wit or humour after his return from Germany, but when he was in the company of some mean women. Upon the whole, it is difficult to determine whether vice or virtue was the most predominant feature in his character. His death gave birth to a dialogue, intitled, Anima eranti di Ferrante Palavicini, or, "The wandering Ghost of Palavicini." Besides his life at the head of his works in two volumes, there is another prefixed to the "Divortio celestis," at Amsterdam in 1696.

PALLENE, a small peninsula of Thrace or Macedonia, formerly called Phigira. It is situated near the bay of Thessalon, and contains five cities, the principal of which is called Pallene. It was famous, according to some of the ancients, for an engagement between the gods and the giants.

Pallet, among painters, a little oval table, or piece of wood, or ivory, very thin and smooth; on and round which the painters place the several colours they have occasion for, to be ready for the pencil. The middle serves to mix the colours on, and to make the tints required in the work. It has no handle, but, instead thereof, a hole at one end to put the thumb through to hold it.

Pallet, among potters, crucible makers, &c. a wooden instrument, almost the only one they use, for forming, heating, and rounding their works. They have several kinds; the largest are oval, with a handle; others are round, or hollowed triangularly; others, in fine, are in manner of large knives serving to cut off whatever is superfluous on the moulds of their work.

Pallet, in gilding, an instrument made of a squirrel's tail, to take up the gold leaves from the pillows, and to apply and extend them on the matter to be gilt. See GILDING.

Pallet, in heraldry, is nothing but a small pale, consisting of one half of it in breadth, and therefore there are sometimes several of them upon one shield.

Pallet, is also a part belonging to the balance of a watch or movement. See the article Watch.
performers to appear in Grecian habits. It is used in contradistinction to toga, in which the scene was laid at Rome, and in which the dresses were Roman. The word palliatus is derived from pallium, which was a part of dress peculiar to the Greeks; whereas the toga belonged to the Romans only. See Toga, Comed., &c.

PALLIATION, or a Palliative Cure, in medicine, is that which, in desperate and incurable diseases, after predicting the fatal event, the physician prescribes some remedies for mitigating the pain or some other urgent symptoms, as in ulcerated cancers, or cancerous fistulas, and the like.

PALLIO Cooperis. It was an ancient cufum, where children were born out of lawful wedlock, and their parents were afterwards married, that those children, together with the father and mother, should stand palla cooperis, under a cloth, while the marriage was solemnizing; which was a kind of adoption, and had the effect of a legitimization. Thus Robert Groschel, the famous Bishop of Lincoln, in one of his letters, says: Infigurum legitimatum, nati ante matrimonium confuentur; poni sub palla super parentes eorum extento, in matrimonio legitimantur.

Selden in his notes on Fleta, adds, that the children of John of Gaunt duke of Lancaster, by Catharine Swinford, though legitimated by Act of Parliament, yet were covered with the pall when their parents were married.

PALLIUM, a word often mentioned in our old historians. Durandus tells us, that it is a garment made of white wool, after the following manner, viz. The nuns of St Agnes, every year, on the feast-day of their saint, offer two white lambs on the altar of their church, during the time they sing Agnus Dei, in a solemn mass; which lambs are afterwards taken by two of the canons of the Lateran church, and by them given to the pope's subdeacons, who feed them to puzzle till bearing time, and then they are worn, and the pall is made of their wool mixed with other white wool. The pall being thus made, is carried to the Lateran church, and there placed on the high altar, by the Spaniards in the ceremony of baptism. They had the head, and the tunic, their church, during the time they stood the body of the bishop leave to be admitted in baptism, which was conferred the Sunday following. They had also then given them the symbol or credo, to get off by heart, to be repeated to the bishop in the ceremony of baptism. 2. They called it Capitulium, the Sunday of washing the head; because those who were to be baptized the following Sunday, were prepared by washing their heads on this day. Some time afterwards they called it Indulgence Sunday, because the emperors and patriarchs used to distribute gifts on that day.

PALM, in botany. See Phoenix.

PALMA, or Palma Nova, a very strong town of Italy in the territory of Venice, and in Friuli. It is a very important place, for the defence of the Venetians against the Austrians and Turks; and was built in 1593, for that very purpose. They have cut a canal near this place, which is very advantageous. It is seated on the sea-side, 10 miles south east of Udine, and 55 north east of Venice. E. Long. 15. 15. N. Lat. 46. 2.

Palma, an island in the Atlantic Ocean, and one of the Canaries, 36 miles north west of Goemera, and about 75 in circumference. It abounds in wine and sugar; and has a handsome town of the same name, which carries on a trade in wine to the West Indies and other parts. Their best wines grown in a soil called the Brinia, where they make 10,000 butts of wine every year, which is well known by the name of Palm wine. There is plenty of cattle, and all sorts of fruits. In 1624 a volcano broke out in this island, with a most violent earthquake; the flame was seen for six weeks together, and a great quantity of ashes were thrown as far as Teneriff. It was conquered by the Spaniards in 1460.

PALME, Palma. Under this name Linnaeus has arranged several genera, which, although capable of a place in separate classes of his system, he chooses to reckon on account of their singular structure, to place apart, in an appendix to the work. —See Areca, Chamerops, Phoenix, Cocos, &c.; and Corypha.

The same plants constitute one of the seven families or tribes into which all vegetables are distributed by Linnaeus in his Philosophia Botanica. They are defined to be plants with simple leaves, which at their summit bear leaves resembling those of the ferns, being a composition of a leaf and a branch; and whose flowers and fruit are produced on that particular receptacle or seat called a sjadix, protruded from a common calyx in form of a sheath or scabard, termed by Linnaeus sjada.

Palm is likewise the name of the first order in Linnaeus's Fragments of a Natural Method. See Botany, p. 457.

PALMARIS MUSCLE, in anatomy. See there, Table of the Muscles.

PALMATED, something resembling the shape of the hand: thus we say palmated leaves, roots, bones, &c.
nine or ten in number, Allt Vili 4· and Kif's, U
was intricate one; yet when we pan; the left from the breadth of it. The Greek
fell, the deposit of a city more extensive and splendid than Rome itself, the deposit of all the arts which Greece in its most flourishing periods could afford. The problem is an intricate one; yet when we divest it of many of its difficulties, we shall bring this stupendous prodigy to no very uncommon magnitude. The coast of Syria was in very early ages rich and populous; and either from the convenience of procuring water, or from the vicinity of India and Egypt, the population, instead of increasing on the mountains, extended to Judea, and from thence through its plains only to the interior parts. The ruins of this numerous people, and of their habitations remain; but as their edifices were not uncommonly splendid, or, as the causes of their destruction were powerful, they have not attracted much attention. Yet the ruins of more than 30 towns are discoverable to the south-east of the Dead Sea, and from thence towards Tadmor or Palmyra: we know the cause of the destruction of these towns, and we know that it did not reach Palmyra. This splendid city was not, therefore, inundated in a mass of sand: it was probably a link of a continued chain of population, or perhaps its termination. The situations of towns in the Sandy Desert must necessarily be determined by local advantages. Tadmor is situated where two hills converge, and beyond the point where they approach these hills afforded water, that necessary aid to animal life; and the aqueducts through which it was brought from them were discovered and described by Mr. Wood. Though the other towns now in ruins afford some remains of luxury and opulence, yet in these respects they are much inferior to Palmyra; and this deserves to be explained. Palmyra was undoubtedly very ancient. "The two springs of fresh water it possesses (says Volney) were above all, a powerful inducement in a desert where else so parched and barren. These double springs were the two principal motives which drew the attention of Solomon, and induced that commercial prince to carry his arms so remote from the limits of Judea." "He built strong walls there (says the historian Josephus), to secure himself in the possession, and named it Tadmor, which signifies the Place of Palm-trees." Hence it has been inferred that Solomon was its first founder; but we should, from this passage, be rather led to conclude that it was already a place of known importance. The palm-trees he found there are not the trees of uninhabited countries. Prior to the days of Moses, the journeys of Abraham and Jacob from Mesopotamia into Syria, sufficiently prove a communication between these countries, which must have been carried on by the Euphrates and Palmyra. At this distance of time, when the greater part of monuments of these early ages have perished, we are liable to form very fallacious opinions concerning the state of these countries in those remote times, and are the more easily deceived, as we admit as historical facts antecedent events of an entirely different character. If we observe, however, that men in all ages are united by the same interests and the same desires, we cannot help concluding, that a commercial intercourse must early have taken place between one nation and another, and that this intercourse must have been nearly the same with that of more modern times. Without, therefore, going higher than the reign of Solomon, the invasion of Tadmor by that prince is sufficient alone to throw a great light on the history of this city. The king of Jerusalem would never have carried his attention to so distant and detached.

**Notes:**

1 Kings, ix. 18. and 2 Chron. viii. 4. and Ant. Jud. lib. i.
After the captivity of Valerian, it was become an opulent city, to which the situation in the vicinity of the Roman and Parthian empires greatly contributed: as the caravans, in going to or returning from the East, frequented the place, and thus rendered it a considerable spot of merchandise. It enjoyed an independency till the time of Trajan; who, having made himself master of almost all the Parthian empire, reduced Palmyra likewise, and it was afterwards accounted part of the Roman dominions. But when the defeat and captivity of Valerian had so much weakened the empire, that the Persians seemed to be in a fair way of becoming masters of all the eastern provinces, the Palmyrenians began to entertain thoughts of recovering the liberty. Odenathus, prince of Palmyra, sent a very respectable letter to Sapor on his return, accompanied with considerable presents; but by that haughty conqueror his letter and embassy were treated with the most provoking contempt. The presents were thrown into the Euphrates; and to his letter Sapor replied, That his insolence in presuming to write to his lord was inexculpable; but if he could stone it in any way, it would be by presenting himself before the throne bound hand and foot, in token of a consciousness of his crime, and the punishment he deserved. With this injurious treatment Odenathus was so provoked, that he swore either to bring down the pride of the haughty conqueror, or die in the attempt. Accordingly, having assembled what forces he could, he fell upon the Persians, destroyed a number of them, took a good part of their baggage, and some of the king's concubines. Of the war of Odenathus with the Persians, however, we know very little; only that though the latter were often vanquished, and the independence of Palmyra considerably diminished, the former was never released from his captivity, though Odenathus earnestly wished to have the honour of rescuing him from his enemies.

Odenathus enjoyed his sovereignty but a very short time; being murdered by his nephew, who was soon after put to death by Zenobia the wife of Odenathus. This lady is said to have been possessed of very extraordinary endowments both of body and mind, being, according to Mr. Gibbon, almost the only Asiatic woman who is recorded to have overcome the obstacles arising from the confined situation of the fair sex in that part of the world. Immediately on taking vengeance for the murder of her husband, she assumed the government and soon strengthened herself so much, that she resolved to submit neither to the Roman nor Parthian powers. The neighbouring states of Arabia, Armenia, and Persia, dreaded her enmity, and solicited her alliance. To the dominions of Odenathus, which extended from the Euphrates to the frontiers of Bithynia, his widow added the inheritance of her ancestors, the populous and fertile kingdom of Egypt. The emperor Claudius acknowledged her merit, and was content that while he pursued the Gothic war, she should avert the dignity of the empire in the East. The conquest, however, of Zenobia, was attended with some ambiguity; nor is it unlikely that she had conceived the design of erecting an independent and hostile monarchy. She blended with the popular manners of Roman princes the stately pomp of the courts of Asia, and exalted from her subjects the same adoration that
Palmyra. was paid to the successors of Cyrus. She bequeathed to her three sons a Latin education, and often showed them to the troops adorned with the imperial purple. For herself she referred the diadem, with the splendid but doubtful title of Queen of the East.

When Aurelian passed over into Asia, against an adversary whose sex alone could render her an object of contempt, his presence restored obedience to the province of Bithynia, already shaken by the arms and intrigues of Zenobia. Advancing at the head of his legions, he accepted the submission of Ancyra; and was admitted into Tyana, after an obstinate siege, by the help of a perfidious citizen. The generous, but fierce spirit of Aurelian, abandoned the traitor to the rage of the soldiers; a superstitious reverence induced him to treat with lenity the countrymen of Appolonius the philosopher. Antioch was deserted on his approach; till the emperor, by his salutary edicts, recalled the fugitives, and granted a general pardon to all who, from necessity rather than choice, had been engaged in the service of the Palmyrenean queen. The unexpected kindess of such a conduct reconciled the minds of the Syrians, and as far as the gates of Emesa, the widows of the people feconded the terror of his arms.

Zenobia would have ill deserved her reputation, had she indolently permitted the emperor of the West to approach within 100 miles of her capital. The fate of the East was decided in two great battles; so familiar in almost every circumstance, that we can scarcely distinguish them from each other, except by observing that the first was fought near Antioch, and the second near Emesa. In both, the queen of Palmyra animated the armies by her presence, and devoted the execution of her orders to Zabdas, who had already signalized his military talents by the conquest of Egypt. The numerous forces of Zenobia confounded for the most part of light archers, and of heavy cavalry clothed in complete plate. The Moorish and Illyrian horse of Aurelian were unable to sustain the ponderous charge of their antagonists. They fled in real or affected disorder, engaged the Palmyreans in a laborious pursuit, harassed them by a defultory combat, and at length dispersed this impenetrable but unwieldy body of cavalry. The light infantry, in the mean time when they had exhausted their quivers, remaining without protection against a clover onset, exposed their naked sides to the swords of the legions. Aurelian had chosen these veteran troops, who were usually stationed on the Upper Danube, and whose valor had been severely tried in the Allemannic war. After the defeat of Emesa, Zenobia found it impossible to collect a third army. As far as the frontier of Egypt, the nations subject to her empire had joined the standard of the conqueror; who detached Pictus, the bravest of his generals, to posts himself of the Egyptian provinces. Palmyra was the last resource of the widow of Odenathus. She retired within the walls of her capital; made every preparation for a vigorous resistance; and declared with the inconstancy of a heroine, that the last moment of her reign and of her life should be the fame.

In his march over the sandy desert between Emesa and Palmyra, the emperor Aurelian was perpetually harassed by the Arabs; nor could he always defend his army, and especially his baggage from those flying troops of active and daring robbers, who watched the moment of surprise, and defied the slow pursuit of the legions. The siege of Palmyra was an object far more difficult and important; and the emperor, who with incessant vigour pressed the attacks in person, was himself wounded with a dart. "The Roman people, (says Aurelian, in an original letter), speak with contempt of the war which I am waging against a woman. They are ignorant both of the character and of the power of Zenobia. It is impossible to enumerate her warlike preparations, of Horses, of arrows, and of every species of military engines. Every part of the walls is provided with two or three balistae, and artificial fires are thrown from her military engines. The fear of punishment has armed her with a desperate courage. Yet I trust fill in the protecting deities of Rome, who have hitherto been favourable to all my undertakings." Doubtful, however, of the protection of the gods, and of the event of the siege, Aurelian judged it more prudent to offer terms of an advantageous capitulation: to the queen, a splendid retreat; to the citizens, their ancient privileges. His proposals were obstinately rejected, and the refusal was accompanied with insult.

The firmness of Zenobia was supported by the hope, that in a very short time famine would compel the Roman army to repose the desert; and by the reasonable expectation that the kings of the East, and particularly the Persian monarch, would arm in the defence of their moat natural ally. But fortune, and the perseverance of Aurelian, overcame every obstacle. The death of Sapor, which happened about this time, discredited the councils of Persia; and the inconsiderable succours that attempted to relieve Palmyra were easily intercepted either by the arms or the liberality of the emperor. From every part of Syria a regular succession of convoys safely arrived in the camp, which was increased by the return of Probus with his victorious troops from the conquest of Egypt. It is then that Zenobia resolved to fly. She mounted the fleetest of her dromedaries; and had already reached the banks of the Euphrates, about 60 miles from Palmyra, when she was overtaken by the pursuit of Aurelian's light-horse, feized, and brought back a captive to the feet of the emperor. Her capital soon after surrendered, and was treated with unexpected lenity. The arms, horses, and camels, with an immense treasure of gold, silver, silk, and precious stones, were all delivered to the conqueror; who, leaving only a garrison of 600 archers, returned to Emesa, and employed some time in the distribution of rewards and punishments at the end of so memorable a war, which restored to the obedience of Rome those provinces that had renounced their allegiance since the captivity of Valeria.

When the Syrian queen was brought into the presence of Aurelian, he sternly asked her, How the had presumed to rise in arms against the emperors of Rome? The answer of Zenobia was a prudent mixture of respect and firmness: "Because I disdained to consider as Roman emperors an Aurusius, or a Gallienus. You alone I acknowledge as my conqueror and my sovereign." But as female virtue is commonly artificial, so it is seldom ready or confident. The courage of Zenobia deserted her in the hour of trial; she trembled at the angry clamours of the folders, who called...
aloud for her immediate execution; forgot the generous despair of Cleopatra, which she had proposed as her model; ignominiously purchased life by the sacrifice of her fame and her friends. It was to their counsels, which governed the weakness of her sex, that she imputed the guilt of her obstinate refusal; it was on their hands that she directed the vengeance of the cruel Aurelian. The fame of Longinus, who was included among the numerous and perhaps innocent victims of her fear, will survive that of the queen who betrayed, or the tyrant who condemned him.

Genius and learning were incapable of moving a fierce unlettered soldier, but they had served to elevate and harmonize the soul of Longinus. Without uttering a complaint, he calmly followed the executioner, pitying his unhappy mistress, and bestowing comfort on his afflicted friends.

Returning from the conquest of the East, Aurelian had already crossed the straits which divide Europe from Asia, when he was provoked by the intelligence that the Palmyrenians had massacred the governor and garrison which he had left among them, and again erected the standard of revolt. Without a moment's deliberation, he once more turned his face towards Syria. Antioch was alarmed by his rapid approach, and the helpless city of Palmyra felt the irresistible weight of his resentment.

We have a letter of Aurelian himself, in which he acknowledges that old men, women, children, and peasants, had been involved in that dreadful execution, which should have been confined to armed rebellion: and although his principal concern seems directed to the re-establishment of a temple of the sun, he discovers some pity for the remnant of the Palmyrenians, to whom he grants the permission of rebuilding and inhabiting their city. But it is easier to destroy than to restore. The seat of commerce, of arts, and of Zenobia, gradually sunk into an obscure town, a trifling fort with, and at length a miserable village.

Little is known concerning the fortunes of Palmyra since the time of Mahomet, except that it was considered as a place of strength; and that in the 12th century there were 2000 Jews in it. With respect to the ruins they appeared to be of two different and distinct periods; the oldest are so far decayed as not to admit of menstruation, and look as if they had been reduced to that state by the hand of time; the others appear to have been broken into fragments by violence. Of the inscriptions none are earlier than the birth of Christ, and none are later than the destruction of the city by Aurelian, except one, which mentions Dioclesian.

Mr Wood is of opinion, that the face of the country which surrounds Palmyra was always the same; but though Palmyra was always laid to be situated in a wilderness, it does not follow that the wilderness was always of the same extent; it is perhaps more probable, that when Palmyra was first settled the rich soil mentioned by Pliny extended much farther; for whatever were the reasons for making a settlement there, Palmyra can scarcely be supported to have invited a greater number of people than it could feed. The palms and fig trees that were formerly found on the hills, and in the borders of the desert, that are now totally barren confirm this opinion. Mr Wood observes, that while he was there a whirlwind happened, which took up such quantities of sand as quite darkened the sky; this sand therefore might by degrees encroach upon the fertile environs of Palmyra, and reduce the number of inhabitants as it reduced their sustenance, till the few wretched families only were left, who found it difficult to furnish food for Mr Wood and his company, though they did not continue longer than a fortnight among them. It will also appear from history, that what is supposed to have happened here has happened at other places, where such an event was much less probable. * On the sea, Memoir, coasts in the neighbourhood of St Pol de Leon, Acad. Lower Bretagne, there is a considerable tract of land which before the year 1566 was inhabited, but which for 1718 was rendered uninhabitable by a sand, which encroaching every year, covered it to the depth of above 20 feet. In the year 1718 it had advanced more than six leagues, and within one league of St Pol; so that it was then thought probable that the town would of necessity be abandoned. This sand is raised by the east or north-east wind, which drives it in clouds with great swiftness, and in a prodigious quantity. It was also attested by the captain of a ship, and all on board, that in the year 1719 there fell in the Atlantic Ocean, at 15 degrees of north latitude, and at the distance of more than eight leagues from any land, a shower of sand, some of which they produced, and deposited in the academy at Paris.†

The company with whom Mr Wood, the publisher, travelled, arrived at length the end of the plain, where a ridge of barren hills, by which it was divided on the right and left, seemed to meet; between them there was a vale, through which an aqueduct formerly conveyed water to Palmyra. On each side of this vale they remarked several sepulchres of the ancient Palmyrenes, which they had scarce passed, when the hills opening on a sudden, they discovered a vast pile of ruins, as they had never seen. They were all of white marble, and towards them, towards the Euphrates, was a wide level stretching farther than the eye could reach, totally defolate, without variety, and without bounds. After having gazed some time upon this prospect, which rather exceeded than fell short of their expectations, they were conducted to one of the huts of the Arabs, of which there are about 30 in the court of the great temple. The inhabitants of both sexes were well shaped, and the women, though very swarthly, had good features. They were veiled, but did not so scrupulously conceal their faces as the eastern women generally do. They paint the ends of their fingers red, their lips blue, and their eye-brows and eye-lashes black. They had large rings of gold or brass in their ears and nostrils; and appeared to be healthy and robust. The walls of the city are flanked by square towers, into which some ancient funeral monuments have been converted; but the walls are in most places level with the ground, and sometimes not to be traced. It is, however, probable, by their general direction, that they included the great temple, and are three miles in circumference. The Arabs showed a tract which was near ten miles in circumference, the foil of which was raised.
Palmyra

raised a little above the level of the desert; this, they said, was the extent of the old city; and that by digging in any part of it ruins were discovered. These ruins consist of temples, palaces, and porticoes of Grecian architecture; and lie scattered over an extent of several miles. They were accidentally discovered by some English travellers from Aleppo; and thrown from the Sun, of which the ruins are spread over a square of 220 yards. It was encompassed with a flately wall, built of large square stones, and adorned with pilasters within and without, to the number of 62 on a side. Within the court are the remains of two rows of very noble marble pillars 37 feet high, with their capitals of most exquisite workmanship. Of these only 58 remain entire; but there must have been many more, for they appear to have gone round the whole court, and to have supported a double piazza. The whole space of the piazza, which is opposite to the front of the castle, seems to have been the most spacious and beautiful. At each end of this line are two niches for statues, with their pediments, borders, sitters, and canopies, carved with the utmost propriety and elegance. The space within this inclosure, which is now filled with the dirt and rubbish of the inhabitants, seems to have been an open court, in the middle of which stood the temple, encompassed with another row of pillars of a different order, and much taller, being 50 feet high; but of these 16 only remain. The whole space contained within these pillars is 59 yards in length, and near 25 in breadth. The temple is no more than 33 yards in length, and 13 or 14 in breadth. It points north and south; and exactly into the middle of the building, on the west side, is a most magnificent entry, on the remains of which are some vases and clusters of grapes, carved in the most bold and masterly imitation of nature that can be conceived. Just over the door are diercarned a pair of wings, which extends its whole breadth; the body to which they belonged is totally destroyed; and it cannot now certainly be known whether it was that of an eagle or a cherub, several representations of both being visible on other fragments of the building. It is observed of the windows of this building, which were not large, that they were narrower at the top than below. The north end of the building is adorned with the most curious fret-work and bas-relief; and in the middle there is a dome or cupula about ten feet diameter, which appears to have been either hewn out of the rock, or moulded of some composition which by time is grown equally hard. North of this place is an obelisk, consisting of several large stones, besides its capital and the wrought work about it. It is about 50 feet high; and, just above the pediment, is 12 feet in circumference. There was probably a statue upon it, which the Turks, in their zeal against idolatry, destroyed. At about the distance of a quarter of a mile from this pillar, to the east and west, are two others, besides the fragment of a third; so that perhaps they were originally a continued row.

About 100 paces from the middle obelisk, straight forward, is a magnificent entry to a piazza, which is 40 feet broad, and more than half a mile in length, inclosed with two rows of marble pillars 26 feet high, and eight or nine feet in compass. Of these there all remain 129; and, by a moderate computation, there could not originally have been left that 560. The upper end of the piazza was fluted by a row of pillars, standing somewhat closer than those on each side. A little to the left are the ruins of a flately building, which appears to have been a banquetting-hall. It is built of better marble, and is finished with yet greater elegance, than the piazza. The pillars which supported it were of one entire stone, which is so strong, that one of them which has fallen down has received no injury. It measures 22 feet in length, and in compass 8 feet 9 inches. In the wide side of the piazza there are several apertures for gates into the court of the palace. Each of these were adorned with four porphyry pillars, not standing in a line with those of the wall, but placed by couples in the front of the gate facing the palace, two on each side. Two of these only remain entire, and but one standing in its place. They are 30 feet long and 9 in circumference. On the east side of the piazza stands a great number of marble pillars, some perfect, but the greater part mutilated. In one place 11 are ranged together in a square; the space which they inclose is paved with broad flat stones, but there are no remains of a roof. At a little distance are the remains of a small temple, which is also without a roof, and the walls are much defaced. Before the entry, which looks to the south, is a piazza supported by six pillars, two on each side of the door, and one at each end. The pedestals of those in front have been filled with inscriptions both in the Greek and Palmyrene languages, which are become totally illegible. Among these ruins are many sepulchers: they are ranged on each side of a hollow way, towards the north part of the city, and extend more than a mile. They are all square towers, four or five stories high. But though they are alike in form, yet they differ greatly in magnitude and splendour. The outside is of common stone, but the floors and partitions of each story are marble. There is a walk across the whole building, just in the middle; and the space on each hand is subdivided into six partitions by thick walls. The space between the partitions is wide enough to receive the largest corpse; and in these niches there are six or seven piled upon one another.

Many inscriptions have been found at Palmyra, which have occupied much of the attention of the learned; and if anything certain could be derived from them, there is no doubt but they would tend very considerably to the elucidation of ancient history. See Batehlemey's Reflections on the Palmyrene Alphabet, published at Paris in 1754; and an Explanation of the Inscriptions at Palmyra hitherto published, by John Swinton of Chrift church, Oxford. See also Phil. Trans. n° 217. and 218; the first volume of the Ancient Universal History; and, above all, confult the Ruins of Palmyra, or Tadmor in the Desert, published by Mr R. Wood, who with M. Bouvier and Mr Dawkins, travelled thither in 1751. The result of their observations was published in 1758, in the form of an atlas. The ruins of this once mighty and celebrated city are represented in 37 copperplates, 16 by 12 inches, printed on imperial paper. They are admirably executed; the drawing is correct and masterly; and the gravings highly finished: nor can they fail to give satisfaction to those who are connoisseurs in the art, or to those who

4 R 2
Delight in the labours of antiquity. In a work like ours, however, it is impossible to give these views at length; we shall content ourselves then, after referring to this splendid work, with a view of the ruins of the Temple of the Sun, and of some other miscellaneous ruins.

Palmyra was visited by Mr Bruce before his journey into Abyssinia; but, on account of the many publications concerning these celebrated ruins, he declined saying much concerning them. He informs us, that, before he came in flight of the ruins, he ascended a hill of white gritty stone, in a very narrow winding road, such as is called a path; but on getting up to the top his eyes were struck with the most stupendous sight which, he believes, ever mortal saw. The whole plain below, which is very extensive, was fo covered with magnificent buildings, that they seemed to touch one another. All of them are finely proportioned, agreeably shaped, and composed of white stones, which at that distance appeared like marble. In taking a draught of these ruins, Mr Bruce divided the whole into six angular views, for which the situation of the place is very convenient. The columns are all uncovered to the very bases, the ground on which they are built being hard and solid. The views he took were upon large paper; some of the columns being represented a foot long, and some of the figures in the foreground of the Temple of the Sun (a magnificent building which stood at one end of the town) being near four inches. Before he left Palmyra he observed its latitude with a reflecting quadrant of Hadley; but as the instrument was out of order, he could not determine it exactly. In his opinion, however, 33° 58' is not far distant from truth. From such observations as he could make on the longitude, he concluded it to be 37° 9' east from Greenwich. Mr R. Wood makes the latitude 34° north.

From Palmyra Mr Bruce proceeded to Baalbec, distant about 130 miles, where he found ruins still more magnificent. The interior part of the great temple at this place, according to our author, surpasses any thing he had seen at Palmyra, or anywhere else.

"All these views of Palmyra and Baalbec (says he) are now in the king's collection. They are the most magnificent offering, in their line, that ever was made by one subject to his sovereign."—In the neighbourhood of Palmyra are some salt-marshes; and to the adjacent country a trade is carried on in kelp from Tripoli in Syria. There are two Arab tribes, almost equally powerful; one of them, called Annecy, remarkable for the finest horses in the world. They possess the country to the south-west, at the back of Liburnus, about Bozrah, and southward towards the borders of Arabia Petraea and Mount Horeb. The other tribe, named Mowali, inhabits the plains east from Damascus, to the Euphrates, and north to near Aleppo. They are fewer in number than the Annecy, but much better riders; and their breed of horses not greatly inferior.

Reflecting the latitude and longitude there are still various opinions, that which appears to be nearest the truth is E. Long. 38°, 50° N. Lat. 33°, 20'. It stands about 50 leagues south-east of Aleppo, as much from Damascus, and 20 leagues west of the Euphrates.

**PALPABLE**, something perceivable by the senses, particularly that of feeling.

**PALPITATION of the Heart.** See Medicine, Palpitation.

**PALSgrave (John), a learned writer, who flourished in the reigns of Henry VII. and Henry VIII.** He received his grammatical learning at London, his native place. He studied logic and philosophy at Cambridge, at which university he resided till he became bachelor of arts; after which he went to Paris, where he spent several years in the study of philosophy and other parts of learning, took the degree of master of arts, and acquired such excellence in the French tongue, that in 1514, when a treaty of marriage was negotiated between Louis XII. king of France, and the Princess Mary, sister of Henry VIII. of England, Mr Palgrave was appointed to be her tutor in that language. But Louis XII. dying soon after his marriage, Palgrave attended his fair pupil back to England, where he taught the French language to many of the young nobility, obtained good preferment in the church, and was appointed by the king one of his chaplains in ordinary. In 1531 he settled at Oxford for some time, and the next year was incorporated master of arts there, as he had before been in Paris, and a few days after was admitted to the degree of bachelor of divinity. At this time he was much esteemed for his learning; and what is very remarkable, though an Englishman, he was the first who ever reduced the French tongue to grammatical rules, or that had attempted to fix it to any kind of standard. This he undertook, and executed with great ingenuity and considerable success, in a large work which he published in that language at London, intituled L'Éclaircissement de la Langue Françoise, in three books in thick folio, 1530, to which he has prefixed a large English introduction, so that the French nation seems to stand originally indebted to England for that universality which their language at present possess, and on which they so much pride themselves. He translated into English a Latin comedy called Acolaphus, written by one Will. Fullovius, an author then living at Hagen in Holland.

At what time Mr Palgrave was born, or how long he lived, it is not easy to say; yet, from the concurrence of several facts, he appears to have been much less than 60 years of age at the time of his publishing the above-mentioned translation, which was in the year 1540.

**Palsy.** See Medicine, Palpitation.

**Paludamentum, in Roman antiquity, a habit that differed but little from the chlamys, except that this last belonged chiefly to the lower class of people. It was worn by the officers and principal men among the Romans in time of war, who are therefore called Paludati; which distinguished them from the common soldiers, who, because they wore the fagum, were called the Segati.** The paludamentum came down only to the navel, was open on the sides, had short sleeves resembling angels wings, and was generally white or red. It is sometimes used to signify the common soldier's coat.

**Palus Meditis, the ancient name of a gulf between Europe and Asia, to the north of the Black Sea, now called the sea of Zaback, or Afric.**

**Paly, or Paly, in heraldry, is when the shield is divided;**
Ruin of the Ancient City of Palmyra.

The Remains of the Great Temple of the Sun in Palmyra from the West.
PAN

PAN... for he was their most ancient god; and we are told by Plutarch, "That they took the first God and the Universe for one and the same thing." Hence his name παν among the Greeks; not that either the Greeks or their masters in theology worshipped, as the first god, mere brute matter, but that spirit which they conceived to be coeternal with matter, and to animate all things, making them one. Thus Orpheus, who imported the Egyptian doctrine into Greece, declares that all things are one; and after him Parmenides, and other philosophers, taught, αἰώνίος τὸ πάν, that "one is the universe!" and that "the universe is immoveable." That the ancient Greek Pan, or the Egyptian Mened, was not the corporeal world, as feneilefs and inanimate, but the whole system of things, animated and eternal, appears further from the following testimony of Macrobius: "Hunc deum Arcades colunt, appellantes παντας όλους ψυχες, non sylvarum dominum, fed univerae flbilatane materias dominatorum;—The Arcadians worship this god, calling him the Lord of all; i.e., not the Lord of the woods, but the Lord of all material substance." In the same manner, Pharnamus, describes the Pan of other Greek gods, not as the corporeal world, though, but as the intellectual principle acting upon and preordinating over it; and he adds, that "Pan was taigned to be mythologicall, lascivious, because of the multitude of pernicious r.uses ret. in the world, and the continual mixtures and generation of things."

The Egyptians, as we learn from Jablonski, had nearly the same notion with the Greeks of the spirit which they worshipped as the Soul of the Universe; on y they gave to it both sexes. As the maker, governor, and bountiful father of universal nature, they considered it as a male, whose symbol was the he-goat of Menedes; and as a female it was adored by the name of θυε, to whom the she-goat was consecrated, though not held in such veneration as the male. From this view of the Egyptian creed, the sacrifice which we have mentioned appears no longer accountable. It was made to a god, believed to be the universal source of fecundity, and to whom, from the well-known character of the animal, whom he was supposed to actuate, they had reason to believe it would be most acceptable.

The Greeks never worshipped their Pan by the emblem of a living goat; but they painted him with the lower parts of a goat, for a reason which shall be afterwards mentioned. How he came to degenerate among people, from one of the Dii majorum gentium, or rather from the first principle of all things, to the rank of a demon or demi-god, we cannot pretend to say; but that such was his fate, is certain; for under this last character mention is made both of his birth and his death.

Whole he was, is not agreed among them. Homer makes him the son of Mercury, and says he was called Παν from πάν, because he charmed all the gods with his flute; others say that he was the son of Demogorgon, and first invented the organ, of seven unequal reeds, jointed together in a particular manner; Having on a time fought with Cupid, that god in spite made him fall in love with the cym nymph Syrinx, who, flying from him to the banks of Fadon, a river of Arcadia, at the instant prayers of the nymphs was turned into...
Pan

a reed, as her name in Greek signifies, which the god
grasping instead of her, made a pipe of it, and for his
music was adored by the Arcadians. The most com-
on sense was, that he was the son of Mercury and
Penelope. But Nat. Com., out of Doris Sanitus,
me his birth scandalous, by saying he was called Pan,
became begot by all Penelope's suitors. He was paint-
ed half-man half-goat, having large goat's horns, a chap-
let of pine on his red face, a pleasant laughter, with
the feet and tail of a goat; a motley skin covering his
body, with a crooked stick in one hand and his pipe
in the other. See him nicely described by

His festival was celebrated on February 15th by the
Romans, brought into Italy by Evander the Arc-
adn, and revived afterwards by Romulus, in mem-
y of his predecessor. He was also called by the Ro-
I. 22. and Serv. in Virg. Æn. VI. 775. The an-
tics, by giving so many adjuncts and attributes to this
idol as we have observed above, seem to have design-
ed him for the symbol of the universe; his upper parts
being human, because the upper part of the world is
fair, beautiful, smiling, like his face; his horns sym-
bolize the rays of the sun and of the moon; his red
face, the splendor of the sky; the spotted skin whereby
he is clothed, the stars which bespangle the firm-
ament; the roughness of his lower parts, beards and
vegetables; his goat's feet, the solidity of the earth;
his pipe, composed of seven reeds; the seven planets,
which they say make the harmony of the spheres; his
crook, bending round at the top, the years circling
in one another. Serv. Interpr.

Having said so much of Pan, both as a self-existent
god and as a generated daemon, we shall conclude the
article with some observations on Plutarch's account of
the prodigy which happened at his death; for in the
Pagan creed, daemons were not all believed immoral-
—In the reign of Tiberius (says our author),
certain perons on a voyage from Asia to Italy, and
tailing towards the evening by the Echinedes, were
there becalmed, and heard a loud voice from the shore
calling on one Thamus an Egyptian pilot whom they
had on board. Thamus, as may be supposed, listened with attention; and the voice, after re-
peating his name thrice, commanded him when he
came to the Peleus, to declare that the Great Pan
was dead. The man, with the advice of his com-
patriots, resolved, that it they should have a quick gale
off the Palodes, he would pass by in silence; but that
if they should be becalmed, he would perform what
the voice had commanded. Adhering to this resolu-
tion, they soon arrived off the destined islands, and
were immediately becalmed, there being neither breath
of wind nor agitation of water. Upon this Thamus
looking from the hinder part of the ship toward the
land, pronounced with a loud voice &c. at Tiber. 98
The Great Pan is dead! and was instantly anw,ered from
the shore by numberless howlings and lamentations.

This story, which has so much the air of impor-
tance, has not only been admitted as truth by men of
the first eminence for learning and acuteness, but has
been applied to our Saviour, whose death (says Cud-
worth) the daemons mourned, not from love, but from
a preface that it would put a period to the tyranny and
domination which they had so long exercised over
the souls and bodies of men. In support of this opi-
nion, he quotes several passages of Scripture, such as,
"Now is the prince of this world judged," and, "Ha-
vie spoiled principaliies and powers (by his death
upon the cross), he triumphed over them in it." He
affirms likewise, that "Pan being taken for that rea-
on or understanding by which all things were made,
and by which they are all governed, or for that di-
vine wisdom which distilleth itself through all things,
is a name which very well signify God mani-
fested in the flesh."

The authority of Cudworth is great; but a ground-
less opinion has seldom been propped by weaker rea-
tion than he makes use of on this occasion. Plu-
tarch indeed says, and seems to believe, that this pro-
digy fell out during the reign of Tiberius; but as he
mentions not the year of that reign, there is no evi-
dence that it was at the crucifixion of our Savi-
our. The daemons who inhabited the Echinedes
knew what had been transacted at Jerusalem far di-
fant from their islands; they knew the name of the pilot
of a strange ship; they knew that the mariners of that
ship had resolved to disobey their command, unless
becalmed off the Pelodes; they had power over both
the winds and waves at the Pelodes, and exerted that
power to enforce obedience to their command; and
yet these all knowing and powerful beings were un-
der the necessity of calling in the aid of a da-
emon, (so he is called,) who inhabited the Ech-
inedes, in order to make the Pagan mariners becalme.

Should it be said that the daemons were compelled by divine power thus pub-
lincly to make known to man Christ's triumph over
the kingdom of darkness, we beg leave to ask why
they were not likewise compelled to give him another
name, since it is certain, that at the era of Tiberius,
and long before, illiterate Pagans, such as common
sheep must be supposed to have been, knew no other
Pan than the fabled son of Penelope and Mercury?—
Indeed the other Pan, taken for that reason or un-
derstanding by which all things were made, could not
possibly be the being here meant; for, erroneous as the
Pagan system was, there is nothing in it to completely
aburd as the death of the soul of the universe, the
maker of all things; nor do we believe that any Pa-
gan ever existed, who dreamed that such a death was
possible.

What then, it will be asked, are we to understand
by
Panama. 

Panama. 

by this story? Plutarch was eminent for knowledge and integrity, and he relates it without expressing a doubt of its truth. He does so; but many a man of worth has been credulous; and though that was not his character, this *prodigy* may be accounted for by natural means. Germanicus was believed to have been poisoned, at least with the knowledge, if not by the command, of Tiberius; and there was nothing which the Romans so deeply deplored as the untimely death of that accomplished prince*. They fancied that his body was animated, not by a human soul, but by a superior daemon: and they decreed to him statues, religious ceremonies, and even sacrifices. His widow was highly honoured, as having been nearly related to a divinity, and his children were adored as demi gods.

Thee facts being admitted, nothing appears to us more probable than the opinion of the learned Mo- theim, who thinks that some shrewd adventurer, who had the preceding year taken impossible to be in *Anns.* Tacit. Vol. ii. 

et lib. iii. cap. 72. 8; et lib. iii. cap. 1.

Note 132.

† Cud- worth's  Anq.  

Intell. Synt.  cap. 4.

Panama, the capital city of the province of Da- rien in South America, where the treasures of gold and silver, and the other rich merchandises of Peru, are lodged in magazines, till they are sent into Europe. W. Long. 82. 15. N. Lat. 8. 57.

When Guzman first touched at this place in 1514, it consisted entirely of fishermen huts. Orios d'Avila settled a colony here in a few years after, and in 1521 it was constituted a city by the emperor Charles V. with the proper privileges. In 1670 it was sacked and burnt by John Morgan, an English adventurer, who had the preceding year taken Porto Bello. This misfortune induced the inhabitants to remove the city to its present situation, distant about a league from the place where it stood before. For the greater security, the new city was inclosed by a free-stone wall, and the houses were built of stone and brick. Since that time several battlements have been added, and now there is always a complete garrison maintained, and the walls are mounted with large cannon. But all these precautions could not save this city from another misfortune; it was entirely consumed by fire in the year 1737. After this accident it was again rebuilt; in the manner as it now stands, with neat elegant houses, but not magnificent. The inhabitants are rather independent in their fortunes than rich; there are few of them opulent, and scarce any in a state of poverty. As to the harbour, it is convenient, and well secured against storms by a number of surrounding islands, and is capable of containing the largest fleets. Here the royal audience is seated, at which the governor of Panama resides; for which reason, this city is commonly deemed the capital of the province.

This place, a little while after it was founded, became the capital of the kingdom of *Terra Firme.* Some hopes were at first entertained from the three provinces of Panama, Darien, and Veragua, which composed it; but this prosperity vanished insantly.

The savages of Darien recovered their independence; and the mines of the other two provinces were found to be neither sufficiently abundant, nor of an alloy good enough to make it worth while to work them. Five or six small boroughs, in which are seen some Europeans quite naked, and a very small number of Indians who have come to reside there, form the whole of this state, which the Spaniards are not ashamed of honouring with the great name of kingdom. It is in general barren and unwholesome, and contributes nothing to trade but pearls.

The pearl fishery is carried on in the islands of the gulf. The greatest part of the inhabitants employ much of their negroes in it as are good swimmers. These slaves plunge and replunge in the sea in search of pearls, till this exercise has exhausted their strength or their spirits.

Every negro is obliged to deliver a certain number of oysters. Those in which their are no pearls, or in which the pearl is not entirely formed, are not reckoned. What he is able to find beyond the stipulated obliga- tion, is considered as his indispensible property; he may sell it to whom he pleases; but commonly he cedes it to his master at a moderate price.

Sea monsters, which abound more about the islands where pears are found than on the neighbouring coasts, render this fishing dangerous. Some of these devour the divers in an instant. The manta fish, which derives its name from its figure surrounds them, rolls a frame under its body, and then secretes them. In order to defend themselves against fierce enemies, every diver is armed with a portad; the moment he perceives any of these voracious fish, he attacks them with precaution, wounds them, and drives them away. Notwithstanding this, there are always some fishermen destroyed, and a great number crippled.

The pearls of Panama are commonly of a very fine water. Some of them are even remarkable for their size and figure; these were formerly fold in Europe. Since art has imitated them, and the passion for diamonds has entirely superseded or prodigiously diminished the use of them, they have found a new martmore advantageous than the first. They are carried to Peru, where they are in great estimation.

This branch of trade has, however, infinitely less contributed to give reputation to Panama, than the advantage which it hath long enjoyed of being the mart of all the productions of the country of the Incas that are defined for the old world. These riches, which are brought thither by a small fleet, were carried, some on mules, others by the river Chagre, to Porto Bello, that is situated on the northern coast of the Isthmus, which separates the two seas. See Da- rien.

Panari, one of the Lipari islands, lying in the, Tucan Sea. It is only five miles in circumference;
PAN, and the soil is barren. E. Long. 15. c. N. Lat. 39. o.

PANARO, a river of Italy, which rises in the Appennines, crosses the valley of Frignano, and running on the confines of the Modone and Bologna, waters Porden, and falls into the Po at Bondeno, ten miles above Ferrara.

PANATHENAEAE, in Grecian antiquity an ancient Athenian festival, in honour of Minerva the protectress of Athens, and called Athenæa. Harpocrates and Sibyls refer the institution of this festival to Erichthonious IV, king of Athens, who lived before Theseus. Theoreot alone says the feast was established by Orpheus. Be this as it will, till Theseus it was never a particular feast of the city of Athens, and was called simply Athenæa; but that prince, uniting all the people of Attica into one republic, they afterwards all assisted at the feast; whence the name Panathenæa, i.e. the feast of all Attica. In effect all Attica was present; and each people sent a bulllock for the sacrifices, and for the entertainment of the vast multitude of people assembled.

There were two festivals under this denomination, the greater and the lesser. The greater panathenæa were exhibited every five years; the less every three, or, according to some writers, annually. Though the celebration of neither, at first, employed more than one day; yet in after-times they were protracted for the space of many days, and solemnized with greater preparations and magnificence than at their first institution.

The ceremonies were the same in the great and the little panathenæa; excepting for a banner, wherein the actions of the gods were represented in embroidery. Pericles, according to some writers, was the first to have been instituted by Pericles. Singers of the first class, accompanied by performers on the flute and cithara, excelled their talents here, upon subjects prescribed by the directors of those exhibitions.

The following is the order observed in this festival, according to M. Barthélemy, who quotes numerous authorities on the occasion: "The inhabitants of the different towns of Attica thronged to the capital, leading with them a great number of victims defined for sacrifices to the gods. In the first morning were the horse-races, in which the sons of the first citizens of Athens contended for the honour of the victory. In the stadium were other young men struggling for the prize at wrestling; and different exercises of the body; and in the Odium were several musicians engaged in gentle and less serious contests. Some executed pieces on the flute or cithara; others sang, and accompanied their voices with one of these instruments. The subject proposed to them was the eulogium of Harmodius, Aristogiton, and Thrasylus, who had rescued the republic from the yoke of the tyrants by which it was oppressed; for, among the Athenians, public institutions are so many monuments for the citizens who have served the state, and leons for those who are called upon to render it service. A crown of olive, and a vessel filled with oil, were the prizes bestowed upon the victors. Crowns were afterwards conferred on individuals, who appeared to the people to have merited that mark of honour by their zeal in the service of their country."

"At the Ceramicus passed a procession, formed without the walls, and which began at that place to file off. It was composed of different classes of citizens crowned with chaplets of flowers, and remarkable for their personal beauty. Among the number were old men of a majestic and venerable appearance, bearing branches of olive; middle-aged men, who, armed with lances and with bucklers, seemed only to prepare for war; youths from eighteen to twenty, who sang hymns in honour of the goddess; beautiful boys, clad in a simple tunic, adorned only with their native graces; and, lastly, girls, who were of the first families in Athens, and whose features shaped, and deportment, attracted every eye. With their hands they held baskets on their heads, which, under a rich veil, contained sacred utensils, cakes, and every thing necessary for the sacrifices. Female attendants, who followed them, with one hand held over them an umbrella, and carried in the other a folding chair. This is a species of servitude imposed on the daughters of all foreigners settled at Athens: a servitude they share in common with their fathers and mothers, who likewise carried on their shoulders vessels filled with water and honey, for the purpose of libations. They were followed by eight musicians; four of whom played on the flute and four on the lyre. After them came rhapsodists finging the poems of Homer; and dancers, armed at all points, who, attacking each other at intervals, represented, to the sound of the flute, the battle of Minerva with the Titans. Next came a ship that appeared to glide over the ground by the power of the wind, and the efforts of a great number of rowers, but which really was put in motion by concealed machinery. The vessel had a fail of light stuff, on which young girls had represented in embroidery the victory of Minerva over the Titans. On it also they had depicted, by order of the government, some heroes whose illustrious deeds had merited to be celebrated with those of the gods. This procession marched on with solemn steps, under the direction of several magistrates; and traversed the most frequented quarter of the city amid a crowd of spectators, most of whom were placed on scaffolds erected for the occasion. When it had reached the temple of the Pythian Apollo, the ship of the flate was taken down and carried to the Acropolis, where it was deposited in the temple of Minerva."

"In the evening, at the academy, was the torch race. The course is only fixed or seven stadia in length. It extends from the altar of Prometheus, which is at the gate of this garden, to the walls of the city. Several young men are stationed in this interval at equal distances. When the flutes of the multitude have given the signal, the first lights his flambeau at the altar, and running with it hands it to the second, who transmits it in the same manner to the third, and so successively. He who suffers it to be extinguished can no more enter the lists; and they who slacken their pace are exposed to the raillery, and even blows, of the
The flower-flake rose from the divisions of the foot-talk of the leaves; but before the flowers opened, the plant decayed.

Ginseng was formerly supposed to grow only in Chin
eese Tartary, affecting mountainous situations, haled
close woods; but it has now been long known that this
plant is also a native of North America, where M.
Sarratif transmitted specimens of it to Paris in the
year 1704, and the ginseng flourished in Canada.

PANAX, Ginseng: A genus of the dicot order,
belonging to the polygama eals of plants. There are
five species of this plant. 1. Quinquefolium. 2.
Trifolium. 3. Fruticosum. 4. Arborea. 5. Spinula.

The flowers appear on slender f oot-stalks, just
at the division of the foot-flakes which sustain the
leaves, and are formed into a small umbel at the top:
they are of an herbaceous yellow, composed of
small yellow petals which are recurved. Woodville*
says they are white; that they are produced in a
roundish or-rimal umbel, and are hermaphrodite
or male on separable plants. The former (see the Plate)
flourish in clove simple umbels: the involucrum
consists of several small, tapering, pointed, permanent
leaves: the proper calyx is tubular, and divided at the
rim into five small teeth: the corolla consists of five
petals, which are oval, equal, and reflexed: the
filaments are five, short, and furnished with fimple
anthers: the germ is roundish, placed below the coro
lla, and supports two short erect styles, crowned by
simple stigmata: the fruit is an umbilicated two-celled
berry, each containing a single irregularly heart-shaped
seed. The flowers appear in the beginning of June;
and are succeeded by compressed, heart-shaped berries,
which are first green, but afterwards turn red; incising
two hard, commiserated, heart-shaped seeds, which ripen
in the beginning of August. The second fruit grows
naturally in the same countries: but Mr. Miller
never saw more than one plant, which was sent to him
from Maryland, and did not live beyond the first year;
being planted in a dry field, in a very dry situation.
The leaf was single, and did not rise more than five inches
in height, dividing into three foot-flakes, each furnished
a trifoliate leaf, whose lobes were longer, narrower,
and deeper indented on their edges, than the former.

* Medical Botany.

The dried root of ginseng, as imported here, is
frequently the thickness of the little finger, about three
or four inches long, frequently forked, tranversely
wrinkled, of a horned texture, and both internally and
externally of a yellowish white colour. On the top
are commonly one or more little knots, which are the
remains of the flake of the preceding years, and from
the number of which the age of the root is judged.

To the table it discovers a much more sweetness,
approaching to that of liquorice, accompanied with
some degree of bitterness, and a slight or mace
ymmetric, with little or no smell. It is far sweeter,
and of a more grateful smell, than the roots of ferreus,
to which it has by some been supposed similar; and
differs likewise remarkably from those roots in the
nature and pharmacological properties of its active
principles, the sweet matter of the ginseng being prefrred
entire in the watery as well as the spirituous extract,
whereas that of ferrum is destroyed or dissipated
in the impregnation of the watery tincture. The slight
atmospheric impregnation of the ginseng is likewise:
good measure retained in the watery extrac, and per
fectly in the spirituous.*

Proper Isl. The Chinese ascribe extraordinary
virtues to the root of ginseng; and have long considerg
it as a foreign remedy in almost all diseases to which
they are liable, having no confidence in any medicine
unless in combination with it. It is obtained by Jar.

489

* Lewis' Nat. Med.

Sarratif was correspondent of the Royal Academy of Sciences, in the history of which his account was published in 1718.

(a) The Chinese ate the whole roots in some measure according to their figure, expecting those very highly which are regularly forked, or have a fancied resemblance to the human form.
PAN... [690]... PAN

PANAX, that the most eminent physicians in China have written volumes on the medicinal powers of this plant; asserting, that it gives immediate relief in extreme fatigue either of body or mind; that it dissolves putrid humour, and renders respiration easy; strengthens the stomach; promotes appetite; stops vomiting; removes hysteric, hypochondriacal, and all nervous affections; and gives a vigorous tone of body even in extreme old age. These, and many other effects of this root equally improbable and extravagant are related by various authors; and Jartoux was so much biaised by this external prejudice in favour of ginseng, that he seems to have given them full credit, and confirms them in some measure from his own experience. He says "Nobody can imagine that the Chinese and Tartars would set so high a value upon this root, if it did not constantly produce a good effect."—I observed the state of my pulse, and then took half of a root raw: in an hour after I found my pulse much fuller and quicker; I had an appetite, and found myself much more vigorous, and could bear labour much better and easier than before. But I did not rely on this trial alone, imagining that this alteration might proceed from the root. I had that day; but four days after, finding myself so fatigued and weary that I could scarcely sit on horseback, a mandarin who was in company with us perceiving it, gave me one of these roots: I took half of it immediately, and an hour after, finding my pulse more quick and forceful, I gave the second dose. We know, however, of no proofs of the efficacy of ginseng in Europe; and from its sensible qualities we judge it to possess very little power as a medicine. Dr Cullen says, "We are told that the Chinese consider ginseng as a powerful aphrodisiac; but I have long neglected the authority of popular opinions, and this is one instance that has confirmed my judgment. I have known a gentleman, a little advanced in life, who chewed a quantity of this root every day for several years, but who acknowledged he never found his faculties in this way improved by it."

A dram of the ginseng root may be sliced and boiled in a quarter of a pint of water to about two ounces; then a little sugar being added it may be drank as soon as it is cool enough. The dose must be repeated morning and evening; but the second dose may be prepared from the same portion of root which was used at first, for it may always be twice boiled.

PANAY, an island of Asia, and one of the Philippine group lying between those of Paraguay and Negro. It is 250 miles in circumference, and is the most populous and fertile of them all. It is watered by a great number of rivers and brooks, and produces a great quantity of rice. Its shape is triangular. The names of its principal capes are Potol, Nafo, and Bulacabi. The coast from Bulacabi to Potol lies east and west, from Potol to Nafo, north and south; from Bulacabi to Iloilo, another cape, less than the great ones, is also north and south; from Iloilo to Cape Nafo, east and west. The middle of the island is in the latitude of ten degrees. On the north side, almost in the middle between the two capes of Potol and Bulacabi, the famous river Panay falls into the sea; and the mouth of the harbour is covered by a small island called Lutaya, in which port the Spaniards had a fresh retreat before they discovered and conquered Manila and Cavite. The fertility of Panay is caused by the many rivers that water it, for there is no travelling a league without meeting a river; but more particularly by the Panay, which gives its name to the island, and runs a course of 40 leagues. The island, for the better administering of justice, is divided into jurisdictions: the first, called Panay, contains all that lies between Cape Potol and Bulacabi; the rest of the island is subject to the alcayde of Otton, who refides at Iloilo, a point of land running out into the sea, on the south side, between the two rivers of Tig Bavan and Jaro, and, with the island Imaras, forms a frigate not above half a league over, or rather an open harbour. On this point the governor Don Gonzalo Ronquillo caused a fort to be built in the year 1681. The island contains about 16,360 tributary Indians, partly belonging to the king and partly to particular encomienderos or lords; but they all pay in rice, the island producing 100,000 bushels, Spanish measure, and but little other grain. The inhabitants are stout, lusty, and industrious farmers, and expert hunters. They live in the most uncouth parts of the mountains with their wives and children, all naked like beasts. They are so swift that they often overtake wild boars and deer. They fly about the dead beast as long as it lasts; for they have no other subsistence but what they acquire with their bow and arrows. They fly from the Spaniards, not much through hatred as from fear. Among the islands about Panay lies Imaras opposite to Iloilo, and about a quarter of a league distant. It is long and low, ten leagues in compass and three in length, the soil fertile, abounding in farafruita, and exceeding good water. On the mountains there are wild boars, deer, and good timber. It has also in it the port of St Anne, three leagues from Iloilo.

PANCARPIUS, in Roman antiquity, a kind of how which the Roman emperors frequented exhibited to the people. The word is formed from the Greek πανερπιόν, and νεφρός fruit. Whence the name was also given by the Athenians to a sacrifice wherein all kinds of fruits were offered. In this spectacle, the Circus being all set over with large trees, represented a forest, into which the beasts being let from the dens underground, the people at a sign given by the emperor, pursued, shot, and killed all they could lay hold of, which they afterwards carried away, to regale upon their return home. The beasts usually given on these occasions were boars, deer, oxen, and sheep.

Calaubon, Cujas, Pithion, &c. make the pancarpus and
PANCRASS, a town of England, in the county of Middlesex, on the north-west side of London, in the highway to Cesthshire-town. Its church is one of the prebends of St. Paul's, of which cathedral some call it the mother, it being thought to be as old as that church even in the reign of Queen Elizabeth, when it is re-prestent as weather-beaten and standing alone, without any company, though it had formerly many buildings about it. In its church-yard lie many Roman Catholics. At a public-house on the fourth side of the church is a medicinal spring.

PANCRATIUM (compound of masc. all, and n prate I overcome), among the ancients, a kind of intermixed exercise, consisting of the lutra or wrestling, and the boxing or pugilate: but it differs in this, that as the athlete are not to feize the body their hands are not armed with gauntlets, and give less dangerous blows. The panкратium was the third gymnastic exercise, and was not introduced till long after the others. The people who were engaged in these exercises were called panкратиατες; which name was also given to fuch as did not confine themselves to one exercise, but succeeded in several different ones.

Barthelemi, in his travels of Anacharhis, gives us a short account of one of thofe at which he supposes him to have been present in thefe words: "The action was soon terminated: a Sicayan named Sophratus, a champion celebrated for the number of prizes he had won, and the strength and skill which had procured them, had arrived the preceding day. The greatest part of the combatants yielded up all pretentions to the crown as soon as he appeared, and the others on the first trial; for in those preliminary essays, in which the athletes try their strength by taking each others hands, he squeezed and twisted the fingers of his adversaries with such violence as instantly to decide the victory in his favour."

PANCREAS, in anatomy. See there, n° 95.

PANDA, in mythology, a god who was invoked and honoured as the protector of travellers and navigators. The goddes of peace was also called Pandar, because she opened the gates of cities which were shut in time of war. According to Varro, Panda is a surname of Ceres, derived from panda danda, because she gave bread to mankind.

PANDATARIA (Suetonius, Pliny, Strabo);
PANDATERIA (Mela, Tacitus): An island in the Tuscian sea; a place of banishment for the more illustrious exiles. Hibris Julia, the Daughter of Augustus, was banished for her incontinence. To this island Tib-rius banished Agrippina, his daughter-in-law (Suetonius). It was the place of confinement of Othav the son of Claudius, married to Nero; a fight that affected every eye (Tacitus). Now Santa Maria, situated between Ponta and Ichin (Holtenius).

PANDEICT, in jurisprudence, the digest or collection, made by Justinian's order, of 534 decisions or judgments of the ancient lawyers, on so many questions occurring in the civil law; to which that emperor gave the force and authority of law, by the epistle prefixed to them.—The word is Greek, Pandectes, composed of pan "all," and dektai cognite, "I take," i.e., a compilation, or a book containing all things.—Though others, as Bartoli, will have it formed from pan, and dektae; as if those books contained the whole doctrine of the law.

The pandects consist of 50 books, and make the first part of the body of the civil law.

They were denoted by two μ, but the copists took those μ for μ, the custom arose of quoting them by ff.

In the year 1137, the pandects of Justinian, which had been brought by an Amalitan merchant from the east, fell into the hands of the Pisans. Angelus Politianus believes this copy to be that which had been compiled by order of the emperor. However that be, it is certain that all other copies are taken from it, as being the most ancient. The Pisans having obtained their request from the emperor, carried the volumes to Pisa, and for near three centuries they were known by the name of the Pandecte Pisan. But, about the year 1416, Pisa being taken by the Florentines, they were transported from thence to Florence, where they are now preserved in the library of the Medici, and known by the name of the Pandecte Florentins. Some authors allege, that Lotharius ordained by an edict that the Pandects should be publicly read and explained at Bologna, and pleaded in the tribunals; but Corringer and Lindenbrogius fully refuse their opinion.

Papies extends the denomination of Pandeta to the Old and New Testament.

There are also Pandecta Medicae, "Pandects of Medicine," a kind of dictionary of things relating to medicine, compiled by Mat. Sylvaticus of Mantua, who lived about the year 1297. Leunclavius has published Pandects of Turkey; and bishop Beveridge, Pandeta Christiana.

PANDICATION, a stretching; or that violent and tenfive motion of the folds, which usually accompanies the act of yawning.

PANDORA, in fabulous history, a woman formed by Prometheus, to whom each of the gods gave some portion. Venus bestowed upon her beauty; Pallas, wisdom; Juno, riches; Apollo, music; and Mercury, eloquence, but Jupiter being displeased at Prometheus for having stolen fire from heaven to animate the mans he had formed, gave Pandora a box, which she was ordered not to open; and then sent her to the earth with this box, in which were included age, diseases, peltience, war, famine, envy, discord, and all the evils and vises that could affect mankind. This fatal box was opened by Epimetheus, Prometheus's brother, when inftantly all the diseases and mischies with which

4 S 2
Pandours. Hungarian infantry; they wear a loose garment fixed tight to their bodies by a girdle, with great sleeves, and large breeches hanging down to their ankles. They use fire-arms, and are excellent marksmen. They also have a kind of fabre near four feet long, which they use with great dexterity.

Pandoria (Liv., Justin, Strabo), an inland town of the Bruttii, and a place of strength on the river Acheron, where Alexander of Epirus, deceased by the oracle of Dodona, met his fate and perished. Now Mendicina (Hollenius). Another of Epirus (Strabo) situated on the river Acheron (Liv.); which Alexander of Epirus was advised to avoid as fatal, but which he met with in Italy. This last is said to have been the residence of the Ænotrian kings, (Strabo).

Pandura, or Pandoron, a musical instrument, used among the ancients, resembling the lute. The word is said to be formed from the Greek oan and anephe, i. e. "all gifts, all sorts of gifts." Ifidore derives the name from its inventor Pandorus; others from Pan, to whom they attribute its invention, as well as that of the flute. It has the same number of strings with the lute; but they are of brass, and of consequence give a more agreeable sound than those of the flute. Its frets are of copper, like those of the guitar; and the rims of its table, as well as its ribs, are cut in semicircles. Du-Cange observes, that Varro, Isidore, and others of the ancients, mention it as having only three strings; whence it is sometimes also spoken of under the denomination σαπεν-φον, τριχορδον.

Paneas (Pliny, Josephus); the apparent spring from which the Jordan rises, on the extremity of the west side of the Trachonitis (Pliny).

Paneas (Coins, Pliny, Josephus), the name of a district adjoining to the spring Paneas, with a cognominial town, either enlarged and adorned, or originally built, by Philip son of Herod, and called Cesaaria by Josephus; and in St. Matthew, Cæsarea of Philip; with a temple erected to Augustus his benefactor, who conferred the Trachonitis upon him (Coin). It was afterwards called Herantia, in honour of Nero (Josephus).

Panegyric, an oration in praise of some extraordinary thing, person, or virtue. The name is Greek, πανεγυρις; formed of ὅν "all," and ἄγω "I assemble;" because anciently held in public and solemn assemblies of the Greeks, either at their games, their feasts, fairs, or religious meetings. To make their panegyrics the more solemn, the Greeks used to begin with the praises of the deity in whose honour the games, &c. were celebrated; then they descended to the praise of the people or country where they were celebrated; then to the princes or magistrates who professed at them; and at length to the champions, especially the conquerors, who had gained the prizes in them.

Panegyricum, in church history, an ecclesiastical book, used by the Greek church, containing the panegyrical orations of various authors, on the solemnities of Jesus Christ and the saints. It is found in MS. in most churches, but it is not the same in all; each church having its particular fancies; and the compilers of this kind of books usually fitted their collections to the taste of their own devotion. They are disposed according to the order of months, and frequently consist of twelve volumes, annulling to the twelve months of the year. Among the principal authors of this work are Athanasius, Cyril, Bathe, Chryseolites, &c.

Panel (Panela, Panellum), according to Sir Edward Coke, denotes "a little part;" but the learned Spelman says, that it signifies hebdomada vel pagina, "a schedule or roll," as a panel of parchments, or a counterpane of an indenture: but it is used more particularly for a schedule or roll, containing the names of such jurors as the sheriff returns to pass upon any trial. And the imposition of a jury is the entering their names in a panel or little schedule of parchment.

Panel, in Scots law, signifies the prisoner at the bar, or person who takes his trial before the court of judicature for some crime.

Pangolin, a species of the manis peculiar to Plate Hindostan. It is certainly a remarkable variety, if not a peculiar different species, of the pangolin of Buffon. According to a paper in the first volume of the Asiatic Researches, "it has hardly any neck; and, though some filaments are discernible between the scales, they can scarce be called bristles. But the principal difference is in the tail; that of Buffon's animal being long, and tapering almost to a point; while that of ours is much shorter, ends obtusely, and ressembles in form and flexibility the tail of a lobster. In other respects it seems to have all the characters of Buffon's pangolin; a name derived from that by which the animal is distinguished in Java, and consequently preferable to Manis, or Polidotus, or any other appellation deduced from an European language. We are told that the Malabar name of this animal is alang. The natives of Bahar call it bayarat, or, as they explain the word, vine-vermine; and in the womb of the animal before us was found about a tea-cup-full of small stones, which had probably been swallowed for the purpose of facilitating digestion; but the name alangus, we believe, to the hardness of the scales; for voraista means in Sanscrit the diamond or thunderbolt rattle; and vora is a common figure in the Indian poetry for any thing exceedingly hard. The vajra is believed by the Pandits to be the animal which gnaws their sacred bone called jatrambola: but the pangolin has apparently no teeth; and the filaments, many of which look as if they had been worm-eaten, are perhaps only decayed in part by exposure to the air.

A female pangolin, described in the first volume of the Asiatic Researches, had a long tongue shaped like that of the cameleon; and if it was nearly adult, as we may reasonably conclude from a young one found in it, the dimensions of it were much less than those which Buffon affirms generally to his pangolin; for he describes its length as six, seven, or eight feet, including the tail, which is almost, he says, as long as the body when it has attained its full growth; whereas ours is but 34 inches long from the extremity of the tail to the point of the snout, and the length of the tail is 14 inches; but, exclusively of the head, which is five inches long, the tail and body are indeed nearly of the same length; and the small difference between them may flow, if Buffon
Pangolin. Buffon be correct in this point, that the animal was young. The circumference of its body in the thickest part is 20 inches, and that of the tail only 12. There are on each foot five claws, of which the outer and inner are small when compared with the other three. There are no distinct toes; but each nail is moveable by a joint at its root. This creature is extremely inoffensive. It has no teeth, and its feet are unable to grasp. Hence it would appear, that nature, having furnished it with a coat of mail for its protection, has, with some regard to justice, denied it the powers of acting with hostility against its fellow creatures. The nails are well adapted for digging in the ground; and the animal is so dexterous in eluding its enemies by concealing itself in holes and among rocks, that it is extremely difficult to procure one.

The upper jaw is covered with a cross cartilaginous ridge, which, though apparently not at all suited to any purposes of mastication, may, by increasing the surface of the palate, extend the field of its tail. The oesophagus will admit a man's forefinger with ease. The tongue at the bottom of the mouth is nearly about the size of the little finger, from whence it tapers to a point. The animal at pleasure protrudes this member a great way from the mouth. The tongue arises from the eniform cartilage and the contiguous muscles of the belly, and paffes in form of a round distinct muscle from over the stomach, through the thorax, immediately under the sternum; and interior to the windpipe in the throat. When disfigured out, the tongue could be easily elongated so as to reach more than the length of the animal exclusive of its tail. There is a cluster of salivary glands seated around the tongue, as it enters the mouth. These will necessarily be compred by the action of the tongue; so as occasionally to supply a plentiful flow of their secretion.

The stomach is cartilagenous, and analogous to that of the gallinaceous tribe of birds. When disfigured, it is generally found full of small stones and gravel, which in India are almost universally cartilaginous. The inner surface of the stomach is rough to the feel, and formed into folds, the interstices of which are filled with a frothy secretion. The guts are filled with a sandy pulp, in which, however, are interpenetrated a few distinct small stones. No vestiges of any animal or vegetable food have been traced in the whole prime viss. The gall bladder is commonly distended with a fluid resembling in colour and consistence the dregs of beer. It is a viviparous animal.

From the contents of its stomach and prime viss, the pangolin has been supposed by Mr Burt, a very eminent surgeon in Bengal, to derive its nourishment from mineral substances. The land we have perhaps no clear idea of the manner in which vegetables extract their nourishment from earth; yet the fact being so, it may not be unreasonable to suppose, that some animal may derive nutriment by a process somewhat similar. When other flesh-eating creatures (author) shall have been detected in the stomach of this animal, my inference, from what I have seen, must necessarily fall to the ground. But if, like other animals with muscular and cartilagenous stomach, this singular quadruped consume grain, it must be surprizing that no vestige of such food was found present in the whole alimentary canal, since in that thinly inhabited country, the wild animals are free to feed without intrusion from man. Nor can it be inferred from the structure of the stomach, that this animal lives on ants or on insects. Animals devoured as food, though of considerable size and solidity, with a proportionally small extent of surface to be acted on by the gastric juice and the action of the stomach, are readily dissolved and digested by animals possessing not a cartilaginous but a membraneous stomach, as, for instance, a frog in that of a snake.

In the stomach many minerals are soluble, and the most active things which we can swallow. Calcareous substances are readily acted on. Dr Priestley has affirmed, May not phlogistic matter be the most essential part of the food and support of both vegetable and animal bodies? I confess, that Dr Priestley's finding causa to propose the question, inclines me to suppose, that the affirmative to it may be true. Earth seems to be the basis of all animal matter. The growth of the animal may be attended with a constant supply, and in the human species there is a copious discharge of calcareous matter thrown out by the kidneys and salivary glands. May not the quadruped in question derive phlogiston from earth; i.e., from mineral substances? And, as it is not deprived of the power of drinking water, what else is necessary to the subsistence of his corporeal machine?

Considering the scaly covering of this animal, we may conceive, that it may be at least necessary for its existence, on that account, to imbibe a greater proportion of earth than is necessary to other animals. It may deserve consideration, that birds are covered with feathers, which, in their constituent principles, approach to the nature of horn and bone. Of these animals, the gallinaceous tribe swallow stones; and the carnivorous take in the feathers and bones of their prey; the latter article is known to be soluble in the membraneous stomachs; and hence is a copious supply of the earthly principles. In truth I do not know that any thing is soluble in the stomach of an animal, which may not be thence absorbed into their circulating system; and nothing can be so absorbed without affecting the whole constitution. These conjectures are not a little confirmed by the experiments of M. Brunetelli, of Pavia, on the authority of M. Crell, by which we learn, that some birds have so great a digestor power in the gastric juice, as to dissolve in their stomachs flints, rock- crystal, calcareous stones, and shells. See MANIS.

PANGONIA, in natural history, the name of a genus of crystalline, consisting of such as are composed of many angles. The word is derived from πανεριος, numerous, and γυναικινοντα, or bonting. The bodies of this genus are tingle-pointed or imperfect crystals, composed of dedecangular or twelve planed columns, terminated by two or planed pyramids, and the whole body therefore made up of twenty-four planes. Of this genus there are only three known species.

PANIC, a motes an ill-grounded terror or fright. Polygenus says, it originates from Pan, one of the captains of Bacchus, who, with a few men put a numerous enemy to rout, by a noise which his soldiers raised in a rocky valley, attended with a great number of echoes. This stratagem making their number appear far greater than it was, the enemy quitted a very commodious encampment,

This stratagem making their number appear far greater than it was, the enemy quitted a very commodious encampment,
PAN

For this purpose a Guinea-gras pasture requires to be kept clean, and supplied in particular places as may be necessary from time to time. The fields ought to be divided into parks by fences, and the cattle shifted from one inclosure to another occasionally.

PANINI (Paolo), a painter of perspective and architecture. He was born at Placentia in 1601, with a most happy genius to painting, which he cultivated by studying at Rome, where he designed every vestige of ancient insignificance, the ruins of superb Roman edifices, cenotaphs, columns, baths, arches, and obelisks, as also some of the most entire buildings, the ornaments of modern Rome.

He studied the works of Ghiberti with peculiar pleasure; he formed his taste, style, and manner, by the compositions of that esteemed artist; and his strongest ambition was to imitate him: so that he soon became eminent in that style beyond all his cotemporaries. His composition is rich; the truth of his perspective is critically exact; and his paintings are universally esteemed for the grandeur of the architecture, for the clearness of his colouring, for the beautiful figures which he generally introduced, and for the elegant talle with which he disposed them. He always designed them correctly, and set them off with suitable attitudes and expression.

However, this description of his merit must be supposed to allude to his early and prime performances; for in his latter time, his pictures were disfigurable by a free and broad touch, but they are feeble in their colouring and effect. At all times, indeed, he was too apt to design his figures rather too large for the architecture, which diminished the grandeur of the most magnificent parts of his composition, and was quite contrary to the practice of Ghiberti; whose works must perpetually afford a pleasing deception to the eye, by the perspectival proportions observed between the figures, buildings, and distances.

At Rivoir, a pleasure-house belonging to the king of Sardinia, there are several of Panini's paintings, which are views of that fine retreat and its environs. They are beautifully coloured, well handled, and with a touch full of spirit; though in some parts the yellow seems a little too predominant, and the lights are not always distributed in such a manner as to produce the most striking effect.

PANIONIA, in antiquity, a festival celebrated in honour of Neptune by a concourse of people from all the cities of Italy. It is remarkable in this festival, that if the bull offered in sacrifice happened to bellow, it was accounted an omen of divine favour; because that sound was thought to be acceptable to Neptune.

PANNARIA, one of the Lipari islands. See LIPARI, and LIPARI.—The ancients called it Theridion, from the hot waters which they found in it. It may be about eight or nine miles in circumference. It bears wheat, and grapes from which the inhabitants make wine. Pannaria, like the other adjacent islands, appears to be a volcano, its original having been destroyed by continued eruptions. Its is now no longer of a conical figure. It contains about 100 inhabitants, reckoning every full, men, women, and children. It is, like Stromboli, governed by a curate, who depends on the priest of the parish of St Joseph in Lipari; and when
PANNUS, when any couple in the island determine to marry, they must cross the sea to Lipari to receive the nuptial benediction in the parish of St. Joseph, or pay a sum for a licence to empower the curate of Pannaria to perform the ceremony. All the other adjoining islands are subject to the same regulation.

The inhabitants of Pannaria live by fishing, and by taking small quantities of game on this and the little contiguous islands. They bring up and tame those birds known by the name of gulls, which are seen in temperance and other flying birds. They are here called corvacina. The body of the bird and the tips of its wings are white; but the head, the tail, and the rest of the wings, are grey; they are of the size of Indian hens; their wings are prodigiously large; they have their nests on the steep inaccessible cliffs of the several islands. When the islands bring these birds up tame, they feed them with fish, which, though of such size that you would think it impossible for their stomachs to receive them, they eagerly stretch their necks and swallow rapaciously. These birds are thus brought up to be as tame as pullets or pigeons; such an attachment do they often acquire to the inhabitants of the island, not being able to judge their flight and the nature of some ancient island, not being able to judge their flight and the nature of some ancient island, whether their wings are prodigious or the surface of the sea. They are thus brought up to be as tame as pullets or pigeons; such an attachment do they often acquire to the having the elevation of the rock, and such an attachment do they often acquire to the having the elevation of the rock, though though through the Amorica and many other flying birds. They are here called corvacina. The body of the bird and the tips of its wings are white; but the head, the tail, and the rest of the wings, are grey; they are of the size of Indian hens: their wings are prodigiously large: they have their nests on the steep inaccessible cliffs of the several islands. When the islands bring these birds up tame, they feed them with fish, which, though of such size that you would think it impossible for their stomachs to receive them, they eagerly stretch their necks and swallow rapaciously. These birds are thus brought up to be as tame as pullets or pigeons: such an attachment do they often acquire to the places in which they are reared, that some of them have been known to return to these islands after being conveyed to Melazzo and Melina.

On the summit of a hill in this island, which projects over the sea, the inhabitants pretend to show a caffle and an inscription. But their castle is only an elevated peak of the rock, which nature seems to have prepared as a retreat for birds. It consists of pazzolana; and has been actually formed by the action of winds and rains, for a long course of time, into a fantastic figure, which may appear, when carelessly viewed from a distance by an undistinguished eye, the remains of some ancient structure. The good people of the island, not being able to judge of it otherwise than from appearance, are persuaded, that it can be nothing but a caffle, which must have been reared for the defense of the island against the Turks and the corsairs of Barbary. These they consider as the most dreadful scourge with which mankind can possibly be afflicted, and fear them much more than the eruptions of the lava, denoting it to be the original mother of the mountain, which pro-duced the figure, which may appear, when carelessly viewed from a distance by an undistinguished eye, the remains of some ancient structure. The good people of the island, not being able to judge of it otherwise than from appearance, are persuaded, that it can be nothing but a caffle, which must have been reared for the defense of the island against the Turks and the corsairs of Barbary. These they consider as the most dreadful scourge with which mankind can possibly be afflicted, and fear them much more than the eruptions of the volcano. When they feel their island shaken, they embark with all their wealth, which a single wave can easily contain; and on board they are safe from both the shaking of the earth and the eruptions of the lava, but not from an holofle fleet.

In this island there appear various remains of ancient buildings, but very ruinous and very scanty. In ploughing the fields, many remains of temples, in different modes of construction are found: some of rough stones, tiles, or bricks; others, consisting each of a single stone. Vases of various sorts and sizes are also said to have been found in the same fields, utensils of different kinds, money, chains, and medals of lead. But none of these relics of antiquity have been preserved: the good people who found them were ignorant of their value, and therefore neglected them as trifles. In places along the shore of the island, where the sea appears to have encroached, there are some hewn stones to be seen: they seem to be remains of walls which must have been very strong and of elegant architecture. In other places farther distant from the shore, there likewise appear fragments of walls sunk in the ground, and apparently overwhelmed with mud, which the winds and rains have brought down from the mountain above. These remains show, that Pannaria, either under the Greeks, or in that period when all the elements were taxed for the gratification of Roman luxury, must have been adorned with superb buildings, as well as the adjacent islands of Lipari, Stromboli, and Bafluzzo.

PANELS of a saddle are two cushions or bolsters filled with cow's, deer, or horse's hair, and placed under the saddle on each side to prevent the bows and bands from galling the horse.

PANNICULUS CARNOSUS, in comparative anatomy, a robust fleshy tunic, situated in forearms between the skin and the fat; by means of which they can move their skin in whole or in part. It is altogether wanting in mankind.

PANNONIA (Pliny, Strabo, Dio), an extensive country of Europe, having the Danube on the north, Dalmatia on the south, Noricum on the west, and Moesia on the east. It is divided into Superior and Inferior (Ptolemy, Dio). The common boundary between both were the river Arabo and mount Cetius, having the Superior to the west, and the Inferior on the east side. This division is thought to be no older than the times of the Antonines. Pannonius the epitaph (Martial).

PANOMPHAEUS, in antiquity, a designation given to Jupiter, because he was said to be the original author of all forts of divination, having the books of fate, and out of them revealing either more or less, as he pleased, to inferior chalones.

PANOPOLES. See ACHEM.

PANORONUS (Polybius, Pananias), a town of Achaia, in Peloponnesus, near the promontory of Rhium.

Another (Ptolemy, Pliny), a town on the north side of Crete—A third (Ptolemy), in Macedonia, on the Aegean sea, near mount Athos.—A fourth, of Samos (Livy).—A fifth, of Sicily; an ancient city, built by the Phoenicians (Thurydides); a principal town of the Carthaginians (Polybius); situated between Lilibaeus and Pheorus (Mel): a Roman colony, New Palus, capital of the island, on the north side. E. Long. 13° 15′; Lat. 38° 30′.—A sixth Pannomus of the Thracian Chereoueus, placed by Pliny on the west side of the peninsula, and mentioned by no other writer.

PANOPUS (Ptolemy), a port of Attica; its name denoting it to be capacious. Another, of Epirus (Strabo, Ptolemy); a large harbour in the heart of the Montes Cenarii, below the citadel Chimara.—A third, of Ionia (Strabo); near Ephesus, with the temple of the Ephesian Diana.

PANOPRA, the Scorpion fly, in zoology, a genus of insects belonging to the order of Neuroptera. The rostrum is horned and cylindrical; there are two pappi, and three flemontae; the feelers are longer than the thorax. The body of this insect is of a black brown colour, yellow on the sides, with a few spots of the same on the top. Its tail, formed by the three last segments of the abdomen, is of a maroon colour; of those three segments, the last is longer, almost round, and terminates in two hooks, which constitute a tail like that of the Scorpion. The wings as long as the body, are diaphanous, reticulated, with fibres and stripes of spots of a brown colour. Sometimes we meet with different varieties of this insect, confitting in the colour of
Pantaloon of the wings. Some, instead of several stripes of spots upon their wings, have only a single black stripe, transverse and irregular, situated on the middle of the wing, the extremity whereof is also black; others have their wings entirely white, excepting the extremity, which is black. The kind of species that is seen at the hinder part of this insect is used by the males to lay hold of their females in their amorous embraces: the threatening tail of the male does no mischief. This insect is found in meadows, by the side of ditches. There are four species, distinguished by the colour and shape of their wings.

PANTALARIA, an island in the Mediterranean sea, between Sicily and the main land of Africa, about 17 miles in circumference. It is near the coast of Tunis, and abounds in cotton, fruit, and wine; but the inhabitants are obliged to bring all their corn to Sicily, as it belongs to the king of the two Sicilies. F. Long. 12. 25. N. Lat. 36. 55.

PANTHENUS, a florid philosopher, born in Sicily (though for many centuries he lived at Alexandria, and was called by the name of a Hebrew) about the beginning of the reign of Commodus. He prefixed over the celebrated school of Alexandria, where, from the time of St Mark, the founder of that church, they had always a divine that was eminent for his learning and piety, to explain the Holy Scriptures, and to instruct them in human learning. This employment he was obliged to leave; for when the Indians required of Demetrius bishop of Alexandria to send them one to instruct them in Christianity, he sent Pantenus, who undertook the mission with joy, and behaved himself very properly in it. We are told, that the Indians had been tainted with Christianity by St Bartholomew the apostle; and that Pantenus met with the Hebrew original of St Matthew's gospel, which the apostle had left there. St Jerome says that Pantenus brought it with him; and that it was, in his time, preferred in the library of Alexandria. But we mistake St Jerome to be mistaken in this respect. When Pantenus returned to Alexandria, he assisted the government of that city, which, it is probable he had, during his absence, committed to the care of St Clement, a presbyter of Alexandria. He explained the scriptures publicly, under the reign of Severus and Antoninus Caracalla; and was, in St Jerome's opinion, more serviceable to the church by his discourses than by his writings. He published some commentaries upon the Bible, which are lost. "That the prophets often express themselves in indistinct terms, and that they make use of the present time instead of the past and future." is a rule of Pantenus, which has been followed by all succeeding interpreters. The dorus has related this rule; but he speaks of it as if Pantenus had rather said than written it.

We may have some notion of Pantenus' manner of explaining the scriptures by the like performance of St Clement of Alexandria, Origen, and others, who were brought up in that school.

PANTALOON, a sort of garment consisting of breeches and stockings all of one piece; said to have been first introduced by the Venetians.

PANTALOON, on the stage, is a buffoon or marked person who performs high and gr.肢体 dance, and those violent and extravagant pollutions and airs. This word is likewise used for the hab'it or dress these buffoons usually wear; which is made precisely to the form of their body, and all of a piece from head to foot.

And hence those who wear a habit of this kind, for convenience, under their other clothes, are called pantaloons of Venice.

PANTARBE, in natural history, a name given to an imaginary stone, the effects of which upon gold were similar to those of the leadstone upon iron. The ancients, as well as some modern writers, seem to have had an opinion that there was such a stone; and the ambrosia of Pliny is described as possessing this remarkable quality; but neither they nor we have ever found reason, from any experiment well ascertained, to believe that there ever was such a stone.

PANTHEA, in antiquity, were single statues, composed of the figures, or symbol, of several different divinities together. Pater Joubert, who calls them pantheas, and who has remarked them sometimes on medals, says their heads are most commonly adorned with the symbols or attributes belonging to several gods. An illustration of this appears in a medal of Antoninus Pius; which presents Scapigia the bull, the Sun by the crown of rays; Jupiter Ammon by the ram's horns; Puto by the large beard; and AEtolius by the serpent twined in his hand. M. Boudet, in a dissertation on the Lares, observes, that the pantheas had their origin from the superposition of these, who, taking several gods for the protectors of their houses, united them all in the same image, by adorning it with the several symbols proper to each of these deities.

PANTHEISM, a philosophical species of idolatry leading to atheism, in which the universe was considered as the supreme God. Who was the inventor of this absurd system, is, perhaps, not known; but it was of early origin, a difference of in several philosophers. Some held the universe to be one immense animal, of which the incorporeal soul was properly their God, and the heavens and earth the body of that God; whilst others held, the universe, partly active and partly passive; and therefore looked upon the visible universe as the only Numin. The earliest Greek Pan heil of whom we read was Orpheus, who called the world the body of God, and its several parts his members, making the whole universe one divine animal. According to Cudworth, Orpheus and his followers believed in the immortal soul of the world; therein agreeing with Aristotle, who certainly held that God and matter are coeternal; and that there is some such union between them as suffices between the souls and bodies of men. See Metaphysics, n. 264.

In the ancient Orphic theology, we are taught, that "this universe, and all things belonging to it, were made w l in God; that all things are contained together in the word of God; that God is the head and middle of all things; that he is the bolts of the earth and heaven; that he is the depth of the sea, the air we breathe, the force of the untameable fire; that he is the sun, moon, and stars; that there is one divine body for, "All these things lie in the great body of God."—But further, to prove that the most ancient Greek philo-
Pantheon, sappers resolved all things into God, and made God all, we shall cite a most remarkable passage from Plutarch’s Defect of Oracles. "Whereas there are two causes of all generations, the divine and the human, the most ancient theologers and poets attended only to the more excellent of these two; resolving all things into God: and pronouncing this of them universally;"

That by the most ancient theologers here mentioned, Plutarch meant Orpheus and his immediate followers, is plain from the Orphic verse by which he proves their antiquity. By their Junior, whom he calls naturely, he could mean no other than the first Greek philosophers, Arrauinander, Anaximenes, and Hippo, who were followed by the atheistical atomists, Leucippus, Democritus, Protagoras, and Epicurus. But with respect to the universal being and God, and all things divine and human being modifications of mere matter, the poets undoubtedly agreed with Anaximander and his followers; for the school of Zeno held but one subsistence. See Metaphysics, p. 265. This impious doctrine, that all things are God, and that there is but one subsistence, was revived in modern times by Sinoza, an apostate Jew. As we shall give a life of him and a view of his principles, we must refer the reader for a fuller account of Pantheism to Sinoza. See also Pan.

Pantheon, a beautiful edifice at Rome, anciently a temple, dedicated to all the gods; but now converted into a church, and dedicated to the Virgin and all the martyrs.

This edifice is generally thought to have been built by Agrippa, in the name of Augustus, because it has the following inscription on the frieze of the portico.

M. Agrippa L. F. Cos. Tertium fecit.

Several antiquarians and artists, however, have suposed that the pantheon existed in the times of the commonwealth; and that it was only embellished by Agrippa, who added the portico. Be this as it will, however, the pantheon, when perfected by Agrippa, was an exceedingly magnificent building; the form of whose body is round or cylindrical, and its roof or dome is spherical: it is 144 feet diameter within; and the height of it, from the pavement to the grand aperture on its top, through which it receives the light, is just as much. It is of the Corinthian order. The inner circumference is divided into seven grand niches, wrought in the thickness of the wall: six of which are flat at the top; but the seventh, opposite to the entrance, is arched. Before each niche are two columns of antique yellow marble fluted, and of one entire block, making in all 14, the finest in Rome. The whole wall of the temple, as high as the grand cornice inclusive, is cased with divers sorts of precious marble in compartments. The frieze is entirely of porphyre. Above the grand cornice rises an attic, in which were wrought, at equal distances, 14 oblong square niches: between each niche were four marble pilasters, and between the pilasters marble tables of various kinds. This attic had a Pantheon-complete entablature; but the cornice projects less than that of the grand order below. Immediately for the cornice springs the spherical roof, divided by bands, which cross each other like the meridians and parallels of artificial terrestrial globe. The space between the hands decrease in size as they approach the top of the roof; which, however, they do not reach, there being a considerable plain space between them and the great opening. That to hold a roof might be as light as possible, the architect formed the subsance of the spaces between the bands of nothing but lime and pumice-stones. The walls below were decorated with lead and brass, and works of carved silver over them; and the roof was covered on the outside with plates of gilded bronze. There was an ascent from the springing of the roof to the very summit by a flight of seven stairs. And if certain authors may be credited, these steps were ornamented with pedestrian statues ranged as an amphitheatre. This notion is founded on a passage of Pliny, who says, "That Diogenes the sculptor decorated the pantheon of Agrippa with elegant statues; yet that it was difficult to judge of their merit, upon account of their elevated situation." The portico is composed of 16 columns of granite, four feet in diameter, eight of which stand in front, with an equal intercolimation all along, contrary to the rule of Vitruvius, who is for having the space answering to the door of a temple, wider than the rest. Of these columns is a pediment, which tympanum, or flat, was ornamented with bas-relief in brasse; the cross beams which formed the ceiling of the portico were covered with the same metal, and so were the doors. The ascent up to the portico was by eight or nine steps.

Such was the Pantheon, the richness of which induced Pliny to rank it among the wonders of the world.

The eruption of Vesuvius, in the reign of Tibetrius, damaged the Pantheon very considerably; it was repaired by Domitian; which occasioned some writers to mention that prince as the founder of the building. The emperor Adrian also did something to it. But it appears, that the pantheon is more indebted to Septimius Severus, than to any one since its erection. The most, perhaps, that any of his predecessors had done, was the adding some ornament to it: Septimius bequeathed official reparations upon it. The following inscription appears upon the architrave:

IMP. CAES. SEPTIMIVS. SEVERVS. PIVS. PERTINAX.
ARABICVS. PARTHICVS. PONTIF.
MAX. TRIB. POT.
XI. COS. III. P. P. ET IMP. CAES.
MARCVS.
AVRELIVS. ANTONIVS. PIVS.
FELIX. AVG. TRIB.
POT. V. COS. PROCOI. PANTEHVM.
VETTVSTATE.
OBVRPFVM. CVM. OMNI. CULTV.
RESTITTVENT.

It is really a matter of astonishment, that a structure, which, granting it to have been built by Agrippa, was not more than 200 years old, should have fallen into decay through age. This single consideration seems sufficient to confirm the opinion of those
Pantheon, who believe it to have flood in the time of the commonwealth.

The temple subsisted in all its grandeur till the incursion of Alaric in the time of Honorius. Zoëmyus relates, that the Romans having engaged to furnish this barbarian prince with 3000 pounds weight of gold and 5000 pounds weight of silver, upon condition that he should depart from their walls; and it proving impossible to raise those sums either out of the public treasury or private purses, they were obliged to strip the temples of their statuery and ornaments of gold and silver. It is probable that the pantheon supplied a good part, as that of Jupiter Capitolinus was the only one in Rome that could vie with it for riches.

Alaric carried off nothing from the Romans besides their precious metals. Thirty-nine years after this, Generific king of the Vandals took away part of their marbles; and whether from a greediness of plunder, or from a relish of the productions of art, loaded one of his ships with statues. It cannot be doubted, but that on this occasion the pantheon was forced to part with more of its ornaments, and that the inestimable works of Diogenes became the prey of this barbarian.

Before these unwelcome visits of the Goths and Vandals, the Christian emperors had issued edicts for demolishing the Pagan temples. But the Romans, whatever were their motives, spared the pantheon, which is known to have suffered no damage from the zeal of the pontiffs, or the indignation of the saints, before the first siege of Rome by Alaric. It remained so rich till about the year 655, as to excite the avarice of Constantinian II. who came from Constantinople to pillage the pantheon, and executed his purpose so far as to strip both of its infide and outside brazen coverings, which he transported to Syracuse, where they soon after fell into the hands of the Saracens.

About fifty years before this, pope Boniface IV. had obtained the pantheon of the emperor Phocas, to make a church of it. The artists of those days were totally ignorant of the excellence of the Greek and Roman architecture, and spoiled every thing they laid their hands upon. To this period certain alterations are to be referred, of which we shall speak by and by.

After the devastations of the barbarians, Rome was contrasted within a narrow compass; the seven hills were abandoned; and the Campus Martius, being an even plain, and near the Tyber, became the ground-plot of the whole city. The pantheon happening to stand at the entrance of the Campus Martius, was formerly surrounded with houses, which spoiled the fine prospect of it; and it was yet more deplorably disfigured by some of them which passed close to its walls. Pedlar shades were built even within its portico, and the intercolumniations were bricked up, to the irreparable damage of the matchless pillars, of which some loft part of their capitals, some of their bases, and others were chiselled out of or broken inches deep, and as many feet high, to let in polls. Which excavations are to this day half filled up with brick and mortar; a sad monument of the licentiousness of the vulgar, and of the stupid avarice of those who sold them the privilege to ruin the noblest piece of art in the world!

This disorder continued till the pontificate of Eugene IV. whose zeal for the decay of a confecrated place, prevailed upon him to have all the houses cleared away that incumbered the pantheon, and so the miserable barracks in the portico were knocked down.

From the time Constantinian carried off the brass plating of the external roof, that part was exposed to the injuries of the weather, or at least was but slightly tiled in, till Benedict II. covered it with lead, which Nicholas V. renewed in a better style.

It does not appear that from this time to Urban VIII. any pope did any thing remarkable to the pantheon.

Raphael Urban, who had no equal as a painter, and who as an architect had no superior, left a considerable sum by his will for the repairation of the pantheon, where his tomb is placed. Perino de la Vaga, Jacomo Udino, Flaminio Carracci, Flamingo Vacca, and the celebrated Archangelo Corelli, did the fame. All the ornaments within, that have any claim to be called good, are of the later times; the paintings merit esteem; and the statues, though not masterpieces, do honour to sculpture, which alone is a proof that they are posterior to the 15th century.

But, with all the respect due to a pontiff, who was otherwise a protector, and even a practitioner of the arts, it was much to be wished that Urban VIII. had not known that the pantheon existed. The inscriptions cut at the side of the door informs us, that he repaired it; yet, at the same time that he built up with one hand, he pulled down with the other. He caused two belfries of a wretched taste to be erected on the ancient front work, and he divided the portico of all the remains of its ancient grandeur, viz. the brazen cover-ture of the crofs beams, which amounted to such a prodigious quantity, that not only the vast baldaquin or canopy of the confecrational in St Peter's was call'd out of it, but likewise a great number of cannon for the castle of St Angelo. This pope, who was of the family of Barbarini, presented also as much of this metal to his nephew, as was sufficient for the decoration of his new palace; on which occasion this remarkable paquinade was stuck up:

Quod non fascerni Barbari fascis Bacarini.

If ever gingle added force to wit, it was certainly in this instance.

It is surprising, that whilst all these operations were carrying on in the portico, he never once thought of repairing the damages which time had wrought in it. Of the 16 pillars which supported this magnificent pile, there were no more than 13 left; the three next the temple of Minerva had disappeared; with these the entablature and an angle of the front had tumbled down. There were not wanting in Rome fragments enough of antique columns that might have been put together, and set up, to have prevented the downfall of a pile which deferred to fland as long as the world endured.

Alexander VII. did what Urban VIII. had neglected to do. At the same time that Bernini was continuing the colonnade of St Peter, this pontiff ordered search to be made for pillars to match those of the portico of the pantheon; and some were found not far from the French church of St Lewis of the very same model. They were granite of the isle of Iva, and thoe
PANTHEON, the door of the portico were Egyptian grante; the colour, however, was the same, so that the effect was equal. The pope’s zeal did not stop here; he cau ded all the old houses before the portico to be pulled down, and the soil and rubbish to be cleared away which covered the steps, and even the bases of some of the pillars. He began covering the roof with marble, and raised a lantern over the aperture, to keep out the rain; but death took him off before his project was completed. Clement IX. his successor, inclosed the portico within iron rails. Several later popes have added to its decorations, which were all in the taste of the times they were done in; and the body of the edifice and its architecture gained nothing from them. The main object of their holinesses liberality was the embellishment of the grand altar. One gave purple curtains, another bestowed silver tabernacles; others again vases, and superb dresses, suited to the solemn ceremonies of religion. All these might be called rich; but they had in no sense a tendency to retrieve the ancient majesty or original splendor of the temple. The true gulf of the ornaments was a little imitated at the revival of the arts. Good statues took place of the skeletons and squat figures that ridiculously disgraced the altars for the space of eight centuries. The paintings of Perugino, Cozza, and Greffi, covered the dull statues, and the green and mottled marble, which were all in the antique found among the old ruins were employed to much advantage.

There was besides at Rome another pantheon, dedicated to Minerva as the goddess of medicine. It was in the form of a deacon, and the distance from one angle to another measured about 22 feet and an half. Between the angles there were nine round chapels, each of which was designed for a deity; and over the gate there was a statue of Minerva. The pantheon of Athens was in many respects little inferior to the Roman one built by Agrippa. The Greek Christians also converted it into a church, dedicated it to the Virgin, under the name of Panegia; and the Turks changed it into a mosque. The pantheon of Nimes was a temple in that city, wherein the greatest gods. In the Escurial is a chapel, called pantheon, 35 feet in diameter, and 38 feet high from the pavement, which is composed of marble and Jasper inlaid. The whole inside of the chapel is of black marble, except the lutehurn, and some ornaments of Jasper and red marble. In this chapel are deposited the bodies of the kings and queens; there are only places for 26, and eight of them are already filled.

PANTHER, in zoology. See Felis.

PANTING, conflicts in a rapid succession of inspirations and aspirations, which happens when we pantomime run or perform any violent motion.

PANTOMIME, among the ancients, a person who could imitate all kind of actions and characters by signs and gestures without speaking. The pantomimes made a part in the theatrical entertainments of the ancients; their chief employment was to express, in gestures and action, whatever the chorus sung, changing their countenance and behaviour as the subject of the song varied. They were very ancient in Greece, being derived from the heroic times, according to some; but however this may be, they were certainly known in Plato’s time. In Rome, it was so late as the time of Augustus before they made their appearance. As to their dress, it was various, being always suited as near as possible to that of the person they were to imitate. The crocota was much used among the Roman pantomimes, in which and other female dresses they perforated women.

We have this account of them in Gibbon’s history: “The pantomimes (a), who maintained their reputation from the age of Augustus to the sixth century, expressed, without the use of words, the various fables of the gods and heroes of antiquity; and the perfection of their art, which sometimes disarmed the gravity of the philosopher, always excited the applause and wonder of the people. The vast and magnificent theatres of Rome were filled by 3000 female dancers, and by 5000 fingers, with the matters of the respective choruses. Such was the popular favour which they enjoyed, that in a time of scarcity, when all strangers were banished from the city, the merit of contributing to the public pleasures exempted them from a law which was strictly executed against the professors of the liberal arts (b).”

Pantomimes are still very common in England; they differ indeed in some respects from those of antiquity; but they retain the name, and like these they confine in the representations of things merely by gestures.

PANUCO, a town and province of North America, in New Spain, lying to the north of Mexico, with a bishop’s see. There are veins of gold, and falt-works, which are the principal revenue of the inhabitants.—It is seated near the mouth of a river of the same name, at a small distance from the Gulph of Mexico. W. Long. 100. 5. N. Lat. 24. 0.

PANZACCHIA (Maria Helena), This painter was born at Bologna in 1668, of a noble family, and appeared to have an extraordinary genius for painting. She learned design under the direction of Emilio Taruffi, and in a short space of time made an astonishing proficiency; so that in the compass of a few years she acquired great readiness in composition, correctness of outline, and a lovely tint of colouring.

She also excelled in painting landscapes; and by the

(a) “See the dialogue of Lucian, intitled, De Saltationibus, tom. ii. p. 265—317. edit. Reitz. The pantomimes obtained the honourable name of 2H7epo\001, and it was required that they should be conversant with almost every art and science. Burette (in the Memoires de P Academie des Inscriptions, tom. i. p. 127, &c.) has given a short history of the art of pantomimes.

(b) “Ammianus, l. xiv. c. 6. He complains, with decent indignation, that the streets of Rome were filled with crowds of females, who might have given children to the state, but whose only occupation was to curl and dree their hair; and justari volubilium syris, dum experimunt immensus semulacra, que fonsere fabula theorale.”
the beauty of her situations and distances allure and
fired the eye of every judicious beholder. The
figures which she infused had abundance of grace;
she designed them with becoming attitudes, and gave
them a lively and natural expression. Her merit was
incontestably acknowledged, and her works were ex-
ceedingly prized and coveted.

PANO-FONG, in China, where the viceroy resides,
is the most considerable city in the province next to
Pekin. It has 20 others under its jurisdiction, three
of the second and 17 of the third classes. The Coun-
try around it is pleasant, and inferior in fertility to no
part of China. It is necessary to pass the city in go-
ing from Pekin to the province of Chan-si.

PAOLO (Marco). See PAOLO.

PAPA, a small but strong town of Lower Hun-
gary, in the country of Veprins. It was taken from
the Turks in 1683, after raising the siege of Vienna,
and is subject to the house of Austria. It is seated on
a mountain, near the river Marchesa, in E. Long.
13° to. N. Lat. 47° 20.

PAP CASTLE, in England, in Bridekirk parish, Cumber-
da, flood two miles from Cockermouth, on the other
side of the Derwent, whose Roman antiquity is proved
by several monuments; and a large green stone, which
was found here, with little images upon it, is supposed
to have been formerly a Danish font for dipping of in-
fants; and has been since used at Bridekirk, in the
neighbourhood for their sprinkling.

The name of Papcastle seems to be contracted from
Pipard its owner: it is said to have been demolished,
and the materials employed to build Cockermouth castle.

Mr Routh, in a letter to Mr Gale, thus describes
the ruins discovered at Papcastle, Jan. 16 1743.

"I made particular inquiry of the man in whose
grounds they were discovered, and of some of the
neighbours present at the discovery. The cloe in
which they lay is a little to the south of the fort, on
the declivity of the hill to the river, and bounded on
the west by a narrow lane, probably the via militaris
continued; and is usually shown to strangers as the most
remarkable here for finding Roman coins. They are
the largest ruins ever known to be discovered in these
parts: for they met with three walls besides the pave-
ment; the first lay east and west, and was covered
with earth near a foot high: parallel to it at seven
yards, they found a second: and between these two,
about two yards deep (the height of the walls, which
were six yards broad, and strongly cemented), they
came to a pavement curiously laid with large flags,
three quarters of a yard square, and two or three
inches thick, as I measured them: but imagining they
must be money under it, they covered it up till night,
and then tore it all up. It was composed of flags of
different thicknes: under the thinner was a coarse
strong cement, which caused them to be broken in tak-
ing up; but the thicker are pretty entire. Part of
the wall flood on the floor, and the edge was secured
by a fine red cement two inches thick, supposing it
to be intended to keep the floor dry. They imagined
themselves at the corner of the building, the third wall
standing at right angles with the first, and the second
parallel to the florly lane, on which was an old hedge.
On the floor they found a stone trough, or rather base
of a pillar, about a foot high, and the hollowed part
square, and two inches deep. They likewise found a
small earthen patera, which I preserved, of the finest
clay, beautifully smooth, with letters imprinted on the
bottom; but so defaced as not to be intelligible.
Some years ago, the man's father who found these
ruins, dug up a conduit. The owner had no coins, nor
knew of any. One of his neighbours showed me a
large brazen one defaced."

Mr Routh, in another letter to Mr Gale, April 13,
1743, describes a fibula, a coin of Trajan, .IANO
AVG... P. M. Rev. the emperor seated on a pile
of arms, a trophy before him, S. P. Q. R. OPTI ...
S. C. and two oaken pieces of the adjoining tim-
er of a house which appeared to have been burnt, in
the gardens of Jerom Tully, Esq; of Carlisle. The
earth as far as they dug was artificial, and antiquities
are only found at a considerable depth.

Dr Stukely says, the Roman castrum lies on the
top of the hill above the village, and traced its whole
circumference, a bit of the Roman wall by the river
side going to Wigton, and there the ditch is plainly
visible, though half filled up with the rubbish of the
wall. A subterraneous vault, floored with large slabs
of fine stone, was found in the nature of the four-
east angle. The name of Boresgate includes both cloes:
where it flood; and they find flowers and plates with
iron pins in them, coins, &c. on the whole spot be-
low it, towards the water-side. It was a beautiful
and well chosen plan, on the four-west side of a hill,
a noble river running under, and pretty good coun-
try about it. Coins of Claudius, Adrian, and a silver
Geta, FONT. REV. PRINCEPS INVICTVS. He supposes
its ancient name Deromis, derived from the Derwent.

PAPAVER, the Puppy: A genus of the mono-
yon order, belonging to the poldandria class of
plants; and in the natural method ranking under the
27th order, Rhoeads. The corolla is tetrapterous;
the calyx diphylous; the capulse bilocular, opening
at the pores below a perfiling stigma.

PAPAVER. 1. The fonniferum, or fonnniferous
common garden-puppy, rifies with an upright smooth tall,
colored or branching a yard or more high; garnished
with large, deeply jagged, amplexicaule, smoth leaves;
and terminated by large, spreading, dark-purple, and
other coloured flowers, in the varieties, having smooth
cups and capsules. There are a great many varieties;
some of them extremely beautiful. The white offici-
nal puppy is one of the varieties of this sort. It
grows often to the height of five or six feet, having
large flowers, both singles and doubles, succeeded by
capules or heads as large as oranges, each containing
about 8000 seeds.

We are told, that in the province of Bahar in the
East Indies, the puppy-feeds are fown in the months
of October and November, at about eight inches dis-
tance, and well watered till the plants are about half
a foot high, when a compost of dung, nitrous earth,
and ashes, is spread over the areas; and a little before
the flowers appear, they are again watered profusely
till the capules are half grown, at which time the
opium is collected; for when fully ripe, they yield
but little juice; two longitudinal incisions from below
upwards, without penetrating the cavity, are made
at funset for three or four succedaneous; in the
morning the juice is scraped off with an iron scoop,
PAP

and worked in an iron pot in the sun's heat till it is of a consistence to be formed into thick cakes of about four pounds weight; these are covered over with the leaves of poppy, tobacco, or some other vegetable, to prevent their sticking together, and in this situation they are dried.

The several quality of the white poppy is well known. This quality resides in the milky juice of the capsule containing the seed, nor is it evaporated by drying the juice; hence the dried capsules are preferred in the shops for making the syrup. The imbibed juice itself is a kind of opium; and for an account of its virtues see the article Opium. The seeds also make a very agreeable emollient, but have no soporific virtue.

It grows in England, generally in neglected gardens, or uncultivated rich grounds, and flowers in July and August. This species is said to have been named white poppy from the whiteness of its seeds; a variety of it, however, is well known to produce black seeds; the double-flowered white poppy is also another variety; but for medicinal purposes, any of these may be employed indiscriminately, as we are not able to discover the least difference in their sensible qualities or effects. The seeds, according to some authors, possess a narcotic power; but there is no foundation for this opinion: they consist of a simple farinaceous matter, united with a bland oil, and in many countries are eaten as food. As a medicine, they have been usually given in the form of emulsion, in cathartics, frangiparis, &c. The heads or capsules of the poppy, which are directed for use in the pharmacopoeias, like the flaks and leaves, have an unpleasant smell, somewhat like that of opium, and an acrid bitterish taste. Both the smell and taste reside in a milky juice, which more especially abounds in the cortical part of the capsules, and in its concrete state constitutes the official opium. These capsules are powerfully narcotic or anodyne; boiled in water, impart to the menstruum their narcotic juice, together with the other juices which they have in common with vegetable matters in general. The liquor, strongly perfumed out, suffered to settle, clarified with whites of eggs, and evaporated to a due consistence, yields an extract which is about one-fifth or one-sixth of the weight of the heads. This possesses the virtues of opium, but requires to be given in double its dose to answer the same intention, which it is said to perform without occasioning a nauseous and giddiness, the usual effects of opium. This extract was first recommended by Mr. Arnott; and a similar one is now received in the Edinburgh Pharmacopoeia. It is found very convenient to prepare the syrup from this extract, by dissolving one dram in two pounds and a half of simple syrup. The syrup papaveris albi, as directed by both colleges, is a useful anodyne, and often succeeds in procuring sleep, where opium fails; it is more especially adapted to children. White poppy heads are also employed externally in fomentations, either alone, or more frequently added to the decoction pro femone. 2. The roces, or wild globular-headed poppy, rises with an upright, hairy, multiformed stalk, branching a foot and a half high; garnished with long, pinna
tified, deeply cut, hairy leaves; the stalk terminated by many red and other coloured flowers in the varieties, succeeded by globular smooth capsules.

This plant is common in corn-fields, and flowers in June and July. It may be distinguished from P. du Woodville blum, to which it bears a general resemblance, by its urn-shaped capsules, and by the hairs upon the peduncles standing in a horizontal direction. The capsules of this species, like those of fominifera, contain a milky juice, of a narcotic quality, but the quantity is very inconsiderable, and has not been applied to any medical purposes; but an extract prepared from them has been successfully employed as a sedative. The flowers have somewhat of the smell of opium, and a mucilaginous taff, accompanied with a slight degree of bitterness. A syrup of these flowers is directed in the London Pharmacopoeia, which has been thought useful as an anodyne and pectoral, and is therefore prescribed in coughs and catarrhal affections; but it seems valued rather for the beauty of its colour than for its virtues as a medicine.

3. The Cambricum, or Welsh poppy, has a per
cennial root, pinnaed cut leaves, smooth, upright, multiformed stalks, a foot and an half high; garnished with small pinnaed leaves, and terminated by many large yellow flowers, succeeded by smooth capsules. — The flowers appear in June.

4. The orientalis, or oriental poppy, hath a large, thick, perennial root; long, pinnaed fawed leaves; upright, rough, uniformal stalks, terminated by one deep red flower, succeeded by oval, smooth, capsules. The flowers appearing in May.

Propagation. All the kinds are hardy, and will prosper anywhere. The two first species being annual, are to be propagated only by seeds; but the two, last by cutting the roots as well as the seeds.

PAPAW, or PAPA-Trees. See CARICA.
of a palm of Madaba; Herman speaks of another palm in the mountains of that country which produces leaves of several feet in breadth. Ray, in his History of Plants, Vol. II. Book xxii. mentions some trees both in India and America, the leaves of which are proper for writing. From the interior substance of these leaves they draw a whitish membrane, large, and somewhat like the pellicle of an egg; but the paper made by art, even of the coarsest materials, is much more convenient in use that any of these leaves.

The Siamese, for example, make two kinds of paper, the one black and the other white, from the bark of a tree which they call Pukkia. These are fabricated in the coarsest manner; but they can be used on both sides with a book of fullers earth.

The nations beyond the Ganges make their paper of the bark of many trees. The other Asiatic nations within the Ganges, excepting those toward the south, make it of old rags of cotton cloth; but from their ignorance of the proper method, and the necessary machinery, their paper is coarse. This, however, is by no means the case with that made in China and Japan, which deferves attention from the beauty, the regularity, the strength, and fineness of its texture. In Europe they have discovered, or rather carried to perfection, the ingenious art of making paper with old rags, originally either from flax or hemp; and since this discovery the paper produced from our manufactures is sufficient for every purpose. And though these materials have been hitherto abundant, several philosophers have attempted to substitute other vegetable substances in their place. In the 6th volume of the Transactions of the Society for the Encouragement of Arts, we have an account of paper made by Mr. Greaves near Warrington from the bark of willow-twig, and it has been observed by a society of able critics, that hop-buds would probably answer this purpose better. The rags in common use for paper-making are a texture of supple and strong fibres separated by a leaf from the bark of the plants. It would be in vain to employ the whole body of the plant, as this substance forms a very improper stuff for the operations of the paper-mill. From these principles we are directed in the choice of vegetable substances fit for the present purpose. The greater or less degree of purity in the materials is not absolutely necessary; for itself, without any preparation, could be made into paper; but it would be extremely coarse, and the bark of nettles or mallows would not bear the expense of labour. Although cotton be used in the fabrication of paper in the Levant, and perhaps in China, we are not to conclude that the down of plants in Europe, without the strength or suppleness of cotton, will answer the same purpose.

**History.**

The chief kinds of paper which merit attention in this work are, 1. The Egyptian paper; 2. The paper made from cotton; 3. Paper from the interior bark of trees or liber; 4. Chinese paper; 5. Japanese paper; 6. Paper made from alab; and, 7. Paper made from linen rags.

This is the famous paper used by the ancients, which was made of a kind of reed called papyrus, growing in Egypt on the banks of the Nile. According to IIdorus, this paper was first used at Memphis, and Lucan terms it to be of the same opinion.

\[\text{Nondum flaminus Memphis concretere illude Novorat.}\]

\[\text{Pharsal. lib. iii. ver. 222.}\]

Whatever truth may be in this, it is certain, that of all the kinds of paper used by the ancients, the papyrus was the most convenient, both from its flexibility and from the ease of fabrication. It was a present from nature, and required neither care nor culture.

It is not certain at what particular time the ancients began to make paper of papyrus; but there are several authorities which prove the use of it in Egypt long before the time of Alexander the Great.

Pliny, lib. xiii. cap. 11, gives a full description of the method of making this paper in Egypt. They divide, says he, with a kind of needle the stem of the papyrus into thin plates or slender pellicles, each of them as large as the plant will admit. These are the elements of which the sheets of paper are composed. The pellicles in the centre are the best; and they diminish in value as they depart from it. As they were separated from the reed, they were extended on a table, and laid across each other at right angles. In this state they were moistened by the water of the Nile, and while wet were put under a press, and afterwards exposed to the rays of the sun. "It was supposed that the water of the Nile had a gummy quality necessary to glue these stripes together. This, says Mr. Bruce, lib. xiii. we may be assured is without foundation, no such qua-

\[\text{lib. iii. ver. 222.}\]

\[\text{lity being found in the water of the Nile;}\]

\[\text{on the contrary, I found it of all others the most improper,}\]

\[\text{till it had settled and was absolutely dried of all the earth gathered in its turbid state.}\]

\[\text{I made several pieces of this paper both in Abyssinia and Egypt; and it appears to me, that the sugar or sweetness with which the whole juice of this plant is impregnated, is the matter that causes the adherence of these stripes together; and that the use of the water is no more than to dissolve this, and put it perfectly and equally in fusion." When there was not enough of sugar in the plant, or when the water did not sufficiently dissolve it, the pellicles were united by a paste made of the finest wheat flour, mixed with hot water and a little vinegar, and when dried they were flattened and smoothed by the beating of a mallet.}\n
The size of this paper varied much; it seldom exceeded two feet, but it was oftentimes smaller. It had different names, according to its size and quality: The first was called **Imperial**, which was of the finest and largest kind, and was used for writing letters by the great men amongst the Romans. The second was called by the Romans the **Legion** paper, from Libia the wife of Augustus; each leaf of this kind was 12 inches. The third sort was called the **Sacred** paper, and was 11 inches in size.

The paper used in the amphitheatres was of the dimensions of nine inches. But what was esteemed of greatest value in it, was its strength, whiteness, and polish. The ink, however, sunk less in paper highly polished; and therefore the characters were more liable to be effaced. When it was not carefully soaked in the first preparation, the paper brought a less price; because
became letters were with difficulty formed upon it, and it sent forth a disagreeable smell. To remedy this defect, the paper went through a new course of beating and hammering; and the sizes used on that occasion was made of light bread steeped in boiling water, and pasted through a filtering cloth. By this means the paper became in the highest degree united, and smoother than the finest linen. It was this paper which gave so long a duration to the works of the Gracchi, Tiberius, and Caligula, in their own handwriting. "I have seen them (says Pliny) in the library of Pompeius Secundus, a poet and citizen of the first rank, near 200 years after they were written." We may add, that manuscripts of this paper still remain, which have undoubtedly been written 1000 or 1200 years ago. It appears from Pliny, that the Egyptians paled together the pellicles of the papyrus by means of the water of the Nile; but that the polishing with ivy, and the operations of the hammer and the prefs, were added by the invention and industry of the Roman artificers. The Egyptians seem to have known the use of fire; but it is evident from the same author, that the Romans used a stronger fire in the making of paper. Notwithstanding the care which was taken to give strength and consanguinity to the paper of Egypt, the leaves, although collected into a book, were too weak to support themselves; and for this reason it was a common practice, after every five leaves, to insert a leaf of parchement. There still remains in the abbey de St Germain de-pres, a fragment of the epistles of St Augustine written in this manner. The manuscript is at least 1100 years old, and in a high state of preservation.

This paper was an important branch of commerce to the Egyptians, which continued to increase towards the end of the Roman republic, and became still more extensive in the reign of Augustus. The demand from foreign nations was often so great, as to occasion a scarcity at Rome; and we read in the reign of Tiberius of a tumult among the people in consequence of this scarcity. In a letter of the Emperor Adrian, the preparing of the papyrus is mentioned as one of the principal occupations at Alexandria. "In this rich and populous city (says he) nobody is seen idle: Some are employed in the manufacture of cloth, some in that of writing paper," etc. During the time of the Antonines, this commerce continued equally to flourish.

Apuleius says, that he wrote on the paper of Egypt with a reed of the Nile prepared at Memphis.

The demand for this paper was so great towards the end of the third century, that when the tyrant Firmus conquered Egypt, he boasted that he had seized as much paper and fize as would support his whole army.

St Jerome informs us, that it was as much in use in the fifth century when he flourished. The duty on the importation of this commodity had grown excessive towards the end of this or the beginning of the sixth century; and being abolished by Theodosius king of Italy, Cassiodorus, in the 38th letter of the 11th book, congratulates the whole world on the discharge of an impost on a merchandise so essentially necessary to mankind.

The fathers Montfaucon and Mabillon mention several fragments written on this paper in the fifth century. One of them was a charter of the Emperor Julian, intitled, Charter plenaria §.c. Father Montfaucon saw in 1698, in the library of Julio Juliani, three or four fragments of paper of Egypt of the same antiquity. And Mabillon speaks of some books of the Jewish antiquities by Josephus translated into Latin, which seemed to have been written in the same century, and which were preserved in the library of St Ambrose of Milan, but he had not seen the manuscripts. The same author mentions to have seen in the library of St Martin of Tours the remains of an old Greek manuscript of the paper of Egypt, and which appeared to him to be of the seventh century. He also believes, that the copy of St Mark's gospel preserved in the register-office of Venice is written on the same paper, that it is the most ancient of any of the evangelical manuscripts, and may be supposed to have been written at the latest in the fourth century.

According to the same antiquarians, the paper of Egypt was used in France, and Italy, and other European countries, both for books of learning and public records; and there still remains, adds he, a great number of thes in the archives of the church at St Dennis, at Corbie, in the abbey de Graffe, and in other convents.

It is probable, that the invention of paper made of cotton, of which we are afterwards to treat, infensibly destroyed the reputation and manufactures of the paper of Egypt; but it is still a question at what particular period the fabrication of the latter totally ceased. Emachius, the learned commentator on Homer, affures us, that in his time in 1170 it was no longer in use; but father Mabillon maintains, that many of the popish bulls were written on the papyrus in the 11th century.

The Count Maffet, in his Histoire Diplomat. lib. ii. lib. xxxi. tom. ii. p. 251, is decidedly of opinion, that the paper of Egypt was not in use in the fifth century. He considers all records written on this paper dated posterior to this period as not authentic; and the popish bulls mentioned by father Mabillon appear to this learned person, as well as the copy of St Mark's gospel, to be written on paper manufactured from cotton. To reconcile in some measure these contradictory accounts, it may be observed, that on some particular occasion, and by some particular persons, the paper of Egypt might have been employed for several hundred years after it ceased to be of general use. Whoever wishes for a fuller account of the paper of Egypt, may consult among the ancients Pliny, lib. liii. and Theophrastus, lib. iv. chap. ix. and among the moderns, Guillaudin, Scaliger, Sansone, Kerckhayer, Nigrifoli; Father Hardouin in his edition of Pliny; Father Mabillon in his work, De re Diplomat. Montfaucon in his Paleography, and in his Collections; the illustrious Maffet in his Histoire Diplomat, the Count de Caylus in the Memoirs of the Academy of Inscriptions; and Mr Bruce in his Travels to discover the Source of the Nile.

It is generally supposed that the invention of the paper called charta bombycina, supplanted the Egyptian cotton, more lasting, and better calculated for all the purposes of writing. It is not precisely known at what period this art, which supposes a great variety of previous...
experiments, was full reduced to practice. The application of cotton to the purposes of paper-making requires as much labour and ingenuity as the use of linen rags; and for this reason if we could determine the precise time that paper was made from cotton, we should also fix the invention of the art of paper-making as it is presently practised in Europe. Father Montfaucon proves, by incontestable authorities, that paper from cotton was in use in 1100. This paper in the Greek language is called καρπος βοδολος, or βοδολος, for although καρπος is the Greek word for fruit, yet in those times it was applied, as well as δολος, to cotton; and hence the Italians to this day call cotton banalaccio.

The most ancient manuscript of this paper which Father Montfaucon saw with the date, was that in the French king's library, written A. D. 1050; but as the manuscripts without date are infinitely more numerous than those which are dated, and as some conjectures can be formed concerning them from the manner of writing, this father believes some of these to have been written in the tenth century.

The researches of the same learned antiquarian amount almost to a proof that this paper was discovered towards the end of the ninth century or beginning of the tenth; for before the twelfth century it was commonly used in the eastern empire, and even in Sicily. Roger king of Sicily says, in a diploma written in 1145, that he had renewed on parchment a charter which had been written on paper of cotton, in the year 1100, and another which was dated in the year 1112. About the same time the empress Irene, in the statutes and edicts of some religious houses at Constantinople, says that she had left three copies of the same statutes, two in parchment and one in paper from cotton. From that period this paper was still more in use through all the eastern empire; and innumerable Greek manuscripts are found written on it in all the great libraries.

This discovery happened at a time when there seems to have been a great facility of parchment; for it was about this period that the Greeks erased the writings of Polybius, Diodorus of Sicily, and many valuable ancient authors, for the sake of the parchment.

It was the invention of this paper of cotton which destroyed the manufacture of the paper of Egypt; for, if we may believe Eusebius, who wrote towards the end of the twelfth century, the latter paper had gone into disuse but a little before his time. We may easily believe, however, that this new invention, although of great advantage to mankind was introduced by degrees.

The manufacture of this kind of paper has flourished in the Levant for many ages, and is carried on with great success even to this day. It is not necessary to lay any thing farther, than that the paper produced from cotton is extremely white, very strong, and of a fine grain.

This paper of the ancients was made from the white pellicle or inner coat found in many trees between the bark and the wood. The trees commonly in use were the maple, the plane-tree, the elm, the beech, the mulberry, and most frequently the lindini tree. The ancients wrote on this inner coat after they had separated it from the bark, beat, and dried it.

The fathers Albion and Montfaucon speak frequently of manuscripts and diplomas written on paper made from bark; and positively distinguish it from the Egyptian paper, because it was thicker and composed of parts less adhering together.

There are many palm trees in India and America to which botanists have given the name papyraceous, because the natives have written with bodkins either on the leaves or the bark. Such is the American palm, called tal by the Indians; and of the same kind is the guajarába of New Spain. Every palm, the bark of which is smooth, and the leaves large and thick, may be used for this purpose.

The art of making paper from vegetables reduced to flour was known in China long before it was practised in Europe; and the Chinese have carried it to a degree of perfection hitherto unknown to the European artists. The fine paper in China is softer and smoother than that of Europe; and these qualities are admirably adapted to the pencil, which the Chinese use in writing. Several kinds of their paper discover the greatest art and ingenuity, and might be applied with much advantage to many purposes. They are capable of receiving, for example, the impression of types; and both maps and prints have been executed with success on the Chinese paper.

The different sorts of paper vary in China according to the materials of which they are composed, and to the different manner of manufacturing those materials. Every province has its peculiar paper. That of Szechuen is made of linen rags as in Europe; that of Foo-kiong, of young bamboo; that of the northern provinces, of the interior bark of the mulberry; that of the province of Kiang-nan, of the ikia which is found in the webs of the silk-worm; finally, in the province of Hu-kuang, the tree chu or ko-chu furnishes the materials with which they make paper.

The method of fabricating paper with the bark of different trees is nearly the same with that which is followed in the bamboo. To give an idea, therefore, of the manner of manufacturing the interior barks of the mulberry, the elm, and the cotton tree, it will be sufficient to confine our observations to the bamboo.

The bamboo is a kind of cane or hollow reed divided by knots; but larger, more elastic, and durable than any other reed.

The whole substance of the bamboo, composed of filaments, and a great abundance of fibrous materials, is employed in this operation. The shoots of one or two years, nearly the thickness of a man's leg, are preferred. They strip the leaves from the stem, cut them into pieces of four or five feet long, make them into parcels, and put them into water to macerate. As soon as they are softened, which generally happens in five days; they wash them in pure water; put them into a dry ditch; cover them with lime for some days; which they water for the purpose of slacking; they wash them carefully a second time; cut every one of the pieces into filaments, which they expose to the rays of the sun to dry and to bleach them. After this they are boiled in large kettles; and then reduced to fluff in mortars of wood, by means of a hammer with a long handle, which the workman moves with his foot.

The fluff being thus prepared, they take some shoots of
of a plant named *ketong*, which, steeped in water four or five days, is reduced to an inoffensive glutinous substance; and when they proceed to make the paper, that is mixed with the fluid in certain exact quantities, for on this mixture depends the goodness of the paper.

When the extract from the *ketong* is mixed with the juice of the bamboo, the whole mixture is beat together in mortars till it becomes a thick and viscous liquor. This is poured into large tubs or reservoirs, so exactly framed that no part of the liquor can escape.

The workmen after this plunge their forms into the liquor; take out what is sufficient for a sheet of paper, which immediately, from the glutinous substance, becomes firm and shining; and is detached from the form by turning down the sheet on the heap of paper already made, without the interpolation of pieces of woollen cloth, as in Europe.

In order to dry this paper, they have a hollow wall, the two fronts of which are smooth and extremely white. At the extremity of this wall is placed a fove, the pipes of which are carried in a circular manner through the whole empty space. The sheets of paper are laid on the surface, to which they adhere till they come over them with a soft brush; and after they are dry, it is easy to distinguish the side which received impressions from the brush from that which adhered to the wall. By means of this fove the Chinese dry their paper as fast as they can make it; but it is only in cold seasons, or in certain provinces, that they find this expedient necessary.

The Chinese paper must be dipped in a solution of alum before it can take either ink or colours. They call this operation *faner* from the Chinese word *fan* which signifies alum. The following is the manner of preparing this solution: Six ounces of *fingiflas* cut very small is put into boiling water, and constantly stirred that it may dissolve equally. When the *fingiflas* is wholly dissolved in the water, they throw in twelve ounces of calcined alum, which is also stirred till it is completely dissolved and mixed with the *fingiflas*. This composition is afterwards poured into a large and deep basin, at the mouth of which is a little round piece of wood; the extremity of every sheet of paper is fixed in another piece of wood, with a flat made to receive it; by means of this equipage they plunge the sheet of paper into the composition of alum and *fingiflas*; and when it is fully penetrated they draw it out, making it glide over the little round piece of wood. The long piece of wood which holds the sheet by one end, and keeps it from tearing, is afterwards suspended with it on a wall till it is sufficiently dry.

The Chinese give the paper intended for different purposes different preparations. We shall confine our observations to the silver colour which they give to some paper. They take two scrupules of *pajte* made of cows hide, one scrupule of alum, and a pint of water: the whole is boiled on a flow fire till the water be evaporated. The sheets of paper are then stretched on a smooth table, and covered over with two or three layers of this paste. They take afterwards a certain quantity of tale, washed and boiled in water, with the proportion of one third of alum: this is dried, reduced to a powder, passed through a sieve, boiled a second time in water, dried in the sun, and again passed through the sieve. This powder is spread equally over the sheets of paper, prepared as we mentioned above; and then they are dried slowly in the shade.

The sheets of paper, covered in this manner with tale, are laid upon a table, and rubbed with a little cotton; which fixes a certain quantity of the tale in the paper, and carries off the superfluous in the shape. This composition, the Chinese dye all manner of figures on their paper.

Formerly the Chinese wrote with a bodkin of iron on tablets of bamboo; afterwards on fatin with a pencil; and during the dynasty of its tyrants, about 150 years before Christ, they discovered the art of making paper.

The paper made from the bamboo is sufficiently white, soft, closely united, without the least inequality on the surface to interrupt the motion of the pencil, or to occasion the rolling of the materials which compose it. Meanwhile every kind of paper made from the bamboo or the bark of trees is ready to crack than that made in Europe; besides, it is more susceptible of moisture, and sooner destroyed by worms. To obviate this last inconvenience, they are obliged frequently to heat their books in China, and to expose them to the sun. It may be observed, however, that the Chinese paper, employed for various purposes in Europe, has been preferred for a long time without receiving damage either from moisture or insects.

According to Kempfer, the bark of the *morus pa­pierosa* Jap. or true paper-tree, is chiefly employed for making paper in Japan. Every year after the fall of the leaves, which happens in the tenth month, corresponding to our December, the Japanese cut the young shoots of this tree into pieces of about three feet, collect them into parcels, which they boil in water into which they have cast a certain quantity of ashes. If the wood is dry, they take care to steep it 23 hours in water before it is boiled. The parcels are kept in a close copper till the bark at the extremity of the shoots is separated from the stem about half an inch; they are then cooled; and the bark alone is fit for making paper. They begin by a preparation which consists of cleaning the bark, and separating the good from the bad. For this purpose they steep it in water three or four hours; and as soon as it is softened they scrape off with a knife whatever is blackish or green, and at the same time separate the strong bark of a year's growth from the flender which covers the young shoots. The first of these gives the whitest and best paper. If there is any of the bark of more than a year's growth, it is laid aside for the coarser.

After the bark has been culled and cleaned in this manner, it is boiled in a clear ley till the matter is of that consistency, that, being touched gently with the finger, it draws off in the form of hairs, or like a collection of fibres. During the time of boiling it is constantly stirred with a strong reed, and the waste by evaporation supplied from time to time with additional quantities of the clear ley. To make this ley, they put two pieces of wood across the mouth of a tub, cover them with straw, on which they lay a bed of
of a few leaves a little moistened; and pouring boiling water on the leaves, the flats contained in them are carried down to the tub. This is what is called a clear ley.

After the bark is in the condition we have just now stated, it is washed with great care; for on this washing depends in a great measure the goodness of the paper. It is put into a kind of sieve through which the water can flow freely; and great care is taken to turn it with the hand till it is sufficiently diluted, and reduced to soft and tender fibres. For the finest paper a second washing is requisite, and a piece of cloth is used instead of a sieve.

When the bark is washed it is laid on a strong and smooth table, and beat with a kind of baton of hard wood till it is reduced to a proper consistence. It becomes indeed so soft, that it resembles paper steeped in water.

The bark prepared in this manner is put into a narrow tub, with a glutinous extract from rice and the root orien, which is very viscosus. These three substances, mixed together, are stirred with the reed till they form a liquor of an equal and uniform consistence. This composition is poured into tubs similar to those used for filling the forms in our paper-mills.

As soon as the sheets are made and detached from the form, they are laid in a heap on a table covered with a double mat. A small chip of cane is placed betwixt every sheet. This piece of cane jutting out, serves to distinguish the sheets and afterwards to raise them. Every one of the heaps is covered with a plate or thin board of the exact size of the paper. In proportion as the paper dries, or is able to bear it without danger of being compressed into one mass, they lay on additional weights. This procedure, intended to carry off any unnecessary moisture, is continued for 24 hours, when the sheets are suspended, by means of the little piece of reed, to long plants, in the open air, till they are completely dried.

The extract from rice is made in an unvarnished earthen pot. The pot agitated at first gently, then more briskly: sew water is poured in, and then it is filtered through a linen cloth. The finishing of the process is determined by the viscositas of the substance.

The infusion of the root orien is made in the following manner: The root is peeled and cut into small pieces, is infused into water for one night, during which time it communicates a viscositas sufficient for the purpose to which it is applied.

The Japanese paper is of so prodigious a strength, that the materials of which it is composed might be manufactured into ropes. There is sold at Serige, the capital city of the province of Japan of that name, a kind of it fit for bed-hangings and wearing apparel; resembling so much fluffs of wool and silk that it is often taken for them. The following is Kempfer's catalogue of trees used in Japan for the manufacture of paper.

1. The true paper-tree, called in the Japanese language kafhi, Kempfer characterizes thus: *Paprus frutus mori caele*- *se* moram, utroque folio longo lanceata cortice chartacea,* 3. The plant which the Japanese call oreni is named by Kempfer *alta radice viscosa f. ephemero magnu pu-

nesco. 4. The fourth tree used for paper is the *fistulosa* frutice *viscosa procumbens folio telephii vulgaris amm. frut. racemosi.*

The description of these trees given more particularly by Kempfer than the limits of this work will permit, may be of great service to lead botanists to discover the European plants and shrubs adapted, like the Japanese, for the fabrication of paper.

Before finishing our reflections on this part of the subject, it will be proper to give a just idea of the attempts which have been made to increase the original materials of paper in Europe.

A flight attention to the process in China in reducing the bamboo to a paste, by a careful and ingenious analysis, and to the long and proper method of the Japanese of separating the principal fibres of the bark of the mulberry, will shew the absurdity not only of taking plants without any kind of choice, but of giving them no preparation except that of pounding them with mallets.

With a proper selection, and good principles, it appears not improbable that many of the European plants might be used with great advantage in constructing several kinds of paper.

It is evident that the materials used by the Chineses require less labour and preparation than the stuff of linen rags. The sheets of the Chinese paper are easily detached from the form; they are laid in heaps without the interposition of pieces of wooden cloth: the superfluous water is immediately discharged; and they require not, as in Europe, the vigorous action of presses to unite the parts more closely together.

The asheflos is a fibrous substance of little strength, Paper the threads of which are easily broken. This sub-stance has the peculiar quality of supporting the action of fire without receiving any damage: whence pieces of cloth and garters made of it are incombustible.

From the knowledge of this property paper has been made of the asheflos. Dr Brukman, professor at Brunswick, published the natural history of this fibell; and four copies of his book, in the library of Wolfenbuttel, are on this paper.

The manner of fabricating this paper is described by M. Lloyd in the Philosophical Transactions, No. 166. A certain quantity of the asheflos is pounded in a mortar of stone till it be reduced to a substance like cotton. All the parts of earth or stone remaining in the asheflos are then taken off by means of a fine sieve, and it is formed into sheets of paper by an ordinary paper-mill. Mixing it with water reduces it to stuff; only, as it is heavier than that from linen rags, it requires to be continually stirred when they are taking it up with the frames. The only excellence of this paper is, that the writing disappears when it is cast into the fire. It must be observed, at the same time, that as it is of a tender consistence, and easily torn, it is more an object of curiosity than use.

This paper is manufactured through all Europe by linen rags collected in the cities and in the country, made from This kind of paper was utterly unknown to the ancients. The libri limini mentioned by Livy, i. lib. iv. Pliny, XIII c. xi. and by other Roman writers, are demonstrated by Guilandin, in his commentary on Pliny, &c. to have been written on pieces of linen cloth, or canvas prepared in the manner of painters.
But it is not sufficient to be certain that paper from linen is a modern invention; it is necessary to know by what nation and at what period it was discovered. Polidore Virgili, De Inventoribus Rerum, C. II. c. viii. confesses his ignorance of these facts. Scaliger, without any kind of proof, gives the glory to the Germans; and count Maffei to the Italians. Other writers ascribe this honour to some Greek refugees at Basil, to whom the manner of making paper from cotton in their own country had suggested the idea. Du Halde is persuaded that Europe derived this invention from the Chinese, who, in several provinces, make paper of rags nearly in the same manner that we do. But this invention was practised by the Europeans before they had any communication with China, and before the taking of Constantinople, at which time the Greek refugees were supposed to have retired to Basil. The precise time of this discovery in Europe is not exactly known. Father Mahillon believes that it was in the twelfth century; and cites a passage of Pierre de Chigny, born A.D. 1100, to prove it. The books which we read every day, says that Abbé in his treatise against the Jews, are written on sheets and calfs skin; or on oriental plants; or, finally, ex rarioris veterrum pannorum. If these last words signify paper, such as we use, there were books of it in the twelfth century. But this citation is the more to be suspected, as Montfaucon himfelf, after the minutest search in France and Italy, could find no book on this paper antecedent to the death of St Louis, A. D. 1270.

The period of this invention was not determined till 1762, M. Mierman having proposed a reward to the person who could procure the most ancient manuscript written on this kind of paper. The collection of all the memoirs sent to him along with the manuscripts was published at the Hague in 1767; and it appeared that this paper had been used in Europe before the year 1300.

In 1782 the Abbé Andrés published a work intitled Dell' Origine, Progressi e Stato attuale d'Ogni letteratura; wherein he speaks of the discovery of many kinds of paper, and particularly of that made of rags. The Abbé Andrés maintains, that paper made from flax was very anciently fabricated in China, and in the eastern parts of Asia; that the art of making this paper was carried from China to Persia about the year 652, and to Mecca in 706. The Arabs suffituted cotton, the commodity of their own country, in place of flax, or rather bamboo. The paper of cotton was carried into Africa and Spain by the Arabs. The Spaniards, from the quantity of linen to be found in the kingdom of Valencia, seem first to have adopted the idea of using linen rags; and the most ancient paper of this kind is of Valencia and Catalonia. From Spain it passed into France, as may be learned from a letter of J.-inville to St Louis about the year 1260. It is discovered to have been in Germany in 1312, and in England in 1320 and 1342. In consequence of the paper made from cotton in the Levant, the paper from linen was introduced much later into Italy. See the work of Abbé Andrés, printed at Parma, 1782; and Mierman's Collection, published at the Hague, 1767.

To give a concise view of this subject, it will be necessary to proceed with all the important parts of the operation in their order.

The selection of the rags is the arranging of them into different lots, according to their quality and to the demand of the paper mill. In general this selection is very much neglected. The degrees of fineness, distinguished with little care, are thought to be the only objects of importance; whereas the hardnefs and softnefs, the being more or less worn, are much more essential in this selection. It is certain, that a mixture of soft and hard rags occasions much more loss in the trituration than a difference in point of fineness or of colour. This exactness in the selection is still more necessary when cylinders are used instead of mallets. We cannot do better than to give the method practised in Holland as worthy of imitation.

They begin by a general separation of the rags into four lots: superfine, fine, middle, and coarse. These lots are given to selectors, who subdivide each of them into five chests. They have besides a bench, on which is fixed vertically a hook, and a piece of fcythe which is terminated by a crooked point.

The person, for example, who has the charge of the fine lot, puts into one of the chests the hard rags, or those which are little used, into another the softer, and into a third the dirty, into a fourth those which are flitched or hemmed, and, finally, into the fifth the superfine rags which happens to be among the fine.

After this process, the women who have the charge of it are at extreme pains to pick out every kind of sewing, and especially the knots of thread and the hems, by means of the hook or fcythe which they have under their hands. They take care also by the same means to cut and reduce the rags exactly by the warp and the woof into small pieces. It is of great advantage to cut or tear the pieces of rags by a thread, whether it be by the warp or woof; because if it is done obliquely, many of the ends are lost in the operation.

When they have selected a certain quantity of each of these subdivisions, they are placed on an iron grate, which covers a large chest where they are beat, and otherwise turned, till the fifth and sixth pass through the bars of the grate and fall into the chest.

The number of lots in the selection of rags must be proportioned to the mass from which the selection is made, and to the kinds of paper produced by the mill. Some mills, the work of which is considerable, make nine lots of their rags, five of which respect the fineness, and the rest the cleanliness and the colour. In ordinary mills there are only four lots, and in some two.

We have already observed, that the selection which regards the hardnefs of the materials is the most essential; because it is of great importance to obtain stuff composed of equal parts, and without any loss. But it is necessary to add, that the fineness and beauty of the paper depend in some cases on a selection not rigorous. Thus, for example, it is of great service to allow...
allow the middle to retain some part of the fine, and for without this the inferior kinds of paper can never be of great value. The most common fault is to mix the rags of the inferior lots with the superior; which, though it augments the quantity of paper, is extremely injurious to the quality. It does much better to mix part of the superior lots with the inferior. It is the want of attention to this mixture which makes some paper-mills excel in the superior sorts of paper, while the inferior kinds are of a very bad quality.

The selection of rags being made with exactness, however, and the lots being fermented and triturated separately, the mixture may be made with much greater advantage when they are both reduced to fluff; always taking care that it be in the same proportion as if it were in the state of rags, and only in the manner which we just now mentioned; for the inferior lots gain more in beauty and quality by this mixture than is lost in fluff; whereas if the fine fluff receives a certain quantity of the inferior, the paper is more damaged in its value than increased in quantity. In this manner the interest of the manufacturer, as in all cases, is intimately connected with the goodness of his commodities.

In some mills the place for fermentation is divided into two parts, one of which serves for washing away the filth from the rags. After allowing them to steep for some time in a large flume vat, they fill them, and pour in fresh water till the impurities connected with the rags run over. When they are as clean as they possibly can be made by this kind of washing, they are laid in a heap to putrefy. In this condition they experience a degree of fermentation, which is first discovered by a mouldiness of the different pieces of cloth. Afterwards the maf grows warm; and then it is of great consequence to attend to the progress of this heat, in order to moderate its effects: for this purpose, the middle of the heap, where the fermentation is strongest, is turned out, and vice versa. In mills where mallets are used, the putrefaction is carried to a great height, which is frequently attended with two inconveniences. The first, is, that a part of the rags is reduced to an earthy sub stance, which is found in great abundance about the cutting-table, which we shall afterwards have occasion to feel. But besides this want, excessive fermentation makes the stuff incapable of fulfilling the action of the mallets till it is equally pounded. A paper made from stuff too hard and too little fermented, is coarse and ill compounded; that made from rags too much fermented is composed of fibres without formness and without strength.

The second inconvenience is, that the rags turn greasy by too much fermentation, and of consequence it is very difficult to separate and reduce them by all the washings of the trituration.

We shall not describe the form of the place for fermentation, because in different paper-works these places are of different constructions: it is sufficient to say, that they are all placed in low situations and made very close. The selected rags are placed in them in heaps, and watered from time to time to bring on the fermentation. In different paper-mills they practice different methods in the putrefaction of their rags.

In certain provinces in France, they lay in the place for putrefaction a heap equivalent to what the mill can triturate in a month. When this is equally and sufficiently moistened by means of moveable pipes, they cover it with an old heap, which has lain a month in a state of fermentation. When this old heap is exhausted by the mill, the new one becomes a covering to another, and so on. From this detail it is easy to perceive, that there must be near three weeks difference of putrefaction in the same heap, and also that in this method there is no allowance for those fea sons in which the fermentation advances more rapidly.

In general the putrefaction goes on more slowly in proportion to the fineness of the rags. But when, on any occasion, it advances more rapidly than the demand from the mill, the rags are turned over and watered, to stop the fermentation and prevent the bad effects.

All the inconveniences attending the excess of putrefaction are remedied in Holland by machines which triturate the rags without having recourse to it; and their success in this manner of preparing the stuff has attracted the notice of the French artists, some of whom have adopted with advantage the Dutch machinery.

Meanwhile, it is possible to carry the method of putrefaction to much greater perfection; and several manufacturers have made attempts to well concerted, as to deserve the attention of those who study the subject.

In the neighbourhood of Brussels some paper-manufacturers, who have constructed their mills after the Dutch plan, have still found it necessary to putrefy their rags; but, at the same time, they have an excellent method for moderating the effects of this putrefaction. In the great galleries connected with the buildings of the paper-mill, they have constructed a continuation of chests, capable each of them of containing a certain quantity of rags; for example, the quantity which the cylinder can triturate in one day. The number of chests is equal to the number of days which the rags in any season require for putrefaction; and the number actually employed is greater or less according to the season. In prosecuting this plan, they lay a heap of rags in one chest, as often as they take one from another. They should also be observed, that, for the sake of the fermentation, the rags are first moistened in a large hollow stone before they are arranged into the chests.

The peculiar advantages of this method are, the equal fermentation of the rags, without any part of them being weakened; great care in washing them; and it is even pretended, that a less degree of fermentation renders the impurities and the discoloured parts both of hemp and linen more soluble, and consequently the stuff of a purer white.

When the rags are reduced to a proper state of putrefaction, they are carried to the cutting table, which table is placed on solid treffs, and inclosed on three sides to contain the rags cut on it. Before the table is fixed vertically a part of the blade of a scythe, the edge of which is turned from the operator. This workman, in a situation rather elevated, takes from the left side a handful of the putrefied rags, and arranging them the long way, gives them a gentle twist,prefes the half-formed rope against the blade of the scythe, and, in the
the manner of sawing, cuts it into three or four pieces, which he throws to the right side of the table. In this operation the rags lose part of their filth, and especially of the earthy particles occasioned by too much putrefaction.

When the rags have been submitted to all the foregoing operations, they are in a condition to be reduced into a fibrous stuff, of which the paper is made. To obtain this stuff, mills are contrived on different principles. Those which have been used for a long time over all Europe, and which by a statement in the Encyclopædia Methodica, published at Paris in 1789, are still used in France, are mills with mallets. But the mills invented by the Dutch, and used in the neighbouring provinces, and, excepting one instance, in every part of Great Britain, are mills with cylinders or rollers. In the former of these, the mallets are raised by notches fixed at convenient distances in a large circular beam of wood. The teeth fixed on the end of the mallet fall into a corresponding gap made the whole breadth of the plate, and the strokes are repeated till the rags are reduced to a proper consistency. Upon supplying the vat with water, and carrying off all the impurities, the operation is nearly similar to that in the mills with cylinders.

Such is the nature of what may be called the old method of making paper. It was proper to speak of this old method, because at one time, and that not very distant, it universally prevailed. That it was inferior to that now in practice, seems very evident, and that the rotted of the rags was peculiarly abort, cannot be denied; as the paper made of fermented stuff could neither be so strong nor so durable as that which is made in the common way without putrefaction. The only kind of paper that, with any propriety, could be made from putrefied stuff, was palteboard; but we are informed by the most intelligent paper-makers in Britain, that they seldom or never even putrefy the rags or retapes of which palteboard is made. It will now be requisite to state the method precisely in practice, with the improvements lately made in the art.

The duffer is made in the form of a cylinder, four and a half feet in diameter, and five feet in length. It is altogether covered with a wire net, and put in motion by its connection with some part of the machinery. A convenient quantity of rags before the feclusion are inclosed in the duffer, and the rapidity of its motion separates the dust from them, and forces it through the wire. It is of considerable advantage to use the duffer before seclusion, as it makes that operation less pernicious to the feelers.

The seclusion is performed much in the same manner as we have already described; only it is found more convenient to have the tables for cutting off the knots and fitching, and for forming them into a proper shape, in the same place with the cutting table. The surface both of these and of the cutting table is composed of a wire net, which in every part of the operation allows the remaining dust and refuse of every kind to escape. The rags, without any kind of putrefaction, are again carried from the cutting table back to the duffer, and from thence to the engine, where, in general, they are in the space of six hours reduced to the stuff proper for making paper. The hard and soft of the same quality are placed in different lots; but they can be reduced to stuff at the same time, provided the foit be put somewhat later into the engine.

The engine is that part of the mill with performs the whole action of reducing the rags to paste, or, as it may be termed, of triturating. The number of the engines depends on the extent of the paper-work, on the force of water, or on the construction of the machinery.

It will afford a sufficient idea of the work, to give in detail a description of the different parts of the engine. See Plate CCCLXXV. Figure 1. represents the chapter which covers the roller. It is four feet three inches in length, and two feet eight inches in breadth. The superior part is pierced with two openings running croswise, 1, 2, 3, 4, into which enter the chaffes or wicker-frames, figures 6, and 7; the first, made of wire cloth, enters into the opening 3 and 4; the second, made of hair-cloth, and strengthened with several cross-bars of wood, enters into the opening 1, 2. Fervices to retain the small pieces of rags which escape through the first, and prevents them from falling into the dentist or hole-supper, fig. 2. This hole-supper is placed across the vat of the engine, parallel to the axle of the roller; the part 9 enters into the notch e of the chapter; and the extremity b enters into the opening d of the tunnel k (fig. 3.), by which means the water dashed through the wicker-frames by every revolution of the roller, is precipitated into the canal h, and loses itself below the engine. The figures 4, 9, and 10, represent the roller in perspective, in plan, and in profile. It is two feet in diameter, and two feet three inches in length. The trundle head A is 16 inches in diameter, about half as much in length, and furnished with seven fiddles of iron, which are screwed to the end of the trundle head, made also of iron. The teeth or blades of the roller are 27 in number, and fitted strongly into the wood which composes its body, parallel to its axis. They are of that thickness as to leave as much empty space as they occupy. The exterior face of each of the blades should be made round, and divided into two parts, with a longitudinal motion, as in the profile a a a, fig. 10.

The axis AB of the roller (fig. 4. and 9.) has two parts perfectly rounded in A and in B, which perform the office of pivots. The pivots rest in the sockets A and B (fig. 8.) in the middle of the levers OAH and OBI. It is by means of these levers that they raise at pleasure, or lower the axis of the roller, and fit it exactly, and in a parallel manner, to the plate. The plates (see fig. 5.) are made of steel cut into channels, in such a manner as to correspond with the blades of the roller. Their channels are not perpendicular, but oblique; and there are two rows of them, bat x, consisting of seven or eight blades each on one plate.

Those bat x, for the purpose of changing the plate, lie in an opposite direction to those in x. The levers are kept in their position near the vat by bands of iron, MN and ma; between which they are made higher or lower by the cogged wheel H, which supports one of the extremities. Wedges Nz are likewise employed to fix the levers at a convenient height above the plates. Finally, every vat is supplied with a small slide-door, which is occasionally raised to carry
the prepared stuff by means of the scuppers of wood to the general repositories.

The prepared stuff is placed in the vat (fig. 4), the roller (fig. 4) is placed above it in such a manner that

the prepared stuff is conveyed into a general repository, which supplies the vat from which the sheets of paper are formed. This vat is made of wood, and generally about five feet in diameter, and two and a half in depth. It is kept in temperature by means of a grate introduced by a hole, and surrounded on the inside of the vat with a cake of copper.

For fuel to this grate, they use charcoal or wood; and, frequently, to prevent smoke, the wall of that building comes in contact with one part of the vat, and the fire has no communication with the place where they make the paper.

Every vat is furnished on the upper part with planks, inclosed inwards, and even raised in wood, to prevent any of the stuff from running over in the operation. Across the vat is a plank which they call the stave, pierced with holes at one of the extremities, and reposing on the planks which surround the vat.

The forms or moulds are composed of wire-cloth, and a moveable frame. It is with these that they fetch up the stuff from the vat, in order to form the sheets of paper. The sides of the form are made of oak, which is previously steeped in water, and otherwise prepared to prevent warping. The wire-cloth is made larger than the sheet of paper, and the excess of it on all sides is covered with a moveable frame. This frame is necessary to retain the stuff of which the paper is made on the cloth; and it must be exactly adapted to the form, otherwise the edges of the paper will be ragged and badly finished. The wire-cloth of the form is varied in proportion to the fineness of the paper and the nature of the stuff.

The felts are pieces of woollen cloth spread over every sheet of paper, and upon which the sheets are laid, to detach them from the form, to prevent them from adhering together, to imbibe part of the water with which the stuff is charged, and to transmit the whole of it when placed under the action of the press.

The two sides of the felt are differently raised; that of which the hair is longest is applied to the sheets which are laid down; and any alteration of this disposition would produce a change in the texture of the paper. The stuff of which the felts are made should be sufficiently strong, in order that it may be stretched exactly on the sheets without forming into folds; and, at the same time, sufficiently pliant to yield in every direction without injury to the wet paper. As the felts have to resist the reiterated efforts of the press, it appears necessary that the wrap be very strong, of combed wool, and well twilled. On the other hand, as they have to imbibe a certain quantity of water, and to return it, it is necessary that the wool be of carded wool, and drawn out into a slack thread.

The sheets, together with the press, which are used in the apartment where the sheets of paper are formed.

The vat being furnished with a sufficient quantity of paper-stuff.
fluff and of water, two instruments are employed to mix them; the one of which is a simple pole, and the other a pole armed with a piece of board, rounded and full of holes. This operation is repeated as often as the fluff falls to the bottom. In the principal paper mills in England, they use for this purpose what is called a bag, which is a machine within the vat that, by means of a small wheel on the outside, is made to turn constantly round, and keep the fluff in perpetual motion. When the fluff and water are properly mixed, it is easy to perceive whether the previous operations have been complete. When the fluff floats close, and in regular flakes, it is a proof that it has been well triturated; and the parts of the bags which have escaped the rollers also appear.

After this operation the workman takes one of the forms, furnished with its frame, by the middle of the short sides, and fixing the frame round the wire-cloth with his thumb, he plunges it obliquely four or five inches into the vat, beginning by the long side, which is nearer to him. After the immersion it rises to a level; by these movements he fetches up on the form a sufficient quantity of fluff; and as soon as the form is raised the water escapes through the wire-cloth, and the superficiency of the fluff over the sides of the frame. The fibrous parts of the fluff arrange themselves regularly on the wire-cloth of the form, not only in proportion as the water escapes, but also as the workman favours this effect by gently shaking the form. Afterwards, having placed the form on a piece of board, the workman takes off the frame or deckle, and glides this form towards the coucher; who, having previously laid his felt, places it with his left hand in an inclined situation, on a plank fixed on the deckle, and glides this form along the trapan of the vat. The coucher then keeps it depending by the eye on that side, which is more or less fine in proportion to the water, two men make a sheet of paper is received, that, in many sorts of paper, two men make upwards of 20 sheets in a day. When the last sheet of the posf is covered with the last sel, the workmen about the vat unite together, and submit the heap to the action of the press. They begin at first to press it with a middling lever, and afterwards with a lever of about fifteen feet in length. After this operation another perfon separates the sheets of paper from the felts, laying them in a heap; and several of these heaps collected together are again put under the press.

The fluff which forms a sheet of paper is received, as we have already said, on a form made of wire-cloth, which is more or less fine in proportion to the fluff, and surrounded with a wooden frame, and supported in the middle by many crofs bars of wood. In consequence of this construction, it is easy to perceive, that the sheet of paper will take and preserve the impressions of all the pieces which compose the form, and of the empty spaces between them. The traces of the wire-cloth are evidently perceived on the side of the sheet which was attached to the form and on the opposite side they form an affem-
operation it is necessary to alter the situation of the heaps, with regard to one another, every time they are put under the presses, and also, as the heaps are highest toward the middle, to place small pieces of felt at the extremities, in order to bring every part of them under an equal pressure. A single man with four or five presses may exchange all the paper produced by two vats, provided the previous pressing at the vats be well performed. The work of the exchange generally lasts about two days on a given quantity of paper.

When the paper has undergone these operations, it is not only softened in the face, but better felted, and rendered more pleasant in the anterior parts of the stuff. In short, a great part of the water which it had absorbed in the operation of the vat is disipated. By the felting of paper is understood the approximation of the fibres of the stuff, and their adhering more closely together. The paper is felted in proportion as the water escapes; and this effect is produced by the management and reiterated action of the presses. Were it not for the gradual operation of the press, the paper would be porous and composed of filaments adhering closely together. The superiority of the Dutch over the French paper depends almost entirely on this operation.

If the sheets of paper are found to adhere together, it is a proof that the business of the press has been badly conducted. To avoid this inconvenience, it is necessary to bring down the press at first gently, and by degrees with greater force, and to raise it as suddenly as possible. By this means the water, which is impelled to the sides of the heaps, and which has not yet escaped, returns to the centre; the sheets are equally dry, and the operation executed without difficulty.

According to the state of dryness in which the paper is found when it comes from the apartment of the vat, it is either pressed before or after the first exchange. The operation of the press should be reiterated and managed with great care; otherwise, if in the soft state of the paper, there is a danger that its grain and transparence be totally destroyed. Another essential principal to the success of the exchange is, that the grain of the paper be originally well raised. For this purpose the wire-cloth of the Dutch forms is composed of a rounder wire than those used in France, by which they gain the greatest degree of transparencv, and are in no danger of destroying the grain. Besides this, the Dutch take care to proportion the wires even where the forms are equal to the thickness of the paper.

Almost every kind of paper is considerably improved by the exchange, and receives a degree of perfection which renders it more agreeable in the use. But it is necessary to observe at the same time, that all papers are not equally susceptible of this improvement; on the contrary, if the stuff be unequal, dry, or weakened by the destruction of the fine parts, it acquires nothing of that lustre and softness, and appearance of velvet, which the exchange gives to stuff properly prepared.

The sheets for drying the paper are in the neighbourhood of the paper-mill, and are furnished with a vast number of cords, on which they hang the sheets both before and after the fizing. The sheets are surrounded with moveable lattices, to admit a quantity of air sufficient for drying the paper. The cords of the sheet are stretched as much as possible; and the paper, four or five sheets of it together, is placed on them by means of a wooden implement resembling a pick-ax. The principal difficulty in drying the paper, consists in gradually admitting the external air, and in preventing the cords from imbibing moisture. With regard to the first of these, the Dutch use very low vats, and construct their lattices with great exactness. By this means the Dutch paper is dried equally, and is extremely supple before they fize it. This prevents the cords from imbibing the water by covering them with wax. In using such cords, the moisture does not continue in the line of contact between the paper and the cord, which prevents the sheet from stretching in that particular place by its weight, and from the folds which the moisture in the subsequent operations might occasion. The Dutch also employ cords of considerable thickness, and place fewer of them under the sheets; by which means they diminish the points of contact, and give a freer and more equal circulation to the air.

The size for paper is made of the threads and pair of the string, and the size goes from the tanners, curriers, and parchment-fizers of makers. All the putrefied parts and the lime are care fully separated from them, and they are enclosed into a kind of basket, and let down by a rope and pulley into the cauldron. This is a late invention, and serves two valuable purposes. It makes it easy to draw out the pieces of leather when the size is extracted from them by boiling, or easily to return them into the boiler if the operation be not complete. When the substance is sufficiently extracted, it is allowed to settle for some time; and it is twice filtered before it is put into the vessel into which they dip the paper.

Immediately before the operation, a certain quantity of alum is added to the size. The workman takes a handful of the sheets, smoothed and rendered as supple as possible, in his left hand, dips them into the vessel, and holds them separate with his right, that they may equally imbibre the size. After holding them above the vessel for a short space of time, he places them on a piece of leather when the size is extracted from them by boiling, or easily to return them into the boiler if the operation be not complete. When the substance is sufficiently extracted, it is allowed to settle for some time; and it is twice filtered before it is put into the vessel in which they dip the paper.

The Dutch are very careful in sizing their paper to have every sheet in the same hand of equal dryness; because it is found that the dry sheets imbibe the size more slowly than those which retain some degree of moisture. They begin by screwing the pads in the drying-house; and after having made them supple, and having destroyed the adherence between the sheets, they separate them into handfuls in proportion to the dryness, each of them containing that number which they can dip at one time. Besides this precaution, they take care to apply two sheets of brown paper of
Paper.

Art of Making Paper in Europe.

As soon as the paper is fixed, it is the practice of some papermills to carry it immediately to the drying house, and hang it there before it cools, in order to prevent the lattices of the Dutch drying-houses from falling, which is generally the case. But the exchange after the fixing, which is generally practiced in Holland, is the best remedy. They begin this operation on the handfuls of paper, either while they are still hot, or otherwise as they find it convenient. But, after the exchange, they are careful to allow the heaps to be altogether cold before they are submitted to the press. Without this precaution, the size would either be wholly squeezed out by the press or the exchange, or the surface of the paper become very irregular. It is of consequence that the paper, till warm from the fixing, grow gradually firm, under the operation of the exchange, in proportion as it cools. By this method it receives that varnish which is afterwards brought to perfection under the press, and in which the excellency of the paper either for writing or drawing chiefly consists. It is in consequence of the exchanging and pressing that the Dutch paper is soft and equal, and that the size penetrates into the body of it, and is extended equally over its surface.

The exchange after the fixing ought to be conducted with the greatest skill and attention, because the grain of the paper then receives impressions which can never be eradicated. When the fixed paper is also exchanged, it is possible to hang more sheets together on the cords of the drying house. The paper dries better in this condition, and the size is pressed out without any sensible waffles, because the sheets of paper mutually prevent the rapid operation of the external air. And as the size has already penetrated into the paper, and is fixed on the surface the insensible progress of a well conducted drying house renders all the good effects more perfect in proportion as it is slowly dried.

If to these considerations be added the damage done to the paper in drying it immediately after the press of the fixing room, whether it be done in rolling the haws by separating the sheets, or in cranking the surface, it is evident that the trouble of the second exchange is infinitely overpaid by the advantage.

When the paper is sufficiently dry, it is carried to the finishing room, where it is pressed, examined, folded, made up into quires, and finally into reams. It is here put twice under the press; first, when it is at its full size, and secondly, after it is folded.

The principal labour of this place consists in assorting the paper into different lots, according to its quality and faults; after which it is made up into quires. The person who does this must possess great skill, and be capable of great attention, because he acts as a check on those who separated the paper into different lots. He takes the sheets with his right hand, folds them, examines them, lays them over his left arm till he has the number requisite for a quire, brings the sides parallel to one another, and places them in heaps under the table. An expert workman, if proper care has been taken in assorting the lots, will finish in this manner near 600 quires in a day.

The paper is afterwards collected in reams of 25 quires each, and for the last time put under the press, where it is continued for 10 or 12 hours, or as long as the demand of the paper-mill will permit.

A method has lately been discovered of bleaching the rags or fluff, which will undoubtedly be adopted everywhere in the preparation of writing paper, provided the expense of the process be not too great. This discovery was made by Scheele, M. Berthollet, and M. Chaptal. The first of those illustrious writers communicated to the Swedish Academy of Sciences an effay on Manganese, containing a numerous series of experiments, intended to investigate the nature and properties of that substance. Among these experiments were several which pointed out a new state of the muriatic acid, or the acid distilled from sea-salt, otherwise known under the name of the acid or form of sea-salt. This state of the muriatic acid was produced by Mr Scheele, in consequence of putting the acid into a retort or distilling vessel, along with the abovementioned substance called manganese, and distilling the acid into a proper receiver; it was found to have changed its nature and properties in a very remarkable manner, while at the same time the manganese remaining in the retort had suffered a very material alteration.

To the new state of the acid thus produced, in consequence of certain theoretic ideas which Mr Scheele entertained respecting the mutual action of the original muriatic acid and the manganese on each other during the process of distillation, he gave the name of deplogiflicated muriatic acid. Since the time of this original discovery, in consequence of certain changes which have occurred in the theory or philosophy of chemistry, this new state of the acid of sea-salt has been called the oxygenated muriatic acid. Among many other properties of it discovered by Mr Scheele, the most remarkable was, that it destroyed the colour of every vegetable substance which was exposed to its action; or, in other words, it bleached them; or, in the language of the dyers, its discharge colors; that is to say, whatever happened to be the colour of any vegetable body that was submitted to the action of the oxygenated acid, it always became white, or lost its colouring matter.

In the year 1786, Dr Beddoes, now professor of chemistry in the university of Oxford, published an English translation of the Chemical Essays of Mr Scheele; and thereby made known to the chemists of Great Britain the power of the oxygenated or deplogiflicated muriatic acid, to bleach or whiten vegetable substances, or to discharge or decompose their colours. But M. Berthollet, a celebrated chemist in France, and one of the members of the Academy of Sciences at Paris, appears to have been the first who thought of rendering the above noted discovery full-service to the purposes of manufacture.

In 1789, he published in the Annales de Chimie an essay calculated entirely for the use of manufacturers, by being divested of theoretic discussions; of which the title is, "Method of bleaching linen or cotton cloths, threads, and yarns, by means of oxygenated muriatic acid, and of some other properties of that liquor which may be useful in manufactures."
In the fame work, and in the fame year, M. Chaptal, another French chemift, published an account of some experiments, in which, among many other applications of the oxygenated muriatic acid to purposes useful in the economical arts, he gives information of having bleached or whitened coarse rags ufed by the paper makers, fo as greatly to improve the quality of the paper into which they were afterwards manufactured. His preparation of this bleeding liquor diflied not from Berthollet's, which is as follows: "Take fix ounces of manganese and fixteen ounces of sea-falt, both reduced to a fine powder; mix these accurately, and introduce them into a retort or distilling vessel: Then take twelve ounces of oil of vitriol and eight ounces of water, mixed together and allowed to cool; add these to the other ingredients in the retort, and connect the retort with a cask or receiver capable of holding twenty seven gallons and a half of water, but only containing twenty five gallons, which is to be impoverished with the gas or vapour of the oxygenated muriatic acid; and proceed to distillation, firft without and afterwards with a fire gradually raised, till the whole acid comes over."

Experiments have been made with this liquor both by some of the principal paper makers in the neighbourhood of Edinburgh and by Mefers Clement and George Taylors of Maidstone in Kent. By the firmer it was found, that paper made of rags and pulp whitened in this manner, was superior to any other made of familiar materials, not only in colour but in fineness of texture. By the latter, the excellence of the ground was found to be fo great, that probably having never heard of Scheele, Berthollet, and Chaptal, and conceiving themselves to be the first inventors of it, they obtained a patent for its exclusive ufe, which other manufacturers will doubtlefs disregard. It is not to be concealed, however, that, even with all the precautions which can pollibly be taken at firft, various circumstances of imperfection must necessarily remain to be removed by means of farther experience, both in the perfecion of the bleeding process and the economy of its application to ufe; but for the attaining of this experience a short time will rarely be sufficient.

SECTION II.

Of the Different Kinds of Paper.

The paper proper for writing should be without knots, without any parts of the fluff not triturated, without folds, and without wrinkles, of a fupple texture, its grain uniform and regular, softened in the exchange, and not destroyed by smoothing. The ground of this paper must be extremely white, or fha­ded with a very light blue, which adds to its natural splendor. It is of great importance that it be fully and equally fixed, otherwise the writing cannot be well finifhed, and the turnings of the letters will be very imperfect. This paper should be made from fluff not putrefied, which takes a better grain, receives more benefit from the exchange, is more equally fized, and finally, is less subjeft to folds and wrinkles in the different operations. To make paper peculiarly fit for durable writing, Dr Lewis recommends the impregnation of it with astringent materials. "It is ob­servable (fays he) that writings firft begin to fade or change their colour on the back of the paper, where the larger frokes have funk in, or are visible thro' it; as if part of the irony matter of the vitriol was in a more fubtile or dissolved state than the reft, and funk further, on account of its not being fully difengaged from the acid, or sufficiently combined with the astringent matter, of the galls. Hence, it fhould be probable, that if the paper was impregnated with astringent matter, the colour of the ink would be more durable. To see how far this notion was well founded, I dipfe some paper in an infufion of galls; and, when dry, repeated the printing a fecond and a third time. On the paper thus prepared, and fome that was unprepared, I wrote with different inks; several of which, that the effects might be more fenfible, had an over-proportion of vitriol. The writings beingexpoed to the weather till the belt of the inks on the unprepared paper had faded and changed their colour, thofe on the prepared paper were all found to retain their blacknefs. It is therefore re­commended to the confideration of the paper-makers, whether a particular kind of paper might not be pre­pared for thofe ufed where the long duration of the writing is of principal importance, by impregnating it with galls or other astringents, in some of the operations it passes through before it receives the glazing; as for instance, by using an astringent infufion instead of common water, in the laft operation, when the matter is reduced into a pulp for being formed into fheets. The brownifh hue which the paper receives from the galling, would not perhaps be any great ob­facle to its ufe; and, if the propofal fhould be thought worthy of being carried into execution, further in­quiries may po­fibly discover the means of obviating the imperfection, and communicating altrigrancy without colour." 

The paper ufed for drawing, or for coloured maps, is in some mills made from one kind of white fluff, either fine or middling; in others from a mixture of three or four kinds of fluff of different colours. The Dutch were not long ago almost wholly in poffeffion of this manufacture. The fame qualities are ne­cessary in this paper as in that for writing. The grain, however, muft be a little more rafed, although softened by the exchange; for, without this grain, the pencil would leave with difficulty the traces of the objects. Great car is alfo necessary in the fizing of this paper, that the drawing be neatly performed, and alfo that the finking of the ink or colours into the irregularities of the fluff be prevented.

This paper is alfo made in greateft perfection by furni­ture paper.

The British and Dutch have had the greateft suc­cess in manufacturing palteboard, which they make in either from a single mass of fluff on the form, or from a collection of several sheets pafted together. In both cafes, the sheets of palteboard are made of fluff not rotted, and triturated with rollers furnished with blades of well tempered fteel. By the operation of the ex­change, and smoothing continued for a long time, the

The French have carried this part of the manufacture of pa­per to the highest state of perfec­tion.

British and Dutch obtain solid and smooth stuffs, which neither break under the folds of cloth nor adhere to them. The stuffs not purified have another advantage in this species of pasteboard, namely, that of resisting the action of heat, which they experience between the folds of cloth, without waiting or tarnishing, and of consequence they may be used for a long time.

In England they have at least equalled any other nation in the manufacture of this paper; and even in Scotland they have arrived to such a degree of perfection in this art, that great part of what they manufacture is sent into England. It requires to be made of a soft and equal stuff, without folds or wrinkles, of a natural whiteness, and with a shade of blue. It must be fixed with strongly than writing paper, but sufficiently well to give neatness to the characters. This paper, thus properly prepared, yields easily to the printing press, and takes a sufficient quantity of ink. The stuff must be without grease, and wrought with that degree of smoothness as to make it spread equally over the form, and take a neat and regular grain; without this the characters will not be equally marked in every part of the page, and the smallest quantity of grain renders the fixing unequal and imperfect. Some artists with considerable success, both to meliorate the grain, and to reduce the inequalities of the surface, have submitted this paper to the exchange. And it is proper to add, that a moderate degree of exchanging and of pre-moistening may be of great service after the sheets are printed, to destroy the hollow places occasioned by the press, and the relief of the letters.

Engraving requires a paper of the same qualities with the left mentioned, with respect to the stuff, which must be pure, without knots, and equally reduced; the grain uniform, and the sheets without folds or wrinkles. To preserve the grain, it is necessary that it be dried slowly in the lowest place of the drying-house. If it is submitted to the exchange, the effects of it must be moderated with the greatest care, and the action of the two, if printed must be equally distributed over the whole mass, otherwise the inequality of the moisture at the middle and sides will expose it to wrinkles in the drying. The fixing of this paper must also be moderate. These circumstances are necessary to make it receive with neatness all the soft and delicate touches of the plate.—

The soft and yielding paper of Auvergne possesses all these advantages; and accordingly a great quantity of this and of printing paper were formerly imported into Britain and Holland from France, where they still continue to rot the materials from which they make engraving paper. The wirewove frame, though lately invented, is, we are told, peculiarly adapted to this kind of paper.

Paper for cards must be manufactured from a pretty firm stuff, in order to take that degree of smoothness which makes the cards glide easily over one another in playing. For this reason the card-makers reject every kind of paper which is flat and without strength. This paper requires to be very much fixed, since the fixing holds the place of varnish, to which the smoothing gives a glazed and shining surface. To answer all these purposes, the rags require to be a little ruddled, and the mallets strongly armed with iron studs. At present Angoumois is almost the only province in France which sells card-paper to the Dutch and the other northern nations. The rags of Angoumois have the peculiar quality of not turning too soft in the purification, and the mills of that province reduce them to stuff though they are not much purified. The French, we believe, excel every other nation in this branch of the manufacture of paper.

To hinder paper from sinking, take about the size of a nut of rock alum, dissolve it in a glass of clear water, and apply it to the paper, which has not been sufficiently fixed, with a fine sponge. It is in this manner that the paper-manufacturers of Paris prepare the paper for drawing called papier levres. When there is occasion to write on a printed book, or on paper too fresh, it is sufficient to mix a little gum with ordinary ink.

To give to writing paper a brilliant varnish, take that which is of an ordinary Messieurs, very smooth, without any kind of stain or hairs on its surface; friction it on a smooth plank, and by means of a hare's foot cover it with a thin and equal layer of fandarac finely powdered. Afterwards, if a whole ream is to be varnished, take eight ounces of rock alum and one ounce of white sugareandy; bring them to boil in fix pints of water; and when the liquor is lukewarm, wet that side of the sheet which has been covered with the fandarac with a fine sponge; lay the sheets in a heap, one sheet exactly above another; and submit the ream to the press for the space of twelve hours; hang them afterwards sheet by sheet on the cords of the drying-house; put them again under the press for some days to fretch them; and finally, beat them with a book-binder's mallet. This paper can only be used for three or four months after it is prepared.

Painters prepare their paper for drawing, and give it a dark ground, which spoils them much labour of pared for the pencil afterwards in those places where shade is necessary. For this purpose, they take white paper and pass a sponge over it, which has imbibed water impregnated with foot, leaving the light places to be formed afterwards. They use also a kind of paper for drawing, which is called tainted paper. A light colour is pasted over the whole ground, which deprives the paper of its original brightness, and makes the light places of the print appear more in relief, and more luminous.

The method most common and most convenient for copying a print, is to use oiled paper. The manner of preparing this paper is to take that which is thin and smooth, known commonly by the name of papier à perçer, and moisten it with a composition, of two parts of the oil of walnuts and one part of the oil of turpentine mixed well together. A sheet of pasteboard and a sheet of paper are laid on a smooth table; above them are placed two sheets of paper to be prepared; and a layer of the oil applied to the uppermost is sufficient to penetrate both. This may be done to any number of sheets, and a strong sheet of pasteboard is placed over the whole. The heap is afterwards submitted to the press, under which it remains for two or three days till the oil be completely dry. Paper prepared in this manner serves to copy very readily and exactly

A method of making oiled paper take colours.

To make emery paper.

Staining or colouring of paper.

To oil paper.

To give paper after the binder, one scruple of white alum, and half a pint of clear water; simmer the whole over a slow fire, till the water is confirmed, or the flame ceases: Then, your sheets of paper being laid on a smooth table, you dip a pretty large pencil into that glue, and daub it over as even as you can, repeating this two or three times; then sift the powder of talc through a fine sieve, made of horse-hair or gauze, over it; and then hang it up to dry; and, when dry, rub off the superfusious talc, which serves again for the same purpose. The tale you prepare in the following manner: Take fine white transparent Muscovy tale; boil it in clear water for four hours; then take it off the fire and let it stand for two days; then take it out, wash it well, and put it into a linen rag, and beat it to pieces with a mallet: to 10 pounds of tale add 3 pounds of white alum, and grind them together in a little hand-mill; sift it through a gauze-sieve; and being thus reduced to a powder, put it into water, and just boil it up; then let it stand to the bottom, pour off the water from it, place the powder in the sun to dry, and it will become a hard consistence. This beat in a mortar to an impalpable powder, and keep it for the use above-mentioned, free from dust.

The common grounds laid in water are made by mixing whiting with the common golvers size, and laying it on the paper with a proper brush in the most even manner. This is all that is required, where the ground is to be left white; and the paper being then hung on a proper frame till it be dry, is fit to be painted. When coloured grounds are required, the same method must be pursued, and the ground of whiting first laid; except in pale-colours, such as flesh-colours or pink, where a second coating may sometimes be spared, by mixing some strong colour with the whiting.

There are three methods by which paper-hangings are painted; the first by painting the paper; the second by using the fonsil; and the third by laying them on with a pencil, as in other kinds of painting.

When the colours are laid on by printing, the impression is made by wooden prints; which are cut in such manner, that the figure to be expressed is made to project from the surface by cutting away all the other part; and this being charged with the colours tempered with their proper vehicle, by letting it gently down on a block on which the colour is previously spread, conveys it from thence to the ground of the paper, on which it is made to fall more forcibly by means of its weight, and the effort of the arm of the person who uses the print. It is easy to conclude, that there must be as many separate prints as there are colours to be printed. But where there are more than one, great care must be taken, after the first to let the print fall exactly on the same part of the paper as that which went before; otherwise the figure of the design would be brought into irregularity and confusion.

In common paper of low price, it is usual, therefore, to print only the outlines, and lay on the rest of the colours by stencilling; which both saves the expense of cutting more prints, and can be practiced by common workmen, not requiring the great care and dexterity necessary to the using several prints.

The manner of stencilling the colours is this. The figure, which all the parts of any particular colour make in the design to be painted, is to be cut out, in a piece of thin leather or oil cloth, which pieces of leather or oil-cloth are called fonsils; and being laid flat on the sheets
flcets of paper to be printed, spread on a table or floor, are to be rubbed over with the colour, properly tempers by means of a large brush. The colour passing over the whole is consequentially spread in those parts of the paper where the cloth or leather is cut away, and give the same effect as if laid on by a print. This is nevertheless only practicable in parts where there are only detached patches or spots of colours; for where there are small continued lines, or parts that run one into another, it is difficult to preserve the connection or continuity of the parts of the cloth, or to keep the smaller corners close down to the paper; and therefore, in such cases, prints are preferable. Stencilling is indeed a cheaper method of printing coarser work than printing; but without such extraordinary attention and trouble as render it equally difficult with printing, it is far less beautiful and easy in the effect. For the outline of the spots of colour want that sharpness and regularity that are given by prints, besides the frequent extractions, or deviations from the just figure, which happens by the original misplacing of the stencils, or the shifting of them during the operation.

Pencilling is only used in the case of nicer work, such as the better imitations of the India paper. It is performed in the same manner as other paintings in water or varnish. It is sometimes used only to fill the outlines already formed by printing, where the price of the colour, or the exactness of the manner in which it is required to be laid on, render the pencilling or printing it less proper; at other times, it is used for forming or delineating some parts of the design, where a spirit of freedom and variety, not to be had in printed outlines, are desired to be had in the work.

The paper designed for receiving the flock is first prepared with a varnish-ground of some proper colour, or by that of the paper itself. It is frequently practised to print some Mosse, or other small running figure in colours, on the ground, before the flock be laid on; and it may be done with any pigment of the colour desired, tempered with varnish, and laid on by a print cut corresponding to that end.

The method of laying on the flock is this. A wooden print being cut, as is above described, for laying on the colour in such manner that the part of the design which is intended for the flock may project beyond the rest of the surface, the varnish is put on a block covered with leather or oil-cloth, and the print is to be used also in the same manner, to lay the varnish on all the parts where the flock is to be fixed. The sheet, thus prepared by the varnished impression, is then to be removed to another block or table and to be fixed over with flock; which is afterwards to be gently compressed by a board, or some other flat body, to make the varnish take the better hold of it; and then the flock is to be hung on a frame till the varnish be perfectly dry; at which time the superfluous part of flock is to be brushed off by a soft camel's hair brush; and the proper flock will be found to adhere in a very strong manner.

The method of preparing the flock is, by cutting woollen-rags or pieces of cloth with the hand, by means of a large bill or chopping knife; or by means of a machine worked by a horse-mill.

There is a kind of counterfeit flock-paper, which, when well managed, has very much the same effect to the eye as the real, though done with less expense. The manner of making this fort is, by laying a ground of varnish on the paper; and having afterwards printed the design of the flock in varnish, in the same manner as for the true; instead of the flock, some pigment, or dry colour, of the same hue with the flock required by the design, but somewhat of a darker shade, being well powdered is thrilled on the printed varnish, and produces nearly the same appearance.

Paper-Money is a term frequently made use of for bank-bills, which pass currently in trade instead of gold and silver.

Concerning this species of currency, the national utility of which has been controverted by some, we have the following observations in Dr Smith's Treatise on the Wealth of Nations: The substitution of paper in the room of gold and silver money replaces a very expensive instrument of commerce with one much less costly, and sometimes equally convenient. Circulation comes to be carried on by a new wheel, which it costs less both to credit and maintain than the old one.

When the people of any particular country have such confidence in the fortune, probity, and prudence of a particular banker, as to believe that he is always ready to pay upon demand such of his promissory notes as are likely at any time to be presented to him, those notes come to have the same currency as gold and silver money, from the confidence that such money can at any time be had for them.

A particular banker lends among his customers his own promissory notes, to the amount we shall suppose, of 100,000l. As those notes serve all the purposes of money, his debtors pay him the same interest as if he had lent them so much money. This interest is the source of his gain. Though some of those notes are continually coming back upon him for payment, part of them continue to circulate for months and years together. Though he has generally in circulation, therefore, notes to the amount of 100,000l. 20,000l. in gold and silver, may frequently be a sufficient provision for answering occasional demands. By this operation, therefore, 20,000l. in gold and silver perform all the functions which 100,000l. could otherwise have performed. Eighty thousand pounds of gold and silver can therefore, in this manner, be spared from the circulation of the country; and if different operations of the same kind should at the same time be carried on by many different banks and bankers, the whole circulation may be thus conducted with a fifth part only of the gold and silver.

Let us suppose, for example, that the whole circulating money of some particular country amounted, at a particular time, to 1,000,000l. sterlings, that sum being
Being then sufficient for circulating the whole annual produce of their land and labour. Let us suppose, too, that, some time thereafter, different banks and bankers issued promissory notes, payable to the bearer, to the extent of 1,000,000l. in gold, and 1,000,000l. of bank notes, or 1,800,000l. of paper and money together. But the annual produce of the land and labour of the country had before required only 1,000,000l. to circulate and diffuse it to its proper consumers, and that annual produce cannot be immediately augmented by those operations of banking. One million, therefore, will be sufficient to circulate it after them. The goods to be bought and sold being precisely the same as before, the same quantity of money will be sufficient for buying and selling them. The channel of circulation, if I may be allowed such an expression, will remain precisely the same as before. One million we have supposed sufficient to fill that channel. Whatever, therefore, is poured into it beyond this sum, cannot run in it, but must overflow. One million eight hundred thousand pounds are poured into it. Eight hundred thousand pounds, therefore, must overflow, that sum being over and above what can be employed in the circulation of the country. But though this sum cannot be employed at home, it is too valuable to be allowed to lie idle. It will therefore be sent abroad, in order to seek that profitable employment which it cannot find at home. But the paper cannot go abroad; because, at a distance from the banks which issue it, and from the country in which payment of it can be effectuated, it will not be received in common payments. Gold and silver, therefore, to the amount of 800,000l. will be sent abroad, and the channel of home circulation (ill) remain filled with 1,000,000l. of paper instead of 1,000,000l. of those metals which filled it before.

But though so great a quantity of gold and silver is thus sent abroad, we must not imagine that it is sent abroad for nothing, or that its proprietors make a profit of it to foreign nations. They will exchange it for foreign goods of some kind or another, in order to supply the consumption either of some other foreign country or of their own.

If they employ it in purchasing goods in one foreign country in order to supply the consumption of another, or in what is called the carrying trade, whatever profit they make will be an addition to the next revenue of their own country. It is like a new fund, created for carrying on a new trade; domicillic business being now transmuted by paper, and the gold and silver being converted into a fund for this new trade.

If they employ it in purchasing foreign goods for home-consumption, they may either first purchase such goods as are likely to be consumed by idle people who produce nothing, such as foreign wines, foreign filks, &c.; or, secondly, they may purchase an additional stock of materials, tools, and provisions, in order to employ an additional number of industrious people, who reproduce, with a profit, the value of their annual consumption.

So far as it is employed in the first way, it promotes prodigality, increases expense and consumption, without increasing production, or establishing any permanent fund for supporting that expense, and is in every respect hurtful to the society.

So far as it is employed in the second way, it promotes industry; and though it increases the consumption of the society, it provides a permanent fund for supporting that consumption, the people who consume, reproducing with a profit, the whole value of their annual consumption. The gross revenue of the society, the annual produce of their land and labour, is increased by the whole value which the labour of those workers adds to the materials upon which they are employed; and their next revenue by what remains of this value, after deducting what is necessary for supporting the tools and instruments of their trade.

That the greater part of the gold and silver, which, being forced abroad by those operations of banking, is employed in purchasing foreign goods for home-consumption, is and must be employed for purchasing those of this second kind, forms not only probable, but almost unavoidable. Though some particular men may sometimes increase their expense very considerably, though their revenue does not increase at all, we may be assured that no class or order of men ever does so; because, though the principles of common prudence do not always govern the conduct of every individual, they always influence that of the majority of every class or order. But the revenue of idle people, considered as a class or order, cannot in the smallest degree be increased by those operations of banking. Their expense in general, therefore, cannot be much increased by them, though that of a few individuals among them may, and in reality sometimes is. The demand of idle people, therefore, for foreign goods, being the same, or nearly the same, as before, a very small part of the money, which being forced abroad by those operations of banking, is employed in purchasing foreign goods for home-consumption, is likely to be employed in purchasing those for their use. The greater part of it will naturally be destined for the employment of industry, and not for the maintenance of idleness.

When we compute the quantity of industry which the circulating capital of any society can employ, we must always have regard to those parts of it only which consist in provisions, materials, and finished work; the other, which consists in money, and which serves only to circulate those three must always be deducted. In order to put industry into motion, three things are requisite: materials to work upon, tools to work with, and the wages or remuneration for the sake of which the work is done. Money is neither a material to work upon, nor a tool to work with; and though the wages of the workman are commonly paid to him in money, his real revenue, like that of all other men, consists not in the money, but in the money's worth; not in the metal pieces, but in what can be got for them.

The quantity of industry which any capital can employ, must evidently be equal to the number of workmen whom it can supply with materials, tools, and a maintenance suitable to the nature of the work. Money may be requisite for purchasing the materials and tools of the work, as well as the maintenance of the workmen. But the quantity of industry which the whole capital can employ, is certainly not equal both
to the money which purchases, and to the materials, tools, and maintenance, which are purchased with it; but only to one or other of those two values, and to the latter more properly than to the former.

“When paper is substituted in the room of gold and silver money, the quantity of the materials, tools, and maintenance, which the whole circulating capital can supply, may be increased by the whole value of gold and silver which used to be employed in purchasing them. The whole value of the great wheel of circulation and distribution is added to the goods which are circulated and distributed by means of it. The operation, in some respects, resembles that of the undertaker of some great work, who in consequence of some improvement in mechanics, takes down his old machinery, and adds the difference between its price and that of the new to his circulating capital, to the funds from which he furnishes materials and wages to his workmen.

“What the proportion is which the circulating money of any country bears to the whole value of the annual produce circulated by means of it, is perhaps impossible to determine. It has been computed by different authors at a fifth, at a tenth, at a twentieth, and at a thirtieth part of that value. But how small soever the proportion which the circulating money may bear to the whole value of the annual produce, as but a part, and frequently but a small part, of that produce, is ever destined for the maintenance of industry, it must always bear a very considerable proportion to that part. When, therefore, by the substitution of paper, the gold and silver necessary for circulation is reduced to perhaps a fifth part of the former quantity, if the value of only the greater part of the other four-fifths be added to the funds which are destined for the maintenance of industry, it must make a very considerable addition to the quantity of that industry, and consequently to the value of the annual produce of land and labour.

“That part of his capital which a dealer is obliged to keep by him unemployed, for answering occasional demands, is so much dead stock, producing nothing either to him or to the country. The judicious operations of banking enable him to make it active and productive. The gold and silver money which circulates in any country, and by means of which the produce of its land and labour is annually circulated and distributed to the proper consumers, is, in the same manner as the ready money of the dealer, all dead stock. It is a very valuable part of the capital of the country, which produces nothing to the country. The judicious operations of banking, by substituting paper in the room of a great part of it, enables the country to make a great part of this dead stock active and productive. The gold and silver money which circulates in any country, may very properly be compared to a highway, which while it circulates and carries to market all the graft and corn of the country, produces itself not a single pile of either. The judicious operations of banking, by providing, if, as may be allowed, so violent a metaphor, a sort of waggon-way through the air, enable the country to convert, as it were, a great part of its highways into good pastures and cornfields, and thereby to increase very considerably the annual produce of its land and labour. The commerce and industry of the country, however, it must be acknowledged, though they may be somewhat augmented, cannot be altogether secure, when they are thus, as it were, suspended upon the Dactylion wings of paper-money, as when they travel about upon the solid ground of gold and silver.

“The whole paper-money of every kind which can easily circulate in any country, never can exceed the value of the gold and silver, of which it supplies the place, or which (the commerce being suppooled the fame) would circulate there if there was no paper-money. If twenty-shilling notes, for example, are the lowest paper-money current in Scotland, the whole of that currency, which can easily circulate there, cannot exceed the sum of gold and silver which would be necessary for transacting the annual exchanges of twenty shillings value and upwards usually transacted within that country. Should the circulating paper at any time exceed that sum, the circulation could neither be sent abroad, nor be employed in the circulation of the country, it must immediately return upon the banks to be exchanged for gold and silver. Many people would immediately perceive that they had more of this paper than was necessary for transacting their business at home, and as they could not find it abroad, they would immediately demand payment of it from the banks. When this superfluous paper was converted into gold and silver, they could easily find a use for it by fending it abroad; but they could find none while it remained in the shape of paper. There would immediately therefore, be a run upon the banks to the whole extent of this superfluous paper, and if they showed any difficulty or backwardness in payment, to a much greater extent; the alarm which this would occasion necessarily increasing the run.” See Bank and Trade.

PAPER OFFICE, an office in the palace of Whitehall, in which all the public writings, matters of state and council, proclamations, letters, despatches, and communications, are deposited through the offices of the secretaries of state, are lodged, by way of deposit.

PAPIER MAChE. This is a substance made of cuttings of white or brown paper, boiled in water, and beaten in a mortar, till they are reduced into a kind of paste, and then boiled with a solution of gum arabic or of size, to give tenacity to the paste, which is afterwards formed into different toys, &c. by pressing it into oiled moulds. When dry, it is done over with a mixture of size and lamp-black, and afterwards varnished. The black varnish for these toys, according to Dr Lewis, is prepared as follows: Some colophon, or turpentine boiled down till it becomes black and friable, is melted in a glazed earthen vessel, and thence as much amber in fine powder sprinkled in by degree, with the addition of a little spirit or oil of turpentine now and then: when the amber is melted, sprinkle in the same quantity of farccoila, continuing to stir them, and to add more spirit of turpentine, till the whole becomes fluid, then strain out the clear through a coarse hair bag, pressing it gently between hot boards. This varnish, mixed with ivory-black in fine powder, is applied, in a hot room, on the dried paper paste; which is then set in a gently heated oven, next day in a hotter oven, and the third day in a very
Paphos [720]

Paphos, a very hot one, and let fland each time till the oven grows cold. The palate thus varnished is hard, durable, glossy, and bears liquors hot or cold.

Paphlagonia (anc. geog.), a country of the Hither Asia, beginning at Parthenius, a river of Bithynia, on the west, and extending in length to the Halys eastward, with the Euxine to the north, and Galatia to the south. Pliny enlarges the limits on the west side to the river Billis, on this side the Parthenius. It is called Pylenia by some (Pliny). Paphlagonia, the people, mentioned by Homer, and therefore of no small antiquity. A superstitious and silly people (Lucian); a brave people (Homer); taking their name from Phileg (Bochart).

Paphos (anc. geog.), two adjoining islands on the west side of the island of Cyprus; one called Hete Paphos (Strabo, Ptolem. Pliny); the other Na Paphos; and when mentioned without an adjective, this latter is always understood. Both dedicated to Venus, and left undisturbed by the poets (Virgil, Horace). Hence Venus was named Paphos, Paphi the people, (Coins, Stephnus) It was restored by Augustus, after a shock of an earthquake, and called Augyrga (Dio).

The Abbé Mariti, in his Travels through Cyprus, gives the following account of the island of Paphos. It is situated (says he) on the southern side: it contained the celebrated temple of Venus; which, together with the city, was destroyed by an earthquake, so that the least vestige of it is not now to be seen. A lake in the neighbourhood, which even in summer overflows with fragrant and corrupt water, renders the air in some degree unhealthy. On the western coast is the new Paphos, called by some of the modern geographers Bafos; a name which is unknown in the island of Cyprus. That we may not positively ascribe to the latter everything that history tells us of Paphos in general, it may not be here improper to mention that it has been several times destroyed. This city had a port, where vessels trading upon that coast shall cast anchor: but this happens only in summer; for, being exposed to every wind, it is extremely dangerous. The bottom of it is full of sharp rocks; which sometimes destroy the cables so much, that mariners are obliged to keep them aloft on the surface of the water, by means of empty cañons fixed to them at certain distances. In the neighbourhood there are two cables; one on the borders of the sea, and the other on the summit of a little hill; but the latter is at present in ruins. The government of Paphos confids of a digedaban or commissary; a cadi; and an aga, who presides over the customhouse. Of all the Christian edifices, there is none remaining but the church of St George, in which service is performed by the Greek ministers. The productions of this part of the island, which are all of an excellent quality, are silk, barley, and other kinds of grain. To discover the origin of the old and new Paphos, would be carrying light into the midst of the densest darkness. When we have added conjecture to conjecture, we are still in the same situation. As this is an attempt superior to my abilities, I shall leave it to the divine, though uncertain, knowledge of our antiquaries. I must, however, obverse, that there was here formerly a temple dedicated to Venus, which was entirely destroyed by an earthquake. In this island St Paul by his eloquence converted Sergius, a Roman proconsul. He here like his wife conferred the deaconship on his disciple and colleague Titus, who soon after suffered martyrdom.

Paphos was an episcopal city in the time of the Lucignans: and it is still the seat of a bishop, who is a suffragan to the archbishop of Nicomedia. On the western side of the island these are a great number of scattered villages; but they are not worthy of notice, being either abandoned or in ruins.

Mr Bruce informs us, that in the neighbourhood of this place many silver medals of excellent workmanship are dug up; they are, however, but of little estimation among the antiquarians, being chiefly of towns of the size of those found at Crete and Rhodes, and in all the islands of the Archipelago. There were some excellent Greek intaglios: generally upon better stones than usual in the islands. This illustrious traveller informs us, that he has seen some heads of Jupiter, remarkable for bulky hair and beard, which were of excellent workmanship, and worthy of any price. All the inhabitants of the island are subject to fevers, but especially those in the neighbourhood of Paphos. The same traveller observes, that Cyprus was very long undiscovered; for though ships had been failing on the Mediterranean 1700 years before Christ, and though the island is only a day's sailing from the continent of Asia on the north and east, and little more from that of Africa on the south, it was not known at the building of Tyre, a little before the Trojan war, that is, 500 years after the building of Solomon's temple; because we do not find that Hiram king of Tyre, though rich in its neighbourhood, ever had recourse to it for wood; though the carriage would undoubtedly have been easier from thence, than to have brought it down from the top of Mount Lebanon. Eratothines informs us, that in ancient times the island was so overgrown with wood, that it could not be tilled; so that they first cut down the timber to be used in the furnaces for melting silver and copper; that after this they built their ships with it; but finding even this insufficient, they gave liberty to all strangers to cut it down for whatever purpose they pleased; and not only so, but they gave them afterwards the property of the ground they had cleared. Matters are now quite altered; and the want of wood is a principal complaint in most parts of the island. About Acanas, however, on the west side of the island, the wood is still thick and impervious, inhabited by large flags and wild boars of a monstrous size. Mr Bruce was informed, that a live elephant had lately been seen there, but gave no credit to the account.

PAPIAS, bishop of Hieropolis, a city of Phrygia, was the disciple of St John the Evangelist, and the companion of Polycarp, as St Jerome observes, and not of John the Ancient, as some other authors have maintained. He composed a work in five books, intitled Excerpta de Difputationes de Nostro Lord, of which there are only some fragments now remaining. He it was who introduced the opinion of the Millenarians.

PAPILIO, the Butterfly; in zoology, a genus of insects belonging to the order of lepidoptera. It has
PAP

Papilio. has four wings, imbricated with a kind of downy scales: the tongue is convoluted in a spirall form; and the body is hairy. The antennae grow thicker towards their extremity, and are in most subjects terminated by a kind of capitulum or head. The wings, when sitting, are erect, so much that their extremities meet or touch one another above the body. They fly in the day-time. There are 273 species, principally distinguished by the colour of their wings. Mr Barbut has divided them into four factions, which he thus characterizes, 1. The equites, or riders, the upper wings being longer from the hindermost angle to the point than to the base: their antennae are often filiform. They are divided into Trojans; for which the most part are black, with blood-like spots on the breast: and Greeks, whose breast has no such marks; the small eye being placed at the angle of the anus; and of these some are without bands or fillets, others with bands or fillets. 2. The heliconians, whose wings are narrow throughout, often bare; the upper elongated, the under ones very short. 3. The Danae, whose wings are entire; the candidi, with whitish wings; the felisivni, with variegated wings. 4. The nymphals, whose wings are denticulated; divided into the gemmati, whose wings have eyes; subdivided into those which have eyes on all the wings; those which have them on the upper wings; those which have them on the under ones; and the phalerati, whose wings are without eyes. 5. The plebeians, whose larva is often contrasted; divided into the rurales, with darkish spots on their wings; and the urbicola, with spots generally transparent on their wings.

The beauties of this elegant part of the creation are well known; and there are few who can contemplate them without astonishment. We have the following account of their various stages of existence in Barbut.*

"The caterpillar (says he) informs us is what manner it prepares for the lethargic sleep, which is to serve as a transition to its metamorphosis. The period of its reptile life being accomplished, it changes its form to become an inhabitant of the air. The chrysalis is at once the tomb of the caterpillar and the cradle of the butterfly. It is within a fillet, or under a transparant veil, that this great miracle of nature is daily wrought. But how does the weak defenceless butterfly, scarce unfolded, go about to make its way through the impenetrable walls that preferred from it in spite of its torpid state? How will it bear the effulgence of the light, and keenness of the air? Take one of their cords, make an aperture in it with a pair of scissors, fix it against a glass, observe the insect, you will perceive the organs gradually displaying themselves: follow his operation with your eye; he struggles to break loose from his confinement. Observe the frothy liquor which it disgorges; that liquor serves to soften the end of the cord, which at length yields to the butting of the insect's head. By degrees the bar is removed, and the butterfly springs forth; the impregnation of the air acts upon its wings, slightly apparent at first, but which afterwards expand with remarkable rapidity. The display of them is sometimes checked by drought, in which case the insect is deprived of the faculty of flying. The rostrate, extended under the covering of the chrysalis, is in this last state rolled up into a spiral, and lodged in a recess prepared for it. The fly is now perfectly formed; it gently flutters, then takes its flight, and pursues its many wanderings over the enamelled mead, plunging its rostrum into the cups of nectarious flowers."

Of Papilio No. 1, Barbut gives the following account. **

"The ground colour of the insect is a beautiful glossy black, the superior wings are ornamented with white forked clouds; the inferior ones are adorned with spots of a blood-colour, of the extremities being of a lunular form, and are indented, terminating in an extended tail, and are edged with white. The apex, or crown of the head, is tint with the same red colour which encircles the shoulders, and terminates the abdomen the space of about five rings."

Of No. 2, he speaks thus: "The form of the wings resembles the preceding insects. They are beautifully variegated with black and yellow; the inferior ones terminate in a tail, and, according to the character of the fiction, are adorned with an eye of a yellowish red colour, circled with blue, which is situated at the edge, nearest the extremity of the abdomen. This is the largest, and one of the most beautiful insects England produces. The caterpillar is large and smooth, of a bright green colour, with transversal bands, of a deep glossy purple upon every ring, which bands are enriched with yellow spots; it feeds on wild fennel and other umbelliferous plants; changes into the chrysalis in July, assumes the winged state in August, and frequents meadows. It sometimes appears in May."

And of No. 3, we have this account: "The peacock, or peacock's eye, is easily known by the peacock's eyes which it bears above, four in number, one upon each wing, which has given it the name it has. Its wings, very angular, are black underneath; above they are of a reddish dun colour. The upper ones have on their superior edge two black oblong spots, with a yellow one between the two. At their extremity is found the eye, large, reddish in the middle, surrounded with a yellow circle, accompanied by a small portion of blue towards the exterior side. On that same side, following the direction of the margin, there are five or six white spots, set in order. The inferior wings are browner, and have each a large eye of a very dark blue in the middle, surrounded by an ash-colour circle. The caterpillar of this butterfly is of a deep black, dotted with a little white."

We cannot conclude this article without noticing some very singular species; of which Mr Reaumur has given an account, and which deserve particular regard.

One species of these he has called the bundle of dry leaves. This, when it is in a state of rest, has wholly the appearance of a little cluster of the decayed leaves of some herb. The position and colour of its wings greatly favour this resemblance, and they have very large ribs; wholly like those of the leaves of plants, and are indented in the same manner at their edges as the leaves of many plants are. This seem to point out the care of nature for the animal, and frequently may prefer it from birds, &c.

The skul butterfly is another singular species, called from its head resembling in some degree a death's head or human skull. This very remarkable appearance is terrible to many people; but it has another yet greater singularity attending it, which is,
that, when frightened, it has a mournful and harsh voice. This appeared the more surprising to Mr. Reaumur, as no other known butterfly had any the least voice at all; and he was not ready of belief that it was a real voice. But supposing the noise, like that of the cicada, to be owing to the attrition of some part of the body; and, in fine, he, by great pains, discovered that this noise was not truly vocal, but was made by a hard and brisk rubbing of the trunk against two other hard bodies between which it is placed.

Another butterfly there is, so small that it might be mistaken for a small fly. This is certainly the extreme in degree of size of all the known butterflies, and cannot but have been proportionally small in the state of a caterpillar and chrysalis; this creature spends its whole life in all the three states of caterpillar, chrysalis, and butterfly, on the leaf of the calendine. It lives on the under side of the leaf; and though in the caterpillar state it feeds on it, yet it does no damage. It does not eat the substance of the leaf, but draws a sweetish fluid out of it, and passes through its three states in so short a time, that there are frequently ten generations of it in one year; whereas, in all the other butterflies, two generations in the year are all that are to be had. These two generations are sufficient to make a prodigious increase; in a large garden, if there are twenty caterpillars in spring, there may be overlooked, and there may be easily concluded to be none there, even on a narrow search; but if these twenty caterpillars afterwards become twenty butterflies, ten of which are male and ten female, and each female lay the same number of eggs that the common silk worm does, that is, four hundred; if all the caterpillars hatched of these become butterflies, and these lay eggs in the same proportion, which remain the winter, and come to be hatched in the succeeding spring; then from these twenty, in only one year, you will have eight hundred thousand; and if we add to this the increase of these in a succeeding year, the account must appear terrible, and such as no art could guard against. The great Ruler of the world has put so many hindrances in the way of this over-abundant production, that it is very rare such years of destruction happen. Some such have happened, however, and much mischief has been dreaded from them, not only from their eating all the herbage, but from themselves being eaten with herbs in fallads and otherwise; but experiments have proven this to be an erroneous notion, and they are found to be innocent, and causable as snails or oysters.

PAPILLONACEOUS, among botanists, an appellation given to the flowers of plants belonging to various classes, from their resembling the wings of a butterfly.

PAPINIAN, a celebrated Roman lawyer of the third century, under the Emperor Severus; who had so high an opinion of his worth, that he recommended his sons Caracalla and Geta to his care. Caracalla having first murdered his brother, ordered Papinian to compose a discourse to excite this murder to the senate and people; which when he refused to undertake, the brutal emperor ordered him to be beheaded; and his body was dragged through the streets of Rome. Papinian wrote several treatises in the line of his profession.

PAPISTS, are those who believe the pope or bishop of Rome to be the supreme pastor of the universal church, who profess to believe all the aules of pope Pius's creed, and who promise implicit obedience to the edicts of the church, especially the decrees of the council of Trent. See Pope and Trent.

PAPPENHEIM, a town of Germany, in the circle of Franconia, and capital of a county of the same name, with a castle where the counts reside. It is seated near the river Altmal, 17 miles north-west of Neuberg, and 32 south of Nuremberg; is subject to its own count. E. Long, 10, 51. N. Lat. 48. 58. The count of Pappenheim is hereditary marshall of the empire, and performs his office at the coronation of the emperor.

PAPPUS, an eminent philosopher of Alexandria, said by Suidas to have flourished under the Emperor Theodosius the Great, who reigned from A. D. 379 to 395. His writings show him to have been a consummate mathematician: Many of them are lost; the rest continued long in manuscript, detached parts having only been occasionally published in the last century, until Carolus Manolefius published his remains entire at Bologna in 1660, in folio.

PAPPUS, in botany, a soft downy substance that grows on the seeds of certain plants, as thistles, hawk-weed, &c. serving to scatter and buoy them up in the air.

PAPYRUS, the famous reed from which was made the far-famed paper of Egypt. Before entering on the description of the papyrus, it is natural to lay a word or two on the opinion generally received in Europe concerning the state of this plant. Supposing this state possible, the date of it must be fixed at no distant period; for it is not 200 years since Guilland and Prosper Alpin observed the papyrus on the banks of the Nile. Guilland saw the inhabitants of the country eating the inferior and succulent part of the stem in the manner of the ancients; a fact which alone shows it to be the papyrus, and of which other travellers seem not to have availed themselves. This practice, together with those related by Prosper Alpin, are sufficient to convince us, that this plant is not wholly useless, although it is not now employed in the fabrication of paper. The alteration on the soil of Egypt, and on the methods of agriculture, have in all probability rendered this plant less common; but causes altogether local could not occasion the destruction of the papyrus, especially as its residence in the marshes would prevent their operation. But it is needless to reason from probabilities or analogy: Mr. Bruce not only lays the papyrus growing both in Egypt and Abyssinia, but actually made paper of it in the manner in which it was made by the ancients. He tells us likewise, that, so far from any part of its being useless, the whole plant is at this day used in Abyssinia for making boats, a piece of the acacia tree being put in the bottom to serve as a keel. That such were the boats of ancient Egypt, we know from the testimony of Pliny, who informs us that the plants were first sewed together, and then gathered up at stem and frond, and tied fast to the keel: "Conferitur bibula Memphitis cymba papyro."

"The
The bottom, root, or woody part of this plant, was likewise of several uses before it turned absolutely hard; it was chewed in the manner of liquorice, having a considerable quantity of sweet juice in it. This we learn from Dioscorides; it was, I suppose, chewed, and the sweetness sucked out in the same manner as is done with sugar-cane. This is still practiced in Abyssinia, where they likewise chew the root of the Indian corn, and of every kind of cyperus; and Harrodus tells us, that about a cubit of the lower part of the stalk was cut off, and roasted over the fire, and eaten.

From the scarcity of wood, which was very great in Egypt, this lower part was likewise used in making cups, moulds, and other necessary utensils: we need not doubt, too, one use of the woody part of this plant was, to serve for what we call boards or covers for binding the leaves, which were made of the bark; we know that this was anciently one use of it, both from Aelian and Anacreon.

The papyrus, says Pliny, grows in the marshes of Egypt, or in the flagrant places of the Nile, made by the flowing of that river, provided they are not beyond the depth of two cubits. Its roots are tortuous, and in thicknefs about four or five inches; its stem is triangular, rising to the height of ten cubits. Propper Alpin gives it about fix or seven cubits above the water; the stem tapers from the bottom, and terminates in a point. Theophratus adds, that the papyrus carries a top or plume of small hairs, which is the thyrsus of Pliny. Guilielmus informs us, that its roots throw to the right and left a great number of small fibres, which support the plant against the violence of the wind, and against the waters of the Nile. According to him, the leaves of the plant are obtuse, and like the typha of the marshes. Mr Bruce, on the other hand, affures us, that it never could have existed in the Nile.

Its plume was of the same reafon, the bottom of the papyrus, and the marfhy places where they grow. The only difference confifts in their size, and in the pofition of the ears, which ferve to diftinguifh them; and they feem to bear a refemblance to the papyrus and the fari, difcribed by ancient authors. The firft is perhaps the papyrus, and the second the fari; but this is only conjecture.

The papyrus, which grew in the waters, is faid to have produced no feed; but this Mr Bruce very properly calls an abfurdiv. "The form of the flower (fays he) fufficiently indicates, that it was made to revolve itself into the covering of one, which is certainly very fimall, and by its exalted situation and thickness of the head of the flower, feme to have needed the extraordinary covering it has to protect it from the violent hold the wind must have had upon it. For the fame reafon, the bottom of the filaments composing the head are feathered in four convee leaves, which keep them clofe together, and prevent injury from the wind getting in between them." Its plume was composed of fender pedicles, very long, and fome what like hair, according to Theophratus. The fame peculiarity exists in the papyrus of Sicily; and the fame is found to exist in another kind of papyrus fent from Madagascar by M. Poivre, correpodent of the academy of sciences.

It is impossible to determine whether the papyrus of Sicily was used in any way by the Romans. In Italy it is called papiro, and, according to Celscin, pipero.
This papyrus of Sicily has been cultivated in the garden of Pisa; and if we can depend on the authority of Cefalpin, who himself examined the plant, it is different from the papyrus of Egypt.

The papyrus, says he, which is commonly called piperon in Sicily, has a longer and thicker stem than the plant cyperus. It rises sometimes to four cubits; the angles are obtuse, and the stem at the base is surrounded with leaves growing from the root; there are no leaves on the stem even when the plant is at the greatest perfection, but it carries at the top a large plume which resembles a great tuft of divelheved hairs; this is composed of a great number of triangular pedicles, in the form of reeds; at the extremity of which are placed the flowers, between two small leaves of a reddish colour like the cyperus. The roots are woody, about the thickness of reeds, jointed, and they throw out a great number of branches which extend themselves in an oblique direction. These fix the plant in what is like the cyperus, but their colour is lighter brown; from the lower part issue many small fibres, and from the higher a number of stems shoot up, and in proportion as they are tender contain a sweet juice.

The plume of the papyrus of Sicily is pretty well described in a short account of it in the second part of the Maugean de Boccone. This plume is a tuft or assemblage of a great number of long slender pedicles, which grow from the same point of division, are disposed in the manner of a paralog, and which carry at the top three long and narrow leaves, from which issue other pedicles, shorter than the former, and terminating in several knots of flowers. Michelii, in his Nova Plantarum Genera, printed at Florence 1728, has given an engraving of one of the long pedicles in its natural length: it is surrounded at the base with a cape of about one inch and a half in height; towards the extremity it carries three long and narrow leaves, and four pedicles, to which are fixed the knots of flowers. Every pedicle has also a small cape surrounding its base. In short, we find in the Grasso Graphia of Schenchez a very particular description of the plume of a kind of cyperus, which appears to be the Sicilian plant. From this account it appears that the papyrus of Sicily is well known to botanists. It were to be wished that we had as particular a description of the papyrus of Egypt; but meanwhile it may be observed, that these two plants have a near affinity to one another; they are confounded together by many authors: and according to Theophratus, the farò and the papyrus nilotica have a decided character of resemblance, and only differ in this, that the papyrus sends forth thick and tall stems, which being divided into slender plates, are fit for the fabrication of paper; whereas the farò has small stems, considerably shorter, and altogether useless for any kind of paper.

The papyrus, which served anecdotingly to make paper, must not be confounded with the papyrus of Sicily; found also in California; for, according to Strabo, the papyrus was to be found in no place excepting Egypt and India. The greatest part of botanists have believed that the Sicilian plant is the same with the farò of Theophratus; others have advanced that the papyrus of Egypt and the farò were the same plant in two different stages of its existence, or considered with respect to the greater or less height; which, according to them, might depend on the qualities of the soil, the difference of the climate, or other accidental causes.

In proof of this, it is maintained, that there is an essential difference between the papyrus growing in the waters and the same plant growing on the banks of rivers and in marshes. The first of these have thick and tall stems, and a plume in the form of a tuft of hair very long and slender, and without any feed: the second differs from the first in all these particulars; it has a shorter and more slender stem, its plume is loaded with flowers, and of consequence it produces feed. In whatever way we consider these facts, it is sufficient for us to know, that the difference between the papyrus and the farò neither depends on climate, nor soil, nor on situation. The plants whole difference depended on these circumstances, both grew in Egypt, and were both employed in the manufacture of paper. But it is an effect of care, that the farò cannot be employed for this purpose.

Finally, the papyrus of Sicily began to be known by botanists in 1770, 1772, 1783, at which periods the works of Lobel, of Guillard, and of Cefalpin, first appeared. The ancients had no manner of knowledge of this plant. Pliny makes no mention of it in his Natural History; from which it is evident that it was neither used in Rome nor in Sicily. If he had seen this plant, he must have been struck with its resemblance to the papyrus and the farò, as they were described by Theophratus; and since he gives a particular description of these last mentioned, he would have most naturally hinted at their conformity to the Sicilian papyrus.

Among many dried plants collected in the East Indies by M. Poivre, there is a kind of papyrus very different from that of Sicily. It carries a plume composed of a considerable tuft of pedicles, very long, very slender, and delicate, like single threads, terminating most frequently in two or three small narrow leaves, without any knot of flowers between them; hence this plume must be altogether barren. Those pedicles or threads are furnished with a pretty long membranous cape, in which they are inclosed; and they issue from the same point of direction, in the manner of a paralog. The plume, at its first appearance, is surrounded with leaves like the radii of a crown. The item which supports it, is according to M. Poivre, about ten feet in height, where there is two feet under water; it is of a triangular form, but the angles are rounded; its thickness is about the size of a walking staff which fills the hand.

The interior substance, although soft and full of fibres, is solid, and of a white colour. By this means the item possesses a certain degree of strength, and is capable of resistence. It bends without breaking; and as it is extremely light, it serves in some sort for a cane: The same M. Poivre used no other during a residence of several months at Madagascar. This item is not of equal thickness in its whole length, it tapers insensibly from the thickest part towards the top. It is without knots, and extremely smooth. When this plant grows out of the waters, in places simply moist, it is much smaller, the items are lower, and the plume is composed of shorter pedicles or threads, terminating at the top in three narrow leaves, a little longer than
Paracelsus

those at the plume, when the plant grows in the water. From the base of these leaves rise small knots of flowers, arranged as they are in the cyperus; but their knots are not elevated above the pedicles, they occupy the centre of the three leaves, between which they are placed, and form themselves into a small head. The leaves which spring from the root and the lower part of the stem resemble exactly those in the cyperus. This plant, which the inhabitants call fangia fangia, grows in great abundance in their rivers and on their banks, but particularly in the river Turias, near the Poule-point in Madagascar. The inhabitants of these cantons use the bark of this plant for mats; makes it also into nets, into cordage for their fishing-houses, and into cords for their nets.

This kind of papyrus, lately discovered, and different from the papyrus of Sicily by the disposition of its flowers, shows, that there are two kinds of the cyperus which might easily be confounded with the papyrus of Egypt: whether we consider, on the one hand, to what purposes the inhabitants of the places where they grow have made them subservient; or, on the other, compare their form, their manner of growth, and the points in which they resemble each other. This comparison can be easily made from the accounts which Pliny and Theophrastus gave of the papyrus of Egypt, and by the figure and description given by Proper Alpin, after having observed the plant on the banks of the Nile. But if we can depend on the testimony of Strabo, who affirms that the papyrus is found nowhere but in Egypt and in India, it is perhaps possible that the papyrus of the isle of Madagascar, situated at the mouth of India, is the same with that of Egypt.

Whatever truth may be in this conjecture, the inhabitants of this island have never derived from it these advantages which have immortalized the papyrus of Egypt. They have not made that celebrated paper quo nifi maxime humanitas, vita, co-flavit et memoria. This remarkable expression of Pliny not only characterizes the Egyptian paper, but every kind which art and industry have sublimated in its place.

Par, in commerce, signifies any two things equal in value. See Exchange.

Parable, a fable or allegorical instruction, founded on something real or apparent in nature or history, from which a moral is drawn by comparing it with something in which the people are more immediately concerned; such are the parables of Dives and Lazarus, of the Prodigal Son, of the Ten Virgins, &c. Dr Blair observes, that “of parables, which form a part of allegory, the prophetic writings are full; and if to us they sometimes appear obscure, we must remember, that in those early times it was universally the mode throughout all the eastern nations to convey sacred truths under mysterious figures and representations.”

Paracelsus (Aurelius Philip Theophrastus Bombautus de Hohenheim), a famous physician, born at Finsfïïlen, a town in the canton of Schwetiz in Switzerland. He was educated with great care by his father, who was the natural son of a prince, and in a little time made a great progress in the study of physic. He afterwards travelled into France, Spain, Italy, and Germany, in order to become acquainted with the most celebrated physicians. At his return to Switzerland, he stopped at Basle, where he read lectures on physic in the German tongue. He was one of the first who made use of chemical remedies with success, by which he acquired a very great reputation. Paracelsus gloried in destroying the method established by Galen, which he believed to be very uncertain; and by this means drew upon himself the hatred of the other physicians. It is said, that he boasted of being able, by his remedies, to preserve the life of man for several ages: but he himself experienced the vanity of his promises, by his dying at Salzburg, in 1540, at 37 years of age according to some, and at 48 according to others. The last edition of his works is that of Geneva in 1658, in 3 vols folio.

Paracentesis, an operation in surgery, commonly called tapping. See Surgery.

Paraclet, the comforter, a name given to the Holy Ghost.

Parade, in a military sense, the place where troops assemble or draw together, to mount guard, or for any other purpose.

Parade, in feining, implies the action of parrying or turning off any thrust.

Paradis (Francis Anglicifin) de Moncrief. See Moncrief.

Paradise, a term principally used for the garden of Eden, in which Adam and Eve were placed immediately upon their creation.

As to this terrestrial paradise, there have been many inquiries about its situation. It has been placed in the third heaven, in the orb of the moon, in the moon itself, in the middle region of the air, above the earth, under the earth, in the place poffessed by the Caipian sea, and under the arctic pole. The learned Huetius places it upon the river that is produced by the conjunctiOn of the Tigris and Euphrates, now called the river of the Arabs, between this conjunction and the division made by the same river before it falls into the Persian sea. Other geographers have placed it in Armenia, between the sources of the Tigris, the Euphrates, the Araxis, and the Phasis, which they suppose to be the four rivers described by Moses. But concerning the exact place we must necessarily be very uncertain, if indeed it can be thought at all to exist at present, considering the many changes which have taken place on the surface of the earth since the creation.

“Learned men (says Mr Milly *) have laboured to Physico find out the situation of paradise, which seems to be Thoel, but a vague and uncertain inquiry; for the Mosaic description of it will not suit any place on the present globe. He mentions two rivers in its vicinity, viz. Pison and Gihoa, or which no vestige can now be found. The other two still remain, viz. the Hiddekel, supposed to be the Tigris, and the Euphrates, whose streams unite together at a considerable distance above the Persian gulf; in some part of which, it is highly probable the happy garden once lay (a). This gulf is

(a) "God (we are told) placed at the east of the garden of Eden cherubins and a flaming sword, which turned every.
Paradise, is eastward both of the land of Midian and the wilderness of Sinai; in one of which places Moses wrote his history. But since the formation of this earth, it has undergone great changes from earthquakes, inundations, and many other causes. The garden, however, seems to have been a peninsula, for the way or entrance into it is afterwards mentioned. We are told that a river went out of it; which, according to some, should be rendered 'run on the outside of it,' and thus gave it the form of a horse-shoe: for had the Euphrates run through the middle of the garden, one half of it would have been useless to Adam, without a bridge or boat wherewith to have crossed it.

The learned authors of the Universal History, in their account of rarities natural and artificial in Syria, mention "a spot which is still shown as the place where once stood the garden of Eden, or Terrestrial Paradise. And indeed it is in all respects so beautiful and rich, and yields so delightful a prospect from the adjacent hills, that there is hardly another place in the world that has a fairer title to the name it bears. Its proximity to Damascus, the capital of Syria, near the fountain head of the Jordan; its situation between the Tigris or Hiddakel, the Euphrates, the Phasis or Phihon, the Araxes or Gihon (which last has those names from its vault rapidly above all other known rivers), its bordering upon the land of Chus, famed for its fine gold; all these and many other marks specified by Moses, together with its charming and surprising fruitfulness, and abundance of verdure, have induced a great number of commentators to feite that celebrated and so much sought-after spot here, and to deem it the most valuable of all the natural rarities of this country."

Christians, however, need not be told, that however curious or amusing this inquiry may be, the determination of it is of no importance, since we are all well assured that the célestial paradise is that place of pure and refined delight in which the souls of the blest enjoy everlasting happiness.

It may not be improper, however, in this place to give a description of the paradise of the Mohammedans. The fen'suality and absurdity of that impostor must be apparent to all men. Their religion has no conformity in its parts, and the descriptions of the future enjoyment of the faithful are miserable inanities of human weaknesses and folly.

"The paradise of the Mohammedans is laid by them to be situated above the seven heavens, or the seventh, and next under the throne of God; and to express the amenity of the place, they tell us that the earth is of the finest wheat flour, or of the purest musk, or of saffron; and that its stones are pearls and jacinths, the walls of its buildings enriched with gold and silver, and the trunks of all its trees of gold, amongst which the most remarkable is the tree: tuba, or tree of happiness. They pretend that this tree stands in the palace of Mohammed, though a branch of it will reach to the house of every true believer, loaded with pomegranates, dates, grapes, and other fruits of surprising bigness, and delicious taints, unknown to mortals. If a man defires to eat of any particular kind of fruit, it will immediately be presented to him; or if he chooses flesh, birds ready dressed will be set before him, and fuel, as he may with for. They add, that this tree will supply the blest, not only with fruit, but with silk garments also, and beasts to ride on, adorned with rich trappings, all which will burst forth from the fruit; and that the tree is so large, that a person mounted on the fleetest horse would not be able to gallop from one end of its shade to the other in 100 years. Plenty of water being one of the greatest additions to the pleasures of any place, the Alcoran often speaks of the rivers of paradise as the principal ornament. Some of these rivers are said to flow with water, some with milk, some with wine, and others with honey: all of them have their fountains in the root of this tree of happiness; and, as if these rivers were not sufficient, we are told that the garden of this paradise is also watered by a great number of lesser springs and fountains, whose pebbles are rubies and emeralds, their earth of camphor, their beds of musk, and their sides of saffron. But all these glories will be eclipsed by the repugnant and exquisite beauty of the girls of paradise, the enjoyment of whose company will constitute the principal felicity of the faithful, These (they say) are not formed of clay, as mortal women, but of pure musk; and are, as their prophet often affirms in his Alcoran, free from all the natural defects and inconveniences incident to the sex. Being also of the strictest modesty, they keep themselves secluded from public view in pavilions of hollow pearls, so large, that, as some traditions have it, one of them will be no less than 16, or, as others say, 60 miles long, and as many broad. With these the inhabitants of paradise may take their pleasures in their height; and for this purpose will be endowed with extraordinary abilities, and enjoy a perpetual youth."

Paradise-Lost, the name of a modern epic poem, the spirit and finct of those composed by Milton.

The subject of this poem is extraordinary; it had never before been attempted, and seemed to be above the efforts of human genius. Angels and devils are not the machinery, but the principal actors in it; so that what would appear marvellous in any other composition, is in this only the natural course of events.

The poet's intention was, as he expresses it himself, to vindicate the ways of God to men. How far Milton was happy in the choice of his subject, may be questioned.

every way, to keep the way of the tree of life. In Scripture, the extraordinary judgments of God are said to be executed by his angels, who are sometimes compared to flames of fire. Therefore the cherubim and the flaming sword may probably mean nothing more than that a large portion of ground on the eastward of Paradise was set on fire during the above awful occasion, and continued burning with such violence, that the flame thereof at a distance appeared like a brandished sword turning every way with the wind. Now if the soil of Eden was bituminous, like that of Gomorrah (which was once so fertile as to be compared to the "garden of the Lord"), the fire would continue burning till it produced the same effect in the one place as it did in the other, and turned a great part of that tract into sea: which seems to countenance the opinion of those who place the situation of Paradise in some part of the Persian Gulph."
Paradise. 

it has led him into difficult ground, though it certainly suited the daring sublimity of his genius. It is a subject for which he alone was fitted; and, in the conduct of it, he has shown a stretch both of imagination and invention which is perfectly wonderful.

**Bird of Paradise.** See the following article.

**PARADISEA,** in ornithology; a genus of birds belonging to the order of ducks. The beak is covered with a belt or collar of downy feathers at the base; and the feathers on the sides are very long.

"Birds of this genus (says Latham) have the bill slightly bending; the base covered with velvet-like feathers. The nostrils are small, and concealed by the feathers. The tail consists of 10 feathers; the two middle ones, and sometimes more in several of the species, are very long, and webbed only at the base and tips. The legs and feet are very large and strong: they have three toes forward, one backward, and the middle connected to the outer one as far as the first joint. The whole of this genus have, till lately, been very imperfectly known; few cabinets possessing more than one species, viz. the Greater, or what is called the common bird of Paradise; nor has any set of birds given rise to more fables, the various tales concerning which are to be found in every author; such as, their never touching the ground, from which they were known by the name of birds of paradise. The whole trouble they were at on this occasion, was merely to skin the bird, and, after pulling off the legs, coarser parts of the wings, &c., thrust a fisk down the throat into the body, letting an inch or two hang out of the mouth, beyond the bill; on the bird's drying the skin collapsed about the fisk, which became fixed, and supported the whole. They had then no more to do than to put this end of it into a pocket fitted to receive it, or fasten it in some manner to the turban, &c. By degrees these were imported into the other islands, and were led by a bird which the inhabitants of Arro call the king. This leader is black, with red spots; and constantly flies higher than the rest of the flock, which never forake him, but follow as soon as he fettles; a circumstance that frequently proves their ruin when the king lights on the ground, whence they are not able to rise on account of the singular structure and disposition of their plumage. They are likewise unable to fly with the wind, which would ruin their loose plumage; but take their flight constantly against it, cautious not to venture out in hard blowing weather, as a flying wind frequently obliges them to come to the ground. During their flight they cry like starlings. Their note, however, approaches more to the croaking of ravens; which is heard very plainly when they are in distress from a fresh gale blowing on the back of their plumage.

The Portuguese first found these birds on the island of Giolo, the Papu islands, and New Guinea; and they were known by the name of *bird of the sun.* The inhabitants of Ternate call them *vanara de curva,* the "bird of God;" whence the name *mono diato,* used by some naturalists, is derived. According to some fabulous accounts, this bird has no legs, lives constantly on wings, and in the air; and, in confirmation of these accounts, the legs of all the dead birds offered to sale were cut off. But the inhabitants of Arro, who retort yearly to Banda, undeceived the Dutch, and freed them from those prejudices. Another reason for cutting off the legs is, that the birds are more easily preserved without them; besides that the Moors wanted the birds without legs, in order to put them on in their mock fights as ornaments to their helmets. The inhabitants of Arro, however, have brought the birds with legs for 80 or 90 years; and Pijaefte, shipmate of Ferdinand Magellan, proved, about the year 1525, an eye-witness that these creatures were not without legs. However, the peculiar length and structure of their scapular feathers renders them from settling in high winds, on trees; and when they are thrown on the ground by these winds, they cannot rise again. If taken by the natives, they are immediately killed, as their food is not known; and they defend themselves with great courage with their formidable bills.

Latham enumerates eight species, but specifies there may be more. We shall satisfy ourselves with the following:

1. The largest bird of Paradise is commonly two feet four inches in length; the head is small; the bill hard and long, of a pale colour. The head and back-part of the neck is lemon-coloured, a little black about the eyes; and the neck, the bird is of the brightest glossy emerald green, soft like velvet; as also the breast which is black: the wings are large, and chestnut-coloured; the back-part of the body is covered with long, straight, narrow feathers, of a pale brown colour, similar to the plumes of the ostrich. These feathers are spread when the bird is on the wing; for which reason he can keep very long in the air. On both sides of the belly are two tufts of stiff and shorter feathers, of a golden yellow, and shining. From the rump proceed two long stiff fluffs, which are feathered on their extremities.

These birds are not found in Key, an island fifty Dutch miles east of Banda; but they are found at the Arro islands, lying 15 Dutch miles farther east than Key, during the wetter or dry monsoon; and they return to New Guinea, as soon as the salt-water or wet monsoon sets in. They come always in a flock of 30 or 40, and are led by a bird which the inhabitants of Arro call the king. This leader is black, with red spots; and constantly flies higher than the rest of the flock, which never forake him, but follow as soon as he fettles; a circumstance that frequently proves their ruin when the king lights on the ground, whence they are not able to rise on account of the singular structure and disposition of their plumage. They are likewise unable to fly with the wind, which would ruin their loose plumage; but take their flight constantly against it, cautious not to venture out in hard blowing weather, as a flying wind frequently obliges them to come to the ground. During their flight they cry like starlings. Their note, however, approaches more to the croaking of ravens; which is heard very plainly when they are in distress from a fresh gale blowing on the back of their plumage.

In Arro, these birds settle on the highest trees, especially on the ficus benjamina of the hortus malabaricus, commonly called the *sea ing tree.* The natives catch them with bird-lime or in *nokoets,* or shot them with blunt arrows; but though fome are still alive when they fall into their hands, the catchers kill them immediately, and sometimes cut the legs off; then they draw out the entrails, dry and fumigate the bodies.
The bird of paradise dies with sulphur or smoke only, and sell them at Banda for half a rix-dollar each; but at Aru they may be bought for a spike-nail or a piece of old iron. Flocks of these birds are often seen flying from one island to the other against the wind. In case they find the wind become too powerful, they fly straight up into the air, till they come to a place where it is less agitated, and then continue their flight. During the eastern monsoon their tails are moulted, so that they have them only during four months of the western monsoon.

2. The smaller bird of paradise is about 20 inches long. His beak is lead-coloured, and paler at the point. The eyes are small, and inclined in black about the neck. The head and back of the neck are of a dirty yellow; the back of a greyish yellow; the breast and belly of a dulky colour; the wings small, and chef-nut-coloured. The long plumage is about a foot in length, and paler than in the large species; as in general the colours of this bird are less bright than the former. The two long feathers of the tail are constantly thrown away by the natives. This is in all respects like the greater fort; and they likewise follow a king or leader, who is, however, blacker, with a purplish cast, and finer in colour than the rest. The neck and bill are larger in the male than the female. They roost on the tops of the highest trees, and do not migrate like the other kind. Some say, that the birds of this species, finding themselves weak through age, soar straight towards the sun till they are tired, and fall dead to the ground. The natives draw the entrails, fear the birds with a hot iron, and put them in a tube of bamboo for preservation.

3. and 4. The large black bird of paradise is brought without wings or legs for sale; so that no accurate description of it hath yet been given. Its figure, when stuffed, is narrow and round, but stretched in length to the extent of four spans. The plumage on the neck, head, and belly, is black and velvet-like, with a hue of purple and gold, which appears very strong. The bill is blackish, and one inch in length. On both sides are two bunches of feathers, which have the appearance of wings, although they be very different, the wings being cut off by the natives. This plumage is soft, broad, similar to peacock feathers, with a glorious gloss and greenish hue, and all bent upwards; which Valentine thinks is occasioned by the birds being kept in hollow bamboo-reeds. The feathers of the tail are of unequal length; those next to the belly are narrow, like hair; the two uppermost are much longer, and pointed; those immediately under them are a span and a half longer than the upper ones; they are stiff, on both sides fringed with a plumage like hair, black above, but glossy below. Birds of this kind are brought only from one particular place of New Guinea. Besides the large black bird of paradise, there is still another fort, whose plumage is equal in length, but thinner in body, black above, and without any remarkable gloss, not having those shining peacock feathers which are found on the greater species. This wants likewise the three long pointed feathers of the tail belonging to the larger black species.

5. The white bird of paradise is the most rare, and has two varieties; one quite white, and the other black and white. The former is very rare. The second has the fore-part black, and the back-part white; with 12 crooked wiry shafts, which are almost naked, tho' in some places, covered with hairs.

6. In the year 1689 a new species of the black bird of paradise was seen in Amboyna. This was only one foot in length, with a fine purple hue, a small head, and a straight bill. On its back, near the wings, are feathers of a blue and purple colour, as on the other birds of paradise; but under the wings and over all the belly they are yellow coloured, as in the common form; on the back of the neck they are mouse-coloured mixed with green. It is remarkable in this species, that there are before the wings two roundish tufts of feathers, which are green-edged, and may be moved at pleasure by the bird, like wings. Instead of a tail, he has 12 or 13 black, naked, wire-like shafts, hanging promiscuously like feathers. His legs are strong, and have sharp claws. The head is remarkably small; and the eyes are also small, and surrounded with black.

7. The last species we shall mention is the king's bird. This creature is about seven inches long, and somewhat larger than a titmouse. Its head and eyes are small; the bill straight; the eyes included in circles of black plumage; the crown of the head is flame-coloured; the back of the neck blood-coloured; the neck and breast of a chestnut colour, with a ring of the brightest emerald-green. Its wings are in proportion strong; and the quill-feathers dark, with red shining plumes, spots, and stripes. The tail is straight, short, and brown. Two long naked black shafts project from the rump, at least a hand-breadth beyond the tail; having at their extremities semilunar twisted plumage, of the most glistening green colour above, and dulky below. The belly is white and green sprinkled; and on each side is a tuft of long plumage, feathered with a broad margin, being on one side green and on the other dulky. The back is blood-red and brown, shining like silk. The legs are in size like those of a lark, three fore-toes and one back-toe. This bird associates not with any of the other birds of paradise; but sits solitary from bush to bush, wherever he feeds red-berries, without ever getting on tall trees.

Those who wish for minute information respecting this curious genus, we must refer to Latham's Synopsis, and Buffon's Birds, vol. ix. &c.

PARADOX, a word in philosophy, a proposition seemingly absurd, as being contrary to some received opinions, but yet true in fact.

The vulgar and illiterate take almost every thing, even the most important, upon the authority of others, without ever examining it themselves. Although this implicit confidence is seldom attended with any bad consequences in the common affairs of life, it has nevertheless, in other things, been much abused; and in political and religious matters has produced fatal effects. On the other hand, knowing and learned men, to avoid this weakness, have fallen into the contrary extreme; some of them believe every thing to be unreasonable, or impossible, that appears so to their first examination; not adverting to the narrow limits of the human understanding, and the infinite variety of objects, with their mutual operations, combinations, and affections, that may be presented to it.
PAR

PARADOX. It must be owned, that credulity has done much more mischief in the world than incredulity has done, or ever will do; because the influence of the latter extend only to such as have some share of literature, or affect the reputation thereof. And since the human mind is not necessarily impelled, without evidence, either to belief or unbeliefe, but may suspend its assent to, or dissent from any proposition till after a thorough examination: it is to be wished that men of learning, especially philosophers, would not hastily, and by first appearances, determine themselves with respect to the truth or falsehood, possibility or imposibility of things.

A person who has made but little progress in the mathematics, though in other respects learned and judicious, would be apt to pronounce it impossible that two lines, which were nowhere two inches asunder, may continually approach towards one another, and yet never meet, though continued to infinity; and yet the truth of this proposition may be easily demonstrated. And many, who are good mechanics, would be as apt to pronounce the same, if they were told, that though the teeth of one wheel should take equally deep into the teeth of three others, it should affect them in such a manner, that, in turning it any way round its axis, it would turn one of them the same way, another the contrary way, and the third no way at all.

No science abounds more with paradoxes than geometry: thus, that a right line should continually approach to the hyperbola, and yet never reach it, is a true paradox; and in the same manner a spiral may continually approach to a point, and yet not reach it in any number of revolutions, however great.

The Copernican system is a paradox to the common people; but the learned are all agreed as to its truth. Geometricians have of late been accused of maintaining paradoxes; and some do indeed use very mysterious terms in expounding themselves about asymptotes, the sums of infinite progressions, the means comprehended between curves and their asymptotes, and the solids generated from those areas, the length of some spirals, &c. But all these paradoxes and mysteries amount to no more than this; that the line or number may be continually acquiring increments, and those increments may decrease in such a manner, that the whole line or number shall never amount to a given line or number. The necessity of admitting it is obvious from the nature of the most common geometrical figures: thus, while the tangent of a circle increases, the area of the corresponding sector increases, but never amounts to a quadrant. Neither is it difficult to conceive, that if a figure be concave towards a base, and have an asymptote parallel to the base (as it happens when we take a parallel to the asymptote of the logarithmic curve, or of the hyperbola, for a base), that the ordinate in this case always increases while the base is produced, but never amounts to the distance between the asymptote and the base. In like manner, a curvilinear area may increase while the base is produced, and approach continually to a certain finite space, but never amount to it; and a solid may increase in the same manner, and yet never amount to a given solid. See Mr. Laurin's Fluxions. See Logarithmic-Curves.

PARADOXI, a sort of mimes or buffoons among the ancients, who entertained the people with extem-pective effusions of drollery. They were also called Paradoxologi, Ordonarii, Nematiologi, and Aretopi. See Mi.,

PARAGUADE, among the Romans, were wreaths of gold, or silk and gold, interwoven in, not sewed to, their garments. The garment was sometimes of one colour, with one paragauda; sometimes of two colours, with two paragaudas; or three colours, with three paragaudas, &c. They were worn both by men and women.

PARAGOG, in grammar, a figure whereby a letter or syllable is added to the end of a word; as med., for med. dicier, for dict., &c.

PARAGRAPH, in general, denotes a division or division of a chapter; and in references is marked thus, q.

PARAGUAY, or LA PLATA, a province of Spanish America, bounded on the north by the river of the Amazon; on the east, by Brazil; on the south, by Patagonia; and on the west, by Chili and Peru. This country was first discovered by Sebastian Cabot, who, in 1526, passed from Rio de la Plata to the river Parana in small karks, and thence entered the river called Uruguay. It was not, however, thoroughly reduced till the Jesuits obtained possession of it. A few of these went to Paraguay soon after the city of Asuncion was founded, and converted about 50 Indian families, who soon induced many others to follow their example, on account of the peace and tranquility they enjoyed under the fathers. They had long refited the Spaniards and Portuguese; but the Jesuits, by learning their language, conforming to their manners &c., soon acquired great authority among them; till at last, by steadily pursuing the same artful measures, they arrived at the highest degree of power and influence, being in a manner the absolute sovereigns of a great part of this extensive country; for above 350,000 families are said to have been subjected to them, living in obedience and awe bordering on adoration, yet procured without the least violence or constraint.

We have the following particular account of the miff: Gene. Mag. of Paraguay, in the words of Don Jorge Juan, &c. 1733.

The territories of the missions of Paraguay comprended not only the province of that name, but also a great part of the provinces of Santa Cruz de la Sierra, Tucuman, and Buenos Ayres. The temperature (a) of the air is good, though somewhat moist, and in some parts rather cold: the soil in many places is fer-

---

(a) The climate of Paraguay differs but little from that of Spain; and the distinctions between the seasons are much the same. In winter, indeed, violent tempests of wind and rain are very frequent, accompanied with such dreadful claps of thunder and lightning as fill the inhabitants, though used to them, with terror and consternation. In summer, the excessive heats are mitigated by gentle breezes, which constantly begin at eight or nine in the morning.
The chief article of their commerce are cotton, tobacco, home sugar, and the herb called Paraguay. Every town gathers annually more than 2000 arrobas of cotton of a quarter of an hundred weight each, which the Indians manufacture into stuffs. There are also great quantities of tobacco produced. But the chief article is the herb Paraguay; for it grows only in the districts of the missions; and there is a vast consumption of this herb in all the provinces of Chili and Peru, especially of that called coca, which is the pure leaf; the infusion of which is called mate, and is drank by the inhabitants of Lima twice a day in lieu of tea or chocolate. The mate which is made by the infusion of the flake is not so much esteemed.

"This new almost two centuries since these missions were first set on foot by the Jesuits. The bad management of the Portuguese greatly offended some of the natives of that nation which is the herb Paraguay, and they were preparing to build others for the reception of the new converts of that nation which were daily made.

"The missions of Paraguay are surrounded on all sides with wild or unconverted Indians; some of whom live in friendship with the towns, but others haras them by frequent incursions. The father-missionaries frequently visit these Indians, and preach to them; and from these expeditions they seldom return without bringing along with them some new converts to incorporate with their civilized subjects. In the performance of this duty they sometimes penetrated 100 leagues into those uncultivated tracts where wild Indians range; and it is observed that they meet with the least success among those nations with whom any fugitive Medizins, or Spanish criminals, have taken refuge. The diligence of these fathers is certainly worthy the imitation of the protestant clergy.

"Every town has its curate, who is assisted by one and very often by two priests of the same order, according to the largeness and extent of the town and its district. These two or three priests, together with six boys who assist them in the service of the church, form a small college in every town, wherein the hours and other exercises are regulated with the same formality and exactness as in the large colleges in the cities of Peru and Chili. The most troublesome part of the duty of the assistant priests are the personal visitations which they are obliged to make to the Indians to prevent their giving themselves up to idleness; for such is the slothfulness of the Guaranies, that if they were not very carefully looked after, the society would receive no benefit or advantage from them. They also attend the public fumblings, where the cattle necessary for the sustenance of the Indians are daily slaughtered, and distribute the flesh among all the families in the town, in proportion to the number of persons whereof each family consists; so that all may have what is necessary.

(8) It produces maiz, manioc, and potatoes, besides many fruits and simples unknown in Europe. Vines, however, do not thrive, except in some particular places. Wheat has also been tried; but it is only used for cakes, and other things of that kind. There are great numbers of poisonous serpents, and others of enormous size, many of which live on fish. It produces also abundance of sugar, indigo, pimento, ipecacuanha, and variety of other drugs; and above all the herb Paraguay, which it exports to the value of 100,000 l. annually to the provinces of Chili and Peru. It is the leaf of a middle-sized tree, resembling an orange-tree, in taste not unlike mallows. There are three gatherings: first, the buds before it unfolds its leaves, which is the best, but too often subject to decay; the second gathering is the full-grown leaves at the first expansion; the third is when the leaves have remained on, some time after they are full blown. The leaves are roasted and then kept in pits dug in the ground to be ready for sale. These trees grow principally in the morasses on the eait side of Paraguay, but now are distributed all over the country. The manner of using it is, to dry and reduce it almost to powder, then put it into a cup with lemon-juice and sugar; boiling water is then poured on it, and the liquor drank as soon as may be. It is supposed to be serviceable in all disorders of the head, breath, and stomach; it preserves the miners from the noxious mineral ritements with which they would otherwise be suffocated; is a sovereign remedy in putrid fevers and the scurvy; allays hunger; and purifies all kind of water, by infusing it therein. The country is diversified with forests, mountains, lowlands (great part of the year under water), fertile meadows, and morasses. Almost every forest abounds with bees, which have their hives in hollow trees. Besides cotton, the country produces hemp, flax, corn, rice, and wool; and there are such numbers of wild cattle, that they are killed only for their hides. The natives differ not materially from those described under the article America.
...the town of Candelaria. The missions are always appointed. The
churches. Nor are the curates the spiritual rulers of Paraguay.
the towns only; they are also in effect civil governors. It is true there are in every town of
millions a governor, regidores, and alcaldes, as there are in the other towns and cities under the Spanish
government. But though the governor is elected by
the Indians, he must be approved by the curate before he enters upon his office; nor can he chafe or punish
delinquents without the curate's permission. The curate examines those who are accused of offences and,
if he finds them guilty, delivers them to the governor to be punished, according to the nature and quality of
the offence committed. He sometimes orders them to be imprisoned for a few days, sometimes to fail,
and, when the fault is considerable, to be whipped, which is the severest punishment that is ever inflicted;
for the regulations and instructions of the curates have been so efficacious, that murder and such like heinous
crimes are never here committed. And even before
they undergo these gentle corrections, the curate discourses the offenders in a mild friendly manner; and
endeavours to excite in them a due sense of
their crime, and of the ill consequences that might flow from it, and to convince them that they merit a much
greater punishment than is inflicted. This mild treat-
ment prevents tumults and insurrections, and acquires
the curates universal veneration and esteem. The alcaldes are chosen annually by the regidores. The go-
vernors, regidores, and alcaldes are all Indians of the
best capacities; and are in effect only so many over-
seers appointed by the curate, and dignified with these
empty titles (c).

Every town has its armory or magazine, in which are
lodged the fire arms and other weapons wherewith the
militia are armed when they take the field to repel
the irruptions of the Portuguese and wild Indians. The militia are very dexterous and expert in the
management of their arms; and are exercised on the
eyes of festivals in the squares and public places of the
towns. The militia is composed of all those who are
able to bear arms; they are formed into companies,
which have each a proper number of officers chosen
from amongst those who are most distinguished for
judgment and conduct. The dress of the officers is
rich, adorned with gold and silver, and the device of
the town to which they belong; they always appear
in their uniforms on festivals, and on the days of mi-
litary exercises. The governor, alcaldes, and regidores
have also proper robes and dresses suitable to their re-
spective offices, in which, they appear on public oc-
casions. There are schools in every town, in which the
common people are taught reading and writing, and
also music and dancing; in which arts they become
very skilful. The Jesuits are very careful in consulting
the natural bent and genius of their scholars, and in
directing their studies and application accordingly.

(a) We call them empty titles; because in all causes the Jesuit or curate of the parish was a kind of sovereign,
regarded as a petty prince, and obeyed as an oracle. Whatever forms might take place in the choice of the
chiefs of the several departments, their success ultimately depended on him. The cacique held of him; the
general received his commision and instructions from him; and all his decisions were without appeal. There
were, we are informed, not less than 60,000 parishes on the banks of the rivers Uruguay and Parana, not
exceeding the distance of 30 miles from each other; in each of which was a Jesuit or curate.
The ladys of the most promising genius are taught the Latin tongue with great success. In one of the courtyards of every curates house are various shops or workhouses of painters, carvers, gilders, silversmiths, carpenters, weavers, and clockmakers, and of several other mechanics and artizans, who daily work for the public under the direction of the curators, and at the same time teach the youth their respective arts and occupations.

The churches are large, well built, finely decorated and enlightened, and not inferior to the richest in Peru. Each church has a choir of music, composed of instruments of all sorts, and very good voices; so that divine service is celebrated here with as much pomp and solemnity as in cathedrals: nor are the public proceedings less splendid, especially that of the feast which, whenever it is carried abroad, is attended by the governor, alcalde, and regidores, in their robes, and also by the militia in a body. The houses of the Indians are as well built and as well furnished as most of the Spanish houses in Peru. The greatest part indeed have mud walls, others are built with brick, and some with stone, but all are covered with tiles. In every town there is a house where gunpowder is made, that they may never want it when they are obliged to take arms, and always have it ready to make artificial fire-works on rejoicing days: for all festivals are here observed with as great ceremony and exactness as in the greatest cities. Upon the proclamation of a new king of Spain, the governors, alcalde, regidores, and officers of the militia, appear drest in new robes and uniforms of a different fashion from those they wore before. There is a sort of a convent in every town; in one part whereof are confined women of an ill life, and the other part is designed for the reception of married women who have no family, and who retire thither when their husbands are absent. For the maintenance of this house, and for the support of orphans, and of old and infirm people, all the inhabitants of the town work two days in every week; and the profits of their labour, which is called the labour of the community, are set apart for this purpose. If the produce of this labour be more than is necessary for their subsistence, the surplus is laid out to buy ornaments for the churches, and clothes for the orphans and aged and infirm people; so that here are no beggars, nor any who want the necessaries of life. In short, by the wise policy and prudent regulations of the Jesuits, the whole community enjoys peace and happiness.

The Guaranies are so profuse and negligent, that the curates are obliged to take into their hands all their goods and fluxes as soon as they are manufactured and made ready for sale; otherwise they would waste and destroy them, and not be able to maintain themselves. The Chiquitos, on the contrary, are diligent and frugal; so that the curates have no other trouble with them than the affilling them in the disfand of their goods, and procuring returns for them. For this purpose the society keeps a factor or procurator at Santa Fe and Buenos Ayres, to whom the merchandise of the missions is sent to be disposed of; and these factors return the value to the fathers in such sorts of European commodities as are wanted. The goods of every town are kept separate; and the royal taxes are taken out of them without any other dis-

As the apparent place of an object is nearer the horizon than its true place, the parallax is therefore to be added to the apparent altitude, to obtain the true altitude. Hence also an object will appear to rise later and set sooner.

The fine of the parallax of an object is inversely as its distance from the earth’s centre.

Demonstration. Let A be the place of an object, and H the place of the same object at another time, or that of another object at the same instant; join EH, then in the triangles AOE, HEO,

\[ R : \text{fine } OAE = AE : OE. \]

Hence fine OHE = fine OAE : AE : EH.

The parallax of an object makes it appear more distant from the meridian than it really is.

2. Parallax in the longitude, latitude, right ascension, and declination of an object, are affected by parallax.

The longitude, latitude, right ascension, and declination of an object are called the parallax in longitude, in latitude, in right ascension, and in declination, respectively. It is apparent that the object is greater or less than the true object when the object is in the meridian; but it is less than the true right ascension when the object is in the western hemisphere.

The apparent object is more distant from the elevated poles of the ecliptic in the declination than in the latitude.

The parallaxes in longitude, latitude, right ascension, and declination, in the spherical hypothesis, may be found by the following formulae, in which \( L \) represents the longitude of the place, diminished by the angle contained between the vertical and radius of the given place; \( P \) the horizontal parallax for that place; \( a \) the altitude of the nonagefimal at the given instant; \( d \) the apparent distance of the object from the nonagefimal; \( l \) the true and apparent latitudes of the object; \( D \) the true and apparent declinations respectively; and \( m \) the apparent distance from the meridian.

Then par. in long. = \( P \) fine. a fine d. cent \( \lambda \) to radius unity; and par. in lat. = \( P \) cofine a. cofine \( \lambda \) to radius unity.

The fine is used when the apparent distance of the object from the nonagefimal and from the elevated pole of the ecliptic are of the same sign, and the sign
The upper or lower sign is to be used, according as the difference of the true place from the meridian or from the elevated pole of the ecliptic is greater or less than 0.00000121216. The difference of the true place from the meridian is additive to, or subtractive from the difference of the true place from the elevated pole of the equator. The difference of the true place from the elevated pole of the equator are of the same sign as that of the true place from the meridian. The upper or lower sign is to be used, according as the difference of the true place from the meridian or from the elevated pole of the ecliptic is greater or less than 0.00000121216.

The difference of the true place from the meridian is additive to, or subtractive from the difference of the true place from the elevated pole of the equator. The difference of the true place from the elevated pole of the equator are of the same sign as that of the true place from the meridian.
PARAPLEGIA, a species of palfy. See Medic wrestling, n° 268.

PARASANG, an ancient Persian measure, different at different times, and in different places: being usually 30, sometimes 40, and sometimes 50 fathoms, or furlongs. The word, according to Littleton, has its rise from *parasang* angustus, *q. d.* the space a footman titles from one station, angustia, to another.

PARASCENIUM, in the Grecian 8. Roman theatres, was a place behind the scenes wherein the actors withdrew to dress and undress themselves. The Romans more frequently called it *Pseudenium.* See Theatre.

PARASELENE, in natural philosophy, a mock moon; meteor or phenomenon encompassing or adjacent to the moon, in form of a luminous ring; wherein are observed sometimes one and sometimes two or more images of the moon.

PARASEMEN, among the Greeks, was the figure carved on the prow of the ships to distinguish them from one another. This figure was generally that of a bull, lion, or other animal; sometimes the movement of a mountain, tree, flower, &c.

PARASITE, among the Greeks, was originally a very reputable title; the parasites being a kind of priests, at least ministrers, of the gods, in the same manner as the epulones were at Rome. They took care of the sacred corn, or the corn defined for the service of the temples and the gods, *viz.* sacrifices, fees, &c. They had even the attendance over sacrificial meat and took care that they were duly performed. At Athens there was a kind of college of 12 parasites; each people of Attica furnishing one, who was always chosen out of the best families. Polyclitus adds, that a parasite was also an honourable title among the ancient Gauls, and was given to their poets. But of late it has been made a term of reproach, and used for a flatterer or mean dependent.

PARASITES, or *practical* plants, in botany, such plants as are produced out of the trunk or branches of other plants, from whence they receive their nourishment, and will not grow on the ground. Such are the Mistletoe, &c.

PARASTATÆ, in anatomy. See Prostate.

PARATALASSIA. See Promorie.

PARBUNCLE, in a ship, the name of a rope almost like a pair of flanges: it is feized both ends together, and then put almost double about any heavy thing that is to be hoisted in or out of the ship; having the hook of the runner hitched into it, to hoist it up by.

PARCE, in heathen mythology, goddesses who were supposed to prejudice over the accidents and events, and to determine the date or period of human life.

The Parce were three, Clotho, Lachesis, and Atropos; because, forsooth, all things have their beginning, progress, and end. Hence the poets tell us: the Parce spun the thread of men's lives; that Clotho held the distaff, and drew the thread; Lachesis twisted the spindle, and spun it; and Atropos cut it. *Clotho columnat, Lachesis retinet, Atropos occa.*

The ancients represent the Parce divers ways: Lucian, in the shape of three poor old women, having large locks of wool, mixed with daffodils on their heads; one of which holds a distaff, the other a wheel, and the third a pair of scissors, wherewith to cut the thread of life. Others represent them otherwise: Clo. Parchment two appearing in a long robe of divers colours, wearing a crown upon her head adorned with seven stars, and holding a distaff in her hand; Lachesis in a robe-beet with stars, with several spindles in her hand; and Atropos, clad in black, cutting the thread with a pair of large scissors.

The ancients imagined that the Parce used white wool for a long and happy life, and black for a short and unfortunate one. See Necrology in Mythology.

PARCHMENT, the skins of sheep or goats prepared after such a manner as to render it proper for writing upon, covering books, &c.

The word comes from the Latin *pergamene,* the ancient name of this manufacture; which is to be understood as having been taken from the city Pergamos, to Eumenes king whereof its invention is usually ascribed; though, in reality, that prince appears rather to have been the improver than the inventor of parchment. For the Persians of old, according to Diodorus, wrote all their records on skins; and the ancient Ionians, as we are told by Herodotus, made use of sheep skins and goat-skins in writing, many ages before Eumenes's time. Nor need we doubt that such skins were prepared and dried for that purpose, after a manner not unlike that of our parchment; though probably not so artificially. The manufacture of parchment is begun by the skinner, and finished by the parchment-maker.

The skin having been stripped of its wool, and placed in the lime-pit, in the manner described under the article Shane, the skincter stretches it on a kind of frame, and pares the flesh from it. After this is done, it is moistened with a rag; and powdered chalk being spread over it, the skinner takes a piece of parchment, flat at bottom, and rubs over the skin, and thuscowers off the flesh; he then goes over it again with the iron instrument, moistens it as before, and rubs it again with the parchment until without any chalk underneath: this smooths and softens the flesh-fide very considerably. He then drains it again, by passing over it the iron instrument as before. The flesh-fide being thus drained, by scraping off the moisture, he in the same manner paves the iron over the wool or hair-fide; then stretches it tight on a frame; and scrapes the flesh-fide again: this finishes its draining; and the more it is drained the whiter it becomes. The skinner now throws on more chalk, sweeping it over with a piece of lamb-skin that has the wool on; and this process it fills farther. It is now left to dry, and when dried, taken off the frame by cutting it all round. The skin thus far prepared by the skinner, is taken out of his hands by the parchment maker, who, first, while it is dry, pares it on a furiner, (which is a calf skin stretched in a frame), with a sharper instrument than that used by the skinner; and working with the arm from the top to the bottom of the skin, takes away about one half of its thickness. The skin thus equally pared on the flesh-fide, is again rendered smooth, by being rubbed with the parchment, on a bench covered with a sack stuffed with flocks. which leaves the parchment in a condition fit for writing upon. The parchings thus taken off the leather, are used in making glue, size, &c. See the article Glue, &c.

What is called *vellum* is only parchment made of the skins of abortives, or at least, the calves. This has
PAR

has a much finer grain, and is whiter and smoother than parchment: but is prepared in the same manner, except its not being passed through the lime-pits.

FARDALIS, in natural history. See PARDIS.

PARDIES (Ignatius Galton), an ingenious and learned French Jesuit, born at Paris in 1636. He taught polite literature for several years; during which time he composed several small tracts, both in prose and verse, with peculiar delicacy of thought and style. At length he devoted himself entirely to mathematics and natural philosophy, and read all authors, ancient as well as modern, in those branches of knowledge. He died in 1673, of an infectious disorder contracted by confessing and preaching to the prisoners in the Bicêtre during the Easter holidays. Father Pardies published several works; of which his Elements of Geometry are well known in England, where a translation of them has gone through several editions. In 1672 he had a dispute with Sir Isaac Newton respecting his Theory of Light and colours; which may be seen in the Philosophical Transactions for that year.

PARDON, in criminal law, is the remitting or forgiving an offence committed against the king.

Law (says an able writer), cannot be framed on principles of compassion to guilt; yet justice, by the constitution of England, is bound to be administered in mercy: this is promised by the king in his coronation oath; and it is that act of his government which is the most personal and most entirely his own. The king condemns no man; that rugged oatn, and it is declared in king condemns no man; that rugged oath; and it is declared in

saying the nation see him personally engaged, it is only in works of legislature, magnificence, or compassion.

To him therefore the people look up as the fountain of nothing but bounty and grace; and these repeated acts of goodness, coming immediately from his own hand, endear the sovereign to his subjects, and contribute more than anything to root in their hearts that filial affection and personal loyalty which are the surest establishment of a prince.

The king may pardon all offences merely against the crown or the public; excepting, 1. That, to preserve the liberty of the subject, the committing any man to prison out of the realm, is by the habeas corpus act, 31 Car. II. c. 2. made a prerogative, unpardonable even by the king. Nor, 2. can the king pardon, where private justice is principally concerned in the prosecution of offenders: Non potest rex gratiam facere eum in jura et domo alieno. Therefore, in appeals of all kinds (which are the suit, not of the king, but of the party injured), the prosecutor may release; but the king cannot pardon. Neither can he pardon a common nuisance, while it remains unredressed, or so as to prevent an abatement of it; though afterwards he may remit the fine: because though the prosecution is vested in the king to avoid the multiplicity of suits, yet (during its continuance) this offence favours more of the nature of a private injury to each individual in the neighbourhood, than of a public wrong. Neither, lastly, can the king pardon an offence against a popular or penal statute, after information brought; for thereby the informer hath acquired a private property in his part of the penalty.

There is also a restriction of a peculiar nature, that affects the prerogative of pardoning, in caife of parliamentary impeachments, viz. that the king's pardon cannot be pleaded to any such impeachment, so as to impede the inquiry, and stop the prosecution of great and notorious offenders. Thereupon, when, in the reign of Charles II. the earl of Danby was impeached by the house of commons of high treason and other misdemeanors, and pleaded the king's pardon in bar of the same, the commons alleged, "That there was no precedent that ever any pardon was granted to any person impeached by the commons of high treason, or other high crimes, depending the impeachment;" and thereupon resolved, "That the pardon so pleaded was illegal and void, and ought not to be allowed in bar of the impeachment of the commons of England:" for which resolution they affirmed this reason to the house of lords, "That the setting up a pardon to be a bar of an impeachment defeats the whole use and effect of impeachments: if this point be admitted, or shall doubted, it would totally discourage the exhibiting any for the future; whereby the chief influence for the prefervation of the government would be destroyed." Soon after the Revolution, this commons renewed the same claim, and voted,

PARDON

Godwin's Inquiry concerning Political Justice.

Pardon. "That a pardon is not pleadable in bar of an impeachment." At length, it was enacted by the act of settlement, 12 & 13 W. III. c. 2. "That no pardon under the great seal of England shall be pleadable to an impeachment by the commons in parliament." But, after the impeachment has been solemnly heard and determined, it is not understood that the king's royal grace is farther restrained or abridged: for, after the impeachment and attainder of the six rebel lords in 1715, three of them were from time to time reprieved by the crown; and at length received the benefit of the king's most gracious pardon.

The effect of such pardon by the king, is to make the offender a new man; to acquit him of all corporeal penalties and forfeitures annexed to that offence for which he obtains his pardon; and not so much to restore his former, as to give him a new credit and capacity. But nothing can restore or purify the blood when once corrupted, if the pardon be not allowed till after attainder, but the high and transcendant power of parliament. Yet if a person attain'd receives the king's pardon, and afterwards hath a son, that son may be heir to his father; because the father being made a new man, might transmit new inheritable blood; tho', had he been born before the pardon, he could never have inherited at all.

Such is the nature of pardons in Britain. These, like other good things, may doubtless be abused; and if they are in any instance, their abuse deserves censure: but that in their nature they should be counted absurd, arbitrary, and destructive of morality, can, we suspect, proceed from nothing but from the presumptuous pertinacity of modern reformers, or from a mistake in the system of civil equality.

We are told, however, by a late champion for the Rights of Man, that "the very word to a reflecting mind is fraught with absurdity. What is the rule that ought in all cases to prescribe to my conduct?" Surely justice: understanding by justice the greatest utility of the whole mass of beings that may be affected by my conduct. What then is clemency? It can be nothing but the pitiable egotism of him who imagines he can do something better than justice. Is it right that I should suffer constraint for a certain offence? The retribution of my suffering must be founded in its tendency to promote the general welfare. He therefore that pardons me, iniquitously prefers the imaginary interest of an individual, and utterly neglects what he owes to the whole. He befores that which I ought not to receive, and which he has no right to give. Is it right, on the contrary, that I should not undergo the suffering in question? Will he, by refusing me from suffering, do a benefit to me, and no injury to others? He will then be a notorious delinquent, if he allow me to suffer. There is indeed a considerable defect in this last supposition. If, while he benefits me, he do no injury to others, he is infallibly performing a public service. If I suffered in the arbitrary manner which the supposition includes, the whole would suffer an unquestionable injury in the injustice that was perpetrated. And yet the man who prevents this odious injustice, has been accustomed to arrogate to himself the attribute of emolument, and the apparently sublime, but in reality tyrannical, name of forgiveness. For, if he does more than has been here described, instead of glory, he ought to take shame to himself, as an enemy to the interest of human kind.

If every action, and especially every action in which the happiness of a rational being is concerned, be susceptible of a certain rule, then caprice must be in all cases excluded: there can be no action, which if I neglect, I shall have discharged my duty; and, if I perform, I shall be entitled to applause."

Such is the reasoning of this zealous democrat; reasoning which, in our opinion, betrays want of feeling or ignorance of human nature. That human nature is such as, in the aggregate, to need control, not one who is acquainted with it will deny; and there appears to be no other method of controlling mankind but by general laws; and these laws may, through the natural imperfection of human affairs, be cruel in one case, where they are just in another. Cases may likewise occur where the sentence of the law, without its execution, will answer every purpose which could be expected from it; and where the execution of it would give rise to extreme cruelty that could be only attended with a name. Our author next goes on to trace the origin of pardons; and instead of a definite system of law, we are told that it is necessary to have a court of reason, to which the decisions of a court of law shall be brought for revision: a remedy apparently too vague and indeterminate to produce any lasting or good effect; and the proposal of which results from supposing mankind more virtuous and more knowing than they really are.

We are next led to consider the abuses of pardons: from whence our author would draw an argument for their abolition; a species of reasoning unfair and unphilosophical. He tells us, that the authority in this case is placed first in the judge and next in the king and council. "Now (far be it), laying aside the propriety or impropriety of this particular selection, there is one grievous abuse which ought to strike the most superficial observer. Those persons, with whom the principal trust is repose, consider their functions in this respect as a matter purely incidental, exercise them with superficialness, and in many instances with the most scanty materials to guide their judgment. This grows in a considerable degree out of the very name of pardon, which implies a work of supererogatory benevolence."

Vol. XIII.

Now it is obvious to remark, that pardons are in general granted in consequence of an application from people who have more than scanty materials to guide their judgments, and on whose fidelity in relating the circumstances of the case, confidence is placed or not according to the several characters. Our author next proceeds to the arbitrary character of pardons. "Such a system (he says), to speak it truly, is a lottery of death, in which each man draws his ticket for reprieve or execution, as undefinable accidents shall decide." The allusion here to a lottery ticket is peculiarly unfortunate and indecorous, nor does the whole sentence show any great degree of candour. It is possible to define
Pardon, a particular crime, and to annex a particular punishment to the commission of it; but the nature of morality confines not in the external action, but in the motives which prompted to it. Definite law cannot, however, always make this distinction; and after the sentence of the law is pronounced, it comes to be considered whether there are any alleviating circumstances in the case; and whether there are or not, must depend on the particulars or accidents of the case; and it is indeed impossible to suppose that these accidents could be previously defined; their nature does not admit of it. To particularize and define every mode of an action which imagination can conceive, or which experience has shown us may happen, would indeed be an Herculean labour; and we might literally say with the apostle, that the world could not contain the books that might be written. We are, however, told that "reason is a thousand times more explicit and intelligible than law; and when we are accustom to consult her, the certainty of her decisions would be such, as men practiced in our present courts are totally unable to conceive." Were reason, however, appointed to be appealed to in all cases, and to be the final criterion, it would leave far greater room for villany than any mode at present in practice. Reason is a very uncertain and indefinite term, and may be made any thing, according to the circumstances or passions of men. In the perturbed state of mankind there are many appeals to Reason contradictory to one another, and the dictates of genuine unbiased reason are rarely attended to.

We are next told that pardons are defrutive to morality. "Another very important consequence (says our author) grows out of the systen of pardons. A system of pardons is a system of unmitigated slavery. I am taught to expect a certain defirable event, from what? From the clemency, the uncontrouled, unmerited kindness of a fellow mortal. Can any leon be more degrading? The pusillusamory of the servility of the man who devotes himself with everlasting obligations to another, because that other having begun to be unjust, relents in his career; the ardour with which he confesses the irditude of his sentences and the enormity of his deterts, will constitute a tale that future ages will find it difficult to understand. What are the sentiments in this respect that are alone worthy of a rational being? Give me that, and that only, which without injustice you cannot refuse. More than justice it would be disgraceful for me to ask, and for you to bestow. I stand upon the foundation of right. This is a title which brute force may refuse to acknowledge, but which all the force in the world cannot annihilate. By resiling this plea you may prove yourself unjust, but in yielding to it you grant me but my due. If, all things considered, I be the fit subject of a benefit, the benefit is merited: merit in any other sense is contradictory and absurd. If you bestow upon me unmerited advantage, you are a recreant from the general good. I may be bafe enough to thank you; but if I were virtuous, I should condemn you. These sentiments alone are consistent with true independence of mind. He that is accustomed to regard virtue as an article of faith, and grace, cannot be consistently virtuous. If he occasionally perform an action of apparent kindness, he will applaud the generosity of his sentiments; and if he abstain, he will acquit himself with the question, 'May I not do what I will with my own?' In the same manner, when he is treated benevolently by another, he will in the first place be unwilling to examine strictly into the reasonableness of this treatment, because benevolence, as he imagines, is not subject to any flexibility of rule; and, in the second place, he will not regard his benefactor with that erect and unembarrassed mien; that complete sense of equality, which is the only immovable basis of virtue and happiness."

Such is Mr. Godwin's conclusion on this subject; and we leave it with our readers to determine, whether his system or that which we at present enjoy would be the more rigorous or unjust; or whether mankind are indeed arrived at that eminent pitch of virtue, as to disdain every favour which they do not absolutely merit. The Christian religion speaks a different language: but amidst the rage of popular reform, its small still voice is unheard and neglected.

PAREGORICS, in pharmacy, medicines that assuage pain, otherwise called ANODYNES.

PAREIRA FRAYA, in the materia medica, a kind of oblong and large root brought from the Brazils.—It is certainly a diuretic of no mean character, and has done great service in nephritic cases. In pleurisy and quinsies, it has been used with more success than almost any medicine we know of singly.

PARELCON, in grammar, a figure by which a word or syllable is added to the end of another.

PAREMBOLE, in rhetoric, a figure wherein something relating to the subject is inferred in the middle of a period. All the difference between the parembole and parenthesis, according to Voifius, is, that the former relates to the subject in hand, whereas the latter is foreign to it.

PARENTHYMA, in anatomy, a term introduced by Erasistratus, signifying all that subflance which is contained in the interstices between the blood-vessels of the viscera, which he imagined to be extrava­stated and concrated blood.

PARENCYM of Plants. Grew applies the term parency­m to the pith or pulp, or that inner part of a fruit or plant through which the juice is supposed to be distributed. See PLANTS.

PARENT, a term of relation applicable to those from whom we immediately derive our being. See Moral Philosophy, n° 129 and 137.

To this article belongs an enquiry into, 1. The legal duties of parents to their legitimate children. 2. Their power over them. 1. The duties of parents to legitimate children confit in three particulars; their maintenance, their pro­tection, and their education.

1. The duty of parents to provide for the maintenance of their children, is a principle of natural law; an obligation, says Puffendorff, laid on them not only by nature her­self, but by their own proper act, in bringing them into the world; for they would be in the highest manner injurious to their issue, if they only gave their children life, that they might afterwards lose them per­ish. By begetting them, therefore, they have entered into a voluntary obligation, to enable, as far as in them lies, that the life which they have bestowed shall be supported and preserved. And thus
The children will have a perfect right of receiving maintenance from their parents. And the precede Mon- tetguiuex has a very just observation upon this head, that the establishment of marriage, in all civilized states, is built on this natural obligation of the father to provide for his children; for that affections and makes known the person who is bound to fulfill this obligation; whereas, in promiscuous and illicit conjunctions, the father is unknown; and the mother finds a thousand obstacles in her way; blame, remorse, the constraint of her fes, and the rigour of laws, that Ville her inclinations to perform this duty; and besides, she generally wants ability.

The municipal laws of all well regulated states have taken care to enforce this duty: though provision has done it more effectually than any laws, by implanting in the breast of every parent that natural parts, or insuperable degree of affection, which not even the deficiency of person or mind, not even the wickedness, ingratitude, and rebellion of children, can totally suppress or extinguish.

The civil law obliges the parent to provide maintenance for his child; and if he refuses, judex de ea re cognovit. Nay, it carries this matter so far, that it will not suffer a parent at his death totally to disinherit his child, without expressly giving his reason for so doing; and there are 14 such reasons reckoned up, which may justify such disinheritance. If the parent alleged no reason, or a bad, or a false one, the child might法定代表, tantum teguntum insequi- fendo, a testament contrary to the natural duty of the parent. And it is remarkable under what colour children were to move to examine the power that they have no right to, than as it is given by the grade that there parent over his own property: By the hand {b:Jall done it in the inclinations to perform this duty; testament to care to he of her wardens Life. By the

But, at her death the relation being dissolved, the husband is under no further obligation.

No person is bound to provide a maintenance for his wife, unless where the children are impotent and unable to work, either through infancy, dilate, or accident; and then is only obliged to find them with neccessaries, the penalty on refusal being no more than 20s. a month. For the policy of our laws, which are ever watchful to promote industry, did not mean to compel a father to maintain his idle and lazy children in ease and indolence; but thought it unjust to oblige the parent, against his will, to provide them with superfluities, and other induclements of fortune; imagining they might truft to the impulse of nature, if the children were desirous of such favours. Yet, as nothing is so apt toistle the calls of nature, as religious bigotry, it is enacted, that if any Popish parent shall refuse to allow his Protestant child a fitting maintenance, with a view to compel him to change his religion, the lord chancellor shall by order of court compel him to do what is just and reasonable. But this did not extend to persons of another religion, of no less bitterness and bigotry than the Popish: and therefore, in the very next year, we find an instance of a Jew of immense riches, whose only daughter having embraced Christianity, he turned her out of doors; and on her application for relief, it was held she was intitled to none. But this gave occasion to another statute, which ordains, that if Jewish parents refuse to allow their Protestant children a fitting maintenance, suitable to the fortune of the parent, the lord chancellor, on complaint, may make such order therein as he shall see proper.

Our law has made no provision to prevent the disinheriting of children by will; leaving every man's property in his own disposal, upon a principle of liberty in this as well as every other action; though perhaps it had not been amiss if the parent had been bound to leave them at the least a necessary subsistence. Indeed, among persons of any rank or fortune, a competence is generally provided for younger children, and the bulk of the estate settled upon the eldest by the marriage-articles. Heirs also, and children, are favours of our courts of justice, and cannot be disinherited by any dubious or ambiguous words; there being required the utmost certainty of the tellator's intentions to take away the right of the heir.

2. From the duty of maintenance we may easily pass to that of protection: which is also a natural duty, but rather permitted than enjoined by any municipal laws: nature, in this respect, working so strongly as to need rather a check than a spur. A parent may, by our laws, maintain and uphold his children in their law-suits, without being guilty of the legal crime of maintaining quarrels. A parent may also justify an assault and battery in defence of the persons of his children; nay, where a man's son was beaten by another boy, and the father went near a mile to find him, and there revenged his son's quarrel by beating the other boy, of which beating he afterwards unfortunately died; it was not held to be murder, but manslaughter merely. Such indulgence does the law show to the frailty of human nature, and the workings of parental affection.

3. The last duty of parents to their children is that of
of giving them an education suitable to their station in life: a duty pointed out by reason, and of far the greatest importance of any. For, as Puffendorf very well observs, it is not easy to imagine or allow, that a parent has conferred any considerable benefit upon his child by bringing him into the world; if he afterwards entirely neglects his culture and education, and suffers him to grow up like a mere beast, to lead a life useless to others and shameful to himself. Yet the municipal laws of most countries seem to be defective in this point, by not requiring the parent to bestow a proper education upon his children. Perhaps they thought it punishment enough to leave the parent who neglects the instruction of his family, to labour under those griefs and inconveniences which his family, so uninstructed, will be sure to bring upon him. Our laws, though their defects in this particular cannot be denied, have in one instance made a wise provision for breeding up the rising generation; since the poor and laborious part of the community, when past the age of nurture are taken out of the hands of their parents, by the statutes for apprenticing poor children; and are placed out by the public in such a manner as may render their abilities, in their several stations, of the greatest advantage to the commonwealth. The rich indeed are left at their own option, whether they will breed up their children to be ornaments or disgrace to their family. Yet in one case, that of religion, they are under peculiar restrictions: for it is provided, that if any person sends any child under his government beyond the seas, either to prevent its good education in England, or in order to enter into, or reside in, any Popish college, or to be instructed, perjured, or strengthened in the Popish religion; in such case, besides the disabilities incurred by the child to fore, the parent or person sending shall forfeit 100 l. which shall go to the sole use and benefit of him that shall discover the offence. And if any parent, or other, shall send or convey any person beyond seas, to enter into, or be resident in, or trained up in, any Popish university, college, or diocess, or house of Jesuits or priests, or in any private Popish family, in order to be instructed, perjured, or confirmed, in the Popish religion; shall contribute any thing towards their maintenance when abroad by any pretext whatever, the person both sending and sent shall be disabled to sue in law or equity, or to be executor or administrator to any person, or to enjoy any legacy or deed of gift, or to bear any office in the realm, and still forfeit all his goods and chattels, and levys all his real estate for life. See Nonconformists.

II. The power of parents over their children is derived from the former consideration, their duty; this authority being given them, partly to enable the parent more effectually to perform his duty, and partly as a recompence for his care and trouble in the faithful discharge of it. And upon this score the municipal laws of some nations have given a much larger authority to the parents than others. The ancient Roman laws gave the father a power of life and death over his children; upon this principle, that he who gave had also the power of taking away. But the rigour of these laws was softened by subsequent constitutions: so that we find a father banished by the emperor Hadrian for killing his son, though he had committed a very heinous crime; upon this maxim, that patriis pofcit in pauper delict, non in aetatis confertione, curare But still they maintained to the last a very large and absolute authority; for a son could not acquire any property of his own during the life of his father; but all his acquisitions belonged to the father, or at least the profits of them, for his life. The power of a parent by the English law is much more moderate; but still sufficient to keep the child in order and obedience. He may lawfully correct his child, being under age, in a reasonable manner; for this is for the benefit of his education. The consent or concurrence of the parent to the marriage of his child under age, was also directed by our ancient law to be obtained; but now it is absolutely necessary; for without it the contract is void. And this also is another means which the law has put into the parent's hands, in order the better to discharge his duty; first, of protecting his children from the maze of artful and designing persons; and next, of settling them properly in life, by preventing the ill consequences of too early and precipitate marriages. A father has no other power over his son's estate, than his trustee or guardian; for though he may receive the profits during the child's minority, yet he must account for them when he comes of age. He may indeed have the benefit of his children's labour while they live with him, and are maintained by him; but this is no more than he is intitled to from his apprentices or servants. The legal power of a father (for a mother, as such, is intitled to no power, but only to reverence and respect), the power of a father, we say, over the persons of his children ceases at the age of 21; for they are then enfranchised by arriving at years of discretion, or that point which the law has established (as some much necessarily be established) when the empire of the father, or other guardian, gives place to the empire of reason. Yet, till that age arrives, this empire of the father continues even after his death; for he may by his will appoint a guardian to his children. He may also delegate part of his parental authority, during his life, to the tutor or schoolmaster of his child; who is then in loco parentis, and has such a portion of the power of the parent committed to his charge, vis. that of restraint and correction, as may be necessary to answer the purposes for which he is employed. In the Gentleman's Magazine for 1750, we have the following case of conscience. A person has his own parents and his own children living, both parties equally indigent, both equally incapable of affisting themselves, and both equally earnest in calling upon him for relief. Things are so circumstanced that he can possibly affilt but one party, and not both. Query. Which party has the greatest claim to his affiance, and to which he is obliged, by all ties human and divine, to give the preference? One resolves this difficulty, by informing us of a pretty print done at Rome, representing a young woman fucking her aged father, on which the following lines are quoted.

My child and father vital nurture crave,
Parental, filial, fondness both would save;
I choose to fare the life I cannot give.
Here we find the preference given to the parent.
and another correspondent gives the same decision in these words. "The obligations arising from nature, and natural affection, seem to be in this case reciprocal and equipollent: the child is as strongly attracted to the parent, as the parent to the child. But will not filial gratitude operate and decide in favour of the parents? Does not the parent, either meditately or immediately, owe his present power and abilities to relief to his parents? and are not they on that account not entitled to relief? Does not the fifth commandment declare more strongly in favour of the parents, than any other divine precept does in favour of the children? If a parent had an opportunity given him of delivering either his parent or his child (but not both) from certain death, I dare say the voice of nature and of mankind would applaud him that saved his parent, and condemn him that should prefer his child. There is more of selfishness in preferring the child; and to save the parent seems to me to be much the more generous, noble, and exalted conduct. "This indeed, upon the whole, a melancholy alternative; but if both parties continue importunate, and neither will relinquish their claims in favour of the other, I say relieve the parent."

There are two correspondents, however, who think differently, and their reasons are as follow: "A person's children have the greatest claim to his affiance, and he is obliged by all ties to prefer them, in that respect, to his parents. It is true, when a man's parents are in want, they have a claim to his affiance; but that claim is not equal to that which his children have. His parents he has of necessity, his children, of choice. It is his duty, before he get children, to consider how he is to provide for them; and by being wilfully the cause of their existence, he comes under such an obligation to provide for their comfortable subsistence, as must be stronger than any obligation of that kind he can be under to persons with whom his connection is involuntary. Both nature and reason point it out as the duty of all parents to provide for their children; but not so much for their children, as for their parents. If a man's parents happen to be indigent, and he himself able, he is bound to maintain them out of respect and gratitude; but his obligation to provide for his children is a debt of strict justice; and therefore ought to be preferred. Nevertheless, the description of the cafe to which the query is subjoined, is so general, that it is easy to figure a cafe according to that description in which the person ought to prefer his parents. This obligation to provide for his children may have been dissolved by monstrous ingratitude, such as their plotting against his life; or he may have given them proper education, and ample provisions, which they have riotously squandered away: in either of which cases it is thought he is undoubtedly discharged from his obligation. But if they have left their portions purely by misfortunes, without their fault, it is thought his obligation to assist them is not wholly extinguished; and in that case there may be great reason to doubt whether their claim to his affiance, or that of his parents, is preferable: it is thought, however, the childrens is preferable."

I find (says the author of the last answer) that all your correspondents agree, that the life of the parent is to be preferred. It is very certain that the relation between me and my child is exactly equal to that which is between me and my parent; and therefore relation cannot decide in favour of the one or the other: I shall then be determined by a different consideration; and I know of none more weighty than the following. If I prefer the life of my child, I am instrumental in giving life to all his descendants, which may, perhaps, be very numerous; but if I prefer the life of my parent, I prefer a single life only, and that a shorter one. I therefore say, relieve the child. But it is thought that the voice of nature will applaud the person who prefers the parent; if so, nature must applaud a rule which she herself does not observe: it is natural for old men to die before young ones. Besides, the command, Be fruitful and multiply, and replenish the earth, may be opposed to the fifth commandment."

Still, however, it is doubtful difficult to determine in such cases when they occur, as there are no fixed rules whereby to decide. With respect to the power of parents and the duty of children, much may be said. There is, however, scarcely any instance where either are often abused than with respect to marriage. This, as it is the most important event in the civil life either of a man or woman, so it is often rendered peculiarly unfortunate, by precipitate folly and want of duty in children; and as often through the unreasonable severity of parents. As a child is bound not to give unreasonable offence to a parent in the choice of a partner; so neither ought the parent to impose any improper or arbitrary restraint upon the child.

The power of a parent in China is very great; for a father, while living, has the power of an absolute despotic tyrant, and after his death is worshipped as a god. Let a son become ever so rich, and a father Payne's ever so poor, there is no submission, no point of obedience, that the latter cannot command, or that the former can refuse. The father is absolute master, not only of his son's estate, but also of his concubines and children, whom, whenever they displeased him, he may fell to strangers. If a father accuses his son before a mandarin, there needs no proof of his guilt; for they cannot believe that any father can be so unnatural as to bring a false accusation against his own son. But should a son be so insolent as to mock his father, or arrive at such a pitch of wickedness as to strike him, all the province where this infamous act of violence is committed is alarmed; it even becomes the concern of the whole empire; the emperor himself judges the criminal. All the mandarins near the place are turned out of their posts, especially that of the town where he lived, for having been so negligent in their instructions; and all the neighbours are reprimanded for neglecting by former punishments, to put a stop to the wickedness of the criminal before it arrived to such flagitiousness. As to the unhappy wretch himself, they cut him into a thousand pieces, burn his bones, level his house to the ground, and even those honours that stand near it, and set up monuments and memorials of the horrid deed.

The emperor of China, who is one of the most powerful and despotic monarchs upon earth, pays the greatest attention to his mother. An instance of this, Pere Amyot relates as having happened at Pekin, A. D. 1752, when the emperor's mother entered her 60th year, which, among the Chinese, is accounted a very remarkable period. Grolier likewise particularly describes the homage the emperor pays his mother.
mother every new year's day in the palace, at which
ceremony all the great officers of his court affiled.

Parent (Unjoin'd), a mathematician, was born at
Paris in 1666. He showed an early propensity to
mathematics. He accustomed himself to write
remarks upon the margins of the books which he
read; and he had filled a variety of books with a kind
of commentary at the early age of thirteen. At four-
teen he was put under a master, who taught rhetoric
at Châtres. It was here that he happened to see a
doodleedon, upon every face of which was deliniated
a fun-dial, except the lowest, whereon it stood. Struck
as it were instantaneously with the curiosity of these
dials, he attempted drawing one himself: but having
a book which only showed the practical part without
the theory, it was not till after his rhetoric master came
to explain the doctrine of the sphere to him that he
began to understand how the projection of the circles
of the sphere formed fun-dials. He then undertook
to write a Treatise upon Gnomonics. The piece was
indeed rude and unpolished; but it was entirely his
own, and not borrowed. About the same time he
wrote a book of Geometry, in the same taste, at Beau-
vois. His friends then sent for him to Paris to study
the law; and, in obedience to them, he studied a
course in that faculty: which was no sooner finis-
hed than, urged by his passion for mathematics, he flung
himself up in the college of Dornans, that no advoca-
cation might take him from his beloved study; and,
with an allowance of less than 200 livres a year, he
lived content in this retreat, from which he never
forsook but to the Royal College, in order to hear the
lectures of M. de la Hire or M. de Sauvage. When
he found himself capable of teaching others, he took
pupils: and fortification being a branch of mathema-
tics which the war had brought into particular notice,
he turned his attention to it; but after some time be-
gan to entertain scruples about teaching.

The first three accounts which parents receive from their
children are the most important; for it is the greatest com-
forts of life, even when all dependence has ceased. It
matters not that there are many instances of extreme de-
pravity. Authors, however, have imagined, and Lord
Kames among the rest, that after the child is provided
with a taste, and no more depends on the parent, all
affection would cease, were it not artificially
prefered and confirmed by habit. Whether his lord-
ship, in this opinion, be right or wrong, we fail not
pretend to say. One thing, however, is certain, that, be it
natural or not, it is one of the greatest comforts of life, even when all
dependence has ceased. It matters not that there are many instances where
this comfort is not felt. Human depravity has often obli-
terated the finest feelings of the mind; and it is not to
be wondered at if in some instances it doth so in the cafe
before us. A good heart certainly can enjoy no
greater satisfaction than that arising from grateful
returns of kindness and affection to an aged parent.
As the vexations which parents receive from their children
haunt the approach of age, and double the force of
years; so the comforts which they reap from them
are balm to all other sorrows, and disquiet the injuries
of time. Parents repeat their lives in their off-
spring; and their concern for them is near, that
they feel all their sufferings, and take all their enjoy-
ments, as much as if they regarded their own persons.
However strong we may suppose the fondness of a
father for his children, yet they will find more lively
marks of tenderness in the bosom of a mother. There
are no ties in nature to compare with those which
unite an affectionate mother to her children, when they
repay her tenderness with obedience and love.

We have a remarkable instance of parental affection
in Zaleucus, prince of the Locrines; who made a de-
cree, that whoever was convicted of adultery should
be punished with the loss of both his eyes. Soon
after this establishment, the legislator's own son
was apprehended in the very fact, and brought to a public
trial. How could the father acquit himself in so
tender and delicate a conjuncture? Should he execute
the law in all its rigour, this would be worse than
death
death to the unhappy youth: should he offend so
notorious a delinquent, this would defeat the design of
his salutary institution. To avoid both these inconveniences,
hed one of his own eyes to be pulled out and one of his

down.

Diodorus Siculus also, lib. 34, gives us a surprizing
instance of the same warm affection. Cambalus, a
young gentleman of character and fortune in the city
of Munzatum, being one day out a courting, was
way-laid, and very near being robbed and murdered
by the banditti who infested that part of the country.
Gorgus, the young gentleman's father, happened to
come by at the very instant, to whom Cambalus
related the danger he was in. The ion was on foot,
the father on horseback; but no sooner had he heard
the melancholy tale, than he leapt from his horse,
desired his son to mount, and make the belt of his way
into the city: but Cambalus, preferring his father's
safety to his own, would by no means consent to it;
the contrary, conjured his father to leave him, and
take care of himself. The father, struck with the
generosity and affection of his son, added tears to
entreaties, but all to no purpose. The contest between
them is better conceived than described—while bathed
in tears, and beseeching each other to preserve his
own life, the banditti approached and stabbed them
both.

Amongst the ancient Greeks, the sentiments of
parental affection were exceedingly strong and ardent.
The mutual tenderness of the husband and the wife
was communicated to their offspring; while the father
viewed in his child the charms of its mother, and
the mother perceived in it the manly graces of its father.
As parental kindness is the most simple and natural
expansion of self-love, so there are innumerable instances
of it in all countries savage and civilized.

Parentalia, in antiquity, funeral obsequies,
or the laity paid by children to their deceased
parents.

PARENTHESES, in grammar, certain intercalary
words, inserted in a discourse, which interrupt the sense
or thread, but seem necessary for the better understand-
ing of the subject.

PARENZO, a small but strong town of Italy, and
in Ifiria, with a bishop's see and a good harbour;
seated on the gulf of Venice, in E. Long. 13. 46.
N. Lat. 39. 28. It submitted to the Venetians in
1267.

PARESIS, in medicine, a palsy of the bladder,
wherein the urine is either suppressed or discharged
involuntarily.

PARETONEUM, in natural history, the name of
an earth found on the shores of Egypt, Cyrene, and
the island of Crete, used by the ancients in painting.

It had its name either from a part of Egypt, near
which it was gathered, or from the name of a town
in that kingdom, where it was usually found. Vitruvius
is of the first opinion, and Vokaterinus of the other.
Of late it was thought to be loft; but it is still common
on the shores of most of the islands of the Archi-
pelago, though not observed or regarded; and is truly
a very heavy and tough clay of a fine white colour,
found in masses of different sizes, generally as soft as
the oyster clays within the Hritara; and, by rolling about
on the beach in this state, it gathers up the sand, small

shells, and other fouleinesses, we always find about it.
It is likely that there are strata of it fine and pure in
the cliffs there, and that the sea washes off masses of
them in forms and high tides, which are what we find.

PARGET, in natural history, a name given to se-
veral kinds of gyptom, or plater-stone.

PARGETING, in building, is used for the plaf-
tering of walls, and sometimes for platter itself.

Pargeting is of various kinds: as, 1. White-lime
and hair mortar laid on bare walls. 2. On bare laths, as
in partitioning and plain ceiling. 3. Rendering the
infides of walls, or doubling partition walls. 4. Rough-
cailing on heart laths. 5. Plastering on brick-work,
in imitation of stone-work; and the like upon heart laths.

PAREHELION, or PARHELION, formed from the
near, and blue fun, in natural philosophy, a mock-fun
or meteor, in form of a very bright light, appearing on
one side of the fun.

Appearances of this kind have been made mention
of both by the ancients and moderns. Aristotle ob-
erves, that in general they are seen only when the fun
is near the horizon, though he takes notice of two
that were seen in Bosphorus from morning to evening;
and Pliny has related the times when such phenomena
were observed at Rome. Gaffendi day's, that in 1637
and 1636 he often saw one mock-fun. Two were ob-
served by M. de la Hire in 1689; and the same
number by Cassini in 1693, Mr Grey in 1700, and Dr
Huiley in 1702: but the most celebrated appearances
of this kind were seen at Rome by Scheiner, by Mul-
chenbroeck at Utrecht, and by Hevelin at Sedin. By
the two former, four mock-funs were observed, and by
the latter seven.

Parhelia are apparently of the same size with the
fun, though not always of the same brightness, nor
even of the same shape; and when a number appear
at once, there is some difference in both these respects
among them. Externally they are tinged with col-
ours like the rainbow; and many have a long fiery
tail opposite to the fun, but paler towards the extremity.
Parhelia are generally accompanied with coronas, some
of which are tinged with rainbow colours, but others
are white. They differ in number and size; but all
agree in breadth, which is that of the apparent diame-
ter of the fun.

A very large white circle, parallel to the horizon,
generally passes through all the parhelia; and, if it
were entire, it would go through the centre of the
fun. Sometimes there are arcs of lefer circles con-
centric to this, touching those coloured circles which
surround the fun. They are also tinged with colours,
and contain other parhelia. There are also said to
have been other circles obliquely situated with respect
to all those we have mentioned; but of this we have
met with no authentic account. The order of the col-
ours in these circles is the same as in the rainbow;
but on the inside, with respect to the fun, they are red,
as is also observed in many other coronas.

Parhelia have been visible for 1, 2, 3, and 4 hours
743 together; and in North America they are said to
continue some days, and to be visible from funrie to
funrie.

When the parhelia disappear, it sometimes rains.

| Parental |
| Paretoneun. |
there falls snow in the form of oblong spicula, as Malard, Weidler, Kraft, and others, have observed; and because the air in North America abounds with such frozen spicula, which are even visible to the eye according to Ellis and Middleton, such particles have been thought to be the cause of all coronas and parhelia.

Mr Wales says, that, at Churchill in Hudson's Bay, the rising of the sun is always preceded by two long streams of red light, one on each side of him, and about 20° distant from him. These rise as the sun rises; and as they grow longer begin to bend towards each other, till they meet directly over the sun, just as he rises, forming there a kind of parhelion or mock sun. These two streams of light, he says, form to have their source in two other parheliona, which rise with the true sun; and in the winter-season, when the sun never rises above the haze or fog, which he says is constantly found near the horizon, all these accompany him the whole day, and set with him in the same manner as they rise. Once or twice he saw a fourth parhelion directly under the true sun; but this, he says, is not common. These facts being constant, are very valuable, and may throw great light on the theory of these remarkable phenomena.

Sometimes parheliona appear in a different manner, as when three suns have been seen in the same vertical circle, well defined, and touching one another. The true sun was in the middle, and the lowest touched the horizon; and they set one after the other. This appearance was seen by M. Maleciew in 1722. Other appearances similar to this are related by M. Mufchenbroeck.

Sometimes the sun rises or sets with a luminous tail projecting from him, of the same breadth with his diameter, and perpendicular to the horizon. Such an appearance was seen by Caffini in 1672 and 1692, by De la Hire in 1702, and by Mr Ellis in Hudson's Bay.

As M. Feuillee was walking on the banks of the river La Plata, he saw the sun rising over the river with a luminous tail projecting downwards, which continued till he was six degrees high.

Parhelions, or mock-moons, have also been seen, accompanied with tails and coloured circles, like those which accompany the parhelion. An account of several, and a particular description of a fine appearance of this kind, may be seen in Mufchenbroeck.

The Roman phenomenon, observed by Schiener, is famous on account of its having been the first appearance of the kind that engaged the attention of philosophers. It is represented in fig. 1; in which A is the place of the observer, B his zenith, C the true sun, AB a plane passing through the observer's eye, the true sun, and the zenith. About the sun C, there appeared two concentric rings, not complete, but diversified with colours. The outer of them, DEF, was fuller, and more perfect; and though it was open from D to F, yet those ends were perpetually endeavouring to unite; and sometimes they did so. The outer of these rings was much fainter, so as scarcely to be discernible. It had, however, a variety of colours; but was very inconspicuous. The inner circle, KLNM, was very large, and all over white, passing through the middle of the sun, and every where parallel to the horizon. At first this circle was entire; but towards the end of the appearance it was weak and ragged, so as hardly to be perceived from M towards N.

In the interfusion of this circle, and the outward iris GKI, there broke out two parhelion or mock-suns, but N and K, not quite perfect; K being rather weak, but N far brighter and stronger. The brightening of the middle of them was something like that of the sun; but towards the edges they were tinged with colours like those of the rainbow; and they were uneven and ragged. The parhelion N was a little waving, and sent out a spiked tail, NP, of a colour somewhat fiery, the length of which was continually changing.

The parhelions at L and M in the horizontal ring were not so bright as the former; but were rounder, and white, like the circle in which they were placed. The parhelion N disappeared before K; and while M grew fainter, K grew brighter, and vanished the last of all.

It is to be observed farther, that the order of the colours in the circles DEF, GKN, was the same as in the common halos, namely, red next the sun; and the diameter of the inner circle was also about 45 degrees; which is the usual size of a halo.

The reverend Dr Hamilton sends the following account of parhelion seen at Cooktown to the Royal Irish Academy.

"Wednesday September 24th, 1783, as I was preparing to observe the sun passing the meridian, before the first limb touched the centre wire, it was obscured by a dark well defined cloud, about 10° in diameter. Upon going to the door of the transit room, to see if it was likely soon to pass off the disk of the sun, I observed the following phenomena: From the western edge of the cloud issued a luminous arc parallel to the horizon, perfectly well defined, extending exactly to the northern meridian; it was about 30° broad, white, and ended in a blunted termination. On it were two parhelions; the nearest to the sun displaying the prismatic colours; the remote one white, and both ill defined. In a short time the cloud had passed off, and showed the luminous almucantar, reaching precisely to the true sun. While things were thus situated, I measured with an accurate sextant the distances of the parhelion; I found the coloured one 26°, the remoter one 90°, from the true sun. Just as I had done this, a new and prismatic circle surrounded the sun, immediately within the prismatic parhelion. And now another coloured parhelion appeared on the eastern broad. The sextant with its face up and down, exactly measured this; and the former at the original distance of 26°; the luminous almucantar still remaining perfect. In about 10 or 12 minutes whisking hazy clouds came on, and obscured all these uncommon appearances.—I did not observe that the atmospheric phenomena before or after were at all uncommon. The wind a light breeze at SSW. Bar. 29 6. Rising. Thermometer 55."

In Fig. 2, SM represents the fourth meridian; NM the north meridian; PP the prismatic circle, with two prismatic suns or parhelions, at 26° distance on each side of the true sun; W the white parhelion, at 90° distance from the true sun; LA the luminous almucantar; and HQ the horizon.
Various hypotheses have been framed by philosophers to account for this phenomenon, particularly by M. Mariotte, Descartes, and Huygens. None of them, however, are satisfactory; but those readers who wish to become acquainted with them may consult Huygen's Dissertation on this subject, in Smith's Optics, book i. ch. 17. Munchenbrock's Introduction, &c. vol. xi. p. 1038, &c. 4to., but especially Dr Priestley's History of Vision, Light, and Colours, vol. ii. p. 613, &c.

PARIAS, or New Andalusia, a country of Terra Firma in South America; bounded on the north by the north sea; on the east by Surinam; on the west by New Granada and the Caracas; and on the south by Guiana. It produces colouring drugs, gums, medicinal roots, Brazil-wood, sugar, tobacco, and some valuable timber; the inland parts being woody and mountainous, but interspersed with fine valleys that yield corn and palluage. Comana is the capital town.

PARIAN-CHRONICLE. See Arundelian-Marbles, and Pari-an-Chronicle.

Under the article Pari-an-Chronicle, we have been as full as the subject seemed to require, or as the nature of our work would admit. It is unnecessary, therefore, to reform it in this place. Such of our readers, however, as wish for further information on this subject (which is equally interesting to the scholar and to the antiquarian) we must refer to Robertson's attack upon their authenticity, and to Gough's learned and judicious vindication of their authenticity, published in Archaeologia for 1789. The extent of his learning, and the solidity of his arguments, appear upon the whole to outweigh the objections of his sensible and plausible opponent. Hewlett's book upon the same side of the question may command some degree of attention. It is ingenious. See Sandwich-Marble.

PARIAN-Marble, in the natural history of the ancients, the white marble used then, and to this day, for carving statues, &c. and called by us at this time flinty marble. Too many of the later writers have confounded all the white marbles under the name of the Parian; and among the workmen, this and all the other white marbles have the common name of alabaster; so that it is in general forgotten among them, that there is such a thing as alabaster different from marble; which, however, is truly the case. Almost all the world also have confounded the Carrara marble with this, though they are really very different; the Carrara kind being of a finer structure and clearer white than the Parian; but less bright and splendid, harder to cut, and not capable of so glittering a polish. The true Parian marble has usually somewhat of a faint bluish tinge among the white, and often has blue veins in different parts of it. It is supposéd by some to have had its name from the island Paros*, one of the Cyclades in the Ægean Sea, where it was first found; but others will have it to have been so called from Agoracritus Parius, a famous flintary, who emboled it by cutting a statue of Venus in it. PARIAS, or Perrea, a tribe of Hindoos, so peculiarly distinguished from all others, that they live by themselves in the outskirts of towns; and, in the country, build their houses apart from the villages, or rather have villages of their own, furnished with wells; for they dare not so much as fetch water from which other families made use of; and, lest these later should inadvertently go to one of theirs, they are obliged to scatter the bones of dead cattle about their wells, that they may be known. They dare not in cities pass through the streets where the Brahmins live; nor set foot in the villages where they dwell. They are likewise forbidden to enter a temple, either of their god Wifnow or Etwara; because they are held impure. They get their bread by psowing, digging, and building the walls of mud hovels: most of those inhabited by the common people being raised by these Parias; who also do such kinds of dirty work as other people do not care to meddle with. Nor is their diet much more cleanly; for they scimble not to eat cows, hores, fowl, or other carrion, which die of themselves, and even flink. One would scarce imagine, that contentions for precedence should ever enter into the thoughts of a people who have renounced all cleanliness, and, like flies, wallow in filth; and yet pride has divided the Parias into two classes: the first are simply called Parias, the other Seriperes. The employment of these later is to go about selling leather, which they dress: also to make bridles, and such kind of things: some of them likewise serve for soldiers. The Parias, who reckon themselves the better family, will not eat in the houses of the Seriperes; but the Seriperes will readily eat with the Parias. For this reason they are obliged to pay them respect, by lifting their hands aloft, and standing upright before them. The Seriperes, when they marry, cannot set up a pandal, a kind of garland, before their houses except the first to be at the expense of some clothes to give the Pariares, these latter must fulfill their beards to be shaven; and when the corpse is carried out of town to be burned or interred, they must do that office; for which each receives a fana, or one piece and a half of silver, worth three sous and a half. These are the same sort of people who are called at Surat Halaabaris; that is, in the Persia language, "cat-all," or eaters at large." Nothing can offend an Hindoo more than to be called an Halalchir; yet these poor people are not offended, cringe and bow to all they pass, and go through their drudgery without noise or concern.

The Parias are very vicious, stupid, and ignorant, occasioned by their wretched way of life: The Brahmins and nobility shun them as if they had the plague, and look on the meeting a Parias as the greatest misfortune. To come near one of them is a sin, to touch them a sacrilege. If a Parias were dying, it is infamy to visit him, or to give him the least attentian, in the utmost danger or distress. A Brahmin who unavoidably should touch a Parias, immediately washes himself from the impurity. Even their shadow and breath being reckoned contagious, they are obliged to live on the east side of their towns, that the westerly winds which reign in this country may keep back their breath. And it is lawful for a Brahmin to kill one
of these unhappy creatures, if he does not avoid it by getting out of his way: In short, they think them reprobated by God, and believe the fouls of the damned enter into the Parais, to be punished for their crimes. Yet the million have found among these dregs of the people very active zealous caitiffs, who by their labours have very much contributed to the conversion of their countrymen, particularly the Rajamanik a Parias soldier, who, of all the inferior millionaries, has distinguished himself most by his labours and sufferings.

**PARIETALIA** 0253, in anatomy. See there n° 13.

**PARIETARIA, Pellitory of the Wall:** A genus of the monoea order, belonging to the polygynia class of plants; and in the natural method ranking under the 53d order, Scbridize. The calyx of the hermafrodite is quadrifid; there is no corolla; there are four stamens; one style; and one seed, superior and elongated. The female calyx is quadrifid; there is no corolla; nor are there any stamens. There is one style; and one seed superior, and elongated. There are five species, of which one named the *Officinales* is used in medicine. This has a creeping root. The stalk grows erect, is rough to the touch, and adhesive. The leaves are alternate, elliptical, lanceolate, veined, and a little rough. The flowers grow out of the axil of the leaves, in sessile, branched, verticillate clusters, of a greenish colour tinged with red. The anthers have a great degree of flexibility; for, if irritated with the point of a pin, they fly from the calyx with elastic force, and throw out their powder. The plant has a cooling and diuretic quality. Three ounces of the juice taken internally, or a fomentation externally applied, have been found serviceable in the strangury. The plant laid upon heaps of corn infected with weevils, is said to drive away those deftructive insects.

**PARIETES,** in anatomy, a term used for the inclosures or membranes that stop up or close the hollow parts of the body; especially those of the heart, the thorax, &c. The parietes of the two ventricles of the heart are of unequal thickness and thickness; the left exceeding the right, because of its office, which is to force the blood through all parts of the body; whereas the right only drives it through the lungs.

**PARIS (Matthew),** one of our best historians from William the Conqueror to the latter end of the reign of Henry III. but of his life few particulars have been transmitted to us. Leland, his original biographer, without determining whether he was born in France or England, informs us, that he was a monk of St Alban's, and that he was sent by Pope Innocent to reform the monks of the convent at Holm in Norway. Bishop Bale, the next in point of time, adds to the above relation, that, on account of his extraordinary gifts of body and mind, he was much esteemed, particularly by King Henry III. who commanded him to write the history of his reign. Fuller makes him a native of Cambridgehire, because there was an ancient family of his name in that country. He also mentions his being sent by the pope to visit the monks in the diocese of Norwich. Bishop Tamer, Bishop Nicholoff, Doctor Du Fin, and the *Neuvain Dictionnaire Historique* add not a single fact to those above related. Matthew Paris died in the monastery of St Alban's in the year 1259. He was double a man of extraordinary knowledge for the 13th century; of an excellent moral character, and, as an historian, of strict integrity. His style is unpoliish'd; but that defect is sufficiently atoned for by the honest freedom with which he relates the truth, regardless of the dignity or falsity of the persons concerned. His works are, 1. *Histoire ad Absum ad Canonum Anglicum,* lib. ii. c. x. 2. Can- tab. c. ix. Most of this book is transcribed from Matthew of Wellminster, into the first part of his *Florilegium.* 2. *Histoire major, seu ratio Anglica­num historiae ad Gul. Congriarius adventu ad annum 43 Henrici III.* &c. several times printed. The first part of this history, viz. to the year 1235, is transcribed almost verbatim from the Chronicle of Roger Wend- ver; and the Appendix, from the year 1260, is the work of William Ralshinger, who was also a monk of St Alban's. 3. *Vita duorum Offorum, Morie regum, S. Albani fundatorum.* 4. *Geoff. 22. obs.­ tum S. Albanii. 5. Additamenta chronicon ad his­ toriam.* printed. 6. *Histoire minor, seu epitome magiae historiae; manuscript.* Besides many other things in manuscript.

**Paris, son of Priam, king of Troy, by Hecuba,** also named *Alexander.* He was decreed, even before his birth, to become the ruin of his country; and when his mother, in the first months of her pregnancy, had dreamed that she should bring forth a torch which would set fire to her palace, the footstrollers foretold the calamities which were to be expected from the imprudence of her future son, and which would end in the ruin of Troy. Priam, to prevent so great and so alarming an evil, ordered his slave Archelaus to destroy the child as soon as he was born. The slave either touched with humanity, or influenced by Hecuba, did not obey, but was satisfied to expel the child on mount Ida, where the shepherds of the place found him, and educated him as their own. Some attribute the preservation of his life, before he was found by the shepherds, to the motherly tenderne's of a she-bear who suckled him. Young Paris, though educated among shepherds and peasants, gave very early proofs of courage and intrepidity; and from his care in protecting the flocks of mount Ida from the rapacity of the wild beasts, he was named Alexander, "helper of men." He gained the esteem of all the shepherds, and his graceful countenance and manly deportment recommended him to the favours of *Eone*, a nymph of Ida, whom he married, and with whom he lived with the most perfect tenderne's. Their conjugal peace was, however, of no long duration. At the marriage of *Peleus and Thetis,* the goddess of discord, who had not been invited to partake of the entertainment, showed her displeasure, by throwing into the assembly of the gods who were at the celebration of the nuptials, a golden apple, on which were written the words *Ditur pulchriori.* All the goddesses claimed it as their own; the contention at first became general; but at last only three, Juno, Venus, and Minerva, wished to dispute their respective right to beauty. The gods, unwilling to become arbiters in an affair so tender and so delicate in its nature, appointed Paris to adjudge the prize of beauty to the fairest of the goddesses; and indeed the shepherd seemed sufficiently qualified.
PAR

qualified to decide so great a contest, as his wisdom was so well established, and his prudence and sagacity so well known. The gods appeared before their judge without any covering or ornament, and each endeavoured by promises and entreaties to gain the attention of Paris, and to influence his judgment. Juno promised him a kingdom; Minerva military glory; and Venus the fairest woman in the world for his wife, as Ovid expresseth it, *Herc. 17., v. 118.*

Uneque cum regna; beli dare altera laudam;
Tyndarids coniux, tertia dixit, eris.

After he had heard their several claims and promises, Paris adjudged the prize to Venus; and gave her the golden apple, to which perhaps she seemed entitled as the goddess of beauty. This decision of Paris drew upon the judge and his family the resentment of the two other goddesses. Soon after, Priam proposed a contest among his sons and other princes, and promised to reward the conqueror with one of the finest bulbs of mount Ida. His emblems were sent to procure the animal, and it was found in the possession of Paris, who reluctantly yielded it. The shepherd was anxious to regain his favourite, and he went to Troy and entered the lists of the combatants. He was received with the greatest applause, and obtained the victory over his rivals, Neithor the son of Nelenus, Cynus son of Neptune, Polites, Helenus, and Deiphobus, sons of Priam. He likewise obtained a superiority over Hector himself; which prince, enraged to see himself conquered by an unknown stranger, pursued him closely; and Paris must have fallen, a victim to his brother's rage, had he not fled to the altar of Jupiter. This sacred retreat preserved his life; and Callandra the daughter of Priam, struck with the similarity of the features of Paris with those of her brothers, inquired his birth and his age. From these circumstances she soon discovered that he was his brother, and as such she introduced him to her father and to her brothers. Priam acknowledged Paris as his son, forgetful of the alarming dreams which had caused him to meditate his death, and all jealousy ceased among the brothers. Paris did not long suffer himself to remain inactive; he equipped a fleet, as if willing to redeem Hecione his father's sister, whom Hercules had carried away and obliged to marry Telamon the son of ELECTUS. This was the pretended motive of his voyage, but the causes were far different. Paris remembered that he was to be the husband of the fairest of women; and, if he had been led to form those expectations while he was an obscure shepherd of Ida, he had now every plausible reason to form them real; even since he was the acknowledged son of the king of Troy. Helen was the fairest woman of the age, and Venus had promised her to him. On these grounds, therefore, he went to Sparta, the residence of Helen, who had married Menelaus. He was received with great respect; but he abused the hospitality of Menelaus, and while the husband was absent in Crotce, Paris persuaded Helen to elope with him and to fly to Asia. Helen consented; and Priam received her into his palace without difficulty, as his sister was then detained in a foreign country, and as he wished to show himself as hostile as possible to the Greeks. This affair was soon productive of serious confusions. When Menelaus had married Helen, all her suitors had bound themselves by a solemn oath to defend her person, and to defend her from every violence; and therefore the injured husband reminded them of their engagements, and called upon them to recover her. Upon this all Greece took up arms in the cause of Menelaus; Agamemnon was chosen general of all the combined forces, and a regular war was begun. Paris, meanwhile, who had refused Helen to the petitions and embassies of the Greeks, armed himself, with his brothers and subjects, to oppose the enemy; but the success of the war was neither hindered nor accelerated by his means. He fought with little courage, and at the very sight of Menelaus, whom he had so recently injured, all his resolution vanished, and he retired from the front of the army, where he walked before like a conqueror. In a combat with Menelaus, which he undertook by means of his brother Hector, Paris must have perished, had not Venus interceded, and stolen him from the resentment of his antagonist. He wounded, however, in another battle, Machaon, Euryphlus, and Diomedes; and, according to some opinions, he killed with one of his arrows the great Achilles.

The death of Paris is differently related; some say that he was mortally wounded by one of the arrows of Philoctetes, which had been once in the possession of Hercules; and that when he found himself languid on account of his wounds, he ordered himself to be carried to the feet of EÜONE, whom he had lately abandoned, and who in the years of his obscurity had foretold him that he would solace her affluence in his dying moments. He expired before he came into the presence of EÜONE; and the nymph, still mindful of their former loves, threw herself upon his body, and stabbed herself to the heart, after she had plentifully bathed it with her tears. According to others, Paris did not immediately go to Troy when he left the Peloponnesus, but he was driven on the coasts of Egypt, where Proteus, who was king of the country, detained him; and when he heard of the violence which had been offered to the king of Sparta, he kept Helen at his court, and permitted Paris to retire. Whatever was the mode of his death, it took place, as we are told, about 1188 B.C. See TROY, &c.

PARIS, the capital of the kingdom of France; is situated on the river Seine, in the ile of France; being one of the largest and finest cities in Europe. It derived its modern name from the ancient Paris; and is supposed by some to have had the Latin name of LATAVIA, from Latum "maid," the place where it now stands having been anciently very marshy and muddy. Ever since the reign of Hugh Capet, that is, for near 800 years, this city hath been the usual residence of the kings of France; it is of a circular form, and, including the suburbs, about five French leagues, or 15 English miles, in circumference. The number of its inhabitants is computed at about 500,000; that of its streets

(a) The latest, and perhaps the most accurate, accounts, have stated the number of inhabitants in Paris at considerably upwards of 800,000. It is supposed to be less than London, but the difference is not thought to be very great.
fruits 912; and that of its houses upwards of 20,000, exclusive of the public structures of all forts. Its
greatest defect according to some, is the want of good
drinking water; but others tell us that very fine wa-
ter is brought by an aqueduct from the village of
Arcueil, not far from Paris, but own that the water
of the Seine, and the city, is not good. The streets are
of a proper breadth, well built, paved, and lighted.
There is a great number of tribunals and officers here;
most of which are kept in the Palais, situated on an
island, to which it gives name. The number of churches,
convents, convents, market-places, fountains, gates,
and bridges, in this city is very great; besides the uni-
versity, several academies, public libraries, royal pa-
laces and cathedrals, and above 100 hotels, some of them
very fine. But to be more particular, that part called
la Cité, lies in the centre, and consists of three islands
formed by the Seine, L'Ile de Palais, L'Ile de la
Notre Dame, and L'Ile Louviers. It is the princi-
pal of the three parts into which the city is divided,
and contains the following remarkable structures:
1. Several bridges; of which some are of wood and
others of stone, and have most of them a row of houses
on each side. The chief of these are the Pont-neuf and
Pont royal: the first consists of 12 arches, which, pro-
perly speaking, make two bridges, the one leading
from the suburbs of St Germain to the city, and the
other from thence to that part called la Ville; there is
a carriage-way in the middle 30 feet broad, and foot-
wakes on each side, raised two feet high; and in the
centre stands a brais statue of Henry IV. on horse-
back. On this bridge is also the building called La
Samaritaine, from a group of figures upon it repre-
senting our Saviour and the Samaritan woman, stand-
ing near Jacob's well. Here is a pump to raise the
water, which through several pipes supplies the quar-
ter of the Louvre, and some other parts of the town.
The Pont royal, which leads to the Thilleries, was
built by order of Lewis XIV. in the room of a wooden
bridge that was carried away by the current in 1684.
2. The cathedral of Notre Dame, or our Lady, being
dedicated to the Holy Virgin, which is a large flately
Gothic structure, said to have been founded by king
Childeric, and built in the form of a cross. Here, be-
Sides other great perfomances, are interred the cardinals
de Retz and Noailles. From the two square towers
belonging to it, is a noble prospect of the city and
neighbouring country. Here is a vast quantity of gold
and silver plate, rich tapestry, and fine paintings; and
the number of the canons is not less than 50. Near
it stands the palace of the archbishop, in which is the
advocates library; the revenue of the archbishop amounts
to about 180,000 livres; and his taxation to the court
of Rome is 4283 guillemets. 3. The priory and parish-
church of St Bartholomew; the last of which is the most
beautiful in all this part of the city, and stands near the
Palais. 4. The Palais, which gives name to an
island, and in which the parliament, with a great
many other courts, are held. It was formerly the re-
idence of the kings; but was given to the officers of
justice by Philip the Fair, who also settled the parlia-
ment here in 1302. The parliament, consisting of fe-
veral chambers, each of which has its department, is
opened the day after Martinmas with a solemn mas,
celebrated by a bishop, and continues sitting till the
8th of September, when a vacation-chamber is appoint-
ed during the interval, for criminal causes, and others
which require dispatch. The jurisdiction of this court
is of great extent. There is a beautiful chapel belong-
ting to the Palais: in which is also the prison, or jail,
for the jurisdiction of the parliament, called in French
La Conciergerie. 5. The Hotel Dien, the most an-
cient and largest hospital in Paris, in which 8000 sick
and infirm poor are taken care of, and attended by the
nuns of the order of St Augustine. 6. The hospital
of St Catharine, where poor women and maidens are
entertained three days, and attended by the above-men-
tioned nuns. 6. The Grande Charite, where some of
the inferior courts of justice hold their seSions. 8. Fort
l'Evêque, in which is the mint and a prison. It stands
in or near the street la Ferroniere, in which Henry IV.
as robbed by Ravilliac. 9. St Germain l'Auxerrois,
which is called the royal palace churcJ; because the
palaces of the Louvre and Thilheries stand in its pa-
riah. 10. The Louvre, an ancient royal palace, of
which a part was rebuilt by Lewis XIV. Had it been
completed on the same plan, it would have been a most
magnificent structure. On one of its gates is the fol-
lowing inscription, Dum totum implet orbem: the mean-
ing of which is, "May it last till the owner of it hath
extended his sway over the whole world:" which im-
plies what the French kings have constantly aimed at.
Another inscription shows, at the same time, the va-
nity of the nation, and their abject flattery of their
grand monarque. It may be rendered in English
thus:

Louve is a palace for great Lewis fit:
God him alone exceeds, as heaven does it.

This palace is joined to the Thilleries by a gallery,
in which are 180 models of fortiresses, some situated in
France, and some in other countries, executed with
the utmost accuracy. Here is a valuable collection
of paintings, the king's printing-house, the mint where-
the king's medals are
pro.

God him alone exceeds, as heaven does it.
composed of four rows of lofty elms, to which vast crowds of people repair in the fine weather, as well as to the gardens. In the palace is a spacious and magnificent theatre; and hard by it are the Elyian fields, where a surprising number of coaches are to be seen in fair weather; not far off is the church of St. Roche, where the celebrated poet Corneille is interred. 13. La place de Louis le Grand, a very beautiful square, in the centre of which is an equestrian statue of that king, which is justly accounted a masterpiece. 14. The Place, or Square des Victoires, which is round, and contains a statue of Louis XIV. of gilt brass, erected by him to the duke de la Faliade, with this inscription, *viro immortali.* 15. The Royal Library in the Rue Vivien, which contains 94,000 printed books, 35,000 manuscripts, and a prodigious collection of copperplates and medals. Near by, in the churchyard of St. Joseph, lies the famous comic poet Moliere. 16. The parish church of St. Eustache, which stands in the quarter of the same name, and contains the tomb of the great minilier Colbert. 17. The gate of St. Dennis, which was erected as a triumphal arch in honour of Louis XIV. 18. The gate of St. Martin, erected also in form of a triumphal arch, in honour of the same king. Not far from hence, in the churchyard of St. Nicholas des Champs, Peter Galiendi, and other learned men, are buried. 19. La Grave, an open place, where all public rejoicings are celebrated, and malefactors executed. 20. The Hotel de Ville, which is a large building of Gothic architecture, though adorned with columns of the Corinthian order. 21. The arsenal in the quarter of St. Paul, consisting of many spacious buildings, among which are a foundery and a house for making saltpetre. Here is a magazine of two barrels, which it is said will pierce a thick board at the distance of six miles; and for discerning an object at that distance, has a telescope fixed to the barrel. 22. The Bastille, formerly a kind of fortress like the Tower of London, which was used as a prison for state criminals, and for such as were taken up by letters de cachet, i.e., by warrants signed by the king, and sealed. 23. La Temple, a commandery of the knights of Malta, which gives name to a quarter, wherein, being a privileged place, artificers that are not freemen may carry on their business without molestation. The temple is the residence of the grand prior of the French nation. 24. That formerly called La Maison profée des Hûtes, in the quarter of St. Anthony, in the church of which the hearts of Lewis XIII. and XIV. are preserved, each in a casket of gold, supported by two angels of mafly silver, and as big as ordinary men, hovering with expanded wings. In the same quarter is a fine looking-glass manufacture, where above 50,000 persons are employed in polishing plates cast at St. Gobain; with a convent of Franciscans, the monks of which are called *Pique-flâs,* or *Prick-flâs.*

In that part of the city called the *UnversiGy,* the principal places are,

1. The university, which gives name to it, and which was first founded, as it is said, by Charles the Great; all the arts and sciences are taught here, particularly law, physic, and divinity. There are above 40 colleges; of which the chief are those of Sorbonne, of Navarre, of the faculty of physic, and of the four nations; but lectures are read only in eleven of them. The head of the university is the rector, who is chosen every three months, but sometimes is continued several years. All the professors have settled salaries; the whole annual income of the university amounting, it is said, to about 50,000 livres. 2. The Gobelins, a house or palace, where a great number of ingenious artists, in various manufactures and handicrafts, are employed by the government. The most curious tapistry of all sorts is made here. 3. The General Hospital, a most noble foundation for the poor of the female sex, near 7000 objects being taken care of and provided for. The sick are carefully tended; and those that are in health are obliged to work; different wards being allotted for foundlings, for girls who owe or knit, prostitutes, idlers, and poor women: of the last, some are kept gratis, and others pay a small matter. In the cattle of Bicetre, belonging to this hospital, and consisting of many large buildings, are near 4000 persons of the other sex, among which are persons dired in their senses, and such as are afflicted with the venerable disease. To this hospital are also sent children who abuse their parents, and lead dissolute lives. The fund for the maintenance of it, and the hospital de la Pietie, where poor children are brought up, together with the Hotel Dieu, amounts to above two millions of livres per annum. 4. The King's Physic Garden, in which are an infinite variety of plants and trees, a certain sum being allotted by the king for keeping the garden in order, and improving it; and, for lectures on botany, anatomy, chemistry, and the materia medica. A curious collection of natural curiosities is kept here. 5. The abbey of St. Victor, in which is a public library, containing some very ancient and scarce books, several curious manuscripts, and a prodigious collection of maps and copperplates. 6. The College of Physicians, to which belong five professors. 7. The Littie Chatelain, an old fortress, now used for a prison. 8. The Rue St. Jacques, chiefly inhabited by booksellers. 9. The Royal College, and that of Lewis the Great: to the former belong twelve professors. 10. The Abbey of St. Genevieve, in which is the marble monument of king Clovis, the shrine of St. Genevieve, a large library, with a cabinet of antiquities and natural curiosities. 11. The Royal Observatory, a most splendid edifice, built on the highest part of the city. Several astronomers were maintained here by the king. 12. The Royal Academy of Surgery, instituted in 1731. 13. The Convent of Franciscans, in the quarter of St. Andrew, the richest in France. In the same quarter are some remains of the palace of Julian the Apostle, in which Childebert, and some other kings of the Franks, afterwards resided. 14. The Play-house. 53. The Convent of Carthusians, in the quarter of Luxembourg, containing fine paintings. 16. The palace of Luxembourg, or Orleans, a magnificent structure, containing also some fine paintings by Rubens, and embellished with a noble garden. In the Hotel des Ambassadeurs, ambassadors extraordinary are entertained for three days, and those of remote countries all the time they stay at Paris. 17. The Abbey of St. Germain des Prés, which contains a very valuable library, the manuscripts alone making 8000 volumes; here also is a cabinet of antiquities. 18. The Hotel royal des Invalides, erected by Lewis XIV. in which,

of

Herv PARI of Canada or of America, Trillium, in

botany, a genus of the hexandria trigynia clafs: The

characters are, that it has a three-leaved spreading em-

fale, and three oval petals; it has fix awl-shaped

flammas, terminated by oblong funnits, and a roundth

germen with three linger recurved tyles, crowned by

fidge fligmas; the germen afterwards becomes a roundth

berry, with three cells filled with roundth seeds.

There are three species.

PARISH, the preceed of a parochial church, or a

circuit of ground inhabited by people who belong to

one church, and are under the particular charge of its

minifter.

The word comes from the Latin parochea, the Greek

perieis habitation; compounded of παροιχή, near, and χαρίς

house.—Accordingly Du Cange observes, that the name

paroieh was ancienly given to the whole territory of

a bishop, and derives it from neighbourhood; because

the primitive Christians, not daring to assemble openly

in cities, were forced to meet secretly in neighbour-

houts.

In the ancient church there was one large edifice in

each city for the people to meet in; and this they

called parochea, “parifh.” But the signification of the

word was afterwards enlarged, and by a parifh was

meant a diocese, or the extent of the jurifdition of a

bishop, confifting of feveral churches; and as we will

suppofe, as fome do, that thole bifhops were only pa-

flors of fingle churches. Du Pin observes, that coun-

try parifhes had not their origin before the 4th cen-

tury; but thole of cities are more ancien. The city

of Alexandria is said to have been the firit that was

divided into parifhes.

How ancient the division of parifhes is, is not indeed

absolutely certain; for in the early ages of Christianity

in Britain, parifhes were unknown, or at leaft signified

the fame that a diocese now does. There was then no

appropriation of ecclefiafical dues to any particular

church; but every man was at liberty to contribute

his tithe to any prieft or church he pleafed, but he

was obliged to do it to fome; or if he made no spe-

cial appropriation thereof, they were paid to the bifhop

whole duty it was to distribute them among the clergy,

and for other pious purpofts, according to his

own difcretion. Cambden fays England was divided

into parifhes by archifhop Honorius about the year

650. Sir Henry Hobart maintains that parifhes were

firft erected by the council of Lateran, held A. D. 1779.

But Mr Selden proves, that the clergy lived in com-

mon without any division of parifhes, long after the

time mentioned by Cambden; and it appears from the

Saxon laws, that parifhes were in being long before

the council of Lateran in 1779. The diftinction of

parifhes occurs in the laws of king Edgar, about the

year 970. It feems pretty clear and certain, fays judge

Blackifone (Com. Vol I. p. 112.), that the bounda-

ries of parifhes were firft ascertained by thofe of a

manor or manors; becaufe it very feldom happens that a

manor extends itself over more than one parifh, though

there are often many manors in one parifh. The lords,

he adds, as Christianity spread, began to build church-

es upon their own demesnes or waftes, in order to

accommodate their tenants in one or two adjoining lord-

ships; and that they might have divine fervice re-

"
gularly performed therein, obliged all their tenants to appropriate their titles to the maintenance of the one officiating minister, instead of leaving them at liberty to distribute them among the clergy of the diocese in general; and this tract of land, the titles of which were so appropriated, formed a distinct parish; and this accounts for the frequent intermixture of parishes one with another. For if a lord had a parcel of land detached from the main of his estate, but not sufficient to form a parish of itself, it was natural for him to endow his newly-erected church with the titles of such lands. Extra-parochial walkes and marlful lands, when improved and drained, are by 17 Geo. II. cap. 37. to be affized to all parochial rates in the parish next adjoining. Camden reckons 9784 parishes in England; and Chamberlayne makes 9913. They are now generally reckoned about 10,000.

Parish-clerk. In every parish the parson, vicar, &c. hath a parish-clerk under him, who is the lowest officer of the church. These were formerly clerks in orders, and their business at first was to officiate at the altar; for which they had a competent maintenance by offerings; but they are now laymen, and have certain fees with the parson on chrismenings, marriages, burials, &c. besides wages for their maintenance. The law looks upon them as officers for law; and they are chosen by the minister of the parish, unless there is a curfew for the parishioners or church wardens to choose them; in which case the canon cannot abrogate such curfew; and when chosen it is to be signed, and they are to be sworn into their office by the archdeacon, for which the court of king's bench will grant a mandamus.

Parisi (anc. geog.), a people of Gallia Celtica, inhabiting the country about the Sequana and Marica. Now a great part of the Isle of France—

Parisi (Ptolemy), a people of Britain, having the Brigantes to the north and west, the German sea to the east, and the Coritani to the south, from whom they were separated by the Humber. Now Hol dernesse, a peninsula of the Earl Riding of Yorkshire.

Parisiorum civitas. See Lutetia.

Parium (anc. geog.), a noble city of Mycia Minor, with a port on the Propontis called Aethaia by Homer, according to Pliny; but Strabo distinguishes them: according to others, the Parias of Homer. Parium, the people (Strabo). The birth-place of Nectolemus, commonly called Glyphographus (Strabo). Here stood a Cupid equal in exquisite workmanship to the Cnidian Venus.

Park (French parcus, i.e. locus inclusus), is a large quantity of ground inclosed and privileged for wild beasts of chase, by the king's grant or prerogation. See CHASE and FOREST.

Manwood defines a chase to be "a privileged place, for beasts of venery, and other wild beasts of the forest and chase, tam sefawiferes quam campesfres" and differs from a chase or Warren, in that it must be inclosed: for if it lies open, it is good cause of jeaure into the king's hands, as a thing forfeited; as a free chase is, if it be enclosed: besides, the owner cannot have an action against such as hunt in his park, if it lies open. No man can erect a park without a licence under the broad seal; for the common law does not encourage matter of pleasure, which brings no profit to the commonwealth. But there may be a park in reputation erected without any lawful warrant; and the owner may bring his action against persons killing his deer.

To a park three things are required. 1. A grant thereof. 2. Inclosures by pale, wall, or hedge. 3. Barriers of a park, such as the buck, doe, &c. And where all the deer are destroyed, it shall no more be accounted a park; for a park consists of vert, venison, and inclosure; and if it is determined in any of them, it is a total dispersing.

Parks as well as chases are subject to the common law, and are not to be governed by the forlorn laws. Park, as connected with gardening. See Gardening.

A park and a garden are more nearly allied than a farm and a garden*, and can therefore be commensurate to each other without any disparagement to either. A farm looses some of its characteristic properties by the connection, and the advantage is on the part of the garden; but a park thus bordered retains all its own excellencies; they are only enriched, not counteracted, by the intermixture. The most perfect composition of a place that can be imagined, consists of a garden opening into a park, with a short walk through the latter to a farm, and ways along its glades to ridings in the country; but to the farm and the ridings the park is no more than a passage; and its woods and its buildings are but circumstances in their views; its scenes can be communicated only to the garden.

The affinity of the two subjects is so close, that it would be difficult to draw the exact line of separation between them. Gardens have lately encroached very much both in extent and in style on the character of a park; but still there are scenes in the one which are out of the reach of the other. The small sequestered spots which are agreeable in a garden would be trivial in a park; and the spacious lawns which are among the cultivated features of the latter, would in the former fatigue by their want of variety; even such as, being of a moderate extent, may be admitted into either, will seem bare and naked, if not broken in the one; and lose much of their greatness, if broken in the other. The proportion of a part to the whole is a measure of its dimensions; it often determines the proper size for an object, as well as the space fit to be allotted to a scene; and regulates the style which ought to be affixed to either.

But whatever distinctions the extent may occasion between a park and a garden, a state of highly cultivated nature is consistent with each of their characters; and may in both be of the same kind, though in different degrees.

The excellencies both of a park and of a garden are happily blended at Hagley (a), where the scenes are equally

(a) Near Stourbridge, in Worcestershire, the seat of Lord Lyttleton.
equally elegant and noble. It is situated in the midst of a fertile and lovely country, between the Clent and the Witchberry hills; neither of which are within the pale, but both belong to the place. The latter rise in three beautiful swells. One of them is covered with wood; ano her is an open sheep-walk, with an obelisk on the summit; on the third, the portico of the temple of Theseus, exactly on the model of that at Athens, and little less in the dimensions, stands boldly out upon the brow, backed by the dark ground of a fur plantation, and has a most majestic appearance above the steeples which fall before and beside it. The house is seen to the greatest advantage from these eminences, and every point of them commands some beautiful prospect. The busy town of Stourbridge is just below them; the ruins of Dudley castle rise in the off-skip; the country is full of industry and inhabitants; and a small portion of the moor, where the minerals, manufactured in the neighbourhood, are dug, breaking upon the horizon, accounts for the richness, without derogating from the beauty, of the landscape. From the Clent hills the view is still greater; they extend on one side to the black mountains in Wales, a long ridge which appears, at 60 miles distance, in the interval between the unwieldy heap of the Malvern hills and the solitary peak of the Wrekin, each 50 miles off, and as many aunder. The smoke of Worcester, the churches in Birmingham, and the houses in Stourbridge, are distinctly visible. The country is a mixture of hill and dale, and strongly inclosed; except in one part, where a heath, varied by rising ground, pieces of water, and several objects, forms an agreeable contrast to the cultivation which surrounds it. From the other extremity of the Clent hills, the prospect is less extensive; but the ground is more rude and broken; it is often overcast with large and beautiful woods; and the view is dignified with numerous feats. The hills also being very irregular, large advanced promontories frequently interrupt the sight, and vary the scene: in other parts, deep valleys shelving down towards the country below, exhibit the objects there in different lights. In one of these hollows is built a neat cottage; under a deep defcent, sheltered besides by plantations, and presenting ideas of retirement in the midst of so much open exposiure; from the heights above it, is seen all that view which before was commanded from the Witchberry hills, but which is seen here upon Hagley park; a noble fore-ground, beautiful in itself, and completing the landscape.

The house, though low in the park, is yet above the adjacent country, which it overlooks to a very distant horizon. It is surrounded by a lawn of fine uneven ground, and diversified with large clumps, little groups, and tingle trees. It is open in front, but covered on one side by the Witchberry hills, on the other side, and behind, by the eminences in the park, which are high and steep, and all overcast with a lofty hanging wood. The lawn preffing to the foot, or creeping up the slopes of those hills, and sometimes winding along glades into the depth of the wood, traces a beautiful outline to a fylvan scene, already rich to luxuriance in maimfines of foliage and flatlines of growth.

But though the wood appears to be entire, it in reality opens frequently into lawns, which occupy much of the space within it. In the number, the variety, and the beauty of these lawns, in the shades of the separations between them, in their beauties also, and their varieties, the glory of Hagley confists. No two of the openings are alike in dimensions, in shape, or in character. One is of no more than five or six acres; another of not less than thirty; and others are of all the intermediate sizes. Some stretch out into lengthened glades; some widen every way; they are again distinguished by buildings, by prospects, and often by the style only of the plantations around them. The boundary of one is described by a few careless lines; that of another is composed of many parts, very different, and very irregular: and the ground is never flat; but falls sometimes in steep declivities, sometimes in gentle declivities, waves along easy swells, or is thrown into broken inequalities, with endless variety.

An eden seat, sacred to the memory of Thomson, and erected on his favourite spot, stands on the brow of a steep; a mead winds along the valley beneath, till it is lost on either hand behind some trees. Opposite to the seat, a noble wood crowns the top, and feathers down to the bottom of a large oval swelling hill. As it depends upon one side, the distant country becomes the off-skip. Over the fall, on the other side, the Clent hills appear. A dull antique tower stands just below them, at the extremity of the wood; and in the midst of it is seen a Doric portico, called Pope's Building, with part of the lawn before it. The scene is very simple: the principal features are great; they prevail over all the rest, and are intimately connected with each other.

The next opening is small, circling about a rotunda on a knoll, to the foot of which the ground rises every way. The trees which surround it are large; but their foliage is not very thick; and their stems appearing beneath, their ramifications between the boughs are, in so confined a spot, very distinguished and agreeable circumstances. It is retired; has no prospect; no visible outlet but one, and that is short and narrow, to a bridge with a portico upon it, which terminates a piece of water.

The grove behind the rotunda separates this from a large, airy, forest glade, thinly skirted with wood, careless of drefs and much overgrown with fern. The wildness is an acceptable relief in the midst of so much elegance and improvement as reign in the neighbouring lawns; and the place is in itself pleasant; in no part confined; and from a Gothic seat at the end is a perspective view of that wood and tower which were seen before in front, together with the Witchberry hills, and a wide range of country.

The tower, which in prospect is always connected with wood, stands however, on a piece of down, which stretches along the broad ridge of a hill, and spreads on each hand for some way down the sides. Thick groves catch the fall. The defcent on the right is soon lost under the trees; but that on the left being fleeper and shorter, it may be followed to the bottom. A wood hangs on the declivity, which is continued in the valley beneath. The tower overlooks the whole; it seems the remains of a castle, partly entire, partly in ruins, and partly overgrown with bushes. A finer situation cannot be imagined: It is placed in an exposed unfrequented spot; commands an extensive prospect; and is everywhere an interesting object.
At the end of the valley below it, in an obscure corner, and flutt out from all view, is an hermitage, composed of roots and mosses; high banks, and a thick covert, thickened with hooe-chestnuts, confine the fequestered spot: a little rill trickles through it, and two small pieces of water occupy the bottom. They are seen on one side through groups of trees; the other is open, but covered with fern. This valley is the extremity of the park; and the Clent hills rise in all their irregularity immediately above it.

The other defcent from the castle is a long declivity, covered like the rest with noble woods, in which fine lawns are again embosomed, differing still from the former, and from each other. In one, the ground is very rough, the boundary is much broken, and marked only by the trunks of the trees which shoot up high before the branches begin. The next is more simple; and the ground falls from an even brow into one large hollow, which fans towards the glen, where it links into the covert. This has a communication through a short glade, and between two groves, with another called the Indian lawn, from the resemblance which it is said to bear to those of that celebrated island: it is accompanied with the flat-leaved trees, all fresh and vigorous, and so full of leaf, that not a branch, not a branch, appears, but large masses of foliage only describe an undulating outline; the effect, however, is not produced by the boughs feathering down to the bottom; they in appearance shoot out horizontally, a few feet above the ground, to a surprising distance, and form underneath an edging of shade, into which the retreat is immediate at every hour of the day. The verdure of the turf is as luxuriant there as in the open space: the ground gently waves in both, over easy swells and little dips, full varying, not breaking, the surface. No strong lines are drawn; no striking objects are admitted; but all is of an even temper, all mild, placid, and serene, in the gayest season of the day not more than cheerful, in the stilllest watch of night not gloomy. The scene indeed is peculiarly adapted to the tranquility of the latter, when the moon seems to repose her light on the thick foliage of the groves, and feally marks the eddy of every bough. It is delightful then to saunter here, and see the glades, and the gofferner which entwines it, glistering with dew, to listen and hear nothing but the occasional fall of a withered leaf dropping gently through a tree; and, sheltered from the chill, to catch the freshfumes of the evening air: a solitary urn, chosen by Mr Pope for the spot, and now inclosed to his memory, when shown by a gleam of moon-light through the trees, fixes the thought, and contributes to compose the mind is infinitely led by the rest of this elegant scene.

The D. of Portland, which also bears his name, the town within sight is near: it is placed on the declivity of a hill; and Thomas's seat, with its groves and appendages, are agreeable circumstances in the prospect before it. In the valley beneath is fixed a bench, which commands a variety of short views; one is up the ascent to the portico, and others through openings in the wood to the bridge and the rotunda.

The next lawn is large: the ground is steep and irregular, but inclines to one direction, and falls from every side into the general declivity: the outline is diversified by many groups of trees on the slopes: and frequent glimpses of the country are seen in perspective through openings between them. In the brown is a seat in the profused situation of all Hawkley; it commands a view down the bold sweep of the lawn, and over a valley filled with the noblest trees, up to the heights beyond. One of these heights is covered with a hanging wood; which opens only to show Thomson's seat, and the groves and the slopes about it; the others are the Witchberry hills, which seem to prefix forward into the landscape; and the mafy heads of the trees in the vale, uniting into a continued surface, form a broad base to the temple of Thebes, hide the swell on which it is built, and crowd up to the very foundation. Farther back stands the obelisk; before it is the sleepwalk; behind it the Witchberry wood. The temple is backed by the first; and both these plantations are connected with that vast sylvan scene which overpreads the other hill and all the intermediate valley. Such extent of wood; such variety in the disposition of it; objects so illustrious in themselves, so ennobled by their situations, each contrasted to each, every one distinct, and all happily united: the parts so beautiful of a whole so great, seen from a charming lawn, and surrounded by a delightful country, compose all together a scene of real magnificence and grandeur.

The several lawns are separated by the faste trees; which sometimes grow in airy groves, chequered with gleams of light, and open to every breeze; but more frequently, whose great branches meeting or crossing each other, cast a deep impenetrable shade. Large boughs feathering down often intercept the sight; or a vacant space is filled with coppice-wood, nut, hawthorn, and hornbeam, whose tufted heads mixing with the foliage and whose little stems cluttering about the trunks of the trees, thicken and darken the plantations. Here and there the division is of such coppice-wood only, which is being left constrained and oppressed, springs up stronger, spreads further, and joins in a low vaulted covering; in other places the shade is high, over-arched by the tallest ash, or spreads under the branches of the most venerable oaks. They rise in every shape, they are disposed in every form in which trees can grow. The ground beneath them is sometimes almost level; sometimes a gentle swell; but generally very irregular and broken. In several places, large hollows wind down the sides of the hills, worn in the stormy months by water-courts, but worn many ages ago. Very old oaks in the midst of the channels prove their antiquity; some of them are perfectly dry moss part of the year; and some are watered by little rills all the summer: they are deep and broad; the sides are commonly steep; often abrupt and hollow; and the trees on the bank sometimes extend their roots, all covered with moss, over the channels of the water. Low down in one of these glens, under a thick shade of horse-chestnuts, is a plain bench, in the midst of several little currents and water falls, running among large loose stones, and the stumps of dead trees, with which the ground is broken. On the brink of another glen, which is distinguished by a numerous rookery, is a seat in a still wilder situation, near a deeper hollow, and in a darker gloom: the falls are nearly perpendicular; the roots of some of the trees are almost bare, from the earth having crumbling away.
Gravel-walks are conducted across the glens, through the woods, the groves, or the thickets, and along the sides of the lawns, concealed generally from the sight, but always ready for the communication, and leading to the principal scenes. The frequency of these walks, the preservation in which all the place is kept, give to the whole park the air of a garden. There is, however, one spot more peculiarly adapted to that purpose, and more artificially disposed than the whole park the air of a garden. There is, however, a large bough of others, sinking with their own weight, seem ready to break from the trunks they belong to; and the finest ash, still growing, lie all along the water-course below, which though the streams run in winter only, yet constantly retains the black tinge of damp, and casts a chill all around.

In the year 1552 he was nominated, by Edward VI. to the deanery of Lincoln, which with his other preferments, enabled him to live in great affluence: but the papist Mary was hardly seated on the throne before he was deprived of every thing he held in the church, and obliged to live in obscurity, frequently changing his place of abode to avoid the fate of the other reformers.

Queen Elizabeth ascended the throne in 1558: and in the following year Dr. Parker from indigence and obscurity, was at once raised to the see of Canterbury (a); an honour which he neither solicited nor desired. In this high station he acted with spirit and propriety. He visited his cathedral and diocese in 1560, 1565, 1570, and 1573. He repaired and beautified his palace at Lambeth at a vast expense. The sum which the repairs of the palace and great hall at Canterbury cost him was upwards of 1400l. Herling, which is at least equal to ten times the sum now a days. Both the palace and great hall were in decay, partly through the injuries of time, and partly through that of fire. The hall, built by Archbishop Huber in the 12th century, was famous in history for the great feasts that had been made there by archbishops and abbots in former times; in particular, at the nuptial feasts of kings Edward L in 1290; at the installation of the abbot of St. Alban's in 1303; at the installation of George Nevill archbishop of York in 1464; and of Archbishop Warham in 1504, when Edward duke of Buckingham acted as lord high steward of his household; and, lastly, for the entertainment given by that archbishop in 1519 to the emperor Charles V. Henry VIII. Queen Catherine, &c. In 1565 Archbishop Parker gave three entertainments in this hall at Whitnundie which lasted three days, on Trinity Sunday, and in affixe time. At the two first of these the archbishop himself sat in the midst of the uppermost table; on his left hand the mayor, &c. and

(a) He was consecrated December 17th 1559, in Lambeth chapel, by Barlow bishop of Chichester, Scory bishop of Hereford, Coverdale bishop of Exeter, and Hodgkin suffragan bishop of Bedford. This deferves to be particularly mentioned, because the Romanists affurred afterwards that he had been consecrated at the Nag's head inn or tavern in Cheapside. But this notorious and improbable falsehood hath been fully confuted by Manton in his Vindication of the Church of England concerning the Consecration and Ordination of Bishops, 1613, folio; by Bramhall in his Confecration of Protestant Bishops vindicated; and by Courayer in his Defence of the Validity of English Ordinations, 1725, 3 vols. 8vo; and even by many Catholics.
PARKER. so on one side of the hall a continued row of men according to their rank filled the other tables; and on his right hand sat only some noble women and ladies of quality, the whole length of the hall, corresponding to the row of men on the other side: which order of placing the women was observed in honour of the queen. The first rank of guests being riven, and the tables cleared, they were furnished again, and filled the second time. At the last feast, which was grander than all the rest, the archbishop entertained the two judges who went that circuit (a), the attorney-general, the high sheriff, with all who met at these assizes, as justices of the peace, advocates and common lawyers, and all the rest of preachers and attorneys; who all (with a promiscuous company) in troops came in. The hall was set forth with much plate of silver and gold, adorned with much tapestry of Flanders; and dainties of all sorts were served in excellent order by none but the archbishop's servants, the table being as before the same day furnished afresh with new guests: while the ladies were nobly entertained in inner parlours by Mrs Parker, the hall being now filled only with gentlemen. Otherwife, at these feasts, it was the archbishop's custom, in honour of matrimony, to entertain both men and their wives. Of this noble hall and palace, now within 200 years, there is little or nothing left except a few ruins. On Whitunday 1572, and the two following days, this archbishop fealed the citizens of Canterbury and their wives in the same manner as he had done before: and on Trinity Sunday (after consecrating Bishop Curteis of Chichester) he made another most archiepiscopal feast, inviting another archbishop (viz. Grindal of York, who came thither for confirmation) to be his guest: besides whom were present Horn bishop of Winchelsea, and Curteis aforesaid of Chichester. At the lower tables sat all the ministers and servants whatsoever, even the children, who belonged to that church; and at the remotest tables, but in the same hall, in sight, sat the poor of both sexes of the hospitals of St John's and Harbledown. On July 11th, being afeizes time, the judges, high-sheriff, gentlemen, and the common fort, were all feated by the archbishop in splendid manner as before. Soon after Bishop Sandys of Worcester, elect of London, came to Canterbury to be confirmed. The archbishop, on his return, lodged the first night at Sittingbourne, and the next night (after dining at Gravesend) came to Lambeth in barges by Thames, with all his family. Sept. 7. 1573, being Q. Elizabeth's birth-day, Archbishop Parker entertained her majesty, and as many noblemen, &c. as were present at Archbishop Warham's entertainment in the same hall 54 years before. The archbishop (to use his own words, in a letter to Archbishop Grindal of York) "met her highness, as she was coming to Dover, upon Flookstone Down. I left her at Dover, and came home to Bekesborne that night; and after that went to Canterbury to receive her majesty there. Which I did, with the bishops of Lincoln and Rochester, and my suffragan [of Dover], at the west door; where, after the grammarian had made his oration to her upon her horse-bak, she alighted. We then meaded down, and said the psalm Deus susceptor in English, with certain other collects briefly; and that in our chimeres and rocheties. The quire, with the dean and prebendaries, stood on either side of the church, and brought her majesty up with a square fong; the going under a canopy, borne by four of her chamber-knights, to her tavertie, placed by the communion-board, where she heard evening fong; and after departed to her lodging at St Aultin's, where I waited upon her. From thence I brought certain of the council, and divers of the court, to my house to supper, and gave them 14 or 15 dishes, furnished with two mefs, at my long table, whereat sat about 20; and in the same chamber a third mefs, at a square table, whereas sat 10 or 12; my left hall having three long tables furnished with my officers, and with the guard, and others of the court: so her majesty came every Sunday to church to hear the sermon. And upon one Monday it pleased her highness to dine in my great hall, thoroughly furnished with the council, Frenchmen, ladies, gentlemen, and the mayor of the town, with his brethren, &c.; her highness sitting in the midst, having two French ambassadors [Gandius and Mather-Fenelon] at the end of the table, and four ladies of honour at the other end. And so three mefs were served by her nobility at washing, her gentlemen and guard bringing her dishes, &c." On which the Archbishop of York, in his answer, made this reflection: "Your grace's large description of the entertainment at Canterbury did so lively set forth the matter, that in reading thereof I almost thought myself to be one of your guests there, and as it were beholding the whole order of all things done there. Sir, I think it shall be hard for any of our coat to do the like for one hundred years, and how long after God knoweth." In this progress Lord Treasurer Burghley was lodged with Mr Pearson, the eleventh prebendary, who, the archbishop says, "had a fine house." He founded several scholarships in Bennet or Corpus Chrifti college in Cambridge, and gave large presents of plate to that and to other colleges in this university. He gave 100 volumes to the public library. He likewise founded a free-school at Rochdale in Lancashire. He took care to have the fees filled with pious and learned men; and, considering the great want of bibles in many places, he, with the assistance of other learned men, improved the English translation, had it printed on a large paper, and dispersed through the kingdom. This worthy prelate died in the year 1575, aged 72, and was buried in his own chapel at Lambeth. He was pious without affectation or austerity, cheerful and contented in the midst of adversity, moderate in the height of power, and beneficent beyond example. He wrote several books; and also published four of our best historians; Matthew of Welfingham, Matthew Paris, Affer's Life of King Alfred, and Tho. Welfingham. The learned archbishop also translated the Plaeter. This version was printed, but without a name; and has been attributed (b) This proves that the judges of assize then came to Canterbury, though it was then a county in itself, being so made in 1461.
PARKER, a learned author of the Psalms.

Parker (Samuel), an English clergyman, who, by a temporizing spirit, aided by excellent parts and considerable learning, raised himself to the bishopric of Oxford. He was born September 1640, at Northampton, where his father John then practiced the law. John had been bred to that profession, in one of the temples at London; and, being afterwards against the king, was made a member of the high court of justice in 1649, where he gave sentence against the three lords, Capel, Holland, and Hamilton, who were beheaded. During Cromwell’s usurpation, he was made an assistant committee man for his county. In 1650 he published a book in defence of the new government, as a commonwealth, without a king or house of lords. June 1655, when Cromwell was protector, he was appointed a commissioner for removing obstructions at Worcester-house in the Strand, near London, and was sworn fejant at law next day. January 1659, he was appointed one of the barons of the exchequer by the Rump-parliament; but, upon a complaint against him, was quickly displaced. However, he was again regularly made fejant at law, on the recommendation of Chancellor Hyde, at the first call after the restoration. In the mean time, he carefully educated his son Samuel among the Puritans in Northampton; whence, being fit for the university, he was sent to Wadham college in Oxford, and admitted, in 1659, under a presbyterian tutor. Here he led a strict and religious life, entered into a weekly society, then called the Grullers, because (as Wood observes) their chief diet was water-gruel; and it was observed that he put more graces in his portage than all the rest. They failed and prayed, and met at a house at Halywell, where he was so zealous and constant at prayers, sermons, and sacraments, that he was esteemed one of the most precious young men in the university. He took the degree of A. B. February 28, 1659-60. Upon the restoration, he hesitated what side to take; but continuing publicly to speak against Episcopacy, he was much discomfited by the new warden Dr Blandford, who had been appointed to that office upon the dawn of the restoration in 1659. Upon this he removed to Trinity college, where, by the advice of Dr Ralph Ruthwell, then a senior fellow of that society, he was rescued from the prejudices of an unhappy education, which in fact he publicly avowed in print. He then became a zealous Anti-puritan, and for many years acted the part of what was then called a true son of the church. In this temper, having taken the degree of M. A. in 1663, he entered into holy orders, reforted frequently to London, and became chaplain to a nobleman; continuing to display his wit upon his old friends the Presbyterians, Independents, &c.

In 1657, he published some Philosophical Essays, and was elected a member of the Royal Society: these Essays, he dedicated to Sheldon, archbishop of Canterbury, who became his patron; and in 1667 made him his chaplain. Being thus in the road to preferment, he left Oxford, and resided at Lambeth, under the eye of his patron; who, in 1670, made him archdeacon of Canterbury, in the room of Dr Sancroft, afterwards archbishop. November the same year, he put himself in the train of William Prince of Orange, who visited Cambridge, and had the degree of D. D. conferred upon him there. November 1672, he was installed a prebendary of Canterbury; and was made rector of Ickham and Chatham in Kent by the archbishop much about the same time. He was very obsequious to the court during the reign of Ch. II. and upon the accession of his brother to the throne, he continued the same servile complaisance; and he soon reaped the fruits of it in the bishopric of Oxford, to which he was appointed by James II. on the death of Dr Fell in 1686, being allowed to hold the archdeaconry of Canterbury in commendam. He was likewise made a privy-councilor, and constituted by a royal mandamus president of Magdalen-college in Oxford. These favours, however, were the price of his religion, which he scrupled not to offer up a sacrifice to his ambition. In this new change, he became one of the Romish mercenaries, prostituting his pen in defending transubstantiation, and the worship of images and the papists. The papists made sure of him as a profligate; one of whom says that he even proposed in council, whether it was not expedient, that at least one college in Oxford should be allowed Catholics, that they might not be forced to be at such charges, by going abroad to study. In the same way, having invited two Popish noblemen, and one of the church of England, to an entertainment, he drank the king’s health, wishing a happy success to all his affairs; adding, that the Protestant religion in England seemed to him to be in no better a condition than that of Buda was before it was taken, and that they were next to Atheists who dared to defend that faith. Nay, so shameful was his conduct, that the cooler among the Romanists condemned it as too hot and precipitate. For example, Father Peter, a Jesuit, and privy-councilor to King James, in a letter to Father la Chaife, confessor to Louis XIV., writes thus: “The bishop of Oxford has not yet declared himself openly; the greatest obstacle is his wife, whom he cannot leave himself of; his design being to continue a bishop, and only change communion, as it is not doubted but the king will permit, and our holy father conform; though I don’t see how he can be farther useful to us in the religion he is in; because he is suspected, and of no esteem among the heretics of the English church; nor do I see that the example of his conversion is like to draw many others after him, because he declared himself so suddenly. If he had believed my counsel, which was to temporize for some time longer, he would have done better; but it is his temper, or rather zeal, that hurried him on to it.” Accordingly his authority in his diocese was so very insignificant, that when he assembled his clergy, and defined them to subside an “Address of Thanks to the King for his Declaration of Liberty of Conscience,” they rejected it unanimously, that he got but one clergyman to concur with him in it. Bishop Baret represents him to be a man of no judgment, and of as little virtue; and as to religion rather impious: that he was covetous and ambitious, and seemed to have no other taste of religion but as a political interest, and a sub.
PAR

Parker

Definition.

PARLIAMENT, the grand assembly of the three kingdoms of England, Scotland, and Ireland, summoned together by the authority of the king, to consider of matters relating to the public welfare, and particularly to enact and repeal laws.

The original or first institution of parliament is one of those matters which lie so far hidden in the dark ages of antiquity, that the tracing of it out is a thing equally difficult and uncertain. The word parliament itself (or collogium, as some of our historians translate it) is, comparatively, of modern date; derived from the French, and signifying "the place where they met and conferred together." It was first applied to general assemblies of the states under Louis VII. in France, about the middle of the 12th century. But it is certain, that, long before the introduction of the Norman language into England, all matters of importance were debated and settled in the great councils of the realm. A practice which seems to have been universal among the northern nations, particularly the Germans; and carried by them into all the countries of Europe, which they overrun at the dissolution of the Roman empire. Relics of which constitution, under various modifications and changes, are still to be met with in the aids of Poland, Germany, and Sweden, and lately in the assembly of the estates in France; for what was there called the parlement, was only the supreme court of justice, consisting of the peers, certain dignified ecclesiastics, and judges; which neither is in practice, nor is supposed to be in theory, a general council of the realm.

In England, however, this general council hath been Antiquity, held immemorially, under the several names of miel-chel- genots, or "great council;" meli-geneots, or "great meeting;" and more frequently wittsing-geneots, or "the meeting of wise men." It was also styled in Latin, commune concilium regni magni comitatus regis, curia magna, concensus magistrorum et procedens legis generalis, and sometimes consilium regis Angliae. We have instances of its meeting to order the affairs of the kingdom, to make new laws, and to amend the old, or, as Pleta expresseth it, novis injustis, etc., nova nova conferendo remedia, so early as the reign of J. a king of the West Saxons, Offa king of the Mercians, and Ethelbert king of Kent, in the several realms of the heptarchy. And after their union, the Mirror informs us, that King Alfred ordained for a perpetual usage, that these councils should meet twice in the year, or oftener, if need be, to treat of the government of God's people; how they should keep themselves from sin, should live in quiet, and should receive right. Our succeeding Saxons and Danes monarchs held frequent councils of this sort, as appears from their respective codes of laws; the titles whereof usually speak them to be enacted, either by the king with the advice of his wittsing-geneots, or wise men, as, Hac sent inflictet, qua Edgardus rex confilto sapientium forum inflictet; or to be enacted by those fages with the advice of the king as, Hac sent judici, etc., Eadwardus rex Ebalbini instructur; or, lastly, to be enacted by them both together as, Hac sent inflicted, qua rex Edmundus et episcopi sui, cum sapientibus suis inflicturerunt.

There is also no doubt but these great councils were, occasionally held under the first princes of the Norman line. Glanvill, who wrote in the reign of Henry II. speaking of the particular amount of an amercement in the sheriff's court, says, it had never yet been accomplished by the general affize or assembly, but was left to the curfew of particular counties. Here the general affize is spoken of as a meeting well known, and its statutes or decisions are put in a manifest contradiction to curfew, or the common law. And in Edward III.'s time, an act of parliament, made in the reign of William the Conqueror, was pleaded in the court of the abbey of St Edmund'sbury, and judicially allowed by the court.

Hence it indisputably appears, that parliaments, or general councils, are coeval with the kingdom itself. How those parliaments were constituted and composed,
The nature of the early parliaments not fully known.

4. The nature of the controversy of this sort, it may be only for Parliament to decide these matters, as other matters of the same sort, particularly, whether the commons were summoned at all; or, if summoned, at what period they began to form a definite assembly. But without entering into these controversies of this sort, it may be sufficient to observe, that it is generally agreed, that in the main the constitution of parliament, as it now stands, was marked out so long ago as the 17th year of King John, A.D. 1215, in the great charter granted by that prince; wherein he promises to summon all archbishops, bishops, abbots, earls, and greater barons, personally; and all other tenants in chief under the crown, by the sheriff and bailiffs; to meet at a certain place, with 40 days notice, to do all aids and services when necessary. And this constitution has subsisted in fact at least from the year 1266, 49 Henry III., there being still extant writs of that date, to summon knights, citizens, and burgesses, to parliament. We proceed therefore to inquire wherein consists this constitution of parliament, as it now stands, and has stood, for the space of at least 500 years. And in the prosecution of this inquiry, we shall consider, first, the manner and time of its assembling. Secondly, Its constituent parts. Thirdly, The Laws and usages relating to parliament. Fourthly, The methods of proceeding, and of making statutes, in both houses. And, lastly, The manner of the parliament's adjournment, prorogation, and dissolution.

8. Parliament summoned only by the king.

I. **At to the manner and time of assembling.** The parliament is regularly to be summoned by the king's writ or letter, issued out of chancery by advice of the privy council, at least 40 days before it begins to sit. It is a branch of the royal prerogative, that no parliament can be convened by its own authority, or by the authority of any, except the king alone. And this prerogative is founded upon very good reason. For, supposing it had a right to meet spontaneously, without being called together, it is impossible to conceive that all the members, and each of the houses, would agree unanimously upon the proper time and place of meeting: and if half of the members met, and half abstained themselves, who shall determine which is really the legislative body, the part assembled, or that which stays away? It is therefore necessary, that the parliament should be called together at a determinate time and place; and, highly becoming its dignity and independence, that it should be called together by none but one of its own constituent parts; and, of the three constituent parts, this office can only appertain to the king; as he is a single person, whose will may be uniform and steady; the first person in the nation, being superior to both houses in dignity; and the only branch of the legislature that has a separate existence, and is capable of performing any act at a time when no parliament is in being. Nor is it an exception to this rule, that, by some modern statutes, on the demise of a king or queen, if there be then no parliament in being, the last parliament revives, and is to sit again for six months, unless dissolved by the successor: for this revived parliament must have been originally summoned by the crown.

It is true, that the convention-parliament which restored King Charles II. met above a month before his return; the lords by their own authority, and the commons in pursuance of writs issued in the name of the keepers of the liberty of England by authority of parliament; and that the said parliament sat till the 29th of December, full seven months after the restoration; and enacted many laws, several of which are still in force. But this was for the necessity of the thing, which supercedes all law; for if they had not done it, it was morally impossible that the kingdom should have been settled in peace. And the first thing done after the king's return was, to pass a act declaring this to be a good parliament, notwithstanding the defects of the king's writ. So that as the royal prerogative was chiefly wounded by its omission, and as the king himself, who alone had a right to object, was unable to wave the objection, this cannot be drawn into an example in prejudice of the rights of the crown. Besides, we should also remember, that it was at that time a great doubt among the lawyers, whether even this healing act made it a good parliament, and held by very many in the negative; though it seems to have been too nice a simple: And yet, out of abundant caution, it was thought necessary to confirm its acts in the next parliament, by statute 13 Car. II. c. 7. and c. 14.

It is likewise true, at the time of the Revolution, A.D. 1688, the lords and commons by their own authority, and upon the summons of the prince of Orange (afterwards King William) met in a convention, and therein disposed of the crown and kingdom. But it must be remembered, that this assembling was upon a like principle of necessity as at the Restoration; that is, upon a full conviction that King James II. had abdicated the government, and that the throne was thereby vacant: which supposition was confirmed by their concurrent revolution, when they actually came together. And, in such a case as the palpable vacancy of a throne, it follows, ex necessitate rei, that the form of the royal writs must be laid aside, otherwise no parliament can ever meet again. For let us put another possible case, and suppose, for the sake of argument, that the whole royal line should at any time fall, and become extinct, which would indispensably vacate the throne: in this situation it seems reasonable to presume, that the duty of the nation, confiding of lords and commons, would have a right to meet and settle the government; otherwise there must be no government at all. And upon this and no other principle did the convention in 1688 assemble. The vacancy of the throne was precedent to their meeting without any royal summons, not a consequence of it. They did not assemble without writ, and then make the throne vacant; but, the throne being previously vacant by the king's abdication, they assembled without writ, as they must do if they assembled at all. Had the throne been full, their meeting would not have been regular; but, as it was really empty, such meeting became absolutely necessary. And accordingly it is declared by statute 1 W. & M. st. 1. c. 1. that this convention was really the two houses of parliament, notwithstanding the want of writs or other defects of form. So that, notwithstanding these two capital exceptions, which were justifiable only on a principle of necessity (and each of which,
Parliament, which, by the way, induced a revolution in the government), the rule laid down is in general certain, that the king, only can convok a parliament.

And this, by the ancient statutes of the realm, he is bound to do every year, or oftener if need be. Not that he is, or ever was, obliged by those statutes, to call a new parliament every year; but only to permit a parliament to fit annually for the redress of grievances, and dispatch of business, if need be. These last words are so loose and vague, that such of the monarchs as were inclined to govern without parliaments, neglected the convoking them, sometimes for a very considerable period, under pretence that there was no need of them. But, to remedy this, by the statute 16 Car. II. c. 1, it is enacted, that the sitting and holding of parliaments shall not be intermitted above three years at the most. And by the statute 1 W. & M. ft. 2. c. 2. it is declared to be one of the rights of the people, that for redress of all grievances, and for the amending, strengthening, and preserving, the laws, parliaments ought to be held frequently. And this indefinite frequency is again reduced to a certainty by statute 6 W. and M. c. 2. which enacts, as the statute of Charles II. has done before, that a new parliament shall be called within three years after the determination of the former.

11. The constituent parts of a parliament are, the king's majesty, siting there in his royal political capacity, and the three estates of the realm; the lords spiritual, the lords temporal (who sit together with the king in one house), and the commons who sit by themselves in another. And the king and these three estates together form the great corporation or body politic of the kingdom, of which the king is said to be caput, principium, et finis. For upon their coming together the king meets them, either in person or by representation; without which there can be no beginning of a parliament; and he also has alone the power of dissolving them.

It is highly necessary for preserving the balance of the constitution, that the executive power should be a branch, though not the whole, of the legislature. The total union of them, we have seen, would be productive of tyranny; the total disjunction of them, for the present, would in the end produce the same effects, by causing that union against which it seems to provide. The legislature would soon become tyrannical, by making continual encroachments, and gradually assuming to itself the rights of the executive power. Thus the long parliament of Charles I. while it acted in a constitutional manner, with the royal concurrence, redressed many heavy grievances and established many statute laws. But when the two houses assumed the power of legislation, in exclusion of the royal authority, they soon after assumed likewise the reins of administration; and, in consequence of these united powers, overturned both church and state, and established a worse oppression than any they pretended to remedy. To hinder therefore any such encroachments, the king is himself a part of the parliament; and as this is the reason of his being so, very properly therefore the share of legislation which the constitution has placed in the crown, confits in the power of rejecting, rather than revolting; this being sufficient to answer the end proposed. For we may apply to the royal negative, in this instance, what Cicero observes of the negative of the Roman tribunes, that the crown has not any power of doing wrong, but merely of preventing wrong from being done. The crown cannot begin of itself any alterations in the present established law; but it may approve or disapprove of the alterations suggested and consented to by the two houses. The legislature therefore cannot abridge the executive power of any rights which it now has by law, without its own consent; since the law must perpetually stand as it now does, unless all the powers will agree to alter it. And herein indeed conffts the true excellence of the Britifh government, that all the parts of it form a mutual check upon each other. In the legislature, the people are a check upon the nobility, and the nobility a check upon the people, by the mutual privilege of rejecting what the other has resolved; while the king is a check upon both, which precedes the executive power from encroachments. And this very executive power is again checked and kept within its true bounds by the two houses, through the privilege they have of interfering into, impeaching, and punishing the conduct (not indeed of the king, which would destroy his constitutional independence; but which is more beneficial to the public) of his evil and pernicious counsellors. Thus every branch of the civil polity supports and is supported, regulates and is regulated, by the rest; for the two houses naturally drawing in two directions of opposite interest, and the prerogative in another still different from them both, they mutually keep each other from exceeding their proper limits; while the whole is prevented from separation, and artificially connected together by the mixed nature of the crown, which is a part of the legislative, and the sole executive magistrate. Like three distinct powers in mechanics, they jointly impel the machine of government in a direction different from what either, acting by itself, would have done; but at the same time in a direction partaking of each, and formed out of all a direction which constitutes the true line of the liberty and happiness of the community.

Having already considered these constituent parts of the sovereign power of parliament, each in a separate view, under the articles King, Lords, and Commons, to which the reader is referred, we proceed.

111. To examine the laws and customs relating to the power of parliament, united together and considered as one aggregate body. The power and jurisdiction of parliament, says Sir Edward Coke, is so transcendent and absolute that it cannot be confined either for causes or persons within any bounds. And of this high court he adds, it may be truly said, Sistantiam jure, ejus temporum, et finis; si dignitatem, ejus honoram, ejus jurisdictiam, ejus capaciorem. It hath sovereign and uncontrollable authority in making, confirming, enlarging, restraining, abrogating, repealing, reviving, and expounding of laws, concerning matters of all possible denominations, ecclesiastical or temporal, civil, military, maritime, or criminal. This being the place where that absolute despotic power, which must in all governments reside somewhere, is entrusted by the constitution of those kingdoms. All mischief and grievances, operations and remedies, that transcend the ordinary course of the laws, are within the reach of this,
Parliament this extraordinary tribunal. It can regulate or new-model the succession to the crown; as was done in the reign of Henry VIII. and William III. It can alter the established religion of the land; as was done in a variety of instances in the reigns of Henry VII. and his three children. It can change and create afresh even the constitution of the kingdom and of parliaments themselves; as was done by the act of union, and the several statutes for triennial and septennial elections. It can, in short, do everything that is not naturally impossible; and therefore some have not scrupled to call its power, by a figure rather too bold, the omnipotence of parliament. True it is, that what the parliament doth, no authority upon earth can undo. So that it is a matter most essential to the rights of the kingdom, that such members be delegated to this important trust as are most eminent for their probity, their fortitude, and their knowledge; for it was a known apothegm of the great lord treasurer Burleigh, "That England could never be ruined but by a parliament;" and as Sir Matthew Hale observes, this being the highest and greatest court, over which none other can have jurisdiction in the kingdom, by any means a misgovernment should any way fall upon it, the subjects of that kingdom are left without all manner of remedy. To the fame purpose the president Montesquieu, though we trust too hastily, prefaces, that as Rome, Sparta, and Carthage, have lost their liberty and perished, so the constitution of England will in time lose its liberty, will perish; it will perish whenever the legislative power shall become more corrupt than the executive.

Mr. Locke's opinion respecting this power, must be owned, that Mr. Locke, and other theological writers, have held, that "there remains still inherent in the people a supreme power to remove or alter the legislature, when they find the legislature act contrary to the trust repose in them; for when such trust is abused, it is thereby forfeited, and devolves to those who gave it." But however just this conclusion may be in theory, we cannot adopt it, nor argue from it, under any dispensation of government at present actually existing. For this devotion of power, to the people at large, includes in it a dilution of the whole form of government established by that people; reduces all the members to their original state of equality; and by annihilating the sovereign power, repeals all positive laws whatsoever before enacted. No human laws will therefore suppo a state, which at once must destroy all law, and compel men to build afreight upon a new foundation; nor will they make provision for to deplore an event, as must render all legal provisions ineffectual. So long therefore as the English condition last, we may venture to affirm, that the power of parliament is absolute and without control.

In order to prevent the mischiefs that might arise, by placing this extensive authority in hands that are either incapable or else improper to manage it, it is provided by the custom and law of parliament, that no one shall fit or vote in either house, unless he be 21 years of age. This is also expressly declared by statute 7 and 8 W. III. c. 25; with regard to the house of commons, doubts have arisen, from some contradictory adjudications, whether or not a minor was incapacitated from sitting in that house. It is also enacted by statute 7 Jac. I. c. 6, that no member be permitted to enter the house of commons till he hath taken the oath of allegiance before the lord steward or his deputy: and by 30 Car. II. r. 2, and 1 Geo. I. c. 13, that no member shall vote or sit in either house, till he hath, in the presence of the house taken the oaths of allegiance, supremacy and abjuration, and subscribed and repeated the declaration against transmutation, and invocation of saints, and the sacrifice of the mass. Aliens, left naturalized by the law of parliament incapable to serve therein; and now it is enacted, by statute 12 & 13 W. III. c. 2, that no alien, even though he be naturalized, shall be capable of being a member of either house of parliament. And there are not only these flandling incapacities; but if any person is made a peer by the king, or elected to serve in the house of commons by the people, yet may the respective houses, upon complaint of any crime in such person, and proof thereof, adjudge him disabled and incapable to sit as a member: and this by the law and custom of parliament.

For as every court of justice hath laws and customs. The court for its direction, name the civil and canon, some the tene customary laws; others their own peculiar laws and customs; to the high court of parliament hath also its own peculiar law, called the act et conjuncto parliamentis; a law which Sir Edward Coke observes is ab exprimenda omnius quaedam. A nullus in re nata, a pauci cognitas, and expressed. This maxim, "That whatever matter arises concerning either house of parliament, ought to be examined, discussed, and adjudged in that house to which it relates, and not elsewhere." Hence, for instance, the lords will not suffer the commons to interfere in settling the election of a peer of Scotland; the commons will not allow the lords to judge of the election of a burgess; nor will either house permit the subordinate courts of law to examine the merits of either case. But the maxims upon which they proceed, together with the method of proceeding, red entirely in the breast of the parliament itself; and are not defined and ascertained by any particular stated laws.

The privileges of parliament are likewise very large, extensive and indefinite; and therefore when, in 43d Hen. VI. privileges, the house of lords propounded a question to the judges concerning them, the chief justice, Sir John Fortescue, in the name of his brethren, declared, "That they ought not to make answer to that question; for it hath not been used aforesaid, that the judges should in anywise determine the privileges of the high court or parliament; for it is so high and mighty in its nature, that it may make law; and that which is law, it may make no law; and the determination and knowledge of that privilege belongs to the lords of parliament, and not to the judges." Privilege of parliament was principally established, in order to protect its members not only from being molested by their fellow-subjects, but also more especially from being oppressed.
Parliaments fought by the power of the crown. If therefore all
to the privilege of parliament were once to be set down
and abandoned, and no privilege to be allowed but
what was so defined and determined, it were easy for
the executive power to devise from new cases, not with-
in the line of privilege, and under pretence thereof to
harass any refractory member, and violate the free-
dom of parliament. The dignity and independence
of the two houses are therefore in great measure pre-
served by keeping their privileges indefinite. Some,
however, of the more notorious privileges of the mem-
bers of either house are privilege of speech, of person,
of their domestics, and of their lands and goods. As
to the first, privilege of speech, it is declared by the
statute 1. W. N. M. fl. 2. c. 2. as one of the liberties of
the people; "That the freedom of speech, and de-
bates, and proceedings in parliament, ought not to be
impaired or questioned in any court, or place of out-
court." And this freedom of speech is particu-
larly demanded of the king in person, by the speaker
of the house of commons, at the opening of every new
parliament. So likewise are the other privileges, of
person, servants, lands, and goods; which are immu-
nities as ancient as Edward the Confessor: in whole
laws we find this precept, *Ad spesos veniuntibus, fev
summoniti fev, free per fe quid aegros habuerint, fit somma
pax; and it is too old the Old Gothic constitutions, Ex-
tendiur hic pax at securitas ad quaterdies dies, convoc.
cato regni fenatus. This included formerly not only privi-
lege from illegal violence, but also from legal arrests
and seizures by process from the courts of law. And
still to assail by violence a member of either house,
or his ministerial servants, is a high contempt of par-
liament, and there punished with the utmost severity. It
has likewise peculiar penalties annexed to it in the
courts of law by the statutes 5 Hen. IV. c. 6. and 11
Hen. VI. c. 11. Neither can any member of either
house be arrested and taken into custody without a
breach of the privilege of parliament.

But all other privileges which derogate from the
common law are now at an end, five only as to the
freedom of the member’s person; which in a peer by
the privilege of peerage is for ever secured and invio-
lable; and in a commoner (by the privilege of parlia-
ment) for forty days after every prorogation, and forty
days before the next appointed meeting; which is now
in effect as long as the parliament subsists, it being
prolonged for more than eighty days at a time.

As to all other privileges which obstruct the ordinary
course of justice, they were restrained by the statutes
12. W. III. c. 3. 2 & 3 Ann. c. 18, and 11 Geo. II.
c. 24. and are now totally abolished by statutes 10 G.
III. c. 50.; which enacts, that any suit may at any
time be brought against any peer or member of par-
liament, their servants, or any other person intitled to
privilege of parliament, which shall not be impeached
or delayed by pretence of any such privilege, except
that the person of a member of the house of commons
shall not thereby be subjected to any arrest or im-
poundment. Likewise, for the benefit of commerce, it
is provided by statute 4 Geo. III. c. 33. that any trader,
having privilege of parliament, may be served with leg-
ral process for any just debt (to the amount of 100l.)
and unless he makes satisfaction within two months, it
shall be deemed an act of bankruptcy; and that com-
}
V. There remains only, in the last place, to add a word or two concerning the manner in which parliaments may be adjourned, prorogued, or dissolved.

An adjournment is no more than a continuation of the session from one day to another; as the word itself signifies; and this is done by the authority of each house separately every day; and sometimes for a fortnight or a month together, as at Christmas or Easter, or upon other particular occasions. But the adjournment of one house is no adjournment of the other. It hath also been usual, when his Majesty hath signified his pleasure that both or either of the houses should adjourn themselves to a certain day, to obey the king's pleasure so signified, and to adjourn accordingly. Otherwise, besides the indecorum of a refusal, a prorogation would avertly follow; which would often be very inconvenient to both public and private business. For a prorogation puts an end to the session; and then such bills as are only begun, and not perfected, must be resumed de novo (if at all) in a subsequent session; whereas, after an adjournment, all things continue in the same state as at the time of the adjournment made, and may be proceeded on without any fresh commencement.

A prorogation is the continuance of the parliament from one session to another; as an adjournment is a continuation of the session from day to day. This is done by the royal authority, expressed either by the lord chancellor in his Majesty's presence, or by commission from the crown, or frequently by proclamation. Both houses are necessarily prorogued at the same time; it not being a prorogation of the house of lords or commons, but of the parliament. The session is never understood to be at an end until a prorogation; though, unless some act be passed, or some judgment given in parliament, it is in truth no session at all. And formerly the session was, for the king to give the royal assent to such bills as he approved at the end of every session, and then to prorogue the parliament, though sometimes only for a day or two; after which all business then depending in the house was to be begun again. Which custom obtained so strongly, that it once became a question, Whether giving the royal assent to a single bill did not of course put an end to the session? And though it was then reviled in the negative, yet the notion was so deeply rooted, that the statute 1 C. R. L. c. 7. was passed to declare, that the king's
Parliament: in the next. A legislative assembly also, which is sure
to be separated again, (whereby its members will them-
selves become private men, and subject to the full ex-
tent of the laws which they have enabled for others),
will think themselves bound in interest as well as duty,
to make only such laws as are good. The utmost ex-
tent of time that the same parliament was allowed to
fit, by the statute 6 W. & M. c. 3, was three years:
after the expiration of which, reckoning from the re-
turn of the first commons, the parliament was to have
no longer continuance. But by the statute 16 & 17
W. & M. c. 38. (in order, professedly, to prevent the great
and continued expenses of frequent elections, and the
violent heats and animosities consequent thereupon, and
for the peace and security of the government then just
recovering from the late rebellion), this term was pro-
longed to four years; and, what alone is an instance of
the vast authority of parliament, the very same house
that was chosen for three years, enacted its own con-
tinuance for seven. So that, as our constitution now
stands, the parliament must expire, or die a natural
death, at the end of every seventh year, if not sooner
dissolved by the royal prerogative.

We shall conclude this article with an account of
some general forms not taken notice of under any of
the above heads.

In the house of lords, the princes of the blood fit
by themselves on the fides of the throne; at the wall,
behind the king's right hand, the two archbishops fit
by themselves on a form. Below them, the bishops of
London, Durham, and Winchester, and all the other
bishops, fit according to the priority of their consecra-
tion. On the king's left hand the lord treasurer, lord
president, and lord privy-seal, fit upon forms above all
dukes, except the royal blood; then the dukes, mar-
quesses, and earls, according to their creation. Across
the room are woollen sacks, continued from an ancient
custom; and the chancellor, or keeper, being of
course the speaker of the house of lords, sits on the
first woollen sack before the throne, with the great seal
or mace lying by him; below these are forms for the
vicounts and barons. On the other woollen sacks are
seated the judges, masters in chancery, and king's
council, who are only to give their advice in points of
law; but they all stand up till the king gives them
leave to fit.

The commons sit promiscuously; only the speaker
has a chair at the upper end of the house, and the
clerk and his assistant sit at a table near him.

When a member of the house of commons speaks,
he stands up uncovered, and directs his speech to the
speaker only. If what he says be answered by anoth-
er, he is not allowed to reply the same day, unless
personal reflections have been called upon him; but
when the commons, in order to have a greater freedom
of debate, have resolved themselves into a committee
of the whole house, every member may speak to a que-
dition as often as he thinks necessary. In the house of
lords they vote, beginning at the paffive, or lowest
baron, and so up orderly to the highest, every one an-
swering, Contempts, or Not content. In the house of com-
mons they vote by yeas and nays; and if it be dubious
which are the greater number, the house divides. If the
question be about bringing any thing into the house,
the yeas go out; but if it be about any thing the house
already has, the nays go out. In all divisions the spe-
aker appoints four tellers, two of each opinion. In a
committee of the whole house, they divide by chang-
ing sides, the yeas taking the right and the nays the
left of the chair; and then there are but two tellers.
If a bill passes one house, and the other demurs to it, a con-
ference is demanded in the painted chamber, where
several members are deputed from each house; and
here the lords sit covered, and the commons stand bare,
and debate the cause. If they disagree, the affair is
null; but if they agree, this, with the other bills that
have passed both houses, is sent up to the king in the
house of lords, who comes thither clothed in his roy-
al robes; before him the clerk of the parliament reads
the title of each bill, and, as he reads, the clerk of
the crown pronounces the royal assent or dissent. If it be a
public bill, the royal assent is given in these words,
Le roy le veut, “The king will have it so;” if private,
S'il faut comme il est déclaré, “Let the request be com-
plied with; if the king refuses the bill, the answer is,
Le roy s’anfère, “The king will think of it,” and if
it be a money-bill, the answer is, Le roy y mande fes
louans fiujets, accepte leur commandement, & affile le
vot: “The king thanks his loyal subjects, accepts
their benevolence, and therefore grants his consent.”

High Court of Parliament, is the supreme court
in the kingdom, not only for the making, but also for
the execution, of laws; by the trial of great and enor-
mous offenders, whether lords or commoners, in the
method of parliamentary impeachment. As for acts
of parliament to attain particular persons of treason
or felony, or to inflict pains and penalties, beyond or
contrary to the common law, to serve a special pur-
pose, we speak not of them; being to all intents and
purposes new laws, made pro re natura, and by no
means an execution of such as are already in being.
But an impeachment before the lords by the commons
of Great Britain in parliament, is a perfonation of
the already known and established law, and has been
frequently put in practice, being a preference to the
most high and supreme court of criminal jurisdiction
by the most solemn grand inquest of the whole king-
dom. A commoner cannot, however, be impeached
before the lords for any capital offense, but only for
high misdemeanors; a peer may be impeached for any
crime. And they usually (in case of an impeachment
of a peer for treason) address the crown to appoint a
lord high steward, for the greater dignity and reg-
ularity of their proceedings; which high steward
was formerly elected by the peers themselves, though
he was generally commissioned by the king; but it
hath of late years been strenuously maintained, that
the appointment of an high steward in such cases is
not indispensably necessary, but that the house may
proceed without one. The articles of impeachment
are a kind of bills of indictment, found by the house
of commons, and afterwards tried by the lords; who
are in cases of misdemeanors considered not only as
their own peers, but as the peers of the whole nation.
This is a custom derived to us from the constitution of the ancient Germans; who in their great councils
sometimes tried capital accusations relating to the pub-
lic: Lictor apud concilium accusare possit, et peculiaris
opus intueri. And it has a peculiar propriety in the
English constitution; which has much improved upon
the
the ancient model imported hither from the continent.

For though in general the union of the legislative and judicial powers ought to be most carefully avoided, yet it may happen that a subject, intruded with the administration of public affairs, may infringe the rights of the people, and be guilty of such crimes as the ordinary magistrate either dares not or cannot punish.

Of these the representatives of the people, or house of commons, cannot properly judge; because their constituents are the parties injured, and can therefore only impeach. But before what court shall this impeachment be tried? Not before the ordinary courts, which represent the people, the popular assemblies, other branch, which the accused; as it is proper that the people should attend, and that the example of parliamentary reform. That is the nature of a British parliament, and in theory at least we should presume it were nearly perfect; but some of our fellow-countrymen, more zealous perhaps than wise, see prodigious faults in it, such indeed as they think must inevitably prove fatal. The consequence of this perfusion has been a loud and incessant call for parliamentary reform. That abuses ought to be reformed, is certain; and that few institutions are so perfect as not to need amendment, is a fact equally indubitable. We shall even suppose that there are many abuses in our parliament which would require to be amended; but, granting all this, and something more if it were necessary, we would recommend in the mean time to the serious consideration of those who call themselves the Friends of the People, whose sincerity in their professions it would be impolite to question, the example of France, and that they would allow it to be a warning to Britain. France wanted reform indeed, and that which was first proposed had the countenance of the court, and the belief of men; but the consequences have been dreadful; and if ever a free and stable government takes place in it, which we sincerely wish may be soon, it will have been purchased at an immense price, by enormities which will disgrace it, and shew the remembrance of them left.

The former Parliaments of France were sovereign courts established by the king, finally to determine all disputes between particular persons, and to pronounce on appeals from sentences given by inferior judges.—There were ten of these parliaments in France, of which that of Paris was the chief, its privileges and jurisdiction being of the greatest extent. It consisted of eight chambers: the grand chamber, where causes of audience were pleaded; the chamber of written law; the chamber of council; the Tournelle criminelle, for judging criminal affairs; the Tournelle civile, and of the grand chamber; and three chambers of inquests, where processe were adjudged in writing; besides these, there was also the chamber of elections, and those of requisites. In 1771 the king thought fit to branch the parliament of Paris into six different parliaments, under the denomination of superior courts, each parliament having similar jurisdiction. Under their second name of king's, this parliament, like that of England, was the king's council; it gave audience to ambassadors, and consulted of the affairs of war and government. The French king, at that time presided in them, without being at all master of their resolutions. But in after times their authority was abridged; as the kings referred the decision of the grand affairs of the public to their own councils; leaving none but private ones to the parliaments. The parliament of Paris also enjoyed the privileges of verifying and registering the king's arrets or edicts, without which those edicts were of little or no value.

Parliament of Sweden, consists of four estates, with the king at their head. These estates are, 1. The nobility and representatives of the gentry; with whom the colonels, lieutenant-colonels, majors, and captains of every regiment, sit and vote. 2. The clergy; one of which body is elected from every rural deanery of ten parishes; who with the bishops and superintendants, amount to about 200. 3. The burgurers, elected by the magistrates and council of every corporation as their representatives, of whom there are four for Stockholm, and two for every other town, amounting in the whole to about 150. 4. The peasants, chosen by the peasants out of every district; who choose one of their own rank, and not a gentleman, to represent them; these amount to about 250.

All these generally meet at Stockholm; and after the state-affairs have been represented to them from the throne, they separate, and sit in four several chambers or houses, in each of which affairs are carried on by majority of votes; and every chamber has a negative in the passing any law.

Parma, an ancient, rich, populous, and handsome town of Italy, capital of the duchy of the same name, with a citadel, a bishop's see, and an university. It has a magnificent cathedral, and the largest opera-house in Europe, which has seats for 8000 people; but as it required a vast number of candles, which occasioned great expense, they have contrived another which has room for 2000 spectators. The dome and the church of St John were painted by the famous Corregio, who was a native of this place. Don Carlos, king of the two Sicilies, carried away by the library to Naples, which contains 18,000 volumes, and a very valuable cabinet of curiosities, as also the rich collection of medals. The citadel, which is very near the city, is built in the same taste as that at Antwerp. In 1734 there was a bloody battle fought here; and in 1741, by the treaty of Aix-la Chapelle, the duchies of Parma, Placentia, and Guastalla, were given to Don Philip, brother to Don Carlos above-mentioned. It is 30 miles south-east of Cremona, and 50 south-east of Milan. E. Long. 10. 51. N. Lat. 44. 50.
P AR
[ 765 ]

PARMA, the duchy of a province of Italy bounded on the north by the Po; on the north-east by the Mantuan; on the east by the duchy of Modena; on the south by Tuscany; and on the west by the duchy of Placentia. The air is very wholesome, on which account the inhabitants live to a great age. The soil is very fertile, in corn, wine, oil, and hemp; the pastures feed a great number of cattle, and the cheese is in very high esteem. Here are considerable mines of copper and silver, and plenty of truffles, which many are fond of.

PARMIGIANO, a celebrated painter, whose true name was Francesco Mazzuoli: but he received the former from the city of Parma, where he was born, in 1504. He was brought up under his two uncles, and was an eminent painter when but 16 years of age. He was famous all over Italy at 19; and at 23 performed such wonders, that when the general of the emperor Charles V. took Rome by storm, some of the common soldiers having, in sacking the town, broke into his apartments, found him intent upon his work, and were instantly so struck with the beauty of his pieces, that instead of involving him in the plunder and destruction in which they were then employed, they resolved to protect him from all manner of violence; which they actually performed. His works are distinguished by the beauty of the colouring, the invention, and drawing. His figures are spirited and graceful, particularly with respect to the choice of attitude, and to their draperies. He also excelled in music, in which he was very delighted.

In large compositions Parmigianino did not always reach an high degree of excellence; but in his holy families, and other familiar subjects, the gracefulness of his heads, and the elegance of his attitudes, are peculiarly delightful. For the celebrity of his name he seems to have been indebted to his numerous drawings and etchings; for his life being short, and a great part of it consumed in the idle study of alchemy, in pursuit of the philosopher's stone, and in the seducing avocations of music and gambling, there was but little time left for application to the laborious part of his business. His paintings in oil are few in number, and held in high esteem, as are also his drawings and etchings; good imitations of these latter being very rarely to be found. He was the first that practiced the art of etching in Italy; and probably he did not at first know that it had been for a year practised in Germany. When he left out for Rome, he was advised to take one of his pictures with him, as a means of getting himself introduced into the remembrance of the nobility and artificers in that celebrated city. One of them is mentioned by his biographers as a master-piece. It was his own portrait painted upon a piece of wood of a convex form, in imitation of a convex mirror. The surface is said to have been so wonderfully executed, that it had the appearance of real glass, and the head, as well as every part of the furniture of the chamber in which he was supposed to sit, were so artfully managed, that the whole formed a very complete piece of deception. At Rome he was employed by pope Clement VII., who was highly pleased with his performances, and rewarded him liberally. A circumlocution which he painted for him was particularly esteemed as a capital work. In it Parmigianino was successful in introducing a variety of lights, without destroying the general harmony. When Charles V. came to Bologna to be crowned emperor of the Romans, Parmigianino failed not to be present at that singular ceremony; and so accurately marked the countenance of the emperor, that at his return home, he was enabled from memory to make out a surprising likeness. In the same piece he introduced the figure of Fame placing a crown of laurel on the head of the emperor, whilst a young Hercules presented him with a globe of the world. Before it was quite finished, the painter and his piece were introduced to Charles by the Pope, but to little purpose; for the emperor left Bologna a few days after, without ordering him any recompence for his labour. In the church of Madona della Stercata at Parma are still to be seen several of the works of this artist; among which one of Sybils, and two others of Mops, and of Adam and Eve, are much admired. So alo is a Dead Christ, with the Virgin in sorrow, in the church of the Dominicans at Cremona. In the Houghton collection of pictures, now in the possession of the empress of Russia, is one of his best pictures, representing Christ laid in the sepulchre, for which he is said to have been knighted by the duke of Parma.

His principal works are at Parma, where he died poor in 1540.

PARNASSIA, gr. Parnassus in botany; a genus of the tetragynia order, belonging to the pentandria class of plants. The calyx is quinquepartite; there are five petals, and as many nectaries, heart-shaped, and ciliated with globular tops; the capsule quadri-valved. There is but one species, having a stalk about a foot high, angular, and often a little twisted, bearing a single white flower at top. The flowers are very beautifully streaked with yellow; so that though it is a common plant, growing naturally in moil pastures, it is frequently admitted into gardens.

PARNASUS (Strabo, Pindar, Virgil), a mountain of Phocis, near Delphi, and the mount Cithaeron and Helicon, with two tops (Ovid, Lucan); the one called Circe, sacred to Apollo; and the other Nysa, sacred to Bacchus, (Juvénal). It was covered with bay trees, (Virgil); and originally called Larneus, from Delphi's larnax or ark, thither conveyed by the flood, (Stephanus, Scholast on Apolloius); after the flood, Parneus; from Har Nahas, changing the k into p, the hill of divination or augury (Peuceris), the oracle of Delphi standing at its foot.

Chandler, who visited it, thus describes it:—

"Parnassus was the western boundary of Phocis, and stretching northward from about Delphi toward the Géan,
Cretan mountains, separated the western Locri from those who pilfered the sea coast before Euboea. It was a place of refuge to the Delphians in times of danger. In the deluge, which happened under Deus-tilian, the natives were saved on it by following the cry of wolves. On the invasion of Xerxes, some transported their families over to Aehina, but many concealed themselves in the mountain, and in Corycium, a grove of the Nymphs. All Paros was renowned for its fertility; but Corycium was the most noted among the hallowed caves and places. On the way to the summit of Parnassus, says Panatius, as much as 60 radia beyond Delphi, is a brazen image; and from thence the ascent to Corycium is easier for a man on foot, than for mules and horses. Of all the caves in which I have been, this appeared to me the best worth seeing. On the coasts, and by the sea-side, are more than can be numbered; but some are very famous both in Greece and in other countries. The Corycian cave exceeds the others in magnificence; I have mentioned, and for the most part may be passed through without a light. It is sufficiently high; and has water, some springing up, and yet more from the roof, which petrifies; so that the bottom of the whole cave is covered with sparay icicles.

The inhabitants of Parnassus esteem it sacred to the Corycian Nymphs; and particularly to Pan.—From the cave to reach the summits of the mountain is difficult even to a man on foot. The summits are above the clouds, and the women called Tyranadas murmured on them in the rites of Bacchus and Apollo. Their frantic orgies were performed yearly. Wheeler, and his company ascended Parnassus from Delphi, some on horses, by a track between the Stadium and the declivities of the mountain. Stairs were cut in the rock, with a cleft under the hill covered with pines and snow. In a long hour, after many travesties, they gained the top, and entering a plain turned to the right, towards the summits of Caiftalia, which are divided by deep precipices. From this eminence they had a fine prospect of the gulph of Corinth, and of the coast; mount Cithinus appearing beneath them as a plain, bounded on the east by the bay of Aegophonia, and on the west by that of Salona. A few shepherds had huts there. They returned to the way through which they had quitted, and crossed a hill covered with pines and snow. On their left was a lake, and beyond it a peak, exceedingly high, white with snow. They travelled to the foot of it through a valley, four or five miles in compass; and revelled by a plentiful fountain called Drapens, the stream boiling up a foot in diameter, and nearly as much above the surface of the ground. It runs into the lake, which is about a quarter of a mile distant to the south-east. They did not discover Corycium, or proceed farther on, but keeping the lake on their right, came again to the brink of the mountain, and defended by a deep and dangerous track to Racovi, a village four or five miles eastward from Delphi. It was the opinion of Wheeler, that no mountain in Greece was higher than Parnassus; that it was not inferior to mount Cenis among the Alps; and that, if detached, it would be seen at a greater distance than even mount Athos. The summits are perpetually increasing, every new fall of snow adding to the perennial heap, while the sun has power only to thaw the superfluities. Calfalis Pleius and innumerable springs are fed; some invisibly, from the lakes and reservoirs, which without these drains and subterraneous vents, would exceed especially after heavy rain and the melting of snow, to fill the valleys, and run over the top of the rocks down upon Delphi, spreading wide an inundation, similar as, has been formed, to the Delphian stream deluge.

PARNELL (Dr Thomas), a very ingenious divine and poet in the early part of this century. He was archdeacon of Clogher, and the intimate friend of Mr Pope; who published his works, with an elegant copy of recommendatory verses prefixed. He died in 1718, aged 39.

John-* says, "The Life of Dr Parnell is a tale of which I should very willingly decline, since it has been lately written by Goldsmith, a man of such variety of powers, and such felicity of performance, that he always seemed to do better that which he was doing; a man who had the art of being minute without tediousness, and general without confusion; whose language was copious without exuberance, exact without con­train, and easy without weakness.

"What such an author has told, who would tell again? I have made an extract from his larger narrative, and shall have the gratification from my attempt, that it gives me an opportunity of paying due tribute to the memory of a departed genius."

"To yep gipt al 11. hwnonon."

"The general character of Parnell is not great extent of comprehension, or fertility of mind: Of the little that appears still left his own. His praise must be derived from the easy sweetness of his diction: in his verses there is more happiness than pains; he is sprightly without effort, and always delights though he never ravishes; every thing is proper yet every thing seems casual. If there is some appearance of elaboration in the Hermit, the narrative, as it is left airy, is left pleasing. Of his other compositions, it is impossible to say whether they are the productions of Nature so excellent as not to want the help of Art, or of Art refined as to resemble Nature."

PARODY, a popular maxim, adage, or proverb.

Parody, is also a poetical pleasantry, consisting in applying the verses written on one subject, by way of ridicule, to another; or in turning a serious work into a burlesque, by affecting to observe as near as possible the same rhymes, words, and cadences.

The parody was first set on foot by the Greeks, from whom we borrow the name. It comes near to what some of our late writers call travesty. Others have more accurately distinguished between a parody and burlesque; and observe, that the change of a single word may parody a verse; or of a single letter a word. Thus, in the last case, Cato expatiated the inconstant disposition of Marcus Fulvius Nobilius, by changing Nobilius into Nobilior. Another kind of parody consists in the mere application of some known verse, or part of a verse of a writer, without making any change in it, with a view to expose it. A fourth imitation is that of writing verses in the taste and style of authors little approved. The rules of parody regard the choice of a subject, and the manner of treating it. The subject should be a known and celebrated work; as to the manner, it should be an exact imitation, and an intermixture of good natural pleasantry.
PAROLOS, in a military sense, the promise made by a prisoner of war, when he has leave to go anywhere, or returning at a time appointed, it not exchanged.

PAROLE, means also a word given out every day in orders by the commanding officer, b'th in camp and garrison, in order to know friends from enemies.

PARONOMASIA, in rhetoric, a pun; or a figure whereby words nearly alike in sound, but of very different meanings, are affectedly or delightedly used. See Oratory, p. 76.

PARONYCHIA, the Whitlow, in surgery, is an abscess at the end of the fingers. According as it is situated more or less deep, it is differently denominated, and divided into species.

It begins with a slow heavy pain, attended with a slight pulsation, with an swelling, redness, or heat: but soon the pain, heat, and throbbing, are intolerable; the part swells large and red, the adjoining fingers, and the whole hand swell up; in some cases, a kind of red and inflamed leath may be observed, which beginning at the affected part, is continued almost to the elbow; nor is it unusual for the patient to complain of a very sharp pain under the shoulder, and sometimes the whole arm is excessively inflamed and swollen; the patient cannot sleep, the fever, &c. increasing; and sometimes delirium or convulsions follow.

1. When it is feated in the skin or fat, in the back or the fore part of the finger, or under or near the nail, the pain is severe, but ends well.

2. When the periophorum is inflamed or corroded, the pain is tormenting.

3. When the nervous coats of the flexor tendons of the fingers or nerves near them are seized, the word symptoms attend. If the first kind suppurates, it must be opened, and treated as abscesses in general; but the best method of treating the other two species is, on the first, or at the first, the second day, to cut the part where the pain is seated quite to the bone; if this operation is longer deferred, a suppuration will come on; on which case supputation should be speedily promoted, and as early a discharge given to the matter as possible. As the pain is so considerable as to occasion a fever, and sometimes convulsions, the tint. th. b. may be added to the suppurring applications, and also given in a draught at bed time. The second species proves very troublesome, and sometimes ends in a caries of the subjacent bone. The third species is very tedious in the cure, and usually the phalanx on which it is seated is destroyed.

PAROS (anc. geog.), an island of the Ægean sea, one of the Cyclades, with a strong cognominal town, 38 miles distant from Delos (Pliny, Nepos). Anciently called Paros and Minos (Pliny); also Donatus, Zephyrus, Hymen, Hyleus, and Cabarnus (Nepos). The country of Archilochus the Iambic poet (Strabo). An island famous for its white marble (Virgil, Horace, Ovid), called lychnites, because dug with lamps (Pliny). The name of Cabarnis is borrowed, according to Stephanus, from one Cabarnus, who first informed Ceres of the rape of her daughter Proserpine; or, according to Herodotus, from the Cabarni, the priests of Ceres being so called by the inhabitants of this island. The name of Minos is derived from Minos king of Crete, who subdued this as he did most of the other islands of the Ægean sea. It was called Paros, which name it retains to this day, from Paros the son of Parrhasius, or, as Stephanus will have it, of Jafon the Argonaut. Paros, according to Pliny’s computation, is distant from Naxos seven miles and a half, and 29 from Delos. Some of the modern travellers will have it to be 56, others only 90 miles in compass. Pliny says it is half as large as Naxos, that is, between 36 and 37 miles in compass. It was a rich and powerful island, being termed the most wealthy and happy of the Cyclades, and by Cornelius Nepos an island elated with its riches. The city of Paros, the metropolis, is flyled by Stephanus a potent city, and one of the largest in the Archipelago; the present city of Paros, now Parikia, is supposed to have been built upon its ruins, the country abounding with valuable monuments of antiquity. The very walls of the present city are built with columns, architraves, pedestals mingled with pieces of ancient marble of a surpassing magnitude, which were once employed in more noble edifices. Paros was indeed formerly famous for its marble, which was of an extraordinary whiteness, and in such request among the ancients that the bell statues used no other (a). The island is provided with several capacious and safe harbours, and was anciently much resorted to by traders. It was according to Thucydides, originally peopled by the Phoenicians, who were the first navigators of the sea. Afterwards the Carians settled here, as we are told by Thucydides and Diodorus. But these two authors differ as to the time when the Carians came first into the island; for Thucydides tells us, that the Carians were driven out by the Cretans under the conduct of Minos; and Diodorus writes, that the Carians did not settle here till after the Trojan war, when they found the Cretans in possession of the island. Stephanus thinks that the Cretans, mixed with some Arcadians, were the only people that ever possessed this island. Minos himself, if we believe Pliny, resided some time in the island of Paros, and received here the melancholy news of the death of his son Androgeus, who was killed in Attica after

(a) Sutherland says, “that while its marble quarries continued to be worked, Paros was one of the most flourishing of the Cyclades; but on the decline of the eastern empire they were entirely neglected, and are now converted into caves, in which the shepherds shelter their flocks. We have been in several of these subterraneous holds, which put me much in mind of Homer’s description of Polyphemus. The common walls are almost entirely composed of marble; and in examining a very small part of one, we found several pieces of columns and baso-relievo. Several fine blocks of marble (fragments of columns) are lying close to the water’s edge, and seem to have been brought there by travellers, who for want of a proper purchase to get them on board, have not been able to carry them farther.”
after he had distinguished himself at the public games. We find the inhabitants of this island chosen from among all the Greeks by the Milesians to compose the differences which had for two generations rent that unhappy state into parties and factions. They acquiesced themselves with great prudence, and reformed the government. They defeated Darius in his expedition against Greece with a confederate squadron; but after the victory obtained by Miltiades at Marathon, they were reduced to great fruits by that general. However, after blocking up the city for 26 days, he was obliged to quit the enterprise, and return to Athens with disgrace. Upon his departure, the Peloponnesians were informed that Timo, a priest of the national gods, and then his prisoner, had advised him to perform some secret ceremony in the temple of Ceres, near the city; assuring him that he would thereby gain the place. Upon this information they sent deputies to consult the oracle of Delphi, whether they should punish her with death, for endeavouring to betray the city to the enemy, and discovering the sacred mysteries to Miltiades. The Pythian answered, that Timo was not the adviser: but that the gods, having resolved to destroy Miltiades, had only made her the instrument of his death. After the battle of Salamis, Themistocles subjugated Paros and most of the other neighbouring islands to Athens, exacting large sums from them by way of punishment for having favoured the Persians. It appears from the famous monument of Adonias, which Cosmo of Egypt has described with great exactness, that Paros and the other Cyclades were once visited by the Ptolemies of Egypt. However, Paros fell again under the power of the Athenians, who continued masters of it till they were driven out by Mithridates the Great. But that prince being obliged to yield to Sulla, to Lucullus, and to Pompey, this and the other islands of the Archipelago submitted to the Romans, who reduced them to a province with Lydia, Phrygia, and Caria.

Mr Sutherland, who lately visited Paros, says, that "the water in it is excellent; and as that which we got at Ephesus has been complained of, as being too hard to make proper ousel-oup for the people, all the casks are ordered to be emptied and refilled. The Ruffians made this place their grand arsenal: their powder magazines, and several other buildings, are still standing; and the island is considerably indebted to them for improving the convenience for water, and for the trade which the casks they expended introduced among the inhabitants."

PAROTIDES, in anatomy. See there, No. 128.

PAROXYSM, in medicine, the severe fit of a disease, under which it grows higher or exasperated; as of the gout, &c.

PARR (Catharine), was the eldest daughter of Sir Thomas Parr of Kendal. She was married to John Nevil, lord Latymer; after whose death she captivated her amorous sovereign, that he raised her to the throne. The royal nuptials were solemnized at Hampton Court on the 12th of July 1543. Being religiously disposed, she was, in the early part of her life, a zealous observer of the Roman rites and ceremonies; but in the drawing of the Reformation, she became as zealous a promoter of the Lutheran doctrine yet with such prudence and circumstentation as her perilous situation required. Nevertheless, we are told, that she was in great danger of falling to a fancier to the Lutheran faction, the chief of whom was Bishop Gardiner: he drew up articles against her, and prevailed on the king to sign a warrant to remove her to the Tower. This warrant was, however, accidentally intercepted, and immediately conveyed to her majesty. What her apprehensions must have been on this occasion may be easily imagined. She knew the monarch, and she could not help recollecting the fate of her former queens. A sudden illness was then the natural consequence. The news of her indisposition brought the king to her apartment. He was reconciled in expressions of affection, and sent her a physician. His majesty being soon after also somewhat indisposed, she prudently returned the visit; with which the king seemed pleased, and began to talk with her on religious subjects, proposing certain questions, concerning which she wanted her opinion. She answered, that such profound speculations were not fitted to her sex; that it belonged to the husband to choose principles for his wife; the wife's duty was, in all cases, to adopt implicitly the sentiments of her husband; and as to herself, it was doubly her duty, being blessed with a husband who was qualified, by his judgment and learning, not only to choose principles for his own family, but for the most wise, and knowing, of every nation. "Not so, by St Mary," replied the king; "you are now become a doctor, Kate, and better fitted to give than receive instruction." She modestly replied, that she was sensible how little she had hitherto been fitted to these prudences; that though she usually declined not any conversation, however sublime, when proposed by her majesty, she well knew that her conversations could serve to no other purpose than to give him a little momentary amusement; that she found the conversation a little apt to languish when not revived by some opposition, and she had ventured sometimes to feign a contrariety of sentiments, in order to give him the pleasure of refuting her; and that she also proposed, by this innocent artifice, to engage him into topics whence she had observed, by frequent experience, that the reaped profit and instruction. "And is it so, sweetheart?" replied the king; "then we are perfect friends again." He embraced her with great affection, and sent her away with assurances of his protection and kindness.

The time being now come when she was to be sent to the Tower, the king, walking in the garden, sent for the queen, and met her with great good humour; when to the chancellor, with forty of the guards, approached. He fell upon his knees, and spoke softly with the king, who called him knave, arrant knave, beast, fool, and commanded him instantly to depart. Henry then returned to the queen, who ventured to intercede for the chancellor: "Ah, poor foal," said the king, "thou little knowest how evil he deferves this grace at thy hands. Of my word, sweetheart, he hath been worthy thee an arrant knave; and so let him go." The king died in January 1547, just three years and a half after his marriage with this second Catharine; who, in a short time, was again espoused to Sir Thomas Seymour lord-admiral of England: for in September...
Parr. September 1543 she died in childbirth. The historian of this period generally infinuates that she was poisoned by her husband, to make way for his marriage with the lady Elizabeth.

That Catharine Parr was beautiful is beyond a doubt: that she was pious and learned is evident from her writings: and that her prudence and sagacity were not inferior to her other accomplishments, may be concluded from her holding up the passion of a capricious tyrant as a shield against her enemies; and that at the latter end of his days, when his passions were enfeebled by age, and his peevish authority increas'd by disease. She wrote, 1. Queen Catharine Parr's lamentation of a finner, bewailing the ignorance of her blind life; Lond. 8vo, 1548, 1563. 2. Prayers or meditations, wherein the mind is stirr'd patiently to suffre all afflictions here, to fet at nought the vain properitie of this world, and always to long for the everlasting felicitee. Collected out of holy worke, by the most virtuous and gracious princesse Katharine, queene of Englelde, France, and Irelande. Printed by John Wayland, 1545, 4to.—1561, 12mo. 3. Other Meditations, Prayers, Letters, &c. unpublisht.

Parr (Thomas), or Old Parr, a remarkable Englishtman, who lived in the reigns of ten kings and queens; married a second wife when he was 120, and had a child by her. He was the son of John Parr, a husbandman of Winstoouge, in the parish of Alderbury, in the county of Salop, where he was born in the year 1483. Though he lived to the vaft age of upwards of 152 years, yet the tenor of his life admitted but of little variety; nor can the detail of it be considered of importance, further than what will arise from the gratification of that curiosity which naturally inquires after the mode of living which could lengthen life to such extreme old age. Following the profession of his father, he laboured hard, and lived on coarse fare. Taylor the water-poet says of him:

Good wholesome labour was his exercise, 
Down with the lamb, and with the lark would rise; 
In mire and toiling sweat he spent the day, 
And to his team he whiffled time away: 
The cock his night-clock, and till day was done, 
His watch and chief fun-dial was the fun. 
He was of old Pythagoras' opinion, 
That green sheele was most wholesome with an onion; 
Coarse muffin bread, and for his daily twig, 
Milk, butter-milk, and water, whey and whig; 
Sometimes methelin, and by fortune happy, 
He sometimes fipp'd a cup of ale most nappy, 
Cyder or perry, when he did repair 
To a Whitton ale, wake, wedding, or a fair, 
Or when in Christmas-time he was a guest 
At his good landlord's house among the rest: 
Elle he had little leasure-time to waife, 
Or at the ale-house huff-cap ale to taffe. 
Nor did he ever hunt a tavern fox; 
Nor ever knew a coach, tobacco, or the—— 
His phyfic was good butter, which the foil 
Of Salop yields, more sweet than Candy oil? 
And garlic he efteeem'd above the rate 
Of Venice treacle, or bell mithridate. 
He entertain'd no gout, no ache he felt, 
The air was good and temperate where he dwelt; 
Vol. XII.

While mavisettes and sweet-tongued nightingsales 
Did chant him roundelayes and madrigales. 
Thus living within bounds of Nature's laws, 
Of his long lasting life may be some caufe.

And the same writer describes him in the following two lines: 
From head to heel, his body had all over 
A quick fet, thick fet, natural hairy cover.

The manner of his being conduci'd to London is also noticed in the following terms: 4 'The Right Hon. Thomas Earl of Arundel and Surrey, earl-marshall of England, on being lately in Shropshire to visit some lands and manors which his worship holds in that county, or for some other occasions of importance which caus'd his lordship to be there, the report of this aged man was signified to his honour, who hearing of so remarkable a piece of antiquity, his lordship was pleas'd to see him; and in his inate, noble, and Christian piety, he took him into his charitable tuition and protection, commanding that a litter and two horses (for the more easy carriage of a man so feeble and worn with age) be provided for him; also, that a daughter of his, named Lucy, shoul'd likewise attend him, and have a horse for her own riding with him: and to cheer up the old man, and make him merry, there was an antique-faced fellow, with a high and mighty no-beard, that had also a horse for his carriage. These were all to be brought out of the country to London by easy journeys, the charge being allowed by his lordship; likewise one of his lordship's own servants named Bryan Kelly, to ride on horse-back with them, and to attend and defray all manner of reckonings and expences. All which was done accordingly as follows.

"Winstoouge is a parish of Alderbury, near a place called the Welsh Pool, eight miles from Shrewsbury; from whence he was carried to Wem, a town of the earl's aforesaid; and the next day to Shifnal, a manor-house of his lordship's, where they likewise stayed one night: from Shifnal they came to Wolverhampton, and the next day to Birmingham, and from thence to Coventry. Although Matter Kelly had much to do to keep the people off, that press'd upon him in all places where he came, yet at Coventry he was most opprest, for they came in such multitudes to see the old man, that those that defended him were almost quite tired and spent, and the aged man in danger of being stiflet: and, in a word, the rabble were so unruly, that Bryan was in doubt he should bring his charge no farther; for greedy are the vulgar to hearken or gaze after novelties. The trouble being over, the next day they paff'd to Daintree, to Stony Stratford, to Radburne, and so to London; where he was well entertained and accommodated with all things, having all the aforesaid attendance at the sole charge and cost of his lordship." When brought before the king, his majesty, with more acuteness than good manners, said to him, "You have lived longer than other men, what have you done more than other men?" He answer'd, "I did penance when I was an hundred years old." This journey, however, proved fatal to him; owing to the alteration in his diet, to the change of the air, and his general mode of life, he lived but a very short time, dying the 5th of November
PAR 

1635 (A); and was buried in Westminster Abbey.

After his death, his body was opened; and an account was drawn up by the celebrated Dr Harvey, part of which we shall lay before our readers.

"Thomas Parr was a poor countryman of Shropshire, whence he was brought up to London by the Right Hon. Thomas Earl of Arundel and Surrey; and died after he had outlived nine princes, in the year of the tenth of the tenth of them, at the age of 152 years and nine months.

"He had a large breast, lungs not fungous, but sticking to his ribs, and dilated with blood; a lividness in his face, as he had a difficulty of breathing a little before his death, and a long lasting warmth in his armpits and breast after it; and, which sign, together with others, were so evident in his body, as they use to be on those that die by suffocation. His heart was great, thick, fibrous, and fat. The blood in the heart blackish and diluted. The cartilages of the sternum not more bony than in others, but flexible and soft. His viscera were found strong, especially the stomach; and it was observed of him, that he used to eat often by night and day, though contented with are: The bill is tapering and a little obtuse; the nostrils are oval, and situated in the middle of the bill. The forehead is a membranous flap half an inch long and nearly as broad.

"It is another difficulty of breathing, the organs of the head, throat, and under parts; the lesser are of a yellowish, as the chavaria to defend them against the numerous birds of prey, no one of which will dare to encounter it. It is never known to desert the flock, and it returns every evening to roost.

The parra Dominica is about the size of the lapwing. The bill is yellow, as are also the head and upper parts; the under are of a yellowish white bordering on rose colour. The legs are also yellow. This species inhabits several of the warmer parts of America and St Domingo. The parra senega is about the same size with the former. Its bill is also yellow tipped with black: the forehead is covered with a yellow skin; the chin and throat are black; the head and upper parts of the body and lesser wing covers are grey-brown. The lower part of the belly, and the upper and under tail-covers are dirty white. At the bend of the wing is a black spur. It inhabits Senegal, and thence derives its name. The negroes call them Uits Uits, the French the squatters, because, as we are told, as soon as they see a man they scream and fly off. They always fly in pairs. The parra jacana, or spur-winged water hen, is about the size of the water-rail. The bill is in length about an inch and a quarter, of an orange colour; and on the forehead is a membranous flap half an inch long and nearly as broad. On each side of the head also is another of the same, about a quarter of an inch broad, and both together surround the base of the bill. The head, throat, neck, breast, and under parts,
Latham's sy}\n
Parrots, some the belly is mixed with white, &c. The birds of this species inhabit Brazil, Guiana, and Surinam; but are equally common at St Domingo, where they frequent the marshy places, sides of ponds, and trees, and wade quite up to the thighs in the water. They are also generally seen in pairs, and when separated call each other continually till they join again. They are very shy, and must common in the rainy seasons in May and November. They are at all times very noisy; their cry sharp and shrill, and may be heard a great way off. This, as well as the other species, is called by the French phururgien. The flesh is accounted pretty good. The parra variabilis, or spurious-winged water-hen, is about nine inches long. The bill is about 1 inch in length, and in colour is orange-yellow. On the forehead is a flap of red skin; the crown of the head is brown, marked with spots of a darker colour; the hind part of the neck is much the same, but of a deeper dye. The sides of the head, throat, forepart of the neck, breast, belly, thighs, under-tail covert, are white, with a few red spots on the sides of the belly and base of the thighs. On the forepart of the wing is a yellow spur, &c. The legs are furnished with long toes, as in all the others, the colour of which is bluish ash. Mr Latham says, that one which came under his inspection from Cayenne was rather smaller. It had the upper parts much paler; over the eye was a fleck of white pilling no further, and unaccompanied by a black one. The hind part of the neck was dusky black. It had only the rudiment of a spur; and the red caruncle on the forehead was less, and laid back on the forehead. From these differences this learned ornithologist conceives it to have differed either in sex or age from the other. This species inhabits Brazil, and is said to be pretty common about Carthagena and in South America. The parra chavaria is, as we have already observed about the size of a dunghill cock, and stands a foot and a half from the ground. The bill is of a dirty white colour; the upper mandible similar to that in the dunghill cock; the nostrils are white, oval, prominent; on both sides, at the base of the bill, is a red membrane, which extends to the temples. The irides are brown. On the hind head are about 12 blackish feathers, three inches in length, forming a crest and hanging downwards. The rest of the neck is covered with a thick black down. The body is brown, and the wings and tail inclined to black. On the bend of the wing are two or three spurs half an inch long. The belly is a light black. The thighs are half bare of feathers. The legs are very long, and of a yellow red colour. The toes are so long as to entangle one another in walking.

This species inhabits the lakes, &c. near the river Xuo, about 30 leagues from Carthagena, in South America, and is said to feed on vegetables. Its gait is somnolent and slow, but it flies easily and swiftly. It cannot run, unless assisted by the wings at the same time. When any part of the skin is touched by the hand, a cracking is felt, though it is very downy beneath the feathers; and indeed this down adheres so closely as to enable the bird to bathe quite in the water. The voice is clear and loud, but far from agreeable. The natives, who keep poultry in great numbers, have one of these tame, which goes along with the flock about the neighbourhood to feed during the day, when this faithful shepherd defends them against birds of prey; being able by means of the spurs on the wings, to drive off birds as big as the carion vulture, and even that bird itself. It is so far of the greatest use, as it never deferts the charge committed to its care, bringing them all home safe at night. It is so tame as to suffer itself to be handled by a grown person; but will not permit children to attempt the same. Parrotels, in a ship, are frames made of trucks, ribs, and ropes, which having both their ends fastened to the yards, are so contrived as to go round about the masts, that the yards by their means may go up and down upon the masts. These also, with the breast-rope, fasten the yards to the masts.

Parrot of Pedred river, has its rise in the southern part of Sommersetshire in England. Near Langport it is joined by the Ordred, augmented by the Tevio; and, about four miles from this junction, it is joined by the Tone, a pretty large river; rising among the hills in the western parts of this county. About two miles below the junction of the Tone, the Parrot receives another considerable stream; and, thus augmented, it passes by the town of Bridgwater, and falls into the Bristol channel in Bridgewater-bay.

Parrahasius, a famous ancient painter of Ephesus, or, as some say, of Athens; he flourished about the time of Socrates, according to Xenophon, who hath introduced him into a dialogue disjuring with that philosopher. He was one of the best painters in his time. Pliny says, that it was he who first gave symmetry and just proportions in that art; that he likewise was the first who knew how to express the truth and life of characters, and the different airs of the face; that he discovered a beautiful disposition of the hair, and heightened the grace of the village. He was allowed even by the masters in this art, that he far outdistanced them in the manner of proceeding in the outlines, in which confits the grand secret of painting. But it is also remarked by Pliny, that Parrahasius became inconvertible with pride; and was so very vain as to give himself the mock flatterer's epithets: such as, the tenderest, the softest, the grandest, the most delicate, and the perfect of his art. He boasted that he was sprung from Apollo, and that he was born to paint the gods; that he had actually drawn Hercules touch by touch: that hero having often appeared to him in dreams; when the plurality of voices was against him at Samos in favour of Timanthes, in the opinion of a picture of Ajax provoked against the Greeks, for adjudging to Ulysses the arms of Achilles, he answer'd a person who contended him in this check, "For my part, I don't trouble myself at the sentence; but I am sorry that the son of Telamen hath received a greater outrage than that which was formerly put upon him so unjustly." Alcam relates this story, and tells us that Parrahasius affected to wear a crown of gold upon his head, and to carry in his hand a batoon, studded with nails of the same metal. He worked at his art with pleasure, and he is very licentious and loose in his pictures: and he is said by way of amusement, to have represented the
of most infamous objects. His Atlantis, with her spouse Meleager, was of this kind. This piece was afterwards devised as a legacy to the Emperor Tiberius, upon condition that, if he was displeased with the subject, he should receive a million sesterties instead of it. The emperor, covetous as he was, not only preferred the picture to that sum, but even placed it in his most favourite apartment. It is also said, that, though Parrhasius was excelled by Timanthes, yet he excelled Zeuxis. Among his pictures is a celebrated one of Thiebus; and another representing Meleager, Hercules, and Pericles in a group together; as also Aneas, with Calloph and Pollux, in a third.

Parrhasius (Janus), a famous grammarian in Italy, who was born at Cofenza in the kingdom of Naples, 1470. He was intended for the law, the profession of his ancestors; but he refused it, and cultivated classical learning. His real name was Johannes Paulus Parfius; but according to the humour of the grammarians of the age, he took instead of it Parrhasius. He taught at Milan with much reputation, being admired for a graceful delivery, in which he chiefly excelled other professors. It was this charm in his voice, which brought a vast concourse of people to his lectures; and among others he had the pleasure to see General Trinules, who was then thirteen years old.

He went to Rome when Alexander VI. was pope; and was like to be involved in the misfortunes of Bernardini Cajetan and Silius Savello, with whom he had some correspondence; but he escaped the danger, by the information of Thomas Phedrus, professor of rhetoric, and cannon of St John Lateran, whose advice he followed in retiring from Rome. Soon after, he was appointed public professor of rhetoric at Milan; but the liberty he took to confute the teachers there as arrant blockheads, provoked them in return to abuse his morals. They say he had a criminal converse with his scholars: which being a crime extremely abhorred by the Milanese, our professor was obliged to leave Milan. He went to Vicenza, where he obtained a larger salary; and he held this professorship till the states of the Venetians were laid waste by the troops of the League, upon which he went to his native country, having made his escape through the army of the enemies. He was at Cofenza, when his old friend Phedrus perjured Julius to send for him to Rome; and though, that design proved abortive by the death of the pope, yet, by the recommendation of John Lafcarius, he was called thither under the succession Leo X. Leo was before favourably inclined to him; and on his arrival at Rome, appointed him professor of polite literature. He had been now some time married to a daughter of Demetrius Chalcondylas; and he took with him to Rome Basil Chalcondylas, his wife's brother, and brother of Demetrius Chalcondylas, professor of the Greek tongue at Milan. He did not long enjoy this employment conferred upon him by the pope: for, worn out by his studies and labours, he became so afflicted with the gout, that for some years he had no part of his body free, except his tongue; having almost left the use of both his legs and both his arms. He laboured besides under so great a degree of poverty, as to put him out of all hopes of being ever in a better situation, so that he left Rome, and returned into Calabria, his native country, where he was tormented a long while with a fever, and at last died in the greatest misery. He left his library to his friend Seripandus, brother to Cardinal Jerome Seripandus, who built him a tomb in the convent of the Austin friars at Naples. There are several books ascribed to him; and in the dedication of one of them, his character is drawn to great advantage by Henry Stephens.

Parrhesia. See Oratory, no. 88.

Parricide, the murder of one's parents or children. By the Roman law, it was punished in a much severer manner than any other kind of homicide. After being scourged, the delinquents were fed up in a leathern fack, with a live dog, a cock, a viper, and an ape, and so cast into the sea. Solon, it is true, in his laws made none against parricide; apprehending it impossible that one should be guilty of so unnatural a barbarity. And the Perrians, according to Herodotus, entertained the same notion, when they adjudged all persons who killed their reputed parents to be females. And upon some such reasoning as this, we account for the omission of an exemplary punishment for this crime in the English laws; which treat it no otherwise than as simple murder, unless the child was also the servant of the parent.

For though the breach of natural relation is unobserved, yet the breach of civil or ecclesiastical connections, when coupled with murder, denominates it a new offence, no less than a species of treason, called parvum proelio, or petit treason: which, however, is nothing else but an aggravated degree of murder; although, on account of the violation of private allegiance, it is dignified as an inferior species of treason. And thus, in the ancient Gothic constitution, we find the breach both of natural and civil relations ranked in the same class with crimes against the state and sovereign.

Parrot, in Ornithology. See Psittacus.

Parshore, a town of England in Worcestershire, seven miles from Worcester, and 102 from London, is a neat old town on the north side of the Avon, near its junction with the river Bow, being a considerable thoroughfare in the lower road from Worcester to London. A religious house was founded here in 604, a small part of which now remains, and is used as the parish church of Holy Cross, the whole of which contained above 10 acres. The abbey church was 250 feet long, and 120 broad. The parish of Parshore is of great extent, and hath within its limits many manors and chapellies. At present it has two parishes, Holy Cross and St Andrew. In Holy Cross church are several very antique monuments. Its chief manufacture is stockings. It contains about 300 houses, and has markets on Tuesday and Saturday; fairs Easter-Tuesday, June 26th, and Tuesday before November 1st.

Parsley, in botany. See Apium.

Parsnip, in botany. See Pastinacia.

Parson and Vicar. A parson, persona eccle- siæ, is one that hath full possession of all the rights of a parochial church. He is called parson, persona, because by his person the church, which is an invisible body, is represented; and he is in himself a body corporate, in order to protect and defend the rights of the church (which he perfonates) by a perpetual sec-
For the flocking of the church: but the appellation of parson (however it may be depreciated by familiar, clownish, and indiscriminate use) is the most legal, most beneficial, and most honourable title that a parship-priest can enjoy; because such a one (Sir Edward Coke observes), and he only, is said *vicem feu personam ecclesie gereur*.

A parson has, during his life, the freehold in himself of the parsonage-house, the glebe, the tithes, the other dues. But these are sometimes appropriated, that is to say, the benefice is perpetually annexed to some spiritual corporation, either folo or aggregating, being the patron of the living; whom the law esteems equally capable of providing for the service of the church as any single private clergyman *.

The appropriating corporations, or religious houses, were wont to dispute one of their own body to perform divine service, and administer the sacraments, in those parishes of which the society was thus the parson. This officiating minister was in reality no more than a curate, deputy, or viceregent of the appropriator, and therefore called vicarious, or vicar.* His stipend was at the discretion of the appropriator, who was, however, bound of common right to find somebody, qui illi de temporali, episcopo de spiritualibus, debet refundere. But this was done in so scandalous a manner, and the parishes suffered so much by the neglect of the appropriators, that the legislature was forced to interpose: and accordingly it is enacted, by statute 15 Ric. II. c. 6. that in all appropriations of churches the diocesan bishop shall ordain (in proportion to the value of the church) a competent sum to be distributed among the poor parishioners annually; and that the vicarage shall be sufficiently endowed. It seems the parishes were frequently sufferers, not only by the want of divine service, but also by withholding those alms for which, among other purposes, the payment of tithes was originally imposed: and therefore in this act a pension is directed to be distributed among the poor parishioners, as well as a sufficient stipend to the vicar. But he, being liable to be removed at the pleasure of the appropriator, was not likely to insist too rigidly on the legal sufficiency of the stipend; and therefore, by statute 4 Hen. IV. c. 12. it is ordained, that the vicar shall be a secular person, not a member of any religious house; that he shall be vicar perpetual, not removable at the caprice of the monastery; and that he should be canonically instituted and inducted, and be sufficiently endowed, at the discretion of the ordinary; for these three express purposes, to do divine service, to inform the people, and to keep hospitality. The endowments, in consequence of these statutes, have usually been by a portion of the glebe or land belonging to the parsonage, and a particular share of the tithes, which the appropriators found it most troublesome to collect, and which are therefore generally called petty or sull tithes; the greater, or perodial tithes, being still referred to their own use. But one and the same rule was not observed in the endowment of all vicarages. Hence some are more liberally, and some more feehiously, endowed: and hence the tithes of many things, as wood in particular, are in some parishes hereditarily, and in some vicarial tithes.

The distinction therefore of a parson and vicar is this: The parson has for the most part the whole right to all the ecclesiastical dues in his parish; but a vicar has generally an appropriator over him, intituled to the best part of the profits, to whom he is in effect perpetual curate, with a standing salary. Though in some places the vicarage has been considerably augmented by a large share of the great tithes; which augmentations were greatly affliated by the statute 27 Car. II. c. 8. enacted in favour of poor vicars and curates, which rendered such temporary augmentations (when made by the appropriators) perpetual.

The method of becoming a parson or vicar is much the same. To both there are four requisites necessary; holy orders, presentation, institution, and induction. The method of conferring the holy orders of deacon and priest, according to the liturgy and canons, is foreign to the present purpose; any farther than as they are necessary requisites to make a complete parson or vicar. By common law, a deacon, of any age, might be instituted and inducted to a parsonage or vicarage: but it was ordained, by statute 13 Eliz. c. 12. that no person under twenty-three years of age, and in deacon's orders, should be preferred to any benefice with cure; and if he were not ordained priest within one year after his induction, he should be ipso facto deprived; and now, by statute 13 and 14 Car. II. c. 4. no person is capable to be admitted to any benefice, unless he had been first ordained a priest; and then he is, in the language of the law, a clerk in orders. But if he obtains orders, or a licence to preach, by money or corrupt practices, (which seems to be the true, though not the common, notion of sine) the parson giving such orders forfeits 40l. and the person receiving, 10l. and is incapable of any ecclesiastical preferment for seven years after.

Any clerk may be preferred to a parsonage or vicarage; that is, the patron, to whom the advowson of the church belongs, may offer his clerk to the bishop of the diocese to be instituted. But when he is preferred, the bishop may refuse him upon many accounts. As, 1. If the patron is excommunicated, and remains in contempit 40 days; or, 2. If the clerk be unfit: which unfitness is of several kinds. First, with regard to his person; as if he be a bailiad, an outlaw, an excommunicate, an alien, under age, or the like. Next, with regard to his faith or morals; as for any particular hardship, or vice that is *malum in se*; but if the bishop alleges only in general, as that he is *scheichaticus inveteratus*, or objects a fault that is *malum prohibitum* merely, as having taverns, playing at unlawful games, or the like, it is not good cause of refusal. Or, lastly, the clerk may be unfit to discharge the pastoral office for want of learning. In any of which cases, the bishop may refuse the clerk. In case the refusal is for hereby, schism, inability of learning, or other matter of ecclesiastical cognizance, there the bishop must give notice to the patron of such his cause of refusal, who being usually a layman, is not supposed to have knowledge of it; else he cannot present by lapsed; but if the cause be temporal, there he is not bound to give notice.

If an action at law be brought by the patron against the bishop for refusing his clerk, the bishop must align the cause. If the cause be of a temporal nature, and the fact admitted, (as, for instance, outlawry), the judges of the king's courts must determine its validity, or
Parson.

or whether it be sufficient cause of refusal: but if the
fact be denied, it must be determined by a jury. If
the cause be of a spiritual nature, (as hereby, particu-
larly alleged), the fact, if denied, shall also be de-
determined by a jury: and if the fact be admitted or found,
the court, upon consultation and advice of learned di-
vine, shall decide its sufficiency. If the cause be want
of learning, the bishop need not specify in what points
the clerk is deficient, but only allege that he is defi-
cient; for the statute 9 Edw. IL st. i. c. 13, is ex-
press, that the examination of the finnels of a person
presented to a benefice belongs to the ecclesiastical
judge. But because it would be nugatory in this case
to demand the reason of refusal from the ordinary, if
the patron were bound to abide by his determination,
who has already pronounced his clerk unfit; therefore
if the bishop returns the clerk to be minus sufficient in
literatura, the court shall write to the metropolitan to
re-examine him, and certify his qualifications; which
certificate of the archbishop is final.

If the bishop hath no objections, but admits the pa-
tron's presentation, the clerk so admitted is next to be
instituted by him; which is a kind of investiture of the
spiritual part of the benefice; for by institution, the
care of the souls of the parish is committed to the charge
of the clerk. When a vicar is instituted, he (besides the
usual forms) takes, if required by the bishop, an oath of perpetual
residence; for the maxim of law is, that vicarius non labet vicarium; and as the non-resi-
dence of the appropriators was the cause of the perpe-
tual establishment of vicarages, the law judges it very
improper for them to defeat the end of their constitution,
and by absence to create the very mischief which they were appointed to remedy; especially as, if any
profits are to arise from putting in a curate and living
at a distance from the parish, the appropriator, who is
the real parson, has undoubtedly the elder title to them.
When the ordinary is also the patron, and
confers the living, the presentation and institution are
one and the same act, and are called a collation to a
 benefice. By collation the church is full, so that there can be no fresh presentation till another
vacancy, at least in the case of a common patron;
but the church is not full against the king till induc-
tion: may, even if a clerk is instituted upon the king's
preference, the crown may be taken before prefenta-
tion, and present another clerk. Upon institution
also the clerk may enter on the parsonage house and
glebe, and take the tithe; but he cannot grant or let
them, or bring an action for them, till induction.

See Induction.

For the rights of a parson or vicar, in his tithes and
ecclesiastical dues, see Tithes. As to his duties, they are so numerous, that it is impractical to recite them
here with any tolerable conciseness or accuracy; but the reader who has occasion may consult Bishop Gib-
on's Codex, Johnson's Clergyman's Fidei Mundus, and Burn's Ecclesiastical Law. We shall therefore only
just mention the article of residence, upon the sup-
position of which the law doth style every parochial
minister an incumbent. By statute 21 Henry VIII.
c. 13, parsons willingly abstaining themselves from their benefices, for one month together, or two months
in the year, incur a penalty of 5l. to the king, and
5l. to any person that will sue for the same; ex-
cept chaplains to the king, or others therein mention-
ed, during their attendance in the household of such
as retain them; and also except all heads of hou-
ses, magistrates, and professors in the universities, and all
students under forty years of age residing there, bona
fide for study. Legal residence is not only in the pa-
ris, but also in the parsonage house; for it hath been
resolved, that the statute intended residence, not only
for serving the cure and for hospitality, but also for
maintaining the house, that the successor also may keep
hospitality there.

We have seen that there is but one way whereby
one may become a parson or vicar: there are many
ways by which one may cease to be. 1. By death. 2. By cession, in taking another benefice; for by statute 21 Hen. VIII. c. 13, if any one having a benefi-
ce of 8l. per annum, or upwards, in the king's books,
(according to the present valuation), accepts any
other, the first shall be adjudged void, unless he ob-
tains a dispensation; which no one is intitled to have
but the chaplains of the king and others therein men-
tioned, the brethren and sons of lords and knights,
and doctors and bachelors of divinity and law, admit-
ted by the universities of this realm. And a vacancy
thus made for want of a dispensation, is called cession.
3. By consecration; for, as was mentioned before,
when a clerk is promoted to a bishopric, all his other
prebends are void, the infant that he is consecrated.
But there is a method, by the favour of the crown, of
holding such livings in commendam. Commenda or ec-
silia commendata, is a living commended by the crown
to the care of a clerk, to hold till a proper pastor is
provided for it. This may be temporary for one, two,
or three years, or perpetual, being a kind of dispensa-
tion to avoid the vacancy of the living, and is called a
commenda retineres. There is also a commenda recipens,
which is to take a benefice de novo in the bishop's own
gift, or the gift of some other patron confenting to
the same; and this is the fame to him as institution
and induction are to another clerk. 4. By resigna-
tion. But this is of no avail till accepted by the or-
dinary, into whose hands the resignation must be made.
5. By deprivation, either by canonical censures, or in
purse of divers penal statutes, which declare the benefice void, for some nonfeasance or neglect, or else
some maladministration or crime: as for simony; for main-
tenance any doctrine in derogation of the king's su-
premacy, or of the thirty-nine articles, or of the book
of common prayer; for neglecting after institution
to read the liturgy and articles in the church, or make
the declarations against Popery; or for the abjuration-
 oath; for using any other form of prayer than the li-
turgy of the church of England; or for abjuring him-
self 60 days in one year from a benefice belonging to a
Popish patron, to which the clerk was presented by
either of the universities: in all which, and similar ca-
es, the benefice is ipso facto void, without any formal
sentence of deprivation.

PARSONAGE, a rectory, or parish church, endow-
ed with a glebe, house, lands, tithes, &c for the
maintenance of a minister, with cure of souls within
such parish. See PARSON.

PARSONS, or PERSONS (Robert), an eminent writer of the church of Rome, was born at Nether-
Stowey, near Bridgewater, in Somersetshire, in 1546,
and educated at Baliol college, Oxford, where he di-
gnified himself as a zealous Protestant and an acute
diff-
P ARTERRE, in gardening, a level division of ground, which for the most part faces the south, or is in front of a house, and is generally furnished with evergreens, flowers, &c. There are two kinds of these, the plain ones and the parterres of embroidery.

Plain parterres are most valuable in England, because of the fineness of the English grass turf, which is superior to that of any other part of the world; and the parterres of embroidery are cut into shell and scroll work, with alleys between them. An oblong, or long square is accounted the most proper figure for a parterre; and a parterre should indeed be always twice as long as it is broad, because according to the known laws of perspective, a long square always sinks to a square; and an exact square always appears less than it really is. As to the breadth of a parterre, it is to be proportionable to the front of the house; but less than 100 feet in breadth is too little.

There should be on each side the parterre a terrace walk raised for a view, and the flat of the parterre between the terraces should never be more than 300 feet, at the utmost, in breadth, and about 140 feet in width, with twice and a half that in length, is esteemed a very good size and proportion.

PARTHENIUM, in botany: A genus of the pentandria order, belonging to the monoeous class of plants; and in the natural method ranking under the 40th order, Composite. The male calyx is common and penta-phylous; the florets of the disk monopetalous: the female has five florets of the radius, each with two male florets behind it; the intermediate female superior; the seed is naked. It has been much neglected in Europe, having on Grofer's account of its smell been banished from their parterres.

General description of China.

It is therefore indebted for its culture to the distinguished rank it holds among the Chinese flowers. The skill of the florists, and their continual care, have brought this plant to so great perfection, that Europeans scarcely know it. The elegance and lightness of its branches, the beautiful indention of its leaves, the splendor and duration of its flowers, seem indeed to justify the rusticana of the Chinese for this plant. They have, by their attention to its culture, procured more than 300 species of it: every year produces a new one. A list of the names of all these kinds would be equally tedious and disgusting; we shall only say in general, that in its flowers are united all the possible combinations of shapes and colors. Its leaves are no less various: some of them are thin, others thick; some are very small; and some large and broad; some are indented like those of the oak, while others resemble those of the cherry-tree; some may be seen cut in the form of fans, and others are found serrated on the margin, and tapering towards the points.

Parthenium is propagated in China by seed, and by suckers, grafts, and slips. When the florists have a fine plant, they suffer the seeds to ripen, and about the end of autumn sow them in well prepared earth. Some keep them in this manner during winter, others sow them in spring. Provided they are watered after the winter, they shoot forth, and grow rapidly. After the parthenium has flowered, all its branches are cut three inches from the root, the earth is hoed around, and a little dung is mixed with it; and when the cold be-
comes fever: the plant is covered with hair, or an inverted pot. Those that are in vases are transported to the green-houses, where they are not watered. In spring they are uncovered and watered, and they shoot forth a number of items; of these some florists leave only two or three, others pull up the stalk, together with the whole root, and divide it into several portions, which they transplant elsewhere. There are some who join two slips of different colours, in each of which, towards the bottom, they make a long notch, almost to the pith, and afterwards tie them together with packthread, that they may remain closely united; by these means they obtain beautiful flowers, variegated with whatever colours they choose.

Parthenium requires a good exposure, and fresh moist air that circulates freely: when shut up closely it is certain, that those

Sidetes pitched battles; in consequence of which he was filled in captivity. Phraates was defeated in three pitched battles; in consequence of which he left the whole Roman empire at that time had been very wealthy. As the enemy had not expected an invasion, they were quite unprepared for resistance; and therefore Crausus overran all Mesopotamia; and if he had taken advantage of the confusion which the Parthians were in, might have also reduced Babylonia. But instead of this, early in the autumn, he repelled the Euphrates, leaving only 7000 foot and 1000 horse to garrison the places he had reduced; and putting his army into winter-quarters in Syria, gave himself totally up to his favourite passion of amassing money.

Early in the spring, the Roman general drew his forces out of their winter-quarters, in order to pursue the war with vigour; but, during the winter, Orodes had collected a very numerous army, and was well prepared to oppose him. Before he entered upon action, however, the Parthian monarch sent ambassadors to Crausus, in order to expostulate with him on his injustice in attacking an ally of the Roman empire; but Crausus, without attending to what they said, only returned for answer, that "they should have his answer at Seleucia."

Orodes, finding that a war was not to be avoided, divided his army into two bodies. One he commanded in person, and marched towards Armenia, in order to oppose the king of that country, who had raised a considerable army to afflict the Romans. The other he sent into Mesopotamia, under the command of Surena or Surenas, a most experienced general, by whom all the cities which Crausus had reduced were quickly retaken. On this some Roman soldiers who made their escape, and fled to the camp of Crausus, filled the minds of his army with terror at the accounts of the number, power, and strength of the enemy. They told their fellow-soldiers, that the Parthians were very numerous, brave, and well-disciplined; that it was impossible to overtake them when they fled, or escape them when they pursued: that their defensive weapons were proof against the Roman darts, and their offensive weapons so sharp, that no buckler was proof against them, &c. Crausus looked upon all this only as the effects of cowardice: but the common soldiers, and even many of the chief officers, were so disheartened, that Crausus, the fame who afterwards confpired against Caesar, and most of the legionary tribunes, advised Crausus to suspend his march, and consider better of the enterprise before he proceeded farther in it. But Crausus obstinately persisted in his former resolution, being encouraged by the arrival of Artabazus king of Armenia, who brought with him 6000 horse, and promised to send 10,000 cuirassiers and 30,000 foot, whenever he should stand in need of them. At the same time, he advised him by no means to march his army through the plains of Mesopotamia, but to take his route over the mountains of Armenia. He told him, that as Armenia was a mountainous country, the enemy's cavalry, in which their main strength consisted, would there be entirely useless; and besides, his army would there be plentifully supplied with all manner of necessaries: whereas, if he marched by the way of Mesopotamia, he would be perpetually harassed by the Parthian horde, and frequently obliged to lead his army through sandy deserts, where he would be distressed for want of water and all other provisions. This faithful advice, however,
The Romans had no sooner crossed the Euphrates, than Cassius advised his general to advance to some of these towns in which the Parthians yet remained, in order to halt and refresh his troops; or if he did not choose to follow this advice, he said that his best way would be to march along the banks of the Euphrates to Seleucia; as by this method he would prevent the Parthians from surrounding him, at the same time that he would be plentifully supplied with provisions from his ships. Of this advice Cassius seemed to approve; but was dissuaded by Abgarus king of Edessa, whom the Romans took for an ally, but who was in reality a traitor sent by Surenas to bring about the destruction of the Roman army.

Under the conduct of this faithless guide, the Romans entered a vast green plain divided by many rivulets. Their march proved very easy through this fine country; but the farther they advanced, the worse the country; but the farther they advanced, the worse the roads became, insomuch that they were at last obliged to climb up rocky mountains, which brought them to a dry and sandy plain, where they could neither find food to satisfy their hunger, nor water to quench their thirst. Abgarus then began to be suspected by the tribunes and other officers, who earnestly intreated Cassius not to follow him any longer, but to retreat to the mountains; at the same time an express arrived from Artauras, acquainting the Roman general that Orodes had invaded his dominions in order to defend the Roman army. Thus they continued their march, with the delights of the road, as far as wide as possible, and tired out the Roman army. The Romans had no sooner given the signal, than the Parthians, riding as it were out of the ground with dreadful cries, and a most frightful noise, advanced against the Romans, who were greatly surprised and dismayed at that sight; and much more so, when the Parthians, throwing off the covering of their arms, appeared in flying cuirasses, and helmets of burnished steel, finely mounted on horses covered all over with armour of the same metal. At their head appeared young Surenas, in a rich dress, and was the first who charged the enemy, endeavouring, with his pikemen to break through the first ranks of the Roman army; but finding it too close and impenetrable, the cohorts supporting each other, he fell back, and retired in a seeming confusion; but the Romans were much surprized when they saw themselves suddenly surrounded on all sides, and galled with continual showers of arrows. Cassius ordered his light-armed foot and archers to advance, and charge the enemy; but they were soon repulsed, and forced to cover themselves behind the heavy-armed foot. The Parthian horse, advancing near the Romans, discharged flowers of arrows upon them, every one of which did execution, the legionaries being drawn up in such close order, that it was impossible for the enemy to miss their aim. As their arrows were of an extraordinary weight, and discharged with incredible force and impetuosity, nothing was proof against them. The two wings advanced in good order to repulse them, but to no effect; for the Parthians flot their arrows with as great dexterity when their backs were turned, as...
Parthia. as when they faced the enemy; so that the Romans, whether they kept their ground, or pursued the flying enemy, were equally annoyed with their fatal arrows.

The Romans, as long as they had any hopes that the Parthians, after having spent their arrows, would either betake themselves to flight, or engage them hand to hand, flood their ground with great resolution and intrepidity; but when they observed that there were a great many camels in their rear loaded with arrows, and that those who emptied their quivers wheeled about to fill them anew, they began to lose courage, and loudly to complain of their general for suffering them thus to stand still, and serve only as a butt to the enemy's arrows, which, they well knew, would not be exhausted till they were all killed to a man. Hereupon Crassus ordered his son to advance, at all adventures, and attack the enemy with 1500 horse, 500 archers, and 8 cohorts. But the Parthians no sooner saw this choice body (for it was the flower of the army) marching up against them, than they wheeled about, and betook themselves, according to their custom, to flight. Hereupon young Crassus, crying out as loud as he could, They fly before us, pulled on full speed after them, not doubting but he should gain a complete victory; but when he was at a great distance from the main body of the Roman army, he perceived his mistake; for those who before had fled, facing about, charged him with incredible fury. Young Crassus ordered his troops to halt, hoping that the enemy, upon seeing their small number, would not be afraid to come to a close fight: but herein he was likewise greatly disappointed; for the Parthians, contenting themselves to oppose his front with their heavy armed horse, surrounded him on all sides; and, keeping at a distance, discharged incessant showers of arrows upon the unfortunate Romans, thus surrounded and pent up. The Parthian cavalry, in wheeling about, raised so thick a dust, that the Romans could scarce see one another, much less the enemy: nevertheless, they found themselves wounded with arrows, though they could not perceive whence they came. In short time, the place where they stood was all thrown with dead bodies.

Some of the unhappy Romans finding their entrails torn, and many overcome by the exquisite torments they suffered, rolled themselves in the sand with the arrows in their bodies, and expired in that manner. Others endeavouring to tear out by force the bearded points of the arrows, only made the wounds the larger and increased their pain. Most of them died in this manner; and those who outlived their companions were no more in a condition to act; for when young Crassus exhorted them to march up to the enemy, some showed him their wounded bodies, others their hands nailed to their bucklers, and some their feet pierced through and pinned to the ground: so that it was equally impossible for them either to attack the enemy or defend themselves. The young commander, therefore, leaving his infantry to the mercy of the enemy, advanced at the head of the cavalry against their heavy armed horse. The thousand Gauls whom he had brought with him from the west, charged the enemy with incredible boldness and vigour; but their lances did little execution on men armed with cuirasses, and horses covered with tried armour; however, they behaved with great resolution; for some of them taking hold of the enemy's spears, and closing with them, threw them off their horses on the ground, where they lay without being able to stir, by reason of the great weight of their armour; others dismounting, crept under the enemy's horses, and thrusting their swords into their bellies, made them throw their riders. Thus the brave Gauls fought, though greatly harrassed with heat and thirst, which they were not accuomed to bear, till most of their horses were killed, and their commander dangerously wounded. They then thought it advisable to retire to their infantry, which they no sooner joined, than the Parthians invested them anew, making a most dreadful havoc of them with their arrows. In this desperate condition, Crassus, flying a rising ground at a small distance, led the remains of his detachment thither, with a design to defend himself in the best manner he could, till succours should be sent him from his father. The Parthians pursued him; and having surrounded him in his new post, continued showering arrows upon his men, till most of them were either killed or disabled, without being able to make use of their arms, or give the enemy proofs of their valour.

Young Crassus had two Greeks with him, who had settled in the city of Carrae. These, touched with compassion, at seeing so brave a man reduced to such straits, pressed him to retire with them to the neighbouring city of Iuches, which had declared for the Romans: but the young Roman rejected their proposal with indignation, telling them, that he would rather die a thousand times than abandon so many valiant men, who sacrificed their lives for his sake. Having returned this answer to his two Greek friends, he embraced and dismissed them, giving them leave to retire and shift for themselves in the best manner they could. As for himself, having now lost all hopes of being relieved, and seeing most of his men and friends killed round him, he gave way to his grief; and, not being able to make use of his arm, which was shot through with a large barbed arrow, he presented his side to one of his attendants, and ordered him to put an end to his unhappy life. His example was followed by Centurions a senator, by Megabacchus an experienced and brave officer, and by most of the nobility who served under him. Five hundred common soldiers were taken prisoners, and the rest cut in pieces.

The Parthians, having thus cut off or taken the whole detachment commanded by young Crassus, of young March without delay against his father, who, up. Crassus, on the first advice that the enemy fled before his son, and were closely pursued by him, had taken heart, the more because those who had remained to make head against him seemed to have much of their ardour, the greatest part of them having marched with the rest against his son. Wherefore, having encouraged his troops, he had retired to a small hill in his rear to wait there till his son returned from the pursuit. Young Crassus had dispatched frequent express to his father, to acquaint him with the danger he was in; but they had fallen into the enemy's hands, and been by them put to the sword: only the lost, who had escaped with great difficulty, arrived safe, and inform...
ed him that his son was lost if he did not send him an immediate and powerful reinforcement. This news threw Craus into the utmost consternation; a thousand affecting thoughts rose in his mind, and disturbed his reason to such a degree, that he scarce knew what he was doing. However, the desire he had of saving his son, and so many brave Romans who were under his command, made him immediately decamp, and march to their alliance; but he was not gone far before he was met by the Parthians, who, with loud shouts, and songs of victory, gave, at a distance, the unhappy father notice of his misfortune. They had cut off young Craus's head, and, having fixed it on the point of a lance, were advancing full speed to fall on the father. As they drew near, Craus was struck with that dismal and affecting sight; but, on this occasion, behaved like an hero: for though he was under the deepest concern, he had the presence of mind to flifle his grief, for fear of discouraging the army, and to cry out to the difmayed troops, "This misfortune is entirely mine; the loss of one man is your rage and grief, but, on this occasion, he had the presence of mind to flifle his grief, for fear of discouraging the army, and to cry out to the difmayed troops, "This misfortune is entirely mine; the loss of one man is entirely mine; the loss of one man is yours, not mine. I have lost my son, but you have lost your country."

When the signal was given, the Parthians, keeping to their old way of fighting, discharged clouds of arrows on the legionsaries, without drawing near them; which did such dreadful execution, that many of the Romans, to avoid the arrows, which occasioned a long and painful death, threw themselves, like men in despair, on the enemy's heavy-armed horse, seeking from their spears a more quick and easy kind of death. Thus the Parthians continued plying them incessantly with their arrows till night, when they left the field of battle, crying out, that they would allow the father one night to lament the death of his son.

This was a melancholy night for the Romans. Craus kept himself concealed from the soldiers, lying not in the general's tent, but in the open air, and on the bare ground, with his head wrapped up in his paludamentum or military cloak: and was, in that forlorn condition, says Plutarch, a great example to the vulgar of the inutility of fortune; to the wise, a still greater of the pernicious effects of avarice, temerity, and ambition. Ædavius, one of his lieutenants, and Caflius, approached him, and endeavoured to raise him up and console him: but, seeing him quite sunk under the weight of his affliction, and deaf to all comfort, they summoned a council of war, composed of all the chief officers; wherein it was unanimously resolved, that they should decamp before break of day, and retire, without sound of trumpet, to the neighbouring city of Carrhâr, which was held by a Roman garrison. Agreeable to this resolution, they began their march as soon as the council broke up; which produced dreadful outrages among the sick and wounded, who, perceiving that they were to be abandoned to the mercy of the enemy, filled the camp with their complaints and lamentations: but their cries and tears, though very affecting, did not stop the march of the others, which, indeed, was very slow, to give the stragglers time to come up. There were only 300 light horse, under the command of one Ægatus, who pursued their march without stopping. These arriving at Carrhâr about midnight, Ægatus, calling to the centinels on the walls, desired them to acquaint Coponius, governor of the place, that Craus had fought a great battle with the Parthians; and, without saying a word more, or letting them know who he was, continued his march with all possible expedition to the bridge of Zeugma; which he passed, and by that means saved his troops, but was much blamed for abandoning his general.

However, the message he sent to Coponius was of some temporary service to Craus. For that commander, widely conjecturing, from the manner in which the unknown person had given him that intelligence, that some misfortune had befallen Craus, immediately ordered his garrison to stand to their arms; and, marching out, met Craus, and conducted him and his army into the city: for the Parthians, though informed of his flight, did not offer to pursue him, observing therein the superstitious custom which obtained among them and the Persians, not to fight in the night; but when it was day, they entered the Roman camp, and having put all the wounded, to the number of 4000, to the sword, dispersed their cavalry all over the plain, in pursuit of the fugitives. One of Craus's lieutenants, named Vargunteius, having separated in the night from the main body of the army, with four cohorts, missed his way, and was overtaken by the enemy; at whose approach, they entered into a neighbouring hill, where he defended himself with great valour, till all his men were killed, except 20, who made their way through the enemy sword in hand, and got safe to Carrhâr: but Vargunteius himself left his life on this occasion. In the mean time Surenas, not knowing whether Craus and Caflius had retired to Carrhâr, or chosen a different route; in order to be informed of the truth, and make his measures accordingly, dispatched a messenger, who spoke the Roman language, to the city of Carrhâr, enjoining him to approach the walls, and acquaint Craus himself, or Caflius, that the Parthian general was inclined to enter into a treaty with them, and demanded a conference. Both the proconful and his quaeter Caflius spoke from the walls with the messenger; and, accepting the proposal with great joy, desired that the time and place for an interview might be immediately agreed upon. The messenger withdrew, promising to return quickly with an answer from Surenas; but that general no sooner understood that Craus and Caflius were in Carrhâr, than he marched thither with his whole army; and, having invested the place, acquainted the Romans, that if they expected any favourable terms, they must deliver up Craus and Caflius to him in chains. Hereupon a council of the chief officers being summoned, it was thought expedient to retire from Carrhâr that very night, and seek for another asylum. It was of the utmost importance that none of the inhabitants of Carrhâr should be acquainted with their design till the time of its execution; but Craus, whose whole conduct evidently shows that he was blinded, as Dio Caflius observes, by
by some divinity, imparted the whole matter in confidence to one Andromachus, choosing him for his guide, and relying injudiciously on the fidelity of a man whom he scarce knew. Andromachus immediately acquainted Surenas with the design of the Romans; promising at the same time, as the Parthians did not engage in the night, to manage matters so, that they should not get out of his reach before day-break. Pursuant to his promise, he led them through many windings and turnings, till he brought them into deep marshy grounds, where the infantry were up to the knees in mire. Then Caillus, suspecting that their guide had led them into those bogs with no good design, refused to follow him any longer; and, returning to Carrhae, took his route towards Syria which he reached with 500 horse. Octavius, with 5000 men under his command, being conducted by truculent guides, gained the mountains called by Plutarch and Appian Sinanias, and there entrenched himself before break of day.

As for Cælius, he was still entangled in the marshes, when Surenas, at the rising of the sun, overtook him, and invested him with his cavalry. The proconsul had with him four cohorts, and a small body of horse, and with these he gained, in spite of all opposition, the summit of another hill within 12 furlongs of Octavius; who, seeing the danger that threatened his general, flew to his assistance, first with a small number of his men, but was soon followed by all the rest, who, being ashamed of their cowardice, quitted their post, tho' very safe, and, charging the Parthians with great fury, disengaged Cælius, and obliged the enemy to abandon the hill. Upon the retreat of the enemy, they formed themselves into an hollow square; and placing Cælius in the middle, made a kind of rampart round him with their bucklers, resolutely protecting, that none of the enemy's arrows should touch their general's body, till they were all killed fighting in his defence. Surenas, loth to let so fine a prey escape, surrounded the hill, as if he designed to make a new attack; but, finding his Parthians very backward, and not doubting but the Romans, when night came on, would pursue their march, and get out of his reach, he had recourse again to artifice; and declared before some prisoners, whom he sion after fet at liberty, that he was inclined to treat with the proconsul of a peace; and that it was better to come to a reconciliation with Rome, than to fow the seeds of an eternal war, by shedding the blood of one of his generals.

Agreeable to this declaration, Surenas, as soon as the prisoners were released, advanced towards the hill where the Romans were posted, attended only by some of his officers, and, with his bow unbent, and open arms, invited Cælius to an interview. So Sudden a change seemed very suspicious to the proconsul; who therefore declined the interview, till he was forced, by his own soldiers, to intrust his life with an enemy whose treachery they had all experienced; for the legionaries flocking round him, not only abused him in an outrageous manner, but even menaced him if he did not accept of the proposals made him by the Parthian general. Seeing, therefore, that his troops were ready to mutiny, he began to advance, without arms or guards, towards the enemy, after having called the gods and his officers to witness the violence his troops offered him; and intreated all who were present, but especially Octavius and Petronius, two of the chief commanders, for the honour of Rome their common mother, not to mention, after his death, the shameful behaviour of the Roman legionaries. Octavius and Petronius could not resolve to let him go alone; but attended him down the hill, as did likewise some legions, keeping at a distance. Cælius was met at the foot of the hill by two Greeks; who, dismounting from their horses, saluted him with great respect: and directed him, in the Greek tongue, to send some of his attendants, who might satisfy him that Surenas, and those who were with him, came without arms. Hereupon Cælius sent two brothers, of the Roxian family; but Surenas, having caused them to be feized, advanced to the foot of the hill, mounted on a fine horse, and attended by the chief officers of his army. Cælius, who waited for the return of his two messengers, was surprized to see himself prevented by Surenas in person, when he least expected it. The Parthian general, perceiving, as he approached Cælius, that he was on foot, cried out, in a seeming surpise, "What do I see? a Roman general on foot, and we on horseback! Let an horse be brought for him immediately." "You need not be surprized (replied Cælius): we are come only to an interview, each after the custom of his country." 'Very well (answered Surenas), there shall be henceforth a lasting peace between king Orodes and the people of Rome: but we must sign the articles of it on the banks of the Euphrates; for you Romans do not always remember your conventions." Cælius would have sent for an horse: but a very lately one, with a golden bit, and richly caparisoned, was brought to him by a Parthian; which Surenas preferring to him, "Accept this horse from my hands (said he), which I give you in the name of my master king Orodes." He had scarce uttered these words, when some of the king's officers, taking Cælius by the middle, sat him upon the horse, which they began to whip with great violence in order to make him quicken his pace. Octavius, offended at this insult, took the horse by the bridle; Petronius, and the few Romans who were present, seconded him, and flogging all round Cælius, flapped his horse. The Parthians endeavoured to repulse them, and clear the way for the proconsul: whereupon they began to jumble and pull one another with great tumult and disorder. At last, Octavius, drawing his sword, killed one of the king's grooms; but, at the same time, another coming behind Octavius, with one blow laid him dead at his feet. Both parties fought with great resolution, the Parthians striving to carry off Cælius, and the Romans to rescue him out of their hands. In this skilful most of the Romans who came to the conference were killed; and, among the Rest, Cælius himself, but whether by a Roman or a Parthian, is uncertain.

Upon his death, the rest of the army either surrendered to the enemy, or dispersing in the night, were pursued, and put to the sword. The Romans lost in this campaign at least 30,000 men; of which 20,000 were killed, and 10,000 taken prisoners.

When the battle of Carrhae was fought, king Orodes was in Armenia, where he had made peace with Artabazus.
Surenas put to death by Orodes.

Surenas did not long enjoy the pleasure of his victory; for Orodes, jealous of his power and authority among the Parthians, soon after caused him to be put to death. Pacorus, the king's favourite son, was put at the head of the army; and, agreeable to his father's directions, invaded Syria: but he was driven out from thence with great loss by Cicero and Caiffius, the only general who survived the defeat of Crassus. After this we find no mention of the Parthians, till the time of the civil war between Caesar and Pompey, when the latter sent ambassadors to solicit succours against his rival. This Orodes was willing to grant, upon condition that Syria was delivered up to him; but as Pompey would not consent to such a proposal, the succours were not only denied, but, after the battle of Pharsalia, he put Lucius Hirtius in irons, whom Pompey had again sent to ask assistance, or at least to desire leave to shelter himself in the Parthian dominions.

Caesar is said to have meditated a war against the Parthians, which in all probability would have proved fatal to them. His death delivered them from this danger. But, not long after, the eastern provinces, being grievously oppressed by Mark Antony, rose up in arms; and having killed the tax-gatherers, invited the Parthians to join them, and drive out the Romans. They very readily accepted the invitation, and crossed the Euphrates with a powerful army under the command of Pacorus and Labienus a Roman general of Pompey's party. At first they met with great success, overran all Asia Minor, and reduced all the countries as far as the Hellepont and the Ægean Sea, subduing likewise Phœnicia, Syria, and even Judea. They did not however long enjoy their new conquests: for being elated with their victories, and despising the enemy, they engaged Ventidius, Antony's lieutenant, before Labienus had time to join them, and were utterly defeated. This so disheartened Labienus' army, that they all abandoned him; and he himself, being thus obliged to wander from place to place in disguise, was at last taken and put to death at Cyprus. Ventidius pursuing his advantage, gained several other victories; and at last entirely defeated the Parthian army under Pacorus, cutting almost the whole of them in pieces, and the prince himself among the rest. He did not, however, pursue this last victory as he might have done; being afraid of giving umbrage to Antony, who had already become jealous of the great honour gained by his lieutenant. He therefore contented himself with reducing those places in Syria and Phœnicia which the Parthians had taken in the beginning of the war, until Antony arrived to take the command of the army upon himself.

Orodes was almost distracted with grief on receiving the dreadful news of the loss of his army and the death of his favourite son. However, when time had restored the use of his faculties, he appointed Phraates, the eldest, but the most wicked, of all his children, to succeed him in the kingdom, admitting him at the same time to a share of the sovereign authority with himself. The consequence of this was, that Phraates very soon attempted to poison his father with hemlock. But this, contrary to expectation, proved a cure for the dropsey, which an excess of grief had brought upon the king, the unnatural son had him stifled in bed; and soon after not only murdered all his own brethren, who were 30 in number, but cut off all the rest of the royal family, not sparing even his own eldest son, left the discontented Parthians should place him, as he was already of age, on the throne.

Many of the chief lords of Parthia being intimidated by the cruelty of Phraates, retired into foreign countries; and among these was one Monees, a person of great distinction, as well as skill and experience in war. This man, having fled to Antony, soon gained his confidence, and was by him easily prevailed upon to engage in a war against his countrymen. But Phraates, justly dreading the consequences of such a perfon's defection, sent a solemn embassy to invite him home on such terms as he should think fit to accept: which greatly provoked Antony; though he did not hinder him from returning, left others should thereby be discouraged from coming over to him. He therefore dismissed him with great civility, sending ambassadors at the same time to Phraates to treat of a peace. Thus he hoped to divert the Parthian monarch's attention from making the necessary preparations for war, and that he should be able to fall upon him in the spring when he was in no condition to make resistance. But herein he was greatly disappointed; for on his arrival at the Euphrates, which he intended to pass, and enter the Parthian dominions on that side, he found all the posts so well guarded, that he thought proper to enter Media, with a design first to reduce that country, and then to enter Parthia.

This plan had been suggested to him by Artabanus the king of Armenia, who in the end betrayed him; for instead of conducting the army the straight way from Zorgma on the Euphrates, to the Araxes which parted Media from Armenia, and which was about 500 miles distant from the place whence he first set out, Artabanus led them over rocks and mountains so far about, that the army had marched above 1000 miles before they reached the borders of Media, where they intended to begin the war. Thus they were not only greatly fatigued, but had not sufficient time, the year being far spent, to put in execution the design on which they had come. However, as Antony was impatient to get back to Cleopatra, he left behind him most of the baggage of the army, and 300 waggons loaded with battering rams and other military engines for sieges; appointing Statianus, one of his lieutenants, with a body of 10,000 men to guard them, and to bring them, by flower marches, after the army.
army. With the rest of the forces he marched more than 300 miles before the reft, without allowing his men any respite till he arrived at Praapha or Phrahaata, the capital of Media, which he immediately invested. But the Parthians, well knowing that he could not make any progress without his military machines, palled by his army, in order to attack Statianus; which they did with such success, that the body commanded by him were all to a man cut off, and all their military engines taken, among which was a battering ram 80 feet long.

Antony, notwithstanding this disaster, continued the siege of Praapha; but was daily harassed by failies of the garrison from within, and the enemy’s army without. At last he began to think of a retreat when his provisions were almost exhausted, finding it impossible to become master of the city. But as he was to march 300 miles through the enemy’s country, he thought proper firft to send ambassadors to the Parthian monarch, acquainting him that the Roman people were willing to allow him a peace, provided he would restore the standards and prisoners taken at Carrhae. Phraates received the ambassadors, sitting on a golden throne; and, after having bitterly inveighed against the avarice and unbounded ambition of the Romans, told them that he would not part with the standards and prisoners; but that if Antony would immediately raise the siege of Praapha, he would suffer him to retire unmolested.

Antony, who was reduced to great straits, no sooner received this anfwer than he broke up the siege, and marched towards Armenia. However, Phraates was not fo good as his word; for the Romans were attacked by the enemy no fewer than 18 times on their march, and were thrice in the utmost danger of being cut off. A famine also raged in the Roman army; upon which they began to defert to the enemy; and indeed Antony would probably have been left by himself, had not the Parthians, in a very cruel as well as impolitic manner, murdered all those who fled to them in flight of the reft. At last, after having lost 32,000 men, and being reduced to such despair that he was with difficulty seduced from laying violent hands on himself, he reached the river Araxes; when his men, finding themselves cut off from the reach of the enemy, fell down on the ground, and killed it with tears of joy.

Antony was no sooner gone, than the kings of Media and Parthia quarrelled about the bootie the had taken; and after various contentions Phraates reduced all Media and Armenia. After this, being elated with his conquests, he oppressed his subjects in such a cruel and tyrannical manner, that a civil war took place, in which the competitors were alternately driven out and restored, till the year 50, when one Vologeses, the son of Gortarzes, a former king, became peaceable possessor of the throne. He carried on some wars against the Romans, but with very indifferently success, and at last gladly consented to a renewal of the ancient treaties with that powerful people.

From this time the Parthian history affords nothing remarkable till the reign of the emperor Trajan; when the Parthian king, by name Cotrites, infringed the treaty with Rome, by driving out the king of Armenia. Upon this Trajan, who was glad of any tenance to quarrel with the Parthians, immediately hastened into Armenia. His arrival there was fo sudden and unexpected, that he reduced almost the whole country without opposition; and took prisoner Parthamapris, the king whom the Parthians had fet up. After this he entered Mesopotamia, took the city of Nifibis, and reduced to a Roman province the whole of that wealthy country.

Early in the spring of the following year, Trajan, who had kept his winter quarters in Syria, took the field again; but was warmly opposed by Cotrites. He found him encamped on the banks of the Euphrates, with a design to dispute his passage; which he did with such vigour, that the emperor, after having several times attempted to ford that river, and being always repelled with great slaughter, was obliged to cause boats to be built on the neighbouring mountains, which he privately conveyed from thence on carriages to the water side; and having in the night time formed a bridge with them, he pulled his army the next day; but not wishing great loss and danger, the Parthians harrying his men the whole time with incessant showers of arrows, which did great execution. Having gained the opposite bank, he advanced boldly into Assyria, the Parthians flying every where before him, and made himself master of Arbela. Thence he pursued his march, subduing, with incredible rapidity, countries where the Roman standard had never been displayed before. Babylonia, or the province of Babylon, voluntarily submitted to him. The city itself was, after a vigorous resistance, taken by storm; by which means he became master of all Chaldea and Assyria, the two richest provinces of the Parthian empire.

From Babylon he marched to Ctesiphon, the metropolis of the Parthian monarchy; which he besieged, and at last reduced. But as to the particulars of these great conquests, we are quite in the dark; this expedition, however glorious to the Roman name, being rather hinted at than described, by the writers of those times. While Trajan was thus making war in the heart of the enemy’s country, Cotrites, having recruited his army, marched into Mesopotamia, with a design to recover that country and cut off all communication between the Romans and Syria. On his arrival in that province, the inhabitants fled to him from all parts; and most of the cities, driving out the garrisons left by Trajan, opened their gates to him. Hereupon the emperor detached Lucius and Maximus, two of his chief commanders, into Mesopotamia, to keep such cities in awe as had not revolted, and to open a communication with Syria. Maximus was met by Cotrites; and having ventured a battle, his army was entirely defeated, and himself killed. But Lucius being joined by Eutichus and Clarius, two other commanders sent by Trajan with fresh supplies, gained considerable advantages over the enemy, and retook the cities of Nifibis and Seleucia, which had revolted.

And now Trajan, seeing himself possessed of all the best and most fruitful provinces of the Parthian empire, but at the same time being well apprized that he could not without a vast expense, maintain his conquests, nor keep in subjection so fierce and warlike a people at such a distance from Italy; resolved to set over them a king of his own choosing, who should hold the crown of him and his successors, and acknowledge...
them as his lords and sovereigns. With this view he repaired to Ctesiphon; and having there assembled the chief men of that nation, he crowned one of the royal family, by name Parthanaepates, king of Parthia, obliging all who were present to pay him their allegiance. He chose Parthanaepates, because that prince had joined him on his first entering the Parthian dominions, conducted him with great fidelity, and shown on all occasions an extraordinary attachment to the Romans. Thus the Parthians were at last subdued, and their kingdom made tributary to Rome. But they did not long continue in this state of subjection: for they so soon heard of Trajan’s death, which happened shortly after, than, taking up arms, they drove Parthanaepates from the throne; and recalling Cofdroes, who had retired into the country of the Hyrcanians, openly revolted from Rome. Adrian, who was then commander in chief of all the forces in the east, and soon after acknowledged emperor by the army, did not care, though he was at that time in Syria with a very numerous army, to engage in a new war with the Parthians; but contented himself with preserving the ancient limits of the empire, without any ambitious prospects of further conquests. Therefore, in the beginning of his reign, he abandoned those provinces beyond the Euphrates which Trajan had conquered; withdrew the Roman garrisons from Syria; and, for the greater safety of other places, made the Euphrates the boundary of and barrier in those parts, polishing his legs on the banks of that river.

Cofdroes died after a long reign, and was succeeded by his elder son Vologeses; in whose reign the Alani breaking into Media, then subject to the Parthians, committed there great devastations; but were prevailed upon, with rich presents sent them by Vologeses, to abandon that kingdom and return home. Upon their retreat, Vologeses, having no enemy to contend with at home, fell unexpectedly upon Armenia; surprised the legions there; and having cut them all in pieces to a man, entered Syria; defeated with great slaughter Attius Cornelius, governor of that province; and advanced without opposition to the neighbourhood of Antioch; putting everywhere the Romans, and those who favoured them, to the sword. Hereupon the emperor Verus, by the advice of his colleague Antoninus fornamed the Philosopher, leaving Rome, hastened into Syria: and having driven the Parthians out of that province, ordered Statius Primus to invade Armenia; and Caiusius, with Marcus Vetus, to enter the Parthian territories, and carry the war into the enemy’s country. Primus made himself master of Artaxata; and in one campaign drove the Parthians, though not without great loss on his side, quite out of Armenia. Caiusius, on the other hand, having in several encounters defeated Vologeses, tho’ he had an army of 400,000 men under his command, reduced, in four years time, all those provinces which had formerly submitted to Trajan, took Seleucia, burnt and plundered the famous cities of Babylon and Ctesiphon, with the stately palaces of the Parthian monarchs, and struck terror into the most remote provinces of that great empire. On his return, he lost above half the number of his forces by sickness and famine: so that, after all, the Romans, as Spartianusobserve, had no great reason to boast of their victories and conquests.

However, Verus, who had never flirred during the whole time of the war from Antioch and Daphne, took upon him the lofty titles of Parthicus and Armenius, as if he had acquired them justly in the midst of his pleasures and debaucheries. After the revolt and death of Caiusius, Antoninus the Philosopher, repaired into Syria to settle the affairs of that province. On his arrival there, he was met by ambassadors from Vologeses; who, having recovered most of the provinces subdued by Caiusius, and being unwilling either to part with them or engage in a new war, solicited the emperor to confirm him in the possession of them, promising to hold them of him and to acknowledge the sovereignty of Rome. To these terms Antoninus readily agreed, and a peace was accordingly concluded between the two empires; which Vologeses did not long enjoy, being soon after carried off by a disentemper, and not murdered by his own subjects, as we read in Constantinus Manaios, who calls him Beleges.

Upon his death, Vologeses III. the son of his brother Sanatruces, and grandson of Cofdroes, was raised to the throne. He sided with Niger against the emperor Severus: who thereupon having settled matters at home, marched with all his forces against him; and advancing to the city of Ctesiphon, whether he had retired, laid close siege to that metropolis. Vologeses made a most gallant defence; but the city, after a long siege, and much bloodshed on both sides, was at length taken by assault. The king’s treasuries, with his wives and children, fell into the emperors hands: but Vologesius himself had the good luck to make his escape; which was a great disappointment to Severus, who immediately dispatched an express to acquaint the senate with the success that had attended him in his expedition against the only nation that was then formidable to Rome. But he had no sooner crossed the Euphrates, than Vologeses recovered all the provinces, except Mesopotamia, which he had reduced. These expeditions were chargeable to the Romans, and cost them much blood, without reaping any advantages from them; for as they had not sufficient forces to keep in awe the provinces they had subdued, the inhabitants, greatly attached to the family of Arsaces, never failed to return to their ancient obedience as soon as the Roman armies were withdrawn. Vologeses was soon after engaged in a war still more troublesome and destructive, with his brother Artabanus, who, encouraged by some of the discontented nobles, attempted to rob him of the crown, and place it on his own head. Vologeses gained several victories over his brother and rebellious subjects; but died before he could restore the empire to its former tranquility.

Artabanus, who had a numerous army at his disposal, did not meet with any opposition in seizing the throne, vacant by the death of his brother, though Tiridates had a better title to it, as being his elder brother. He had scarce settled the affairs of his kingdom, when the emperor Caracalla, desirous to dignify himself, as several of his predecessors had done, by some memorable exploit against the Parthians, sent a solemn embassy to him, desiring his daughter in marriage. Artabanus, overjoyed at this proposal, which
which he thought would be attended with a lasting peace between the two empires, received the ambassadors with all possible marks of honour, and readily complied with their request. Soon after, Caracalla sent a secret embassy to acquaint the king that he was coming to formalise the negotiations; whereupon Artabanus went to meet him attended with the chief of the nobility and his bulk troops, all unarmed, and in most propitious habits; but this peaceable train, no sooner approached the Roman army, than the soldiers, on a signal given them, falling upon the king’s retinue, made a most terrible slaughter of the unarmed multitude, Artabanus himself escaping with great difficulty. The treacherous Caracalla, having gained by this exploit great booty, and, as he thought, no least glory, wrote a long and boding letter to the senate, assuming the title of Parthian for this piece of treachery; as he had before that of Germanicus, for murdering, in like manner some of the German nobility.

Artabanus, resolving to make the Romans pay dear for their inhuman and barbarous treachery, raised the most numerous army that had ever been known in Parthia, crossed the Euphrates, and entered Syria, putting all to fire and sword. But Caracalla being murdered before this invasion, Macrinus, who had succeeded him, met the Parthians at the head of a mighty army, composed of many legions, and all the auxiliaries of the Hyrcanian. The two armies no sooner came in sight of each other, but they engaged with the utmost fury. The battle continued two days; both Romans and Parthians fighting so obstinately, that night only parted them, without any apparent advantage on either side; though both retired when night had put an end to the contest, crying, Victory, Victory. The field of battle was covered all over with dead bodies, there being already above 40,000 killed, including both Romans and Parthians: nevertheless Artabanus was heard to say, that the battle was only begun, and that he would continue it till either the Parthians or Romans were all to a man cut in pieces. But Macrinus, being well apprised that the king came highly enraged against Caracalla in particular, and dreading the consequences which would attend the destruction of his army, sent an herald to Artabanus, acquainting him with the death of Caracalla, and proposing an alliance between the two empires. The king, understanding that his great enemy was dead, readily embraced the proposals of peace and amity, upon condition that all the prisoners who had been taken by the treachery of Caracalla should be immediately restored, and a large sum of money paid him to defray the expenses of the war. These articles being performed without delay or hesitation, Artabanus returned into Parthia, and Macrinus to Antioch.

As Artabanus left on this occasion the flower of his army, Artaxerxes, a Perian of mean descent, but of great courage and experience in war, revolting from the Parthians, prevailed on his countrymen to join him, and attempt the recovery of the sovereign power, which he said they had been unjustly deprived of, first by the Macedonians, and afterwards by the Parthians, their valets. Artabanus, upon the news of this revolt, marched with the whole strength of his kingdom to suppress it; but being met by Artaxerxes at the head of a no less powerful army, a bloody battle ensued, which is said to have lasted three days. At length the Parthians, though they beheld with the utmost bravery, and fought like men in despair, were forced to yield to the Persians, who were commanded by a more experienced leader. Most of their troops were cut off in the flight; and the king himself was taken prisoner, and soon after put death at Artaxerxes’s order. The Parthians, having left in this fatal engagement both their king and their army, were forced to submit to the conqueror, and become vassals to a nation which had been subject to them for the space of 475 years.

For an account of the manners, customs, &c. of the ancient Parthians, see the article PARTIA.

PARTI, PARTIE, Pa ty, or Prised in heraldry, is applied to a field or etchelon denting, it divided or marked out into partitions.

PARTI per pale, is when the field is divided perpendicularly into two halves, by a cut in the middle from top to bottom.

PARTI per fess, is when the cut is across the middle from side to side.

PARTI per bend sinister, is when the cut comes from the upper corner, defends a part to the opposite lower corner.

PARTI per bend sinister, is when the cut comes from the upper right corner, defends across to the opposite lower one.

All these partitions, according to M. de la Colombarie, have their origin from the cuts and bruises that have appeared on shields after engagements: and, being proofs of the dangers to which the bearers had been exposed, they gained them esteem; for which reason they were transmitted to posterity, and became arms and marks of honour to their future families.

PARTIALITY. See self-partiality and Prejudice.

PARTICLE, in grammar, an adjective formed of a verb; so called, because it participates partly of the properties of a noun, and partly of those of a verb: See Grammar.

PARTICLE, in physiology, the minute part of a body, an assemblage of which constitutes all natural bodies.

In the new philosophy, particle is often used in the same sense with atom in the ancient Epicurean philosophy, and corpuscle in the latter. Some writers, however, distinguish them: making particle an assemblage or composition of two or more primitive and physically indivisible corpuscles or atoms: and corpuscle, or little body, an assemblage or mass of several particles of secondary corpuscles. The distinction, however, is of little moment, and, as to most purports of physics, particle may be understood as synonymous with corpuscle. Particles are then the elements of bodies; it is the various arrangement and texture of these, with the difference of the cohesion, &c. that constitute the various kind of bodies, hard, soft, liquid, dry, heavy, light, &c. The smallest particles of corpuscles cohere with the strongest attractions, and always compose bigger particles of weaker cohesion; and many of these cohering compose bigger particles, whose vigour is still weaker; and thus on for divers successions, till the progress ends in the biggest particles, wherein the operations in chemistry, and the
colours of natural bodies, depend, and which by cohesion compose bodies of sensible bulbs.

The cohesion of the particles of matter, according to the Epicureans, was effected by hooked atoms; the Aristotelians thought it managed by newts, that is, by nothing at all. But Sir Isaac Newton shows it is done by means of a certain power, whereby the particles mutually attract or tend towards each other, which is still perhaps giving a faq without the cause. By this attraction of the particles he shows that most of the phenomena of the lefser bodies are affected, as those of the heavenly bodies are by the attraction of gravity. See Attraction and Cohesion.

Particle, a term in theology, used in the Latin church for the crumbs or little pieces of consecrated bread, called in the Greek church μισθον. The Greeks have a particular ceremony, called τοιο μισθον, of the particles, wherein certain crumbs of bread, not consecrated, are offered up in honour of the Virgin, St John Baptist, and several other saints. They also give them the name of ὑποτελον, oblation. Gabriel archbishop of Philadelphia wrote a little treatise express τοιο τω μισθων, wherein he endeavours to show the antiquity of this ceremony, in that it is mentioned in the liturgies of St. Chriftolom and Basil. There has been much controversy on this head between the reformed and catholic divines. Aubertin and Blondel explain it, endeavours to show that the passage itself is an interpolation, not being found in the ancient copies of manuscripts, and consequently that the dispute is very much grounded.

Organic Particles, are those small moving bodies which are imperceptible without the help of glaziers; for besides those animals which are perceptible to the sight, some naturalists reckon this exceedingly small species as a separate class, if not of animals properly so called, at least of moving bodies, which are found in the femen of animals, and which cannot be seen without the help of the microscope. In consequence of these observations, different students of generation have been proposed concerning the spermatic worms of the male and the eggs of the female. In the second volume of Buffon's Natural History, several experiments are related, tending to show that those moving bodies which we discover by the help of glaziers in the male semen are not real animals, but organic, lively, active, and indestructible molecules, which possefs the propriety of becoming a new organized body similar to that from which they were extrated. Buffon found such bodies in the female as well as in the male semen; and he supposes that the moving bodies which he observed with the microscope in infusions of the germs of plants are likewise vegetable organic molecules. Needham, Writberg, Spallanzani, and several other writers on the animal economy, have pursued the same track with M. de Buffon.

Some suppose that these organic molecules in the semen answer no purpose but to excite the venereal desire; but such an opinion cannot be well founded; for eunuchs, who have no seminal liquor, are nevertheless subject to venereal desire. With respect to the beautiful experiments which have been made with the microscope on organic molecules, M. Bonnet, that learned and excellent observer of nature, remarks that they seem to carry us to the farthest verge of the sensible creation; but they have not yet shown us that the smallest visible globule of seminal liquor is the commencement of another universe, which, from its infinite smallness, is beyond the reach of our best microscopes.

-Animalcula, properly so called, must not be confused with the wonderful organic particles of Buffon. See Animalcula.

Particle, in grammar, a denomination for all those small words that tie or unite others, or that express the modes or manners of words. See Grammar.

Parting, in metallurgy. See Metallurgy.

Parting, in chemistry an operation by which gold and silver are separated from each other. As these two metals resist equally well the action of fire and of lead, they must therefore be separated by other methods. This separation could not be effected if they were not soluble by different mercurums. Nitrous acid, marine acid, and sulphur, which cannot dissolve gold, attack silver very easily; and therefore these three agents furnish methods of separating silver from gold, or of the operation called parting.

Parting by nitrous acid is the most convenient, and therefore most used, and even almost the only one employed by goldsmiths and coiners. Wherefore it is called simply parting. That made with the marine acid is only made by cementation, and is known by the name of concentrated parting. Lastly, parting by sulphur is made by fusion, which chemists call the dry way, and is therefore called dry parting.

Parting by aquafortis. Although parting by aquafortis be easy, as we have said, it cannot however succeed or be very exact, unless we attend to some essentiel circumstances.

1. The gold and silver must be in a proper proportion; for if the gold was in too great quantity, the silver would be covered and guarded by it from the action of the acid.

Therefore, when eflayers do not know the proportion of these two metals in the mass to be operated upon, they discover it by the following method.

They have a certain number of needles composed of gold and silver allayed together in graduated proportions, and the alloy of each needle is known by a mark upon it. These are called proof needles.

When eflayers want to know nearly the proportion of gold and silver in a mass, they rub this mass upon a touchstone, so as to leave a mark upon it. They then make marks upon the touchstone with some of the needles the colour of which they think comes nearest to that of the mass. By comparing the marks of these needles with the mark of the mass, they discover nearly the proportion of the gold and silver in the mass.

If this trial shows, that in any given mass the silver is not to the gold as three to one, this mass is improper for the operation of parting by aquafortis. In this case, the quantity of silver necessary to make an alloy of that proportion must be added.

This operation is called Quaquation, probably because it reduces the gold to a fourth part of the whole mass.

2. That the parting may be exact, the nitrous acid or
Parting or aquafortis employed must be very pure, and especially free from mixture of vitriolic and marine acids. For if this was not attended to, a quantity of silver proportionable to these two foreign acids would be separated during the solution: and this portion of silver reduced by these acids to the oxide of silver and to luna cornes would remain mingled with the gold, which consequently would not be entirely purged by the operation.

When the metallic mass is properly alloyed, it is to be reduced to plates, rolled up spirally, called cornets; or to grains. These are to be put into a matras, and upon them a quantity of aquafortis is to be poured, the weight of which is to that of the silver as three to two: and as the nitrous acid employed for this operation is rather weak, the solution is assisted, especially at first, by the heat of a sand bath, in which the matras is to be placed. When, notwithstanding the heat, no further mark of solution appears, the aquafortis charged with silver is to be decanted. Fresh nitrous acid is to be poured into the matras, stronger than the former, and in less quantity, which must be bled on the residuous mass, and decanted as the former. Aquafortis must even be boiled a third time on the remaining gold, that all the silver may be certainly dissolved. The gold is then to be washed with boiling water. This gold is very pure if the operation has been performed with due attention. It is called gold of parting.

No addition of silver is required, if the quantity of silver of the mass is evidently much more considerable than that of the gold: persons who have not proof needles and other apparatus to determine the proportion of the alloy, may add to the gold an indeterminate quantity of silver, observing that this quantity be rather too great than too small, and so considerable as to render the mass nearly as white as silver; for a large quantity of silver is rather favourable than hurtful to the operation: It has no other inconvenience than an useless expense, as the larger the quantity is of silver the more aquafortis must be employed. We ought to attend to this fact, that the colour of gold is scarcely perceptible in a mass two-thirds of which is silver and one-third is gold; this colour thea must be much less perceptible when the gold is only one-fourth part, or less, of the whole mass.

If the quantity of gold exceeds that of the silver, the mass may be exposed to the action of aqua-regia, which would be a kind of inverse parting, because the gold is dissolved in that menstruum, and the silver is not, but rather reduced to a luna cornea, which remains in form of a precipitate after the operation. But this method is not much practised, for the following reasons.

First, the gold cannot be easily separated from the aqua-regia; for if the parting has been made with an aqua-regia prepared with sal-ammoniac, or if the gold be precipitated by a volatile alkali, this gold has a fulminating quality, and its reduction requires particular operations. If the aqua-regia has been made with spirit of salt, and the precipitation effected by a fixed alkali, the gold will not then be fulminating, but the precipitation will be very slow, and probably incomplete.

Secondly, in the parting by aqua regia, the silver is indeed precipitated into a luna cornea, and thus separated; but this separation is not perfect, as a small quantity of luna cornea will always remain dissolved by the aqua-regia, tending to reduce the purity of the gold. Accordingly, the silver is not so accurately separated from the gold by aqua-regia, as the gold is from the silver by aquafortis.

The gold, after the parting by aquafortis, is much more easily collected when it remains in small masses than when it is reduced to a powder.

When the masses has been regularly parted, that is, when it contains three parts of silver and one part of gold, we must employ, particularly for the first solution, an aquafortis so weakened that heat is required to assist the solution of the silver; by which means the solution is made gentle; and the gold which remains prefers the form of the small masses before the solution. If the aquafortis employed were stronger, the parts of the gold would be disunited and reduced to the form of a powder, from the activity with which the solution would be made.

We may indeed part by aquafortis a mass containing two parts of silver to one part of gold; but then the aquafortis must be stronger, and if the solution be not too much hastened, the gold will more easily remain in masses after the operation. In both cases, the gold will be found to be tarnished and blackened, probably from what was lately called the phlogiston of the nitrous acid. Its parts have no cohesion together, because the silver dissolved from it has left many interstices; and the cornets or grains of this gold will be easily broken, unless they be handled very carefully. To give them more solidity, they are generally put into a taff under a muffle and made red-hot; during which operation they contract considerably, and their parts are approximated. These pieces of gold are then found to be rendered much more solid, so that they may be handled without being broken. By this operation also the gold changes its colour and lustre; and as it generally has the figure of cornets, it is called gold in cornets, or grain gold. Eissayers avoid melting it, as they choose to preserve this form, which shows that it has been parted.

The gold and silver thus operated upon ought to have been previously refined by lead, and freed from all alloy of other metallic matters, so that the gold which remains should be as pure as is possible. However, as this is the only metal which refits the action of aquafortis, it might be purified by parting from all other metallic substances; but this is not generally done, for several reasons. First, because the refining by lead is more expeditious and convenient for the separation of the gold from the imperfect metals; secondly, because the silver, when afterwards separated from the aquafortis, is pure; lastly, because most imperfect metals do not remain completely and entirely dissolved in nitrous acid, from the portion of phlogiston which this acid deprives them of; the gold would be found after the parting mixed with the part of these metals which is precipitated.

The gold remaining after the parting ought to be well washed, to cleanse it from any of the solution of silver which might adhere to it; and for this purpose dilufed water ought to be used, or at least water the purity
The aquafortis ought to be so strong as to be capable of acting feebly on silver when cold, but not so strong as to act violently. If the aquafortis be very strong, however pure, and if the vessels be well closed, a small quantity of the gold will be dissolved along with the silver, which is to be guarded against.

Little heat ought to be applied at the beginning, the liquor being apt to swell and rise over the vessel; but when the acid is nearly saturated, the heat may be safely increased.

When the solution ceases, which may be known by the discontinuance of the effervescence, or emission of air-bubbles, the liquor is to be poured off. If any grains appear entire, more aquafortis must be added, that all the silver may be dissolved. If the operation has been performed slowly, the remaining gold will have still the form of distinct mallees, which are to receive solidity and colour by fire, in the manner directed by the author of the dictionary. If the operation has been performed hastily, the gold will have the appearance of a black mud or powder, which after five or six washings with pure water, will become a cement.

The silver is finally recovered by precipitating it from the aquafortis by means of copper-vessels into which the liquor is poured, or of plates of copper which are thrown along with the liquor into glass-vessels. A considerable heat is required to accelerate this precipitation. Dr Lewis says, he has observed that when the aquafortis was perfectly saturated with silver, no precipitation was occasioned by plates of copper, till a drop or two of aquafortis was added to the liquor, and then the precipitation began and continued as usual.

The precipitated silver must be well washed in boiling water, and fused with some nitre; the use of which is to free any cupreous particles which may adhere to the silver.

From the solution of copper in aquafortis, a blue pigment, called verditer, is obtained by precipitation with whiting. Notes to Chem. Dict.

Concentrated Parting, also called Parting by Cementation, because it is actually performed by cementation, is used when the quantity of it is so great in proportion to the silver, that it cannot be separated by aquafortis. This operation is done in the following manner.

A cement is first prepared, composed of four parts of bricks powdered and sifted, of one part of green vitriol calcined till it becomes red, and of one part of common salt. The whole is very accurately mixed together, and a firm paste is made of it by moistening it with a little water or urine. This cement is called cement royal, because it is employed to purify gold, which is considered by chemists as the king of metals.

The gold to be cemented is to be reduced to plates as thin as small pieces of money. At the bottom of the crucible or cementing pot, a stratum of cement, of the thickness of a finger, is to be put, which is to be covered with plates of gold; upon these another stratum of cement is to be laid, and then more plates of gold, till the crucible or pot is filled with these alternate strata of cement and of gold. The whole is then to be covered with a lid, which is to be luted with a mixture of clay and sand. This pot is to be placed in a furnace, or oven, and heated by degrees till it is moderately...
Parting. Moderately red, which heat is to be continued during 24 hours. The heat must not be so great as to melt the gold. The pot or crucible is then left to cool, and the gold is to be carefully separated from the cement, and boiled at different times in a large quantity of pure water. This gold is to be effayed upon a touchstone or otherwise; if it be found not sufficiently purified, it is to be cemented a second time in the same manner.

The vitriolic acid of the bricks and of the calcined vitriol dissolves the acid of the common salt during this cementation: and this latter acid dissolves the silver alloyed with the gold, and separates it by that means.

This experiment proves, that although marine acid, while it is liquid, cannot attack silver, it is nevertheless a powerful solvent of that metal. But for this purpose it must be applied to the silver in the state of vapours, extremely concentrated, and assisted with a considerable heat. All these circumstances are united in the concentrated parting.

This experiment proves also, that notwithstanding all these circumstances, which favour the action of the marine acid, it is incapable of dissolving gold.

Lastly, the marine acid in this state more effectually dissolves the silver than the nitrous acid does in the parting by aquafortis, since this operation succeeds well when the silver is in so small a proportion as that it would be protected from the action of the nitrous acid in the ordinary parting.

Instead of sea-salt, nitre may be used with equal success; because the nitrous acid is then put in a state to attack the silver, notwithstanding the quantity of gold which covers it.

Dry-Parting. Dry-parting, or parting by fusions, is performed by sulphur, which has the property of uniting easily with silver, while it does not attack gold.

This method of separating these two metals would be the cheapest, the most expedients and convenient of any, if the sulphur could dissolve the silver, and separate it from the gold as well and as easily as nitrous acid does; but, on the contrary, we are obliged to employ a particular treatment, and a kind of concentration, to begin the union of the sulphur alloyed with gold. Then repeated and troublesome fusions must be made, in each of which we are obliged to add different intermediate substancess, and particularly the metals which have the strongest affinity with sulphur, to assist the precipitation, which in that case does not give a regular of pure gold, but a gold still alloyed with much silver, and even with a part of the precipitating metals: so that, to complete the operation, cupellation is necessary, and also parting by aquafortis.

From what we have said concerning this operation, we may perceive, that it ought not to be made but when the quantity of silver with which the gold is alloyed is so great, that the quantity of gold which might be obtained by the ordinary parting is not sufficient to pay the expences; and that it is only proper for concentrating a large quantity of gold in a smaller quantity of silver. As this dry parting is troublesome, and even expensive, it ought not to be undertaken but on a considerable quantity of silver alloyed with gold. Accordingly, Cramer, Schlutter, Schlinder, and all good chemists and artists who have given procéedés for the parting, recommended its use only in the abovemention cases. We think that this operation could be improved: it would be more advantageous if it could be done by two or three fusions; and it by these a more exact separation could be obtained of a small quantity of gold mixed with a large quantity of silver.

As this operation for extræcting a small quantity of gold from a large quantity of silver, appears to be by means of sulphur, which unites with and corrodes the silver without affecting the gold; but as sulphurated silver does not flow thin enough to suffer the small particles of gold dissolved through it to reunite and settle at the bottom, some addition is necessary for collecting and carrying them down.

In order to the commixture with the sulphur, 50 or 60 pounds of the mixed metal, or as much as a large crucible will receive, are melted at once, and reduced into grains, by taking out the fluid matter, with a small crucible made red-hot, and pouring it into cold water stirred with a rapid circular motion. From an eighth to a fifth of the granulated metal, according as it is richer or poorer in gold, is reserved, and the rest well mingled with an eighth of powdered sulphur. The grains envelopes with the sulphur and are again put into the crucible, and the fire kept gentle for some time, that the silver, before it melts, may be thoroughly penetrated by the sulphur: if the fire was hastily urged, great part of the sulphur would be disintegrated without acting upon the metal.

If to sulphurated silver in fusion pure silver be added, the latter falls to the bottom, and forms there a distinct fluid not miscible with the other. The particles of gold, having no affinity with the sulphurated silver, join themselves to the pure silver, wherever they come in contact with it, and are thus transferred from the former into the latter, more or less perfectly according as the pure silver was more or less thoroughly soiled through the heat. It is for this use that a part of the granulated metal was reserved. The sulphurated mass being brought into perfect fusion, and kept melted for near an hour in a close covered crucible, one-third of the reserved grains is thrown in; and as soon as this is melted, the whole is well stirred, that the fresh silver may be distributed through the mixed, to collect the gold from it. The stirring is performed with a wooden rod: an iron would be corroded by the sulphur, so as to deprive the mixed of its due quantity of sulphur, and likewise render the subsequent purification of the silver more troublesome. The fusion being continued an hour longer, another third of the un sulphurated grains is added, and an hour after this the remainder; after which the fusion is further continued for some time, the matter being stirred at least every half hour from the beginning to the end, and the crucible kept closely covered in the intervals.

The sulphurated silver appears in fusion of a dark-brown colour; after it has been kept melted for a certain
Partly, in the course of the crucible, according to Mr. Scheffer, the surface becomes white, and some bright drops of silver, about the size of peas, are perceived on it. When this happens, which is commonly in about three hours after the last addition of the referred grains, sooner or later according as the crucible has been more or less closely covered, and the matter more or less stirred, the fire must be immediately discontinued; for otherwise more and more of the silver, thus losing its sulphur, would sublime and mingle with the part at the bottom in which the gold is collected. The whole is poured out into an iron mortar, greased and duly heated; or if the quantity is too large to be safely lifted at once, a part is first taken out from the top with a small tab, and the rest poured into the mortar. The gold, diffused at first through the whole mass, is now found collected into a part of it at the bottom, amounting only to about as much as was referred unfulphurated. This part may be separated from the fulphurated silver above it by a chisel and hammer; or more perfectly, the surface of the lower mass being generally rugged and unequal, by placing the whole mass with its bottom upwards in a crucible; the fulphurated parts quickly melt, leaving unmelted that which contains the gold, which may thus be completely separated from the other. The fulphurated silver is effayed by keeping a portion of it in fusion in an open crucible till the sulphur is diffipated, and then dissolving it in aquafortis. If it should be found to contain any gold, it is to be melted again; as much more unfulphurated silver is to be added as was employed in each of the former injections, and the fusion continued about as hour and a half.

The gold thus collected into a part of the silver, may be further concentrated, and the other part, by granulating the mass and repeating the whole process. The operation may be again and again repeated, till so much of the silver is separated, that the remainder may be parted by aquafortis without too much expense.

The foregoing process, according to Mr. Schlutter, is practised at Rammelsberg in the Lower Hartz. The prevailing metal in the ore of Rammelsberg is lead; the quantity of lead is at most 40 pounds on a quintal or 100 pounds of the ore. The lead worked off on a teft or concave hearth yields about 110 grains of silver, and the silver contains only a 384th part of gold; yet this little quantity of gold amounting scarcely to a third of a grain in a hundred weight of this ore, is thus collected with profit. The author above-mentioned confines this method of separation to such silver as is poor in gold, and reckons parting with aquafortis more advantageous where the gold amounts to above a 45th of the silver; he advises also not to attempt concentrating the gold too far, as a portion of it will always be taken up again by the silver. Mr. Scheffer, however, relates (in the Swedish Memoirs for the year 1752), that he has by this method brought the gold to perfect fineness; and that he has likewise collected all the gold which the silver contained; the silver of the last operations, which had taken up a portion of the gold, being referred to be worked over again with a fresh quantity of gold-holding silver. The fulphurated silver is purified by continuing it in fusion for some time with a large surface exposed to the air; the fulphur gradually exhalcs, and leaves the silver entire.

PARTITION, in the art of war a person dexterous in commanding a party; who, knowing the country well, is employed in getting intelligence, or surprising the enemy's convoy, &c. The word also means an officer sent out upon a party, with the command of a body of light troops, generally under the appellation of the partizan's corps. It is also necessary that this corps should be composed of infantry, light-horse, and hussars.

PARTNERSHIP, is a contract among two or more persons, to carry on a certain business, at their joint expense, and share the gain or loss which arises from it. Of this there are four kinds.

1. Occasional joint trade, where two or more merchants agree to employ a certain sum in trade, and divide the gain or loss so soon as the adventure is brought to an issue. This kind of contract being generally private, the parties concerned are not liable for each other. If one of them purchase goods on trust, the furnisher, who grants the credit through confidence in him alone, has no recourse, in case of his insolvency, against the other partners. They are only answerable for the share of the adventure that belongs to the insolvent partner.

If it be proposed to carry the adventure farther than originally agreed on, any partner may withdraw his interest; and if it cannot be separated from the others, may infilt that the whole shall be brought to an issue.

2. Standing companies, which are generally established by written contract between the parties, where the firm, the duration, the division of the gain or loss, and other circumstances, are infcribed. All the partners are generally authorized to sign by the firm of the company, though this privilege may be confined to some of them by particular agreement. The firm ought only to be subscribed at the place, where the copartnery is established. If a partner has occasion, when absent, to write a letter relating to their affairs, he subcribes his own name on account of the company. When the same partners carry on businesses at different places, they generally choose different firms for each. The signature of each partner is generally sent to new correspondents; and when a partner is admitted, although there be no alteration in the firm, his signature is transmitted, with an intimation of the change in the copartnery to all their correspondents. Houses that have been long established, often retain the old firm, though all the original partners be dead or withdrawn.

The powers of each partner are, in general, discretionary; but they ought not to act, in matters of importance, without confulting together, where there is an opportunity. No partner is liable to make good the losses arising from his judging wrong in a case where he had authority to act. If he exceeds his power, and the event prove unsuccessful, he must bear the loss; but if it prove successful, the gain belongs to the company; yet if he acquaint the company immediately of what he has done, they must either acquiesce therein or leave him the chance of gain, as well as the risk of loss.

All debts contracted under the firm of the company are
PAR

are binding on the whole partners, though the money was borrowed by one of them for his private use, without the consent of the rest. And if a partner exceeds his power, the others are nevertheless obliged to implement his engagements: though they may render him responsible for his misbehaviour.

Although the sums to be advanced by the partners be limited by the contract, if there be a necessity for raising more money to answer emergencies or pay the debts of the company, the partners must furnish what is necessary in proportion to their shares.

A debt to a company is not cancelled by the private debts of the partner; and when a partner becomes insolvent, the company is not bound for his debts or private debts of the partner; yet, when there are more partners than two, the company’s partner, his share responsible for his misbehaviour.

The debts of a company are preferable, on the condition of the company’s affairs to a very inconvenient manner. Sometimes the debts and effects are sold at auction; sometimes they are divided among the partners; and when there are two partners, one divides them into shares, as equal as possible, and the other chooses either share he thinks best.

If a partner withdraws, he continues responsible for his former partners till it be publicly known that he hath done so. A deed of separation, registered at a public office, is sufficient presumption of such authority.

111. Companies, where the business is conducted by officers. There are many companies of this kind in Britain, chiefly established for purposes which require a larger capital than private merchants can command. The laws with respect to these companies, when not confirmed by public authority, are the same as the former, but the articles of their agreement usually vary. The capital is sometimes increased, and divided into a certain number of shares, whereof each partner may hold one or more, but is generally restrained to a certain number. Any partner may transfer his share; and the company must admit his assignee as a partner. The death of the partners has no effect on the company; but the execution of their business is intrusted to officers, for whom they are responsible; and, when the partners are numerous, the superintendence of the officers is committed to directors chosen annually, or at other appointed times, by the partners.

IV. Companies incorporated by authority. A close charter is necessary to enable a company to hold lands, to have a common seal, and enjoy the other privileges of a corporation. A charter is sometimes procured, in order to limit the risk of the partners: for, in every private company, the partners are liable for the debts, without limitation; in incorporated societies, they are only liable for their shares in the flock of the society. The incorporation of societies is sometimes authorized by act of the legislature; but this high authority is not necessary, unless for conferring exclusive privileges.

Mr. Paley says, “I know of nothing upon the subject of partnership that requires explanation, but how the profits are to be divided where one partner contributes money and the other labour, which is a common cafe.

“Rule. From the flock of the partnership deduct the sum advanced, and divide the remainder between the moneyed partner and the labouring partner, in the proportion of the interest of the money to the wages of the labour, allowing such a rate of interest as money might be borrowed for, on the same security, and such wages as a journeyman would require for the same labour and trust.

“Example. A advances 1000L. but knows nothing of the business; B produces no money, but has been brought up to the business, and undertakes to conduct it. At the end of the year the flock and effects of the partnership amount to 1200L. consequently there are 200L. to be divided. Now nobody would lend money upon the event of the business succeeding, which is A’s security, under 6 per cent. therefore A must be allowed 60L. for the interest of his money, B, before he engaged in the partnership, earned 50L. a year in the same employment; his labour, therefore, ought to be valued at 30L., and the 200L. must be divided between the partners in the proportion of 60 to 50; that is, A must receive 153L. 6s. 8d. and B 66L. 13s. 4d. If there be nothing gained, A loses his interest, and B his labour, which is right. If the original flock be diminished, by this rule, B loses only his labour as before; whereas A loses his interest and part of the principal; for which eventual disadvantage A is compensated, by having the interest of his money computed at 6 per cent. in the division of the profits when there is any. It is true, that the division of the profit is seldom forgotten in the constitution of the partnership; and is therefore commonly settled by express agreement; but these agreements, to be equitable, should purport the principle of the rule here laid down. All the partners are bound by what any one of them does in the course of the business; for, quod facit, each partner is considered as an authorized agent for the rest.”

PARTRIDGE, in ornithology. See Terrastris.

The partridge is so valuable at the table, that a great many ways of taking it have been invented by sportsmen, all of which succeed from the natural folly and timidity of the animal.

The places partridges delight in are corn-fields, especially
Partridges, especially whilst the corn grows, for under that cover they shelter and breed; neither are those places unfrequented by them when the corn is cut down, by reason of the grain they find there, especially in wheat-stubble, the height of which they delight in, being to them a covert or shelter. When the wheat stubble is much trodden by men or beasts, they then beak themselves to the barley stubble, provided it be fresh and untrodden; and they will, in the furrows, amongst the roots, branches, and long grass, hide both themselves and eggs, which are sometimes 20 in number by May in a covert.

When the winter-scan is arrived, and the stubble-fields are ploughed up, or over-foiled with cattle, partridges resort into the upland meadows and lodge in the dead-grafs, or fog under hedges, amongst moli-hills, or under the roots of trees: sometimes they resort to coppices, and under-woods, especially if any corn-fields are adjacent, or where there is grown broom, brake, ferns, &c.<br><br>In the harvest-time, when every field is full of men and cattle, in the daytime they are found in the fallow-fields which are next adjoining to the corn-fields, where they lie looking till evening or morning, and then they feed among the sheaves of corn.<br><br>When their haunts are known, according to the situation of the country and season of the year, the next care must be to find them out in their haunts, which is done several ways. Some do it by the eye only; and this art can never be taught, but learned by frequent experience: the colour of the birds being so like that of the earth at a distance, that no eye: but a very conversant one could distinguish them. When they are once seen, the business is to keep the eye upon them, and then to keep in continual motion. They are a very lazy bird, and by this means will let a person almost tread upon them; though if the person stands still to eye them, they will rise immediately though: they be at a considerable distance.<br><br>Another method of discovering them is, by going to their haunts very early in the morning, or at the close of the evening, which is called the jucking-time. The noise of the cock partridge is to be at ended to at this time, and is very loud and earnest. The hen will soon come up to the cock after making the noise, which she does by way of answer; and when they are got together, their chattering will discover them. Thus they may always be found at these times. But there is yet a better method of finding this bird, which is by the call. The business, in order to have success in this way, is carefully to learn the note of the partridge, and be able to imitate all the several sounds. When perfect in this, the person is to go to the haunts morning and evening, and placing himself in some place where he can see the birds, without being seen by them, he is to listen to their calling; and when they are heard, he is to answer in the same notes, doubling again as they do: by continuing this, they may be brought so near, that the person lying down on his back may count their whole number. Having in this manner found where the birds are, the next care is to catch them.<br><br>They are so foolish, that it is extremely easy to take them in nets. In order to this, there needs no more than the going out, provided with two or three nets, with meshes somewhat smaller than those of the pheasants, fant nets, and walking round about the covert, a net is to be fixed so as to draw over them, on pulling a line at a distance. All this may be easily done; for so long as the sportsman continues moving about, and does not fix his eye too intensively upon them they will let him come near enough to fix the net without moving. If they lie so struggling, that one net will not cover them, then two or three must be fixed in the same manner. The sportsman may then draw the nets over them, and they will often lie fast with the nets upon them till he comes up to fright them; then they will rise and be entangled in the net.<br><br>A second method of taking them is with bird-lime; this is done by means of wheat-straws. These must be large, and cut off between knot and knot; they must be well lined with the belt and strongest bird-lime, and the sportsman must carry a great number out with him. Having found a field where there are partridges, he is to call; and if they answer, he is then to tick up the lined straws in rows across two or three lands, and going backward, call again to them, leading them on in the road where the straws are; they will follow one another like a flock of chickens, and come out to the call; and will in their way run upon the straws, and laming themselves they will daub one another by crowding together, so that very few of them will be able to escape.<br><br>But there is yet a pleasanter way of taking them than this, that is, by driving of them. In order to this, an engine is to be made of canvas, stuffed with straw, to represent a horse; this horse and nets are to be taken to the haunts of the partridges, and the nets being placed planting or slopwise in the lower part of the field, the sportsman is to take the wind in his back and get above them, driving them downwards; his face is to be covered with something green or blue, and placing the horse before him, he is to go towards them slowly and gently; and by this means they will be raised on their legs, but not on their wings, and will run before the horse into the nets. In this way they go into a wrong path, the horse is to be moved to face them; and they will thus be driven back again, and driven every way the sportsman pleases.<br><br>The partridges of Abyssinia, we are told, are very large, being as big as capons.<br><br>In Jeremiah xvi. 11, we have the following curious passage: "As the partridge sitteth on an egg and hatcheth them not, so be that gettest riches, and not by right, shall leave them in the midst of his days, and at his end shall be a fool," which is explained by Mr. Pool as follows. It is no wonder if we cannot be certain as to the sense of their words, so far as they concern natural history, when we are not certain what bird it is to which this doth relate. We transliterate partridge; others would have it to be a cuckow; but certain it is, that it is the same word which we transliterate partridge: (1 Sam. xxvi. 20.) and cuckowes use not to be much hunted after. How the partridge is said to fit on eggs and hatch them not, is yet a greater question. It may be occasioned so many ways, viz. either sitting upon wind-eggs; or being killed before the eggs are hatch-colored; or having its eggs destroyed by the male partridge, or by some dog or other vermin; or, its nest being found, having its eggs taken from her, that it is hard to
PAR

[ 793 ]

PARTITION to determine which the prophet means. Of all others, I leave approve of that which Jerome makes the fenoe, though the thing be true (if we may believe, Calcidius and several natural historians, Aldrovandus, &c.), that partridges have such a love and desire to hatch young ones, that having lost their own eggs, they will steal the eggs of other partridges and hatch them; which being hatchet, the young ones knowing the way of their own parents, having them call, leave the partridge that hatched them (which is one thing quoted by Aldrovandus, to show the fagacity of that bird); but if this were the sene, the words would be, "as the partridge fitteth on eggs, and hatcheth them, but enjoyeth them not;" whereas they are, 'hatcheth them nor t; that is, having lost them, either by some man that hath taken them from her, or by some vermin or wild beast." Poet's Annot in Loc.

The words in the original are, ἀλυκτὴν θέτει, ἢν δὲν περίκει, &c. "The partridge cried; it gathered together what it had produced;" and some translate the Hebrew, "The partridge lays many oocysts; but does not hatch them all." Le Clerc, upon the authority of Bochart, understands the Hebrew word bare here to signify a woodcock. Le Clerc's translation is as follows: Rheiulica ova coligat, sed non portat. etsi fœdor est, sed fine jure, medius juter dehinc esse relinquat, auge ad extremum fulla ob.

PARTITION, the art of bringing forth or being delivered of young. See Midwifery.

PARTY, in a military sense, a small number of men, &c.; or foot, sent upon any kind of duty; as into an enemy's country to pilage, to take prisoners and to oblige the country to come under contribution. Parties are often sent out to view the roads and ways, get intelligence, seek forage; to reconnoitre, or amuse the enemy upon a march; they are also frequently sent upon the flanks of an army or regiment, to discover the enemy if near, and prevent surprize or ambuscade.

PARU, in natural history, the name of a very singular American fish. It is broad, flat and rounded; not very thick, and usually of about five or six inches long and more than four broad. It has fins one large and long, one on the back, and another on the belly behind the anus; each of these reaches from the tail, and has toward the end a long firing or cord, made of a single filament, that on the back fin being longer than that on the belly; behind the gills it has also two fins of two fingers breadth long and one broad; and two others on the belly, which are very narrow; its head is small, and its mouth elevated and small, and furnished with small teeth; its scales are of a moderate size, and are half black and half yellow; so that the fish appears of a black colour, variegated with yellow half moons; its gills, and the beginning of its fins, are also yellow; and it has, on each side near the head, a yellow spot; it is edible.

PARVICH, an island near Dalmatia, and one of the best peopled and most considerable of those which are under the jurisdiction of Sibenico. It contains a great number of fishermen, and a considerable number of persons who give themselves up to agriculture. It contains many Roman antiquities, which evidently show that it was a Roman station. It seems to be among the number of those islands which Pliny calls Caladus, which is supposed to be an inversion of Caladus, which...
differing from all others of this genus. The top of the head from the bill to the hind part, is white, mixed with a few dark-grey feathers: this bed of white is entirely surrounded with a broad stroke of black; which rising on each side of the upper mandible, passes over each eye, unites at the hind part of the head, and stops middle along the middle of the back to the rump. The feathers on each side of this black stroke are of a purplish red, as are those immediately incumbent on the tail. The tail is the longest, in proportion to the bulk, of any British bird, being in length three inches, the form, not unlike that of a magpie, consisting of 12 feathers of unequal length, the middlemost the longest, those on each side growing gradually shorter. These birds are often seen passing through our gardens, going from one tree to another, as if in their road to some other place, never making any halt. They make their nests with great elegance, of an oval shape, and about eight inches deep, having near the upper end a hole about a length. The natural materials are mosses and lichens curiously interwoven with wool. On the inside it is very warmly lined with a thick bed of feathers. The female lays from 10 to 17 eggs. The young follow their parents the whole winter; and, from the fineness of their bodies and great length of tail, appear, while flying, like as many darts cutting the air.

6. The bimnus, or bearded titmouse, has a short, strong, and very convex bill, of box colour; the head of a fine grey; the chin and throat white; the middle of the breast fleth coloured; the sides and thighs of a pale orange; the hind part of the neck and back of orange bay; the tail is two inches and three quarters long; the legs of a deep flshing black. The female wants the fleth-colour on the breast, and a triangular tuft of black feathers on each side the bill which adorns the male. They are found in marshy places.

7. The remiz, or small species of titmouse. It is called parus pendulinus, and is often found in Lithuania. Mr Coxe, in his Travels through Poland, gives the following account of this little animal. "The wondrous structure of its pendent nest induced me to give an engraving of both that and the birds themselves. They are of the smallest species of titmouse. The head is of a very pale bluish ash colour; the forepart of the neck and the breast tinged with red; the belly white; wings black; back and rump of a yellowish rufi colour; quill feathers cinereous, with the exterior sides white; tail rufh coloured. The male is singularly distinguished from the female by a pair of black-pointed whiskers. Its nest is in the shape of a long purse, which it forms with an artful art, by interweaving down, gofferman, and minute fibres, in a close and compact manner, and then lining the inside with down alone, so as to make a snug and warm lodge for its young brood. The entrance is at the side, small, and round, with its edge more strongly marked than the rest of this curious fabric; the bird, attentive to the preservation of its eggs or little ones from noxious animals, suspends it at the lefser end to the extremity of the slender twigs of a willow or some other tree over a river. Contrary to the custom of titmice, it lays only four or five eggs; possibly Providence hath ordained these scantiness of eggs to the remiz, because by the singular instinct imparted to it, it is enabled to secure its young much more effectually from destruction, than the other species, which are very prolific."

PASCAL (Blaise), one of the greatest geniuses and best writers France has produced, was born at Clermont in Auvergne, in the year 1623. His father, Stephan Pascal, born in 1588, and of an ancient family, was president of the court of aids in his province; he was a very learned man, an able mathematician, and a friend of Descartes. Having an extraordinary tenderness for this child, his only son, he quitted his office in his province, and went and settled at Paris in 1631, that he might be quite at leisure for the instruction of him; and Blaise never had any matter but his father. From his infancy he gave proofs of a very extraordinary capacity; for he desired to know the reason of every thing: and when good reasons were not given him, he would seek for better; nor would he ever yield his opinion but upon such as appeared to him well grounded. There was room to fear, that with such a call of mind he would fall into free thinking, or at least into heterodoxy; yet he was always very far from any thing of this nature.

What is told of his manner of learning the mathematics, as well as the progress he quickly made in that science, seems almost miraculous. His father, perceiving in him an extraordinary inclination to reasoning, was afraid left the knowledge of the mathematics, would hinder his learning the languages. He kept him therefore as much as he could from all notions of geometry, locked up all his books of that kind, and restrained even from speaking of it in his presence. He could not, however, make his son refrain from musing upon proportions; and one day surprized him at work with charcoal upon his chamber-floor, and in the midst of figures. He asked him what he was doing? I am searching, says Pascal, for such a thing; which was just the 32d proposition of the first book of Euclid. He asked him then how he came to think of this? It was, says Pascal, because I have found out such another thing: and so going backward, and using the names of bar and round, he came at length to the definitions and axioms he had formed to himself. Does it not seem miraculous that a boy should work his way into the heart of a mathematical book, without ever having seen that or any other book upon the subject, nor knowing any thing of the terms? Yet we are assured of the truth of this by Madame Pierier, and several other writers, the credit of whose testimony cannot reasonably be questioned. He had, from henceforward, full liberty to indulge his genius in mathematical pursuits. He understood Euclid's Elements as soon as he cast his eyes upon them; and this was not strange; for, as we have seen, he understood them before. At 16 years of age he wrote a treatise of conic sections, which was acclaimed by the most learned a mighty effort of genius; and therefore it is no wonder that Descartes, who had been in Holland a long time, should, upon reading it, choose to believe that Mr Pascal the father was the real author of it. At 19, he contrived an admirable arithmetical machine, which was esteemed a very wonderful thing, and would have done credit as an invention to any man verified in science, and much more to such a youth— About this time his health became impaired, and he was in consequence obliged to suspend his labours; for
nor was he in a condition to resume them till four years after. About that period, having seen Torricelli's experiment respecting a vacuum and the weight of the air, he turned his thoughts towards those objects; and in a conference with Mr. Pepys, intendant of fortifications, proposed to make farther researches. In consequence of this idea, he undertook several new experiments, one of which was as follows: Having provided a glass tube, 46 feet in length, open at one end, and filled hermetically at the other, he filled it with red wine, that he might distinguish the liquor from the tube. He then elevated it in this condition; and having placed it perpendicularly to the horizon, stopped the bottom, and plunged it into a vessel full of water, to the depth of a foot; after which he opened the extremity of the tube, and the surface of the water rose in it, so that it was partly filled with wine, and partly with water. He made also a great many experiments with spigots, syringes, bellows, and all kinds of tubes, making use of different liquors, such as quicksilver, water, wine, oil, &c.; and having published them in 1647, differed his work throughout all France, and transmitted it also to foreign countries. All these experiments, however, averted effects, without demonstrating the causes. Pascal knew that Torricelli conjectured that those phenomena which he had observed were occasioned by the weight of the air (a); and, in order to discover the truth of this theory, he made an experiment at the top and bottom of a mountain in Auvergne, called Le Puy de Dome, the result of which gave him reason to conclude that air was weighty. Of this experiment he published an account, and sent copies of it to most of the learned men in Europe. He likewise renewed it at the top of several high towers, such as those of Notre Dame at Paris, St Jacques de la Boucherie, &c.; and always remarked the same difference in the weight of the air, at different elevations. This fully convinced him of the weight of the atmosphere; and from the discovery he drew many useful and important inferences. He composed also a large treatise, in which he thoroughly explained this subject, and replied to all the objections that had been started against it. As he thought this work rather prolix, and as he was fond of brevity and precision, he divided it into two small treatises, one of which he entitled, A Dissertation on the Equilibrium of Liquors; and the other, An Essay on the Weight of the atmosphere. These labours procured Pascal so much reputation, that the greatest mathematicians and philosophers of the age propounded various questions to him, and confuted him respecting such difficulties as they could not solve.

Some years after, while tormented with a violent fit of the tooth-ache he discovered the solution of a problem proposed by Father Mercenne, which had baffled the penetration of all those who had attempted it. This problem was to determine the curve described in the air by the nail of a couch wheel, while the machine is in motion. Pascal offered a reward of 40 pinsles to any one who should give a satisfactory answer to it. No one however, having succeeded, he published his own at Paris; but as he began now to be disgusted with the sciences, he would not put his real name to it, but sent it abroad under that of A. d'Ettenville.

This was the last work which he published in the mathematics; his infirmities now encreafing so much that he was under the necessity of renouncing severe study, and of living to recluse, that he scarcely admitted any person to see him.

After he had thus laboured abundantly in mathematical and philosophical disquisitions, he forook those studies and all human learning at once; and determined to know nothing, as it were, for the future, but Jesus Christ and himself. He was not 24 years of age, when the reading some pious books had put him upon taking this holy resolution; and he became, as great a devotee as any age has produced. Mr. Pascal now gave himself up entirely to a state of prayer and meditation. He had always in his thoughts these great maxims, of renouncing all pleasure and all superfluity; and this he practised with rigour even in his illnesses, to which he was frequently subject, being of a very invalid habit of body: for instance, when his sickness obliged him to feed somewhat delicately, he took great care not to relish or taste what he eat. He had no violent affection for those he loved; he thought it sinful, since a man poiffesses a heart which belongs only to God. He found fault with some discourses of his father, which he thought very innocent; as if she had failed upon occasion, that she had seen a beautiful woman, she would be angry, and tell her, that she might raise bad thoughts in both men and young people. He frequently wore an iron girdle full of points next to his skin; and when any vain thought came into his head, or when took particular pleasure in any thing, he gave himself some blows with his elbow, to redouble the prickings, and to recall himself to his duty.

Though Mr. Pascal had thus abstained himself from the world, yet he could not forbear paying some attention to what was doing in it; and he even interspersed himself in the contest between the Jesuits and the Jansenists. The Jesuits, though they had the popes and kings on their side, were yet decried by the people, who brought up atheism against them the affitution of Henry the Great, and all the old stories that were likely to make them odious. Pascal went farther; and by his Lettres Provinciales (a), published in 5 H 2 1656,

(a) Before this period, all those effects which are now known to be produced by the weight of the atmosphere, were attributed to Nature's abhorrence of a vacuum.

(b) The origin of these letters was this: for the sake of unbending his mind, Pascal used often to go to Port Royal des Champs, where one of his sisters had taken the veil, and where he had an opportunity of seeing the celebrated Mr. Arnaud, and several of his friends. This gentleman's dispute with the Doctors of the Sorbonne,
Pascal, 1656, under the name of 

Leslie de Monfieur, made them the subject of ridicule. "These letters (says Voltaire) may be considered as a model of eloquence and humour. The best comedies of Molière have not more wit than the first part of these letters; and the sublimity of the latter part of them is equal to any thing in Bossuet. It is true, indeed, that the whole book was built upon a false foundation; for the extravagant notions of a few Spanish and Flemish Jesuits were artfully ascribed to the whole society. Many absurdities might likewise have been discovered among the Dominican and Franciscan caustics; but this would not have answered the purpose; for the whole raillery was to be levelled only at the Jesuits. These letters were intended to prove, that the Jesuits had formed a design to corrupt mankind; a design which no sect or society ever had, or can have." Voltaire calls Pascal the first of their fatirists; for Despleaux, says he, must be considered as only the second. In another place, speaking of this work of Pascal, he says, that "examples of all the various species of eloquence are to be found in it. Though it has been now written almost 100 years, yet not a single word occurs in it, favouring of that vicititude to which living languages are so subject. Here then we are to judge when our language may be said to have assumed a lettered form. The bishop of Lucon, son of the celebrated Buffy, told me, that asking one day the bishop of Meaux what work he would covet most to be the author of, supposing his own performances set aside, Bossuet replied, The Provincial Letters." These letters have been translated into all languages, and printed over and over again. Some have said, that there were decrees of formal condemnation against them; and also that Pascal himself, in his last illness, detested them, and repented of having been a Jansenist; but both these particulars are false and without foundation. Father Daniel was supposed to be the anonymous author of a piece against them, intitled, The Dialogues of Closter and Evadon.

Pascal was only about the age of 30 when these letters were published, yet he was extremely infirm, and his disorders increasing soon after, so much that he conceived his end fast approaching, he gave up all further thoughts of literary composition. He resolved to spend the remainder of his days in retirement and pious meditation; and with this view he broke off all his former connections, changed his habitation, and spoke to no one, not even to his own domestics. He made his own bed, fetched his dinner from the kitchen, carried it to his apartment, and brought back the plates and dishes in the evening; so that he employed his servants only to cook for him, to go to town, and to do such other things as he could not absolutely do himself. In his chamber nothing was to be seen but two or three chairs, a table, a bed, and a few books. It had no kind of ornament whatever; he had neither a carpet on the floor nor curtains to his bed; but this did not prevent him from sometimes receiving visits; and when his friends appeared surprized to see him thus without furniture, he replied, that he had what was necessary, and that any thing else would be superfluity, unworthy of a wise man. He employed his time in prayer, and in reading the Holy Scriptures; and he wrote down such thoughts as this exercise inspired. Though his continual infirmities obliged him to live very delicate food, and though his servants employed the utmost care to provide only what

Sorbonne, who were endeavouring to condemn his opinions, was of course frequently brought upon the carpet. Mr Arnaud, solicited to defend a defence, had composed a treatise, which, however, did not meet with approbation, and which he himself considered as a very indifferent work. Pascal being one day in company, some of those present, who were sensible of his abilities, having said to him, "You who are a young man ought to do something;" he took the hint, and composed a letter, which he showed to his friends, and which was so much admired, that they insisted on its being printed. The object of this letter is an explanation of the terms, mediocrity, sufficient grace, and absolute grace; and the author here shows, as well as in two others which followed it, that a regard for the faith was not the motive which induced the Doctors of the Sorbonne to enter into dispute with Mr Arnaud, but a desire of oppressing him by ridiculous questioners. Pascal, therefore, in other letters which he published afterwards, attacks the Jesuits, whom he believed to be the authors of this quarrel, and in the most elegant style, season'd with wit and satire, endeavours to render them not only odious but ridiculous. For this purpose he employs the form of dialogue, and introduces an ignorant person, as men of the world generally are, who requests information respecting the questions in dispute from these Doctors, whom he consults by proposing his doubts; and his answers to their replies are so conjunctive, pertinent, and just, that the subject is illustrated in the clearest manner possible. He afterwards exposes the morality of the Jesuits, in some conversation between him and one of their caustics, in which he still represents a man of the world, who seeks for instruction, and who, hearing maxims altogether new to him, seems astonished, but still Catilines with moderation. The caustic believes that he is sincere, and refutes these maxims; and under this persuasion he discovers everything to him with the greatest readiness. The other is still surprized; and as his instructor attributes this surprize only to the novelty of his maxims, he still continues to entertain himself with the same confidence and freedom. This instructor is a simple kind of man, who is not overburdened with acuteness, and who insensibly engages himself in details which always become more particular. The person who lists, wishing neither to contradict him nor to subscribe to his doctrine, receives it with an ambiguous kind of raillery; which, however sufficiently flows what opinion he entertains of it. The Jesuits reproached the author with having employed only raillery against them, and with having misrepresented several passages of their authors; which induced Pascal to write eight more in vindication of himself. All these letters, in number 18, written in a style altogether new in France, appeared in 4to, one after another, from the month of January 1656, to the month of March of the year following.
what was excellent, he never relished what he eat, and seemed quite indifferent whether what they brought him was good or bad. When any thing new and in season was presented to him, and when he was ailed, after he had finished his repast, how he liked it, he replied, "You ought to have informed me before hand, I should have then taken notice of it." His indifference in this respect was so great, that though his taste was not vitiated, he forbade any sauce or ragout to be made for him which might excite his appetite. He took without the least repugnance all the medicines that were prescribed for the re-establishment of his health; and when Madame Perrier, his father, seemed astounded at it, he replied ironically, that he could not comprehend how people could ever show a dislike to a medicine, after being apprised that it was a disagreeable one, when they took it voluntarily; for violence or surmise ought only to produce that effect.

Though Pascal had now given up intense study, and though he lived in the most temperate manner, his health continued to decline rapidly; and his disorders had so enfeebled his organs, that his reason became in some measure affected. He always imagined that he saw a deep abyss on his left side, and he never would sit down till a chair was placed there, to secure him from the danger which he apprehended. His friends did every thing in their power to banish this melancholy idea from his thoughts, and to cure him of his error, but without the desired effect; for though he would become calm and composed for a little, the phantom would in a few moments again make its appearance and torment him. The cause of his seeing this singular vision for the first time, is said to have been as follows: His physicians, alarmed on account of the exhausted state to which he was reduced, had advised him to substitute easy and agreeable exercises for the fatiguing labours of the closet. One day, in the month of October 1654, having gone according to custom to take an airing on the Pont de Neufly, in a coach and four, the two first horses suddenly took fright, oppose to a place where there was no parapet, and threw themselves violently into the Seine; but the traces luckily giving way, the carriage remained on the brink of the precipice. The shock which Pascal, in his languishing situation, must have received from this dreadful accident, may easily be imagined. It threw him into a fit, which continued for some time, and it was with great difficulty that he could be restored to his senses. After this period his brain became so deranged, that he was continually haunted by the remembrance of his danger, especially when his disorders prevented him from enjoying sleep. To the same cause was attributed a kind of vision or ecstasy that he had some time after: a memorandum of which he preferred during the remainder of his life in a bit of paper, put between the cloth and the lining of his coat, and which he always carried about him. Some of the Jesuits had the baseness and inhumanity to reproach this great genius with the derangement of his organs. In the Dictionary of Junius Books, he is called a hypochondriac, and a man of a wrong head, and a bad heart.

But, as a celebrated writer has observed, Pascal's disorder had in it nothing more surprising or disgraceful than a fever, or the vertigo. During the last years of his life, in which he exhibited a melancholy example of the humiliating reverses which take place in this transitory frame, and which, if properly considered, might teach mankind not to be too proud of those abilities which a moment may take from them, he attended all the salutations (c) and wrote every church in which relics were exposed, and had always a spiritual almanac, which gave an account of all those places where particular acts of devotion were performed. On this occasion it has been said, that "Religion renders great minds capable of little things, and little minds capable of great."

In company, Pascal was distinguished by the amiableness, of his behaviour; by his easy, agreeable, and instructive conversation, and by great modesty. He possessed a natural kind of eloquence, which was in a manner irrefitable. The arguments he employed for the most part produced the effect which he proposed; and though his abilities intituled him to assume an air of superiority, he never displayed that haughty and imperious tone which may often be observed in men of shining talents. The philosophy of this great man consisted in renouncing all pleasure, and every superfluity. He not only denied himself the most common gratifications; but he took also without reluctance, and even with pleasure, either as nourishment or as remedies, whatever was disagreeable to the senses; and he every day retrenched some part of his drafts, food, or other things, which he considered as not absolutely necessary. Towards the close of his life, he employed himself wholly in pious and moral reflections, writing down those which he judged worthy of being preferred. The first piece of paper he could find was employed for this purpose; and he commonly put down only a few words of each sentence, as he wrote them merely for his own use. The bits of paper upon which he had written these thoughts, were found after his death filed upon different pieces of writing, without any order or connection; and being copied exactly as they were written, they were afterwards arranged and published.

The celebrated Bayle, speaking of this great man, says, "An hundred volumes of sermons are not of so much avail as a simple account of the life of Pascal. His humility and his devotion mortified the libertines more than if they had been attacked by a dozen of millionaires. To a word, Bayle had so high an idea of this philosopher, that he calls him a "poet" in the human species." "When we consider his character (says he), we are almost inclined to doubt that he was born of a woman, like the man mentioned by Lucretius:

"Ut vix humana videatur flirpe creatura."

Mr. Pascal died at Paris the 19th of August 1662, aged (c) Certain solemn prayers, which are repeated at certain hours, and on certain days, in the Popish churches.
He had been some time, Parcель, "--y--

for having invented the Latin more of other people's than their would do better (added he

gives by his Provincial Letters, and by some of his other works, that he was born with a
great fund of humour, which his infirmities could never entirely destroy. In company, he readily indulged
in that harmful and delicate railery which never gives offence, and which greatly tends to enliven
conversation; but its principal object generally was of a moral nature. For example, ridiculing those authors who say, My Book, my Commentary, my History, they would do better (added he) to say, Our Book, our Commentary, our History; since there are is them much more of other people's than their own." An elegant Latin epitaph was inscribed on his tomb.

PASchal, something belonging to the passo/ies, or Easter. See PASover and Easter.

PASAP, the chief of the Lamas, particularly eminent for having invented characters for the Moguls. He was much esteemed by the Chinese, though the literati exclaimed against the manner in which the people demonstrate their affection. There is still at Pekin a myan or temple, built in honour of Pasap in the time of the Mogul emperors. He died in 1279.

PASIPHAE (Fab.hift.), daughter of the Sun by Per/feus, who married Minos king of Crete. She disgraced herself by an unnatural passion for a bull, which we are told was enabled to gratify by means of the artist De/dalus. This celebrated bull had been given to Minos by Neptune, to be offered on his altars. But as the monarch refused to sacrifice the animal on account of his beauty, the god avenged his disobedience by inspiring Pasiphae with an unnatural love for him. This fable, which is universally believed by the poets, who observe, that the minotaur was the fruit of this infamous commerce, is refuted by some writers; who suppose that the infidelity of Pasiphae to her husband was betrayed in her affection for an officer of the name of Taurus, and that De/dalus, by permitting his house to be the asylum of the two lovers, was looked upon as accessory to the gratification of Pasiphae's lust. From this amour with Taurus, as it is further remarked, the queen became mother of twins; and the name of Minotaurus arises from the resemblance of the children to the husband and the lover of Pasiphae. Minos had four sons by Pasiphae, Cadmus, Deucalion, Glau­cus, and Androgus; and three daughters, Hecate, Ariadne, and Phaedra.

PASQUIN, a mutuated statue at Rome, in a corner of the palace of the Ursi/i. It takes its name from a collector of that city called Pasquin, famous for his verses and gibes, and who diverted himself by passing his jokes on all those that went through that street. After his death, as they were digging up the pavement before his door, they found in the earth the statue of an ancient gladiator, well cut, but maimed and half spoiled: this they set up in the place where it was found, and by common consent named it Pasquin. Since that time all satires are attributed to that figure; and are either put into its mouth, or pasted upon it, as if they were written by Pasquin redivivus; and these are ad­ressed by Pasquin to Marforio, another statue at Rome. When Marforio is attacked, Pasquin comes to his assistance; and, when Pasquin is attacked, Marforio affils him in his turn; that is, the people make the statues speak just what they please.

PASQUINADE, a satirical libel fastened to the statue of Pasquin; these are commonly short, witty and pointed; and from hence the term has been applied to all lampoons of the same kind.

PASS, or PASADE, in fencing an advance or leap forward upon the enemy. Of these there are several kinds; as passades, within, beneath, to the right. The measure of the pafs is when the swords are so near as that they may touch one another.

PASS, in a military sense, a strait and difficult passade which shuts up the entrance into a country.

PAS Parole, in military affairs, a command given at the head of an army, and hence communicated to the rear, by passing it from mouth to mouth.

PASSADE, in the manege, is a turn or course of a horse backwards or forwards on the same spot of ground. Hence there are several sorts of passades, according to the different ways of turning, in order to part or return upon the same treads, which is called closing the passade; as the passade of one time, the passade of five times, and the raised or high passades into which the demivoltes are made into curves. See Horsesmanship.

North-west Passage, North-east Passage. See NORTH-west PASsage, NORTH-east PASsage. East Passage and Pole.
Right of Passage, in commerce, is an imposition or duty exacted by some princes, either by land or sea, in certain close and narrow places in their territories, on all vessels and carriages, and even sometimes on persons or passengers, coming in or going out of ports, &c. The most celebrated passage of this kind in Europe is the Sound: the dues for passing which island belong to the king of Denmark, and are paid at Elsinore or Cronenburg.

Passant, in heraldry, a term applied to a lion or other animal in a shield, appearing to walk leisurely: for most beasts, except lions, the strippant is frequently used instead of passant.

Passau, an ancient, handsome, and celebrated town of Germany, in Lower Bavaria, with a bishop's see and fort. The houses are well-built, and the cathedral is thought to be the finest in all Germany. It is divided into four parts, three of which are fortified; but the other is only a suburb, and has nothing but an old castle in which the bishop generally resides. It is seated at the confluence of the rivers Inn and Iltz. in E. Long. 13° 34'. N. Lat. 48° 26'.

Passau, a bishopric of Germany, lying between Lower Bavaria, Austria, and Bohemia. It extends not above 20 miles where largest; and has no considerable place, except the capital, which is of the same name.

Passerat (John), a celebrated professor of eloquence in the royal college of Paris, and one of the politest writers of his time, was born at Troyes, in the province of Champagne, in 1534. He spent three years in studying the law under the famous Cujacias at Bourges, where he became professor of eloquence in 1572. He was an indefatigable student, passing frequently whole days without eating a morsel; yet to an extraordinary erudition he joined an uncommon politeness of manners and pleasantry, having nothing of the mere scholar except the gown and hood. He gained the esteem of the kings Charles IX. Henry III. and of all the men of wit and learning in his time. He died in 1602, and left several admired works behind him.

Passeres, the name of a class of birds. See Zoology.
