ENCYCLOPÆDIA; OR, A DICTIONARY OF ARTS, SCIENCES, AND MISCELLANEOUS LITERATURE; Constructed on a Plan, by which THE DIFFERENT SCIENCES AND ARTS Are digested into the Form of distinct TREATISES OR SYSTEMS, COMPREHENDING THE HISTORY, THEORY, AND PRACTICE, of each, According to the Latest Discoveries and Improvements; AND FULL EXPLANATIONS GIVEN OF THE VARIOUS DETACHED PARTS OF KNOWLEDGE, WHETHER RELATING TO.

NATURAL and Artificial Objects, or to Matters Ecclesiastical, Civil, Military, Commercial, &c.

Including ELUCIDATIONS of the most important Topics relative to Religion, Morals, Manners, and the Economy of Life.

TOGETHER WITH

A Description of all the Countries, Cities, principal Mountains, Seas, Rivers, &c. throughout the World;

A General History, Ancient and Modern, of the different Empires, Kingdoms, and States;

And

An Account of the Lives of the most Eminent Persons in every Nation, from the earliest ages down to the present times.

Compiled from the writings of the best authors in several languages; the most approved Dictionaries, as well of general science as of its particular branches; the Transactions, Journals, and Memoirs, of various Learned Societies, the MS. Lectures of Eminent Professors on different sciences; and a variety of Original Materials, furnished by an Extensive Correspondence.

THE FIRST AMERICAN EDITION, IN EIGHTEEN VOLUMES, GREATLY IMPROVED.

ILLUSTRATED WITH FIVE HUNDRED AND FORTY-TWO COPPERPLATES.

VOL. XIII. NEH-PAS

INDUGIT DISCIPT, ET AMENI MEMINISSE ERIT.

PHILADELPHIA:
PRINTED BY THOMAS DOBSON, AT THE STONE-HOUSE, NO. 41, SOUTH SECOND-STREET.
M.DCC.XCVIII.
[Copy-Right secured according to law.]
NEHEMIAH

NEHEMIAH, or NEEMIAS, son of Hachaliah

Nehemiah being arrived at Jerusalem with the king's

commission, went round the city; and having viewed

the condition of the walls, assembled the chief of the

people, produced his commission, and exhibited

them to undertake the repairation of the gates and walls

of the city. He found every person ready to obey him;

whereupon he immediately began the work. The

enemies of the Jews, observing these works in such

forwardness, made use of all the means in their power

to deter Nehemiah from this undertaking, and made

everal attempts to surprize him; but finding that

their designs were discovered, and that the Jews kept upon

their guard, they had recourse to craft and stratagem,

endeavouring to draw him into an ambuscade in the fields,

where they pretended they would finish the dispute at

an amicable conference: but Nehemiah gave them to

understand, that the work he had begun required his

personal attendance; and therefore he could not come
to them. He sent the same answer to four several

messengers that they sent one after another on the same

subject, (id. iv. and vi.)

Sanballat, the chief of the enemies of the Jews, to

together with his associates, wrote word, that a report was

spread that the Jews were building the walls of Jeru­

usalem only with a design to make it a place of strength,

to support them in an intended revolt; that it was

said also that Nehemiah had suborned false prophets
to favour his designs, and to encourage the people to

choose him king; and to stop the course of these ru­
mours, he advised him to come to them, that they might

confederate together, and take such resolutions as should
be found convenient. Nehemiah gave himself no

trouble on this account, but returned for answer, that

all those accUSAutions were false and made at random.

About the same time he discovered, that a false prophet,
called Shemaiah, had been corrupted by his ene­

emies, and that some of the chief of the city were se­
crecily in confederacy with them. Yet all this did not

discourage him: he went on with his work, and hap­
pily completed it in two and fifty days after it had

been begun.

Then he made a dedication of the walls, of the

towers, and of the gates of Jerusalem, with the solemn­
The book which in the English bible, as also in the Hebrew, has the name of Nehemiah, in the Latin bible is called the book of Ezdras; and it must be confessed, that though this author speaks in the first person, and thought that first reading one would think that he had writ it day by day as the transactions occurred, yet there are some things in this book which could not have been written by Nehemiah himself; for example, memorials are quoted wherein were registered the names of the priests in the time of Jonathan the son of Elia-shib, and even to the times of the high priest Jaddus, who met Alexander the Great. These therefore must have been added afterwards.

It may well be questioned, whether this Nehemiah be the same that is mentioned in Ezra, (ii. 2. and Neh. vii. 7.) as one that returned from the Babylonish captivity under Zerubbabel; since from the first year of Cyrus to the twentieth of Artaxerxes Longimanus, there are no less than ninety-two years intervening; so that Nehemiah must at this time have been a very old man, upon the lowest computation an hundred, consequentially utterly incapable of being the king's cup bearer, of taking a journey from Susa to Jerusalem, and of behaving there with all the courage and activity that is recorded of him. Upon this precaution therefore, we may conclude that this was a different person, though of the same name, and that Tirhatha (the other name by which he is called, Ezra ii. 63, and Neh. vii. 65.) denotes the title of his office, and both in the Persian and Chaldean tongues was the general name given to the kings deputies and governors.

NEHOW, one of the Sandwich Islands, discovered by Captain Cook in his last voyage to the Pacific Ocean; they are eleven in number, and are situated from 18° 44' to 22° 15' N. Lat. and from 154° 56' to 160° 24' W. Long. They are not very particularly described in any account that has hitherto appeared.

NEIGHBOUR, 1. One who dwells or is seated near to another (2 Kings iv. 3.) 2. Every man to whom we have an opportunity of doing good (Matt. xxii. 39.) 3. A fellow-labourer of one and the same people (Acts vii. 27.) 4. A friend (Job. xvi. 21.) At the time of our Saviour, the Pharisees had restrained the word neighbour to signify those of their own nation only, or their own friends; being of opinion that to hate their enemy was not forbidden by their law. But our Saviour informed them, that the whole world were their neighbours; that they ought not to do to another what they would not have done to themselves; and that this charity ought to be extended even to their enemies (Matt. v. 43. Luke x. 29. &c.)

NEISSE, a landside town of Silefia in Germany, and the residence of the bishop of Breflaw, who has a magnificent palace here. The air is very wholesome and provisions are cheap; the inhabitants carry on a great trade in wine and linen. This place suffered greatly by an inundation and fire in 1729. It was taken by the Prussians in 1741, who augmented the fortifications after the peace in 1742, and built a citadel to which they gave the name of Prussia. It is seated on a river of the same name, in E. Long. 17° 35'. N. Lat. 50° 32'.

NEIUS MONS (anc. geog.), at the foot of which stood Ithaca, a town of the island of that name, (Homer).
NELSON (Robert), a learned and pious English gentleman, was the son of Mr John Nelson a considerable Turkey merchant, and was born in June 1656. He had the first part of his education at St. Paul’s school, London; but the principal part was under a private tutor in his mother’s house, after which he studied at Trinity College, Cambridge. In 1680 he was chosen a fellow of the Royal Society; being probably inclined to receive that honour out of respect to his friend and school-fellow Dr Edmund Halley, for whom he had a particular regard, and in whose company he set out in his travels abroad the December following. In the road to Paris, they saw the remarkable comet which gave rise to the cometical astronomy by Sir Isaac Newton; and our author, apparently by the advantage of his fellow traveller’s instructions, sent a description of it to Dr. afterwards Archbishop Tillotson, by whom he was very much esteemed. Before he left Paris, he received a letter from a friend in the English court, inviting him to purchase a place there, by the promise of his assistance in it. This proposal was made by Mr Henry Saville, brother to Lord Halifax; he had been sworn vice-chamberlain of the king’s household in December 1780, and was at this time envoy from Charles II. to the court of France; though now at London, whence he sent this offer in a letter to Mr Nelson; who being but young, and having a great affection for King Charles and the duke of York, was pleased with the thoughts of figuring it near their persons; but as he could not resolve upon an affair of such consequence without the approbation of his mother and uncle, he first applied to Tillotson to found them, with assurances of determining himself by their judgment and advice, including also that of the Dean; who finding them both averse to it, thereupon dropped the matter, and pursu’d his journey with his fellow traveller to Rome. Here he fell into the acquaintance of Lady Theophila Lucy, widow of Sir Kingmill Lucy of Broxbourne, in Hertfordshire, bar. and second daughter of George earl of Berkeley, who soon discovered a strong passion for him: this concluded in marriage, after his arrival in England in 1682. But it was some time before he confessed to Mr Nelson the change of her religion; which was owing to her acquaintance with Bossuet and conversations at Rome with Cardinal Philip Howard, who was grandson of the earl of Arundel, the Collector of the Arundelian marbles, &c. and had been raised to the purple by Pope Clement X., in May 1675. Nor was this important alteration of her religious sentiments confined to her own mind, but involved in it her daughter by her first husband, whom she drew over to her new religion; and her zeal for it prompted her even to engage in the public controversy then depending. She is the supposed author of a piece written in 1686, 410, under the title of, “A discourse concerning a judge of controversy in matters of religion, showing the necessity of such a judge.”

This misfortune touched her husband very nearly. He employed not only his own pen, but those of his friends Dr Tillotson and Dr Hickes, to recover her: but all proved ineffectual; and she continued in the communion of the church of Rome till her death. She was a person of fine sense and understanding. Dr Tillotson particularly laments her case on that account; and even seems not to be entirely free from all apprehensions of the influence she might have upon her husband in this important affair. But Mr Nelson’s religion was too much the result of his learning and reason to be shaken by his love, which was equally steady and inviolable. Her change of religion made no change in his affections for her: and when the republican party in Italy, which always consisted of such a bad state of health as obliged her to go and drink the waters at Aix, he attended her thither in 1688: and not liking the prospect of the public affairs at home, he proceeded to make a second trip to Italy, taking his lady, together with her son and daughter by her former husband, along with him. He returned through Germany to the Hague, where he spent some time with Lord Dursley, who was married to his wife’s sister.

From the Hague he arrived in England, in the latter end of 1691; where being averse to the Revolution, he declined himself a nonjuror, and left the communion of the church of England. In this last point he had consulted Dr Tillotson, and followed his opinion, who thought it no better than a trick, (detestable in any thing, and especially in religion), to join in prayers where there was any petition which was held to be sinful. Thus, notwithstanding their difference of opinion respecting the lawfulness of the revolution, the friendship between them remained the same; and the good archbishop expired in his friend’s arms in 1694. Nor did Mr Nelson’s friendship end there: he continued it to his grace’s widow, and was very instrumental in procuring her pension from the crown to be augmented from 400 l. to 600 l per annum. It is very remarkable, that the great regard he had always shown to Tillotson, added to his own reputation for learning, judgment, and candour, induced Dr Barker, who published the archbishop’s pithomous sermons, to consult our author on that occasion. Among the manuscripts, there was found one discourse wherein the archbishop took an occasion to complain of the usage which he had received from the nonjurors, and to expose, in return, the inconsistency of their own conduct; remarking particularly, that, upon a just comparison of their principle or non-resistance with their actual non-affiliation to king James II. they had little reason to boast of their loyalty to him: and yet, severer as this discourse was upon that party, Mr Nelson, notwithstanding his attachment to them, was very zealous to have it printed; alleging, that they deserved such a re-uke for their unjust treatment of so good a man. However, the sermon was then suppressed, and is now probably lost.

Our author’s new character unavoidably threw him into some new connections. Among these we find mentioned particularly Mr Kettlewell, who had resigned his living at Colehill in Warwickshire on account of the new oaths, and afterwards resided in London. This pious and learned divine agreed with him, in leaving the communion of the established church; yet at the same time persuaded him to engage in the general service of piety and devotion; offering to him, that he was very able to compose excellent books of that kind, which would be apt to do more good as coming from a layman. This address...
correspond with the truly catholic spirit of our author; who accordingly published many works of piety, which are deservedly esteemed. Indeed it was this spirit, more than their agreement in state principles, that first recommended them to one another. Mr Nelson is observed to have encouraged Kettlewell to proceed in that just and gentle manner, in which he excelled, in managing the nonjurors' controversy, and animating him besides to begin and prosecute some things for a public good, which otherwise would not have been the light. Mr Kettlewell died in 1695, and left Mr Nelson his sole executor and trustee; in consequence of which, he published a posthumous piece of piety, intitled, "An Office for Priorsors, &c." in 1697. He also published five other of his friend's posthumous pieces, and furnished the chief materials for the account of his life afterwards.

At the same time he engaged zealously in every public scheme for the honour and interest, as well as for propagating the faith, and promoting the practice of true Christianity, both at home and abroad; several proposals for building, repairing, and endowing churches, and charity-schools particularly.

Upon the death of Dr William Lloyd, the deprived bishop of Norwich, in the end of the year 1709, he returned to the communion of the church of England. Dr Lloyd was the last surviving of the deprived bishops by the Revolution, except Dr Kenn, by whose advice Mr Nelson was determined in this point. It had been a cafe in view some time, which had been bandied on both sides, whether the continuance of their separation from the church should be schismatical or no, when that case became a fait; and our author had some conferences upon it with Dr Hickey, who was for perpetuating the nonjurors, and charging the schism upon the church established. (See an account of this dispute, with some letters that passed between them on the occasion, in "The Constitution of the catholic church, and the nature and consequences of Schism set forth, in a collection of papers written by the late George Hickey, D. D. 1716. 8vo.") Mr Nelson's tutor, Dr George Bull, bishop of St David's, dying before the expiration of this year, he was early prevailed upon by that prelate's son to draw up an account of his father's life and writings, as he had maintained a long and intimate friendship with his lordship, which gave him an opportunity of being acquainted with his solid and substantial worth. The life was published in 1713; and as our author had long before laboured under a constitutional weakness, which had brought on an album and dropy in the breast, the distemper grew to such a height soon after the publication of that work, that, for the benefit of the air, he retired at length to Kenington, where he expired on the 16th of January 1714-15, aged 59.

He was interred in the cemetery of St George's chapel, now a parochial church in Lamb's Conduit Fields, where a monument is erected to his memory, with a long and elegant Latin inscription, written by Bishop Smalridge. He was the first person buried in this cemetery, and as it was done to reconcile others to the place, who had taken an unfounded prejudice against it, it proved a most prevailing precedent, and had the desired effect. He published several works of piety, and left his whole estate to pious and charitable uses, particularly to charity-schools. A good portrait of him was given by Mr Nichol, in 1779, to the company of stationers, and is placed in the parlour of their public hall. After the death of Sir Berkeley Lucy, Mr Nelson's library was sold by auction in 1760, together with that of Sir Berkeley, forming, united, a most extraordinary assemblage of devotion and infidelity. Several of Mr Nelson's original letters, highly characteristic of his benevolence, may be seen in the Anecdotes of Bowyer. Mr Nichols has also in his possession in MS. two excellent letters of advice from Mr Nelson to his young cousins George and Gabriel Hunger, on their going to settle in Turkey; which have been obligingly offered for the use of any future biographer, but are too long for our limits.

NEMEAUS, or NEMEAUM, (anc. geog.) the capital of the Areococi in Gallia Narbonensis: a colony, (Coin), with the surname Augustus, (Inscription). In it stands a Roman amphitheatre, which is still almost entire. Now Nîmes in Languedoc.

NEMEA (Strabo, Livy): a river of Achaia, running between Sicyon and Corinth, the common boundary of both territories, and falling into the Corinthian bay.

NEMEA (anc. geog.), situated between Cleone and Philus in Argolis: whether town, diocese, or other thing, uncertain: there a grove stood in which the Argives celebrated the Nemean games, and there happened all the fabulous circumstanes of the Nemean lion. The diocese Nemea is called Bembinadia, (Pli ny) a village, Bembina, standing near Nemea, (Strabo). Stephanus places Nemea in Elis; though not in Elis, but on its orders; Pliny, erroneously, in Arcadia. In the adjoining mountain is still shown the den of the lion, distant 15 status from the place Nemea, (Pausanias); in which stands a considerable temple of Jupiter Nemeus and Cleoneus, from the vicinity of these two places. This place gave name to the Nemean games, celebrated every year.

NEMEAN GAMES, so called from Nemea, a village between the cities of Cleone and Philus, where they were celebrated every third year. The exercises were chariot-races, and all the parts of the Pentathlon. These games were instituted in memory of Opheltes or Archermus, the son of Eupheus and Creusa, who was nursed by Hypsipyle; who leaving him in a meadow while she went to show the besiegers of Thebes a fountain, at her return found him dead, and a serpent twined about his neck; whence the fountain, before called Langia, was named Archermus; and the captives, to comfort Hypsipyle, instituted these games. Others ascribe their institution to Hercules, after his victory over the Nemean lion. Others allow, that they were instituted first in honour of Archermus; but intermitted, and revived again by Hercules. The victors were crowned with garlands, and herb used at funerals, and designed to have sprung from Archermus's blood. The Argives preferred at these games.

NEMESIANUS (Aurelius Olympius), a Latin poet who was born at Carthage, and flourished about the year 281, under the emperor Carus, and his sons Carinus and Numerian, the last of which emperors was so fond of poetry that he composed the glory with Nemesianus,
Nemefius, who had written a poem upon fishing and maritime affairs. We have still remaining a poem of his author, called Cyngelion, and four logiogues: they were published by Paulus Manutius in 1538; by Barthlet in 1631; at Leyden in 1653, with the notes of Janus Vitius. Giraldi hath preferred a fragment of Nemefius, which was communicated to him by Sannazarius, to whom we are obliged for our poet's works: for having found them written in Gothic of Nemefianus, which is greatly inferior to those of Atticus. Jupiter and the eighth century, that it was written among the classies in the public schools, particularly in the time of Charlemagne, as appears from a letter of the celebrated Hincmar bishop of Rheims to his nephew Hincmar of Laon.

NEMESIS, in Pagan worship, the daughter of Jupiter and Necceffy, or, according to others, of Oceanus and Nix, had the care of revenging the crimes which human justice left unpunished. She was also called Adrastea, because Adrastus king of Argos first raised an altar to her; and Rhamnus (from her having a magnificent temple at Rhamnus in Attica). She had likewise a temple at Rome in the Capitol. She is represented with a horn in her hand and a pair of scales in the other.

NEMESIS, a Greek philosopher who embraced Christianity, and was made bishop of Emesa in Phocicia, where he had his birth: he flourished in the beginning of the fifth century. We have a piece by him, intitled De natura hominis, in which he refutes the fatality of the Stoics and the errors of the Manichees, the Apollinarists, and the Eunomians: but he expouses the opinion of Origen concerning the pre-existence of souls (a). This treatise was translated by Valla, and printed in 1535. Another version was afterwards made of it by Ellebodius, and printed in 1665; it is also inserted in the Biblia Sacra, Parisiana, in Greek and Latin. Lately, another edition was published at Oxford in 1674, folio, with a learned preface, wherein the editor endeavours to prove, from a passage in this book, that the circulation of the blood was known to Nemefius; which, however, was since shown to be a mistake by Dr. Fruin, in his History of Physic.

NEMINE CONTRADICENTIS, "none contradicting it;" a term chiefly used in parliament when anything is carried without opposition.

NEMOURS, a town of the Isle of France in the Gâtinois, with the title of a duchy. It is seated on the river Loing, in E. long. 2. 45, N. lat. 48. 14.

NENAGH, a poft and fair town of Ireland in the county of Tipperary, and province of Munster, 75 miles from Dublin. It is situated on a branch of the river Shannon which runs into Lough-Derg. Here stands the ruins of an old castle called Nenagh-round. Also those of an hospital founded in the year 1200, for canons following the rule of St. Auguin. It was dedicated to St John the Baptist, and was usually called Tredon, or St John's house. In the reign of Henry III. a friary for conventual Franciscans was also founded here, and esteemed the richest foundation of that order in the kingdom. Here is a barrack for two troops of horse. This town was burnt on St Stephen's day 1348, by the Irish. The fair held here are four.

NENIA, or NEMIA, in the ancient poetry, a kind of funeral song sung to the music of flutes at the obsequies of the dead. Authors represent them as sorry compositions, sung by hired women mourners called Prefes. The first rule of Nenia is ascribed to the physicians. In the heathen antiquity, the goddess of tears and funerals was called Nenia; whom I suppose to have given that name to the funeral song, and others to have taken her name from it.

NECESARIO, (Pline), a town of Pontus on the south or the left side of the Lyceus. About the year 342, when Leontius and Sallustius were consuls, it was entirely ruined by a dreadful earthquake, except the church and the bishop's habitation, who was saved, with the clergy and some other pious persons, while the rest of the inhabitants were buried in its ruins.

NEOMAGUS, (Ptolemy); NOVIOMAGUS, (Antonine): a town of the Regni in Britain: now thought to be Guildford in Surrey, (Lhuyd); or Croydon, (Salbot). But Camden takes it to be Woodcote, two miles to the south of Croydon, where traces of an ancient town are still to be seen.

NOVIOMAGUS, (Ptolemy); NOVIOMAGUS, (Antonine): a town of the Trivi on the Miscelle. Now Numagen, 14 miles east, below Tiers.

NOVIOMAGUS, (Ptolemy); Noviomagus Nemoeum, (Antonine). Now Spire, a city of the palatinate, on the left or west side of the Rhine.

NOVIOMAGUS, (Ptolemy); a town of Gallia Narbonensis; on the confines of the Trifalinni. Now Nyons in Dauphiné.

NEOMENIA, or NOUMENIA, a festival of the ancient Greeks, at the beginning of every lunar month, which, as the name imports, was observed upon the day of the new moon, in honour of all the gods, but especially Apollo, who was called Neomenios, because the sun is the fountain of light; and whatever distinction of times and feasons may be taken from other planets, yet they are all owing to him as the original of those borrowed rays by which they shine.

The games and public entertainments at these festivals were made by the rich, to whose tables the poor flocked in great numbers. The Athenians at these

(a) It is much more probable that he and Origen both brought their opinion with them from the schools of philosophy, than that either of them borrowed it from the other. See Metaphysics, Part 3d. chap. 4.
The Jews had also their neomenia, or feast of the new moon, on which peculiar sacrifices were appointed; and on this day they had a sort of family entertainment and rejoicing. The most celebrated neomenia of all others was that at the beginning of the civil year, or first day of the month Tisri, on which no servile labour was performed: they then offered particular burnt-sacrifices, and founded the trumpets of the temple. The modern Jews keep the neomenia only as a feast of devotion, which any one may observe or not as he pleases.

NEOPHYTES, "new plants," a name given by the ancient Christians to those heathens who had newly embraced the faith; such persons being considered as regenerated, or born anew by baptism. The term neophytes has been also used for new priests, or those just admitted into orders, and sometimes for the novices in monasteries. It is still applied to the converts made by the missionaries among the infidels.

NEPA, in zoology, a genus of insects belonging to the order of hemiptera. The rothum is infected; the antenna are shorter than the thorax; and the hind-feet are hairy, and fitted for swimming. There are seven species. The four wings are folded together crosswise, with the anterior part coriaceous. The two fore feet are cheliform or resemble the claws of a crab; the other four are formed for walking. We have but three species of this genus, all three of which are found in the water, where they dwell, as do their larva and chrysalids. It is likewise in the water that we find the eggs of the water scorpion. Those eggs, of an oblong shape, have at one of their extremities two or more bristles or hairs. The insect sinks its egg into the flalk of a bull-rush or some other water-plant, so that the egg lies concealed, and only the hairs or bristles flick out, and are to be seen. One may easily perceive in water those stalks loaded with eggs, and see the young water-scorpions hatched under one's own roof, or at least their larva. These insects are voracious, and feed on other aquatic animals, which they pierce and tear with their sharp rostrum, while they hold them with the forceps of their fore-feet. — They fly well, especially in the evening and night, and they convey themselves from one pool to another, especially when that they are in begins to dry up. Mr. Ray observes, that the pedes cheliformes, or fore-feet of the nepa, are the antenna of the insect, which according to him, has but four feet.

NEPENTHESES, in botany: A genus of the tetrandra order, belonging to the gymnandria class of plants; and in the natural method ranking among those of which the order is doubtful. The calyx is quadripartite; there is no corolla; the capsule is quadrilocular.

NEPET, CATMINT, or NEP, in botany: A genus of the gymnospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 42nd order, Verticillata. The under lip of the corolla has a small middle segment crenated; the margin of the throat is reflexed; the stamina approach one another. There are 14 species; the most remarkable is the catnip, common nep, or catmint. This is a native of many parts of Britain, growing about hedges and in waste places. The stalk is a yard high, and branched; the leaves are hoary; the flowers flesh-coloured growing verticillate in spikes at the top of the branches; the middle segment of the lower lip is spotted with red. The plant has a bitter taste, and strong smell, not unlike pennyroyal. An infusion of this plant is reckoned a good cephalic and emenagogue; being found very efficacious in chlorotic cases. Two ounces of the expressed juice may be given for a dose. It is called catmint, because cats are very fond of it, especially when it is withered; for then they will roll themselves on it, and tear it to pieces, chewing it in their mouths with great pleasure. Mr. Ray mentions his having transplanted some of the plants of this fort from the fields into his garden, which were soon destroyed by the cats; but the plants which came up from seeds in his garden escaped: this verifies an old proverb, viz. "If you set it, the cats will eat it; if you sow it, the cats will not know it." Dr. Withering is of opinion, that where there is a quantity of plants growing together, the cats will not meddle with them: but Mr. Millar affirms, that he has frequently transplanted one of these plants from another part of the garden, within two feet of which some came up from seeds; in which case the latter have remained unhurt, when the former have been torn to pieces and destroyed: he acknowledges, however that where there is a large quantity of the herb growing together, they will not meddle with it. This plant is very hardy, and is easily propagated by seeds. If sown upon a poor dry soil, the plants will not grow too rank, but will continue longer, and appear much handsomer, than in rich ground, where they grow too luxuriant, and have not so strong a scent.

NEPHELIO, in botany: A genus of the pentandria order, belonging to the monogenea class of plants. The male calyx is quinquidentate; there is no corolla; the female calyx is quadrifid; there is no corolla. — There are two germes and two styles on each; the fruit is two dry plumbs, maricated, and monofpermos.

NEPHEW, a term relative to uncle and aunt, signifying a brother's son or sister's daughter; who according to the civil law, is in the third degree of consanguinity, but according to the canon in the second.

NEPHTRIC, something that relates to the kidneys. See KIDNEY.

NEPHTRIC WOOD, (lignum nephticum), a wood of a very dense and compact texture, and of a fine grain brought to us from New Spain in small blocks, in its natural state, and covered with its bark. It is to be chosen of a pale colour, sound and firm, and such as has not left its acrid taste; for the surest test of it is the infusion it is in water; for a piece of it infused only half an hour in cold water gives it a changeable colour, which is blue or yellow as variously held to the light. If the vial it is in be held between the eye and the light, the tincture appears yellow; but if the eye be placed between the light and the vial, it appears blue. We often meet with this wood adulterated with others of the same pale colour; but the dufkiest black hue of the bark is a striking character of this.

The tree is the cauli of Hernandez. It grows to the height of our pear-tree, and its wood while fresh is much of the same texture and colour; the leaves are small and oblong, not exceeding half an inch in the
Nephritic. length, or a third of an inch in breadth; the flowers are small, of a pale-yellow colour, and oblong shape, standing in spikes; the cups they stand in are divided into five segments at the edge, and are covered with a reddish down. This is the best description of the tree that can be collected from what has been hitherto written of it; nobody having yet had an opportunity of taking its true characters.

This wood is said to be a very good diuretic, and we are told it is used among the Indians in all diseases of the kidneys and bladder, and in fibruphren of urine, from whatever cause. It is also recommended in fevers, and in obstructions of the viscera. The way of taking it among the Indians is only an infusion in cold water. These uses are not however properly ascertained. See Gulielmiana.

Nephritic Stone. See Jade Stone.

Menophritics, in pharmacy, medicines proper for diseases of the kidneys, especially this stone.—Such medicines are the roots of althea, dog's grass, aquavus, lago, pellitory of the wall, mallows, pimpernell, red chick-pea, peach kernels, turpentine, &c.

Nephritis, or inflammation of the kidneys. See Medicine, n 200.

Neapos (Cornelius), a celebrated Latin biographer, who flourished in the time of Julius Caesar, and lived, according to St Jerome, to the sixth year of Augustus. He was an Italian, if we may credit Catullus, and born at Holfilia, a small town in the territory of Verona, in Chalpine Gaul. Autunus, however, will have it that he was born in the Gauls; and in that they may both be in the right, provided that under the name of Gaul is comprehended Gallia, Chalpina which is in Italy. Leander Alberti thinks Neapos's country was Verona; and he is sure that he was either born in that city or neighbourhood. For the rest, Cicero and Atticus were friends of our author; who wrote the lives of the Greek historians, as he himself attests in that of Dion, speaking of Phileius. What he says, also, in the lives of Cato and Hannibal, proves that he had also written the lives of the Latin captains and historians. He wrote some other excellent works which are lost.

All that we have left of his at present is, "The Lives of the Illustrious Greek and Roman Captains," which were a long time ascribed to Amilus Probus, who published them, as it is said, under his own name, to infirm his history thereby into the favour of the emperor Theodosius; but in the course of time, the fraud has been discovered, although several learned persons have confounded the two authors. This piece has been translated into French by the Steur de Claveret, with a dedication to the duke of Longueville, in 1663: and again by M. le Gras, then of the congregation of the oratory at Paris 1729, 12mo. We have an excellent translation of it in English, by several hands at Oxford, which has gone through several editions.

Neptune in Pagan worship, the god of the sea, was the god of Saturn and Vesta, or Ops, and the brother of Jupiter and Pluto. He afflicted Jupiter in his expeditions; on which that god, when he arrived at the supreme power, affiigned him the sea and the islands for his empire. He was, however, expelled from heaven with Apollo for conspiring against Jupiter, when they were both employed by Laomedon king of Phrygia in building the walls of Troy: but that prince dismissing Neptune without a reward, he sent a sea monster to lay waste the country, on which he was obliged to expose his daughter Hesione. He is said to have been the first inventor of horsemanship and chariot racing; on which account Mithridates king of Pontus threw chariots drawn by four horses into the sea in honour of this god; and the Romans instituted horse-races in the circus at his festival, during which all other horses left working, and the mules were adorned with wreaths of flowers.

In a contest with Minerva he produced a horse by striking the earth with his trident; and on another occasion, in a trial of skill with Minerva and Vulcan, produced a bull, whence that animal was sacrificed to him. His favourite wife was Amphytrite, whom he long courted in vain, till sending the dolphin to intercede for him, he met with success; on which he rewarded the dolphin by placing him among the stars.

He had also two other wives, one of whom was called Salapia from the salt-water; the other Venusia from the ebbing and flowing of the tides. He had like-wise many concubines, by whom he had a great number of children. He is represented with black hair, with a garment of azure or sea-green, holding his trident in his hand, and seated in a large shell drawn by sea-horses, attended by the sea-gods Polemon, Glaucus, and Phorcys, and the sea goddesses Theis, Melita, and Panopza, and a long train of tritons and sea-nymphs.

This deity was in Egypt known by the name of Canopus, or Canopus, and was worshipped as the numen aquae or spirit of the Nile. His emblem was the figure of certain vases or pitchers, with which the Egyptians filtrated the water of their sacred river, in order to purify it and render it fit for use. From the month of each of their vases, which were charged with hieroglyphics, arose the head, and sometimes the head and hands, of a man or woman. Such are the emblems which still remain of the Egyptian Neptune or Canopus; and it was by this emblem that the tutelar god of Egypt vanquished the god of Chaldea in the ridiculous manner mentioned by Rutilius in his ecclesiastical history*

* Lib. 1.

"The Chaldeans (says he) who adored the fire, cap. 29, carried their god into various countries that he might try his strength in contests with other gods. He vanquished, as we may easily conceive, the images made of gold, silver, brass, and wood, &c. by reducing them to ashes; and thus the worship of fire was every where establisbed. The priest of Canopus, unwilling, as became him, to admit the superiority of strange gods, contrived to make his god vanquish the god of Chaldea in a pitched battle. The vases which were worshipped as the emblems of Canopus being used for filtering the waters of the Nile, were of course perforated on all sides with very small holes. This faithful priest having dipped all the holes in one of these with wax, and painted the vase of different colours for a reason which the reader will admit to be a good one, filled it up with water, and fitted to its mouth the head of an idol. This emblem of Canopus was then placed in a small fire brought by the
Chaldean as the emblem of their god; and thus the gods of Egypt and Chaldea were forced into battle. The contest, however, was of short duration. The heat melting the wax made way for the water to run out, which quickly extinguished the fire; and thus Canopus vanquished the god of the Chaldeans."

Ridiculous as this story is, it is perfectly suitable to the genius of paganism and the mean artifices of the pagan priesthood; but we suspect that the historian laboured under one mistake, and substituted the Chaldeans instead of the Persians. See Polytheism.

**NEREIDS**, in the Pagan theology, sea nymphs, daughters of Nereus and Doris.—The Nereids were esteemed very handpome; insomuch that Calliope, the wife of Cepheus king of Ethiopia, having triumphed over all the beauties of the age, and daring to vie with the Nereids, they were so enraged that they sent a prodigious sea-monster in the country; and, to appease them, she was commanded by the oracle to expose her daughter Andromeda, bound to a rock, to be devoured by the monster. In ancient monuments, the Nereids are represented riding upon sea-horses: sometimes with an entire human form, and at other times with the tail of a fish.

**NEREIS**, in zoology, a genus of animals belonging to the order of vermains mollusca. The body is oblong, linear, and fitted for creeping; it is furnished with lateral pincelled tentacula. There are 14 species; of which the most remarkable are the five following: 1. The *Nereis patula*, or nereitic nereis, which inhabits almost every sea, and is one of the causes of the luminousness of the water. These creatures think like glow-worms, but with a brighter splendour, so as at night to make the element appear as if on fire all around. Their bodies are 30 minutes to an hour examination by the naked eye.

It is sometimes called *neris phosphorum*; and is thus described by Grifelin: The head is roundish and flat, and the mouth acuminate. The two horns or feelers are short and fringed. The eyes are very minute and placed on each side of the head. The body is composed of about 23 segments or joints, which are much less nearer the tail than at the head. These segments on both sides the animal all end in a short conical apex, out of which proceeds a little bundle of hairs; from under these bundles the feet grow in the form of small flexible fringed segments delimit of any thing like claws. It is scarcely two lines long, and is quite pellucid, and its colour is that of water green. They are found upon all kinds of marine plants; but they often leave them and are found upon the surface of the water, they are frequent at all seasons; but especially in summer before stormy weather, when they are more agitated and more luminous. Their numbers, and wonderful agility, added to their pellucid and shining quality, do not a little contribute to their illuminating the sea, for myriads of these animalcules may be contained in the portion of a small cup of sea-water. Immeasurable quantities of them lodge in the cavities of the rocks of islands, and to them probably do the fishes owe this nereitic quality. "I have observed with great attention (says Barbin), a fish just caught out of the sea, whose body was almost covered with them; and I have examined them in the dark; they twist and curl themselves with amazing agility, but soon retire out of our contracted sight; probably their glittering numbers dazzling the eye, and their extreme minuteness eluding our researches. It is to be observed, that when the unctuous moisture which covers the scales of fishes is exhausted by the air, these animals are not to be seen; nor are the fishes then nereitic, that matter being perhaps their nourishment when living, as they themselves afford food to many marine animals. They do not shine in the daytime, because theolar rays are too powerful for their light; however aggregate or immense their number." Their appearance is particularly brilliant when the wind is in the east and south east point, and in winter nights preceded by a warm day. If water containing these animalcules be kept warm, they retain their light two whole days after they are dead; but in cold water lose it in eight hours: motion and warmth, which increase their vivacity and strength, increase their light alio.

2. *Nereis laevis*, or bog nereis. The body of the Fig. 2. size of a hog's short bristle, transparent, as it were articulated, and on either side at every articulation provided with a short fleshy foot; internally it seems to consist in a manner of oval shaped articulations and a back formed by two lines bent backwards. It inhabits marshes abounding in clay, where it remains under ground, pushing out its outer extremity by reason of its continual motion. When taken out it twists itself up. Is frequent in Sweden.

3. *Nereis cirrosa*, or waving nereis. The body is Fig. 3. red, lumbriformic, with 65 notches, furnished on both sides with two rows of bristles. At each side of the head ten filaments, at the sides of the mouth many, twice as long as the former. It dwells in Norway, on rocks at the bottom of the sea. It vomits a red liquor with which it tinges the water.

4. *Nereis carinata*, or blue nereis. It inhabits the Fig. 4. ocean; where it destroys the perpule and teredines.

5. *Nereis gigantea*, or giant nereis. This is a pe-Fig. 5. larus species of thread large worms that make their way into decayed piles driven down into the sea, which they bore through and feed upon, whence they are called *sea worms* or nereis. From head to tail they are all equal in either side with small tufts terminating in three points; which are like the fine hair pencils used by painters, and composed of shining brillres of various colours. The upper part of the body in this worm is all covered with small hairs. The rings of which it is formed are closely pressed together, and yield to the touch. The three rows of small tufts we have been describing, serve this nereis instead of feet, which it uses to go forwards as fishes do their fins.

**NEREUS** (nat. hist.), a marine deity, was the son of Oceanus and Theous. He settled in the Egean Sea, was considered as a prophet, and had the power of acknowledging what form he pleased. He married his sister Doris, by whom he had 50 daughters called the *Nereids*, who constantly attended on Neptune, and when he went abroad surrounded his chariot.

**NERI** (S. Philippe de), founder of the congregation of the Oratory in Italy, was born of a noble family at Florence, on the 25th of July 1515. Educated in the principles of piety and learning, he soon became
became distinguished for his knowledge and virtue. At the age of 19 he went to Rome, where he improved his mind, aided the sick, and gave many proofs of self-denial and humility. Philippe, being raised to the priesthood at the age of 36, instituted, in 1550, a celebrated fellowship in the church of St. Saviour del Campo, for the relief of poor foreigners, of pilgrims, and of convalescents, who had no place whither they could retire. This society was the cradle, if we may say so, of the congregation of the Oratory. The holy founder having gained over to God Salvati brother to the cardinal of the same name, Tarugio afterwards cardinal, the celebrated Baronius, and several others, they began to form themselves into a society in 1564. The spiritual exercises had been transferred in 1558 to the church of Saint Jerom de la Charité, which Philippe did not leave till 1574, when he went to stay at Saint John of the Florentines. Pope Gregory XIII. gave his approbation of the congregation charity might prove to be the good of his people and when he was desired to sign his name to a list of malefactors that were to be executed, he exclaimed, Would to heaven I could not write! He hated flattery; and when the senate had liberally commended the wisdom of his government, he defired them to keep their praises till he deferred them. These promising virtues soon, however, proved to be artificial: Nero soon displayed the real propensities of his nature. He delivered himself from the sway of his mother, and at last ordered her to be murdered. This unnatural act of barbarity might afohnish some, but Nero had his devoted adherents; and when he declared that he had taken away his mother's life to save himself from ruin, the senate applauded his measures, and the people signified their approbation. Many of his courtiers shared her unhappy fate; and Nero sacrificed to his fury or caprice all such as obstructed his pleasure or diverted his inclination. In the night he generally went from his palace to visit the meanest taverns, and all the scenes of debauchery which Rome contained. In this nocturnal riot he was fond of insulting the people in the streets; and his attempts to offer violence to the wife of a Roman senator nearly cost him his life. He also turned actor, and openly appeared on the Roman stage in the meanest characters. In his attempts to excel in music, and to conquer the disadvantages of a hoarse disagreeable voice, he moderated his meals, and often passed the day without eating. The Olympian games attracted his notice: he went into Greece, and presented himself a candidate for the public honour. He was defeated in wrestling; but the flattery of the spectators adjudged him the victory, and he returned to Rome with all the pomp and splendor of an eastern conqueror, drawn in the chariot of Augustus, and attended by a band of musicians, actors, and stage dancers from every part of the empire. These private and public amusements of the emperor were indeed innocent; his character only was injured, and not the lives of the people. His conduct however, soon became more abominable: he disguised himself in the habit of a woman, and was publicly married to one of his eunuchs. This violence to nature and decency was soon exchanged for another: Nero returned his love, and celebrated his nuptials with one of his meanest catamites: and it was on this occasion hat one of the Romans observed that the world would have been happy if Nero's father had had a wife. But this cruelty was now displayed in a still higher degree, for he sacrificed to his vacantness his wife Octavia Poppea, and the celebrated writers, Seneca, Lucan, Petronius, &c. Nor did the Christians escape his barbarity. He had heard of the burning of the library; and as he wished to renew that dismal scene, he caused Rome to be set on fire in different places. The conflagration became soon universal, and during nine successive days the fire continued. All was devastation: nothing was heard but the lamentations of mothers whole
whom children had perished in the flames, the groans of the dying, and the continual fall of palaces and buildings. Nero was the only one who enjoyed the general conflagration. He placed himself on the top of a high tower, and he feng on his lyre the destruction of Troy, a dreadful scene which his barbarity had realized before his eye. He attempted to avert the public odium from his head by a pretended commination of the miseries of his subjects. He began to repair the streets and the public buildings at his own expense. He built himself a celebrated palace, which he called his golden house. It was liberally adorned with gold, with precious stones, and with everything rare and exquisite. It contained spacious fields, artificial lakes, woods, gardens, orchards, and whatever exhibited a beautiful scene. The entrance of this edifice could admit a large colossal of the emperor 120 feet high; the galleries were each a mile long, and the whole was covered with gold. The roofs of the dining halls represented the firmament, in motion as well as in figure; and continually turned round night and day, showering down all sorts of perfumes and sweet waters. When this grand edifice which, according to Pliny extended all round the city, was finished, Nero said that now he could lodge like a man. His prestation was not left remarkable in all his other actions. When he went a fishing, his nets were of gold and silk. He never appeared twice in the same garment; and when he took a voyage there were thousands of servants, to take care of his wardrobe. This continuation of debauchery and extravagance at last roused the people. Many conspiracies were formed against him; but they were generally discovered, and such as were acceditory suffered the severest punishments. The most dangerous conspiracy against Nero’s life was that of Piso, from which he was saved by the confession of a flave. The conspiracy of Galba proved more successful, who, when he was informed that his plot was known to Nero, declared himself emperor. The unpopularity of Nero favoured his cause; he was acknowledged by all the Roman empire, and the senate condemned the tyrant to be dragged naked through the streets of Rome, and whipped to death, and afterwards to be thrown down from the Turpeian rock like the meanest malefactor. This, however, was not executed: for Nero prevented it by a voluntary death. He killed himself, A. D. 68, in the 32d year of his age, after a reign of 13 years and eight months. Rome was filled with acclamations at it; and the citizens, more strongly to indicate their joy, wore caps, such as were generally used by slaves who had received their freedom. Their vengeance was not only exercized against the statues of the deceased monster, but many of his friends were the objects of the public resentment; and many were crushed to pieces in such a violent manner, that one of the senators, amid the universal joy, said that he was afraid they should soon have cause to wish for Nero. The tyrant, as he expired, requested that his head might not be cut off from his body, and exposed to the insolence of the populace, but that the whole might be burned on the funeral pile. His requiem was granted by one of Galba’s freedmen, and his obsequies were performed with the usual ceremonies. Though his death seemed to be the source of general gladness, yet many of his favorites lamented his fall, and were grieved to see that their pleasures and amusements were stopped by the death of this patron of debauchery and extravagance. Even the king of Parthia sent ambassadors to Rome, to condem with the Romans, and to beg that they would honour and revere the memory of Nero. His statues were also crowned with garlands of flowers; and many imagined that he was not dead, but that he would soon make his appearance and take vengeance on his enemies. It will be sufficient to observe, in finishing the character of this tyrannical monster, that the name of Nero is even now used emphatically to express a barbarous and unfeeling oppressor. Pliny calls him the common enemy and fury of mankind; and so indeed he has been called by all writers, who exhibit Nero as a pattern of the most execrable barbarity and unpardonable wantonness. The same Pliny furnishes us with this singular anecdote of him: “Nero had ordered himself to be painted under the figure of a colossus, upon cloth or canvas, 120 feet in height.” He adds, “that this preposterous picture, when it was finished, met with its fate from lightning, which consumed it, and involved likewise the most beautiful part of the gardens where it was placed in the coufignation.”

NERVA (Cocceius), a Roman emperor after Domitian, who was the last of the 12 Caesars. He was a native of Narnia in Umbria; his family however was originally of Crete. Dio Callius says he was born on the 17th of March, in the 18th year of Tiberius’s reign, and of the Christian era the 33d. Nero in the 17th year of his reign made him prætor, and erected a statue for him in the palace on account of his poems (for he was one of the best poets of his age), some of which were inscribed to him. He was consul in 71 with Vespasian, and in 90 with Domitian. Ancient authors uniformly celebrate him as a prince of a most mild and humane temper, of great moderation and generosity, who looked on his office for religion, and for his own advantage, but for that of his people; and whilst he reigned, which was however but for a short time, he made the happiness of his subjects his only end and pursuit. He narrowly escaped death under Domitian; was naturally of a weak and timorous disposition; and, as some say, addicted to excessive drinking. The Romans unanimously chose him emperor; and they had no cause to repent of their choice, for he was constantly attentive to what could make them happy; he was generous, merciful, and disinterested. An influence of his great lenity appears in his pardoning Calpurnius Caius, who conspired against him. In short he omitted nothing that might contribute to the re-forming of the empire to its former lustre; recalling those who had been banished for religion, and redressing all grievances that came to his knowledge. He however found his strength failing, and that it would be impossible for him to finish his desings, in consequence of which he adopted Trajan. After his death which happened in the year 98, he was ranked among the gods. He was the first Roman emperor of foreign extraction.

NERVES, in anatomy, certain white glit­tering cords, proceeding from the brain and spinal marrow, and dividing into very small branches, which are sent off throughout all parts of the body; and which are found
found to be the organs of sensation and motion. See Anatomv, n° 136.

NERVOUS fluid. See Anatomy, n° 136.

NESSUS (fab. hist.), a celebrated centaur, son of Ixion and the Cloud. He offered violence to Dejanira whom Hercules had entrusted to his care, with orders to carry her across the river Evenus. Hercules saw the diffidence of his wife from the opposite shore of the river, and immediately he let fly one of his poisoned arrows, which struck the centaur to the heart. Nesus, as he expired, gave the tunic he had entrusted to his care, with the centaur to the heart. Dejanira, as he expired, gave the tunic he had received it with pleasure, and this most foul present caused the death of Hercules.—A river which separates Thrace from Macedonia. It is also called Neus, Nesus, and Nesus.

ESTABLE BIRDS. See Birds Nesus.

NESTOR (fab. hist.), a son of Neleus and Chloris, nephew to eleven brothers, and spared his life and placed him upon the throne for each generation. He soon married Eurydice the daughter of Clymenus; or, according to others, Anaxibia was his first wife. He was present at the nuptials of Perithous, when a tender age detained him at home and was the cause of his preservation. The conqueror spared his life and placed him upon the throne of Troy. He is said to have been fubstantially in the field of battle, and was present at the nuptials of Perithous, when a bloody engagement took place between the Lapiade and centaurs. As king of Troy and Meffenia he led his subjects to the Trojan war, where he distinguished himself among the rest of the Grecian chiefs, by eloquence, address, wisdom, justice, and uncommon prudence. Homer displays his character as the most perfect of all his heroes; and Agamemnon exclaims, that if he had 20 generals like Nestor, he should soon see the walls of Troy reduced to ashes. After the Trojan war Nestor retired to Greece, where he enjoyed in the bosom of his family the peace and tranquillity which were due to his wisdom and to his age. The manner and the time of his death are unknown: the ancients are all agreed that he lived three generations of men; which length of time is fuppofed to be 300 years, though more probably only 90 years, allowing 30 years for each generation. From that circumstance, therefore, it was usual among the Greeks and the Latins, when they wished a long and happy life to their friends, to wish them to live the years of Nestor. He had many children; two daughters, Phidice and Polynde; and seven sons, Pericles, Statius, Aratus, Echepron, Piliftratus, Antiochus, and Trafmedes. Nestor was one of the Argonauts, according to Valerius Flaccus, v. 380, &c.—A poet of Lycocia in the age of the emperor Severus. He was father to Epander, who under the emperor Alexander wrote some fabulous stories.—One of the body guards of Alexander.

Nestor, whose pectoral name is not known, was a native of Russha, and the earliest historian of the north. He was born in 1576 at Biederozer, and in the 19th year of his age he assumed the monastic habit in the convent of Pocherki at Kief, and took the name of Nefer. He there made a considerable proficiency in the Greek language; but seems to have formed his style and manner rather from the Byzantine historians, Cedrenus, Zonaras, and Synkelius, than from the ancient classics. The time of Nestor's death is not ascertained, but he is supposed to have lived to an advanced age, and to have died about the year 1115.

His great work is his Chronicle, to which he has prefixed an introduction, which, after a short sketch of the early state of the world, taken from the Byzantine writers, contains a geographical description of Russia and the adjacent regions; an account of the Scelovan nations, their manners, their emigrations from the banks of the Danube, their dispersion, and settlement in the several countries wherein their descendants are now established. He then enters upon a chronological series of the Russian annals, from the year 858 to about 1113. His style is simple and unadorned, such as suits a mere recorder of facts; but his chronological exactness, though it renders his narrative dry and tedious, contributes to ascertain the era and authenticity of the events which he relates.

It is remarkable (says Mr. Coxe, from whom we have taken this narrative), that an author of such importance, whose name frequently occurs in the early Russian books, should have remained in obscurity above 600 years; and been scarcely known to his modern countrymen, the origin and actions of whose ancestors he records with such circumstantial exactness. A copy of his Chronicle was given in 1668 by Prince Radvilov to the library of Konigsburgh, where it lay unnoticed until Peter the Great, in his passage through that town, ordered a transcript of it to be sent to Peterburgh. But it still was not known as the performance of Nestor: for when Muller in 1732 published the first part of a German translation, he mentioned it as the work of the abbot Theodosius of Kiof; an error which arose from the following circumstance; The ingenious editor not being at that time sufficiently acquainted with the Scelovian tongue, employed an interpreter, who, by misreading a letter in the title, supposed it to have been written by a person whose name was Theodosius. This ridiculous blunder was soon circulated, and copied by many foreign writers, even long after it had been candidly acknowledged and corrected by Muller.

NESTORIANS, a sect of ancient Christians, still said to be subsisting in some parts of the Levant; whose distinguishing tenet is, that Mary is not the mother of God. They take their name from Nestorius, bishop of Constantiople, whose doctrines were spread with much zeal through Syria, Egypt, and Persia.

One of the chief promoters of the Nestorian cause was Barfumas, created bishop of Nifibis, A.D. 435. Such was his zeal and success, that the Nestorians, who still remain in Chaldea, Persia, Assyria, and the adjacent countries, consider him alone as their parent and founder. By him Pherozes the Persian monarch was persuaded to expel those Christians who adopted the opinions of the Greeks, and to admit the Nestorians in their place, putting them in possession of the principal seat of ecclesiastical authority in Persia, the fee of Seleucia, which the patriarch of the Nestorians has always held even down to our time. Barfumas also erected a school at Nifibis, from which...
Nestorian doctors who in the fifth and sixth centuries spread abroad their tenets through Egypt, Syria, Arabia, India, Tartary, and China.

He differed considerably from Nestorius, holding that there are two persons in Jesus Christ, as well as the Virgin was not his mother as God, but only as man.

The abettors of this doctrine refuse the title Nestorians; alleging that it had been handed down from the earliest times of the Christian church.

In the tenth century, the Nestorians in Chaldea, where they are sometimes called Chaldæans, extended their spiritual conquests beyond mount Imaus, and introduced the Christian religion into Tartary, properly so called, and especially into that country called Karit, and bordering on the northern part of China. The prince of that country, whom the Nestorians converted to the Christian faith, affirmed, according to the vulgar tradition, the name of John after his baptism, to which he added the surname of Prefbyter, from a principal of modesty; whence it is said his successors were each of them called Prefbyter John until the time of Gengis Khan. But Mothém observes, that the famous Preflor John did not begin to reign in that part of Asia before the conclusion of the 11th century, the Nestorians formed so considerable a body of Christians, that the millionaries of Rome were inducible in their endeavours to reduce them under the papal yoke. Innocent IV. in 1246 and Nicolas IV. in 1278, used their utmost efforts for this purpose, but without success. Till the time of pope Julius III. the Nestorians acknowledged but one patriarch, who resided first at Bagdad, and afterwards at Mosul; but a division arising among them, in 1551, the patriarchate became divided, at least for a time, and a new patriarch was consecrated by that pope, whose successors fixed their residence in the city of Ormus, in the mountainous part of Persia, where they still continue, distinguished by the name of Simeon; and so far down as the last century, these patriarchs persisted in their communion with the church of Rome, but feem at present to have withdrawn themselves from it. The great Nestorian pontiffs, who formed the opposite party, and contended on this little patriarch, have since the year 1559 been distinguished by the general denomination of Elias, and reside commonly in the city of Mosul. Their spiritual dominion is very extensive, in a great part of Asia, and comprehends also within its circuit the Arabian Nestorians, and also the chritians of St. Thomas, who dwell along the coast of Malabar. It is observed, to the lasting honour of the Nestorians, that of all the Christian societies establisht in the East, they have been the most careful and successful in avoiding a multitude of superfluous opinions and practices that have infected the Greek and Latin churches. About the middle of the 17th century, the Roman millionaries gained over to their communion a small number of Nestorians, whom they formed into a congregation or church; the patriarchs or bishops of which reside in the city of Amida, or Diarbekir, and all assume the denomination of Josaphat. Nestorius and the Nestorians in general persevered to our own times in their refusal to enter into the communion of the Romish church, notwithstanding the earnest intreaties and alluring offers that have been made by the pope's legate to conquer their inflexible constancy.

NESTORIUS, from whom the sect of Nestorian Christians derive their name, was born in Germania, a city of Syria. He received his education at Antioch, where he was likewise baptized; and soon after his baptism he withdrew himself to a monastery in the suburbs of that city. Upon his being admitted to the order of priesthood, he quickly acquired so great a reputation by the eloquence of his preaching, and the regularity of his life, that by the emperor Theodosius he was deemed a fit person to fill the second see in the Christian church, and was accordingly consecrated bishop of Constantinople in the year 429.

In one of his first sermons after his promotion, he publicly declared his intention to make war upon heretics; and with that intolerant spirit which has so often disgraced the preachers of the mild religion of Jesus, he called upon the emperor to free the earth from heretics, promising to give him heaven as a reward for his zeal. To this spiritual motive he added one, that though carnal, he professedly judged of equal force. Joining with me (said he) in war against them, and I will adft you against the Persians. Although the wiser and better parts of his audience were amazed at such a man, before he had tasted (as the historian Socrates expresses himself) the water of his city, declare that he would persecute all who were not of his opinion; and yet the majority of the people approved of this discourse, and encouraged him to execute his purpose. Accordingly, five days after his consecration, he attempted to demolish the church in which the Arians secretly held their assemblies; and he succeeded so far in his design that these people, growing desperate, set it on fire themselves, and consumed it with some of the neighbouring houses. This fire excited great commotions in the city, and Nestorius was afterwards called an incendiary.

From the Arians he turned his persecution against the Novatians, but was stopped in his career by the interpolation of the emperor. He then let loose his fury upon those Christians of Asia, Lydia, and Caria, who celebrated the feast of Easter upon the 14th day of the moon; and for this unconsidered deviation from the Catholic practice, many of those people were murdered by his agents both at Mileten and at Sardis. One cannot but be sorry that such a relentless persecutor should himself be afterwards condemned as an heretic, for holding an opinion which no man who speaks or thinks with philosophic accuracy will now venture to controvert. This obnoxious tenet, which produced a schism in the church, and was condemned by a general council, was nothing more than that "the Virgin Mary cannot with propriety be called the mother of God." The people being accustomed to hear this expression, were much inflamed against their bishop, imagining that he had revived the error of Paulus Sa-nostomus and Philonicus, who taught that Jesus Christ was a mere man. The monks declared openly against him, and, with some of the most considerable men in Constantinople, separated themselves from his communion. Several bishops wrote to him earnest perjuries to acknowledge that Mary was the mother of God; and when he would not comply, they procured his con-
NET

condemnation in the council of Ephesus, which deprived him of his see. He then retired to his ancient monastery at Antioch, whence he was taken four years afterwards by the emperor's order, and banished in 435 to Tarsus. That city being taken and destroyed by the barbarians, he was removed to Panopolis, a city of Thebai; where he was not suffered to remain long, but was compelled to go from place to place, till, being in one of his journey's mortally bruised by a fall, death relieved him from the fury of his persecutors.

If we examine such of his writing as remain, we shall find that he was very unjustly condemned. It appears that he rejected the errors of Arist, Paulus Samaritanus, and Plato; that he maintained in express terms, that the divine Word was united to the human nature in Jesus Christ in the most strict and intimate sense possible; that these two natures, in this state of union, make but one Christ and one person; that the properties of the Divine and human natures, may both be attributed to this person; and that Jesus Christ may be said to have been born of a virgin, to have suffered and died; but he never would admit that God could be said to have been born, to have suffered or to have died.

When we consider that every person partakes of the substance of his mother, and that it is this which constitutes the parental and filial relation between them, it is indeed surprising that the expression "Mother of God" should ever have been admitted in the Christian Church, or that any man who understands the meaning of the words should condemn Nectarius for not having used them.

NESTUS, or Nessus, a river which separates Thrace from Macedonia. It falls into the Egean sea near the island Thaïs. It is sometimes called Neïs, and Neïs.

NET, a device for catching fish and fowl. See the article Fishery.

The taking of nets by nests is the readiest and most advantageous of all others, where numbers are to be taken. The making the nets is very easy, and what every true sportsman ought to be able to do himself. All the necessary tools are wooden needles, of which there should be several of different sizes, some round and others flat; a pair of round pointed and flat scissors; and a wheel to wind off the thread. The pack thread is to be of different strength and thickness, according to the sort of birds to be taken; and the general size of the meshes, if not for very small birds, is two inches from point to point. The nets should neither be made too deep nor too long, for they are then difficult to manage; and they must be verged on each side with twisted thread. The natural colour of the thread is too bright and pale, and is therefore in many cases to be altered. The most usual colour is the ruffle; which is to be obtained by plunging the net, after it is made, into a tanner's pit, and letting it lie there till it be sufficiently tinged: this is of a double service to the net, since it preserves the thread as well as alters the colour. The green colour is given by chapping some green wheat and boiling it in water, and then soaking the net in this green tincture. The yellow colour is given in the same manner with the decoction of celandine; which gives a pale straw colour, which is the colour of flubble in the harvest-time. The brown nets are to be used on ploughed lands, the green on grass grounds, and the yellow on flubble lands.

Net-Day, among fowlers, a net generally used for taking such small birds as play in the air, and will flock either to prey, gig, or the like; as larks, linnets, buntings, &c. The time of the year for using this net is from August to November; and the best time is very sportful early in the morning: and it is to be observed, that the milder the air, and the brighter the sun is, the better will be the sport, and of longer continuance. The place where this net should be laid, ought to be plain champain, either on short flubbles, green lays, or flat meadows, near corn-fields, and somewhat remote from towns and villages: you must be sure to let your net lie close to the ground, that the birds creep not out and make their escape. The net is made of a fine packthread with a small mesh, not exceeding half an inch square; it must be three fathom long, and but one broad; it must be verged about with a small but strong cord; and the two ends extended upon two small long poles, suitable to the breadth of the net, with four flakes, tail-turings, and drawinglines. This net is composed of two, which must be exactly alike, and are to be laid opposite to one another, so even and close, that when they are drawn and pulled over, the fides must meet and touch each other. You must flake this net down with strong stakes, very stiff on their lines, so that you may with a nimble touch cast them to and fro at pleasure; then fasten your drawing-cords or hand-lines (of which there must be a dozen at least), and each two yards long) to the upper end of the foremost flakes: and so extend them of such a straightness, that with a little strength they may rise up in the nets, and cast them over.

Your nets being thus laid, place your gigs, or playing-wants, about 20 or 30 paces beyond, and as much on this side your nets; the gig must be fastened to the tops of long poles, and turned into the wind, so as they may play to make a noise therein. These gigs are a sort of toys made of long goose feathers, like shuttle-cocks, and with little small tunnels of wood running in broad and flat sivan quills, made round like a small hoop; and so, with longer fringes fastened to a pole, will, with any small wind or air, move after such a manner, that birds will come in great flocks to play about them.

When you have placed your gigs, then place your flake; which is a small flake of wood, to prick down into the earth, having in it a mortice-hole, in which a small and slender piece of wood, about two feet long, is fastened, so as it may move up and down at pleasure: and fasten to this longer flack a small line, which, running through a hole in the flack above-mentioned, and so coming up to the place where you are to fit, you may, by drawing the line up and down with your right hand, raise up the longer flack as you see occasion.

Fit ten a live lark, or such like bird, to this longer flack, which, with the line making it to flit up and down by your pulling, will entice the birds to come to your net.

There is another flake, or enticement, to draw on these birds, called a lo king glafs; which is a round flake of wood, as big as a man's arm, made very sharp,
NET. [14] NET.

at the end, to thrust it into the ground: they make it very hollow in the upper part, above five fingers deep; into which hollow they place a three-square piece of wood about a foot long, and each two inches broad, lying upon the top of the flake, and going with a foot into the hollowness; which foot must have a great knob at the top, and another at the bottom, with a deep flenderness between; to which flenderness you are to fasten a small pack-thread, which, running through a hole in the side of the flake, must come up to the place where you fit. The three-square piece of wood, which lies on the top of the flake, must be of such a poise and evenness, and the foot of the socket so smooth and round, that it may whirl and turn round upon the leaf touch; winding the packthread so many times about it, which being suddenly drawn, and as suddenly let go, will keep the engine in a constant rotary motion; then fasten with glue on the uppermost flat squares of the three-square piece, about 20 small pieces of looking-glass, and paint all the square wood between them of a light and lively red; which, in the continual motion, will give such a reflection, that the birds will play about to admiration until they are taken.

Both this and the other flake are to be placed in the middle between the two nets, about two or three feet distance from each other; so that, in the falling of the nets, the cords may not touch or annoy them; neither must they stand one before or after another; the glass being kept in a continual motion, and the bird very often fluttering. Having placed your nets in this manner, as also your gigs and itales, go to the further end of your long drawing-lines and flake lines; and, having placed yourself, lay the main drawing line across your thigh, and, with your left, pull the flake-line to show the birds; and when you perceive them to play near and about your nets and itales, then pull the net over with both hands, with a quick but not too hasty motion; for otherwise you sport will be spoiled.

See Plate CCCXLV, where A shows the bodies of the main net, and how they ought to be laid. B, the tail-lines, or the hinder-lines, flaked to the ground. C, the fore lines flaked also to the ground. D, the bird-flake. E, the looking-glass flake. G, the line which draws the bird-flake. H, the line that draws the glass-flake. I, the drawing, double lines of the nets, which pulls them over. K, the flake which flake down the four nether points of the nets and the two tail-lines. L, the flake that flake down the four lines. M, the flake which flake down the four lines. N, the flake that flake down the single line, and where the man should sit; and O, the gig.

NET, neat, in commerce, something pure, and unadulterated with any foreign mixture. Thus, wines are said to be neat when not falsified or adulterated; and coffee, rice, pepper, &c. are neat when the filth and ordures are separated from them. See NEAT.

A diamond is said to be neat when it has no flaws or flaws; a crystal, when transparent throughout.

NET is also used for what remains after the tare has been taken out of the weight of any merchant-dile; i.e. when it is weighed clear of all packages. See TARE.

Thus we say, a barrel of cochineal weighs 450 pounds; the tare is 50 pounds, and there remains neat 400 pounds.

NET-produce, a term used to express what any commodity has yielded, all tare and charges deducted.

The merchants sometimes use the Italian words netto produce, for net produce.

NETHERLANDS, anciently called Belgium, but since denominated Low Countries, or Netherlands, from their low situation, are situated between 2° and 7° of east longitude, and between 50° and 55° 30' of north latitude; and are bounded by the German sea on the north, Germany on the east, by Lorrain and France on the south, and by another part of France and the British seas on the west; extending near 300 miles in length from north to south, and 200 miles in breadth from east to west. They consist of 17 provinces; 10 of which are called the Austrian and French Netherlands, and the other seven the United Provinces.

The greatest part of the Netherlands was conquered by the Romans; and the part which lies towards Gaul continued in their subjection till the decline of that empire; after which the Francs became masters of it; and, under the French monarchy, it was part of the kingdom of Metz or Ausonia.

Towards the end of the 15th century Maximilian of Austria, son of the emperor Ferdinand III. acquired by marrying the only daughter of the duke of Burgundy, the duchies of Brabant, Limburg, and Luxemburg; the counties of Flanders, Burgundy, Hainault, Holland, Zeeland, and Namur; and the lordships of Friesland. Philip of Austria, son to Maximilian and Mary, married Jane the daughter of Ferdinand king of Arragon and of Isabella queen of Castile; by which means their son Charles inherited not only almost all Spain and the great countries then lately discovered in America, but also those noble provinces of the Netherlands, and was chosen emperor under the name of Charles I. Towards the latter end of the year 1527, he added to his dominions the temporalities of the bishopric of Utrecht on both sides of the Yssel; and Henry of Bavaria, being distressed through war with the duke of Gueldreland, and tired with the continual rebellion of his own subjects, surrendered to the emperor the temporalities of his diocese, which was confirmed by the pope, and the states of the country. In 1536, Charles V. bought of Charles of Egmond the reverieon of the duchy of Gueldreland and the country of Zutphen, in cafe that prince should die without issue. The same year the city of Groningen took the oath of allegiance, and submitted to Charles V. and in 1543 he put a garrison into the city of Cambrai, and built a citadel there. Having thus united the 17 provinces, as it were in one body, he ordered that they should continue for ever under the same prince, without being ever parted or di­membered; for which purpose he published in November 1549, with the consent and at the request of the states of all the provinces, a perpetual and irrevocable edit or law, by which it was enacted, that in order to keep all those provinces together under one and the same prince,
 prince, the right of representation, with regard to the
succession of a prince or princes, should take place
for ever, both in a direct and collateral line, notwith-
standing the common laws of some provinces to the
contrary. Charles had even a mind to incorporate
these provinces with the Germanic body, and to make
of them a circle of the empire, under the title of the
circle of Burgundy, in order thereby to engage princes
of the empire to concern themselves for the preserva-
tion of those provinces. But the Netherlands, always
jealous of their liberty, did not seem to like that in-
corporation; and when they were demanded to pay
their share towards the expenses of the empire, they
refused it; whereupon the princes of Germany refused,
in their turn, to take any part in the wars in Flanders,
and looked upon those provinces as by no means
belonging to the Germanic body.

Philip of Austria and his son Charles, who were
born in the Netherlands, had for these provinces that
natural affection which men used to have for their na-
tive country; and, knowing how jealous the inha-
bilants were of their liberty, and of the privileges
granted to them by their former princes, they took
great care to preserve them, and suffered willingly
that the states, who were the guardians of the people's
liberty and privileges, should in a manner share the
supreme authority with them. Philip II., son to the
Emperor Charles V., had not the same affection for the
Netherlands, nor those generous sentiments which his
father had endeavoured to inspire him with. Being
born in Spain of a Portuguese woman, he had no re-
gard but for his native country; and, when he re-
moved out of the Netherlands, he left them to the
weak government of a woman, to the proud and
haughty spirit of Cardinal de Granvelle, and to the
wild ambition of some lords of these provinces, who,
availing themselves of the imprudent conduct and con-
tinual blunders of the council of Spain, found their
private interest in the disturbances they could not fail
to produce. Philip II., also, instead of the mild and
moderate measures which his predecessors had success-
fully employed on many occasions, as well suiting the
genius and temper of the people, had recourse to the
most violent and cruel proceedings; which, far from
curing the evil, served only to exasperate it the more
and render it incurable. The Spaniards, whom he
sent thither, being born and educated in an absolute
monarchy, jealous of the liberties and envious of the
riches of the people, broke through all their privi-
leges, and used them almost after the same manner as
they had done the inhabitants of their new and ill-
gotten dominions in America. This treatment oc-
casioned a general insurrection. The counts Hoorn,
Egmont, and the prince of Orange, appearing at the
head of it, and Luther's reformation gaining ground
about the same time in the Netherlands, his disciples
joined the malcontents; whereupon King Philip in-
truded a general of inquisition in order to suppress
them, and many thousands were put to death by that
court, besides those that perished by the sword; for
these persecutions and encroachments had occasioned
a civil war, in which several battles were fought.
The counts Hoorn and Egmont were taken and be-
hanged; but the prince of Orange, retiring into Hol-
land, did, by the assistance of England and France,
preserve Holland and some of the adjacent provinces,
which entered into a treaty for their mutual defence
at Utrecht in 1579, and they have ever since been
fyleld the United Provinces; but the other provinces
were reduced to the obedience of Spain by the duke
of Alva and other Spanish generals. However, their
ancient privileges were in a great measure restored;
every province was allowed its great council or parlia-
ment, whose concurrence was required to the making
of laws, and raising money for the government, though
these assemblies were too often obliged to follow the
dictates of the court.
The late emperor Joseph II., endeavoured to de-
prive them even of the form of their free constitution;
and he might very probably have succeeded, had he
not attempted at the same time a reformation of the
church. The Austrian Netherlands are wholly Catho-
lic, and so bigotted to the Romish superstition,
and though they had tamely submitted to many en-
croachments of the arch-ducal house on their civil
right, no sooner did the monarch encroach upon the
property of the holy mother-church than they refiited
his authority, and claimed all their ancient privileges
political and religious. The same attachment to
their ancient faith and worship made them very lately
contribute to expel from their territories the French,
whom they had invited to relieve them from the Au-
strian yoke. Thus her religious bigotry for once saved
a free people from the iron rod of despotism on the
one hand, and the cruelties of frantic democrats on
the other. The provinces under the government of
France were, till the late revolution, under the same
severe arbitrary dominion as the other subjects of that
crown, and they now experience the same miseries
with the rest of the republic.
The Spaniards continued possessed of almost eight
of these provinces, until the Duke of Marlborough,
generall the allies, gained the memorable victory of
Ramillies. After which, Bruges the capital, and
great part of these provinces, acknowledged Charles VI.
(afterwards emperor) their sovereign; and his daugh-
ter, the late empress queen, remained possessed of
them till the war that followed the death of her father,
when the French made an entire conquest of them, ex-
cept part of the province of Luxembourg; but they
were restored by the peace of Aix-la-Chapelle in 1748,
and the French retained only Artois, the Cambrésis,
part of Flanders, part of Hainault, and part of Lux-
emburg, of which they have had the dominion now
upwards of eighty years.
The soil is generally fruitful, but differs in the se-
veral parts. The climate also differs in the several
provinces; in those towards the south it does not dif-
fer much from that of England, though the seasons
are more regular. In the northern provinces the win-
ter is generally very sharp, and the summer very hot;
but the extreme cold and excessive heat seldom con-
tinue above five or six weeks. The air is reckoned
ever wholesome, but is subject to thick fogs in win-
ter, through the moistness of the country, which
would be very noxious, were it not for the dry easterly
winds, which, blowing off a long continent for two
or three months in the year, clear the air, and occasion
very sharp frosts in January and February; during
which, the ports, rivers, and canals, are commonly

---
 NET[16] NEV

Netherims,\footnote{4130} hut up. The face of the country is low and flat; for, except some small hills and a few rising grounds in Utrecht and Guelderland, and in the parts lying towards Germany, there is no hill to be seen in the whole 17 provinces. This is the reason that they have been called the Low Countries. French Flanders abounds in grain, vegetables, flax, and cattle, but is in want of wood.

For the Dutch Netherlands, see United Provinces.

NETHINIMS, among the Jews, the pottery of the Gibeonites, who were condemned by Joia to be hewers of wood and drawers of water for the house of God.

NETTOPION, a name given by the ancients to a very fragrant and costly ointment, consisting of a great number of the finest spicy ingredients. Hippocrates, in his Treatise of the Diseases of Women, frequently prescribes the netopion in diseases of the uterus; and in other places he speaks of its being poured into the ear as a remedy for deafness; these compositions, by their attenuating qualities, dividing the viscous and thick humours. The word netopion is also sometimes used to express the unguentum Egyptian, and sometimes family of oil of almonds.

NETSCHER (Gaspard), an eminent painter, born at Prague in Bohemia in 1639. His father dying while he was an engineer in the Polish service, his mother was obliged, on account of her religion, suddenly to leave Prague with her three sons. When she had proceeded three leagues, she stopped at a cattle; which being soon after besieged, two of her sons were starved to death; but she herself found means to escape out of the fortress by night, and to save her only remaining child. Carrying him in her arms, she reached Arnheim in Guelderland, where she found means to support herself, and breed up her son. At length a doctor of phyfic took young Netscher into his patronage, with the view of giving him an education proper for a physician; but Netscher’s genius leading him to painting, he could not forbear scrawling out designs upon the paper on which he wrote his themes; and it being found impossible to conquer his fondness for drawing, he was sent to a glazier, who was the only perfon in the town that understood drawing. Netscher soon finding himself above receiving any farther alliance from his master, was sent to Deventer, to a painter named Terburg, who was an able artift and burgomifer of the town; and having acquired under him a great command of his pencil, went to Holland, where he worked a long time for the dealers in pictures, who paid him very little for his pieces, which they sold at a high price. Difgusted at this ungenerous treatment, he resolved to go to Rome; and for that purpofe embarked on board a veifel bound for Bordeaux. But his marrying in that city prevented his travelling into Italy; and therefore, returning into Holland, he fetted at the Hague; where observing that portraif-painting was the moft profitable, he applied himself folesy to it, and acquired fuch reputation, that there is not a confiderable family in Holland that has not fome of his portraits; and besides, the greatest part of the foreign miniftris could not think of quitting Holland without carrying with them one of Netscher’s portraits, whence they are to be feen all over Europe. He died at the Hague, in 1684; leaving two fons, Theodore and Conffantine Netscher, both of them good portrait-painters.

NETTINGS, in a ship, a fort of grates made of small ropes feized together with rope-yarn or twine, and fixed on the quarters and in the tops; they are sometimes stretched upon the ledges from the wafte-trees to the roof-trees, from the top of the forecastle to the poop, and sometimes are laid in the waffe of a ship to serve instead of gratings.

NETTLE, in botany, see URTICA.

SEI. NETTLE. See MIDUSA and Animal-Flower.

NETSCHER-Tree. See CElTIS.

NETTUNO, a handsome town of Italy, in the Campagna of Rome. It is but thinly peopled, though faeted in a fertile foil. The inhabitants are almost all hunters. E. Long. 12. 57. N. Lat. 41. 30.

NEVA, a river at Peterburgh, in Russia. The views upon the banks exhibit the moft grand and lively scenes. The river is in moft places broader than the Thames at London. It is deep, rapid, and transparent as crytal, and its banks are lined on each fide with a continued range of handsome buildings. On the north fide the fortrefs, the academy of sciences that are the moft ftriking objects; on the oppofite fide are the imperial palace, the admiralty, the manifons of many Russian nobles, and the English line, fo called becaufe (a few houses excepted) the the whole row is occufed by the English merchants. In front of these buildings, on the fourth fide, is the quay, which ftreches for three miles, except where it is interrupted by the admiralty; and the Neva, during the whole of that space, has been lately embanked at the expence of the emprefs by a wall, parapet, and pavement of hewn granite; a moft elegant and durable monument of imperial munificence. There is a communication between the oppofite fides of the river by a bridge of pontoons, which, when any thing is apprehended from the force of ice rushing down the fream, can be, and is generally indeed, removed. The great depth of the river, it appears, prevents the building of a fone-bridge; and if it could be built, there is no reafon to fuppofe it could possibly reft the force of thofe vall fmalts of ice which in the beginning of winter come down this rapid river. An attempt, however, has been made to remedy this inconvenience; and a Russian peafant has actually projected the plan of throwing a wooden bridge of one arch across it, which in its narroweft part is 980 feet in breadth. As we think this a matter of very conliderable importance, as well as of curiofity, we fhall give the following copious account of the plan and its author, in Mr. Cox’s own words; who tells us that the artift had then executed a model 98 feet in length, which he faw and examined with conliderable attention.

“The bridge is upon the fame principle with that of Shnifhafen, excepting that the mechanism is more complicated, and that the road is not fo level. I fhall attempt to defcribe it by fepping it finished, as that will convey the beft idea of the plan. The bridge is roofed at the top, and covered at the fides; it is formed by four frames of timber, two on each fide, composed of various beams or trubbles, which fupport the whole machine. The road is not, as is usual, carried over the top of the arch, but is fupported in the middle.

“The following proportions I noted down with the
Length of the abutment on the north end, 658 feet.
Span of the arch, - - - - - 980
Length of the abutment on the south end, 658
Length of the whole structure, including the abutments, - - - - - 2296
The plane of the road upon its first ascent makes an angle of five degrees with the ordinary surface of the river.
Mean level of the river to the top of the bridge in the centre, - - - - - 168
Ditto to the bottom of the bridge in the centre, - - - - - 126
Height of the bridge from the bottom to the top in the centre, - - - - - 42
Height from the bottom of ditto to the water, - - - - - 84
Height from the water to the spring of the arch, - - - - - 56
So that there is a difference of 35 feet between the road at the spring of the arch and the road at the centre; in other words, an ascent of 35 feet in half 980, or in the space of 490 feet, which is little more than eight-tenths of an inch to a foot. The bridge is broadest towards the sides, and diminishes towards the centre.
In the broadest part it is - - - - - 168 feet.
In the centre or narrowest - - - - - 42
The breadth of the road is - - - - - 28

"The artist informed me, that to complete the bridge would require 49,650 iron nails, 12,968 large trees, 5,150 beams to strengthen them, and that it would cost 300,000 roubles, or L. 60,000. He speaks of this bold project with the usual warmth of genius; and is perfectly convinced that it would be practicable, I own I am of the same opinion, though I hazard it with great diffidence. What a noble effect would be produced by a bridge striking across the Neva, with an arch 980 feet wide, and towering 168 feet from the surface of the water? The description of such a bridge seems almost chimerical; and yet upon inspection of the model we become reconciled to the idea. But whether the execution of this stupendous work may be deemed possible or not, the model itself is worthy of attention, and reflects the highest honour on the inventive faculties of that unimproved genius. It is in compactly constructed, and of such uniform solidity, that it has supported 5540 pounds, or 127,440 pounds, without having in the least swerved from its direction, which I am told is far more, in proportion to its size, than the bridge if completed would have occasion to sustain from the pressure of the carriages added to its own weight.

"The person who projected this plan is a common Russian peasant. This extraordinary genius was apprenticed to a shopkeeper at Nihunci Novgorod; opposite to his dwelling was a wooden clock, which excited his curiosity. By repeated examinations he comprehended the internal structure, and without any assistance formed one exactly similar in its proportion and materials. His success in this first essay urged him to undertake the construction of metal clocks and watches. The empress, hearing of these wonderful exertions of his native genius, took him under her protection, and sent him to England; from whence, on account of the difficulties attending his ignorance of the language, he soon returned to Russia. I have a repeating watch of his workmanship at the academy of sciences; it is about the size of an egg; in the inside is represented the tomb of our Saviour, with the flaming sword of the angel at the entrance, and the centinels upon duty; suddenly the flame is removed, the centinels fall down, the angels appear, the women enter the sepulchre, and the same chant is heard which is performed on Easter-eve. These are trifling, although curious performances, but the very planning of the bridge was a most sublime conception. This person, whose name is Kulbin, bears the appearance of a Russian peasant; he has a long beard, and wears the common dress of the country. He receives a pension from the empress, and is encouraged to follow the bent of his mechanical genius (A.)."

NEVIL, or NIEBEL, in the Jewish antiquities, a kind of musical instrument. See NERIBUM.

NEVERS, is the capital of the Neversois in France, and government of Orleans. It is situated E. longitude 3° 17', N. latitude 46° 50', on the river Loire, which here receives the rivulet Niverne, from which the city derives its name. It is a place of great antiquity, supposed to be Caesarius Noviodunum in Aeduis, where he erected magazines for his armies. Francis I. made it a duchy and peerage in 1521, in favour of Francis of Cleve, to whom it came by marriage. It devolved afterwards to the house of Mantua, and then to the Palatine family, who in 1651 sold it to Cardinal Mazarin. The cardinal obtained a title of duke and peer for his nephew Philip Mancini, in whose family it continued till the late revolution, though it is impossible, in the present unsettled state of France, to say whose property it may be now. The town is fortified with walls, defended with many high towers and deep ditches, and is the seat of a bishopric, suffragan of Sens, as likewise of a bailiwick and chamber of accounts.

(A) We have given this detail in Mr Coxe's own words, as it appears to us to deserve attention on account of the greatness of the project, which would have excited admiration had it been attempted by one enlightened by science and liberal arts, much more when it comes through the humble medium of a Russian peasant. It was never executed, as we are just informed by a gentleman who left St. Peterburgh about the beginning of June 1793; but the model remains, and is still shown. The same gentleman (who quotes his own words) adds, "that every mechanic thinks it practicable; and that the general belief is, that the empress would have built it, had she not found use for all her money in carrying on her warlike and diplomatic transactions with other courts."
NEUCHÂTTEL, a tolerably handsome town of Switzerland, capital of a county of the same name. There are several ancient ruins near it, which show its former extent; and there are two large churches, besides a cathedral where the governor resides. The town contains about 3,000 inhabitants. It is situated partly on a small plain between Mount Jura and the lake of Neuchâtel, which is 17 miles long and five broad; the side of the harbour is the usual walk of the inhabitants. Part of it too is built upon the side of the mountain; whence some of its streets are very steep. In this small place several public works have lately been executed, which Mr. Cox hints are far beyond the revenues, or even the wants, of such a little state. Among these he mentions a superbe causeway and a town-house "built (says he) of such solid materials as if it was intended to survive to the most distant posterity, and to rival the duration of the most famous Roman capitol." At the beginning of the present century, commerce was very little followed in this town, owing to an stupid opinion which prevailed among the inhabitants of its being disgraceful; but this prejudice is now extinguished, and the town in a much more flourishing situation than before. The chief article of exportation is wine, which is much esteemed; and manufactures of printed linens and cotton have been established with considerable success. The flourishing state of Neuchâtel is principally owing to the benefactions of Mr. David Pury, late banker of the court at Lisbon. He was born at Neuchâtel in 1709; but having received his education there, he quitted it in great poverty and repaired to Geneva, where he served his apprenticeship, but in what line is not mentioned. From Geneva he went to London, where he acted as clerk to a dealer in precious stones, and acquired great reputation by estimating the value of diamonds at sight. After a long residence in England he went to Lisbon, where he carried on a very extensive commerce; and having been appointed court-banker, his fortune rapidly increased. His generosity, however, kept pace with his wealth; and he not only remitted large sums to Neuchâtel while living, but left his country his heir when he died. His contributions in all are estimated by Mr. Cox at £200,000; a considerable part of which has been employed in constructing the public works already mentioned. Mr. Cox hints, that notwithstanding the superb edifices already mentioned, there are many conveniences still wanting to render Neuchâtel agreeable; the public walks, for instance, might be greatly improved, the streets, which are very dirty, might be kept clean, and a torrent which runs through the town, and frequently threatens it with inundations, might be turned. Encouragement ought also to be given to literature; for our author observes, that the inhabitants of Neuchâtel are much more ignorant than those of other parts in Switzerland, which no doubt is in a great measure owing to their having not a single seminary of learning which deserves the name in the place. It has a grand and little council: the first is composed of 40 persons, with two masters of the keys; the little council consists of 24 members, comprehending the mayor, who is president. These two councils assemble regularly every month. The ecclesiastics likewise assemble every month, to consult on affairs belonging to the church, and to fill up the places of ministers that die. They choose a dean every year, who is president of the general assembly, which are called cluffs, and sometimes he is confirmed in this dignity. E. Long. 7. 10. N. Lat. 47. 5.

Neuchâtel, a sovereign county of Switzerland, bounded on the west by the Franche Comté, on the north by the bishopric of Baule, and on the east and south by the cantons of Berne and Freiburg. This principality of Neuchâtel and Valléngin extends from the lake of Neuchâtel to the borders of Franche Comté, being in length about 12 leagues, and in breadth the plain with the lower part of the mountains is occupied by the district of Neuchâtel, but Valléngin is totally inclosed by Jura. Parallel chains of these mountains run from east to west, forming several valleys in the most elevated parts. The lower grounds of this chain consist of arable lands and vineyards; the higher of large tracks of forest, which in many parts have been cleared and converted into pasture-grounds, intersected with fields of barley and oats. The inhabitants are numerous, and remarkable for their genius, polite, and active industry. It contains three cities, one town, 90 villages, and about 600 huts. In 1525 they entered
of cattle; and there are plenty of deer
in the forests; besides large
trouts, and other good fish,
in the lakes and rivers. The
mildness of the government,
and agreeable situation of
the inhabitants in general
in these districts, is evident
from the great increase of
population in the space of
32 years. In 1752 they con-
tained only 28,017 subjects
and 4,138 aliens; but in 1784
the number was augmented to
51,576 subjects and 9,704 aliens;
being an increase of
nearly a fourth part in that
time. The facility with
which the burghehip of
Neuchattel is acquired, may
also be accounted one of the
means of augmenting its
population; for between the
years 1760 and 1770,
the magistrates admitted
41 persons to this privilege:
from 1780 to 1785, 51:
in all 138; many of
whom had children before
they purchased their burghehip,
and 38 of them were
foreigners, either German,
French, or Dutch.

The districts of Neuchattel
and Vallengin now make
part of the Prussian dominions.
It had its own counts
for a long time; the last of
whom dying in 1694
without issue, it came to
Mary of Orleans duchess
of Nemours, his only
follower, who also died
without issue in 1703.
There were then 13
competitors, among
whom was Frederick I.
king of Prussia, who
claimed as heir to the
prince of Orange. His right
was acknowledged by the
flates of the country in
1707; but in this part of
his dominions the Prussian
monarch is far from having
such an absolute authority as
in others.

On the accession of
Frederick I., some general
articles were agreed on, by
which the prerogatives of
the prince and the rights of
the people were settled.
Diplomats, however,
occurred between the king
and his subjects, which were
not thoroughly settled till
the year 1768, when the
general articles were not
only renewed, but explained
wherever their tenor had
been mistaken, confirming also
several privileges in
favour of the people which
had hitherto been equivocal
or not duly observed. The most important
of these general articles were,
1. The establishment of
the reformed religion, and
the toleration of no other,
except in two places where it was already prevalent.
2. No civil or military office to be posted by
foreigners, that of governor only excepted.
3. All subjects have a right to enter into the service of a
foreign prince not actually at war with the king as
sovereign of Neuchattel; the state may also continue
neutral when the king is engaged in wars which do
not concern the Helvetic body.
4. The proper
administration of justice; for which the three
estates of Neuchattel and Vallengin shall be annually assemble.
5. The magistrates to hold their places during good
behaviour; but of this certain persons appointed at
Neuchattel, and not the king, are to judge.
6. The
sovereign, on his accession, shall take an oath to main-
tain the rights, liberties, and customs of the people,
written and unwritten.

This last article is no less
important than it is sin-
gular; for upon an unwritten custom one of their
most essential privileges depends; viz. that the five-

Now (says Mr Coxe), this privilege, in
conjunction with the third article just cited, forms the basis
of their civil liberty. By the former the
prince, when absent, can only address his subjects through
his governor and the council of state; and no subject
may be tried out of the country, or otherwise than by
judges appointed by the constitution; by the latter,
should the king of Prussia be at war with all Ger-
many, the people of Neuchattel and Vallengin are by
no means obliged to arm in his defence; but individuals
may even serve against him, as long as the
powers whom they serve are not engaged in any hostili-
ties against their own country." A remarkable instance
of this last our author gives in the following anecdote.

When Henry duke of Longueville, and
sovereign of Neuchattel was, in 1650, sent to the castle of
Vincennes, Felix de Mareval, captain of the Swiss guards,
kept guard in his turn, though he was citizen of Neu-
chattel, at the door of the prizon where his sovereign
was confined.

The king confers nobility, names the principal
officers of state, appoints the presidents of the courts of
justice called chalelines and maors; but his revenues
scarcely amount to L. 5000 a-year. They arise from
certain demesnes; from a small land tax, the tythes
of wine and corn, and a tenth part of the value of all
immovables. No subject pays any duty upon goods
either exported or imported, except for foreign wines
brought into the town itself.

Neuchattel enjoys very considerable privileges,
having the care of the police within its own district,
and is governed by its own magistracy consisting of a
grand and little council. The three estates of the
country form the supreme tribunal, and receive appeals
from the inferior court of justice. They consist of 12 judges
divided into three estates: the judges in the first and
second division hold their places for life; but those in
the third are chosen annually. The estates usually
meet once a-year in the month of May, but are con-
voked extraordinarily upon particular occasions,
and the town of Neuchattel is always the place of meeting.

They are not, however, the representatives of
the people, nor do they possess any legislatice authority.
Properly speaking, they are the supreme court of
judicature, which receives all appeals, and decides finally
upon all causes, even those which relate to the
sovereignty of the country, of which we have an
example in the revolution of 1797. The ordinary
administration of government is vested in the council
of state, which superintends the general police, and is
the medium by which the sovereign exercises his juris-
diction. The members are nominated by the king,
and are not restricted to any number, but he is always
considered as personally presiding in the assembly,
and the president has no other powers than those of con-
voking the assembly, proposing the subjects of
consideration, collecting the votes, and deciding when
the voice is equal. The ordinances of this council
are previously communicated to the ministraux of Neu-
chattel, who must certify that they contain nothing
contrary to law. The ministraux are a kind of com-
mmittee from the council of the town, and are entrusted
with the administration of the police. They con-
By the three estates, the former fix are changed every two years; and the banne-
ret, or guardian of the liberties of the people. The
former fix are changed every two years; and the ba-
neral, is chosen by the general assembly of the citi-
zens, and continues in office during six years.

When the causes are decided in the month of May
by the three estates, the four judges, who form the third
estate, retire, and their place is supplied by the four
miniftraux. The attorney general then defires the
members of the three estates to take into considera-
tion whether it is necessary to frame any new laws.
If a new ordinance is propofed, a declaration is drawn
up and delivered to the council of State for their de-
liberation, whether it be contrary to the prerogatives
of the prince or the rights of the subject; from thence
it is communicated to the council of the town in or-
der to be examined, whether it infringes the privi-
leges of the citizens. If adopted by the council of
State and the council of the town, it is propofed to
the prince for his approbation or reje&ion; in the
former cafe it is again publicly read before the three
estates, and the governor or prefident declares the
approbation of the foeverign. It is then promul-
gated, or put into a law by the three estates. The
people of Vallengin have always been conulfed upon
the framing a new law since the accession of the
house of Brandenburg. For this purpofe the three
mater bufathers of Vallengin examine, whether it con-
tains any thing inconsistent with the franchises of that
diftrict; in which cafe they have the power of remon-
frating to the governor in council. Every year at
the conclusion of the assembly of the estates of Neu-
chatel, thofe of Vallengin, as confituting the supreme
court of judicature for that country, meet at Vallen-
gin, and decide finally all appeals from the inferior
courts of jujtice. Both principaIities are divided into
a certain number of diftricts, each of which has its
criminal court of jujtice. Every criminal is brought
to trial immediately after he is arraigned, and sentence
is read to him in prifon. Next morning he appears
again before the judges, assembled in the open air;
the former proceedings of the trial are read, and the
judges once more deliver their opinion. In formasten-
sences the governor is immediately made acquainted
with the circumstances of the cafe; and if he does
not mitigate the fentence, it is put in execution with
out delay. Torture, though feldom used, is not en-
tirely abifhcd in these diftricts. Great circum-
NEW [ 21 ] NEW

NEUTRALITY, the state of a person or thing that is neuter, or that takes part with neither side.

NEW-ABBEY, situated near Kilcullen bridge, in the county of Kildare, and province of Leinster, in Ireland. It was founded by Rowland Euface, of a great and ancient family in this county; the tower is still standing, and some parts of the abbey; the ruins of the hall have contributed to build several dwellings near it. In the infide Rowland Euface and his lady lie buried; their figures, clothed in armour, are to be seen there. Near this is a handsome seat of the Carter family, on the opposite side of the River Liffey.

NEWARK, upon Trent, in the county of Nottingham, is a great thoroughfare in the York-road, 124 miles from London. It has bridges over the Trent, which forms an island here, by dividing itself into two streams; two miles above the town, which meet again two miles below it. A magnificent castle was built here in the reign of King Stephen, which held out stoutly in the barons’ wars for King John, who died here, October 19th 1216; and it also stood out for King Charles I. to the last; but after he had put himself into the hands of the Scots army then before it, the governor by his order surrendered it, after which it was demolished.—It was situated near the river; the walls of the towers are very thick, and of a very high height; and were there no historical testimony, there remain is sufficient evidence that it was formerly of great importance. In the court before these ruins is a very fine bowing-green, and near it a manufactury of facking. The town being subject to inundations from the river Trent, and often from that circumstance made imovable, a turnpike road, at the instigation of a publican, was made about 20 years ago, so high as to be passed with safety in the greatest floods, by arches of brick being made in several places to carry off the water, constructed by Mr Smeeaton, at the expence of £12,000. Near the town there is a bridge constructed for the same purpose, made mostly upon dry land, consisting of nine arches. It has a neat though small new street, and a market-place that is handsome, though not very spacious. Its church, which is reckoned one of the finest in the kingdom, was built by Henry VI. and has a lofty spire. It was incorporated by king Charles II. with a mayor and 12 aldermen.—The same king, in gratitude to the town for its loyalty to his father, gave it the privilege of sending members to parliament. It has a good trade in corn, cattle, wool, &c, and has a charity-school for 36 boys. Its market is on Wednesday; fairs on the Friday before Palm-Sunday, May 14th, Whit-Tuesday, August 12th, Nov. 18th, and Monday before December 11th. Here was an abbey of Augustine Friars. A free-school was founded here, endowed with the lordship of Everett in this county; and the vicar of Newark, and the brethren of the Trinity Guild for the time being, who were then the chief governors of this town, were made perpetual trustees for this foundation. Many Roman urns and other antiquities have been found about this town, from whence it has been supposed that they had some town in the neighbourhood.

NEWBOROUGH, or NEWBURY, in the Isle of Anglesey, North Wales, distant from London 254 miles, though but a small town, situated over again in Caernarvon in North Wales, about 17 miles southward.

NEUTER, among chemists, those compounded of an acid with any other substance capable of uniting with it and destroying its acidity. Those in which the acid is saturated with an earth or a metal are called imperfect, but those in which a pure alkaline is employed are called perfect, neutrals.

NEUTER, or Neuter, is a term used in grammar to define a class of nouns, which are neither masculine nor feminine. See Gender.

The Latin has three kinds of genders, masculine, feminine, and neuter. In English, and other modern tongues, there is no such thing as neuter nouns. See Noun.

Verbs Neuter, by some grammarians called intransitive verbs, are those which govern nothing, and that are neither active nor passive. See Vi.r.

When the action expressed by the verb has no object to fall upon, but the verb alone supplies the whole idea of the action; the verb is said to be the neuter: as, I sleep, thou wakend, he freezes, we walk, ye run, they stand still.

Some divide verbs neuter into 1. Such as do not signify any action, but a quality; as albent, "it is white!" or a situation, as selet, "he fits!" or have some relation to place; as aqefl, "he is present!" or to some other state or attribute, as regnat, "he rules," &c. And, 2. Those that do signify actions, though such as do not pass into any subject from the ador; as to dine, to sup, to play, &c.

But this latter kind sometimes cease to be neuter, and commence active; especially in Greek and Latin, when a subject is given them: as, vivere vitam, ambulare viam, pugnare pugnam. Thus the old French poets say, Soupirer pour tourment; the English, to lug his oars, &c.

But this is observed only to obtain, where something particular is to be expressed, not contained, in the verb: as, vivere vitam beatam, to live a happy life; pugnare bonam pugnam, to fight a good fight, &c.

According to the abbot de Dangeau, verbs neuter may be divided into active and passive; the first, those that form their tenses in English, by the auxiliary verb to have; in French, by avoir. The second, those that form them in English with the verb to be; in French être.—Thus, to sleep, to yawn, dormir and éternuer, are neuter active.—To come, and to arrive, are neuters passive.

NEUTRALITY, among chemists, those compounded of an acid with any other substance capable of uniting with it and destroying its acidity. Those in which the acid is saturated with an earth or a metal are called imperfect, but those in which a pure alkaline is employed are called perfect, neutrals.
NEWBURG, the name of several towns of Germany, two of which are the chief towns of duchies of the same name; one in Bavaria, and the other in the Palatinate.

NEWBURY, a town in the county of Berks in England, 16 miles from Reading, and 56 from London, arose on the decay of Spinham-Land. Notwithstanding its name signifies New-Borough, it is as old almost as the Conquest. It made its much broad-cloth formerly, that in the reign of Henry VIII. here flourished John Wincumb, commonly called Jack of Newbury, one of the greatest clothiers that ever was in England, who kept 100 looms in his house; and in the expedition to Flodden-field against the Scots, marched with 100 of his own men, all armed and clothed at his own expense; and he built all the west part of the church. Also Mr Kenric, the fon of a clothier here, though afterwards a merchant in London, left L. 4000 to the town, as well as L. 7500 to Reading, to encourage the woollen manufacture. It makes a great quantity of shalloons and druggets, but not near so much broad cloth now as formerly, yet it is a flourishing town, with spacious streets, and a large market place, in which is the guild-hall. The church is a good one, of stone, suppos'd to have been built about 1640. It has seven lots of almshouses. In the neighbourhood, on the banks of the Kennet, there is a tract of petrified wooden dug out for firing, when they frequently find trunks of large oaks yet undecayed, with petrified hazel nuts, fir cones, &c. With the bones and horns of stag's, antelopes, &c. tufts of bors, and heads of beavers. The river Kennet, which abounds with excellent trout, eels, and cray-fish, runs through the town; and here is plenty of all other provisions. It was made a corporation by Queen Elizabeth, and is governed by a mayor, high-bailiff, aldermen, &c. It sends a great quantity of malt to London, has good inns, and has a charity-school for 40 boys. Its market, which is well supplied with corn, is on Thursdays; and fairs on Holy-Thurday, July 5th, Aug. 24th, and Oct. 28th.

NEWCASTLE Under-Lin: a town in England, in the county of Stafford, on a branch of the Trent, is 15 miles north of Stafford, 33 south-east of Warrington, and 149 from London; and a castle, now in ruins; and is said to have been an old castle, which formerly stood two miles off, at Chesterfield under Line. It was incorporated by King Henry I. and again by queen Elizabeth and King Charles II. and is governed by a mayor, two bailiffs, and 24 commoners. The clothing-trade flourishes here; but its chief manufactory is hats, here being an incorporated company of felt-makers. The streets are broad and well paved, but most of the buildings low and thatched. The market is on Mondays; fairs on Easter-Monday, Whits-Monday, July 6th, first Monday in September, and November 6th, for cattle. It has also a great beef market every other Monday. The corporation has a court, which holds
Newcastle. — In the reign of Henry VIII. this place is said to have exceeded in the strength and magnificence of its works all the cities of England, and most places in Europe. The town is governed by a mayor, 12 aldermen, a recorder, sheriff, town-clerk, two coroners, eight chamberlains, a sword-bearer, a water-bailiff, and seven sergeants at mace. Its situation, especially the most part of it towards the river is very uneven, it being built on the declivity of a steep hill, and the houses very close. The castle overlooks the whole town. That part built by Robert was of great strength, and square, and surrounded by two walls; the square was 62 feet by 55, and the walls 13 feet thick, within which was a chapel. The outward fortifications are now defaced, and their own houses. It is now the county prison, and in the principal entrance is to the south. This castle belongs to the county, and makes no part of the liberties.—It is now the county prison, and in the great hall the judges hold the assizes. Here Bailiwick of Scotland did homage to king Edward I. in 1292; as did Edward Balloch in 1334 to king Edward III. Here is a magnificent exchange and a custom-house; and the finest quay in England, except that at Yarmouth, being 700 yards long, it being far more spacious and longer than those at London or Bristol, though not equal to either for business. There is a handsome mansion-house for the mayor, who is allowed L. 1000 a-year for his table, besides a coach and barage. The old bridge was carried away in a flood, and the present one erected about 1755, of nine noble elliptic arches. With the old bridge 22 houses were thrown down, and six lives lost. It was originally built of wood; but having been destroyed by fire in 1248, was rebuilt of stone, and consisted of 12 arches, three of which on the north side were closed up, and served for cellars; this was again rebuilt about 1450, and was crowded with wooden buildings; but near the middle was a tower with an iron gate, used as a town prison. A strong building crost the bridge, which was used as a magazine. On the south front was a statue of king Charles II. The water which destroyed this bridge, on November 11, 1771, was upwards of 12 feet above high water mark in spring-tides.—On destroying the ruined peers of the old bridge to erect the present, by observations made, and medals found, part of it is supposed to have existed from the time of the Romans. It is computed that above 6000 boys are employed here, who have formed themselves into a friendly society; and, by their own contributions, built a noble hospital containing 30 chambers, for such of their fraternity as are poor, disabled, or pant their labour; and it is supported by the contribution of those that are in health. The town is extremely populous; and, notwithstanding the multitude of those employed in and about the coal-pits, with which the town is in a manner surrounded, has abundance of poor; but it has also many wealthy inhabitants, and it is said they pay above L. 4000 a-year to their relief. It is observed, that this town has the greatest public revenue in its own right as a corporation, of any town in England, it being computed at no less than L. 8000 a-year. In 1774, the receipts of the corporation were L. 20,360: 9: 8; and their disbursements about L. 19,445. The number of inhabitants far exceeds 30,000. Here are four churches or chapels. That of St. Nicholas is the mother-church, a curious fabric, built cathedral-wise by David king of Scots, 240 feet long, 75 broad, and proportionally high, with a tower 194 feet in height, of Gothic architecture; also St. Andrew's, St. John's, and All Saints late rebuilt on the site of the old structure, of a circular form. Here are several meeting houses, and four charity-schools for 500 children; a fine hall for the surgeons, and a large prison called Newgate; also an hospital for lunatics, another for the lying-in of married women, as well as a fund raised for the relief of those who are delivered at their own houses. Here is a well endowed and large infirmary, and an assembly-room that attracts attention, containing every useful apartment, and a ballroom 93 feet by 40: The front is ornamented with six Ionic pillars, &c. In another part of the town is a new theatre. Here is a very neat set of baths. A free grammar-school was granted by James I. from an old foundation of St. Mary's hospital, in the vestry-room of whose chapel is the election of the officers of the corporation. There were formerly several palaces in this city, viz., Pampedon-hall, Lamley place, Earl's place, Northumberland-houfe, Weftmordand-place, &c. The free-masons have lately erected an elegant hall, richly ornamented, to hold their lodge in, near High-frier chair, capable of holding above 4000 of that ancient fraternity. Here is a hospital for 30 decayed freemen and their widows; and another for three clergymen's widows and three merchants widows. The Maiden's hospital, built in 1753, is endowed with L. 2400, for six maiden women and six poor men. Dr. Tho'mlin, a prebendary of St. Paul's, and rector of Whicham in the diocese of Durham, lately gave a library of above 6000 valuable books to the corporation, and settled a rent-charge of L. 5 a-year for ever for buying new ones; and Water Blackett, Esq.; one of its representatives in parliament, built a neat repository for them, and settled L. 25 a-year for ever on a librarian. The upper or north part of the town, inhabited by the poorer sort of people, is much pleasanter than that part next the river, and has three level, well-built, and spacious streets. The river all the way up from Shields to Newcastle is broad, the channel safe, and the tide flows with a strong current to the town, and far beyond it. In the beginning of the late civil wars, this town was taken and plundered by the Scots, who here hold their king, Charles I. for L. 200,000 in hand and security for as much more. The glass-works are very curios, and have more bufines of the fine sort than most other places. Befide, it has a considerable manufacture of broad and narrow cloths, and several frap-boileries; and this place is famous for grindstones; for which there is such a demand, that scarce a ship firs without them; from whence came the proverb, "That a Scotsman and a Newcastle grindstone travel all the world over." Ships fit for the coal trade are built here to perfection, with great strength. Here is a considerable manufactory of hard ware and wrought-iron, after the manner of that at Sheffield.—Its markets are on Tuesdays and Saturdays. Its fairs in August, which last nine days, and October 20th, which
NEWCASTLE, which last nine days. By an act of Queen Mary, the price of the carriage of goods hither from London by wagons was settled at 2d. per lb. London alone is said to consume at least 766,887 chaldrons of its coal every year; but as for the fish vended in that city by the name of Newcastle fish, it is more properly called Berwick fish, the fresh salmon being taken near 50 miles farther, as far as the Tweed, and is brought on the backs of horses to Shields, where it is cured, pickled, and sent on board for London. It is worth remembering, that at the affizes here in 1743, two old men were subpenaed hither as witnesses from a neighbouring village, viz. one 135 years of age, and his son 95, both hearty, and having their fight and hearing; and that in 1744, one Adam Turnbull died in this town aged 112, who had had four wives, the last of whom he had married when he was near 100 years old.

The annual amount of the revenue of customs at this port, which Mr Brand in his history of Newcastile rates at 41,000 l. is now very considerably upwards of 70,000 l.

The coals carried out of it annually (on an average from 1785 to 1791) were nearly 440,000 Newcastile chaldrons; the weight of which is 1,187,200 tons.

The manufacture of earthen-ware is greatly increased, and carried on to great perfection in its neighbourhood, in seven potteries; and their produce exported hence to foreign parts, as well as to the different ports of this kingdom; some of which potteries constantly employ upwards of 100 persons, men, women and children.

New works of considerable extent for the manufacture of iron have been established; as also a very capital manufactory for white lead, milled lead, &c.

The trade with the West India islands is increasing, and may in time become very considerable; as the port has great advantages, in being able to supply on the cheapest terms many articles wanted in those islands; such as coals, grindstones, lime, bricks, tiles, iron-ware, &c.; and is most advantageously situated for the re-exportation of the West-India produce to the ports on the Baltic, to Germany, the United Provinces, Flanders, and part of France; and moreover, the risk of navigation, and the rate of insurance, not being greater than between those islands and Liverpool, and some other ports on the western coast of the kingdom.

The town of Newcastle is daily increasing in its population and opulence; and it would be well if it could not be added, in luxury, the almost necessary consequence of riches: but it should not be omitted, that it is noted for hospitality and good living.

Great improvements have been made in the town, by opening new streets, and paving the principal ones, in the same manner as in London. It cannot be said that it is well lighted, the few lamps scattered here and there serving but to make darkness visible; nor have the orders repeatedly given by the magistrates for cleansing the streets been attended with the full desired effect.

To the lift of public edifices of modern creation, and mentioned above, viz. the grand assembly room, and the elegant theatre, which were built by subscription, and the superb parish-church of All Saints, built at a very great expense by the parishioners, may be added a commodious riding-houfe, built also by subscription.

NEWCASTLE, a borough town of Ireland, in the county of Dublin, and province of Leinster, which returns two members to parliament, and holds two fairs, 9th of May and 8th of October.

NEWCASTLE is also the name of a handsome town in the county of Limerick and province of Munster, on the high road to Kerry, 114 miles from Dublin. Here was a religious house possessed by the knights templars. It is said, they used some barbarous customs which greatly disquieted the Irish, who, watching a favourable opportunity, attacked a number of the knights riding out together and put them to death; the place is still remembered where their remains were interred. This order was suppressed in the famous council of Vienna, 22d of March 1312. Newcastle consists of a large square where markets and fairs are held; on the northern side stands a market house, with an assembly-room; on the south side is the church, which is the nearest in the county, and it was finished in 1777 at the sole expense of Lord Courtenay. It stands close to the walls and franchises of the knights templars, of which one of the castles is fitted up for Lord Courtenay's agent.

NEWCASTLE, a small town in America, 35 miles below Philadelphia, on the west bank of Delaware river. It was first settled by the Swedes about the year 1627, and called Stockholm. It was afterwards taken by the Dutch, and called New Amsterdam. When it fell into the hands of the English, it was called by its present name. It contains about 60 houses, which have the aspect of decay, and was formerly the seat of government. This is the first town that was settled on Delaware river.

NEWCASTLE (Duke of). See CA Vendish.

New Forest of Hampshire in England, is a tract of at least 40 miles in compass, which had many populous towns and villages, and 36 mother-churches, till it was destroyed and turned into a forest by William the Conqueror. There are nine walks in it; and to every one a keeper, under a lord-warden, besides two rangers, and a bow-bearer. As this large tract lay many ages open and exposed to invasions from foreigners, King Henry VIII. built some castles in it; and it has now several pretty towns and villages. It is situated in that part of Hampshire which is bounded on the east by Southampton river, and on the south by the Britith Channel. It possesses advantages of situation, with respect to the convenience of water-carriage and nearness to the dock-yards, superior to every other forest, having in its neighbourhood several ports and places of shelter for shipping timber, among which Lymington is at the distance of only two miles, Bembridge about half a mile, and Redbridge three or four miles from the Forest; and the navigation to Portland, the most considerable dock-yard in this kingdom, is only about 30 miles from the nearest of those places. This is the only forest belonging to the crown of which the origin is known. Domestic book contains the most distinct account of its aforesaid by William the Conqueror: the contents of e
New Forrest.

Every field, farm, or estate afforested, in hides, carucates, or virgates, by which the extent of land was then computed, together with the names of the hundreds and villages, and of the former proprietors (which are for the most part Saxon), the rent or yearly value of each portion, and the tax which had been paid for it to the crown during the reign of Edward the Confessor, before the inhabitants were expelled, and that part of the country laid waste, are all to be found in that most curious and venerable record. With the discovery of the original extent of the forest, we extracted, for our own information, all that relates to it in that ancient survey. The extract is far too voluminous for insertion. The names of many of the places having been changed since that time, it is difficult to ascertain with precision what were then the limits of the forest. The oldest perambulation which we have met with is among the Pleas of the Forest, in the eighth year of King Edward I. preferred in the Chapter-house at Westminster. The boundaries there described include all the country from Southampton river on the east to the Avon on the west, following the sea coast as far as the southern boundary between those rivers, and extending northwards as far as North Chadford, or North Charford, on the west, and to Wade and Orehugg, or Overbridge, on the east; and the greatest part, if not the whole, of that extensive district, is mentioned in a Domesday-book to be the forest belonging to the crown. Another perambulation was however made in the 29th of the same king, which leaves out a great part of the country contained within the former. This perambulation, which is preserved in the tower of London, confines the forest limits which, as far as we can trace them, appear to have been followed in the 22d year of the reign of Charles I., when the forest was again perambulated. By the Charta de Foresta, all lands not belonging to the crown which had been afforested by Henry II. Richard I. or King John, were to be disafforested; but as no provision was made for the reduction of the more ancient afforestations, it was easy to account for the great diminution of this forest in the reign of Edward I., who was not a prince likely to submit to any encroachment on his rights. The perambulation of the 22d of Charles II. is the last which we find on record; it contains the present legal bounds of the forest, and was given to the surveyors as their guide, in taking the plan which they have made lately by direction. From that plan, with the approbation of the lords commissioners, with his majesty's treasurer, an engraving was made. According to the latter-mentioned perambulation and the plan, the forest extends from Godhull on the north-west to the sea on the north-east, about 20 miles; and from Hardley on the east to Ringwood on the west, about 15 miles; and contains within those limits about 92,356 acres, of which 14,000 acres are copyhold or customary lands belonging to his majesty's manor of Lyndhurst; about 1004 acres are lease-hold under the crown, granted for certain terms of years, and forming part of the demised land-revenue, under the manage- ment of the surveyor-general of crown-lands; about 901 acres are purpures or encroachments on the forest; about 1193 acres more are inclosed lands held by the mallet keepers and groom-keepers, with their respective lodges; and the remainder, being about 63,845 acres, are woods and waste lands of the forest.

To perpetuate the spot where William Rufus was killed by the glance of an arrow shot at a stag, a triangular stone was erected in 1745. George III. visited this spot in 1789. In August 1782, a curious ancient golden cross was found here by a labouring man digging turf. It weighed above an ounce of gold, and had on one side an engraving of our Saviour, and on the other, the ladder, spear, nails, and other emblems of his sufferings.

New Years Gifts. Presents made on the first day of the new year. Nonius Marcellus refers the origin of this custom among the Romans to Taurus king of the Sabines, who reigned at Rome conjointy with Romulus, and who having considered as a good omen a present of some branches cut in a wood consecrated to Strenua, the goddess of strength, which he received on the first day of the new-year, authorized this custom afterwards, and gave to these persons the name of strenue. However this may be, the Romans on that day celebrated a festival in honour of Janus, and paid their respects at the same time to Juno; but they did not pass it in idleness, left they should become incontinent during the rest of the year. They sent presents to one another of figs, dates, honey, &c. to show their friends that they wished for a happy and agreeable life. Clients, that is to say, those who were under the protection of the great, carried presents of this kind to their patrons, adding to them a small piece of silver. Under Augustus, the senate, the knights, and the people, presented such gifts to him, and in his absence deposited them in the capitol. Of the succeeding princes some adopted this custom and others abolished it; but it always continued among the people. The early Christians condemned it, because it appeared to be a relic of Paganism, and a species of superstition; but when it began to have no other object than that of being a mark of veneration and esteem, the church ceased to disapprove of it.

NEWEIL, in architecture, is the upright post which a pair of winding stairs turn about; this is properly a cylinder of stone, which bears on the ground, and is formed by the end of the steps of the winding stairs.

NEWFIDLER-SEA, a lake in Hungary, 17 miles in length, and 6 in breadth.

NEWFOUNDLAND, a large island of North America, belonging to Great Britain, lying between 45 50, and 51 30 N. Lat. and between 53 30, and 58 20 W. Long, from London. The form is that of an irregular triangle, the base or south side being 80 leagues in extent; the east side is the longest; and the whole circumference about 150 leagues. It is bounded on the north by the Straits of Bellefleis, which separate it from Labrador; on the east and
fouth it hath the Atlantic Ocean, and on the west
the Gulph of St Lawrence. The climate is rather
severe; and the soil at least on the sea-coast, which
is all that we know of it, is poor and barren. A
few kitchen vegetables with strawberries and raspberries
are all its produce. The country within land
is mountainous, and abounds with timber; there are
several rivers which are plentifully
settlements, and at each of these there is a fort: the
number of people who remain here in the winter hath
been computed at 4000. The French, by the treaty
of Utrecht, were permitted to fish from Cape Bonai-
viota on the east side round the north of the island to
Point Rich on the west; and by the treaty of Paris,
they are allowed the isles of St Pierre and Miquelon,
upon which they are to dry their fish, but not to
return home in six months, there cannot be a more
noble nursery for seamen. The artificers and traders
employed in building, victualling, and repairing these
vessels, are very numerous in the respective ports from
which they fail. These circumstances justify the par-
ticular attention paid by government to this branch of
the public service; in respect to which, they may be
well informed, an annual and very distinct account,
by which the whole is seen at one view, is delivered
by the proper officer to the governor of Newfound-
land, that is, to the commodore of his majesty's squa-
dron. Mr Pennant in the appendix to his Arctic
Zoology, gives us from what appears to be a very good
authority, the following account of this island.

Within the circuit of 60 miles of the southern
part, the country is hilly but not mountainous. The
hills increase in height as they recede from the sea;
their course is irregular not forming a chain of hills,
but rise and fall abruptly. The coasts are high, and
the shores most remarkably bold. The same may be
said of almost every part of this vast island. The
country is much wooded, and the hills (such which
have not flat tops to admit the rain to stagnate on
them) are clothed with birch, with hazel, spruce, fir,
and pine, all small; which is chiefly owing to the in-
habitants taking off the bark to cover the fish
fiches.

The cod are caught only by a hook; and an expert
fisher will take from 150 to 300 and upwards in a day
for the fish never bite in the night, and the labour is
very great. The season is from May to October, in
the height of which there are from 500 to 700 fail up-
on the banks at a time. The fish caught in the spring-
049; stretching 300 miles in length and 75 in breadth.
To the east of this lies the False Bank; the next is
fyled Vert or the Green Bank, about 240 miles long,
and 120 over; then Banquiero, about the same size;
the shoals of Sand Island, Whale Bank, and the Bank of
St Peter's, with several others of lesser note, all abounding
with fish.

The cod are caught only by a hook; and an expert
fisher will take from 150 to 300 and upwards in a day
for the fish never bite in the night, and the labour is
very great. The season is from May to October, in
the height of which there are from 500 to 700 fail up-
on the banks at a time. The fish caught in the spring-
months are beat; they are cured in very different ways.
Some are fyled white fish, others must fish, which are
ferved in the hold in the hold long, but the beat and most valuable are the dried cod. The
quantity taken is prodigious; yet in some seasons and in different places varies considerably, as the fish
frequently change their stations. The fishing ships, as
they are called, lie upon the banks, with the help of
their boats take and cure their own fish, and as soon as
they are full fail for a market. The fack-ships proceed
direfly to the island, where they purchase fish from the
inhabitants either by barter or bills of exchange.
The principal markets for cod are Spain, Portugal,
Italy, and the West Indies. The value of this fishery
is computed at some hundred thousand pounds annually;
employing, besides several hundred ships, some
thousands of seamen, and affording a maintenance to
a number of tradesmen of different occupations, by which
many large towns on the west side of England accumu-
late much wealth, and at the same time contribute
in many respects to the benefit of the public. There
that we know of this fishery, was very early feen, and very vigorously pursued; for in the begin-
ing of the reign of king James I. we had two hun-
dred and fifty fail employed therein. It is computed
that three quintals of wet fish make one quintal of
dried cod. Besides, the lives of every hundred quintals
make one hoghead of oil; and exclusive of these,
there are many other advantages that go in diminution
of the expense. The fishery as we have said above,
produces differently in different seasons; but it is judged
to be a very good one when it produces 300,000 quintals
of fish and 3000 barrels of oil, both equally fale-
able and valuable commodities. As every ship carries
twelve, and each of their boats eight men, and as these
return home in six months, there cannot be a more
noble nursery for seamen. The artificers and traders
employed in building, victualling, and repairing these
vessels, are very numerous in the respective ports from
which they fail. These circumstances justify the par-
ticular attention paid by government to this branch of
the public service; in respect to which, they may be
well informed, an annual and very distinct account,
by which the whole is seen at one view, is delivered
by the proper officer to the governor of Newfound-
land, that is, to the commodore of his majesty's squa-
dron. Mr Pennant in the appendix to his Arctic
Zoology, gives us from what appears to be a very good
authority, the following account of this island.

Within the circuit of 60 miles of the southern
part, the country is hilly but not mountainous. The
hills increase in height as they recede from the sea;
their course is irregular not forming a chain of hills,
but rise and fall abruptly. The coasts are high, and
the shores most remarkably bold. The same may be
said of almost every part of this vast island. The
country is much wooded, and the hills (such which
have not flat tops to admit the rain to stagnate on
them) are clothed with birch, with hazel, spruce, fir,
and pine, all small; which is chiefly owing to the in-
habitants taking off the bark to cover the fish
fiches.

This peninfula is so indented by the fine and deep bays
that we commonly meet with, but seldom above three or four
miles inland, and in valleys; the hills in the
interior part of the
are high, and
remarkably narrow. The
mountains on the south west side, near the sea,
are very high, and terminate in lofty headlands. Such
are Chapeau rouge, a most remarkably high promon-
tory, Cape St Mary's, and Cape le Hune. Such in
general is the formation of the island, on the north-
east, most of the hills in the interior part of the coun-
try terminate pyramidal, but form no chain. The
interior parts of the country confift chiefly of mor-
fels, or dry barren hammocks, or level land, with fre-
quently lakes or ponds, and in some places covered with
fatted black spruce. The rivers of Newfoundland
are unfit for navigation, but they are of use in float-
ing down the wood with the summer floods. Still
the rivers and the brooks are excellent guides for the
hunters of beavers and other animals, to penetrate up
the country, which as yet has never been done deeper
than 50 miles. Near the brooks it is that timber is
commonly met with, but seldom above three or four
miles inland, and in valleys; the hills in the northern
district being naked and barren.
NEW [ 27 ]

NEW.

NEWfoundland. Newmarket.

Sufficiently large for the building of merchant ships: the hulk is made of juniper, and the pine furnishes masts and yards; but as yet none has been found large enough for a mast for a large cutter. The fishery is divided into two sections: that on the shore, or the shore, commences about the 20th of April; and ends about the 10th of October; the boats fish in from four to 20 fathoms water. The most important, the bank-filling section, begins the 10th of May, and continues till the 20th of September, and carried on in 30 to 45 fathoms depth of water. Banking vessels have filled from St John’s to the bank as early as the 12th of April. At first they use pork or birds for a bait; but as they catch fish, they supply themselves with a shell fish called clams, which is found in the belly of the cod. The next bait is the lobster; after that the herring and the lashe, which left June, when the cappel comes on the coast, and is another bait. In August the squid comes into use, and finally the herring again.

The greatest number of cod-fish taken by a single fisherman in the season has been 12,000, but the average is 7,000. The largest fish which has been taken was four feet three inches long, and weighed 46 pounds. A banking vessel of 10,000 fish ought to be filled in three weeks, and 60 in proportion; and 80 quintals (112 lb. each) for a boat in the same time.

In 1785, 541 English vessels filled on the bank, a number exceeding that of the French. A heap of dried fish, 20 feet long and ten wide, and four deep, contains 300 quintals. Such an heap settles, in the course of 48 hours after it is made, about 74. An extraordinary splitter will split five quintals of fish in an hour. The average in that time is two. There is no filling during winter, on account of the inclemency of the weather. It is supposed that the fish in a great measure quit the banks before that time, as in general they are very scarce when the fishing vessels go upon the banks early in the spring.

There are a few small towns on the coasts, which have gardens town with English pulse; but many of the inhabitants quit the country in winter.

An admiral or some sea officer is governor of Newfoundland. He fails from England in May, and returns by the 30th of November.

NEWMARKET, in Cambridgeshire, 13 miles from Cambridge, 13 from St Edmundsbury, and 60 from London, is a town with one long street, the north side in Suffolk, the south side in Cambridgeshire. It is a healthy place and a great thoroughfare in the road from London to Norfolk; but stands moity by the horse-races every year in April and October, here being the finest course in England; on which there is a house for the king when he comes to the races, which was built by Charles II. The king gives a plate or two every year, besides those given by the nobility; and wagers are laid upon the horses, which are seldom under 500 l. and often above 1,000 l. Here are two coffeehouses, at which, every night and morning during the races, there is gaming, as there is also at the houses of the nobility and gentry. Here also are cock-matches. Here is a little chapel, which is a chapel of ease to the mother church at Ditton; and another in the Suffolk side, which is parochial. The town was burnt in 1683, but soon rebuilt. Here are two charity-schools, one for 20 boys, another for 20 girls, supported by 50 l. a year, first settled by Queen Anne. Here is a market on Tuesdays and Thursdays; and fairs on October 28, and Whitmonday.

NEWROSS, a borough town in the county of Wexford, and province of Leinster in Ireland, 67 miles from Dublin. It returns two members to parliament; the patronage is in the families of Tottenham and Leigh. This town was formerly walled, and some of the gates still remain. It lies on the river Barrow which is here very deep, and ships of burden can come up to the quay even when the tide is out. The church is large, but the custom house and quay are both small, and sometimes overflowed many feet.

It is one of the flabe ports for exporting wool, yet its trade is but inconsiderable; beef and butter are the principal articles exported. Here is a barracks for a troop of horse, and a good ferry into the county of Kilkenny. Near this town is a charter-school. It is also a poft town, and gives title of earl to the family of Gore. It was formerly fortified, and adorned with many religious houses, among which was a crouched friary, built on the summit of a hill in the town; but one of the friars having killed a principal inhabitant, the whole body of the people arose, put the friars to death, and totally destroyed the friary; on the site of which the monastery of St Saviour, for conventual Franciscans, was afterwards erected by Sir John Devereux; and the east end of this last building is now the parish-church. A friary for Eremites, following the rule of St Augustine, was also founded here in the reign of Edward III.

NEWS-PAPERS, periodical publications, daily, weekly, &c. for the purpose of communicating to the world every thing of importance, whether political or literary, &c. which is going on. They have tended much to the dissemination of learning, and have served many other valuable purposes; and while they are carried on with candour, impartiality, and ability, they are unquestionably a great national benefit. When this, however, is not the case, and it often happens, they disgrace their authors, and are highly injurious to the public. They were first published in England, August 22, 1662. Journal des Sçavans, a French paper, was first published in 1665, though one was printed in England, under the title of the Public Intelligence, by Sir Roger L’Estrange, 1663, which he dropped, on the publication of the first London Gazette. Newspapers and pamphlets were prohibited by royal proclamation 1680. Though at the revolution prohibitions of this kind were done away, and the press set at liberty, yet newspapers were afterwards made objects of taxation, and for this purpose were first stamped 1713. The number of them, however, gradually increased; and there were printed in the whole kingdom during the years 1775, 12,680,000; 1776, 11,830,000; 1777, 13,150,042; 1778, 13,440,059; 1779, 14,106,842; 1780, 14,217,371; 1781, 14,397,602; 1782, 15,372,519. They are now far more numerous.

NEW-STYLE, first used in England in 1752, was introduced into the western world by Pope Gregory XIII. See CHRONOLOGY, no 24.
NEWTON, or Eft, in Zoology, the common lizard. See Lacerta.

NEWTON (Sir Ifaac), one of the greatf! philosophers and mathematicians the world has ever produced, was the only child of Mr John Newton of Coleworth, not far from Grantham in Lincolnshire, who had an estate of about 120 l. per annum, which he kept in his own hands. He was born at that place on Christmas day 1642. His father dying when he was young, his mother’s brother, a clergyman of the name of Ayfough, or Askew, who lived near her, and directed all her affairs after the death of Mr Newton, put his son to school at Grantham. When he had finished his school leaving, his mother took him home, intending, as she had no other child, to have the pleasure of his company; and that as he was father had done, should occupy his own estate. But his uncle happening to find him in a hay-loft at Grantham working a mathematical problem, and having otherwise observed the boy’s mind to be uncommonly bent upon learning, he prevailed upon her to part with him, and sent him to Trinity College in Cambridge, where her brother, having himself been a member of it, had still many friends. Ifaac was soon taken notice of by Dr Ifaac Barrow; who, observing his bright genius, contracted a great friendship for him. M. de Fontenelle tells us, “That in learning mathematics he did not study Euclid, who seemed to him too plain and simple, and unworthy of taking of his time. He understood him almost before he read him; and a cabt of his eye upon the contents of his theorems was sufficient to make him master of them. He advanced at once to the geometry of Descartes. He depended upon it, that he had made his great discoveries in geometry, and laid the foundation of his two famous works the Principia and the Optics, by the time he was 24 years of age.”

In 1664, he took the degree of bachelor of arts; and in 1668 that of master, being elected the year before fellow of his college. He had before this time discovered the method of fluxions; and in 1669 he was chosen professor of mathematics in the university of Cambridge, upon the resignation of Dr Barrow. The same year, and the two following, he read a course of optical lectures in Latin, in the public schools of the university; an English translation of which was printed at London in 1728, in 8vo, as was the Latin original the next year in 4to. From the year 1671 to 1679, he held a correspondence by letters with Mr Henry Oldenburgh secretary of the royal society, and Mr John Collins fellow of that society; which letters contain a variety of curious observations.

Concerning the origin of his discoveries, we are told, that as he sat alone in a garden, the falling of some apples from a tree led him to a speculation on the power of gravity; that as this power is not diminished at the remote distances from the centre of the earth to which we can rise, it appeared to him reasonable to conclude, that it must extend much farther than was usually thought; and pursuing this speculation, by comparing the periods of the several planets with their distances from the sun, he found, that if any power like gravity held them in their courses, its strength must decrease in the duplicate proportion of the decrease of distance. This inquiry was dropped; but renewed again, and gave rise to his writing the treatise which he published in 1687, under the name of Mathematical Principles of Natural Philosophy, a work looked upon as the production of celestial intelligence rather than of a man. The very same year in which this great work was published, the university at Cambridge was attacked by king James II. when Mr Newton was one of its most zealous defenders, and was accordingly nominated one of the delegates of that university to the high-commission court; and the next year he was chosen one of their members for the convention parliament, in which he sat till it was dissolved. In 1696, Mr Montague, then chancellor of the exchequer, and afterwards earl of Halifax, obtained for him the office of warden of the mint; in which employment he was of signal service, when the money was called in to be recouped. Three years after, he was appointed master of the mint; a place of very considerable profit, which he held till his death. In 1699, he was elected one of the members of the royal academy of Sciences at Paris. In 1701, he was a second time chosen member of parliament for the university of Cambridge. In 1704 he published his Optics; which is a piece of philosophy so new, that the science may be considered as entirely indebted to our author. In 1705, he was knighted by queen Anne. In 1707, he published his Arithmetica Universalis. In 1711, his AnalySis per Quantitatum Series, Fluxiones et Differentias, &c. was published by William Jones, Esq. In 1712, several letters of his were published in the Commercium Episcopum. In the reign of George I. he was better known at court than before. The princefs of Wales, afterwards queen of England, used frequently to propose questions to him, and to express that she thought herself happy to live at the same time with him, and have the pleasure and advantage of his conversation. He had written a treatise of ancient chronology, which he did not think of publishing; but the princefs desired an abstract, which she would never part with. However, a copy of it stole abroad and was carried into France; where it was translated and printed, with some observations, which were afterwards answered by Sir Ifaac. But, in 1728, the Chronology itself was published at London in quarto; and was attacked by several persons, and as zealously defended by Sir Ifaac’s friends. The main design of it was to find out, from some tracts of the most ancient Greek astronomy, what was the position of the colures with respect to the fixed stars, in the time of Chiron the centaur. As it is now known that these stars have a motion in longitude of one degree in 72 years, if it is once known thro’ what fixed stars the colure passed in Chiron’s time, by taking the distance of these stars from those through which it now passes, we might determine what number of years is elapsed since Chiron’s time. As Chiron was one of the Argonauts, this would fix the time of that famous expedition, and consequently that of the Trojan war; the two great events upon which all the ancient chronology depends. Sir Ifaac places them 500 years nearer the birth of Christ than other chronologers generally do.

This great man had all along enjoyed a settled and equal state of health to the age of 80, when he began to be afflicted with an incontinence of urine,
...ure. However, for the five following years, he had great intervals of ease, which he procured by the ob-
...erence of a strict regimen. It was then believed that he certainly had the flux; and when the pa-
...ryptoms were so violent, that large drops of sweat ran
down his face, he never uttered the least complaint, or
...pressed the smallest degree of impatience; but, as
...soon as he had a moment's ease, would smile and talk
with his usual cheerfulness. Till then he always read
and wrote several hours in a day. He had the perfect
use of all his faculties and understanding till the day be-
fore he died, which was on the 20th of March 1726-7,
in the 85th year of his age. He lay in state in the Jeru-
salem chamber at Westminster, and on the 28th of
March his body was conveyed into Westminster ab-
...e side of the design he had of publishing his opti-
cic lectures, we find him reflecting on that dispute,
into which he was unavoidably drawn thereby, in these
terms: "I blamed my own impudence for parting
with so real a blessing as my quiet, to run after a shad-
...w. It is true, this shadow (as Mr Fontenelle ob-
...er) did not escape him afterwards, nor did it cost
him that quiet which he so much valued, but proved
as much a real happiness to him as his quiet itself; yet
this was a happiness of his own making: he took a
resolution, from these disputes, not to publish any
more about that theory till he had put it above the reach
of controversy, by the exactest experiments and the strik-
etest demonstrations; and accordingly it has never
been called in question since. In the same temper, af-
...ter he had sent the manuscript of his "Principia to the
Royal Society, with his consent to the printing of it
by them, upon Mr Hook's injuriously infilling that
himself had demonstrated Kepler's problem before our
author, he determined, rather than be involved in a
controversy, to suppress the third book, and was very
hardly prevailed upon to alter that resolution. It
is true, the public was thereby a gainer; that book,
which is indeed no more than a corollary of some pro-
positions in the first, being originally drawn up in the
popular way, with a design to publish it in that form;
whereas he was now convinced that it would be best
to let it go abroad without a strict demonstration.
After all, notwithstanding his anxious care to avoid
every occasion of breaking his intense application to
study, he was at a great distance from being steeped
in philosophy; on the contrary, he could lay aside his
thoughts, though engaged in the most intricate re-
searches, when his other affairs required his attend-
ance; and, as soon as he had leisure, resume the sub-
ject at the point where he had left off. This he seems
to have done not so much by any extraordinary strength
of memory, as by the force of his inventive faculty, to
which every thing opened itself again with ease, if no-
thing intervened to ruffle him. The readiness of his
invention made him not think of putting his memory
much to the trial: but this was the offspring of a vi-
gorous intenseness of thought, out of which he was but
a common man. He spent, therefore, the prime of his
age in those abstruse researches, when his situation in
a college gave him leisure, and even while study was his
proper profession. But as soon as he was removed to
the mint, he applied himself chiefly to the business
of that office; and so far quitted mathematics and phi-
losophy, as not to engage in any pursuits of either kind,
afterwards.

The amiable quality of modesty is represented as
standing foremost in the character of this great man's
mind and manners. It was in reality greater than can
be easily imagined, or will be readily believed: yet it
always continued so without any alteration, though
the whole world, says Fontenelle, comprised against it,
and let us add, though he was thereby robbed of his invention of fluxions. Nicholas Mercator publishing his *Logarithometria* in 1668, where he gave the quadrature of the hyperbola by an infinite series, which was the first appearance in the learned world of a series of this sort drawn from the particular nature of the curve, and that in a manner very new and abstrated: Dr Barrow, then at Cambridge, where Mr Newton, at that time about 26 years of age, resided, recollected that he had met with the same thing in the writings of that young gentleman; and there not confined to the hyperbola only, but extended, by general forms, to all sorts of curves, even such as are mechanical; to their quadratures, their rectifications, and their centres of gravity; to the solids formed by their relations, and to the superficies of those solids; so that, when their determinations were possible, the series stopped at a certain point, or at least their sums were given by stated rules; and, if the absolute determinations were impossible, they could yet be infinitely approximated; which is the happiest and most refined method, says Mr Fontenelle, of supplying the defects of human knowledge that man's imagination could possibly invent. To be master of so fruitful and general a theory was a mine of fortune to him; for it gave him to whom the discovery was made the opportunity of supplying the company with his treasure and securing the company which his merit drew to him, he was not sensible of any vacancy in life, nor of the want of a companion at home. He left 32,000l. at his death; but made no will, which Mr Fontenelle tells us was because he thought a legacy was no gift. As to his works, besides what were published in his life-time, there were found after his death, among his papers, several discourses upon the subjects of antiquity, history, divinity, chemistry, and mathematics, several of which were published at different times.

**NEWTONIAN PHILOSOPHY**, the doctrine of the universe, and particularly of the heavenly bodies, their laws, affections, &c., as delivered by Sir Isaac Newton.

The term *NEWTONIAN PHILOSOPHY* is applied very differently; whence divers confounded notions relating thereto. Some authors under this philosophy include all the corporeal philosophy, considered as it now stands corrected and reformed by the discoveries and improvements made in several parts thereof by Sir Isaac Newton. In which sense it is that Gravelinde calls his elements of physics, *Introductio ad Phisicam NEWTONIANAM*. And in this sense the Newtonian is the same with the new philosophy; and stands contradistinguished from the Cartesian, the Peripatetic, and the ancient Corporeal.

Others, by *NEWTONIAN PHILOSOPHY*, mean the method or order which Sir Isaac Newton observes in philosophizing; viz.: the reasoning and drawing of conclusions directly from phenomena, exclusive of all previous hypotheses; the beginning from simple principles; deducing the first powers and laws of nature from a few select phenomena, and then applying these laws, &c., to account for other things. And in this sense the *NEWTONIAN PHILOSOPHY* is the same with the experimental philosophy, and stands opposed to the ancient Corporeal.

Others, by *NEWTONIAN PHILOSOPHY*, mean that wherein physical bodies are considered mathematically, and where geometry and mechanics are applied to the solution of the appearances of nature. In which sense the Newtonian is the same with the mechanical and mathematical philosophy.

Others again, by *NEWTONIAN PHILOSOPHY*, understand that part of physical knowledge which Sir Isaac Newton has handled, improved, and demonstrated, in his *PRINCIPIA*.

Others, lastly, by *NEWTONIAN PHILOSOPHY*, mean the new principles which Sir Isaac Newton has brought into philosophy: the new system founded thereon; and the new solutions of phenomena thence deduced; or
Newtonian or that which characterizes and distinguishes his philosophy from all others.—Which is the oneness wherein we shall chiefly consider it.

As to the history of this philosophy, we have nothing to add to what has been given in the preceding article. It was first made public in the year 1687, by the author, then a fellow of Trinity-college, Cambridge; and in the year 1713, republished with considerable improvements.—Several authors have since attempted to make it plainer; by setting aside many of the more sublime mathematical researches, and subtilizing either more obvious reasonings or experiments in lieu thereof; particularly Whiston in his "Prælect. Phil. Mechanicae; Gravitation in Element. &c."

The whole of the Newtonian Philosophy, as delivered by the author, is contained in his "Principia, or Mathematical Principles of Natural Philosophy." He founds his system on the following definitions.

1. The quantity of matter is the measure of the fame, arising from its density and bulk conjunctly.—Thus air of a double density, in a double space, is quadruple in quantity; in a triple space, sextuple in quantity, &c.

2. The quantity of motion is the measure of the fame, arising from the velocity and quantity of matter conjunctly. This is evident because the motion of the whole is the motion of all its parts; and therefore in a body double in quantity, with equal velocity, the motion is double, &c.

3. The 'vis inerita,' or innate force of matter, is a power of resisting, by which every body, as much as in it lies, endeavours to persevere in its present state, whether it be of rest, or moving uniformly forward in a right line.—This definition is proved to be just, only by the difficulty we find in moving any thing out of its place; and this difficulty is by some reckoned to proceed only from gravity. They contend, that in those cases where we can prevent the force of gravity from acting upon bodies, this power of resistance becomes insensible, and the greatest quantities of matter may be put in motion by the very least force. Thus there have been balances formed so exact, that when loaded with 200 weight in each scale, they would turn by the addition of a single drachm. In this case 400 lb. of matter was put in motion by a single drachm, i.e., by \( \frac{1}{370} \) parts of its own quantity; and even this small weight, they say, is only necessary on account of the inaccuracy of the machine; so that we have no reason to suppose, that, if the friction could be entirely removed, it would take more force to move a ton weight than a grain of sand. This objection, however, is not taken notice of by Sir Isæus; and he belittles on the resisting power abovementioned the name of 'vis inerita;' a phrase which is perhaps not well chosen, and with which inferior writers have endeavoured to make their readers merry at the expense of Newton. A force of resistance, it has been said, is a first cause of the principle of the world of this doctrine than those which merely respect the term 'vis inerita.' An endeavour to remove it at rest (we are told*) is unnecessary, whilst nothing attempts to disturb the rest. It is likewise impossible to be conceived, as it implies a contradiction. Newtonian Philosophy.

A man, by opposing force to force, may endeavour not to be moved; but this opposition is an endeavour to move, not with a design to move, but by counteracting another force to prevent being moved. An endeavour not to move therefore cannot exit in bodies, because it is absurd; and if we appeal to fact, we shall find every body in an actual and constant endeavour to move." It has been likewise observed, and we think justly, that "if bodies could continue to move by any innate force, they might also begin to move by that force. For the same cause which can move a body with a given velocity at one time, could do it, if present, at any other time; and therefore if the force by which bodies continue in motion were innate and essential to them, they would begin to move of themselves, which is not true." Newton indeed says that this innate force is the cause of motion under certain circumstances only, or when the body is acted upon by a force impressed as extra. But if this impressed force do not continue as well as begin the motion, if it cease the infant that the impression is over, and the body continue to move by its 'vis inerita,' why is the body ever stopped? "If in the beginning of the motion the body, by its innate force, overcomes a certain resistance of friction and air, in any following times, the force being undiminished, it will overcome the same resistance for ever. Those resistances, therefore could never change the state of a moving body, because they cannot change the quantity of its motive force. But this is contrary to universal experience." For these reasons we are inclined to think that bodies are wholly passive; that they endeavour nothing; and that they continue in motion not by any innate force or 'vis inerita,' but by that force, whatever it be, which begins the motion, and which, whilst it remains with the moving body, is gradually diminished, and at last overcome by opposite forces, when the body of course ceases to move.

4. An impressed force is an action exerted upon a body, in order to change its state, either of rest, or of moving uniformly forward in a right line.—This force coexists in the action only; and remains no longer in the body when the action is over. For a body maintains every new state it acquires by its 'vis inerita' only.

It is here implied, and indeed fully expressed, that motion is not continued by the same power that produced it. Now there are two grounds on which the truth of this doctrine may be supposed to rest.

"First, On a direct proof that the impressed force does not remain in the body, either by showing the nature of the force to be transitory and incapable of more than its first action; or that it acts only on the surface, and that the body escapes from it; or that the force is somewhere else, and not remaining in the body. But none of these direct proofs are offered.

"Secondly, It may rest on an indirect proof, that there is in the nature of body a sufficient cause for the continuance of every new state acquired; and that therefore any adventitious force to continue motion, though necessary for its production, is superfluous and inadmissible. As this is the very ground on which the supposition stands, it ought to have been indubitably certain that the innate force of the body..."
NEW

Newtonian Philosophy is sufficient to perpetuate the motion it has once acquired, before the other agent, by which the motion was communicated, had been dismissed from the office. But the innate force of body has been shown not to be that which continues its motion; and therefore the proof, that the implied force does not remain in the body, fails. Nor Indeed is it in this case defirable to give the proof; because the phenomenon then be left without any reason for the continuance of motion*. When we mention an implied force, we mean such a force as is communicated either at the surface of the body or by being diffused through the mass.

5. A centripetal force is that by which bodies are drawn, impelled, or any way tend towards a point, as to a centre. The quantity of any centripetal force may be considered as of three kinds, absolute, accelerative, and motive.

6. The absolute quantity of a centrifugal force is the measure of the same, proportional to the efficacy of the cause that propagates it from the centre, through the spaces round about.

7. The accelerative quantity of a centripetal force is the measure of the same, proportional to the velocity which it generates in a given time.

8. The motive quantity of a centripetal force is a measure of the same, proportional to the motion which it generates in a given time. This is always known by the quantity of a force equal and contrary to it, that is just sufficient to hinder the descent of the body.

SCHOLIA.

1. Absolute, true, and mathematical time, of itself, and from its own nature, flows equally, without regard to any thing external, and, by another name, is called duration. Relative, apparent, and common time, is some sensible and external measure of duration, whether accurate or not, which is commonly used instead of true time; such as an hour, a day, a month, a year, &c.

5. Space. Absolute space, in its own nature, without regard to any thing external, remains always similar and immovable. Relative space is some moveable dimension or measure of the absolute space; and which is vulgarly taken for immovable space. Such is the dimension of a subterraneous, an aerial, or celestial space, determined by its position to bodies, and which is vulgarly taken for immovable space; as the distance of a subterraneous, an aerial, or celestial space, determined by its position in respect of the earth. Absolute and relative space are the same in figure and magnitude, but they do not remain always numerically the same. For if the earth, for instance, moves, a space of our air which, relatively and in respect of the earth, remains always the same, will at one time be one part of the absolute space into which the earth passes; at another time it will be another part of the same; and so, absolutely understood, it will be perpetually mutable.

6. Place defined. Place is a part of space which a body takes up and is, according to the space, either absolute or relative. Our author says it is part of space; now the situation, not the external surface of the body. For the places of equal folids are always equal; but their superficies, by reason of their dissimilar figures, are often unequal. Positions properly have no quantity, nor are they so much the places themselves as the properties of places. The motion of the whole is the same thing with the sum of the motions of the parts; that is, the translation of the whole out of its place is the same thing with the sum of the translations of the parts out of their places; and therefore the place of the whole is the same thing with the sum of the places of the parts; and for that reason it is internal, and in the whole body.

IV. Absolute motion is the translation of a body of motion from one absolute place into another, and relative motion the translation from one relative place into another. Thus, in a ship under sail, the relative place of a body is that part of the ship which the body possesses, or that part of its cavity which the body fills, and which therefore moves together with the ship; and relative rest is the continuance of the body in the same part of the ship, or of its cavity. But real absolute rest is the continuance of the body in the same part of that immoveable space in which the ship itself, its cavity, and all that it contains, is moved. Wherefore, if the earth is really at rest, the body which relatively rests in the ship will really and absolutely move with the same velocity which the ship has on the earth. But if the earth also moves, the true and absolute motion of the body will arise partly from the true motion of the earth in immovable space; partly from the relative motion of the ship on the earth; and if the body moves also relatively in the ship, its true motion will arise partly from the true motion of the earth in immovable space, and partly from the relative motions as well of the ship on the earth as of the body in the ship; and from these relative motions will arise the relative motion of the body on the earth. As that part of the earth where the ship is, was truly moved towards the east, with a velocity of 10010 parts; while the ship itself with a fresh gale is carried towards the west, with a velocity expressed by 10 of these parts; but a sailor walks in the ship towards the east with one part of the said velocity: then the sailor will be moved truly and absolutely in immovable space towards the east with a velocity of 10011 parts; and relatively on the earth towards the west, with a velocity of 9 of those parts.

Absoluted time, in astronomy, is distinguished from relative, by the equation or correction of the vulgar time. For the natural days are truly unequal, though they are commonly considered as equal, and used for a measure of time: astronomers correct this inequality for their more accurate deducing of the celestial motions. It may be that there is no such thing as an equable motion whereby time may be accurately measured. All motions may be accelerated or retarded; but the true or equable progress of absolute time is liable to no change. The duration of the perseverance of the existence of things remains the same, whether the motions are swift or slow, or none at all; and therefore ought to be distinguished from what are only sensible measures thereof and out of which we collect it by means of the astronomical equation. The necessity of which equation for determining the times of a phenomenon is evinced, as well from the experiments of the pendulum-clock as by eclipses of the satelliters of Jupiter.
As the order of the parts of time is immutable, so also is the order of the parts of space. Suppose these parts to be moved out of their places and they will be moved (if we may be allowed the expression) out of themselves. For time and spaces are, as it were, the places of themselves, as of all other things. All things are placed in time as to order of succession; and in space as to order of fixation. It is from their essence or nature that they are places; and that the primary places of things should be moveable, is absurd. These are therefore the absolute places; and translations out of these places are the only absolute motions.

But because the parts of space cannot be seen, or distinguished from one another by the senses, therefore in their stead we use sensible measures of them. For, from the positions and distances of things from any body, considered as immoveable, we define all places; and then with respect to such places, we determine all motions, considering bodies as transferred from some of those places into others. And so, instead of absolute places and motions, we use relative ones; and that without any inconvenience in common affairs: but in philosophical disquisitions we ought to abstract from our senses, and consider things themselves distinct from what are only sensible measures of them. For it may be, that there is no body really at rest, to which the places and motions of others may be referred.

But we may distinguish rest, and motion, absolute and relative, one from the other by their properties, causes, and effects. It is a property of rest, that bodies really at rest do not move in respect of each other. And therefore, as it is possible, that, in the remote regions of the fixed stars, or perhaps far beyond them, there may be some body absolutely at rest, tho’ it be impossible to know from the position of bodies to one another in our regions, whether any of these do keep the same position to that remote body; it follows, that absolute rest cannot be determined from the position of bodies in our regions.

It is a property of motion, that the parts which retain given positions to their wholes do partake of the motion of their wholes. For all parts of revolving bodies endeavour to recede from the axis of motion; and the impetus of bodies moving forwards arises from the joint impetus of all parts. Therefore if surrounding bodies are moved, those that are relatively at rest within them will partake of their motion. Upon which account the true and absolute motion of a body cannot be determined by the translation of it from those only which seem to rest; for the external bodies ought not only to appear at rest, but to be really at rest. For otherwise all included bodies, beside their translation from near the surrounding ones, partake likewise of their true motions; and though that translation was not made, they would not really be at rest, but only seem to be so. For the surrounding bodies stand in the like relation to the surrounded, as the exterior part of a whole does to the interior, or as the shell does to the kernel; but if the shell moves, the kernel will also move, as being part of the whole, without any removal from near the shell.

A property near akin to the preceding is, that if a place is moved, whatever is placed therein moves along with it; and therefore a body which is moved from a place in motion, partakes also of the motion of its place. Upon which account all motions from places in motion, are no other than parts of entire and absolute motions; and every entire motion is composed of the motion of the body out of its first place: and the motion of this place out of its place; and so on, until we come to some immoveable place, as in the above-mentioned example of the sailor. Wherefore entire and absolute motions can be no otherwise determined than by immoveable places. Now, no other places are immoveable but those that from infinity to infinity do all retain the same given positions one to another: and upon this account must ever remain unmoveed, and do thereby constitute what we call immoveable space.

The causes by which true and relative motions are distinguished one from the other, are the forces impressed upon bodies to generate motion. True motion is neither generated nor altered, but by some force impressed upon the body moved: but relative motion may be generated or altered without any force impressed upon the body. For it is sufficient only to impress some force on other bodies with which the former is compared, that, by their giving way, that relation may be changed, in which the relative rest or motion of the other body did consist. Again, true motion suffers always some change from any force impressed upon the moving body; but relative motion does not necessarily undergo any changes by such force. For if the same forces are likewise impressed on those other bodies with which the comparison is made, that the relative position may be preserved; then that condition will be preserved, in which the relative motion consists. And therefore any relative motion may be changed when the true motion remains unaltered, and the relative may be preserved when the true motion suffers some change. Upon which account true motion does by no means consist in such relations.

The effects which distinguish absolute from relative motion are, the forces of receding from the axis of circular motion. For there are no such forces in a circular motion purely relative: but, in a true and absolute circular motion, they are greater or less according to the quantity of the motion. If a vessel, hung by a long cord, is so often turned about that the cord is strongly twisted, then filled with water, and let go, it will be whirled about the contrary way; and while the cord is unwinding itself, the surface of the water will at first be plain, as before the vessel began to move; but the vessel, by gradually communicating its motion to the water, will make it begin sensibly to revolve, and recede by little and little from the middle, and ascend to the fides of the vessel, forming itself into a concave figure; and the fwerter the motion becomes, the higher will the water rise, till at last, performing its revolutions in the same times with the vessel, it becomes relatively at rest in it. This accet of the water shows its endeavour to recede from the axis of its motion; and the true and absolute circular motion of the water, which is here directly contrary to the relative, discovers itself, and may be measured by this endeavour. At first, when the relative motion in the water was greatest, it produced no end
deavour to recede from the axis; the water showed no
tendency to the circumference, nor any ascent towards
the sides of the vessel, but remained of a plain surface;
and therefore its true circular motion had not yet be-
gun. But afterwards, when the relative motion of the
water had decreased, the ascent thereof towards the
sides of the vessel proved its endeavour to recede from
the axis; and this endeavour showed the real circular
motion of the water perpetually increasing, till it had
acquired its greatest quantity, when the water relented
relatively in the vessel. And therefore this endeavour
does not depend upon any translation of the water in
respect of the ambient bodies: nor can true circular
motion be defined by such translations. There is only
one real circular motion of any one revolving body,
corresponding to only one power of endeavouring to
recede from its axis of motion, as its proper and ade-
quate effect; but relative motions in one and the same
body are innumerable, according to the various rela-
tions it bears to external bodies; and, like other rela-
tions, are altogether delusive of any real effect, other-
wise than they may perhaps partake of that only
true motion. And therefore, in the system which sup-
pposes that our heavens, revolving below the sphere of
the fixed stars, carry the planets along with them, the
several parts of those heavens and the planets, which
are indeed relatively at rest in their heavens, do yet
really move. For they change their position one to
another, which never happens to bodies truly at rest;
and being carried together with the heavens, partici-
pate of their motions, and, as parts of revolving wholes,
endeavour to recede from the axis of their motion.

Wherefore relative quantities are not the quantities
themselves whose names they bear, but those sensible
measures of thems either accurate or inaccurate, which
are commonly used instead of the measured quantities
themselves. And then, if the meaning of words is to
be determined by their use, by the names time, space,
place, and motion, their measures are properly to be
understood; and the expression will be unqualified and
purely mathematical, if the measured quantities them-

It is indeed a matter of great difficulty to discover,
and effectually to distinguish the true motions of par-
ticular bodies from those that are only apparent: be-
cause the parts of that immoveable space in which those
motions are performed, do by no means come under
the observation of our senses. Yet we have some things
to direct us in this intricate affair; and these arise
partly from the apparent motions which are the dif-
tinction of the true motions, partly from the forces
which are the causes and effects of the true motions.
For instance, if two globes, kept at a given distance
one from the other by means of a cord that connects
them, were revolved about their common centre of
gravity: we might, from the tension of the cord, dis-
cover the endeavour of the globes to recede from the
axis of motion, and from thence we might compute the
quantity of their circular motions. And then, if any equal forces should be impressed at once on the al-
ternate faces of the globes to augment or diminish
their circular motions, from the increase or decrease of
the tension of the cord, we might infer the incre-
ment or decrement of their motions; and thence
would be found on what faces those forces ought to
be impressed, that the motions of the globes might be
most augmented; that is, we might discover their hin-
dermost faces, or those which follow in the circular
motion. But the faces which follow being known, and
consequently the opposite ones that precede, we should
likewise know the determination of their motions. And
thus we might find both the quantities and determina-
tion of this circular motion, even in an immense va-
cuum, where there was nothing external or sensible,
with which the globes might be compared. But now,
if in that space some remote bodies were placed that
kept always a given position one to another, as the
fixed stars do in our regions; we could not indeed de-
termine from the relative translation of the globes
among those bodies, whether the motion did belong
to the globes or to the bodies. But if we observed the
cord and found that its tension was that very tension
which the motions of the globes required, we might
conclude the motion to be in the globes, and the bo-
dies to be at rest; and then, lastly, from the transla-
tion of the globes among the bodies, we should find the
determination of their motions.

Having thus explained himself, Sir Isaac proposes
to shew us how we are to collect the true motions, from
their causes, effects, and apparent differences; and vice
verfa, how, from the motions, either true or apparent,
we may come to the knowledge of their causes and
effects. In order to this, he lays down the following
axioms or laws of motion.

1. Every body perseveres in its state or rest, Laws of
or of uniform motion in a right line, unless it
is compelled to change that state by forces im-
pressed upon it. — Sir Isaac's proof of this axiom is as
follows: "Projectiles persevere in their motions: so far as
they are not retarded by the resistence of the air,
or impelled downwards by the force of the gravity. A
top, whose parts, by their cohesion, are perpetually
drawn aside from rectilinear motions, does not cease its
rotation otherwise than as it is retarded by the air. The
greater bodies of the planets and comets, meeting with
the resistance in more free spaces, preserve their mo-
tions, both progressive and circular, for a much longer
time." — Notwithstanding this demonstration, however,
the axiom hath been violently disputed. It hath been
argued, that bodies continue in their state of motion
because they are subjected to the continual impulse of
inanimate and subtle fluid, which always pours in from
behind, and of which all places are full. It hath been
affirmed that motion is as natural to this fluid at rest is
to all other matter. It is said, moreover, that it is im-
possible we can know in what manner a body would be
influenced by moving forces if it was entirely deftri-
tute of gravity. According to what we can observe
the momentum, of a body, or its tendency to move
depends very much on its gravity. A heavy cannon-
ball will fly to a much greater distance than a light one
though both are actuated by an equal force. It is by
no means clear, therefore, that a body totally destitute
of gravity would have any proper momentum of its
own; and if it had no momentum, it could not con-
tinue its motion for the smallest space of time after
the moving power was withdrawn. Some have imagined
that matter was capable of beginning motion by itself,
and consequently that the axiom was false; because we
see plainly that matter in some cases hath a tendency
to
Newtonian to change from a state of motion to a state of rest, and from a state of rest to a state of motion. A paper appeared on this subject in the first volume of the Edinburgh Philosophical Essays; but the hypothesis never gained any ground.

2. The alteration of motion is ever proportional to the motive force impressed; and is made in the direction of the right line in which that force is impressed — Thus, if any force generates a certain quantity of motion, a double force will generate a double quantity, whether that force be impressed all at once, or in successive moments. To this law no objection of consequence has ever been made. It is founded on this self-evident truth, that every effect must be proportional to its cause. Mr Young, who seems to be very ambitious of detecting the errors of Newton, finds fault indeed with the expressions in which the law is stated; but he owns, that if thus expressed, The alteration of motion is proportional to the actions or resistances which produce it, and is in the direction in which the actions or resistances are made, it would be unexceptionable.

3. To every action there always is opposed an equal reactive; or the mutual action of two bodies upon each other is always equal, and directed to contrary parts. — This axiom is also disputed by many. In the abovementioned paper in the Physical Essays, the author endeavours to make a division between reactive and resistive; and the same attempt has been made by Mr Young. "When an action generates no motion (says he), it is certain that its effects have been destroyed by a contrary and equal action. When an action generates two contrary and equal motions, it is also evident that mutual actions were exerted, equal and contrary to each other. All cases where one of the conditions are not found, are exceptions to the truth of the law. If a finger presses against a stone, the stone, if it does not yield to the pressure, presses, as much upon the finger: but if the stone yields, it reacts less than the finger acts; and if it should yield with all the momentum that the force of the pressure ought to generate, which it would do if it were not impeded by friction, or a medium, it would not react at all. So if the stone drawn by a horse, follows after the horse, it does not react so much as the horse acts; but only to such an extent that the velocity of the stone is diminished by friction, and it is the re-action of friction only, not of the stone. The stone does not react because it does not act, but resistance is not action."

In the loss of motion from a striking body, equal to the gain in the body struck, there is a plain solution without requiring any re-action. The motion itself is identically that which is found in the other body; this supposition accounts for the whole phenomenon in the most simple manner. If it be not admitted, but the solution by re-action is inquired upon, it will be incumbent upon the party to account for the whole effect of communication of motion; otherwise he will lie under the imputation of rejecting a solution which is simple, obvious, and perfect; for one complex, unnatural, and incomplete. However this may be determined, it will be allowed, that the circumstances mentioned, afford no ground for the inference, that action and re-action are equal, since appearances may be explained in another way (A).

Others grant that Sir Isaac's axiom is very true in respect to terrestial substances; but they affirm, that,
in these, both action and re-action are the effects of

Newtonian Philosophy

which in any finite time converge continually to equa-

Lem. I. Quantities, and the ratios of quantities,

bodies possessed of equal momenta can exert different actions, it being admitted that bodies resist proportional to their masses, and that their power of overcoming resistance is proportional to their momenta?

It is incumbent on those who maintain the doctrine of universal re-action, to free it from these difficulties and

one to the other than by any given difference, become ultimately equal. If you deny it; suppose them to be ultimately unequal, and let D be their ultimate difference. Therefore they cannot approach nearer to equality than by that given difference D; which is against the supposition.

Concerning the meaning of this lemma philosophers Objections are not agreed; and unhappily it is the very funda-

mental notion on which the whole of the system rests.

Many objections have been raised to it by people who supposed themselves capable of understanding it. They say, that it is impossible we can come to an end of any infinite series, and therefore that the word ultimate can in this case have no meaning. In some cases the

lemma is evidently false. Thus, suppose there are two quantities of matter A and B, the one containing half a pound, and the other a third part of one. Let both be continually divided by 2; and though their ratio, or the proportion of the one to the other, do not vary, yet the difference between them perpetually becomes less, as well as the quantities themselves, until both the difference and quantities themselves become less than any assignable quantity; yet the difference will never totally vanish, nor the quantities become equal, as is evident from the two following series.

Thus we see, that though the difference is continually diminishing, and that in a very large proportion, there is no hope of its vanishing, or the quantities becoming equal. In like manner, let us take the proportions or ratios of quantities, and we shall be equally unsuccessful. Suppose two quantities of matter, one containing 8 and the other 10 pounds; these quantities already have to each other the ratio of 8 to 10, or of 4 to 5; but let us add 2 continually to each of them, and though the ratios continually come nearer to that of equality, it is vain in hope for a perfect coincidence. Thus.

8 10 12 14 16 18 20 22 24 &c.
10 12 14 16 18 20 22 24 &c.

Ratio \( \frac{4}{5} \) \( \frac{6}{7} \) \( \frac{8}{9} \) \( \frac{10}{11} \) &c.

For this and his other theses Sir Isaac makes the

following apology. "These theses are premised, to avoid the tediousness of deducing perplexed demonstrations ad absurdum, according to the method of ancient geometers. For demonstrations are more contradicted by the method of indivisibles: but because the hypothesis of indivisibles seems somewhat harsh, and therefore that method is reckoned less geometrical, I chose rather to reduce the demonstrations of the following propositions to the first and last sums and ratios of nascent and evanescent quantities, that is, to the limits of those sums and ratios; and so to premise, as short as I could, the demonstrations of those limits.

For
For hereby the same thing is performed as by the method of indivisibles; and now those principles being demonstrated, we may use them with more safety. Therefore, if thereafter I would happen to consider quantities as made up of particles, or should use little curve lines for right ones; I should not be understood to mean indivisibles, but evanescent divisible quantities; not the sums and ratios of determinate parts, but always the limits of sums and ratios; and that the force of such demonstrations always depends on the method laid down in the foregoing lemmas.

"Perhaps it may be objected, that there is no ultimate proportion of evanescent quantities, because the proportion, before the quantities have vanished, is not the ultimate, and, when they are vanished, is none. But by the same argument it may be alleged, that a body arriving at a certain place, and there stopping, has no ultimate velocity; because the velocity before the body comes to the place is not its ultimate velocity; when it is arrived, it has none. But the answer is easy: for by the ultimate velocity is meant that with which the body is moved, neither before it arrives at its place and the motion ceases, nor after; but at the very instant it arrives; that is, that velocity with which the body arrives at its last place, and with which the motion ceases. And in like manner, by the ultimate ratio of evanescent quantities is to be understood the ratio of the quantities, not before they vanish, nor afterwards, but with which they vanish. In like manner, the first ratio of nascent quantities is that with which they begin to be. And the first or last sum is that with which the body is moved, neither before it arrives at its place and the motion ceases, nor after; but limits of sums and ratios; and so all quantities, and proportions that begin and cease to be. And, since such limits are certain and definitive, to determine the fame is a problem strictly geometrical. But whatever is geometrical we may be allowed to make use of in determining and demonstrating any thing that is likewise geometrical.

"It may be also objected, that if the ultimate ratios of evanescent quantities are given, their ultimate magnitudes will be also given; and so all quantities will consist of indivisibles, which is contrary to what Euclid has demonstrated concerning incommensurables, in the roth book of his elements. But this objection is founded on a false supposition. For those ultimate ratios with which quantities vanish, but limits towards which the ratios of quantities decrease continually approach.

LEM. II. If any figure Ace E (Pl. CCCXLV. n. 1.) terminated by the right line Aa, AE, and the curve a E, there be inscribed any number of parallelograms A B, B C, C D, &c. comprehended under equal bases AB, BC, CD, &c. and the sides BE, EC, DC, &c. parallel to the base AE of the figure; and the parallelograms KB, B LM, ME D, &c. are completed. Then if the breadth of these parallelograms be supposed to be diminished, and their number augmented in infinitum: the ultimate ratios which the inscribed figure A K L E M D, the circumscribed figure A L M B E D, and curvilinear figure A, a b c d E, will have to one another, are ratios of equality. For the difference of the inscribed and circumscribed figures is the sum of the parallelograms K K, L m, M n, D d; that is, (from the equality of all their bases), the rectangle under one of their bases K b, and the sum of their altitudes A a, that is, the rectangle A B b a. But this rectangle, because its breadth A B b is supposed diminished in infinitum, becomes less than any given space. And therefore, by lem. 1. the figures inscribed and circumscribed become ultimately equal the one to the other; and much more will the intermediate curvilinear figure be ultimately equal to either.

LEM. III. The same ultimate ratios are also ratios of equality, when the breadths AB, BC, CD, &c. of the parallelograms are unequal, and are all diminished in infinitum. The demonstration of this differs but little from that of the former.

In his succeeding lemmas, Sir Isaac goes on to prove, in a manner similar to the above, that the ultimate ratios of the fine, chord, and tangent of arcs infinitely diminished, are ratios of equality, and therefore that in all our reasonings about these we may safely use the one for the other:—that the ultimate form of evanescent triangles made by the arc, chord, and tangent, is that of fimilitude, and their ultimate ratio is that of equality; and hence, in reasonings about ultimate ratios, we may safely use these triangles for each other, whether made with the fine, the arc, or the tangent. He then shows some properties of the ordinates of curvilinear figures; and proves that the spaces which a body describes by any finite force urging it, whether that force is determined and immutable, or is continually augmented or continually diminished, are, in the very beginning of the motion, one to the other in the duplicate ratio of the powers. And, lastly, having added some demonstrations concerning the evanescence of angles of contact, he proceeds to lay down the mathematical part of his system, and which depends on the following theorems.

THEOR. I. The areas which revolving bodies describe by radii drawn to an immovable centre of force, lie in the same immovable planes, and are proportional to the times in which they are described. For, suppose the time to be divided into equal parts, and in the first part of that time, let the body by its innate force describe the right line AB (no. 2); in the second part of that time, the same would, by law 1. if not hindered, proceed directly to c along the line B c = AB; so that by the radii AS, BS, SC, drawn to the centre, the equal areas ASB, BSC, would be described. But, when the body is arrived at B, suppose the centripetal force acts at once with a great impulsion, and turning aside the body from the right line BC, compels it afterwards to continue its motion along the right line BC. Draw cE parallel to BS, meeting BC in C; and at the end of the second part of the time, the body, by cor. 1. of the laws, will be found in C, in the same plane with the triangle ASB. Join SC; and because SC and cE are parallel, the triangle SBC will be equal to the triangle SBC, and therefore also to the triangle S A E. By the like argument, if the centripetal force acts successively in C, D, E, &c. and makes the body in each single particle of time to describe the right lines CD, DE, EF,
NEW [ 38 ] NEW

Newtonian Philosophy

Newtonian EF, &c., they will all lie in the same plane; and the triangle SCD will be equal to the triangle SBC, and SDE to SCD, and SEF to SDE. And therefore, in equal times, equal areas are described, in one immoveable plane; and by composition, any sums SADS, SAFS, of those areas, are, one to the other, at the times in which they are described. Now, let the number of those triangles be augmented, and their size diminished in infinitum; and then by the preceding lemmas, their ultimate perimeter ADF will be a curve line: and therefore the centripetal force by which the body is perpetually drawn back from the tangent of this curve will act continually; and any described areas SADS, SAFS, which are always proportional to the times of description, will in this case also, be proportional to those times Q.E.D.

Cor. 1. The velocity of a body attracted towards an immoveable centre, in spaces void of resistance, is reciprocally as the perpendicular let fall from that centre on the right line which touches the orbit. For the velocities in those places A, B, C, D, E, are as the bases AB, BC, DE, EF, of equal triangles; and those bases are reciprocally as the perpendiculars let fall upon them.

Cor. 2. If the chords AB, BC, of two arcs successively described in equal times by the same body, in spaces void of resistance, are completed into a parallelogram ABCV, and the diagonal BV of this parallelogram, in the position which it ultimately acquires, when those arcs are diminished in infinitum, is produced both ways, it will pass through the centre of force.

Cor. 3. If the chords AB, BC, and DE, EF, of arcs described in equal times, in spaces void of resistance, are completed into the parallelograms ABCV, DEFZ, the forces in B and E are one to the other in the ultimate ratio of the diagonals BV, EZ, when those arcs are diminished in infinitum. For the motions BC and EF of the body (by cor. 1. of the laws), are compounded of the motions BS, BV and EF, EZ; but BV and EZ, which are equal to Cc and Ee, in the demonstration of this proposition, were generated by the impulses of the centripetal force in B and E, and therefore proportional to those impulses.

Cor. 4. The forces by which bodies in spaces void of resistance, are drawn back from rectilinear motions, and turned into curvilinear orbits, are one to another as the versed sines of arcs described in equal times; which versed sines tend to the centre of force, and bisect the chords when those arcs are diminished to infinitum. For such versed sines are the halves of the diagonal mentioned in cor. 3.

Cor. 5. And therefore those forces are to the force of gravity, as the said versed sines to the versed sines perpendicular to the horizon of those parabolic arcs which projectiles describe in the same time.

Cor. 6. And the same things do all hold good (by cor. 5. of the laws) when the planes in which the bodies are moved, together with the centres of force, which are placed in those planes, are not at rest, but move uniformly forward in right lines.

Theor. II. Every body that moves in any curve line described in a plane, and, by a radius drawn to a point either immoveable or moving forward with an uniform rectilinear motion, describes about that point areas proportional to the times, is urged by a centripetal force directed to that point.

Case I. For every body that moves in a curve line is (by law 1.) turned aside from its rectilinear course by the action of some force that impels it; and that force by which the body is turned off from its rectilinear course, and made to describe in equal times the least equal triangles SAB, SBC, SCD, &c. about the immoveable point S, (by Prop. 40. E. 1. and law 2.) acts in the place B according to the direction of a line parallel to C; that is, in the direction of the line BS; and in the place C according to the direction of a line parallel to D, that is, in the direction of the line CS, &c.; and therefore acts always in the direction of lines tending to the immoveable point S. Q.E.D.

Case II. And (by cor. 5. of the laws) it is indifferent whether the superfluous in which a body describes a curvilinear figure be quiescent, or moves together with the body, the figure described, and its point, uniformly forward in right lines.

Cor. 1. In non-refilling spaces or mediums, if the areas are not proportional to the times, the forces are not directed to the point in which the radii meet; but deviate therefrom in consequentia, or towards the parts to which the motion is directed, if the description of the areas is accelerated; but in antecedentia if retarded.

Cor. 2. And even in refilling mediums, if the description of the areas is accelerated, the directions of the forces deviate from the plane in which the radii meet, towards the parts to which the motion tends.

Scholium.

A body may be urged by a centripetal force compounded of several forces. In which case the meaning of the proposition is, that the force which results out of all tends to the point S. But if any force acts perpetually in the direction of lines perpendicular to the described surface, this force will make the body to deviate from the plane of its motion, but will neither augment nor diminish the quantity of the described surface; and is therefore not to be neglected in the composition of forces.

Theor. III. Every body that, by a radius drawn to the centre of another body, however moved, describes areas about the centre proportional to the times, is urged by a force compounded of the centripetal forces tending to that other body, and of the whole accelerative force by which that other body is impelled.—The demonstration of this is a natural consequence of the theorem immediately preceding.

Hence, if the one body L, by a radius drawn to the other body T, describes areas proportional to the times, and from the whole force by which the first body L is urged, (whether that force is simple, or, according to cor. 2. of the laws compounded of several forces), we subduct that which whole accelerative force by which the other body is urged; the whole remaining force by which the first body is urged will tend to the other body T, as its centre.

And vice versa, if the remaining force tends nearly to the other body T, those areas will be nearly proportional to the times.
If the body $L$, by a radius drawn to the other body $T$, describes areas, which, compared with the times, are very unequal, and that other body $T$ being either at rest, or moves uniformly forward in a right line, the action of the centripetal force tending to that other body $T$ is either none at all, or it is mixed and combined with very powerful actions of other forces: and the whole force compounded of them all, if they are many, is directed to another (immoveable or moveable) centre. The same thing obtains when the other body is acted upon by any other motion whatever; provided that centripetal force is taken which remains after subducting that whole force acting upon that other body $T$.

**Scholium.**

Because the equable description of areas indicates that a centre is reflected by that force with which the body is most affected, and by which it is drawn back from its rectilinear motion, and retained in its orbit, we may always be allowed to use the equable description of areas as an indication of a centre about which all circular motion is performed in free spaces.

**Theor. IV.** The centripetal forces of bodies which by equable motions describe different circles, tend to the centres of the same circles; and are one to the other as the squares of the arcs described in equal times applied to the radii of circles. For these forces tend to the centres of the circles, (by theor. 2. and cor. 2. theor. 1.) and are to one another as the versed sines of the least arcs described in equal times, (by cor. 4. theor. 1.) that is, as the squares of the same arcs applied to the diameters of the circles, by one of the lemmas; and therefore, since those arcs are as arcs described in any equal times, and the diameters are as the radii, the forces will be as the squares of any arcs described in the same time, applied to the radii of the circles. Q. E. D.

**Cor. 1.** Therefore, since those arcs are as the velocities of the bodies, the centripetal forces are in a ratio compounded of the duplicate ratio of the velocities directly, and of the simple ratio of the radii inversely.

**Cor. 2.** And since the periodic times are in a ratio compounded of the ratio of the radii directly, and the ratio of the velocities inversely; the centripetal forces are in a ratio compounded of the ratio of the radii directly, and the duplicate ratio of the periodic times inversely.

**Cor. 3.** Whence, if the periodic times are equal, and the velocities therefore as the radii, the centripetal forces will be also as the radii; and the contrary.

**Cor. 4.** If the periodic times and the velocities are both in the subduple ratio of the radii, the centripetal forces will be equal among themselves; and the contrary.

**Cor. 5.** If the periodic times are as the radii, and therefore the velocities equal, the centripetal forces will be reciprocally as the radii; and the contrary.

**Cor. 6.** If the periodic times are in the fequipli­cate ratio of the radii, and therefore the velocities reciprocally in the subduplicate ratio of the radii, the centripetal forces will be in the duplicate ratio of the radii inversely; and the contrary.

**Cor. 7.** And universally, if the periodic time is as any power $R^n$ of the radius $R$, and therefore the velocity reciprocally as the power $R^{n-1}$ of the radius, the centripetal force will be reciprocally as the power $R^{2n-2}$ of the radius; and the contrary.

**Cor. 8.** The same things hold concerning the times, the velocities, and forces, by which bodies describe the similar parts of any similar figures, that have their centres in a similar position within those figures, as appears by applying the demonstrations of the preceding caBes to these. And the application is easy, by only substituting the equable description of areas in the place of equable motion, and using the distances of the bodies from the centres instead of the radii.

**Cor. 9.** From the same demonstration it likewise follows, that the arc which a body uniformly revolving in a circle by means of a given centripetal force describes in any time, is a mean proportional between the diameter of the circle, and the space which the same body, falling by the same given force, would descend through in the same given time.

"By means of the preceding proposition and its corollaries (says Sir Isaac), we may discover the proportion of a centripetal force to any other known force, such as that of gravity. For if a body by means of its gravity revolves in a circle concentric to the earth, this gravity is the centripetal force of that body. But from the defect of heavy bodies, the time of one entire revolution, as well as the arc described in any given time, is given (by cor. 9. of this theorem). And by such propositions Mr Huygens, in his excellent book De Horologio Oscillatorio, has compared the force of gravity with the centrifugal forces of revolving bodies.

The preceding proposition may also be demonstrated in the following manner. In any circle suppose a polygon to be inscribed of any number of sides. And if a body, moved with a given velocity along the sides of the polygon, is reflected from the circle at the several angular points; the force with which, at every reflection it strikes the circle, will be as its velocity: and therefore the sum of the forces, in a given time, will be as that velocity and the number of reflections conjunctly; that is, (if the species of the polygon be given), as the length described in that given time, increased or diminished in the ratio of the same length to the radius of the circle; that is, as the square of that length applied to the radius; and therefore, if the polygon, by, having its sides diminished in infinitum, coincides with the circle, as the square of the arc described in a given time applied to the radius. This is the centrifugal force, with which the body impels the circle; and to which the contrary force, wherewith the circle continually repels the body towards the centre, is equal.

On these principles hangs the whole of Sir Isaac Newton's mathematical philosophy. He now shows how to find the centre to which the forces impelling any body are directed, having the velocity of the body given; and finds the centrifugal force to be always as the versed sine of the nascent arc directly, and as the

**Newtonian Philosophy**
he lays down such principles as entirely overthrow the
primary arc. From these premises he deduces the method
of finding the centripetal force directed to any given
point when the body revolves in a circle; and this
whether the central point is near or at an immense
distance; so that all the lines drawn from it may be
taken as parallels. The same thing he does with re­
gard to bodies revolving in spirals, ellipses, hyper­
bolas, or parabolas. — Having the figures of the orbits
given, he shows also how to find the velocities and
moving powers; and, in short, solves all the most
difficult problems relating to the celestial bodies with an
astonishing degree of mathematical skill. These pro­lems and demonstrations are all contained in the first
book of the Principia; but to give an account of them
here would far exceed our limits; neither would many
of them be intelligible, excepting to first-rate mathe­
maticians.

In the second book, Sir Isaac treats of the proper­
ties of fluids, and their powers of resistance; and here
he lays down such principles as entirely overthrow the
doctrine of Des Cartes's vortices, which was the fas­
tionable fytlem in his time. In the third book, he
begins particularly to treat of the natural phenomena,
and applies them to the mathematical principles former­
ly demonstrated; and, as a necessary preliminary to
this part, he lays down the following rules for reason­
ing in natural philosophy.

1. We are to admit no more causes of natural
things than such as are both true and sufficient to
explain their natural appearances.
2. Therefore to the same natural effects we must al­
always assign, as far as possible, the same causes.
3. The qualities of bodies which admit neither in­
tention nor remission of degrees, and which are found
to belong to all bodies within the reach of our exper­i­ments, are to be esteemed the universal qualities of
all bodies whatsoever.
4. In experimental philosophy, we are to look upon
propositions collected by general induction from phe­
omena as accurately or very nearly true, without­
standing any contrary hypotheses that may be ima­
gined, till such time as other phenomena occur, by
which they may either be made more accurate, or li­
able to exceptions.

The phenomena first considered, are, 1. That the fa­
ettes of Jupiter by radii drawn to the centre of their
primary, describe areas proportional to the times of
their description; and that their periodic times, the
fixed stars being at rest, are in the sesquiquadrate ratio
of their distances from its centre. 2. The same thing is
likewise observed of the phenomena of Saturn. 3. The
five primary planets, Mercury, Venus, Mars, Jupiter,
and Saturn, with their several orbits, encompass the sun.
4. The fixed stars being supposed at rest, the periodic
times of the five primary planets, and of the earth,
about the sun, are in the sesquiquadrate proportion of
their mean distances from the sun. 5. The primary
planets, by radii drawn to the earth, describe areas no
ways proportional to the times; but the areas which
they describe by radii drawn to the sun are propor­
tional to the times of description. 6. The moon,
by a radius drawn to the centre of the earth, describes
an area proportional to the time of description. All

these phenomena are undeniable from astronomical ob­
servations, and are explained at large under the article
ASTRONOMY. The mathematical demonstrations are
next applied by Sir Isaac Newton in the following
prepositions.

Prop. I. The forces by which the satellites of Ju­
piter are continually drawn off from rectilinear mo­tion,
and retained in their proper orbits, tend to the
centre of that planet; and are reciprocally as the
squares of the distances of those satellites from that
centre. The former part of this proposition appears
from theor. 2.; the latter from cor. 6. of theor. 5.; and the same thing we are to understand of the
satellites of Saturn.

Prop. II. The forces by which the primary planets
are continually drawn off from rectilinear motions, and
retained in their proper orbits, tend to the sun; and
are reciprocally as the squares of the distances from
the sun's centre. The former part of this proposition is
manifest from phenomenon 5. just mentioned, and
from theor. 2.; the latter from phenomenon 4. and
cor. 6. of theor. 4. But this part of the proposition is
with great accuracy deducible from the quiescence of
the apogee points. For a very small aberration from
the reciprocal duplicate proportion would pro­
duce a motion of the apsides, sensible in every single
revolution, and in many of them enormously great.

Prop. III. The force by which the moon is retained
in its orbit, tends towards the earth; and is reciprocally
as the square of the distance of its place from the
centre of the earth. The former part of this propo­
sition is evident from phenomenon 5. and theor. 2.; the
latter from phenomenon 6. and theor. 2. or 3. It is also
evident from the very slow motion of the moon's apo­
gee; which, in every single revolution, amounting but to
3° 3' in conterminia, may be neglected; and this
more fully appears from the next proposition.

Prop. IV. The moon gravitates towards the earth,
and by the force of gravity is continually drawn off
from a rectilinear motion, and retained in its orbit.—
The mean distance of the moon from the earth in the
fyzigies in semidiameters of the latter, is about 60.
Let us assume the mean distance of 60 semidiameters
in the fyzigies; and suppose one revolution of the moon
in respect of the fixed stars to be completed in 27° 7'.
43; as astronomers have determined; and the circum­
erference of the earth to amount to 123,249,600 Paris
feet. Now, if we imagine the moon, deprived of all
motion, to be let go, so as to descend towards the earth
with the impulse of all that force by which it is
retained in its orbit, it will, in the space of one minute
of time, describe in its fall 15 Paris feet. For the
very first thing of that arc which the moon, in the space
of one minute of time, describes by its mean motion
at the distance of 60 semidiameters of the earth, is
nearly 15; Paris feet; or more accurately, 15 feet
1 inch and one line. Wherefore since that force, in
approaching to the earth, increaseth in the recipro­
al duplicate proportion of the distance; and, upon
that account, at the surface of the earth is 60X60
times greater than at the moon; a body in our re­
gions, falling with that force, ought, in the space of
one minute of time, to describe 60X60X15', Paris
feet; and in the space of one second of time to de­
scribe 15', of thebe feet; or, more accurately, 15 feet
And with this very force we actually find that bodies here on earth do really descend.

For a pendulum oscillating second in the latitude of Paris, will be three Paris feet and $\frac{1}{2}$ of one Paris foot, as Mr Huygens has observed. And the space which a heavy body describes by falling one second of time is half the length of the pendulum in the duplicate ratio of the circumference of the circle of its diameter; and is therefore $15$ Paris feet, $1$ inch, $1$ line. And therefore the force by which the moon is retained in its orbit, becomes, at the very surface of the earth, equal to the force of gravity which we observe in heavy bodies there. And therefore (by rule 1. and 2.) the force by which the moon is retained in its orbit is that very same force which we commonly call gravity. For were gravity another force different from that, then bodies descending to the earth with the joint impulse of both forces, would fall with a double velocity, and, in the space of one second of time, would describe $30$ Paris feet: altogether against experience.

The demonstration of this proposition may be more distinctly explained after the following manner. Suppose several moons to revolve about the earth, as in the system of Jupiter or Saturn, the periodic times of those moons would (by the argument of induction) observe the same law which Kepler found to obtain among the planets; and therefore their centripetal forces would be reciprocally as the squares of the distances from the centre of the earth, by Prop. 1. Now, if the lowest of these were very small, and were so near the earth as almost to touch the tops of the highest mountains, the centripetal force thereof, retaining it in its orbit, would be very nearly equal to the weights of any terrestrial bodies that should be found upon the tops of these mountains; as may be known from the foregoing calculation. Therefore, if the same little moon should be deflected by its centrifugal force that carries it through its orbit, it would descend to the earth; and that with the same velocity as heavy bodies do actually descend with upon the tops of those very mountains, because of the equality of forces that oblige them both to descend. And if the force by which that lowest moon would descend were different from that of gravity, and if that moon were to gravitate towards the earth, as we find terrestrial bodies do on the tops of mountains, it would then descend with twice the velocity, as being impelled by both these forces conspiring together. Therefore, since both these forces, that is, the gravity of heavy bodies, and the centripetal forces of the moons, respect the centre of the earth, and are similar and equal between themselves, they will (by rule 1. and 2.) have the same cause. And therefore the force which retains the moon in its orbit, is that very force which we commonly call gravity; because otherwise, this little moon at the top of a mountain must either be without gravity, or fall twice as swiftly as heavy bodies use to do.

Having thus demonstrated that the moon is retained in its orbit by its gravitation towards the earth, it is easy to apply the same demonstration to the motions of the other secondary planets, and of the primary planets round the sun, and thus to flow that gravitation prevails throughout the whole creation; after which, Sir Isaac proceeds to shew from from the same principles, that the heavenly bodies gravitate towards each other, and contain different quantities of matter or have different densities in proportion to their bulk.

Prop. V. All bodies gravitate towards every planet; and the weights of bodies towards the same planet, at equal distances from its centre, are proportional to the quantities of matter they contain.

It has been confirmed by many experiments, that all sorts of heavy bodies (allowance being made for the inequality of retardation by some small refilience of the air) descend to the earth from equal heights in equal times; and that equality of times may distinguish to a great accuracy by the help of pendulums. Sir Isaac Newton tried the thing in gold, silver, lead, glass, sand, common salt, water, and wheat. He provided two wooden boxes, round and equal, filled the one with wood, and suspended an equal weight of gold in the centre of oscillation of the other. The boxes hanged by equal threads of $1$ foot, made a couple of pendulums, perfectly equal in weight and figure, and equally receiving the refilience of the air. And placing the one by the other, he observed them to play together forwards and backwards, for a long time, with equal vibrations. And therefore the quantity of matter in the gold was to the quantity of matter in the wood, as the action of the motive force (or vis matrix) upon all the gold, to the action of the same force upon all the wood; that is, as the weight of the one to the weight of the other. And the like happened in the other bodies. By these experiments, in bodies of the same weight, he could manifestly have discovered a difference of matter less than the thousandth part of the whole, had any such been. But, without all doubt, the nature of gravity towards the planets is the same as towards the earth. For, should we imagine a terrestrial body removed to the orb of the moon, and there, together with the moon deprived of all motion, to be let go, so as to fall together towards the earth; it is certain, from what we have demonstrated before, that, in equal times, they would describe equal spaces with the moon, and of consequence are to the moon, in quantity of matter, as their weights to its weight. Moreover, if the satellites of Jupiter perform their revolutions in times which observe the sequelclicate proportion of their distances from Jupiter’s centre, their accelerative gravities towards Jupiter will be reciprocally as the squares of their distances from Jupiter’s centre; that is, equal at equal distances. And therefore, these satellites, if supposed to fall towards Jupiter from equal heights, would describe equal spaces in equal times, in like manner as heavy bodies do on our earth. And by the same argument, if the circumfolar planets were supposed to be let fall at equal distances from the sun, they would, in their descent towards the sun, describe equal spaces in equal times. But forces, which equally accelerate unequal bodies, must be as those bodies; that is to say, the weights of the planets towards the sun must be as their quantities of matter. Further, that the weights of Jupiter and of his satellites towards the sun are proportional to the several quantities of their matter, appears from the exceeding regular motions of the satellites. For if some of those bodies were more strongly attracted to the sun in proportion to their quantity of matter than others, the motions of the satellites would be disturbed by that inequality of attraction. If, at equal

equal distances from the sun, any satellite, in proportion to the quantity of its matter, did gravitate towards the sun, with a force greater than Jupiter in proportion to his, according to any given proportion, suppose of to 1; then the distance between the centres of the sun and of the satellite's orbit would be always greater than the distance between the centres of the sun and of Jupiter nearly in the subduplicate of that proportion. And if the satellite gravitated towards the sun with a force less in the proportion of to , the distance of the centre of the satellite's orb from the sun would be less than the distance of the centre of Jupiter's from the sun in the subduplicate of the same proportion. Therefore, if, at equal distances from the sun, the accelerative gravity of any satellite toward the sun were greater or less than the accelerative gravity of Jupiter towards the sun but by part of the whole gravity; the distance of the centre of the satellite's orbit from the sun would be greater or less than the distance of Jupiter from the sun by part of the whole distance; that is, by a fifth part of the distance of the utmost satellite from the centre of Jupiter, an eccentricity of the orbit which would be very sensible. But the orbits of the satellites are concentric to Jupiter; therefore the accelerative gravities of Jupiter, and of all its satellites, towards the sun, are equal among themselves. And by the same argument, the weight of Saturn and of his satellites towards the sun, at equal distances from the sun, are as their several quantities of matter; and the weights of the moon and of the earth towards the sun, are either none, or accurately proportional to the masses of which they contain.

But further, the weights of all the parts of every planet towards any other planet are one to another, as the matter in the several parts. For if some parts gravitated more, others less, than in proportion to the quantity of their matter; then the whole planet according to the for of parts with which it most abounds, would gravitate more or less than in proportion to the quantity of matter in the whole. Nor is it of any moment whether these parts are external or internal. For if, as an instance, we should imagine the terrestrial bodies with us to be raised up to the orb of the moon, to be there compared with its body; if the weights of such bodies were to the weights of the external parts of the moon as to the quantities of matter in the one and in the other respectively, but to the weights of the internal parts in a greater or less proportion; then likewise the weights of those bodies would be to the weight of the whole moon in a greater or less proportion; against what we have shewed above.

Cor. 1. Hence the weights of bodies do not depend upon their forms and textures. For if the weights could be altered with the forms, they would be greater or less, according to the variety of forms in equal matter; altogether against experience.

Cor. 2. Universally, all bodies, about the earth gravitate towards the earth; and the weights of all, at equal distances from the earth's centre are as the quantities of matter which they severally contain. This is the quality of all bodies within the reach of our experience; and therefore (by rule 3.) to be affirmed of all bodies whatsoever. If either, or any other body, were either altogether void of gravity, or were to gravitate less in proportion to its quantity of matter; then, because (according to Arithmet, Des Cartes, and Newtonians) there is no difference betwixt that and other bodies, but in mere form of matter, by a successive change from form to form, it might be changed at last into a body of the same condition with those which gravitate most in proportion to their quantity of matter; and, on the other hand, the heaviest bodies, acquiring the first form of that body, might by degrees quite lose their gravity. And therefore the weights would depend upon the forms of bodies, and with those forms might be changed, contrary to what was proved in the preceding corollary.

Cor. 3. All spaces are not equally full. For if all spaces were equally full, then the specific gravity of the fluid which fills the region of the air, on account of the extreme density of the matter, would fall nothing short of the specific gravity of quick-silver or gold, or any other the most dense body; and therefore, neither gold, nor any other body, could descend in air. For bodies do not descend in fluids, unless they are specifically heavier than the fluids. And if the quantity of matter in a given space can by any rarefaction be diminished, what should hinder a diminution to infinity?

Cor. 4. If all the solid particles of all bodies are of the same density, nor can be rarified without pores, a void space or vacuum must be granted. [By bodies of the same density, our author means those whose specific gravity is in the proportion of their bulk.]

Prob. VI. That there is a power of gravity tending to all bodies, proportional to the several quantities of matter which they contain.

That all the planets mutually gravitate one towards another, we have proved before; as well as that the force of gravity towards every one of them, considered apart, is reciprocally as the square of the distance of places from the centre of the planet. And thence it follows, that the gravity tending towards all the planets is proportional to the matter which they contain.

Moreover, since all the parts of any planet A gravitate towards any other planet B, and the gravity of every part is to the gravity of the whole as the matter of the part to the matter of the whole; and (by law 3.) to every action corresponds an equal reaction: therefore the planet B will, on the other hand, gravitate towards all the parts of the planet A; and its gravity towards any one part will be to the gravity towards the whole, as the matter of the part to the matter of the whole.

Cor. 1. Therefore the force of gravity towards any whole planet, arises from, and is compounded of, the forces of gravity towards all its parts. Magnetic and electric attractions afford us examples of this. For all attraction towards the whole arises from the attractions towards the several parts. The thing may be easily understood in gravity, if we consider a greater planet as formed of a number of lesser planets, meeting together in one globe. For hence it would appear that the force of the whole must consist from the forces of the component parts. It if be objected, that according to this law, all bodies with us must mutually gravitate one towards another, whereas no such gravitation any where appears: it is answered, that, since the gravitation towards these bodies is to the gravitation towards the whole earth, as these bodies are to the whole earth, the gravitation towards them must be far less than to fall.
Newtonian Philosophy

NEW [ 43 ]

Cor. 2. The force of gravity towards the several equal particles of any body, is reciprocally as the square of the distance of places from the particles.

Prop. VII. In two spheres mutually gravitating each towards the other, if the matter, in places on all sides round about and equidistant from the centres, is similar; the weight of either sphere towards the other will be reciprocally as the square of the distance between their centres.

For the demonstration of this, see the Principia, book i. prop. 72. and 76.

Cor. 1. Hence we may find and compare together the weights of bodies towards different planets. For the weights of bodies revolving in circles about planets are as the diameters of the circles directly, and the squares of their periodic times reciprocally; and their weights at the surfaces of the planets, or at any other distances from their centres, are (by this prop.) greater or less, in the reciprocal duplicate proportion of the distances. Thus from the periodic times of Venus, revolving about the sun, in 224d. 16th; of the utmost circumjovial satellite revolving about Jupiter, in 16d. 16 1/2h. of the Hyugenean satellite about Saturn in 15d. 223h.; and of the moon about the earth in 27d. 7h. 43 1/2 min.; compared with the mean distance of Venus from the sun, and with the greatest heliocentric elongations of the utmost circumjovial satellite from Jupiter's centre, 8' 16 1/2; of the Hyugenean satellite from the centre of Saturn, 3' 4 1/2; and of the moon from the earth, 10' 33 1/2; by computation our author found, that the weight of equal bodies, at equal distances from the centres of the sun, of Jupiter, of Saturn, and of the earth, towards the sun, Jupiter, Saturn, and the earth, were one to another as \( \frac{1}{3} \), \( \frac{1}{10} \), \( \frac{1}{25} \), and \( \frac{1}{36} \) respectively. Then, because as the distances are increased or diminished, the weights are diminished or increased in a duplicate ratio; the weights of equal bodies towards the sun, Jupiter, Saturn, and the earth, at the distances 10000, 997, 979, and 109, from their centres, that is, at their very surfaces, will be as 10000, 945, 529, and 435 respectively.

Cor. 2. Hence likewise we discover the quantity of matter in the several planets. For their quantities of matter are as the squares of gravity at equal distances from their centres, that is, in the sun, Jupiter, Saturn, and the earth, as 1, \( \frac{1}{10000} \), \( \frac{1}{997} \), \( \frac{1}{979} \), and \( \frac{1}{109} \); and if the parallax of the sun be taken greater or less than 10' 30", the quantity of matter in the earth must be augmented or diminished in the triplicate of that proportion.

Cor. 3. Hence also we find the densities of the planets. For (by prop. 72. book i.) the weights of equal and similar bodies towards similar spheres, are, at the surfaces of those spheres, as the diameters of the spheres. And therefore the densities of dissimilar spheres are as those weights applied to the diameters of the spheres. But the true diameters of the Sun, Jupiter, Saturn, and the Earth, were one to another as 10000, 997, 979, and 109; and the weights towards the same, as 10000, 945, 529, and 435 respectively; and therefore their densities are as 100, 945, 529, and 435. The density of the earth, which comes out by this computation, does not depend upon the parallax of the sun, but is determined by the parallax of the moon, and therefore is here truly defined. The Sun therefore is a little denser than Jupiter, and Jupiter than Saturn, and the earth four times denser than the Sun; for the Sun, by its great heat, is kept in a rarefied state. The moon also is denser than the earth.

Cor. 4. The smaller the planets are, they are, ceteris paribus, of so much the greater density. For the powers of gravity on their several surfaces come nearer to equality. They are likewise, ceteris paribus, of the greater density as they are nearer to the sun. S. Jupiter is more dense than Saturn, and the Earth than Jupiter. For the planets were to be placed at different distances from the sun, that, according to their degrees of density, they might enjoy a greater or less proportion of the sun's heat. Our water, if it were removed as far as the orb of Saturn, would be converted into ice, and in the orb of Mercury would quickly fly away in vapour. For the light of the sun, to which its heat is proportional, is seven times denser in the orb of Mercury than with us: and by the thermometer Sir Isaac found, that a sevenfold heat of our summer sun will make water boil. Nor are we to doubt, that the matter of Mercury is adapted to its heat, and is therefore more dense than the matter of our earth; hence, in a denser matter, the operations of nature require a stronger heat.

It is shown in the scholiun of prop. 32. book 2. of the Principia, that, at the height of 200 miles above the earth, the air is more rare than it is at the superficies of the earth, in the ratio of 30 to 0,000,000,000,000,000 to 1 nearly. And hence the planet Jupiter, revolving in a medium of the same density as that of superior air, would not lose by the resistance of the medium the 100000th part of its motion in 100000 years. In the spaces near the earth, the resistance is produced only by the air, exhalations, and vapours. When these are carefully exhausted by the air-pump from under the receiver, heavy bodies fall within the receiver with perfect freedom, and without the least sensible resistance; gold itself, and the lightest down, let fall together, will descend with equal velocity; and though they fall through a space of 10, 20, or 40, and even 80 feet, they will come to the bottom at the same time; as appears from experiments that have often been made. And therefore the celestial regions being perfectly void of air and exhalations, the planets and comets meeting no sensible resistance in those spaces, will continue their motions through them for an immense space of time.

NEWTON (Richard) D. D. the founder of Hertford college, is a man of whom we regret that we can give but a superfluous and rather a vague account. By one writer he is said to have been a Northamptonshire gentleman; by another, we are told that his father enjoyed at Lavendon Grange in Bucks a moderate estate, which is still in the family, though he lived in a house of Lord Northampton's in Yardley-Chace, where in 1675 our doctor was born. All agree that the family from which he sprung had long been respectable, though its fortunes had been much injured during the great rebellion.

The subject of this article was educated at Westminster school, and from that foundation elected to a studentship of Christ-church, Oxford. At what age
Newton. he was admitted into the university we have no certain information; but in the list of graduates he is thus distinguished: "Newton (Richard,) Christ-church, M. A. April 12th 1701; B. D. March 18th 1707; Hart-hall, D. D. December 7th 1710." He was appointed a tutor in Christ-church as soon as he was of the requisite standing in his college, and discharged the duties of that important office with honour to himself and advantage to the society of which he was a member. From Oxford he was called (we know not at what precise period) into Lord Pelham's family to superintend the education of the late duke of Newcastle and his brother Mr Pelham; and by both these illustrious persons he was ever remembered with the most affectionate regard. In 1710 he was by Dr Aldrich, the celebrated dean of Christ-church, induced principal of Hart-hall, which was then an appendage to Exeter college. From this state of dependence Dr Newton was set at liberty, especially from the learned Dr Conybear, afterwards dean of Christ-church and bishop of Bristol. In no contest, it has been observed, were ever two men more equally matched; and the papers that passed between them, like Junius's letters, desired to be collected for the energetic beauty of their style and the ingenuity of their arguments. Dr Newton, however, proved successful; and in 1740 obtained a charter, converting Hart-hall into Hertford college; of which, at a considerable expense to himself, and with great aid from his numerous friends, he was thus the founder and first head.

Though this excellent man was Mr Pelham's tutor, and, if report be true, had by him been more than once employed to furnish king's speeches, he never received the smallest preterment from his pupil when first minister: and when that statesman was asked, why he did not place in a proper station the able and meritorious Dr Newton? his reply was, "How could I do it? he never asked it of me." He was a zealous friend to religion, the university, the clergy, and the poor; and such was his liberality of sentiment, that he admitted to his friendship every man, whatever might be his religious creed, who was earnestly employed in the same good works with himself—the promotion of virtue and unaffected piety. Of his works we have seen only his Theophrastus, which was published after his death; and his Pluralities Indefensible; but he published several other things during his life, and left a volume of sermons prepared for the presb at his death.

Newton (Thomas), late lord bishop of Bristol and dean of St Paul's, London, was born on the 1st of January 1704. His father, John Newton, was a conspicuous brandy and cider merchant, who, by his industry and integrity, having acquired what he thought a competent fortune, left off trade several years before he died.

He received the first part of his education in the free school of Litchfield; a school which, the bishop observes with some kind of exultation, he however neglected by all the great. Dr Compton, bishop of London, who had a just sense of his merits, had, at an early period of his life, collated him to the rectory of Sudbury in the county of Northampton, which he held together with the headship of Hart-hall. He resided for some years on that living, and discharged all the parts of his office with exemplary care and fidelity. Amongst other particulars he read the prayers of the liturgy in his church at seven o'clock in the evening of every week-day (hay-time and harvest excepted,) for the benefit of some of his parishioners as could then assemble for public devotion. When he left the place, returning again to Oxford about 1724, he enjoined his curates to observe the same pious practice; and was fortunate enough to have three successively who trode in the footsteps of their worthy principal. Being always an enemy to pluralities with cure of souls, he exerted his utmost endeavours from time to time with Dr Gibson, Bishop Conway's successor in the See of London, for leave to resign his rectory in favour of his curate. To the reformation his lordship could have no objection; but being under some kind of engagement to confer the living on another, Dr Newton retained it himself, but bestowed all the emoluments upon works of charity in the parish, and curates who so faithfully discharged their duty. Dr Sherlock, who succeeded Bishop Gibson, being under no engagement of a like nature, very readily granted Dr Newton's request, by accepting his resignation, and collating to the rectory Mr Saunders, who was the last of his curates. Upon a vacancy of the public orator's place at Oxford, the head of Hertford college offered himself a candidate; but as the race was not always to the swift nor the battle to the strong, Dr Digby Coates carried the point against him. He was afterwards promoted to a canonry of Christ-church, but did not long enjoy it; for in April 1753 death deprived the world of this excellent man in the 78th year of his age.

He was allowed to be as polite a scholar, and as accomplished a gentleman, as almost any of the age in which he lived. In closeness of argument, and perplicity of style, he had no superior. Never was any private person employed in more trusts, nor were trusts ever discharged with greater integrity. He was a zealous friend to religion, the university, the clergy, and the poor; and such was his liberality of sentiment, that he admitted to his friendship every man, whatever might be his religious creed, who was earnestly employed in the same good works with himself—the promotion of virtue and unaffected piety. Of his works we have seen only his Theophrastus, which was published after his death; and his Pluralities Indefensible; but he published several other things during his life, and left a volume of sermons prepared for the presb at his death.

From Litchfield he was removed to Westminster school, in 1717, under the care of Dr Friend and Dr Nicoll.

During the time he was at Westminster, there were, he observes, more young men who made a distinguishing figure afterwards in the world, than perhaps at any other period, either before or since. He particularly mentions William Murray, the late earl of Mansfield, with whom he lived on terms of the highest friendship to the last.

He continued six years at Westminster school, five of which he passed in the college. He afterwards went to Cambridge, and entered at Trinity college. He here constantly resided eight months at least in every year, till he had taken his Bachelor of Arts degree. Being then Fellow of his college, he came afterwards to settle in London. As it had been his inclination from a child, and as he was also designed for holy orders, he had sufficient time to prepare himself, and composed some sermons, that he might have a stock in hand when he entered on the ministry. His title for orders was his fellowship; and he was ordained deacon in December 1729, and priest in the February following, by Bishop Gibson.
At his first setting out in his office, he was curate at St George's, Hanover-square; and continued for several years assistant-preacher to Dr Trebeck. His first preferment was that of reader and afternoon-preacher at Grofton chapel, in South-Audley street.

This introduced him to the family of Lord Tyrconnel, to whom he became tutor. He continued in this situation for many years, very much at his ease, and on terms of great intimacy and friendship with lord and lady Tyrconnel, "without so much (says he) as an unkind word or a cool look ever intervening."

In the spring of 1744, he was, through the interest of the earl of Bath (who was his great friend and patron, and whose friendship and patronage were returned by grateful acknowledgments and the most flattering encomiums, presented to his rectory of St Mary le Bow; so that he was 40 years old before he obtained any living.

At the commencement of 1745, he took his doctor's degree. In the spring of 1747 he was chosen lector of St George's, Hanover-square, by a most respectable vote of noblemen and gentlemen of high distinction. In August following he married his first wife, the eldest daughter of Dr Trebeck; an unaffected, modest, decent young woman, with whom he lived very happy in mutual love and harmony near seven years.

In 1749 he published his edition of Milton's Paradise Lost, which (says he, very modestly) it is hoped hath not been ill received by the public, having, in 1775 gone through eight editions. After the Paradise Lost, it was judged (says he) proper that Dr Newton should also publish the Paradise Regained, and other poems of Milton; but these things he thought detained him from other more material studies, though he had the good fortune to gain by them more than Milton did by all his works put together. But his greatest gain (he says) was their first introducing him to the friendship and intimacy of two such men as Bishop Warburton and Dr Jortin, whose works will speak for them better than any private commendation.

In 1754 he lost his father, at the age of 83; and within a few days his wife, at the age of 38. This was the severest trial he ever underwent, and almost overwhelmed him. At that time he was engaged in writing his Dissertation on the Prophecies; and happy it was for him: for in any affliction he never found a better or more effectual remedy than plunging deep into study, and fixing his thoughts as intently as he possibly could upon other subjects. The first volume was published the following winter; but the other did not appear till three years afterwards; and as a reward for his patience and incitement to future labours, he was appointed, in the mean time, to preach the Boyle's lectures. The bishop informs us, that 1250 copies of the Dissertations were taken at the first impression, and 1000 at every other edition: and "though (says he) some things have been since published upon the same subjects, yet they still hold up their head above water, and having gone through five editions, are again prepared for another. Abroad, too, their reception hath not been unfavourable, if accounts from thence may be depended upon." They were translated into the German and Danish languages, and received the warmest encomiums from persons of learning and rank.

In the spring of 1757, he was made prebendary of Westminster in the room of Dr Green, and promoted to the deanship of Salisbury. In October following, he was made sub-almoner to his majesty. This he owed to Bishop Gilbert. He married a second wife in September 1761. She was the window of the Rev. Mr Hand, and daughter of John Lord-Viccount Lifburn. In the same month he kissed his majesty's hand for his bispope.

In the winter of 1764, Dr Stone, the primate of Ireland, died. Mr Grenville lent for Bishop Newton, and in the most obliging manner desired his acceptance of the primacy. Having maturely weighed the matter in his mind, he declined the offer. In 1768 he was made dean of St Paul's. His ambition was now fully satisfied: and he firmly resolved never to ask for anything more.

From this time to his death, ill health was almost his constant companion. It was wonderful that such a poor, weak, and slender thread as the bishop's life, should be spun out to such an amazing length as it really was. In the autumn of 1781 (usually the most favourable part of the year to him) he laboured under repeated illnesses; and on Saturday the 9th of February 1782, he began to find his breath much affected by the first. His complaints grew worse and worse till the Thursday following. He got up at five o'clock, and was placed in a chair by the fire; complained to his wife how much he had suffered in bed, and repeated to his servant that portion of the Psalms, "O my God, I cry unto thee in the day-time," &c. &c. About six o'clock he was left by his apothecary in a quiet sleep.

Between seven and eight he awoke, and appeared rather more easy, and took a little refreshment. He continued dozing till near nine, when he ordered his servant to come and dress him, and help him down stairs. As soon as he was dressed, he inquired the hour, and bid his servant open the window of St Paul's. The servant answered, he was up on the stroke of nine. The bishop made an effort to take out his watch, with an intent to set it; but sunk down in his chair, and expired without a sigh or the least visible emotion, his countenance still retaining the same placid appearance which was so peculiar to him when alive. Of his numerous works, his Dissertations on the Prophecies are by much the most valuable. His learning was undoubtedly very considerable; but he seldom exhibits evidence of a very vigorous mind. On one occasion, indeed, he appears to have thought with freedom; for we believe he was the first dignitary of the church of England who avowed his belief of the final retribution of all things to harmony and happiness.

NEWTYA, a port little known, on the coast between Goa, the capital of the Portuguese settlements in India, and the English settlement of Bombay. Mr Rennel conjectures it to be the Nitrias of Pliny; near which the pirates cruised for the Roman ships. The same writer places it near to 15° 52' 30" North Latitude, and 73° 16' 30" East Longitude.

NEXI, among the Romans, persons free-born, who for debt were reduced to a state of slavery. By the laws of the twelve tables it was ordained, that insolvent debtors should be given up to their creditors to be bound in fetters and cords, whence they were called Nesi; and though they did not entirely lose the rights of
NGO

[46]

NIA

NGO-CHIEF, a town of Upper Hungary, capital of a county of the same name, with a bishop's see; feated on the river Neitra, 40 miles north east of Presburg. E. Long. 17. 49. N. Lat. 48. 28.

NGAN-KING-FOU, a city of China, and capital of the western part of the province of Kiang-nan. It is governed by a particular viceroy, who keeps a large garrison in a fort built on the banks of the river Yang-tie-kiang. Its situation is delightful; its commerce and riches render it very considerable; and every thing that goes from the southern part of China to Nan-kung mull passes through it. All the country belonging to it is level, pleafant, and fertile. It has under its jurisdiction only five cities o. the third class.

NGO-KIA, a Chinefe drug, of which the composition will no doubt appear singular, as the numerous properties ascribed to it. In the province Chang tong, near Ngo-hien, a city of the third class, is a well, formed by nature, which is reckoned to be seventy feet in depth, and which has a communication, as the Chinefe fay, with fome subterranean lake, or other large refervoir. The water drawn from it is exceedingly clear, and much heavier than common; and if it be mixed with muddy water, it purifies it, and renders it limpid, by precipitating all its impurities to the bottom of the well. This water is employed in making the ngo-kia, which is nothing else but a kind of glue procured from the skin of a black fafs.

The animal is killed and flayed, and the skin is fleeperd for five days in water drawn from this well. At this period, it is taken out to be scraped and cleaned; it is afterwards cut into small pieces, which are boiled over a fmall fire, in the fame kind of water, until it is reduced to a jelly, which is drained, while warm, through a cloath, to free it from all the granf matter which could not be melted. When this glue is cool, and has acquired a conftance, it is formed into square cakes, upon which the Chinefe imprint characters and coats of arms, or the figns of their fhips.

This well is the only one of the kind in China; it is always flufh, and fealed by the governor of the place with his own feal, untill the courtly day of making the emperor's glue. This operation generally falls from the autumnal harvest till the month of March. During this time, the neighbouring people and merchants treat for the purchase of the glue with thofe who guard the well, and with the people who make it. The latter manufacture as much of it as they can, on their own account, with this difference, that it is not so pure, and that they are less scrupulous in examining whether the afs be fat, or of a very black colour: however, all the glue made here is as much esteemed at Peking as that which the mandarins who are on the spot transmit to court and to their friends.

As this drug is in the greatest request, and as the quantity of it made at Ngo-hien is not sufficient to supply the whole empire, there are not wanting people who counterfeit it elsewhere, and who manufacture a puripous kind from the skins of mules, horses, and camels, and sometimes even from old boots; it is, however, very easy to distinguish that which is genuine; it has neither a bad smell nor a difagreeable taffe when applied to the mouth; it is brittle and friable, and always of a deep black colour, fometimes inclining to red. The qualities of the counterfeit kind are entirely different; both its taffe and smell are disagreeable, and it is vifous and fuffy even when made of the skin of a hog, which is that which imitates the true kind the beft.

The Chinefe attribute a great number of virtues to this drug. They aflire us that it diures phlegm, facilitates the play and effalificy of the lungs, gives a free refpiration to thoee who breath with difficulty; that it comforts the breath, increases the blood, cures feveral fpecies of diathesies, provokes urine, and strengthens children in the womb. Without warranting the truth of all thefe properties, it appears, at leaft, certain, by the testimony of the millionaires, that this drug is serviceable in all diforders of the lungs. It is taken with a decoction of fimples, and fometimes in powder, but very seldom.

NIAGARA, a fort of North America, which was taken by the English from the French 1759, and ceded to the United States of America, by the treaty of peace in 1783, but still retained in possession by the British Government, contrary to that treaty; probably because the fort is in a manner commands all the interior parts of the continent; is a key to the north-westem territories of the United States; and is surrounded by Six Nations of Indians, with whom the English have been long in alliance. It is situated on a small peninsula formed by the river Niagara as it flows into the lake Estero. About fix leagues from the fort is the greatest cataract in the world, known by the name of the Waterfall of Niagara. The river at this fall runs from SSW to NNW; and the rock of this fall croifes it not in a right line, but forms a kind of figure like an hollow femicircle or horifontal. Above the fall, in the middle of the river, is an island about 800 or 1000 feet long; the lower end of which is juft at the perpendiculat edge of the fall. On both fides of this island runs all the water that comes from the lakes of Canada; viz. Lake Superior, Lake Mitchigan, Lake Huron, and Lake Erie, which have fomelarge rivers that open themfelves into them. Before the water comes to this island, it runs but slowly compared with its motion afterwards, when it grows the most rapid in the world, running with a surprifing velocity before it comes to the fall. It is perfectly whife, and in many places is thrown high up into the air. The wat r that runs down on the weft fide is more rapid, in greater abundance, and whiter, than that on the eait fide; and seems almost to outfly an arrow in swifhneas. When you are at the fall, and look up the river you may fee that the water is every where exceedingly steep, almost like the fide of an hill; but when you come to look at the fall itself, it is impossible to exprès the aterraent it occasions. The height of it, as measured by mathematical instruments, is found to be exactly 137 feet; and when the water is come to the bottom, it jumps back to a very great
great height in the air. The noise may be heard the distance of 45 miles, but seldom further; nor can it be heard even at Fort Niagara, which is only six leagues distant, unless Lake Ontario is calm. At that fort it is observed, that when they hear the noise of the fall more loud than ordinary, they are sure that a north-east wind will follow; which is the more surprising, as the fort lies south-west from the fall. At times the fall makes a much greater noise than at others: and this is held for an insallable sign of approaching rain or other bad weather.

From the place where the water falls there arises abundance of vapour like very thick smoke, inoffensive than when viewed at a distance you would think that the Indians had let the foresters on fire. Their vapours rife high in the air when it is calm, but are dispersed by the wind when it blows hard. If you go into this vapour or fog, or if the wind blows it on you, it is so penetrating, that in a few moments you will be as wet as if you had been under water. Some are of opinion that when birds come flying into this fog or smoke of the fall, they drop down and perish in the water; other because their wings are become wet, or that the noise of the fall affrights them, and they know not where to go in the darknes: but others think that seldom or never any bird perishes in that manner: because among the abundance of birds found dead below the fall, there are no other forts than such as live and swim frequently in the water: as swans, geese, ducks, water-hens, teal, and the like. And very often great flocks of them are seen going to destruction in this manner; they swim in the river above the fall, and so are carried down lower and lower by the water; and as water fowl commonly take great delight in being carried with the stream, they indulge themselves in enjoying this pleasure so long, till the swiftness of the water becomes so great, that it is no longer possible for them to rise, but they are driven down the precipice and perish. They are observed, when they draw near the fall, to endeavour with all their might to take wing, and leave the water; but they cannot. In the months of September and October, such abundant quantities of dead water-fowl are found every morning below the fall, on the shore, that the garrisons of the fort for a long time live chiefly upon them. Before the fowl they find also several forts of dead fish, also deer, bears, and other animals which have tried to cross the water above the fall; the larger animals are generally found broken to pieces. Just below, a little way from the fall, the water is not rapid, but goes all in circles, and whirls like a boiling pot, which however does not hinder the Indians going upon it in small canoes a fishing; but a little further, and lower, the other smaller falls begin. When you are above the fall, and look down, your head begins to turn; even such as have been here numberless times, will seldom venture to look down, without at the same time keeping a firm hold of some tree with one hand.

It was formerly thought impossible for any body living to come at the island that is in the middle of the fall; but an accident that happened about 50 years ago made it appear otherwise. The history is this: Two Indians of the Six Nations went out from Niagara fort to hunt upon an island that is in the middle of the river, or strait, above the great fall, on which there used to be abundance of deer. They took some French brandy with them from the fort, which they tasted several times as they were going over the carrying-place; and when they were in their canoe, they took now and then a dram, and so went along the strait towards the island where they proposed to hunt; but growing sleepy, they laid themselves down in the canoe, which getting loose drove back with the stream, farther and farther down till it came nigh that island that is in the middle of the fall. Here one of them, awakened by the noise of the fall, cries out to the other, that they were gone: Yet they tried it possible to save life. This island was neglected, and with much working they got on shore there. At first they were glad; but when they had considered every thing, they thought themselves hardly in a better state than if they had gone down the fall, since they had now no other choice, than either to throw themselves down the fall, or perish with hunger. But hard necessity put them to invention. At the lower end of the island the rock is perpendicular, and no water is running there. The island has plenty of wood: they went to work then, and made a ladder of several sorts of dead places. So they went down along their new stairs, and when they came to the bottom in the middle of the fall they rested a little: and as the water next below the fall is not rapid, as before-mentioned, they threw themselves out into it, thinking to swim on shore. We have said before, that one part of the fall is on one side of the island, the other on the other side. Hence it is, that the waters of the two cataracts running against each other, turn back against the rock that is just under the island. Therefore hardly had the Indians begun to swim, before the waves of the eddy threw them down with violence against the rock from whence they came. They tried it several times, but at last grew weary, and by being often thrown against the rock they were much bruised, and the skin torn off their bodies in many places. So they were obliged to climb up stairs again to the island, not knowing what to do. After some time they perceived Indians on the shore, to whom they cried out. These saw and pitied them, but gave them little hope or help; yet they made haste down to the fort, and told the commandant where two of their brothers were. He persuaded them to try all possible means of relieving the two poor Indians; and it was done in the following manner;

The water that runs on the east side of this island is shallow, especially a little above the island towards the eastern shore. The commandant cautioned poles to be made and pointed with iron, two Indians took upon them to walk to this island by the help of these poles, to save the other poor creatures, or perish themselves. They took leave of all their friends, as if they were going to death. Each had two such poles in his hands, to let to the bottom of the stream, to keep them steady; and in this manner reached the island; and having given poles to the two poor Indians there, they
all returned safely to the main land. These two Indians (who in the abovementioned manner were first brought to this island) were nine days on the island, and almost ready to starve to death. Now since the road to this island has been found, the Indians go there often to kill deer, which have tried to cross the river above the fall, and are driven upon it by the current. On the east side of the river are some small islands or rocks, of no consequence. The east side of the river is almost perpendicular, the west side more sloping. In former times, a part of the rock at the fall which is on the west side of the island, hung over in such a manner, that the water which fell perpendicularly from it left a vacancy below, so that people could go under between the rock and the water: but the prominent part some years since broke off and fell down. The breadth of the fall, as it runs in a semicircle, is reckoned to be about 300 feet. The island is in the middle of the fall, and from it the water on each side is almost the same breadth; the breadth of the island at its lower end is about 100 feet. Below the fall in the holes of the rocks, are great plenty of eels, which the Indians and French catch with their hands without any other means. Every day when the sun shines, you see here from ten o’clock in the morning to two in the afternoon, below the fall, and under you, where you land at the side of the fall, a glorious rainbow, and sometimes two, one within the other. The more vapours, the brighter and clearer is the rainbow. When the wind carries the vapours from that place, the rainbow is gone, but appears again as soon as new vapours come. From the fall to the landing above it, where the canoes from Lake Erie put ashore (or from the fall to the upper end of the carrying-place), is half a mile. Lower the canoes dare not come, lest they should be obliged to try the fate of the two Indians, and perhaps with them success. They have often found below the fall pieces of human bodies, perhaps drunken Indians, that have unhappily come down to the fall. The French say, that they have often thrown whole great trees into the water above, to see them tumble down the fall: they went down with surprising swiftness, but could never be seen afterwards; whence it was thought there was a bottomless deep or abyss just under the fall. The rock of the fall consists of a grey limestone.

Having mentioned the Six Nations which live on the banks of the Niagara, we shall here, in addition to what we have said else where (see America, No. 171.),็บן in a few particulars relative to those nations, which, as they seem not to be well understood even in America, are probably still less known in Europe. The information which we have to give was communicated to the Royal Society of London by Mr Richard M’Canfland Surgeon to the 8th regiment of foot, who, writing from the best authority, informs us, that each nation is divided into three tribes, of which the principal are called the turtle-tribe, the wolf-tribe, and the bear-tribe.

Each tribe has two, three, or more chiefs, called sachems; and this distinction is always hereditary in the family, but descends along the female line; for instance, if a chief dies, one of his sister’s sons, or one of his own brothers, will be appointed to succeed him. Among these no preference is given to proximity or primogeniture; but the sachem, during his lifetime, pitches upon one whom he supposes to have more abilities than the rest: and in this choice he frequently, though not always, consults the principal men of the tribe. If the successor happens to be a woman, the offices of the post are performed by some of his friends until he is of sufficient age to act himself.

Each of these posts of sachem has a name which is peculiar to it, and which never changes, as it is always adopted by the successor; nor does the order of precedence of each of these names or titles ever vary. Nevertheless, any sachem, by abilities and activity, may acquire greater power and influence in the nation than those who rank before him in point of precedence; but this is merely temporary, and dies with him.

Each tribe has one or two chief warriors; which dignity is also hereditary, and has a peculiar name attached to it.

These are the only titles of distinction which are fixed and permanent in the nation; for although any Indian may by superior talents, either as a counsellor or as a warrior, acquire influence in the nation, yet it is not in his power to transmit this to his family.

The Indians have also their great women as well as their great men, to whose opinions they pay great deference; and this distinction is also hereditary in families. They do not sit in council with the sachems, but have separate ones of their own. When war is declared, the sachems and great women generally give up the management of public affairs into the hands of the warriors. It may however so happen, that a sachem may at the same time be also a chief warrior.

Friendships seem to have been instituted with a view towards strengthening the union between the several nations of the confederacy; and hence friends are called the friends of the Six Nations. An Indian has therefore generally one or more friends in each nation. Befides the attachment which subsists during the lifetime of the two friends, whenever one of them happens to be killed, it is incumbent on the forvivor to replace him, by presenting to his family either a scalp, a prisoner, or a belt consisting of some thousands of wampum: and this ceremony is performed by every friend of the deceased.

The purpose and foundation of war-parties, therefore, is in general to procure a prisoner or scalp to replace the friend or relation of the Indian who is the head of the party. An Indian who wishes to replace a friend or relation presents a belt to his acquaintance: and as many as choose to follow him accept this belt and become his party. After this, it is of no consequence whether he goes on the expedition or remains at home (as it often happens that he is a child); he is still considered as the head of the party. The belt he presented to his party is returned fixed to the scalp or prisoner, and passed along with them to the friends of the person he replaces. Hence it happens that a war-party, returning with more scalps or prisoners than the original intention of the party required, will often give one of these supernumerary scalps or prisoners to another war-party whom they meet.
NICAEA, (anc. geog.), the metropolis of Bithynia, situated on the lake Acanthus, in a large and fertile plain; in compafs 16 miles; first built by Antigonus, the son of Philip, and thence called Antigona; afterwards completed by Lyfimachus, who called it Nicoa, after his consort the daughter of Antipater. According to Ptol.-A second ed it tile plain; in compafs 16 miles; Asia the Less, situated on the lake Ascanius, in a large and fertile plain, return without going to war.

Nicander, poet, and phyfician, who lived about the middle of the 5th century, was descended of a good family at Didyma, and not fists or sea-monsters. He held a correspondence with the learned men of his time as the Abbe Velley, and A Discourse upon the Form and Structure of the Country of that name on the North Sea.

Nicastro, an episcopal town of Italy, in the kingdom of Naples, and in the Farther Calabria; 13 miles south of Cofenza. E. Long. 15. 59. N. Lat. 39. 15.

NICE, an ancient, handsome, and considerable town on the confines of France and Italy, and capital of a county of the same name, with a strong citadel, a bishop's see, and a senate, which is a kind of democracy. It has been several times taken by the French, and laft of all in 1744, but restored after the treaty of Aix-la-Chapelle. It is very agreeably situated, four miles from the mouth of the river Var, 83 miles S. by W. of Turin, and 85 east of Aix. E. Long. 6. 22. N. Lat. 43. 42.

NICE, a county and province in the dominions of the duke of Savoy. The inhabitants supply Genoa with a great deal of timber for building ships, and carry on a great trade in linen-cloth, paper, oil wine, and honey. - "Although the county of Nice be on
Nice [50] NICE

this side of the mountains, geographers have always considered it as a province of Italy, since they have
given to this beautiful part of Italy the river Vard
for a western limit, which is also the boundary of the
county, and flows into the sea at a league distance
from the capital. This province is partly covered
by the maritime Alps; and is bordered on the east by
Piedmont and the states of Genoa; on the south by the
Mediterranean; on the west by the Vard; and on the
north by Dauphiny. Its length is about 20
leagues of the country, which make about 35 Eng-
lish miles; its breadth is 10 leagues; and its popula-
tion is about 120,000 souls.

"The city of Nice is the capital, and the seat
of the Senate, bishoipry, and government. It has
become, within the last years, a delightful abode,
by the number of strangers who assemble there in the
winter, either to re-establish their health, or to
enjoy the mildness of the climate, and the beauty of the
country, where an unceasing verdure presides eternal
springing.

"The town is situated on the sea-shore, and is backed
by a rock entirely insulated, on which was formerly
a castle, much esteemed for its position; but
it was destroyed in the year 1796 by Marechal Ber-
wick, the garrison being too thin to defend the extent
of the works. There is a division between the old and the new town; this last is regular, the
houses are well built, and the streets are wide. Its
position is by the side of the sea, and it is terminated,
on one side, by a charming terrace, which serves for
a promenade.

"Any person may live peaceably in this province,
without fear of being troubled on point of faith,
provided he conduct himself with decorum. The
town has three suburbs. 1st, That of St John, which
con ducts to Cimiez, about three leagues north from
Nice, &c. The promenades this way are very de-
lightful, and may be enjoyed in a carriage. 2d, That of the Pondiere. 3d, That of the Croix de Mar-re,
of Marble Crofs. This suburb is new; and the Eng-
lisli almost all lodge in it, being very near the town.
The houses are commodious, facing on one side the
great road which leads to France, and on the other a
fine garden, with a prospect of the sea. All the
houses are separate from each other; the company
hire them for the season, i.e. from October till May.
Apartments may be had from 15 to 250 louis. The
proprietors commonly furnish linen, plate, &c. There
are also in the town very large and commodious
houses as well as the new road, which is opened from
the town to the port, by cutting that part of the
rock which inclined towards the sea. The situation
is delightful, and warmest in winter, being entirely
covered from the north wind, and quite open to the
south.

"The company is brilliant at Nice, and the
amusements of the carnival are, in proportion to the
size of the town, as lively as in any of the great ones
in France. There is always an Italian opera, a con-
cert and masked ball, alternately: and the company
play rather high.

"It is impossible to find a happier climate than
Nice, both for summer and winter. Reaumur's ther-
ometer, in 1781, never fell more than three degrees
below the freezing point, and that only for two days:
while at Geneva it fell ten; and in the course of the
winter of 1785 it fell only two degrees; while at Ge-
neva it fell 15. The month of May is rarely so fine in
France as February at Nice. The summer is not so hot
as might be expected. The thermometer never rises
more than 24 degrees above temperate in the shade; and there
is always an agreeable sea-breeze from ten in the
morning till sun-set, when the land breeze comes on.
There are three chains of graduated mountains, the
last of which confound their summits with the Alps;
and to this triple rampart is owing the mild tempera-
ture so sensibly different from the neighbouring parts.

"The cultivation of the ground is as rich as can
be defried. There are alternately rows of corn and beans,
separated by vines attached to different fruit-trees, the
almond and the fig; so that the earth being incessantly
cultivated and covered with trees, olive, orange, ce-
dar, pomegranate, laurel, and myrtle, causes the con-
stant appearance of spring, and forms a fine contrast
with the summits of the Alps, in the background, cov-
ered with snow."
Nicophorus (Blemmidas), a priest and monk of Mount Athos, flourished in the 15th century. He refused the patriarchate of Constantinople, being favourable to the Latin church, and more inclined to fake the world, he consulted one of his superiors, who belonged to the order of Bernabite Jesuits. This uncle examined him; and, not dissatisfied with his election, introduced him as a probationer to that society at Paris. He was received there in 1702, took the habit in 1703, and made his vows in 1704, at the age of 19.

After he had professed himself, he was sent to Montarges, to go through a course of philosophy and theology; thence he went to Leches in Touraine to teach those sciences. He received the priesthood at Poitiers in 1708. As he was not arrived at the age to assume this order, a dispensation, which his uncommon piety had merited, was obtained in his favour. The college of Montarges having recalled him, he was their professor of rhetoric two years, and of philosophy four. In spite of all these avocations, he was humbly attentive to every call and work of charity, and to the instruction of his fellow-creatures, many of whom heard him deliver out fit rules of conduct for them, not only from the pulpits of most of the churches within the province, but even from those of Paris.—In 1716, his superiors invited him to that city, that he might have an opportunity of following, with the more convenience, those studies for which he always had expressed the greatest inclination. He not only understood the ancient but the modern languages; a circumstance of infinite advantage in the composition of those works which he has given to the public, and which he carried on with great assiduity to the time of his death, which happened, after a short illness, July 8, 1738, at the age of 53. His works are, 1. Le grand Feuille ; or, a Dissertation to prove, that common water is the best remedy in fevers, and even in the plague; translated from the English of John Hancock, minister of St Margaret's, London, in 12mo. This little treatise made its appearance, amongst other pieces relating to this subject, in 1720; and was attended with a success which carried it through three editions; the last came out in 1730, in 2 vols. 12mo, intitled, A Treatise on Common Water; Paris, printed by Caviller. 2. The Voyages of John Ovington to Surat, and divers parts of Asia and Africa, containing the history of the revolution in the kingdom of Golconda, and some observations upon silk-worms; Paris 1725, 2 vols. 12mo. 3. The Conversion of England to Christianity, compared with its pretended Reformation, a work translated from the
Nicholas, born in London in the year 1699. His father was a barrister at law, and both his parents were of good families in Cornwall. After receiving the first rudiments of his education at a private school in the country, where his docility and sweetmell of temper endeared him equally to his master and his school fellows, Frank was in a few years removed to Westminster, and from thence to Oxford, where he was admitted a commoner (or fojourner) of Exeter College, under the tuition of Mr John Haviland, on March 4th, 1714. There he applied himself diligently to all the usual academical studies, but particularly to natural philosophy and polite literature, of which the fruits were most conspicuous in his subsequent lectures on physiology. After reading a few books on anatomy, in order to perfect himself in the nomenclature of the animal parts then adopted, he engaged in dissections, and then devoted himself to the study of nature, perfectly free and unbiased by the opinions of others.

On his being chosen reader of anatomy in that university, he employed his utmost attention to elevate and illustrate a science which had been long depressed and neglected; and by quitting the beaten track of former lecturers, and minutely investigating the texture of every bowel, the nature and order of every vessel, &c. he gained a high and just reputation. He did not then reside at Oxford; but, when he had finished his lectures, used to repair to London, the place of his abode, where he had determined to settle. He had once an intention of fixing in Cornwall, and for a short time practised there with great reputation; but being soon tired of the fatigues attendant on that profession in the country, he returned to London, bringing back with him a great infight, acquired by diligent observation, into the nature of the military fever, which was attended with the most fatal effects in his subsequent practice at London.

About this time he resolved to visit the continent, partly with a view of acquiring the knowledge of men, manners, and languages; but chiefly to acquaint himself with the opinions of foreign naturalists on his favourite study. At Paris, by conversing freely with the learned, he soon recommended himself to their notice and esteem. Winlow's was the only good fsytem of physiology at that time known in France, and Morgagni's...
Nicholls was chosen a fellow of the Royal Society, to which he afterwards communicated the description of an uncommon disorder, in which Tulpius has strangely mistaken it, coughed up by an athonmonic perfon. He also made observations (in the same volume of the Transactions) on a Treatise, by M. Helvetius of Paris, reader of medicine at Oxford. At his return to London, he undertook the office of grand apothecary, and other parts of the human body which serve for the secretion of the urine; and the causes, symptoms, and cure, of the diseases occasioned by the stone. In 1739, he delivered the anniversary Harveian oration. In 1743, he married Elizabeth, youngest daughter of the celebrated Dr Mead, by whom he had five children, two of whom died young. Two sons and a daughter survived him. In 1748, Dr Nicholls undertook the office of chirurgical lecturer, beginning with a learned and elegant dissertation on the Anima Medica. About this time, on the death of Dr John Cunningham, one of the elects of the college, Dr Abraham Hall was chosen to succeed him, in preference to his author, who was his senior, without any apparent reason. With a just respectment, he immediately resigned the office of chirurgical lecturer, and never afterwards attended the meetings of the fellows, except when busines of the utmost importance was in agitation.

In 1754, he took some revenge in an anonymous pamphlet, entitled “The Petition of the Unborn Babes to the Censors of the Royal College of Physicians of London,” in which Dr Neffit (Pofus), Dr Maule (Michaer), Dr Barrowby (Barthone), principally, and Sir William Brown, Sir Edward Hulfe, and the Scots incidentally, are the objects of his satire.

In 1755, on the death of Sir Hans Sloane, Bart. in his 94th year, Dr Nicholls was appointed to succeed him as one of the king’s physicians, and held that office till the death of his royal master in 1760, when this most illustrious physician was succeeded with some thing like the offer of a pension, which he rejected with disdain.

The causes, &c. of the uncommon disorder of which the late king died, viz. a rupture of the right ventricle of the heart, our author explained in a letter to the earl of Macclesfield, president of the Royal Society, which was published in the Philosophical Transactions, vol. 1.

In 1772, to a second edition of his treatise De Anima Medica, he added a dissertation De motu cordis et sanguinis in homine nato et non nato, inscribed to his learned friend and coadjutor the late Dr Lawrence.

Tired at length of London, and also desirous of superintending the education of his son, he removed to Oxford, where he had spent most agreeably some years in his youth. But when the study of the law recalled Mr Nicholls to London, he took a house at Epom, where he passed the remainder of his life in a literary retirement, not attentive to natural philosophy, especially the cultivation of grain, and the improvement of barren soils, and contemplating also with admiration the internal nature of plants, as taught by Linneaus.

His constitution never was robust. In his youth, at Oxford, he was with difficulty recovered from a dangerous fever by the skill of Doctors Frampton and Frewen; and afterwards at London he had frequently been afflicted with a catarrh, and an inveterate athematic cough, which, returning with great violence at the beginning of the year 1778, deprived the world of this valuable man on January 7th, in the 80th year of his age.

Dr Lawrence, formerly president of the college of physicians, who gratefully ascribed all his physiological and medical knowledge to his precepts, and who, while he lived, loved him as a brother, and revered him as a parent, two years after printed, and gave to his friends, a few copies of an elegant Latin Life of Dr Nicholls (with his head prefixed, a striking likeness, engraved by Hall from a model of Goofet, 1779); from which, through the medium of the Gentleman’s Magazine, the above particulars are chiefly extracted.

NICIAS, a celebrated painter of Athens, flourished about 322 years before the Christian era, and was universally extolled for the great variety and noble choice of his subjects, the force and relievo of his figures, his skill in the distribution of the lights and shadows, and his dexterity in representing all sorts of four-footed animals, beyond any master of his time. His most celebrated piece was that of Tartarus or Hell, as it is described by Homer, for which king Ptolemy the son of Lagus offered him 60 talents, or 11,250 l., which he refused, and generously presented it to his own country. He was much esteemed likewise by all his contemporaries for his excellent talent in sculpture.

NICKEL, in chemistry and mineralogy, a substance clasped among the femimetals, though several eminent chemists are of opinion that it is a copper; and Mr Bergman, who has made more experiments upon it than any other perfon, conjectures that it is a modification of iron.

It was first obtained from an ore called Lifer or ‘el, sometimes...
had the appearance of containing copper, not the substances. A particle of that metal concerning the discovery of ores and other mineral bodies was obtainable from its ore. This ore, called kupfer-nickel, is never able to be smelt; but it is from the city of Bremen, as described by Mr Bergman, 111 Helle, in the years 1751 and 1754, shewed by many accurate experiments that it contained a new metallic, or at least that a regulus different from all others was obtainable from its ore. This ore, called kupper-nickel, or false copper as has already been observed, is of a coppery lead colour, and is almost always covered with a greenish-grey efflorescence. It is (says Mr Fourcroy) very common at Freiberg in Saxony, where it is often mixed with the grey ore of cobalt; but it is distinguished from it by its red colour. Mr Bergman, however, complains greatly of the scarcity of this mineral, so that he could hardly procure a quantity sufficient to make experiments upon. Fourcroy also tells us, that Mr Sage, having treated this ore with sal-ammoniac, obtained iron, copper, and cobalt, and thinks that it is composed of these three metallic matters, together with arsenic. It likewise contains a small proportion of gold, according to this chemist. It is proper to observe, that these results do not agree with those of Mr Bergman; he is said to have operated on the kupfer-nickel of Biber, in Hesse, and of Allemont in Dauphiny. Mr Bergman himself, however, informs us, that he undertook his experiments expressly with a view to discover whether the theory of Mr Sage was just; and that he operated mostly on some regulus made by Mr Cronfeldt, and found in the Suabian collection.

"Cronfeldt (says Mr Fourcroy) affirms us, that the metallic matter, called speifs by the Germans, which is collected in the crucibles used in the melting of smalt, affords nickel. Mr Monnet thinks, that the speifs of the manufacture of Gengenbach, 14 leagues from Strauburg, is true nickel: and as the ore of cobalt made use of in that place to make smalt is very pure, he concludes, that nickel is necessarily a product of cobalt itself. But Mr Beaume has obtained nickel from almost all the ores of cobalt by means of sulphur; it therefore seems, that the ore of cobalt, which is wrought at Gengenbach, contains nickel not distinguishable by the eye, on account of the intimate union of these two metallic matters."

"To obtain the regulus of nickel (says Mr Bergman), the ore must be first subjected to roasting; during which a quantity of sulphur and arsenic, greater or less according to the nature of the ore, is expelled; so that it sometimes loses above half its weight, but is not above 0.3. This ore, though long and completely calcined, does not always acquire the same colour, but in general becomes greener in proportion as it is more rich. Sometimes (especially if suffered to be at rest) its upper surface is covered with green vegeations, somewhat of the form of coral, which are hard and sonorous. A double or triple quantity of black flux is to be added to the roasted powder, and the mixture well fused in a forge in an open crucible covered with common fult, in the usual method. The vessel being broken, a metallic globule is found at the bottom, the weight of which amounts to 0.1, 0.2, or at the most to 0.5 of the crude ore. The regulus thus obtained, however, is far from being pure; for although the roasting be ever so violent and long continued, yet a considerable quantity of sulphur, but especially arsenic, will remain concealed, exclusive of cobalt, and a great proportion of iron; which left is so generally prevalent, as to make the regulus magnetic: and this variety of heterogeneous matter is the cause why the regulus varies much, not only in respect to its fracture, the polished surface of which is either smooth or lamellated, but also in regard to its white colour, which is more or less yellow or red."

He has not been able to determine the properties of nickel when perfectly pure, as the continual presence of iron in some respect obscures them: From the calculations which he makes, however, Mr Bergman concludes, that the specific gravity of nickel is not less than 9.000 at the least. If a small portion of gold enter the composition, the greatness of the weight might thence be explained; but though this metal is almost always absent, yet 36 parts of it, 48 of iron, and one of copper, were formed by fusion into a globule, the specific gravity of which was 8.8571, but was little soluble in nitrous acid; yet after lying about two hours in the acid, the gold was plainly to be seen, and with volatile alkali the meniscus yielded nothing but a ferruginous brown precipitate, which in the fire put on the appearance of calcined iron.

The solutions of nickel in all the acids are green. The vitriolic scarcely attacks the regulus unless by evaporation to dryness. The nitrous acid, by the assistance of heat, dissolves both the calc and the regulus; as does likewise the marine acid, but flowily, and not without the assistance of heat. Acid of arsenie unites with the calc into a green saline mass; but with the regulus it separates a saline powder difficult of fusion. Fluor acid dissolves the calc with difficulty, and forms crystals of a diluted green colour. Acid of borax fiercely dissolves nickel directly, but takes it up by a double elective attraction. Vinegar forms with the calcspathic crystals of an intense green colour, which can scarce be decomposed by acid of tartar. The faccharine acid converts both regulus and calc into a white powder, not easily soluble in water. Acid of phosphorus attracts it but little. The acid of antimony, by decotion or long digestion, attacks the newly precipitated calc; for the solution is green, and upon evaporation yields crystals of a deep green colour, hemispherical, formed of filaments diverging from a centre, and pellucid. They are not soluble in spirit of wine, and scarcely in water, unless it be acidulated. Lemon-juice seems not to act at all upon nickel. All the acids are deeply tinged by dissolving nickel; and this property belongs to the first regulus as well as that which is most highly depurated. Volatile alkali dissolves it, and the solution is of a blue colour; the fixed alkali dissolves it very sparingly, and forms a yellow solution.
Nickel. Nickel becomes the more difficult of fusion, in proportion to its purity, so that at last it requires nearly as great a heat for this purpose as malleable iron. It is easily melted with other metals, but its great scarcity has prevented this matter from being thoroughly investigated. It may, however, be observed, that the impure regulus cannot be united with silver, which must be attributed to the cobalt it contains; for when well freed from that metal, it easily unites in equal proportions with silver, and that without any remarkeable diminution of the whiteness or dultery of the latter. This mixture, fused with borax, tinges it of an hyacinthine colour. Copper unites more slowly with depurated nickel, yielding a red and dulcile metallic mass, which tinges borax of a reddish hyacinthine colour. It produces only a brittle mass with tin; in which respect it differs from cobalt. It could not be amalgamated with mercury by trituration.

Nickel, when well depurated, does not easily part with its phlogiston, or, in the language of the new nomenclature, receive an accession of Carbonne; for it only affumes a brown colour, and that with great difficulty in the ordinary way of calcination in the assay furnace. By means of nitre, however, it is more completely depurified, and becomes green. The metallic calx, vitrified with borax, produces an hyacinthine tinge; which yet, if occasioned by a regulus not well depurated, vanishes on continuing the fire, a light blue tinge being produced by the addition of nitre; but a calx of well depurated regulus of nickel forms a permanent colour. The calx of nickel communicates also an hyacinthine colour to microcosmic salt; which, by long-continued fusion on charcoal, may indeed be weakened, but can hardly be quite discharged. On the addition of nitre it changes to a violet, but becomes again hyacinthine on augmenting the quantity of microcosmic salt. If the calx of nickel be added to saturation, the fused glass assumes a blood-colour; but on being fused, becomes more and more yellow.

Under the article Chemistry, No. 1315, and in the present article, we have observed, that Mr. Bergman conjectures nickel to be only a modification of iron. He examines, however, with great care, the opinion of other authors, who suppose it to be composed of arsenic, copper, cobalt, and iron. With respect to arsenic (says he) we may very safely exclude it from the number of experiments show that it may be entirely expelled. It cannot be doubted that copper is present in some ores of nickel, and therefore may easily be mixed with the regulus; but the greater number are entirely without it. It is true that nickel is totally soluble in volatile alkalies; and that this solution is of a blue colour; but if this argument held good, there would be nothing found here but copper; in which case very different phenomena would take place from those which are produced by nickel. The blue colour, produced both by copper and nickel, can no more prove their identity than the yellow colour produced both by gold and iron, when dissolved in aqua regia, can prove the identity of these two metals. Nickel and copper agree also in this property, that they are both precipitated from acids and from volatile alkalies by iron; but a considerable difference appears in the manner in which this precipitation is accomplished. When a polished piece of iron is put into a solution of nickel, a yellow pellicle of the latter will by degrees adhere to it; but this soon disappears on touching, and grows black, unless the acid be well saturated, or sufficiently diluted with water. A similar precipitation is observed if zinc be made use of instead of iron; but in solution of copper so much diluted, that the precipitation on iron may be nearly similar to that of nickel, zinc is immediately covered with a crust of the colour of mountain braze.

An invincible argument that cobalt is no essential ingredient in nickel, is, that a solution of the latter in hydro sulphuric is precipitated by the former. In the same way nickel tinged borax, or the microcosmic salt, in the dry way, is thrown down by the addition of a proper quantity of copper; but this is not the case with cobalt. A remarkable difference likewise occurs with all the acids. 1. Cobalt tinges all these manifera of a red colour, yielding crystals either of a yellow or bluish red. But nickel produces solutions and concretions of a fine green: it sometimes happens, indeed, that these solutions yield greenish crystals; but this is to be attributed to nickel in small proportion mixed with the cobalt. 2. Cobalt united with the marine acid yields sympathetic ink; but depurated nickel does not. 3. Cobalt, dissolved in volatile alkalies, affords a red solution, but nickel dissolved in the same alkalies is blue. 4. Cobalt does not, like nickel, separate, on the addition of arsenical acid, a powder difficult of solution. Iron therefore only remains; and indeed, says Mr. Bergman, there are many and weighty reasons, which induce us to think that nickel, cobalt, and manganese, are perhaps to be considered in no other light than modifications of iron.

1. Unequal portions of phlogiston, united to the same iron, or, according to the new nomenclature, iron containing different proportions of carbon, change its quality in a remarkable manner: for instance, how very much do the different kinds of iron and steel differ? It is then to be observed, that nickel, cobalt, and manganese, whatever operations they may be subjected to, are far from being deprived of iron, that, on the contrary they thereby become more dulcile, magnetic, and refractory. Again, the various colours which nickel, cobalt, and manganese exhibit, both by solution and by fire, are also exhibited by iron. Cobalt and manganese occasion a red colour in acids, and the latter in glas; nickel and manganese occasion an hyacinthine colour when fused with borax; a green is produced in acids, by nickel, as also by its calx, and by manganese when long and strongly calcined; and it often leaves behind a tinge of the same colour, if the reduction be performed with a saline flux. Lastly, Cobalt occasions a blue or rather violet colour in glas; and the fame is true of manganese dissolved in fixed, and of nickel in volatile, alkalies. Iron exhibits all these varieties; for the acids form with this metal solutions of a green colour as long as it contains a certain quantity of phlogiston; but in proportion to the diminution of this principle, a yellow, red, or brownish red colour is produced. It tinges glass in the same manner green, yellow, black, or red. Exposed to the fire for many hours together with nitre, blue, greenish blue, or greenish purple flowers, indeed are transmitted through the crucible; but an efflorescence of the same kind is produced by nitre alone, which, by long continued fire penetrates the vessel, and is decomposed by the contact of the burning fuel, the alkaline efflorescences.
The ores already mentioned, from which nickel has been obtained are as follow:

1. Mr Rinman afferts, that it has been found native in a mine of cobalt in Helles. It is very heavy, and of a liver colour or dark red. When pulverized, and roasted under a muffle, it forms green excrences, and the smoke has no particular smell, nor can it be inhaled without discomfort. When it is dissolved in acid, the solution is green, and it is insoluble in alkalis. It is also found in Sweden, without any visible quantity of nickel in its composition, in clay which contained much silver.

2. Aerated nickel is found in form of a calx, and is commonly mixed with the calx of iron; in which case it has the name of nickell-ochre. This is green, and is found in form of flowers on kupfer-nickel. It has been found in Sweden, without any visible quantity of nickel in its composition, in clay which contained much silver.

3. Kupfer-nickel is of a reddish yellow bright colour, as has already been mentioned, and its texture is either uniform, granular, or scaly. It is bright when broken, very heavy, and generally covered with a greenish efflorescence. By calcination it loses much of its sulphur, and becomes green, forming fungous ramifications. Mr. Hafte informed M. Magellan, that nickel was found mineralized with sulphurated iron and copper in a mine near Nellstone in Cornwall. The fine grained and scaly kinds are found in loose cobalt mines in the province of Helsingland in Sweden, where they are of a lighter colour than in other countries, and have often been confounded with the liver-coloured marcasite.

4. Nickel mineralized with the acid of vitriol is of a beautiful green colour, and may be extracted from the nickell-ochre, or green efflorescences of kupfer-nickel already mentioned.

To the properties of nickel already mentioned, we may add that of its being constantly attracted by the magnet, and that not at all in proportion to the quantity of iron it contains; for the more it is purified from this metal, the more magnetic it becomes; and even acquires what iron does not, viz. the properties of a true lodestone.

NICOBAR ISLANDS, the name of several islands in Asia, lying at the entrance of the gulph of Bengal. The largest of these islands is about 40 miles long and 15 broad, and the inhabitants are said to be a harmless sort of people, ready to supply the ships that stop there with provisions. The south end of the great Nicobar is Captain Ritchie placed in east longitude 94° 13' 20"; and we collected from Mr Rammel's Memoir, that it is within the 12th degree of north latitude.

Of these islands very little that can be depended upon is known in Europe. Of the Northernmost, which is called Carnicobar, we have indeed, in the second volume of the Asiatic Researches, some interesting information respecting both the produce and natural history of the country, and the manners of its inhabitants. The author of the memoir is Mr G. Hamilton, who in his account of this island, says, "It is low, of a round figure, about 40 miles in circumference, and appears at a distance as if entirely covered with trees; however there are several well-cleared and delightful spots upon it. The soil is a black kind of clay, and marlhy. It produces in great abundance, and with little care, most of the tropical fruits, such as pine-apples, plantains, papayas, cocoa-nuts, and areca-nuts; also excellent yams, and a root called cachoo. The only four-footed animals upon the island are, hogs, dogs, large rats, and an animal of the lizard kind, but larger, called by the natives "tolongui;" these frequently carry off owls and chickens. The only kind of poultry are hens, and these not in great plenty. There are abundance of snakes of many different kinds, and the inhabitants frequently die of their bites. The timber upon the island is of many sorts, in great plenty, and some of it remarkably large, affording excellent materials for building or repairing ships."

The natives are low in stature but very well made, and surprisingly active and strong: they are copper-coloured, and their features have a cast of the Malay; quite the reverse of elegant. The women in particular are extremely ugly. The men cut their hair short, and the women have their heads shaved quite bare, and wear no covering but a short petticoat, made of a sort of ruff or dry grass, which reaches half way down the thigh. This grass is not interwoven, but hangs round the person something like the thing that is hung upon a houset. Such of them as have received presents of cloth petticoats from the ships, commonly tie them round immediately under the arms. The men wear nothing but a narrow strip of cloth about the middle, in which they wrap up their weights of stuff; and by squeezing into the holes large planks of wood, or hanging heavy weights of thistles, they contrive to render them wide, and disagreeable to look at. They are naturally disposed to be good humoured and gay, and are very fond of sitting at table with Europeans, where they eat every thing that is set before them; and they eat most enormously. They do not care much for wine, but will drink bumpers of arrack as long as they can fare. A great part of their time is spent in feasting and dancing. When a feast is held at any village, every one that chooses goes uninvited, for they are utter strangers to ceremony. At these feasts they eat immense quantities of pork, which is their favourite food. Their hogs are remarkably fat, being fed upon the cocoa-nut kernel and sea-water; indeed all their domestic animals, fowls, dogs, &c. are fed upon the same. They have likewise plenty of small fish, which they strike very dexterously with lances, wading into the sea about knee deep. They are sure of killing a very small fish at 10 or 12 yards distance. They eat the pork almost raw, giving it only a halffy grill over a quick fire. They roast a fowl, by running a piece of wood thro'
Nicobar, it, by way of spit, and holding it over a brisk fire until the feathers are burnt off, when it is ready for eating, in their taife. They never drink water; only cocoa-nut milk and a liquor called faura, which oozes from the cocoa-nut tree after cutting off the young sprouts or flowers. This they suffer to ferment before it is used, and then it is intoxicating; to which quality they add much by their method of drinking it, by fucking it slowly through a small straw. After eating, the young men and women, who are fancifully dressed with leaves, go to dancing, and the old people surround them smoking tobacco and drinking faura. The dancers, while performing, sing some of their tunes, which are far from wanting harmony, and to which they keep exact time. Of musical instruments they have only one kind, and that the simplest. It is a hollow bamboo about 2; feet long and three inches in diameter, along the outside of which there is stretched from end to end a single string made of the threads of a split cane, and the place under the string is hollowed a little to prevent it from touching. This instrument is played upon in the same manner as a guitar. It is capable of producing but few notes; the performer however makes it speak harmoniously, and generally accompanies it with the voice.

"Their houses are generally built upon the beach in villages of 15 or 20 houses each: and each house contains a family of 20 persons and upwards. Their habitations are raised upon wooden pillars about 10 feet from the ground; they are round, and having no windows, are like beehives, covered with thatch. The entry is through a trap-door below, where the family mount by a ladder, which is drawn up at night. This manner of building is intended to secure the houses from being infested with snakes and rats; and for that purpose the pillars are bound round with a smooth kind of leaf, which prevents animals from being able to mount; besides which, each pillar has a broad round flat piece of wood near the top of it, the projecting of which effectually prevents the further progress of such vermin as may have passed the leaf. The flooring is made with thin strips of bamboo, laid at such distances from one another as to leave free admission for light and air; and the inside is neatly finished and decorated with fishing lances, nets, &c.

"The art of making cloth of any kind is quite unknown to the inhabitants of this island; what they have is got from the ships which come to trade in cocoa-nuts.

"They purchase a much larger quantity of cloth than is furnished upon their own island. This is intended for the Choury market. Choury is a small island to the southward of theirs, to which a large fleet of their boats sails every year about the month of November, to exchange cloth for canoes; for they cannot make these themselves. This voyage they perform by the help of the sun and flars, for they know nothing of the compass.

"In their disposition there are two remarkable qualities. One is their entire neglect of compliment and ceremony; and the other, their avarice to dil棕色ly. A Carnicobarian travelling to a distant village, upon business or amusement, passes through many towns in Vol. XIII.

"Their intercourse with strangers is so frequent, that they have acquired in general the barbarous Portuguese so common over India; their own language has a sound quite different from most others, their words being pronounced with a kind of slop, or catch in the throat, at every syllable.

"They have no notion of a God, but they believe firmly in the devil, and worship him from fear. In every village there is a high pole erected with long fibrings of ground-rattans hanging from it, which, it is said, has the virtue to keep him at a distance. When they see any signs of an approaching storm, they imagine that the devil intends them a visit, upon which many superstitious ceremonies are performed. The people of every village march round their own boundaries, and fix up at different distances small sticks at the top, into which split they put a piece of cocoa-nut, a wisp of tobacco, and the leaf of a certain plant: whether this is meant as a peace offering to the devil, or a fearcrow to frighten him away, does not appear.

"When a man dies, all his live flock, cloth, hatchets, fishing-lances, and in short every movable thing he possessed, is buried with him, and his death is mourned by the whole village. In one view this is an excellent custom, seeming it prevents all disputes about the property of the deceased amongst his relations. His wife must conform to custom by having a joint cut off from one of her fingers; and if she refuses this, the muft submit to have a deep notch cut in one of the pillars of her house.

"I was once present at the funeral of an old woman. When we went into the house which had belonged to the deceased, we found it full of her female relations; some of them were employed in wrapping up the corpse in leaves and cloth, and others tearing to pieces all the cloth which had belonged to her. In another house hard by, the men of the village, with a great many others from the neighbouring towns, were fmiting drinking faura and smoking tobacco. In the mean time two stout young fellows were busy digging a grave in the sand near the house. When the women had done with the corpse, they set up a most hideous bowl, upon which the people began to assemble round the grave, and four men went up into the house to bring down the body; in doing this they were much interrupted by a young man, son to the deceased, who endeavoured with all his might to prevent them, but finding it in vain, he clung round the body, and was carried to the grave along with it: there, after a violent struggle, he was turned away and conducted back to the house. The corpse being now put into the grave, and the lannahings which bound the legs and arms cut, all the live-flock which had been the property of the deceased, consisting of
Nicodemus, a disciple of Jesus Christ, a Jew by nation, and by sect a Pharisee (John iii. 1, &c.) The scripture calls him a ruler of the Jews, and our Saviour gives him the name of a master of Israel. When our Saviour began to manifest himself by his miracles at Jerusalem, at the first passover that he celebrated there after his baptism, Nicodemus made no doubt but that he was the Mediator, and came to him by night, that he might learn of him the way of salvation. Jesus told him, that no one could see the kingdom of heaven except he should be born again. Nicodemus taking this in the literal sense, made answer, "How can a man that is old be born again? Can he enter a second time into his mother's womb?" To which Jesus replied, "If a man be not born of water and of the spirit, he cannot enter into the kingdom of God. That which is born of the flesh is flesh, and that which is born of the spirit is spirit." Nicodemus asks him, "How can these things be?" Jesus answered, "Are you a master of Israel, and are you ignorant of these things? We tell you that we know, and you receive not our testimony. If you believe not common things, and which may be called earthly, how will you believe me if I speak to you of heavenly things? Nobody has ascended into heaven but the Son of God, who came down from thence. And just as Moses lifted up the brazen serpent in the wilderness, so must the Son of Man be lifted up on high. For God so loved the world that he has given his only son, that no man who believes in him shall perish, but shall have eternal life."

After this conversation Nicodemus became a disciple of Jesus Christ; and there is no doubt to be made, but he came to bear him as often as our Saviour came to Jerusalem. It happened on a time, that the priests and Pharisees had sent officers to seize Jesus (John vii. 45, &c.), who returning to them, made their report, that never man spoke as he did; to which the Pharisees replied, "Are you also of his disciples? Is there any one of the elders or Pharisees that have believed in him?" Then Nicodemus thought himself obliged to make answer, saying, "Does the law permit us to condemn any one before he is heard?" To which they replied, "Are you also a Galilean? Read the scriptures, and you will find that never any prophet came out of Galilee." After this the council was dismissed. At last Nicodemus declared himself openly a disciple of Jesus Christ (id. xix. 39, 40.), when he came with Joseph of Arimathea to pay the last duties to the body of Christ, which they took down from the cross, embalmed, and laid in a sepulchre.

We are told, that Nicodemus received baptism from the disciples of Christ; but it is not mentioned whether before or after the passion of our Lord. It is added, that the Jews being informed of this, deposed him from his dignity of a sect, excommunicated him, and drove him from Jerusalem, but that Gamaliel, who was his cousin-german, took him to his country house, and maintained him there till his death, when he had him buried honourably near St Stephen. There is still extant an apocryphal gospel under the name of Nicodemus, which in some manuscripts bears the title of the Acts of Pilate.

NICOLAITANS, in church history, Christian heretics who assumed this name from Nicholas of Antioc; who, being a Gentle by birth, first embraced Judaism and then Christianitv; when his zeal and devotion recommended him to the church of Jerusalem, by whom he was chosen one of the first deacons. Many of the primitive writers believe that Nicholas was rather the occasion than the author of the infamous practices of those who assumed his name, who were expressly condemned by the Spirit of God himself, Rev. ii. 6. And indeed their opinions and actions were highly extravagant and criminal. They allowed a community of wives, and made no distinction between ordinary meats and those offered to idols. According to Eusebius, they subsisted but a short time;
NICOMEDES (St.), an island of the Atlantic Ocean, and one of the most considerable of those of Cape Verde, lying between Santa Lucia and St. Jago. It is of a triangular figure, and about 75 miles in length. The land is rocky, mountainous, and barren; but there are a great many goats in a valley inhabited by the Portuguese. W. Long. 33° 35'. N. Lat. 17° 0'.

NICHOLAS (St.), an island of the Atlantic Ocean.

NICODEMUS, the name of several kings of the

NICOMEDES, the name of several kings of the

NICODEMUS III. summoned by Antiphon, Philostratus, because he had murdered his father to get possession of his crown. This monarch having entered into alliance with Mithridates the Great King of Pontus, invaded Paphlagonia; and having seized on that country, he attempted to make himself master of Cappadocia. This country, however, was at that time subject to his powerful ally; who, upon marching into Bithynia at the head of an army, drove Nicomedes from the throne, and raised his brother Socrates to it in his room. The dethroned prince had recourse to the Romans, who expelled the usurper, and restored him to his hereditary dominions. For this favour they prefixed him, and at length prevailed upon him, contrary to his own inclination, and the opinion of his friends, to make inroads into the territories of Mithridates, whom Rome wanted a subject of dispute. The king of Pontus bore for some time the devastations committed by Nicomedes with great patience, that he might not seem to be the aggressor; but at last he routed his army on the banks of the Amnias, drove him a second time from his dominions, and obliged him to seek for shelter in Paphlagonia, where he led a private life till the time of Sulla, who replaced him on the throne. He was succeeded by his son.

NICOMEDES IV. who performed nothing which the many writers who flourished in his time have thought worth transmitting to posterity. As he died without issue male, he left his kingdom by his last will to the Romans, who reduced it to the form of a province. Sallust, disagreeing with the ancients, tells us, that Nicomedes left a son named Mya or Myt, and introduces Mithridates as complaining of the Romans to Arsecar king of Parthia, for seizing on the kingdom of Bithynia, and excluding the son of a prince who had on all occasions shown himself a steady friend to their republic. But this Mya was the daughter and not the son of Nicomedes, as we are told in explicit terms by Suetionius, Velleius Paterculus, and Appian. All we know of her is, that upon the death of her father she claimed the kingdom of Bithynia for her son, as the next male heir to the crown; but without success, no motives of justice being of such weight with the ambitious Romans as to make them part with a kingdom.

NICOMEDIA (anc. geog.), metropolis of Bithynia, built by Nicomedes the grandfather of Prusias. Situated on a point of the Sinus Altacenus, (Pliny;) surnamed the beautiful, (Athenaeus;) the largest city of Bithynia, (Pausanias,) who says it was formerly called Altacenus; though Pliny distinguishes Altacum and Nicomedia as different cities. Nicomedia was very famous, not only under its own kings, but under the Romans; it was the royal residence of Diolemon, and of Constanine while Constanineople was building, if we may credit Nicephorus. It is still called Nicomedia, at the bottom of a bay of the Propontis in the Hither Asia. E. Long. 30° 0'. N. Lat. 41° 20'.
NICOMEDUS, a geometrical, famous on account of the invention of the curve called conchoid, which is equally useful in resolving the two problems of doubling the cube and trisecting the angle. It appears that he lived soon after Eratosthenes, for he rallied that philosopher on the mechanism of his meolabe. Geminus, who lived in the second century before Jesus Christ, has written on the conchoid, though Nicomedes was always esteemed the inventor of it. Those who place him four or five centuries after Jesus Christ must be ignorant of these facts, by which we are enabled to ascertain pretty nearly the time in which he lived.

Nikon, a native of Russia, was born in 1613, in a village of the government of Nizhnei Novgorod, of such obscure parents, that their names and station are not transmitted to posterity. He received at the baptismal font the name of Nikita, which afterwards, when he became monk, he changed to Nicom, the appellation by which he is more generally known. He was educated in the convent of St. Macarius, under the care of a monk. From the course of his studies, which were almost solely directed to the Holy Scriptures, and the exhortations of his preceptor, he imbibed at a very early period the strongest attachment to a monastic life; and was only prevented from following the bent of his mind by the persuasions and authority of his father. In conformity, however, to the wishes of his family, though contrary to his own inclination, he entered into matrimony; and, as that state precluded him from being admitted into a convent, he was ordained a secular priest. With his wife he continued 10 years, partly in the country and partly at Moscow, officiating as a parish priest. The loss of three children, however, gave him a total disgust to the world; in consequence of which, his wife was persuaded to take the veil, and he became a monk; his retreat was in an island of the White Sea, and a kind of ecclesiastical establishment was formed, as remarkable for the austerity of its rules as the situation was for its solitude. There were about 12 monks, but they all lived in different cells. Such a system combined with the most gloomy ideas, occasioned so much clouded pride as tarnished his character, when he was afterwards called up to fulfil the duties of a public and exalted station. Our limits do not permit us to be minute in our account of his life; we must therefore be content with barely reciting general facts. Within less than the space of five years, Nikon was successively created archimandrite, or abbot of the Novospadok convent, archbishop of Novgorod, and patriarch of Russia. That he was worthy of these rapid promotions few will doubt who are acquainted with his character; for he was possessed of very extraordinary qualities, such as even his enemies allow and admire. His courage was undaunted, his morals irreproachable, his charity extensive and exalted, his learning deep and comprehensive, and his eloquence commanding. —When archbishop, he obtained the respect of the inhabitants by his unwearyed affability in the discharge of his trust; and conciliated their affections by acts of unbounded charity: Nor was he less confipi

Cus in the discharge of the office of patriarch, to which dignity he was appointed in 1652, in the 39th year of his age.

Nor was he only distinguished in his own profession, for he shone even as a statesman. At length, however, he fell a victim to popular discontents; which, though he was far from deserving it, was certainly the effect of imprudence. He abdicated the office of patriarch, which would otherwise have been taken from him, in July 1658, and bore his reverse of fortune with heroic magnanimity: he returned to a cell, and commenced his former austerities. His innocence, however, could not protect him from further misfortunes: his enemies obtained him to be formally deposed in 1666. This degradation was followed by imprisonment, which was for some time very rigorous, because he, conscious of his own innocence, refused to accept pardon for crimes of which he was not guilty. In 1675, however, he was removed to the convent of St. Cyril, and enjoyed perfect liberty.

Nikon survived his deposition 15 years. In 1681, he requested and obtained permission to return to the convent of Jerusalem, that he might end his days in that favourite spot; but he expired upon the road near Yarolla, in the 66th year of his age. His remains were transported to that convent, and buried with all the ceremonies used at the interment of patriarchs.

NICOPOLI, a town of Turkey in Europe, and in Bulgaria, famous for being the place where the first battle was fought between the Turks and Christians in 1356, and where the latter were defeated with the loss of 20,000 men. E. long. 25° 33' N. Lat. 43° 46'.

NICOSIA, the capital of the island of Cyprus, where a Turkish bath now stands. It is delightfully situated between the mountains of Olympus and a chain of others; and was formerly well fortified by the Venetians; but the works are now in ruins. It is about 31 miles in circumference; and there are plantations of olives, almonds, lemons, oranges, mulberries, and cypress-trees, interspersed among the houses, which give the town a delightful appearance. The church of Santa Sophia is an old Gothic structure, which the Turks have turned into a mosque, and destroyed the ornaments. It is 100 miles west of Tripoli, and 160 south-west of Aleppo. E. long. 34° 45', N. Lat. 34° 54'.

NICOT (John), lord of Villemain, and master of requisits of the French king's household, was born at Niimes, and was sent ambassador to Portugal in 1559; whence he brought the plant which, from his name, was called Nicotiana, but is now more generally known by the name of Tobacco. He died at Paris in 1603. He wrote a French and Latin dictionary in folio; a treatise on navigation; and other works.

NICOTIANA, tobacco, in botany: a genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 28th order, Luride. The corolla is funnel-shaped with a plaited limb; the flamina inclined; the capsule bivalved and bilocular. There are seven species, of which the most remarkable is the tabacum, or common tobacco-plant. This was first discovered in America by the Spaniards about the year 1560, and by
Nicotiana, by them imported into Europe. It had been used by the inhabitants of America long before; and was called by those of the islands yali. and petun by the inhabitants of the continent. It was sent into Spain from Tabaco, a province of Yucatan, where it was first discovered, and from whence it takes its common name. Sir Walter Raleigh is generally said to have been the first that introduced it into England about the year 1585, and who taught his countrymen how to smoke it. Dr Cotton Mather, however, (in his Christian Philosopher) says, that in the above year one Mr Lane carried over some of it from Virginia, which was the first that had ever been seen in Europe. Tobacco is commonly used among the oriental nations, though it is uncertain by whom it was introduced among them. Considerable quantities of it are cultivated in the Levant, on the coasts of Greece and the Archipelago, in Italy, and in the island of Malta.

There are two varieties of that species of Nicotiana which is cultivated for common use, and which are distinguished by the names of Oronoko, and sweetened tobacco. They differ from each other only in the figure of their leaves; those of the former being longer and narrower than the latter. They are tall herbaceous plants, growing erect with fine foliage, and rising with a strong stem from six to nine feet high. The stalk, near the root, is upward of an inch diameter, and surrounded with a kind of hairy or velvet clammy sallabrance, of a yellowish green colour. The leaves are rather of a deeper green, and grow alternately at the distance of two or three inches from each other. They are oblong, of a spear-shaped oval, and sifle; the largest about 20 inches long, but decreasing in size as they ascend, till they come to be only 10 inches long, and about half as broad. The face of the leaves is much corrugated, like those of spinach when full ripe. Before they come to maturity, when they are about five or six inches long, the leaves are generally of a full green, and rather smooth; but as they increase in size, they become rougher, and acquire a yellowish cast. The stem and branches are terminated by large bunches of flowers collected into clusters, of a delicate red; the edges, when full-blow, inclining to a pale purple. They continue in succession till the end of the summer; when they are succeeded by feeds rather rougher, and inclining to be sandy; but as they increase in size, they become rougher, and acquire a yellowish cast. The stem and branches are terminated by large bunches of flowers collected into clusters, of a delicate red; the edges, when full-blow, inclining to a pale purple. They continue in succession till the end of the summer; when they are succeeded by feeds which are very small, each capsule containing about 1000; and the whole produce of a single plant is reckoned at about 350,000. The feeds ripen in the month of September.

Mr Carver informs us, that the Oronoko, or, as it is called, the long Virginia tobacco, is the kind best suited for bearing the rigour of a northern climate, the strength as well as the scent of the leaves being greater than that of the other. The sweetened fort flourishes most in a sandy soil, and in warm climates, where it greatly exceeds the former in the celebrity of its growth; and is likewise, as its name intimates, much more mild and pleasant.

Culture. Tobacco thrives best in a warm, kindly, rich soil, that is not subject to be over-run by weeds. In Virginia, the soil in which it thrives best, is warm, light, and inclining to be sandy; and therefore, if the plant is to be cultivated in Britain, it ought to be planted in a soil as nearly of the same kind as possible. Other kinds of soil might probably be brought to suit it, by a mixture of proper manure; but we must remember, that whatever manure is made use of, must be thoroughly incorporated with the soil. The best situation for a tobacco plantation is the southern declivity of a hill rather gradual than abrupt, or a spot that is sheltered from the north winds; but at the same time it is necessary that the plants enjoy a free air; for without that they will not prosper.

As tobacco is an annual plant, those who intend to cultivate it ought to be as careful as possible in the choice of the feeds; in which, however, with all their care, they may be sometimes deceived. The feeds are to be sown about the middle of April, or rather sooner in a forward season, in a bed prepared for this purpose of such soil as has been already described, mixed with some warm rich manure. In a cold spring, hot-beds are most eligible for this purpose, and gardeners imagine that they are always necessary; but Mr Carver tells us, that he is convinced, when the weather is not very severe, the tobacco-feeds may be raised without doors; and for this purpose gives us the following directions.

"Having sown the feed in the manner above directed, on the leaf apprehension of a frost after the plants appear, it will be necessary to spread mats over the beds, a little elevated from the ground by poles laid across, that they may not be crushed. These, however, must be removed in the morning soon after the sun appears, that they may receive as much benefit as possible from its warmth and from the air. In this manner proceed till the leaves have attained about two inches in length and one in breadth; which they will do in about a month after they are sown, or near the middle of May, when the frosts are usually at an end. One invariable rule for their being able to bear removal is, that the fourth leaf is sprouted, and the fifth joint appears. Then take the opportunity of the first rains or gentle showers, when you may have enough to transplant them into such a foil and situation as before described; which must be done in the following manner.—The land must be ploughed, or dig up with spades, and made as mellow and light as possible. When the plants are to be placed, raise them in the small hillocks at the distance of two feet or a little more from each other, taking care that no hard fods of lumps are in it; and then indent the middle of each, without drilling holes, as for some other plants.

"When your ground is thus prepared, dig in a gentle manner from their native bed such plants as have attained the proper growth for transplanting above mentioned; and drop, as you pass, one on every hillock. Inset a plant gently into each centre, pressing the soil around it gently with your fingers; and taking the greatest care, during the operation, that you do not break off any of the leaves, which are at this time exquisitely tender. If the weather proves dry after they are thus transplanted, they must be watered with soft water, in the same manner as is usually done to coleworts, or plants of a similar kind. But though you now seem to have a sufficient quantity of plants for the space you intend to cultivate, it is yet necessary that you continue to attend to your bed of feedlings, that you may have enough to supply any deficiencies which through accident may arise. From this time great care must be taken to keep the ground felt and free
The difference of this climate from that in which I have been accustomed to observe the progress of this plant, will not permit me to direct with certainty the time which is most proper to take off the top of it, to prevent it from running to feed. This knowledge can only be acquired by experience. When it has rifen to the height of more than two feet, it commonly begins to put forth the branches on which the flowers and seeds are produced; but as this expansion, if suffered to take place, would drain the nutriment from the leaves, which are the most valuable part, and thereby lessen their size and efficacy, it becomes needful at this stage to nip off the extremity of the stalk to prevent its growing higher. In some other climates, the top is commonly cut off when the plant has 15 leaves; but if the tobacco is intended to be a little longer than usual, this is done when it has only 13 ; and sometimes, when it is designed to be remarkably powerful, 11 or 12 are only allowed to expand. On the contrary, if the planter is desirous of having his crop very mild, he suffers it to put forth 18 or 20: but in this calculation, the three or four lower leaves next the ground, which do not grow so large and fine as the others, are not to be reckoned.

This operation, denominated "topping" the tobacco, is much better performed by the finger and thumb than with any instrument; because the grasp of the fingers closes the pores of the plant; whereas, when it is done by instruments, the juices are in some degree exhausted. Care must also be taken to nip off the sprouts that will be continually springing up at the junction of the leaves; with the stalks. This is termed "facing off," or "fucking," the tobacco, and ought to be repeated as often as occasion requires.

As it is impossible to ascertain the due time for topping the plant, so it is equally impossible, without experiment, to ascertain the time it will take to ripen in this country. The apparent signs of its maturity are these: The leaves, as they approach a state of ripeness, become more corrugated or rough; and when fully ripe, appear mottled with yellowish spots on the raised parts; whilst the cavities retain their usual green colour. They are at this time also thicker than they have before been, and are covered with a downy velvet, like that formerly mentioned, on the stalks. If heavy rains happen at this critical period, they will wash off this excrescent substance, and thereby damage the plants. In this case, if the frosts nights are not begun, it is proper to let them stand a few days longer; when, if the weather be moderate, they will recover this substance again. But if a frost unexpectedly happens during the night, they must be carefully examined in the morning, before the sun has any influence upon them: and those which are found to be covered with frothy particles, whether thoroughly ripe or not, must be cut up; for though they may not all appear to be arrived at a state of maturity, yet they cannot be far from it, and will differ but little in goodness from those that are perfectly so.

Tobacco is subject to be destroyed by a worm; and without proper care to exterminate this enemy, a whole field of plants may soon be lost. This animal is of the horned species, and appears to be peculiar to the tobacco-plant; so that in many parts of America it is distinguished by the name of the "tobacco-worm." In what manner it is first produced, or how propagated, is unknown: but it is not discernible till the plants have attained about half their height; and then appears to be nearly as large as a gnat. Soon after this it lengthens into a worm; and by degrees increases in magnitude to the bigness of a man's finger. In shape it is regular from its head to its tail, without any diminution at either extremity. It is indented or ribbed round at equal distances, nearly a quarter of an inch from each other; and having at every one of these divisions a pair of feet or claws, by which it fastens itself to the plant. Its mouth, like that of the caterpillar, is placed under the fore-part of the head. On the top of the head, between the eyes, grows a horn about half an inch long, and greatly resembling a thorn: the extreme part of which is of a brown colour, a firm texture, and the extremity sharp-pointed. It is easily crushed; being only, to appearance, a collection of green juice inclosed in a membraneous covering, without the internal parts of an animated being. The colour of its skin is in general green, intermixed with several spots of a yellowish white; and the whole covered with a short hair fearfully to be discerned. These worms are found the most predominant during the latter end of July and the beginning of August; at which time the plants must be particularly attended to, and every leaf carefully searched. As soon as a worm is discovered, and it will not be long before it is perceptible, care must be taken to destroy the cause of it, which will be found near it, and from its unsubstantial texture may easily be crushed: but the best method is to pull it away by the horn, and then crush it.

When the tobacco is fit for being gathered, as will appear from an attention to the foregoing directions, on the first morning that promises a fair day, before the sun is risen, take an ax or a long knife, and holding the stalk near the top with one hand, sever it from its root with the other, as low as possible. Lay it gently on the ground, taking care not to break off the leaves, and there let it remain exposed to the rays of the sun throughout the day, or until the leaves, according to the American expression, are entirely "wilted" that is, till they become limber, and will bend any way without breaking. But if the weather should prove rainy without any intervals of sunshine, and the plants appear to be fully ripe, they must be housed immediately. This must be done, however, with great care, that the leaves, which are in this state very brittle, may not be broken. They are next to be placed under proper shelter, either in a barn or covered hovel, where they cannot be affected by rain or too much air, thinly scattered on the floor; and if the sun does not appear for several days, they must be left to wilt in that manner; but in this case the quality of the tobacco will not be quite so good.

When the leaves have acquired the abovementioned flexibility, the plants must be laid in heaps, or rather in one heap if the quantity is not too great, and in about 24 hours they will be found to sweat. But during this time, when they have lain for a little while, and begin to ferment, it will be necessary to turn them;
Nicotiana, the plants which are in the middle of the surface, and placing those which are at the surface in the middle. The longer they lie in this situation, the darker-coloured is the tobacco; and this is termed sweating the tobacco. After they have lain in this manner for three or four days, for a longer continuance might make the plants turn mouldy, they may be fastened together in pairs with cords or wooden pegs, near the bottom of the stalk, and hung across a pole, with the leaves suspended in the same covered place, a proper interval being left between each pair. In about a month the leaves will be thoroughly dried, and of a proper temperature to be taken down. This state may be ascertained by their appearing of the same colour with those imported from America. But this can be done only in wet weather. The atmosphere, which gives it a pliability that is rare. But this can be done only in wet weather—the atmosphere, which gives it a pliability that is rare. But this can be done only in wet weather.

Curse. As soon as the plants are taken down, they must again be laid in a heap, and pressed with heavy logs of wood for about a week; but this climate may not be too intense; for in large quantities this will sometimes be the case, and considerable damage will be occasioned by it. When they are found to heat too much, that is, when the heat exceeds a moderate glowing warmth, part of the weight by which they are pressed must be taken away: and the cause being removed, the effect will cease. This is called the second or last sweating; and, when completed, which it generally will be about the time just mentioned, the leaves may be stripped from the stalks for use. Many omit this last sweating; but Mr. Carver thinks that it takes away any remaining harshness, and renders the tobacco more yellow. The strength of the stalk also is diffused by it through the leaves, and the whole mass becomes equally melleriated.—When the leaves are stripped from the stalks, they are to be tied up in bunches or hands, and kept in a cellar or other damp place; though if not handled in dry weather, but only during a rainy season, it is of little consequence in what part of the house or barn they are laid up. At this period the tobacco is thoroughly cured, and as proper for manufacturing as that imported from the colonies.

Our author advises the tobacco-planter, in his first trials, not to be too avaricious, but to top his plants before they have gained their utmost height; leaving only about the middle quantity of leaves directed before, to give it a tolerable degree of strength. For though this, if excessive, might be abated during the cure by an increafe of sweating, or be remedied the next season by suffering more leaves to grow, it can never be added; and, without a certain degree of strength, the tobacco will always be tasteless and of little value. On the contrary, though it be ever so much weakened by sweating, and thereby rendered mild, yet it will never lose the aromatic, flavour, which accompanied that strength, and which greatly adds to its value.

The following extract, which is copied from a manuscript of Dr. Barham (A), for directing the raising, cultivating, and curing tobacco in Jamaica, is perhaps worthy of the attention of those who wish to be further acquainted with this subject.

"Let the ground or woodland wherein you intend planting tobacco be well burned, as the greater the quantity of wood ashes the better. The spot you intend raising your plants on must be well strewn with ashes, laid smooth and light; then blow the seed from the plain of your hand gently on the bed, and cover it over with palm or plantain leaves.

"When your plants are about four inches high, draw them and plant them out about three feet a distance; and when they become as high as your knee, cut or pluck off the top; and if there are more than 12 leaves on the plant, take off the overplus, and leave the rest entire.

"The plant should now be daily attended to, in order to destroy the caterpillars that are liable to infest it; as also to take off every sprout or sucker that puts out at the joints, in order to throw the whole vegetable nourishment into the large leaves.

"When the stalks begin to turn a little yellow, cut down the stalks about ten o'clock in the morning, taking the opportunity of a fine day, and be careful the dew is fully off the plant, and do not continue this work after two in the afternoon. As fast as it is cut let it be carried into your tobacco-house, which must be so close as to shut out all air, (on this much depends), and hung up on lines tied across, for the purpose of drying.

"When the stalks begin to turn brownish, take them off the lines, and put them in a large binn, and lay on them heavy weights for 12 days: then take them out, and strip off the leaves, and put them again into the binn, and let them be well pressed, and so as no air gains admission for a month. Take them out; tie them in bundles about 60 leaves in each, which are called monocots, and are ready for sale. But observe to let them always be kept close till you have occasion to dispose of them,"

"Let your curing-house be well built, and very close and warm: if a boarded building, it will not be amiss, in a wet situation, to cover the whole outside with thatch and plantain træth, to keep off the damp; for by this care you preserve the fine volatile oil in the leaves. Oliberce, no smoke is to be made use of or admitted into your curing-house.

"Ufe. Since the introduction of tobacco into Europe in 1560, various medical properties have been ascribed to it at different times by Stathm and other German physicians;"
Nicotiana; but the manner in which of late years it has been spoken of by the generality of writers on materia medica, has occasioned it to be almost wholly disfigured from modern practice, at least from internal use; but this circumstance has not deterred Dr Fowler, a physician of eminence in Staffordshire from commencing an inquiry into its medicinal effects; and he has given the result of his experiments, which seem to be accurately and faithfully related.

That tobacco, under proper regulations, may be administered internally, not only as a safe but as an efficacious remedy, especially as a diuretic in cases of dropsy and dysuria, seems certain enough. This property, among the vast number that have been attributed to it, however, seems scarcely ever to have been hinted at.

The forms in which Dr Fowler ordered it were either in infusion, tincture or pills.

Take of tobacco leaves dried an ounce; boiling water one pound: infuse them for an hour in a close vessel set in a warm place, and strain off about 14 ounces. Then add two ounces of rectified spirit of wine.

Take of dried tobacco leaves an ounce, of rectified spirits, Spanish white wine or vinegar, one pint, to be infused for four days.

Take of dried tobacco leaves in powder 1 drachm, of the conserve of roses enough to make it in a mass; which is to be divided into 60 pills.

Of the infusion, or tincture, Dr Fowler gives from 6 to 100 drops twice a day in water, or in a cordial julep, or other proper vehicle, sufficient to produce the effect in adults; but in irritable habits he seldom exceeded 25 drops. To a patient of 10 years old he gave 50 drops; to a child of five years old 20 drops; but to patients under five years old he never ventured to prescribe it.

The first effects of the infusion are a transient heat in the stomatch and throat, as if the patient had taken a dram. The next general effect in a modern dose is diuretic, with or without a flight vertigo and giddiness, and frequently nausea. In painful cases, it proves anodyne, and in some cases occaious drowsiness and sleep; in others drowsiness, with a sense of heat and restlessness.

Dr Fowler gave this medicine in 115 cases; in 93 of which it proved diuretic; in 40 of these cases it occasioned purging; 79 of these patients complained of vertigo. In 52 of the number it excited nausea; in the two last cases he directed the medicine to be suspended, and the doselesstened. Dr Fowler tried it in 30 cases of dropsy, viz. four of anaehema, or general dropsy; two of ascites; and 12 of dropsical swellings of the legs, were all cured. In ten other cases it afforded considerable relief; and in three cases only it was of no use. In ten instances of dysury, the infusion was anodyne and diuretic, thereby abating pain, relaxing the urinary passages, and promoting urine.

In dysuries from gravel, it facilitates the expulsion of calcareous or gritty matter.

Dr Fowler speaks of the use of tobacco in injections; an ounce of the infusion in a pint of water-greel at a time, and repeated in cases of obstructive complication, as the cuse may require. In the dry belly-aches, in the West Indies, injections of the smoke of tobacco have long been employed with the happiest effects.

After all, the internal use of tobacco should be very limited, and can only be safe in the hands of a skilful and attentive practitioner. Tobacco is sometimes used externally in ungues for destroying cutaneous inflamations, cleansing old ulcers, &c. Beaten into a mash with vinegar or brandy, it has sometimes proved serviceable for removing hard tumours of the hypochondriac; an account is given in the Edinburgh Essays of two cases of this kind cured by it. Two of the common uses of this plant, however, are either as a stimulant when taken by way of snuff as a masticatory by chewing it in the mouth, or as effluvia by smoking it; and when taken in moderation, it is not an unheathful amusement.

Before pipes were invented, it was usually smoked in cegars, and they are still in use among some of the southern nations. The method of preparing there is at once simple and expeditions. A leaf of tobacco being formed into a small twisted roll, somewhat larger than the stem of a pipe, and about eight inches long, the smoke is conveyed through the winding folds which prevent it from expanding, as through a tube; so that one end of it being lighted, and the other applied to the mouth, it is in this from used without much inconvenience. But, in process of time, pipes being invented, they were found more commodious vehicles for the smoke, and are now in general use.

Among all the productions of foreign climes introduced into these kingdoms, scarce any has been held in higher estimation by persons of every rank than tobacco. In the countries of which it is a native, it is considered by the Indians as the most valuable offering that can be made to the beings they worship. They use it in all their civil and religious ceremonies. When once the spiral wreaths of its smoke ascend from the feathered pipe of peace, the compact that has been just made is considered as sacred and inviolable. Likewise, when they address their great Father, or his guardian spirits, retiing, as they believe, in every extraordinary production of nature, they make liberal offerings to them of this valuable plant, not doubting but that they are thus secured of protection.

Tobacco is made up into rolls by the inhabitants of the interior parts of America, by means of a machine called a tobacco wheel. With this machine they spin the leaves after they are cured, into a twist of any size they think fit; and having folded it into rolls of about 20 pounds each, they lay it by for use. In this state it will keep for several years, and be continually improving, as it always grows milder. The Illinois usually form it into carrots; which is done by laying a number of leaves, when cured, on each other after the ribs have been taken out, and rolling them round with packthread, till they become cemented together. These rolls commonly measure about 18 or 20 inches in length, and nine round in the middle part.

Tobacco forms a very considerable article in commerce; for an account of which see the article Glas­gow and Virginia.

NICTITATING MEMBRANE, a thin membrane chiefly found in the bird and fih kind, which covers the eyes of these animals, sheltering them from the dajt or too much light; yet so thin and pellucid, that they can see pretty well through it.
NIEUWENELT (Bernard), an able philosopher and learned mathematician, was born at Weissenhaffel, in the year 1654, and became counsellor and burgomaster of the town of Purmerend, where he was employed for his integrity and learning, and died in 1718. He wrote, in Dutch, 1. An excellent treatise, intitled, The Exitus of God demonstrated by the Works of Nature. 2. A refutation of Spinoza: 3. Some Pieces against the Infinitefinals, &c.

NIGELLA, or Diesel-flower, or Dwell in a Bath: A genus of the pentagynia order, belonging to the pentandria class of plants. There is no calyx; the petals are five; and five trifid nectaries within the corolla; there are five connected capsules. There are five species, all of them natives of the warm parts of Europe, and rising from a foot to a hand, and half high, adorned with blue or yellow flowers. They are propagated by seeds, which in a dry and warm situation will thrive very well; and the plants ripen seeds in this country.

NIGER (C. Pefcennius Julius), a celebrated governor in Syria, well known by his valour in the Roman armies while but a private man. At the death of Pertinax he was declared emperor of Rome; and his claims to that elevated station were supported by a sound understanding, prudence of mind, moderation, courage, and virtue. He proposed to imitate the actions of the venerable Antoninus, of Trajan, of Titus, and M. Aurelius. He was remarkable for his fondness of ancient discipline. He never suffers his soldiers to drink wine, but obliged them when thirsty to use water and vinegar. He forbade the use of silver or gold utensils in his camp. All the bakers and cooks were driven away, and the soldiers were ordered to live during the expedition they undertook merely upon bickets. In his punishments Niger was inexorable: he condemned ten of his soldiers to be beheaded in the presence of the army, because they had stolen and eaten a fowl. The sentence was heard with groans. The army interfered; and when Niger consented to diminish the punishment, for fear of kindling rebellion, he yet ordered the criminals to make each a restoration of ten fowls to the person whose property they had stolen. They were besides ordered not to light a fire the rest of the campaign, but to live upon cold aliments and to drink nothing but water. Such great qualifications in a general seemed to promise the restoration of ancient discipline in the Roman armies; but the death of Niger frustrated every hope of reform. Severus, who had also been invested with the imperial purple, marched against him; some battles were fought, and Niger was at last defeated A. D. 195. His head was cut off and fixed to a long spear, and carried in triumph through the streets of Rome. He reigned about a year.
NIGER, a great river of Africa, supposed to have its origin near that of the Nile; but this is very uncertain. We are assured, however, that it is a river of very great extent; especially if we suppose, according to the opinion of the best modern geographers, that it has its source in the kingdom of Gorhan, not far from the confines of Upper Ethiopia; for then it will cross almost the whole continent of Africa, where it is widest. In its course it receives many considerable rivers, which swell it high enough to be able at all times to carry vessels of good burden; it splits itself into several branches, which uniting again form very large and fertile islands, well filled with towns and villages. It passes also through several lakes, and has many cataracts. After having run from east to west during a prodigious long course, it turns at last short to the south, at a league and a half distance from the western ocean; leaving but a very narrow tract between it and the sea, into which it opens its way in lat. 15° 35', after having run about 25 leagues from north to south. Its mouth is sometimes half a league broad; but is shut up by a bank of quick-sand, called the bar of Senegal, where the water is so shallow, that it is very difficult and dangerous to pass over it. The bar is formed by the mud and sand which the river brings with it during the inundation, and which the sea continually drives back upon the shore. This would effectually exclude all shipping, had not the violence of the current, and the weight of the waters, made two openings or channels, which are commonly called the passes of the bar. The largest of those is generally not above 150 or 200 fathoms broad, and about 10 feet deep; so that none but barks of 40 or 50 tons can get thro' this channel; the other is so narrow and shallow, that it is passable by canoes only. These channels are not always in the same place; for the river, as it is more or less swelled, or the current more or less rapid, opens those passes sometimes in one place and sometimes in another. The bar itself also frequently shifts its place; so that the island of Senegal is sometimes four leagues distant from it, at other times only two. It is this bar only which hinders ships of 400 or 500 tons to go up the river. See Guinea and Negro Land.

Night, that part of the natural day during which the sun is underneath the horizon; or that space wherein it is dusky.

Night, originally divided by the Hebrews and other eastern nations into three parts or watches. The Romans, and after them the Jews, divided the night into four parts or watches; the first of which began at sunset, and lasted till nine at night; according to our way of reckoning; the second lasted till midnight; the third till three in the morning; and the fourth ended at sunrise. The ancient Gauls and Germans divided their time not by days but by nights; and the people of Iceland and the Arabs do the same at this day. The like is observed of the Anglo-Saxons. The length and shortness of night or of darkness is according to the season of the year and position of the place; and the causes of this variety are now well known. See Astronomy, &c.

Night, in scripture-language, is used for the times of heathenish ignorance and profaneness (Rom. xiii. 12.); for adversity and affliction (I. xxi. 12.); and, lastly, for death (John ix. 4.)

Night-Angling, a method of catching large and fly fish in the night-time. Trout, and many others of the better sorts of fish, are naturally fly and fearful; they therefore prey in the night as the securer time. The tackle must be strong, and need not be so fine as for day-fishing, when every thing is seen; the hook must be baited with a large earth-worm, or a black snail, and thrown out into the river; there must be no lead to the line, so that the baits may not sink, but be kept drawing along, upon or near the surface. Whatever trout is near the place will be brought thither by the motion of the water, and will seize the worm or snail. The angler will be alarmed by the noise which the fish makes in rising, and must give him line, and time to swallow the hook; then a flight touch secures him. The baited and large fishs are found to bite thus in the night; and they rise moly in the flill and clear deeps, not in the swift and shallow currents. Sometimes, though there be fish about the place, they will not rise at the bait; in this case the angler must put on some lead to his line, and sink it to the bottom.

Night-Mare, or Inebrius. See Medicine, No. 329.

Night-Walkers, in medicine. See Medicine, No. 329, and Noctambuli.

Night-Walker, in law, are such persons as sleep by day and walk by night, being oftentimes pilferers or disturbers of the public peace. Contables are authorized by the common law to arrest night-walkers and suspicious persons, &c. They may also arrest night-walkers, and hold them until the morning: and it is said, that a private person may arrest any suspicious night-walker, and detain him till he give a good account of himself. One may be bound to the good behaviour for being a night-walker; and common night-walkers, or haunters of bawdy-houses, are to be indicted before justices, &c. But it is not held lawful for a contable, &c. to take up any woman as a night-walker on bare suspicion only of being of ill fame, unless she be guilty of a breach of the peace, or some unlawful act, and ought to be found misbehaving.

Nightingale, in ornithology; a species of motacilla. See Motacilla, and Plate CCCXV.

The nightingale takes its name from night, and the Saxon word galan, "to sing;" expressive of the time of its melody. Its size and colour has been described already under Motacilla; to which account we add, that its eyes are remarkably large and piercing; and though it is about equal in size to the redstart, it is longer in body, and more elegantly made.

Mr Hunter found, by dissection, that the muscles of the larynx are stronger in the nightingale than in any other bird of the same size. Sibbald places them in his list of Scotch birds; but they certainly are unknown in that part of Great Britain, probably from the scarcity and the recent introduction of hedges there. Yet they visit Sweden, a much more severe climate. In England they frequent thick hedges, and low coppices: and generally keep in the middle of the bush, so that they are very rarely seen. When the young ones first come abroad, and are helpless, the old birds make a plaintive and jarring noise with a fort of
Thee quotations from the best judge of melody—
we thought due to the sweetness of our feathered
cribifers; and we believe no reader of taste will think
them tedious.

Virgil seems to be the only poet among the an-
cents who hath attended to the circumstance of this
bird's singing in the night-time.

Georg. IV. 1. 511.

As Philomela in poplar shades, alone,
For her loft offspring pours a mother's moan,
Which some rough ploughman marking for his prey,
From the warm nest, unheld, hath dragg'd away;
Pench'd on a bough, she all night long complains,
And fills the grove with sad repeated strains.

F. Warce.

Plisty has described the warbling notes of this bird
with an elegance that bespeaks an exquisite sensibility
of taste, lib. x. c. 29.

If the nightingale is kept in a cage, it often begins
to sing about the latter end of November, and con-
tinues its song more or less till June. A young canary-
bird, linnet, fly-lark, or robin (who have never heard
any other bird), are said to learn best the note of a
nightingale.

Mock-Nightingale. Ser Motacilla, sp. 8.

Virginian Nightingale, in ornithology, the com-
m, but improper, name of a bird of the gros-
beaked kind, called by authors the coccothraustes Indica
eritata.

It is a little smaller than the blackbird; it has a
black ring surrounding the eyes and nostrils; the beak
is very large and thick, but not altogether so large as
in the common gros-beak; and its head is orna-
minated with a very high and beautiful crest, which
it moves about very frequently; it is all over of a very
fine and lively red, but paler on the head and tail than
elsewhere; it is brought to us from Virginia, and is
much valued in England for its beauty and delicate
manner of singing; it is very fond of almonds and the
like fruits.

NIGHTSHADE, in botany. See Solanum.

Deadly Nightshade. See Atropa.—The berries
of this plant are of a malignant poisonous nature; and,
being of a sweet taste, have frequently proved destruc-
tive to children. A large glass of warm vinegar,
taken as soon as possible after eating the berries,
will prevent their bad effects.

NIGIDIUS FIGULUS (Publius), one of the most
learned men of ancient Rome, flourished at the same
time with Cicero. He wrote on various subjectes; but
his pieces appeared so refined and difficult that they
were not regarded. He admired Cicero, with great
prudence, in defeating Catiline's conspiracy, and did
him many services in the time of his adversity. He

the day.
NIL

adhered to Parape in opposition to Cæsar; which occasioned his exile, he dying in banishment. Cicero, who had always entertained the highest esteem for him, wrote a beautiful consolatory letter to him (the 13th of Lib. 4. ad Familiares).

NIGRINA, in botany; a genus of the monogynia order, belonging to the pentandria class of plants. The corolla is funnel-shaped; the calyx inflated; the stigma obsolete; the capsule bilocular.

NIGRITIA. See Negroland.

NIGUA. See Chegdo.

NILE, a large and celebrated river of Africa, to which the country of Egypt owes its fertility; and the exploring of the sources of which has, from the remotest ages, been accounted an impracticable undertaking. Of late this problem has been solved by James Bruce, Esq; of Kinnaird, in Scotland; who spent several years at the court of Abyssinia, and by the favour of the emperor and great people of the country was enabled to accomplish the arduous task.

In the account of his travels lately published, this gentleman has been at particular pains to shew, that none of those who undertook this task ever succeeded in it but himself. The inquiry concerning its springs, he says, began before either history or tradition, and is by some supposed to be the origin of hieroglyphics. Though Egypt was the country which received the greatest benefit from this river, it was not there that the inquiries concerning its inundation began; it being probable that every thing relative to the extent of the inundations increase and periodical time of that inundation would be accurately settled (which could not be done but by a long series of observations) before any person would venture to build houses within its reach.

The philosophers of Meroe, in our author's opinion, were the first who undertook to make a number of observations sufficient to determine these points; their country being so fitted, that they could perceive every thing relative to the increase or decrease of the river without any danger from its overflowing. Being much addicted to astronomy, it could not long escape them, that the heliacal rising of the dog star was a signal for Egypt to prepare for the inundation; without which it was vain to expect any crop. The connection of this celestial sign with the annual rising of the river would undoubtedly soon become a matter of curiosity; and as this could not easily be discovered, it was natural for an ignorant and superstitious people to ascribe the whole to the action of the dog star as a deity. Still, however, by those who were more enlightened, the phenomenon would be ascribed to natural causes; and a great step towards the discovery of the fountains of the Nile became an object to the greatest monarchs. Sesostris is said to have preferred the honour of discovering them almost to all the victories he obtained. Alexander the Great is well known to have had a great curiosity to discover these fountains. On his arrival at the temple of Jupiter Ammon, he is said to have made inquiry concerning the fountains of the Nile, even before he asked about his own descent from Jupiter. The priests are said to have given him proper directions for finding them; and Alexander took the most ready means of accomplishing his purpose, by employing natives of Ethiopia to make the search. These discoverers, in the opinion of Mr Bruce, misled their aim, by reason of the turn which the Nile takes to the east in the latitude of 9°, where it begins to surround the kingdom of Gojam; but which they might imagine to be only a winding of the river, soon to be compensated by an equal turn to the west. "They therefore (says he) continued their journey south till near the line, and never knew it more; as they could have no possibility of it had turned back behind them, and that they had left it as far north as latitude 9°. They reported then to Alexander what truth, that they had ascended the Nile as far south as latitude 9°; where it unexpectedly took its course to the east, and was seen no more. The river was not known, nor to be heard of near the line, or farther southward, nor was it diminished in size, nor had it given any symptoms that they were near its source; they had found the Nile calentem (warm), while they expected its rise among melting snows."

Mr Bruce is of opinion that this turn of the Nile to the eastward was the occasion of Alexander's extravagant mistake, in supposing that he had discovered the fountains of the Nile when he was near the source of the Indus; and which he wrote to his mother, though he afterwards caused it to be erased from his books.

Ptolemy Philadelphus succeeded Alexander in his attempts to discover the source of the Nile; but he likewise proving unsuccessful, the task was next undertaken by Ptolemy Euergetes, the most powerful of the Greek princes who sat on the throne of Egypt, "In this (says Mr Bruce) he had probably succeeded, had he not mistaken the river itself. He supposèd the Siris, now the Tacazze, to be the Nile; and ascending in the direction of its stream, he came to Axum, the capital of Sira and of Ethiopia. But the story he tells of the snow which he found knee-deep on the mountains of Samen, makes me question whether he ever crossed the Siris, or was himself an ocular witness of what he says he observed there."

Cæsar had the same curiosity with other conquerors to visit the springs of the Nile, though his situation did not allow him to make any attempt for that purpose. Nero, however, was more active. He sent two centurions into Ethiopia, with orders to explore the unknown fountains of this river; but they returned without having accomplished their errand. They reported, that, after having gone a long way, they came to a king of Ethio. ia, who furnished them with necessaries, and recommendations to some other kingdoms adjacent; passing which, they came to immense lakes, of which nobody knew the end, nor could they ever hope to find it. Their story, however, is by Mr Bruce supposed to be a fiction; as the Nile forms no lakes throughout its course, excepting that of Tzana or Dembo, the limits of which are easily perceived.

No other attempt was made by the ancients to discover the fountains of this celebrated river; and the matter was looked upon to be an impossibility, infomuch that caput Nili quarerere became a proverb, denoting the impossibility of any undertaking. The first who, in more modern ages, made any attempt of this kind,
kind was a monk sent into Abyssinia in the year 522, by Nomelius, ambassadoer from the Emperor Julian. This monk is called Cosmas the Hermite, and likewise Induplastus, from his supposed travels into India. He proceeded as far as the city of Axum, but did not visit that part of the country where the head of the Nile lies; nor, in Mr Bruce's opinion, would it have been practicable for him to do so. The discovery, however, is said to have been made at last by Peter Paez the missionary. But the truth of this account is denied by Mr Bruce, for the following reasons: 1. "No relation of this kind, (says he) was to be found in three copies of Peter Paez's history, to which I had access when in Italy, on my return home. One of these copies I saw at Milan; and, by the interest of friends, had an opportunity of perusing it at my leisure. The other two were at Boologna and Rome. I ran through them rapidly; attending only to the place where the description ought to have been, and where I did not find it: but having copied the first and last page of the Milan manuscript, and comparing them with the two last mentioned, I found that all the three were, word for word, the same, and none of them contained one syllable of the discovery of the source. 2. Alphonso Mendez came into Abyssinia about a year after Paez's death. New and delineable as that discovery must have been to himself, to the people of Spain, and all his great principalties in Portugal and Italy; though he wrote the history of the country, and of the particulars concerning the million in great detail and with good judgment, yet he never mentions this journey of Peter Paez, though it probably must have been conveyed to Rome and Portugal after his inspection and under his authority. 3. Bishaihor Tellez, a learned Jew, has written two volumes in foine, with great censure and impartiality, containing the spirit of the last times; and he declares his work to be compiled from those of Alphonso Mendez the patriarch, from the two volumes of Peter Paez, as well as from the regular reports made by the individuals of the company on some places, and by the provincial letters in others; to all which he had complete access, as also to the annual reports of Peter Paez, among the rest from 1598 to 1622; yet Tellez makes no mention of such a discovery, though he is very particular as to the merit of every missionary during the long reign of Facilidas, which occupies more than half the two volumes."

The first, and indeed the only account of the fountain of the Nile published before that of Mr Bruce, was Kircher's; who says that he took it from the writings of Peter Paez. The time when the discovery is said to have been made is the 12th of April 1618; at which time the rains are begun, and therefore very unwholesome; so that the Abyssinian armies are not without extreme necessity in the field; between September and February at the fairest the time they are abroad from the capital and in action.

"The river (says Kircher) at this day, by the Ethiopians, is called Alavy; it rises in the kingdom of Gojam, in a territory called Sibbr, whose inhabitants are called Alyons. The source of the Nile is situated in the west part of Gojam, in the highest part of a valley which resembles a great plain on every side surrounded by high mountains. On the 21st of April 1618, being here, together with the king and his army, I ascended the place and observed every thing with great attention; I discovered first two round fountains each about four palms in diameter, and saw, with the greatest delight, what neither Cyrus the Perisan, nor Cambyses, nor Alexander the Great, nor the famous Julius Cæsar, could ever discover. The two openings of these fountains have no issue in the plain on the top of the mountain, but flow from the root of it. The second fountain lies about a stone-calf west from the former; the inhabitants say that this whole mountain is full of water; and add, that the whole plain about the fountain is floating and unsteady, a certain mark that there is water concealed under it; for which reason the water does not overflow at the fountain, but forces itself with great violence out at the foot of the mountain. The inhabitants, together with the emperor, who was then present with his army, maintain, that that year it trembled very little on account of the drought; but in other years, that it trembled and overflowed so, that it could scarce be approached without danger. The breadth of the circumference may be about the call of a fling; below the top of this mountain the people live about a league distant from the fountain to the west; and this place is called Geefh; and the fountain seems to be about a cannon-shot distant from Geefh; moreover the field where the fountain is, is so all fides difficult of access, except on the north side, where it may be ascended with ease."
However, filled with wild beasts, especially huge, long-haired baboons, which we frequently met walking upright. Through these high and difficult mountains we have only narrow paths, like those of sheep, made by the goats, or the wild beasts we are speaking of, which, after we had walked on them for a long space, landed us frequently at the edge of some valley or precipice, and forced us to go back again to seek a new road. From towards Zeegam to the westward, and from the plain where the river winds so much, is the only easy access to the fountains of the Nile; and they that ascend to them by this way will not even think that approach too easy."

Peter Heyling, a Protestant of Lubec, resided several years in the country of Gojam, and was even governor of it, but he never made any attempt to discover the source of the Nile; dedicating himself entirely to a studious and solitary life. The most extraordinary attempt, however, that ever was made to discover the source of this or any other river, was that of a German nobleman named Peter Joseph de Reas, comte de Defraval. He had been in the Danish navy from the year 1721; and, in 1739, was made rear-admiral. That same year he resigned his commission, and began his attempt to discover the source of the Nile in Egypt. To this country he took his wife along with him; and had no sooner reached Cairo, than he quarrelled with a Turkish mob on a point of etiquette; which instantly brought upon them the janizaries and guards of police, to take them into custody. The countess exerted herself in an extraordinary manner; and, armed only with a pair of scissors, put all the janizaries to flight, and even wounded several of them; so that her husband was left at liberty to pursue his plan of discovery. To accomplish this, he provided a barge with small cannon, furnished with all necessary provisions for himself and his wife, who was still to accompany him. Before he set out, however, it was suggested to him, that supposing government might protect him so far as to allow his barge to pass the confines of Egypt safely, and to the first cataract; supposing also that she was arrived at Ibrim, or Deir, the last garrisons depending on Cairo; yet still some days journey above the garrisons of Deir and Ibrim began the dreadful deserts of Nubia; and further south at the great cataract of Jan Adel, the Nile falls 20 feet down a perpendicular rock—so that here his voyage must undoubtedly end. The count, however, flattened himself with being able to obtain such assistance from the garrisons Ibrim and Deir, as would enable him to take the vessels to pieces, and to carry it up above the cataract, where it could again be launched into the river. To facilitate this scheme he had even entered into a treaty with some of the barbarians named Kennoufs, who reside near the cataract, and employ themselves in gathering fen, which abounds in their country. They promised to assist him in this extraordinary adventure; but, luckily for the count, he suffered himself at Ibrim to be persuaded by some Venetian merchants at Cairo not to proceed in person on such a dangerous and unheard of navigation, but rather to depute Mr Norden, his lieutenant, who was likewise to serve as his draughtsman to reconnoitre the forts of Ibrim and Deir, as well as the cataract of Jan Adel, and renew his treaty with the Kennoufs. This gentleman accordingly embarked upon one of the vessels common on the Nile, but met with a great many difficulties and disasters before he could reach Syene and the first cataract; after which having with still greater difficulty reached Ibrim, instead of meeting with any encouragement for the count to proceed on his voyage, he was robbed of all he had by the governor of the fort, and narrowly escaped with his life; it having been for some time determined by him and his soldiers, that Mr Norden should be put to death. By these difficulties the count was so much disheartened, that he determined to make no more attempts on the Nubian side. He now resolved to enter Abyssinia by the island of Maunah. With this view he undertook a voyage round the Cape of Good Hope, in order to reach the Red Sea by the straits of Babelmandel; but having begun to use his Spanish commission, and taken two English ships, he was met by commodore Barnett, who made prizes of all the vessels he had with him, and sent home the count himself passenger in a Portuguese ship to Lisbon.

Thus Mr Bruce considers himself as the first European who reached the sources of this river. He informs us that they are in the country of the Agows, as Kircher had said; so that the latter must either have visited them himself, or have had very good information concerning them. The name of the place thro' which is the passage to the territory of the Agows, is Abala; a plain or rather valley, generally about half a mile, and never exceeding a whole mile, in breadth. The mountains which surround it are at first of an inconsiderable height, covered to the very top with herbage and acacia trees; but as they proceed to the southward they become more rugged and woody.—On the top of these mountains are delightful plains, producing excellent pasture. Those to the west join a mountain called Aformalsa, where, from a direction nearly south-east, they turn south, and incline the villages and territory of Sacalla, which lie at the foot of them; and still lower, that is, more to the westward is the small village of Geefh, where the fountains of the Nile are situated. Here the mountains are in the form of a crescent; and along these the river takes its course. Those which incline the east side of the plain run parallel to the former in their whole course, making part of the mountains of Lechtambara, or at least joining with them; and these two, when behind Aformalsa, turn to the south, and then to the south-west, taking the same form as they do; only making a greater curve, and inclining them likewise in the form of a crescent, the extremity of which terminates immediately above a small lake named Goode-roo in the plain of Abala, below Geefh, and directly at the fountains of the Nile.

Having passed several considerable streams, all of which empty themselves into the Nile, our traveller found himself at last obliged to ascend a very deep and rugged mountain, where no other path was to be found but a very narrow one made by the sheep or goats, and which in some places was broken, and full of holes; in others, he was obstructed with large stones, which seemed to have remained there since the creation. The whole was covered with thick wood; and he was every where flopped by the contusses, as well as by several other thorny plants,
plants, almost as troublesome as that. Having at last, however, reached the top, he had a sight of the Nile immediately below him; but so diminished in size, that it now appeared only a brook scarce sufficient to turn a mill. The village of Geesb is not within sight of the fountains of the river, though not more than 600 yards distant from them. The country about that place terminates in a cliff of about 300 yards high, which reaches down to the plain of Afric, continuing in the same degree of elevation till it meets the Nile again about 17 miles to the southward, after having made the circuit of the provinces of Gopam and Damot. In the middle of this cliff is a vast cave running straight northward, with many bye-paths forming a natural labyrinth, of sufficient bigness to contain the inhabitants of the whole village with their cattle. Into this, Mr Bruce advanced about 100 yards, but he did not choose to go farther, as the candle he carried with him seemed ready to go out; and the people assured him that there was nothing remarkable to be seen at the end. The face of this cliff, fronting the south, affords a very picturesque view from the plain of Afric below; parts of the houses appearing at every stage through the bushes and thickets of trees. The mouths of the cavern above mentioned, as well as of several others which Mr Bruce did not see, are hid by almost impenetrable fences of the work of kind of thorn; nor is there any other communication between the upper part and the houses but by narrow winding steep-paths, very difficult to be discovered; all of them being allowed to be overgrown, as a part of the natural defence of the people. The edge of the cliff is covered with lofty and high trees, which seem to form a natural fence to prevent people from falling down; and the beauty of the flowers which the Abyssinian thorns bear, seem to make some amends for their bad qualities. From the edge of the cliff of Geesb, above where the village is situated, the ground slopes with a decent due north, till we come to a triangular marsh upwards of 86 yards broad, and 286 from the edge of the cliff; and from a priest's house where Mr Bruce refided. On the east, the ground descends with a very gentle slope from the large village of Sacala, which gives its name to the territory, and is about six miles distant from the fountain, though to appearance not above two. About the middle of this marsh, and not quite 40 yards from the foot of the mountain of Geesb, rises a circular hillock about three feet from the surface of the marsh itself, though founded apparently much deeper in it. The diameter of this hillock is not quite 12 feet, and is surrounded by a shallow trench which collects the water and feeds it off to the eastward. This is firmly built of sod brought from the sides, and kept constantly in repair by the Agows, who worship the river, and perform their religious ceremonies upon this as an altar. In the midst of it is a circular hole, in the formation or enlargement of which the work of art is evidently discernible. It is always kept clear of grass and aquatic plants, and the water in it is perfectly pure and limpid, but without any eddiction or motion discernible on its surface. The mouth is some parts of an inch less than three feet diameter, and at the time our author first visited it (Nov. 5, 1770), the water flowed about two inches from the brim, nor did it either increase or diminish during all the time of his residence at Geesb. On putting down the flint of a lance, he found a very sensible refullance at six feet four inches, as if from weak ruffles and grubs; and about six inches deeper he found his lance had entered into soft earth, but met with no obstruction from stones or gravel: and the same was confirmed by using a heavy plummer, with a line besmeared with soap. This is the first fountain of the Nile.

The second fountain is situated at about ten feet distant from the former, a little to the west of south; and is only 11 inches in diameter, but eight feet three inches deep. The third is about 20 feet SSW from the first; the mouth being somewhat more than two feet in diameter, and five feet eight inches in depth. These fountains are made use of as altars, and from the foot of each issues a brisk running rill, which unites with the water of the first trench, goes off at the call side in a stream which, our author conjectures, would fill a pipe about two inches diameter. The water of these fountains is extremely light and good, and intensely cold, though exposed to the scorching heat of the sun without any shelter; there being no trees nearer than the cliff of Geesb. The length of the principal fountain was found by Mr Bruce to be 56° 55' 30" E. from Greenwich. The elevation of the ground according to his account, must be very great, as the barometer stood only at 22 English inches. "Neither (says he) did it vary sensibly from that height any of the following days I first at Geesb; and thence I inferred, that at the sources of the Nile I was then more than two miles above the level of the sea a prodigious height, to enjoy a sky perpetually clear, as also a hot sun never overcast for a moment with clouds from rising to setting." In the morning of Nov. 6. the thermometer stood at 44° at noon 96°, and at sun set 46°. It was sensibly cold at night, and fell more so about an hour before sunrise.

The Nile thus formed by the union of streams from these three fountains runs eastward through the marsh for about 30 yards, with very little increase of its water, but still distinctly visible, till it is met by the grassy brink of the land descending from Sacala. By this it is turned gradually NE, and then due north; and in the two miles in which it flows in that direction it receives many small streams from springs on each side; so that about this distance from the fountains it becomes a stream capable of turning a common mill. Our traveller was much taken with the beauty of this spot. "The small rising hills about us (says he) were all thick covered with verdure, especially with clover, the largest and finest I ever saw; the tops of the heights covered with trees of a prodigious size; the stream, at the banks of which we were sitting, was limpid, and pure as the finest crystal; the sod covered thick with a kind of bulby tree that seemed to affect to grow to no height, but thick with foliage and young branches, rather to affilt the surface of the water; whilst it bore in prodigious quantities, a beautiful yellow flower, not unlike a single role of that colour, but without thorns; and indeed, upon examination, we found that it was not a species of the rose, but of the hypericum."

Here Mr Bruce exults greatly in his success; as ha-
the river itself running in a small stream; so that the ancient faying of the poet,

_Nee uisus populi parvae ni eile videre_

could not be applied to him. Here he passed over it, he says, more then 50 times, though he had told us, in the preceding page, that it was three yards over. From this ford, however, the Nile turns to the westward; and, after running over loose stones occasionally in that direction about four miles farther, there is a small cataract of about fix feet in height; after which it leaves the mountainous country, and takes its course in that direction about five miles further; forming more than one arch, and winds in its direction more than any river he ever saw; forming more than 20 sharp angular peninsulas in the space of five miles. Here the soil is composed of a marshy clay, quite deficate of trees, and very difficult to travel through; and where its stream receives no considerable addition. Iffuing out from thence, however, it is joined by several rivulets which fall from the mountains on each side, so that it becomes a considerable stream, with high and broken banks covered with old timber trees for three miles. In its course it inclines to the north east, and winds very much, till it receives first a small river named Dicra, and then another named Det-skea, or the river Dee. Turning then sharply to the east, it falls down another cataract, and about three miles below receives the Jemma, a pure and limpid stream, not inferior in size to itself. Proceeding still to the northward, it receives a number of other streams, and at last crosses the southern part of the lake Tzana or Dembea, preferring the colour of its stream during its passage, and flowing out at the west side of it in the territory of Dara.

There is a ford, though very deep and dangerous, at the place where the Nile first assumes the name of a river, after emerging from the lake Dembea: but the stream in other places is exceedingly rapid; the banks in the course of a few miles become very high, and are covered with the most beautiful and variegated verdure that can be conceived. It is now confined by the mountains of Begemder till it reaches Alata, where is the third cataract. This, we are informed by Mr Bruce, is the most magnificent sight he ever beheld; but he thinks that the height has rather been exaggerated by the missionary, who made it 50 feet; and after many attempts to measure it, he is of opinion that it is nearly 40 feet high. At the time he visited it, the river had been pretty much swollen by rains, and fell in one sheet of water, without any interval, for the space of half an English mile in breadth, with such a noise as stunned and made him giddy for some time. The river, for some space both above and below the fall, was covered with a thick mist, owing to the small particles of the water dashed up into the air by the violence of the shock. The river, though swollen beyond its usual size, retained its calmness, and fell into a natural basin of rock; the stream appearing to run back against the foot of the precipice over which it falls with great violence; forming innumerable eddies and waves, being in excessive commotion, as may easily be imagined. Jerome Lobo pretends that he was able to reach the foot of the rock, and sit under the prodigious arch of water spouting over it; but Mr Bruce does not hesitate to pronounce this to be an absolute falsehood. The noise of the cataract, which, he says, is like the loudest thunder, could not fail to confound and destroy his sense of hearing; while the rapid motion of the water before his eyes would dazzle the sight, make him giddy, and utterly deprive him of all his intellectual powers. "It was a most magnificent sight (says Mr Bruce), that ages, added to the greatest length of human life, would not deface or eradicate from my memory: it struck me with a kind of stupor, and a total oblivion of where I was, and of every other sublunary concern."

About half a mile below the cataract, the Nile is confined between two rocks, where it runs in a narrow channel with impetuous velocity and great noise. At the village of Alata there is a bridge over it, consisting of one arch, and that no more than 25 feet wide. This bridge is strongly fixed into the solid rock on both sides, and some part of the parapets still remain. No crocodiles come to Alata, nor are any ever seen beyond the cataract.

Below this tremendous water-fall the Nile takes a south east direction, along the western side of Begemder and Amhara on the right, enclosing the province of Gojam. It receives a great number of streams from both sides, and after several turns takes at last a direction almost due north, and approaches within 62 miles of its source. Notwithstanding the vast increase of its waters, however, it is still fordable at some seasons of the year; and the Galla crosses it at all times without any difficulty, either by swimming, or on goats’ skins blown up like bladders. It is likewise crossed on small rafts, placed on two skins filled with sand; or by twirling their hands round the tails of the horses which cross over; a method always used by the women who follow the Abyssinian armies, and are obliged to cross unfordable rivers. In this part of the river crocodiles are met with in great numbers; but the superstitious people pretend they have charms sufficiently powerful to defend themselves against their voracity. The Nile now seems to have forced its passage through a gap in some very high mountains which bound the country of the Ganges, and falls down a cataract of 280 feet high; and immediately below this are two others, both of very considerable height. These mountains run a great way to the westward, where they are called Dyre or Taka, the eastern end of them joining the mountains of Kueira, where they have the name of Fazuelo. These mountains, our author informs us, are all inhabited by Pagan nations: but the country is less known than any other on the African continent. There is plenty of gold washed down from the mountains by the torrents in the rainy season; which is the fine gold of Sennar named Tekar.

The Nile, now running close by Sennar in a direction nearly north and south, makes afterwards a sharp turn to the east, affording a pleasant view in the far distance, when it is brim-full, and indeed the only ornament of that bare and inhospitable country. Leaving Sennar, it passes by many large towns inhabited by Arabs, all of them of a white complexion; then passes over Geri, and turning to the north-east, it joins the Tacazze, falling during its course through this country,
try a large and populous town named Chenbi, probably the Candare of the ancients. Here Mr Bruce supposes the ancient island or peninsula of Meroe to have been situated. Having at length received the great river Atbara, the Affarobas of the ancients, it turns directly north for about two degrees; then making a very unexpected turn west by south for more than two degrees in longitude, and winding very little, it arrives at Korti, the first town in Barabra, or kingdom of Dongola. From Korti it runs almost south-west till it passes Dongola, called also Byja, the capital of Barabra; after which it comes to Mocho, a considerable town and place of refreshment to the caravans when they were allowed to pass from Egypt to Ethiopia. From thence turning to the north, it meets with a chain of mountains in about 22° 15' of N. latitude, where is the seventh cataract named Jan Ada. This is likewise very tremendous, though not above half as high as that of Ataka. This course is now continued till it falls into the Mediterranean; there being only one other cataract in the whole space, which is much inferior to any of those already described.

This very particular and elaborate account of the sources of the Nile and of the course of the river given by Mr Bruce, hath not escaped criticism. We find him accused by the reviewers, not only of having brought nothing to light that was not previously known to the learned, but even of having revealed nothing which was not previously published in Guthrie's Geographical Grammar. This, however, seems by no means a fair and candid criticism. If the sources of the Nile, as described by Mr Bruce, were known to the author of Guthrie's Grammar, they must likewise have been fo to every retailer of geography since the time of the millionaries; which, as the reviewers have particularized that book, would not seem to have been the case. If any thing new was pretended by them in respect of Mr Bruce's work, it must probably have been derived indirectly from himself; of which clandestine method of proceeding that gentlemen have had frequent occasion to complain in other cases. It is alleged, however, that he has given the name of Nile to a stream which does not deserve it. This, like all other large rivers, is composed of innumerable branches; to visit the top of every one of which would be indeed an Herculean task. The source of the largest branch therefore, and that which has the longest course, is undoubtedly to be accounted the source of the river; but here it is denied that Mr Bruce had sufficient information. "Of the innumerable streams (say they) that feed the lake of Tzana, there is one that ends in a bog, to which Mr Bruce was conducted by Woldo, a lying guide, who told him it was the source of the Nile. Mr Bruce, in a matter of far less importance, would not have taken Woldo’s word; but he is persuaded, that in this case he spoke truth; because the credulous barbarians of this neighbouring district paid something like worship to this brook, which, at the distance of 14 miles from its source, is not 20 feet broad, and nowhere one foot deep. Now it is almost unnecessary to observe, that the natives of that country being, according to Mr Bruce's report, pagans, might be expected to worship the pure and solitary stream; to which, with other extraordinary qualities, their superstition ascribed the power of curing the bite of a mad dog. Had he traced to its source any of the other rivulets which run into the lake Tzana, it is not unlikely that he might have met with similar instances of credulity among the ignorant inhabitants of its banks. Yet this would not prove any one of them in particular to be the head of the Nile. It would be trifling with the patience of our readers to say one word more on the question, whether the Portuguese Jesuits or Mr Bruce discovered what they erroneously call the head of the Nile. Before either they or he had indulged themselves in vain triumphs over the labours of antiquity, they ought to have been sure that they had effectually shewn that antiquity was unable to accomplish. Now the river described by the Jesuit Kircher, who collected the information of his brethren, as well as by Mr Bruce, is not the Nile of which the ancients were in quest. This is amply proved by the prince of modern geographers, the incomparable D'Anville (at least till our own Rennell appeared), in a copious Memoir published in the 26th volume of the Memoirs of the Academy of Dijtis Lettes, p. 45.

To this learned dissertation we refer our readers; adding only what seems probable from the writings of Dirodorus Siculus and Herodotus, that the ancients had two meanings when they spoke of the head or source of the Nile; First, Literally, the head or source of that great western stream now called the White River; which contains a much greater weight of water, and has a much longer course than the river described by the Jesuits and by Mr Bruce; and, 2dly, Metaphorically, the cause of the Nile's inundation. This cause they had discovered to be the tropical rains, which in the extent of 15 degrees on each side of the line; which made the Sacerdote of Minerva's temple of Sais in Egypt tell that inquisitive traveller Hero- dotus, that the waters of the Nile run in two opposite directions from its source, the one north into Egypt, the other south into Ethiopia; and, on the reports of all travellers into Africa serve to explain and confirm this observation. The tropical rains, they acknowledge, give rise to the Nile and all its tributary streams which flow northward into the kingdom of Sennaar, as well as to the Zeboe, and so many large rivers which flow south into Ethiopia; and then, according to the inclination of the ground, fall into the Indian or Atlantic Ocean. Such then, according to the Egyptian priests, is the true and philosophical source of the Nile; a source discovered above 3000 years ago, and not, as Mr Bruce and the Jesuits have supposed, the head of a paltry rivulet, one of the innumerable streams that feed the lake Tzana."

On this severe criticism, however, it is obvious to remark, that if the source of the Nile had been discovered so many years ago, there is not the least probability that the finding of it should have been deemed an impossible undertaking, which it most certainly was, by the ancients. —That the finding out the fountain of the river itself was an object of their inquiry cannot be doubted; and from the accounts given by Mr Bruce, it appears very evident that none of the ancients had equal success with himself; though indeed the Jesuits, as has already been observed, seem to have a right to dispute it with him. From the correspondence of his accounts with that of the Jesuits, it
The Nile, which flows into the lake Tzana takes its rise from the fountain of Geeth already described; and that it is the most considerable plainly appears from its stream being visible through the whole breadth of the lake, which is not the case with any of the rest. The preference given to this stream by the Agows, who worship it, seems also an incontestible proof that they look upon it to be the great river which passes through Ethiopia and Egypt; nor will the argument of the Reviewers hold good in supposing that other streams are worshipped, unless they could prove that they are so. As little can it be any objection or disparagement to Mr Bruce’s labours, that he did not discover the sources of the western branch of the Nile called the White River. Had he done so, it might next have been objected that he did not visit the springs of the Tacazze, or any other branch. That the origin of the White River was unknown to the ancients may readily be allowed; but so were the fountains of Geeth, as evidently appears from the erroneous position of the sources of the eastern branch of the Nile laid down by Ptolemy. Our traveller, therefore, certainly has the merit, if not of discovering the sources, at least of confirming the accounts which the Jesuits have given of the sources, of the river called the Nile; and of which the White River, whether greater or smaller, seems to be accounted only a branch. The superior veneration paid to the eastern branch of this celebrated river will also appear from the variety of names given to it, as well as from the import of these names; of which Mr Bruce gives the following account.

By the Agows it is named Cisir, Cisofa, or Scir; the first of which terms signifies a god. It is likewise named As, father; and has many other names, all of them implying the most profound veneration. Having descended into Gojam it is named Abay; which, according to Mr Bruce, signifies the river that suddenly swells and overflows periodically with rain. By the Gongas on the south side of the mountains Dhre and Tagle, it is called Dabbi, and by those on the north side Konofa; both of which names signify a washing dog, the laterator anus, or dog bar. In the plain country between Fazurolo and Sennar it is called Nile, which signifies blue; and the Arabs interpret this name by the word Aserge; which name it retains till it reaches Halasa, where it receives the White River.

Formerly the Nile had the name of Sefir, both before and after it enters Beja, which the Greeks imagined was given to it on account of its black colour during the inundation; but Mr Bruce assures us that the river has no such colour. He affirms, with great probability, that this name in the country of Beja imports the river of the dog bar, on whose vertical appearance this river overflows; “and this idolatrous worship (says he) was probably part of the reason of the question the prophet Jeremiah asks: And what hast thou to do in Egypt to drink the water of Sefir, or the water profaned by idolatrous rites?” As for the first, it is only the translation of the word laber applied to the Nile. The inhabitants of the Barabara to this day call it Bahar el Nih, or the sea of the Nile, in contradistinction to the Red Sea, for which they have no other name than Bahar el Moleb, or the Salt Sea. The junction of the three great rivers, the Nile flowing on the west side of Merowe; the Tacazze, which washes the east side, and joins the Nile at Maggiran in N. Lat. 17°; and the Mareb, which falls into this last somethings above the junction, gives the name of Triton to the Nile.

The name Egypt, which it has in Homer, and which our author supposes to have been a very ancient name even in Ethiopia, is more difficult to account for. This has been almost universally supposed to be derived from the black colour of the inundation; but Mr Bruce, for the reasons already given, will not admit of this. “Egypt” (says he) in the Ethiopia is called Gipt, Agar; and an inhabitant of the country, Gypt, for precisely so it is pronounced; which means the country of ditches or canals, drawn from the Nile on both sides at right angles with the river: nothing surely is more obvious than to write y Gipt, so pronounced, Gyet; and, with its termination y or os, Egyptus. The Nile is also called Kronides, Jupiter; and has had several other appellations bestowed upon it by the poets; though these are rather of a transitory nature than to be ranked among the ancient names of the river. By some of the ancient fathers it has been named Geon; and by a strange train of miracles they would have it to be one of the rivers of the terrestrial paradise; the same which is said to have encompassed the whole land of Cufh or Ethiopia. To effect this, they are obliged to bring the river a great number of miles, not only under the earth, but under the sea also; but such reveries need no refutation.”

Under the article Egypt we have so fully explained the cause of the annual inundation of the Nile, that, with regard to the phenomena itself, nothing further seems necessary to be added. We shall therefore only extract from Mr Bruce’s work what he has said concerning the mode of natural operation by which the tropical rains are produced; which are now universally allowed to be the cause of the annual overflowing of this and other rivers.

According to this gentleman, the air is so much relieved by the sun during the time that it remains almost stationary over the tropic of Capricorn, that the other winds loaded with vapours rush in upon the land from the Atlantic ocean on the west, the Indian ocean on the east, and the cold Southern ocean beyond the Cape. Thus a great quantity of vapour is gathered, as it were, into a focus; and as the same causes continue to operate during the progress of the sun northward, a vast train of clouds proceeds from south to north, which, Mr Bruce informs us, are sometimes extended much farther than at other times. Thus he tells us, that for two years some white dappled clouds were seen at Gondar on the 7th of January; the sun being then 34° distant from the zenith, and not the least cloudy speck having been seen for several months before. About the first of March, however, it begins to rain at Gondar, but only for a few minutes at a time, in large drops; the sun being then about 5° distant from the zenith. The rainy season commences with violence at every place when the sun comes directly over it; and before it commences at Gondar, green boughs and leaves appear floating in the Baharrel Abaid, or
Nile or White River, which, according to the accounts given by the Galla, our author supposes to take its rise in about 5° north latitude.

The rains therefore precede the sun only about 5°; but they continue and increase after he has passed it. In April all the rivers in the southern parts of Abyssinia begin to swell, and greatly augment the Nile, which is now also farther augmented by the vast quantity of water poured into the lake Tzana. On the first days of May, the sun passes the village of gerri which is the limit of the tropical rains; and it is very remarkable, that though the sun still continues to operate with unabated vigour, all his influence cannot bring the clouds farther north than this village; the reason of which Mr Bruce, with great reason, supposes to be the want of mountains to the northward.

In confirmation of this opinion, he observes, that the tropical rains stop at the latitude of 14° instead of 16° in the western part of the continent. All this time, however, they continue violent in Abyssinia; and in the beginning of June the rivers are all full, and continue so while the sun remains stationary in the tropic of Cancer.

This extensive rain, which would sweep off the whole soil of Egypt into the sea were it to continue without intermission, begins to abate as the sun turns southward; and on his arrival at the zenith of each place, on his passage towards that quarter, they cease entirely; the reason of which is no less difficult to be discovered than that of their coming on when he arrives at the zenith in his passage northward. Be the reason what it will, however, the fact is certain; and not only so, but the time of the rains ceasing is exact to a single day; inomuch, that on the 25th of September the Nile is generally found to be at its highest at Cairo, and begins to diminish every day after. Immediately after the sun has passed the line, he begins the rainy reason to the southward; the rains constantly coming on with violence as he approaches the zenith of each place; but the inundation is now promoted in a different manner; according to the difference of circumstances in the situation of the places. From about 6° S. lat. a chain of high mountains runs all the way along the middle of the continent towards the Cape of Good Hope, and intercepts the southern part of the peninsula nearly in the same manner that the Nile does the northern. A strong wind from the south, stopping the progress of the condensed vapours, dashes them against the cold summits of these ridges of mountains, and forms many rivers, which escape in the direction either of east or west as the level prevails itself. If this is towards the west, they fall down the sides of the mountains into the Atlantic, and if on the east into the Indian ocean.—

The clouds (says Mr Bruce), drawn by the violent action of the sun, are condensed, then broken, and fall as rain on the top of the high ridges, and swell every river; while a wind from the ocean on the east blows like a monsoon up each of these streams, in a direction contrary to their current, during the whole time of the inundation; and this enables breezes to ascend into the western parts of Saffa, and the interior country to the mountains, where lies the gold. The same effect, from the same cause is produced on the western side towards the Atlantic; the high ridge of mountains being placed between the different countries west and east; is at once the source of their riches, and of those rivers which conduct to the treasures, which would otherwise be inaccessible, in the eastern parts of the kingdoms of Benin, Congo, and Angola.

"There are three remarkable appearances attending the inundation of the Nile. Every morning in Abyssinia is clear, and the sun shines. About nine a small cloud not above four feet broad, appears in the east, whirling violently round as if upon a staff; but arrived near the zenith, it first abates its motion, then loses its form, and extends itself greatly, and seems to call up vapours from all the opposite quarters. These clouds having attained nearly the same height, rush against each other with great violence, and put me always in mind of Elitha foretelling rain on mount Carmel. The air impelled before the heaviest mists, or invincible mover, makes an impression of its form on the collection of clouds opposite; and the moment it has taken possession of the space made to receive it, the most violent thunder possible to be conceived instantly follows; with rain; after some hours the sky again clears, with a wind at north; and it is always disagreeably cold when the thermometer is below 63°.

"The second thing remarkable is the variation of the thermometer. When the sun is in the southern tropic, 36° distant from the zenith of Gondar, it is seldom lower than 72°; but it falls to 66°, and 63° when the sun is immediately vertical; so happily does the approach of rain compensate the heat of a too searing sun.

"The third is that remarkable stop in the extent of the rain northward, when the sun, that has conducted the vapours from the line, and should seem now more than ever to be in possession of them, is here over-ruled suddenly; till, on its return to Gorri, again it resumes the absolute command over the rain, and reconciles it to the Lines, to furnish distant deluges to the southward."

With regard to the Nile itself, it has been said that the quantity of earth brought down by it from Abyssinia is so great, that the whole land of Egypt is produced from it. This question, however, is discussed under the article Egyt, where it is shown that this cannot possibly be the case.—Among other authorities there quoted was that of Mr Volney, who strenuously argued against the opinion of Mr Savary and others, who have maintained that Egypt is the gift of the Nile. Notwithstanding this, however, we find him asserting that the soil of Egypt has undoubtedly been augmented by the Nile: in which case it is not unreasonable to suppose that it has been produced by it altogether.—"The reader (says he) will conclude, doubtless, from what I have said, that writers have flattered themselves too much in supposing they could fix the precise limits of the enlargement and rise of the Egyt. But, though I would reject all illusory circumstances, I am far from denying the fact to be well founded; it is too plain from reason, and an examination of the country. The rise of the ground appears to be demonstrated by an observation on which little stress had been laid. In going from Rosetta to Cairo, when the waters are low, as in the month of March, we may remark, as we go up the river, that the shores rise gradually above the water; so that it overflowed

K. 2 two
two feet at Rosetta, it overflows from three to four
at Faona, and upwards of twelve at Cairo (A). Now
by reaoning from this fact, we may deduce the proof
of an increase by sediment; for the layer of mud be
ing in proportion to the thickness of the sheets of wa
ter by which it is deposited, must be more or less con
siderable as these are of a greater or less depth; and
we have seen that the like gradation is observable from
Asuan to the sea.

"On the other hand, the increase of the Delta man
difests itself in a striking manner, by the form of Egypt
along the Mediterranean. When we consider its figure
on the map, we perceive that the country which is in
the line of the river, and evidently formed of foreign
materials, has assumed a semicircular shape, and that
the shores of Arabia and Africa, on each side, have a
direction towards the bottom of the Delta; which ma
nifiely discovers that this country was formerly a
gulf, that in time has been filled up.

"This accumulation comes along all the rivers, and is
accounted for in the same manner in all: the rain wa
ter and the snow descending from the mountains into
the valleys, hurry incessantly along with them the earth
they wash away in their descent. The heavier
parts, such as pebbles and sands, soon settle, unless for
ced along by a rapid current. But when the waters meet
only with a fine and light earth, they carry away
large quantities with the greatest facility. The Nile,
meeting with such a kind of earth in Abyssinia and
the anterior parts of Africa, its waters are loaded and
its bed filled with it; and it is frequently so em bar­
sed, that it has a striking appearance similar to the
sea; and evidently formed of foreign materials. The
Delta, in the very same manner that others have
the anterior parts of Africa, its waters are loaded and
and the

water is driven along by a rapid

course. But when the inundation
refores to its natural energy, it drives the mud that has
accumulated towards the sea, at the same time that it brings
down more for the ensuing season; and this, arrived
at its mouth, heaps up, and forms shoals, where the
decay does not allow sufficient action to the cur­
nenent, and where the sea produces an equilibrium of
resistance. The stagnation which follows, occa
sions the groarser particles, which till then had floated, to
sink; and this takes place more particularly in those
places where there is least motion, as towards the shores,
till the sides become gradually enriched by the
spoils of the upper country and of the Delta itself:
for if the Nile takes from Abyssinia to give to the Theban,
it likewise takes from the Thebais to give to the Delta,
and from Delta to carry to the sea, Wherever its waters have a current, it depoils the land in a manner that it enriches. As we ascend towards Cairo, when the river is low, we may observe the banks
worn steep on each side and crumbling in large flakes.
The Nile, which undercuts them, depriving their
light earth of support, it falls into the bed of the ri
ver; for when the water is high, the earth imbibles
it; and when the sun and drought return, it cracks and
moulders away in great flakes, which are hurried along
by the Nile."

Thus does Mr Volney argue for the increase of the
Delta in the very same manner that others have
argued for the production of the whole country of
Egypt; an opinion which he is at great pains to
refute. Under the article Egypt, however, it is
shown that the Nile does not bring down any
quantity of mud sufficient for the purposes assigned
and with regard to the argument drawn from the
shallowness of the inundation when near the sea,
this does not prove any rise of the land; but, as Mr Ren
nel has judiciously observed in his remarks on the in
undation of the Ganges, arises from the nature of the
fluid itself. The reason, in short, is this; The surface
of the sea is the lowest point to which the waters of
every inundation have a tendency; and when they ar
rive there, they spread themselves over it with more
ease than anywhere else, because they meet with less
resistance. Their motion, however, by reason of the
small declivity, is less swift than that of the waters
farther up the river, where the declivity is greater;
and consequently the latter being somewhat impeded
in their motion, are in some degree accumulated. The
face of the inundation, therefore, does not form a
perfectly level plain, but one gradually sloping from the
anterior parts of the country towards the sea; so that
at the greatest distance from the ocean the water will
always be deeper, even if we should suppose the whole
country to be perfectly smooth, and composed of the
most solid materials.—This theory is easily under­
stood from observing a quantity of water running along a
wooden spout, which is always more shallow at the
end of the spout where it runs off than at the other.

With regard to Mr Volney's other arguments they
are without doubt contradictory; for if, as he says,
the river takes from Abyssinia to give to the Thebais,
from Thebais to give to the Delta, and from Delta to
the sea, it undoubtedly follows, that it gives nothing to
any part of the land whatever, but that altogether
is swept into the Mediterranean sea; which, indeed,
some very trifling quantities excepted, is most probably
the case.

It has been remarked by Mr Pococke, a very judi
cious traveller, that in the beginning of the in
undation, the waters of the Nile turn red, and sometimes
green; and while they remain of that colour, they are
unwholesome. He explains this phenomenon by sup­
poSing, that the inundation at first brings away that red
or green fluid which may be about the lakes where it
takes its rise; or about the sources of the small rivers
which flow into it, near its principal source; but
n says he, though there is so little water in the Nile
when at lowest, that there is hardly any current in
many parts of it, yet it cannot be supposed that the
water should stagnate in the bed of the Nile so as to
become green. Afterwards the water begins to be
red and still more turbid, and then it begins to be
wholesome."—This circumstance is explained by Mr
Bruce in the following manner. The country about
Narea and Caffa, where the river Abiad takes its rise,
is full of immense marshes, where, during the dry sea
fon, the water stagnates, and becomes impregnated
with every kind of corrupted matter. These, on the
commencement of the rains, overflow into the river
Abiad, which takes its rise there. The overflowing

(A) "It would be curious to ascertain in what proportion it continues up to Asouan. Some Copts, whom I
have interrogated on the subjects assured me that it was much higher through all the Said than at Cairo."
of the Nile partakes first carry the discoloured water into Egypt; after which follows that of the great lake Tzana, through which the Nile paves; which having been flagnated and without rain, under a fcorching fun for fix months, joins its putrid waters to the former. In Abyffinia alfo, there are very few rivers that run after November, but all of them stand in prodigious pools, which, by the heat of the fun, likewife turn putrid, and on the commencement of the rains throw off their flagnant water into the Nile; but at laft the rains becoming conflant, all this putrid matter is carried off, and the fources of the inundation become sweet and wholesome. The river then paffing thro' the kingdom of Sennaar, the foil of which is a red bole, becomes coloured with that earth; and this mixture, along with the moving sands of the deferts, of which it receives a great quantity when raifed by the winds precipitates all the viscid and putrid matter, which float in the waters; whence Mr Pocock, judiciously obferves, that the Nile is not wholesome when the water is clear and green, but when it red and turbid that it rains the water of the Mediterranean.

The rains in Abyffinia, which cease about the 8th of September, generally leave a fickly feafon in the low country; but the difeafes produced by these rains are removed by others which come on about the end of October, and cease about the 8th of November. On these rains depend the latter crops of the Abyffinians; and for thefe the Agows pray to the river, or the genius or fpirit reffiding in it. In Egypt, however, the effect of them is feldom perceived; but in fome years they prove exceflive; and it has been obferved that the Nile, after it has fallen, has again rifen in fuch a manner as to alarm the whole country. This is faid to have happened in the time of Cleopatra, when it was fuppofed to prefage the extinction of the government of the Ptolemies; and in 1737, it was likewife imagined to portend fome dreadful calamity.

The quantity of rain, by which all this inundation is occasioned, varies considerably in different years; at laft at Gonder, where Mr Bruce had an opportunity of measuring it. In 1770 it amounted to 355 inches; but in 1771 it amounted to no lefs than 414 inches; but the general quantity for the 8th of September. What our author fays concerning this variation of the rainy months, seems totally irreconcilable with what he had before advanced concerning the extreme regularity of the natural cafes by which the tropical rains are produced. In 1770 (fays he) August was the rainy month; in 1771, July. When July is the rainy month, the rains generally ceafe for fome days in the beginning of August, and then a prodigious deal falls in the latter end of that month and firft week of September. In other years July and August are the violent rainy months, while June is fair. And laftly, in others, May, June, July, August, and the firft week of September. If this is the cafe, what becomes of the regular attraction of the clouds by the fun as he advances northward; of the coming on of the rains when he arrives at the zenith of any place, in his paftage to the tropic of Cancer; and of their ceafing when he comes to the fame point in his return southward?

Under the article Ethileia we have mentioned a threat of one of the Abyffinian monarchs, that he would direct the course of the Nile and prevent it from fertilizing the land of Egypt; and it has likewise been related, that confiderable progres was made in this undertaking by another emperor. Mr Bruce has fowed an entire chapter on the fubje& and is of opinion, that "there feems to be no doubt that it is po{ible to diminish or divert the course of the Nile, that it fhould be insufficient to fertilize the country of Egypt; because the Nile, and all the rivers that run into it, and all the rains that swell thefe rivers, fall in a country two miles above the level of the sea; therefore, it cannot be denied, that there is level enough to divert many of the rivers into the Red Sea, or perhaps fill easier by turning the course of the river Abiad till it meets the level of the Niger, or pafs through the defart into the Mediterranean."—Alphonfo Albuquerque is faid to have written frequently to the king of Portugal to fend him pioneers from Madeira, with people accustomed to level grounds, and prepare them for sugar canes; by whose affiftance he meant to turn the Nile into the Red Sea. This undertaking, however, if it really had been projected, was never accom{plihed; nor indeed is there any probability that ever fuch a mad attempt was propofed. Indeed, though we cannot deny that there is a possibility in nature of accomplishing it, yet the vaf{ difficulty of turning the course of fo many large rivers may juftly fignumize it as impracticable; not to mention the obstacles which must naturally be fuggested from the apparent inutility of the undertaking, and which would arise from the opposition of the Egyptians.

It has already been obferved in a quotation from the Reviewers, that Herodotus was informed by the facrilan or fecretary of the treasury of Minerva, that one half of the waters of the Nile ran north and the other fouth. This is alfo taken notice of by Mr Bruce; who gives the following explanation of it, "The fecretary was probably of that country himself, and feems by his obfervation to have known more of it than all the ancients together. In fact we have feen, that between 13° and 14° north latitude, the Nile, with all its tributary freams, which have their rife and course within the tropical rains, falls down into the flat country (the kingdom of Sennaar), which is more than a mile lower than the high country in Abyffinia; and thence, with a little inclination, it runs into Egypt. Again, in latitude 9°, in the kingdom of Gingoio, the Zebee runs south or fouth-east into the Inner Ethiopia, as do alfo many other rivers, and, as I have heard from the natives of that country, empty themselves into a lake, as those on the north fide of the line do into the lake Tzana, thence distributing their waters to the eft and weft. These become the heads of great rivers, that run through the interior countries of Ethiopia (corresponding to the fouth-efl of Melinda and Momboro) into the Indian Ocean; whilft, on the weftward, they are the origin of the vaf{ freams that fall into the Atlantic, paffing through Benin and Congo, south-ward of the river Gambb and the Sierra-leona. In short, the periodical rains from the tropic of Capricorn to the line, being in equal quantity with those that fall between the line and the tropic of Cancer, it is plain, that if the land of Ethiopia flowed equally from the line southward and northward, the rains that would fall..."
The Nile, the one half north and the other half south; but as the ground from 5° north declines all southward, it follows, that the rivers which run to the southward must be equal to those that run northward, plus the rain that falls in the 5° north latitude, where the ground begins to slope to the southward; and there can be little doubt that this is at least one of the reasons why there are in the southern continent so many rivers larger than the Nile, that run both into the Indian and Atlantic Oceans."

From this account given to Herodotus, it has been supposed, by some writers on geography, that the Nile divides itself into two branches, one of which runs northward into Egypt, and one through the country of the negroes westward into the Atlantic ocean. This opinion was first broached by Pliny. It has been adopted by the Nubian geographer, urging in support of it, that if the Nile carried down all the rains which fall into it from Abyssinia, the people of Egypt would not be safe in their houfes. But to this Mr Bruce answers, that the waife of water in the burning deserts through which the Nile passes is so great, that unless it was supplied by another stream, the white river, equal in magnitude to itself, and which, rising in a country of perpetual rains, is thus always kept full, it never could reach Egypt at all, but would be lost in the sands, as is the case with many other very considerable rivers in Africa. "The rains (says he) are collected by the four great rivers in Abyssinia; the Mareb, the Bowiba, the Tacazze, and the Nile. All these principal, and their tributary streams, would, however, be absorbed, nor be able to pass the burning deserts, or find their way into Egypt; were it not for the White river, which having its source in a country of almost perpetual rains, joins to it a never-failing stream equal to the Nile itself."

We shall conclude this article with some account of the Agows who inhabit the country about the sources of the Nile. These, according to Mr Bruce, are one of the most confiderable nations in Abyssinia, and can bring into the field about 8000 horse and a great number of foot; but were once much more powerful than they are now, having been greatly reduced by the invasions of the Galla. Their province is no where more than 60 miles in length, or 30 in breadth; notwithstanding which they supply the capital and all the neighbouring country with cattle, honey, butter, wax, hides, and a number of other necesssary articles: whence it has been customary for the Abyssinian princes to exact a tribute rather than military service from them. The butter is kept from putrefaction during the long carriage by mixing it with a small quantity of a root somewhat like a carrot, which they call harnacc. It is of a yellow colour, and answers the purpuse perfectly well: which in that climate it is very doubtful if milk could do. The latter is besides used as money; being circulated instead of silver coin, and used as change for gold. Brides paint their feet, hands, and nails, with this root. A large quantity of the seed of the plant was brought into Europe by Mr Bruce.

The Agows carry on a considerable trade with the Shangalla and other black savages in the neighbourhood, exchanging the produce of their country for gold, ivory, horns of the rhinoceros, and some fine cotton. The barbarity and the wild disposition of both nations, however, render this trade much inferior to what it might be.

In their religion the Agows are great idolators, paying divine honours to the Nile, as has already been observed. Mr Bruce, who lodged in the house of the priest of the river, had an opportunity of becoming acquainted with many particulars of their devotion. He heard him address a prayer to the Nile, in which he styled it the "Most High God, the Saviour of the world." In this prayer he petitioned for seasonable rain, plenty of grass, and the preparation of a kind of serpents; deprecatting thunder also very pathetically. The most sublime and lofty titles are given by them to the spirit which they suppose to reside in the river Nile: calling it everlasting God, Light of the world, Eye of the World, God of Peace, their Saviour, and father of the Universe.

The Agows are all clothed in hides, which they manufacture in a manner peculiar to themselves. These hides are made in the form of a skin, reaching down to their feet, and tied about the middle with a kind of fætus. The people, however, when hungry, have not the skin made into a large double petticoat; one fold of which they turn back over their shoulders, fastening it with a brooch or skewer across their breast before, and the married women carry their children in it behind. The younger forts generally go naked. The women are marriageable at nine years of age, though they commonly do not marry till eleven: and they continue to bear children till 30, and sometimes longer. They are generally thin, and below the middle size, as well as the men. Barrenness is quite unknown among them.

The country of the Agows has a very elevated situation, and is of course to temperate that the heat may easily be borne, though little more than 10° from the equator. The people, however, are but short-lived; which may in part be owing to the oppression they labour under. This, according to Mr Bruce, is excessive. "Though their country (says he) abounds with all the necessaries of life, their taxes, demands, or girdle. The lower part of it resembles the lands, which they have been so great and frequent, that they are only the manufactures of the commodities they sell, to satisfy these constant exorbitant demands, and cannot enjoy any part of their own produce themselves, but live in penury and misery scarce to be conceived. We saw a number of women wrinkled and sun-burnt so as scarce to appear human, wandering about under a burning sun, with one and sometimes two children upon their backs: gathering the seeds of bent grass to make a kind of bread."

NILEMETER, or Niloscope, an instrument used among the ancients to measure the height of the water of the river Nile in its overflows. The word comes from nosos, Nile (and that from nos, "new," "now", "now," or, as some others will have it from nos, "I flow," and nos, "mad"), and metrē, "measure." The Greeks more ordinarily call it NILESTROMETER.

The nilometer is fixed, by several Arabian writers, to have been first set up, for this purpose by Joseph during his regency in Egypt; the measure of it
Nilometer, was 16 cubits, this being the height of the increase of the Nile, which was necessary to the fruitfulness of Egypt.

From the measure of this column, Dr Cumberland deduces an argument, in order to prove that the Jewish and Egyptian cubit were of the same length.

In the French king's library is an Arabic treatise on nilometers, intitled Neil jah al Nil; wherein are described all the overflows of the Nile, from the first year of the Hegira to the 875th.

Herodotus mentions a column erected in a point of the island Delta, to serve as a nilometer; and there is still one of the same kind in a mosque of the same place.

As all the riches of Egypt arise from the inundations of the Nile, the inhabitants used to supplicate them at the hands of their Serapis; and committed the most execrable crimes, as abominations, forsooth, of religion, to obtain the favour. This occasioned Constantine expressly to prohibit these sacrifices, &c. and to order the nilometer to be removed into the church; whereas, till that time, it had been in the temple of Serapis. Julian the apostate had it replaced in the temple, where it continued till the time of the great Theodosius.

The only rational and consistent account, however, which we have of the nilometer is given by the celebrated traveller Mr Bruce. "On the point of the island Rhodo, between Geera and Cairo, near the middle of the river, is a round tower inclosing a neat well or cistern lined with marble. The bottom of this well is on the same level with the bottom of the Nile, which has free access to it through a large opening like an embrasure. In the middle of the well rise a thin column of eight faces of blue and white marble; of which the foot is on the same plane with the bottom of the river. This pillar is divided into 20 pecks, of 22 inches each. Of these pecks the two lowermost are left, without any division, to stand for the quantity of sludge which the water deposits there. Two pecks are then divided, on the right-hand, into 24 digits each; then on the left, four pecks are divided into 24 digits; then on the right, four; and on the left another four; again, four on the right, which completes the number of 18 pecks from the first division marked on the pillar, each peck being 22 inches. Thus the whole marked and unmarked amounts to something more than 36 feet English.

On the night of St John, when, by the falling of the dew, they receive the rain-water from Ethiopia mixed with the Nile at Cairo, they begin to announce the elevation of the river, having then five pecks of water marked on the nilometer, and two unmarked for the sludge, of which they take no notice. Their first proclamation, supposing the Nile to have risen 12 digits, is 12 from 6, or it wants 12 digits to be filled. When it has risen three more, it is nine from six; and so on, till the whole is filled, when all the land of Egypt is fit for cultivation. Several canals are then opened, which convey the water into the defert, and hinder any further inundation on the fields. There is indeed a great deal of more water to come from Ethiopia; but were the inundation suffered to go on, it would not drain away enough to fit the land for tillage; and to guard against this misuse, the chief is the principal use of the nilometer, though the Turkifh government makes it an engine of taxation. From time immemorial the Egyptians paid, as tribute to the king, a certain proportion of the fruit of the ground; and this was annually ascertained by the elevation of the water on the nilometer, and by the measurement of the land actually overflowed. But the Saracen government, and afterwards the Turkifh, has taxed the people by the elevation alone of the water, without attending to its course over the country, or the extent of the land actually overflowed; and this tax is sometimes cruelly oppressive.

NIMBUS, in antiquity, a circle observed on certain medals, or round the heads of some emperors; answering to the circles of light drawn round the images of saints.

NIMEGUIEN, a large, handsome, and strong town of the Netherlands, and capital of Dutch Guelderland, with a citadel, an ancient palace, and several forts. It is noted for the peace concluded there in 1679. It has a magnificent town-house, and its inhabitants are greatly given to trade. It is seated on the Vahal or Wabar, between the Rhine and the Meaf. It is the utmost eastern boundary of the Netherlands. It contains two Dutch churches, a French Calvinift and a Lutheran church, five Popift, and several hospitals. It was once a Han's-town and an imperial city. It is now the seat of government, has a canal to Arnhem, and considerable trade to several parts of Germany: it trades also in fine beer brewing, fattening of cattle, and exporting of its butter, which is extremely good, into all the other provinces. It is in E. Long. 5°. 50. N. lat. 51°. 55.

NIMETULAHITES, a kind of Turkifh monks, so called from their founder Nimetulahi, famous for his doctrines and the austerity of his life.

NIMPO, a city and sea-port town of China, in the province of Chekiang. It is seated on the eastern sea of China, over against Japan. It is a city of the first rank, and stands at the confluence of two small rivers, which, after their union, form a channel that reaches to the sea, and is deep enough to bear vessels of 200 tons burden. The walls of Nimpo are 3000 paces in circumference, and are built with freestone. There are five gates, besides two water-gates for the passage of barges into the city; a tower lined with stones high, built of bricks; and a long bridge of boats, fastened together with iron chains, over a very broad canal. This city is commanded by a castle built on a very high rock, by the foot of which all vessels must necessarily pass. The Chinese merchants of Siam and Batavia go to this place yearly to buy silks, which are the finest in the empire. They have also a great trade with Japan, it being but two days sail from hence: thither they carry silks, stuffs, sugar, drugs, and wine; and bring back copper, gold, and silver.

NIMROD, the sixth son of Cush, and in all appearance much younger than any of his brothers: for Moses mentions the sons of Raamah, his fourth brother, before he speaks of him. What the sacred historian says of him is short; yet he says more of him than of any other of the posterity of Noah, till he comes to Abraham. He tells us, that "Nimrod began to be a mighty one in the earth," that he was
Nimrod, a "mighty hunter before the Lord," even to a proverb; and that the beginning of his kingdom was Babel, and Eresh, and Accad, and Cainah, in the land of Shinar.

From this account he is supposed to have been a man of extraordinary strength and valour. Some represent him as a giant; all consider him as a great warrior. It is generally thought, that by the words a mighty hunter, is to be understood, that he was a great tyrant; but some of the Rabbins interpret those words favourably, saying, that Nimrod was qualified by a peculiar dexterity and strength for the chase, and that he offered to God, the game which he took; and several of the moderns are of opinion, that this passage is not to be understood of his tyrannical oppressions, or of hunting of men, but of beasts. It must be owned, that the phrase before the Lord may be taken in a favourable sense, and as a commendation of a person's good qualities; but in this place the generality of expositors understand it otherwise.

Hunting must have been one of the most useful employments in the times just after the dispersion, when all countries were overrun with wild beasts, of which it was necessary they should be cleared, in order to make them habitable; and therefore nothing seemed more proper to procure a man esteem and honour in those ages, than his being an expert hunter. By that exercise, we are told, the ancient Persians fitted their kings for war and government; and hunting is still, in many countries, considered as one part of a royal education.

There is nothing in the short history of Nimrod which carries the least air of reproach, except his name, which signifies a rebel; and that is the circumstance which seems to have occasioned the injurious opinions which have been entertained of him in all ages. Commentators, being prejudiced in general, that the curse of Noah fell upon the posterity of Ham, and finding this prince stigmatized by his name, have interpreted every passage relating to him to his disadvantage. They represent him as a rebel against God, in persecuting the descendants of Noah to disobey the divine command to disperse, and in setting them to build the tower of Babel, with an impious design of healing heaven. They brand him as an ambitious usurper, and an inoffent oppressor; and make him the author of the adoration of fire, of idolatrous worship given to men, and the first perverter on the scope of religion. On the other hand, some account him a virtuous prince, who, far from advising the building of Babel, left the country, and went into Assyria, because he would not give his consent to that project.

Nimrod is generally thought to have been the first king after the flood; though some authors, supposing a plantation or dispersion prior to that of Babel, have made kings in several countries before his time. Misraim is thought by many who contend for the antiquity of the Egyptian monarchy, to have begun his reign much earlier than Nimrod; and others, from the uniformity of the languages spoken in Assyria, Babylonia, Syria, and Canaan, affirm those countries to have been peopled before the confusion of tongues.

The four cities Moses gives to Nimrod constituted a large kingdom in those early times, when few kings had more than one; only it must be observed, that possessions might at first have been large, and afterwards divided into several parcels; and Nimrod being the leader of a nation, we may suppose his subjects settled within those limits; whether he became possessed of those cities by conquest or otherwise, does not appear; it is most probable he did not build Babel, all the posterity of Noah seeming to have been equally concerned in that affair; nor does it appear that he built the other three, though the founding of them, and many more, with other works, are attributed to him by some authors. It may seem also a little strange, that Nimrod should be preferred to the regal dignity, and enjoy the most cultivated part of the earth then known, rather than any other of the elder chiefs or heads of nations, even of the branch of Ham.

It was considered on him for his dexterity in hunting; or, it may be, he did not assume the title of king till after his father Cush's death, who might have been seated there before him, and left him the sovereignty; but we incline to think, that he seized Shinar from the descendants of Shem, driving out Abur, who from thence went and founded Nineveh and other cities in Assyria.

The scripture does not inform us when Nimrod began his reign: Some date it before the dispersion; but such a conjecture does not seem to fit with the Mosaical history; for before the dispersion we read of no city but Babel; nor could there then be more, while all mankind were yet in a body together; but when Nimrod assumed the regal title, there seem to have been other cities; a circumstance which shows it was a good while after the dispersion. The learned writers of the Universal History place the beginning of his reign 30 years from that event, and in all likelihood it should be placed rather later than earlier.

Authors have taken a great deal of pains to find Nimrod in profane history; some have imagined him to be the same with Belus, the founder of the Babylonish empire; others take him to be Ninus, the first Assyrian monarch. Some believe him to have been Ezechous, the first Chaldean king after the deluge; and others perceive a great resemblance between him and Bocchus, both in actions and name. Some of the Mahometan writers suppose Nimrod to have been Zohak, a Persian king of the first dynasty; others contend for his being Cay Caus, the second king of the second race; and some of the Jews say he is the same with Arimatheus, the king of Shinar, mentioned by Moses. But there is no certainly in these conjectures, nor have we any knowledge of his immediate successors.

The scripture mentions nothing as to the death of Nimrod; but authors have taken care that such an event should not be wanting. Some of the rabbins pretend he was slain by Esau, whom they make his contemporary. There is a tradition that he was killed by the fall of the tower of Babel, which was overthrown by tempestuous winds. Others say, that as he led an army against Abraham, God sent a squadron of gnats, which destroyed most of them; and particularly Nimrod, whose brain was pierced by one of those insects.

Nine, the last of the radical numbers or characters; from the combination of which any definite number, however large, may be produced. "It is observed
NINEVEH, or Ninian, commonly called St Ninian, a holy man among the ancient Britons. He refided at or near a place called by Ptolemy Lucopolis, and by Bede Canida Rafa; but the English and Scotch called it Whitbar. We mention him, because he is said to have been the first who converted the Scots and Picts to the Christian faith; which he did during the reign of Theodorus the younger. Bede informs us, that he built a church dedicated to St Martin, in a style unknown to the Britons of that time; and adds, that during his time the Saxons held this province (Gallovitio now Galloway), and that, as in consequence of the labours of this saint the converts to Christianity increased, an Episcopal see was established there. Dr Henry, considering that "few or none of the writings of the most ancient fathers of the British church are now extant, and since little being said of them by their contemporaries, we can know little of their personal history and of the extent of their erudition," gives a short account of some of them. Of St Ninian he says, "he was a Briton of noble birth and excellent genius. After he had received as good an education at home as his own country could afford, he travelled for his further improvement, and spent several years at Rome, which was then the chief seat of learning as well as of empire. From thence he returned into Britain, and spent his life in preaching the gospel in the most uncultivated parts of it, with equal zeal and success."

There is a small town called St Ninian about a mile south of Stirling. Its church had been occupied by the rebels in 1745 as a powder-magazine; who on their return blew it up in such haste, as to destroy some of their own people and about fifteen poplars.

NING-po-rous, called by the Europeans Liamp, is
NIN

[ 82 ]

NIO

Ninon

an excellent port, on the eastern coast of China, opposite to Japan. Eighteen or twenty leagues from this place is an island called Teshou chun, where the English first landed on their arrival at China.

The silk manufactured at Ning-po are much esteemed in foreign countries, especially in Japan, where the Chinese exchange them for copper, gold, and silver. This city has four others under its jurisdiction, besides a great number of fortresses.

NINON LENCOIS, a celebrated lady in the court of France, was of a noble family, and born at Paris in the year 1619; but rendered herself famous by her wit and gallantry. Her mother was a lady of exemplary piety; but her father early inspired her with the love of pleasure. Having lost her parents at 14 years of age, and finding herself mistress of her own actions, she resolved never to marry: she had an income of 10,000 livres a year; and, according to the lefions she had received from her father, drew up a plan of life and gallantry, which she pursued till her death.

Never delicate with respect to the number, but always in the choice, of her pleasures, she sacrificed nothing to interest; but loved only while her taste for it continued; and had among her admirers the greatest lords of the court. But though she was light in her amours, she had many virtues. She was constant in her friendships, faithful to what are called the laws of honour, of strict veracity, disinterested, and more particularly remarkable for the exactitude of propriety. Women of the most respectable characters were proud of the honour of having her for their friend; at her house was an assemblage of every thing most agreeable in the city and its suburbs—there were not fewer than 400 men de Kous of sending their sons to that school of polite;

nons and good taste, that they might learn sentiments of honour and propriety, and those other virtues that render men amiable in society. But the illustrious Madame de Sevigne with great justness remarks in her letters, that this school was dangerous to religion and the Christian virtues; because Ninon Lenclos made use of seducing maxims, capable of depriving the mind of those invaluable treasures. Ninon was esteemed beautiful even in old age; and is said to have inspired violent passions at 80. She died at Paris in 1705. This lady had seven children: one of whom, named Chevalier de Villiers, occasioned much discourse by the tragical manner in which he ended his life. He became in love with Ninon, without knowing that she was his mother; and when he discovered the secret of his birth, flabb'd himself in a fit of despair. There have been published the pretended Letters of Ninon Lenclos to the marquis de Scevigne.

NINOTH, in music. See INTERVAL.

NINOUS, the first king of the Affyrians, was, it is said, the son of Belus. It is added, that he enlarged Nineveh and Babylon; conquered Zoroaster king of the Bafrians; married Semiramis of Afcaon; subdued almost all Asia; and died after a glorious reign of 52 years, about 1150 B.C.; but all these facts are uncertain. See SEMIRAMIS.

NIO, an island of the Archipelago, between Naxi to the north, Armago to the east, Santerino to the south, and Sikino to the west, and is about 35 miles in circumference. It is remarkable for nothing but Homer's tomb, which they pretend is in this island; for they affirm that he died here in his passage from Samos to Athens. This island is well cultivated, and not fo steep as the other islands, and the wheat which it produces is excellent; but oil and wood are scarce.

It is subject to the Turks. E. Long. 25. 53. N. Lat. 36. 45.

NIODE, (fab. hist.) according to the fictions of the poets was the daughter of Talantaus, and wife of Apollon king of Thebes by whom she had four sons and as many daughters. Having become fo proud of her fertility and high birth, as to prefer herself before Latona, and to flight the sacrifices offered up by the Theban matrons to that goddess, Apollo and Diana, the children of Latona, refented this contempt. The former flew the male children and the latter the female; upon which Ninon was struck dumb with grief, and remained without sensation. Cicero is of opinion, that on this account the poets feigned her to be turned into fione.

The story of Ninon is beautifully related in the fifth book of the Metamorphoses of Ovid. That poet thus describes her transformation into fione.

Widow'd and childles, lamentable fate! A doleful flight, among the dead the fat;Harden'd with woes, a statue of defpair,To ev'ry breath of wind unmov'd her hair;Her cheek's frill redd'nng, but its colour dead,Faded her eyes, and left within her head.No more her pliant grace, nor fair profpe,But flands congeal'd within her frozen lips.Stagnate and dull, within her purple veins,Its current brine'd, the lifeless blood remains;Her feet their usual offices refuse,Her arms and neck their graceful gueftures lose:Action and life from every part are gone,And ev'n her entrails turn to folid fione.Yet still she weeps; and whirrl'd by stormy winds, Borne thro' the air, her native country finds;There fix'd, she flands upon a bleaky hill;There yet her marble cheeks eternal tears difil.

Ninon in this statue is represented as in an ecclafy of grief for the los of her offspring, and about to be converted into fione herself. She appears as if deprived of all fenfation by the excess of her sorrow, and incapable either of shedding tears or of uttering any lamentations, as has been remarked by Cicero in the third book of his Tusculan Questions. With her right hand, she is putting the clasps one of her little daughters, who throws herself into her bosom: which attitude equally shows the ardent affection of the mother, and expreffes that natural confidence which children have in the protection of a parent. The whole is executed in such a wonderful manner, that this, with the other statues of her children, is reckoned by Pliny among the most beautiful works of antiquity: but he doubts to whom of the Grecian artists he ought to ascribe the honour of them (a). We have no certain information at what period

(a) Par hestatio in templo Apollinis foifani, Niobem cum liberis morientem, Scopas an Praxiteles fecerit.

The return was there, where distress cooperated with beauty, and where our pity met our love. Had he sought it one step farther in expression, he had lost it.

In the following epigram this statue is ascribed to Praxiteles:

Et Donum me Osci donem habui. Ex de ludite
Zonnt Praxiteles creatum esquenesse.

While for my children fate I vainly mourn'd,
The angry gods to malady stone me turn'd;
Praxiteles a nobler fate has done,
He made me live again from being stone.

The author of this epigram, which is to be found in the 3d book of the Anthologia, is unknown. See Lessig the father, in his Farrago Epigii antiquii, p. 172, ascribes it to Callimachus; but this appears to be only conjecture. Calligius Callagignus has made a happy translation of it into Latin.

Vroom olim in lapidem vertentur nominas; sed me
Praxiteli nonveam reddidit ex lapide.

And perhaps the following French version of it will appear no less happy:

De vivant que j'éois, les Dieux
M'ont changé en pierre mauvaise;
Praxitèle a fait beaucoup mieux,
De pierre il m'a vu rendre vie.

NIPHON, the largest of the Japan islands, being 600 miles long and 100 broad. See JAPAN.

NIPIERS, in the manage, are four teeth in the fore-part of a horse's mouth, two in the upper, and two in the lower jaw. A horse puts them forth between the second and third year.

NIPLIES, in anatomy. See there, n° 112.

NIPPLE-WORT, in botany. See LAPSEANA.

NISAN, a month of the Hebrews, answering to our March, and which sometimes takes from February or April, according to the course of the moon. It was the first month of the sacred year, at the coming out of Egypt (Exod. xii. 2), and it was the seventh month of the civil year. By Mofes it is called Abib.

The name Nifan is only since the time of Ezra, and the return from the captivity of Babylon.

On the first day of this month the Jews halted for the death of the children of Aaron (Lev. x. 1, 2, 3.) On the tenth day was celebrated a fast for the death of Miriam the sister of Mofes; and every one provided himself with a lamb for the passover. On this day the Israelites passed over Jordan under the conduct of Joshua (iv. 19.) On the fourteenth day in the evening they sacrificed the paschal lamb; and the day following, being the fifteenth, was held the solemn passover (Exod. xii. 18. &c.) The sixteenth they offered the sheaf of the ears of barley as the first-fruits of the harvest of that year (Levit. xxii. 9. &c.) The twenty-first was the octave of the passover, which was solemnized with particular ceremonies. The twenty-sixth the Jews fasted in memory of the death of Joshua. On this day they began their prayers to obtain the rains of the spring. On the twenty-ninth they called to mind the fall of the walls of Jericho.

NISSI PRIUS, in law, a judicial writ which lies in causes where the jury is impanelled and returned before the judges of the bank, by the parties requisits to have such a writ for the sake of the country, in order that the trial may come before the judges in the same county on their coming thither. The purport of a writ of nisi prius is, that the sheriff is thereby commanded to bring to Westminster the men impanelled, at a certain day, before the judges, nisi prius jubilari domini regis ad officias expendiat onerem.

NISIBIS (anc. geog.), a city both very ancient, very noble, and of very considerable strength, situated in a district called Mydonia, in the north of Mesopotamia, towards the Tigris, from which it is distant two days journey. Some ascribe its origin to Nimrod, and suppose it to be the Achad of Mofes. The Macedonians called it Antiochia of Mydonia (Flutarch; situated at the foot of Mount Mafaus (Strabo.) It was the Roman bulwark against the Parthians and Persians. It contained three memorable sieges against the power of Sapor, A.D. 388, 346, and 350; but the emperor Jovianus, by an ignominious peace, delivered it up to the Persians, A.D. 353.—A colony called Sepiim'a Nisibitana.—Another Nisibis, of Aria, (Ptolemy), near the lake Arias.

Mr Ives who passed through this place in 1758, tells us, that "it looked pretty at a distance, being seated on a considerable eminence, at the foot of which runs a river, formerly called the Mydonius, with a stone bridge of eleven arches built over it. Just by the river, at the foot of the hill, or hills (for the town is seated on two), begins the ruins of a once more flourishing place, which reaches quite up to the present town. From every part of this place the most delightful prospects would appear, were the soil but properly cultivated and planted; but instead of those extensive woods of fruit trees which Rawolf speaks of as growing near the town, not above thirty or forty straggling trees of any kind can be perceived; and instead of that great extent of arable land on which he dwells so much, nothing but a very inconsiderable number of acres are now remaining. The town itself is despicable, the streets extremely narrow, and the houses, even those which are the largest, of stone, are mean. It suffered grievously by the famine of 1757, losing almost all its inhabitants either by death or desertion. The streets presented many miserable objects, who greedily devoured kinds of cucumbers, and every other refuse article of food thrown out into the highway. Here the price of bread had risen near 4000 per cent. within the last 14 years.

NISMES, an ancient, large, and flourishing town of France, in Languedoc, with a bishop's see, and an academy. It has such a number of manufactures of cloth
cloth of gold and silk, and of stuffs formerly known by the name of serge of Nismes, as exceeds that of all the rest of the province. There are several monuments of antiquity, of which the amphitheatre is the principal, built by the Romans. The mausoleum, or the square-house, is a piece of architecture of the Corinthian order, and one of the finest in the world. The temple of Diana is in part gone to ruin. It was taken by the English in 1447. The inhabitants were all Calvinists; but Louis XIV. demolished their church in 1685, and built a castle to keep them in awe. It is seated in a delightful plain, abounding with wine, oil, game, and cattle. It contains a considerable remains of ancient woods; particularly that of Holywood, three miles from Dumfries, noted for an antique church, built out of the ruins of an ancient abbey; and also for being the birthplace of the famous astrologer, hence called Franès de Sorre Boffes. Mr. Pennant calls it a beautiful vale, improved in appearance by the boll curves of the meandering stream, and for some space, he says, is adorned with groves and gentlemen's seats.

NITOCRIS, the mother of Belihazzar (whom father was Evil Merodach and his grandfather Nebuchadnezzar), was a woman of extraordinary abilities; she took the burden of all public affairs upon herself; and while her son followed his pleasures, did all that could be done by human prudence to sustain the tottering empire. She perfected the works which Nebuchadnezzar had begun for the defence of Babylon; raised strong fortifications on the site of the river, and caused a wonderful vault to be made under it, leading from the old palace to the new, 12 feet high and 15 wide. She likewise built a bridge across the Euphrates, and accomplished several other works, which were afterwards ascribed to Nebuchadnezzar. Philostrates, in describing this bridge, tells us, that it was built by a queen, who was a native of Media; whence we may conclude this illustrious queen to have been by birth a Mede. Nisocris is said to have placed her tomb over one of the most remarkable gates of the city, with an inscription to the following effect:—

If any king of Babylon after me shall be in distress for money, he may open this sepulchre, and take out as much as may serve him; but if he be in no real necessity, let him forbear, or he shall have cause to repent of his presumption.

This monument and inscription are said to have remained untouched till the reign of Darius, who, considering the gate was useless, no man caring to pass under a dead body, and being invited by the hopes of an immense treasure, broke it open; but, instead of what he sought, is said to have found nothing but a corpse, and another inscription, to the following effect:—

Hadst thou not . . . . moat iniquitously arduous and greedy of the moat forbid gain, thou wouldst never have violated the above of the dead.

Niptraria, in botany: A genus of the monogyra order, belonging to the dodecandria class of plants; and in the natural method ranking under the 32d order, Pagiânâceæ. The calyx is quinquedentate; the capsule monospermous, and terminated by a ligulated wing.

Nithsdale, Nithsdale, or Niddisdale, a division of Dumfriesshire in Scotland, lying to the westward of Annandale. It is a large and mountainous tract, deriving its name from the river Nid, which issues from a lake called Loch cure, runs by the towns of Sanquhar, Morton and Dumlanrig, and discharges itself into the Solway Frith. This country was formerly shamed by noble forests, which are now almost destroyed; so that at present, nothing can be more naked, wild, and savage. Yet the bowels of the earth yield lead, and, as it said, silver and gold: the mountains are covered with sheep and black cattle; and here are still some considerable remains of the ancient woods: particularly that of Holywood, three miles from Dumfries, noted for an antique church, built out of the ruins of an ancient abbey; and also for being the birthplace of the famous astrologer, hence called Franès de Sorre Boffes. Mr. Pennant calls it a beautiful vale, improved in appearance by the boll curves of the meandering stream, and for some space, he says, is adorned with groves and gentlemen's seats.
mentioned is inhabited by young ladies of the first quality, who are not confined therein as in numeraries but may go out and marry whenever they see convenient, or a proper match offers. E. Long. 4. 20. N. Lat. 50°.15.

Nivelle de la Charité (Peter Claude), a comic poet, born in Paris; acquired great reputation by inventing a new kind of entertainment, which was called the voyage comique. Instead of imitating Aristophanes, Terence, Molier, and the other celebrated comic poets who had preceded him; and instead of exciting laughter by painting the different ridiculous characters, giving strokes of humour and absurdities in conduct; he applied himself to represent the weakness of the heart, and to touch and soften it. In this manner he wrote five comedies: 1. La sautée Antipathie. 2. Le Préjudice à la Mule; this piece met with great success. 3. Mélanide. 4. Amour pour Amour, and 5. L'École des Mères. He was received into the French academy in 1736; and died at Paris in 1753, at 63 years of age. He also wrote a tragedy, intituled, Maxiadiames; and an Epitome to Cito, an ingenious didactic poem.

NIVOIS, an inland province of France, with the title of a duchy, lying on the west side of Burgundy, and between it Bourbonnais and Barri. It is pretty fertile in wine, fruit and corn; except the part called Albion, as afo mines of iron; as also iron-mines; as afo mines of great number of rivers; except the part called Allier, the Loire, and the Yonne, are navigable. Nevers is the capital.

NIVÉGAL, in Pembrokehire, South Wales, a small village and beach on the coast, remark it only for the discovery of an immense quantity of the stumps of trees appearing below low-water-mark, after and during a storm in the year 1590, notwithstanding the country all round it is entirely barren of wood.

NIXAPA, a rich and considerable town in New Spain, with a rich convent of Dominicans. The country about it abounds in cochineal, indigo, and sugar. E. Long. 97°. 25. N. Lat. 15°. 20.

NIZAM (says Gibbons), one of the most illustrious ministers of the east, was honoured by the caliph as an oracle of religion and science; he was trusted by the caliph as the faithful viceroy of his power and justice. After an administration of 30 years, the fame of the vizir, his wealth and even his services, were transformed into crimes. He was overthrown by the infamous arts of a woman and a rival; and his fall was hastened by a rash declaration, that his cap and ink-horn, the badges of his office, were connected by the divine decree with the throne and diadem of the sultan. At the age of 93 years, the venerable statesman was dismissed by his master, accursed by his enemies, and murdered by a fanatic; the last words of Nizam attested his innocence, and the remainder of Malek's life was short and inglorious.

NO, (Jeremiah, Ezekiel), No-AMMON, (Nahum); a considerable city of Egypt, thought to be the name of an idol which agrees with Jupiter Ammon. The Septuagint translate the name in Ezekiel, Diospolis, "the city of Jupiter." Bochart takes it to be Thesee of Egypt; which, according to Strabo and Ptolemy, No-Man's-land was called Diospolis. Jerome, after the Chaldee paraphrase of Jonathan, supposes it to be Alexandria, named by way of anticipation; or an ancient city of that name is supposed to have flood on the spot where Alexandria was built.

No-Man's-Land, a space between the after part of the belfrey and the fore part of a ship's boat, when the said boat is flowed upon the booms, as in a deep-water vessel. Those booms are laid from the fore castle nearly to the quarter-deck, where their after-ends are usually sustained by a frame called the galpon, which consists of two strong posts, about six feet high, with a cross piece reaching from one to the other, athwart ships, and serving to support the ends of those booms, masts, and yards, which lie in reserve to supply the places of others carried away, &c. The space called No-Man's-land is used to contain any blocks, ropes, tackles, &c. which may be necessary on the forecastle. It probably derives this name from its situation, as being neither on the starboard nor larboard side of the ship, nor on the waist or forecastle; but, being situated in the middle, partakes equally of all those places.

NOAH, or NOS, the son of Lamech, was born in the year of the world 1556. Amidst the general corruption into which all mankind were fallen at this time, Noah alone was found to be just and perfect in his generation, walking with God. (Gen. vi. 9.) This extraordinary person having therefore found favour in the eyes of the Lord, and God seeing that all flesh had corrupted their ways, told Noah, that he was resolved to destroy mankind from the face of the earth, by a flood of waters; and not them alone, but all the heaths of the earth, and every creeping thing as well as the fowls of the air. (Ib. 7.) The Lord therefore directed Noah, as a means of preserving him and his family (for he had three sons, Shem, Ham, and Japheth, who were all married before the flood), to build an ark or vessel, of a certain form and size fitted to that end, and which might besides accommodate such numbers of animals of all sorts, that were liable to perish in the flood, as would be sufficient to preserve the several species, and again replenish the earth; together with all necessary provisions for them; all which Noah performed, as may be seen more particularly under the article Ark.

In the year of the world 1556, and in the second year of his age, Noah, by God's appointment, entered the ark, together with his wife, his three sons, their wives, and all the animals which God caused to come to Noah; and being all entered, and the door of the ark being shut upon the inside, the waters of the deluge began to fall upon the earth, and increased in such a manner, that they were fifteen cubits above the tops of the highest mountains, and continued thus upon the earth, for 150 days; so that whatever had life upon the earth, or in the air, was destroyed, except such as were with Noah in the ark. But the Lord remembering Noah, sent a wind upon the earth, which caused the waters to subside; so that upon the seventeenth day of the seventh month the ark rested on the mountains of Ararat; and Noah having uncovered the roof of the ark, and observing the earth was dry, he received orders from the Lord to come out of it, with all the ani-
Then he offered as a burnt sacrifice to the Lord one of all the pure animals that were in the ark; and the Lord accepted his sacrifice, and said to him, that he would no more pour out his curse upon the whole earth, nor any more destroy all the animals as he had now done. He gave Noah power over herbs and fruits of the earth; except only the blood, the use of which God did not allow him. He bid him increase and multiply, made a covenant with him, and God engaged himself no more to send an universal deluge upon the earth; and as a memorial of his promise he let his bow in clouds, to be as a pledge of the covenant he made with Noah. (Gen. ix.)

Noah being an husbandman, began now to cultivate the vine; and having made wine and drank thereof, he unwarily made himself drunk, and fell asleep in his tent, and happened to uncover himself in an indecent posture. Ham, the father of Canaan, having observed him in this condition, made himself sport with him, and acquainted his two brothers with it, who were without. But they, instead of making it a matter of sport, turned away from it, and going backwards they covered their fathers nakedness, by throwing a mantle over him. Noah awaking, and knowing what Ham had done, said, that Canaan the son of Ham should be accursed, that he should be a slave of slaves in respect of his brethren. It is thought he had a mind to spare the person of his son Ham, for fear the curse might light upon the other children of Ham, who had no part in this action. He cursed Canaan by a spirit of prophecy, because the Canaanites his descendants were after this to be rooted out from the Israelites. Noah added, Let the Lord, the God of Shem, be blessed, and let Canaan be the servant of Shem. And he was in effect, in the person of the Canaanites subdued by the Hebrews. Lastly, Noah said, Let God extend the peace of Japheth; let Japheth dwell in the tents of Shem, and let Canaan be his servant. This prophecy had its accomplishment, when the Grecians, and afterwards the Romans, being descended from Japheth, made a conquest of Asia, which was the portion of Shem.

But Noah lived yet after the deluge three hundred and fifty years; and the whole time of his life having been nine hundred and fifty years, he died in the year of the world 2006. He left three sons, Shem, Ham, and Japheth, of which mention is made under their several names; and according to the common opinion he divided the whole world amongst them, in order to repeople it. To Shem he gave Asia, to Ham Africa, and Europe to Japheth. Some will have it, that besides these three sons, he had several others. The fabulous Berossus gives him thirty, called Titans, from the name of their mother Tita. They pretend that the Teutons, or Germans, are derived from a son of Noah called Thubron. The false Methodus also makes mention of Jovithus or Joniceus, a pretended son of Noah.

St Peter calls Noah a preacher of righteousness (2 Peter ii. 5.) because before the deluge he was incessantly preaching and declaring to men, not only by his discourses, but by his unblameable life, and by the building of the ark, in which he was employed five score years, that the wrath of God was ready to pour upon them. But his preaching had no effect, since, when the deluge came, it found mankind plunged in their former enormities. Mat. xxiv. 37.)

Several learned men have observed that the Heathen confounded Saturn, Deucalion, Ogyges, the god Cœlus or Uranus, Janus, Prometheus &c. with Noah. The wife of Noah is called Norah by the Gnostics; and the fable of Deucalion and his wife Pyrrha is manifestly invented from the history of Noah.

The Rabbins pretend, that God gave Noah and his sons (all who are not of the chosen race of Abraham they call Noachide) certain general precepts, which contain, according to them, the natural right which is common to all men indifferently, and the observation of which alone will be sufficient to save them. After the law of Moses, the Hebrews would not suffer any stranger to dwell in their country, unless he would conform to the precepts of the Noachides.

In war they put to death without quarters, all that were ignorant of them. These precepts are feven in number.

The first directs that obedience be paid to judges, magistrates, and princes.

By the second, the worship of false gods, superition, and sacrilege, are absolutely forbidden.

The third forbids cursing the name of God, blasphemies, and false oaths.

The fourth forbids all incestuous and unlawful conjunctions, as sodomy, bestiality, and crimes against nature.

The fifth forbids the effusion of blood of all sorts of animals, murder, wounds, and mutilations.

The sixth forbids thefts, cheats, lying, &c.

The seventh forbids to eat the parts of an animal still alive, as was practised by some pagans.

To these the Rabbins have added some others; but what inclines us to doubt the antiquity of these precepts is, that no mention is made of them in Scripture, or in the writings of Josephus or Philo; and that none of the ancient fathers knew any thing of them.

NOB, a sacerdotal city of the tribe of Benjamin or Ephraim. St Jerom says, that in his time it was entirely destroyed, and that the ruins of it might be seen not far from Diospolis. When David was driven away by Saul, he went to Nob, and asked the high-priest Abimelech for some provisions and arms, the priest gave him the shew-bread which had been lately taken off the holy table, and the sword of Goliath. Saul being informed of this by Doeg, caufed all the priests of Nob to be slain, and the city to be destroyed. 1 Sam. xxii.

NOBAH, a city beyond Jordan. It took the name of Nobah from an Israelite of this name who had made a conquest of it, (Numb. xxxiv. 42.) Gideon purified the Midianites as far as this city, (Judg. viii. 2.) Eusebius says, that there is a debate place of this name about eight miles from Hebron towards the south. But this could not be the Nobah now mentioned, because it was much farther to the north.

NOBILIARY, in literary history, a book containing
Nobility. taining the history of the noble families of a nation or province: such are Chorier's Nobility of Dupleine, and Cauwarm's Nobility of Provence. The Germans are said to be particularly careful of their Nobilities, in order to keep up the dignity of their families.

NOBILITY in general signifies dignity, grandeur, or greatness; more particularly it signifies antiquity of family, joined with riches; in the common acceptance of the word, it means that quality or dignity which raises a man above the rank of a peasant or a commoner.

At a time when the public mind is so much agitated on this subject, or subjects nearly allied to it, perhaps the less that is said on it the better. We should therefore (as far as concerns the question about its expediency in civil life, or the contrary) most cheerfully pass it over in silence, did we not esteem it our duty to give our readers at least some idea of it, and were it not our business to lay before them a few of those arguments which of late have been so copiously retailed both for and against this illusory order of civil society: leaving them, however, that liberty which every man unquestionably ought to be allowed, of judging for themselves as they shall see most proper.

Whether that equality of rank and condition which has of late been so loudly contended for would be more agreeable to the order of nature, or more conducive to the happiness and prosperity of mankind, may indeed be made a question; but it is a question, we apprehend which cannot receive different answers from men capable of reflecting without prejudice and partiality. A state of perfect equality can subsist only among beings possessing equal talents and equal virtues; but such beings are not men. Were all mankind under the confiant influence of the laws of virtue, a distinction of ranks would be unnecessary; but in that case civil government itself would likewise be unnecessary, because men would have attained all that perfection to which it is the object of civil government as well as of religion to guide them: every man then would be a law unto himself. But whilst, in so many breasts, the selfish passions predominate over those which are social, violence must be restrained by authority; and there can be no authority without a distinction of ranks, such as may influence the public opinion.

It is well observed by Hume, that government is founded not only on opinion; and that this opinion is of two kinds, opinion of interest, and opinion of right. When a people are persuaded that it is their interest to support the government under which they live, that government must be very stable. But among the worthies and unthinking part of the community, this persuasion has seldom place. All men, however, have a notion of rights—of a right to property and a right to power; and when the majority of a nation considers a certain order of men as having a right to that eminence in which they are placed, this opinion, call it prejudice or what we will, contributes much to the peace and happiness of civil society. There are many, however, who think otherwise, and imagine that the society in which the greatest equality prevails must always be the most secure. These men conceive it to be the business of a good government to distribute as equally as possible those blessings which humanity nature offers to all. It may readily be allowed that this reasoning is conclusive; but the great question returns, "How far can equality prevail in a society which is secure? and what is possible to be done in the equal distribution of the blessings of nature?" Till whose questions are answered, we gain nothing by deciding on the rights and equality of men; and the answers which have sometimes been given to them suppose a degree of perfection in human nature, which, if it were real, would make all civil institutions useless, as well as the revolutions of these reformers. The conduct of the democratic states of Pagan antiquity, together with the oppressive anarchy and shameful violence which we have seen and still see in a neighbouring kingdom, will be considered by many as a full and satisfactory answer, deduced from experience, to all the schemes of the visionary theorist: such facts at least render the abolition of the order of nobility a matter of more importance, and of infinitely greater difficulty, than those who plead for it are disposed to allow.

It is an opinion not uncommon, and at least plausible, that the nobility of a well regulated state is the best security against monarchical despotism or lawsless usurpation on the one hand, and the continuance of democratic intolerance on the other. Self-interest is the most powerful principle in the human breast; and it is obviously the interest of such men to preserve that balance of power in society upon which the very existence of their order depends. Corrupted as the present age confessedly is, a very recent instance could be given, in which the British House of Peers rescued at once the sovereign and the people from the threatened tyranny of a faction. As it is our business, however, to exhibit all opinions of any celebrity, we shall lay before our readers a short extract from Duveau's Critical History of the French Nobility, which contains, in few but forcible words, some of the common arguments against this distinction of ranks.

"Nobility (says he), a distinction equally impolitic and immoral, and worthy of the times of ignorance and of rapine, which gave it birth, is a violation of the rights of that part of the nation that is deprived of it; and as equality becomes a fiiiiue towards distinction, so on the other hand this is the radical vice of a government and the source of a variety of evils. It is almost impossible that there should be any uncommon instances of virtue in a state, when recompences belong exclusively to a certain class of society, and when it coasts them no more to obtain these than the trouble of being born. Amongst this list of privileged persons, virtues, talents, and genius, much of course is much less frequent than in the other classes, since, without the possession of any of these qualities, they who belong to it are still honoured and rewarded. Those who profit by this absurd subversion of principles, and those who lose by this unjust distribution of favours, which seem to have grown into a right, cannot have any other than false, immoral and pernicious ideas concerning merit." A perfect equality, however, in rank and fortune has seldom been contended for, except by the most ignorant enthusiasts. It is indeed doubtful whether:
it could possibly exist. The more moderate and rational reformers have acknowledged, that as these differences have always existed in some way or other, so, from the infinite variety of talents and attainments in the world, we have reason to expect they will exist in every form of government and among every people. The question, therefore, is reduced to this: Whether the present mode of distinction, or any other which could be instituted in its stead, be upon the whole the best? That the present is not perfect, or wholly without fault, few will be fanekme enough to contradict: and a wise man in the sober hour of philosophical reflection will scarce presume to assert, that any other scheme which human ingenuity can plan would be wholly without imperfection, or altogether free from error. The case is, the errors of our own system are present, and on this account we fee and feel them with peculiar force: the other plan we look forward to, perhaps in too fanciful a manner, and we probably forget, in the delusive heat of imagination, that if distinction depended entirely on merit, we should scarce find a society of men so honest, or so able, as always to reward it according to its deserts; or if this were possible, as perhaps in the nature of things it is not, such is the self-partiality of the generality of men, that few would think he were dealt justly by if he were not promoted as well as his neighbour; and it is clearly impossible to promote every one. For such reasons then, and many more which our limits oblige us to omit, many think (and we are inclined to think) that it is safer to remain as we are, as we know the evils that attend our situation, and are still able to bear them, rather than to hazard a change, which, with some benefits, might also perhaps increase the troubles, and destroy many of the pleasures, of social life.

Perhaps it may not be amiss to lay before our readers the following observations from that most judicious commentator on the laws of England, Mr Justice Blackstone, on this important subject.

"The distinction of rank and honours (says he) is necessary in every well-governed state, in order to reward such as are eminent for their services to the public, in a manner the most desirable to individuals, and yet without burden to the community: exciting thereby an ambitious, yet laudable ardour, and generous emulation, in others. And emulation, or virtuous ambition, is a spring of action which, however dangerous or invidious in a mere republic or under a despotic sway, will certainly be attended with good effects under a free monarchy; where, without detroying its existence, its excels may be continually restrained by that superior power from which all honour is derived. Such a spirit, when nationally diffused, gives life and vigour to the community; it sets all the wheels of government in motion, which, under a wise regulator, may be directed to any beneficial purpose; and thereby every individual may be made subservient to the public good, while he principally means to promote his own particular views. A body of nobility is also more peculiarly necessary in our mixed and compound constitution, in order to support the rights of both the crown and the people, by forming a barrier to withstand the encroachments of both. It creates and prefers that gradual scale of dignity, which proceeds from the peasant to the prince; rising like a pyramid from a broad foundation, and diminishing to a point as it rises. It is this ascending and contracting proportion that adds stability to any governments; for when the departure is sudden from one extreme to another, we may pronounce that state to be precarious. The nobility, therefore, are the pillars which are reared from among the people, more immediately to support the throne; and, if that falls, they must also be buried under its ruins. Accordingly, when in the last century the commons had determined to extirpate monarchy, they also voted the house of lords to be useless and dangerous. And since titles of nobility are thus expedient in the state, it is also expedient that their owners should form an independent and separate branch of the legislature. If they were confounded with a mass of the people, and like them had only a vote in electing representatives, their privileges would soon be borne down and overwhelmed by the popular torrent, which would effectually level all distinctions. It is therefore highly necessary that the body of nobles should have a distinct assembly, distinct deliberations, and distinct powers from the commons."—These remarks, at a time like the present, deserve our serious attention: nor do we suppose our readers will be displeased, if we add the following observations on the subject from a periodical publication of long standing and very considerable merit.

"Birth and nobility are a stranger obligation to virtue than is laid upon meaner persons. A vicious or diabolical nobleman is in effect prejurer; for his honour is his oath.

"Under the patriarchal scheme, and at the first settling out of the tribes, the heads of families had their particular escutcheons, and their genealogies recorded with the utmost exactness; even the Ancient of Days confirmed this: he often put his name on his son, who was, perhaps, the reason the family was named: but the family, administered by father and son, was in a manner the representative of the whole people; and the French are but little to be excused, if they add the following observations on the subject from a periodical publication of long standing and very considerable merit.

"The ancient Greeks and Romans paid great regard to nobility; but when the levelling principle obtained, and the people shared power and honour, those states soon dwindled and came to ruin. And in present Rome, great respect is paid to the renowned families of Colonna and Cestarii. In Venice, the notion of nobility is carried so high, as to become insufficient with a republican scheme. The Spaniards pay more regard to their old nobles than to their old Christians; and the French are but little behind them. What was said of the duke of Montmorency by Henry IV. "That he was a better gentleman than himself," was, perhaps, the reason why the last heir of so illustrious a family was cut off, to make the house of Bourbon..."
Nobility. Bourbon, the first in France.—The Welch, Irish, and Polanders, are remarkable for their attachments to blood and pedigree.

It is for the sake of the meanest of our people, that the high value and regard for quality should be kept up; for they are but governed by those who seem formed for power: the rule of authority suits easily upon them, and submission is as much our choice as our duty; but upstarts prove the worst of tyrants.

"The ancient legislators, who studied human nature, thought it advisable, for the better government of states, that the people should be divided into the noble and the common. They judged it for the universal good of mankind, that the valiant and the wise should be separated from the rest, and appointed for counsel and command.

"To this I take it that the institution of nobility is owing in all countries; even those nations which we are pleased to call savages, distinguish the wise and the valiant, obey them as counsellors, and commanders, which is placing them in the rank of nobles.

"Some, I know, look upon the institution of nobility to be one of the grossest impositions upon the common fende of mankind; they conceive, indeed, that no hereditary nobility; they allow, that those who have done the commonwealth any signal service should be distinguished with honours, but it seems an absurdity to them that a man should be born a legislator, as if wisdom or a knowledge of government run in the blood. But if they would consider how strongly the love of posterity is planted in human nature, they must allow that nothing can be a stronger motive to great and worthy actions, than the notion that a man's posterity will reap the honour and profit of his labours. Besides, we are to suppose that men born to honours and a high fortune may be bred up in generous sentiments, and formed for the station they are to fill; that they must be strangers to those vicious falsehoods and corruptions which necessity first, and then habit, puts men upon practising whose lives are spent in pursuit of their fortunes. I will own, notwithstanding all these advantages, that many of them are like rocks whose heads are in the clouds, but are barren, that they are quite incapable of producing anything; but in general, were their minds only upon a level with those of other men, we should expect better fruit from them.

"As authority is founded in opinion, all wise commonwealths have been extremely jealous in keeping up the honour of their nobility. Wherever they become base, effeminate, cowardly, or servile, their authority sinks, they fall into contempt; then the people begin to consider them as useless to government, and look upon their privileges as a grievance to society, and perhaps they think how to get rid of them, as happened in the commonwealth of Florence, where, after the expulsion of the duke of Athens, a petty tyrant of that city, many of the nobility having behaved servilely to him, and insolutely to the people, were degraded from the senate and the magistracy, and rendered incapable of holding any employment in the commonwealth.

"Father Paul, the Venetian, says, that you must either keep your nobility free from taint, or have no nobility at all: That the high employments of the commonwealth should be bestowed amongst the most ancient families, unless where a person should distinguish himself by some signal service to the state. Such a man would think himself sufficiently rewarded by the honour of being put upon a foot with the ancient nobility; and the nobility would be pleased to find that no commoner, except some of great reputation and merit, was to hold any of the employments usually poiffessed by their body. If the person so preferred should not be rich enough to support the dignity of the office, the state may give him a pension, but by no means should employments be made lucrative; which not only exhaust and weaken the commonwealth, but wherever the high employments are sought for profit, the nobility lose their generous sentiments, and it is a means of introducing corruption amongst them."

The origin of nobility in Europe is by some referred to the Goths; who, after they had seized a part of Europe, rewarded their captains with titles of honour, to distinguish them from the common people. We shall only in this place further consider the manner in which in our own country they may be created, and the incidents attending them; referring for a fuller account of their origin in Europe to the articles Revolution, and Society (Civil).

1. The right of peerage seems to have been originally territorial; that is, annexed to lands, honours, castles, manors, and the like; the proprietors and possessors of which were (in right of those estates) allowed to be peers of the realm, and were summoned to parliament to do suit and service to their sovereign: and, when the land was alienated, the dignity passed with it as appantant. Thus in England the bishops still sit in the house of lords in right of succession to certain ancient baronies annexed, or supposed to be annexed, to their episcopal lands; and thus in 11 Henry VI. the possession of the castle of Arundel was adjudged to confer an earldom on its possessor.

But afterwards, when alienations grew to be frequent, the dignity of peerage was confined to the individual of the party ennobled, and instead of territorial became personal. The creation of a tenure by barony became no longer necessary to constitute a lord of parliament; but the record of the writ of summons to him or his ancestors was admitted as a sufficient evidence of the tenure.

Peers of Great Britain are now created either by writ or by patent; for those who claim by prescription must suppose either a writ or patent made to their ancestors, though by length of time it is lost. The creation by writ, or the king's letter, is a summons to attend the house of peers, by the style and title of that barony which the king is pleased to confer: that by patent is a royal grant to a subject of any dignity and degree of peerage. The creation by writ is the more ancient way; but a man is not ennobled thereby, unless he actually take his seat in the house of lords; and some are of opinion that there must be at least two writs of summons, and a sitting in two distinct parliaments, to evidence an hereditary barony: and therefore the most usual, because the furest, way is to grant the dignity by patent, which endures to a man and his heirs.
N O B L E Y.

heirs according to the limitation thereof, though he never himself makes use of it. Yet it is frequent to call up the eldest son of a peer to the house of lords by writ of summons, in the name of his father’s barony; because in that case there is no danger of his children losing the nobility in case he never takes his seat; for they will succeed to their grandfather. Creation by writ has also one advantage over that by patent; for a peer created by writ holds the dignity to him and his heirs, without any words to that purpose in the writ; but in letters patent there must be words to that effect, or the dignity extends only to the grantee for life. For a man or woman may be created noble for their own lives, and the dignity not descend to their heirs at all, or descend only to some particular heirs; as where a peerage is limited to a man and the heirs male of his body by Elizabeth his present lady, and not to such heirs by any former or future wife.

2. Let us next take a view of a few of the principal incidents attending the nobility,—exclusive of their capacity as members of parliament and as hereditary counsellors of the crown, for both which we refer to the articles Lords and Parliament.

And first we must observe, that in criminal cases a nobleman shall be tried by his peers. The great are always obnoxious to popular envy: were they to be judged by the people, they might be in danger from the prejudice of their judges; and would moreover be deprived of the privilege of the meanest subjects, that of being tried by their equals, which is secured to all the realm by magna charta, c. 29. It is said, that this does not extend to bishops; who, though they are lords of parliament, and fit there by virtue of their baronies which they hold jure eclefsiae, yet are not ennobled in blood, and consequently not peers with the nobility. As to peeresses, no provision was made for their trial when accused of treason or felony, till after Eleanor duchess of Gloucester, wife to the lord protector, had been accused of treason, and found guilty of witchcraft, in an ecclesiastical synod, through the intrigues of Cardinal Beaufort. This very extraordinary trial gave occasion to a special statute, 20 Hen. VI. c. 9, which enacted, that peeresses, either in their own right or by marriage, shall be tried before the same judicature as peers of the realm. If a woman, noble in her own right, marries a commoner, she still remains noble, and shall be tried by her peers; but if she be only noble by marriage, then by a second marriage with a commoner she loses her dignity; for as by marriage it is gained, by marriage it is also lost. Yet if a duchess-dowager marries a baron, she continues a duchess still; for all the nobility are paries, and therefore it is no degradation. A peer or peeress (either in her own right or by marriage) cannot be arrested in civil cases: and they have also many peculiar privileges annexed to their peerage in the course of judicial proceedings. A peer sitting in judgment, gives not his verdict upon oath, like an ordinary jurymen, but upon his honour; he answers also to bills in chancery upon his honour, and not upon his oath: but, when he is examined as a witness in civil or criminal cases, he must be sworn; for the reflect which the law flows to the honour of a peer does not extend so far as to overturn a settled maxim, that in judicio non creditur nisi juratus. The honour of peers is however so highly tendered by the law, that it is much more penal to spread false reports of them, and certain other great officers of the realm, than of other men: scandal against them being called by the peculiar name of scandalum magnatum, and subjected to peculiar punishment by divers ancient statutes.

A peer cannot lose his nobility but by death or attainder; though there was an instance, in the reign of Edward IV. of the degradation of George Neville duke of Bedford by act of parliament, on account of his poverty, which rendered him unable to support his dignity. But this is a singular instance: which serves at the same time, by having happened, to show the power of parliament; and, by having happened but once, to show how tender the parliament hath been in exerting so high a power. It hath been said indeed, that if a baron waifes his estate, so that he is not able to support the degree, the king may degrade him: but it is expressly held by later authorities, that a peer cannot be degraded but by act of parliament.

Aton. Matthæus observes, that nobility, among the Romans, was a quite different thing from what it is among us. The nobles, among the Romans, were either those raised to the magistrature, or descended from magistrates: there was no such thing as nobility by patent.

Bartoli says, that doctors, after they have held a professor’s chair in a university for 20 years, become noble; and are intitled to all the rights of counts.

But this claim is not admitted at court, &c. though Bartoli’s sentiments be backed with those of several other authors, particularly Chaffaneus in his Constatudin. Burgundiae Beyer fur la Coutume de Berry; Faber C. de Dig. Def. 9. &c. which last, however, restrains Bartoli’s rule to doctors in law, and princes’ physicians.

By an edict of the French king in 1669, it is declared, that trade shall not derogate from nobility, provided the person do not sell by retail.

In Bretagne, by ancient custom, a nobleman looses nothing by trading even in retail: but he reassumes all his rights as soon as he ceases traffic, his nobility having slept all the time.

In Germany, a woman, not noble by birth, doth not become, v. gr. a countess or baroness by marrying a count or baron; a lady of the higher degree indeed becomes a princess by marrying a prince; but this doth not hold of a lady of the lower nobility.

On the coast of Malabar, children are only capable of being noble by the mother’s side; it being allowed them to take as many husbands as they please, and to quit them whenever they think good.

NOBLE, Nobilitas, a person who has a privilege which raises him above a commoner or peasant, either by birth, by office, or by patent from his prince. The word comes from the Latin nobilitas; formed from the ancient n'sibilis, “distinguisheable, remarkable.”

In England, the word noble is of a narrower import than in other countries; being confined to persons above the degree of knights; whereas, abroad, it comprehends not only knights, but what we firmly call gentlemen. The nobles of England are also called paries regni, as being nobilitatus parae, though gradu impares.

The Venetian nobilito is famous; it is in this that the
NOCERA [91]

Nocera, a town in Italy, in the dominions of the king of Naples and Sicily, or, as he is more commonly called, the king of the Two Sicilies. It is an ecclesiastical city, but might with greater propriety be styled a cluster of villages: its several parts being extended along the foot of the mountains, form the Città Sotana, or low town: and the bishop's palace, together with some convents embowered in cypress groves, cover the peak of a single hill in a very picturesque manner, and compose the Città Sopranza.

Nocera (A), it is reported, contains near 30,000 inhabitants; they are dispersed in forty patches of habitation. Their houses are constructed of two kinds of stone: the common walls are built with yellow tufa dug out of the hills that lie about a mile to the east of the town; which stone seems unquestionably to have been formed by a conflagration of substances thrown out of Vefuvius; because, opening these quarries, the workmen have frequently discovered tombs, vases and coins locked up in the body of the stone.

The cafes of their doors and windows are made of a black stone drawn from the hill of Fiana, two miles to the north; it lies eight feet below the surface, in a bed or vein 140 feet thick, resting upon a bale of sand. This seems evidently to be a stream of lava congealed.

Nocera is a place of very considerable antiquity: in the 13th century it was called de Pagni, to distinguish it from a city in Umbria of a similar name; this addition was in allusion to a colony of Saracens which Frederick of Subia brought from Sicily, and settled here, that they might be out of the way of their dangerous connections with Africa: hence Nocera has often been confounded with Lucera by the negligent or ignorant chroniclers of the succeeding ages. The most remarkable event that occurs in its history is the siege of its castle, A. D. 1384. E. Long. 12 55' N. L. 43 2'.

Terra Noceriana, Earth of Nocera, in the materia medica, a species of bole remarkably heavy, of a greyish white colour, of an infipid taste, and generally with some particles in it which grate between the teeth. It is much esteemed by the Italians as a remedy for venous bites, and in fevers; but, excepting as an absorbent and afflurment, no dependence is to be had on it.

NOCTAMBULI, Noctambulones, or Nightwalkers: a term of equal import with somnambuli, applied to persons who have a habit of raving and walking about in their sleep. The word is a compound of the Latin nos, "night," and ambulo, "I walk."

Schenkious, Horfius, Clauderus, and Hildanus, who have wrote of sleep, give us divers unhappy histories of such noctambuli. When the disease is moderate, the persons affected with it only repeat the actions of the day on getting out of bed, and go quietly to the places they frequented or at other times; but those who have it in the most violent degree, go up to dangerous places, and do things which would terrify them to think of when they are awake. These are some called lunatic night-walkers, because fits are observed to return with the most frequency and violence at the changes of the moon.—For the cure of these recommend purging and a cooling regimen: others are of opinion that the best method is to place a vessel of water at the patients bedside in such a manner that he will naturally step into it when he gets out of bed; or if that should fail, a perfon should sit up to watch and beat him every time it happens. See Sleep walkers, or Somnambuli.

NOCTILUCA, a species of phosphorus, so called because it flines in the dark without any light being thrown upon it: such is the phosphorous made of urine.

NOCTURNAL, something relating to the night, in contradistinction to diurnal.

NOCTURNAL, Noturblabium, an instrument chiefly used at sea to take the altitude or depression of some stars about the pole, in order to find the latitude and hour of the night. Some nocturnals are hemispheres, or planispheres,
on the plane of the equinoctial. Those commonly in use among seamen are two; the one adapted to the polar star, and the first of the guards of the Little Bear; the other to the pole star, and the pointers of the Great Bear.

This instrument consists of two circular plates, applied to each other. The greater, which has a handle to hold the instrument, is about 4½ inches diameter, and is divided into twelve parts, agreeing to the twelve months; and each month subdivided into every fifth day; and so as that the middle of the handle corresponds to that day of the year wherein the star has regained the same right attention with the sun. If the instrument be fitted for two flars, the handle is made moveable. The upper left circle is divided into twenty-four equal parts for the twenty-four hours of the day, and each hour subdivided into quarters. Those twenty-four hours are noted by the plane of the month on the under plate; and the hour 12 are diftinguished by their length. In the centre of the two circular plates is adjusted a long index, moveable upon the upper plate; and the three pieces, viz. the two circles and index, are joined by a river which is pierced through the centre with a hole, through which the star is to be observed.

To use the nocturnal, turn the upper plate till the long tooth, marked 12, be against the day of the month on the under plate; then, bringing the instrument near the eye, suspend it by the handle with the plane nearly parallel to the equinoctial; and viewing the pole star through the whole of the centre, turn the index about, till, by the edge coming from the centre, you see the bright star or guard of the Little Bear, (if the instrument be fitted to that star): then that tooth of the upper circle, under the edge of the index, is at the hour of the night on the edge of the hour circle: which may be known without a light, by counting the teeth from the first star, as well as the septuagint, and the Baptists, and all the Nephilites.

If the instrument be fitted for tow stars, the handle is made moveable. The upper left circle is divided into twenty-four equal parts for the twenty-four hours of the day, and each hour subdivided into quarters. Those twenty-four hours are noted by the plane of the month on the under plate; and the hour 12 are distinguished by their length. In the centre of the two circular plates is adjusted a long index, moveable upon the upper plate; and the three pieces, viz. the two circles and index, are joined by a river which is pierced through the centre with a hole, through which the star is to be observed.

To use the nocturnal, turn the upper plate till the long tooth, marked 12, be against the day of the month on the under plate; then, bringing the instrument near the eye, suspend it by the handle with the plane nearly parallel to the equinoctial; and viewing the pole star through the whole of the centre, turn the index about, till, by the edge coming from the centre, you see the bright star or guard of the Little Bear, (if the instrument be fitted to that star): then that tooth of the upper circle, under the edge of the index, is at the hour of the night on the edge of the hour circle: which may be known without a light, by counting the teeth from the first star, as well as the septuagint, and the Baptists, and all the Nephilites.

NOD, or the land of Nod. It was to this country that Cain withdrew after his fratricide. (Gen. iv. 16.) The septuagint, as well as Josephus, read Naab instead of Nod, and have taken it for the name of a place. It is not easily known what country this was, unless perhaps it was the country of Nyle or Nyfis, towards Hyrcania. St Jerom and the Chaldean interpreters have taken the word Nod in the sense of an appellative, far nágabond or fugitive; "He dwelt a fugitive in the land." But the Hebrew reads, "He dwelt in the land of Nod." (Gen. iv. 16.)

NODAB, a country bordering upon Iurea and Idumea, but now unknown. We read in the Chronicles, that the tribe of Reuben, afflicted by those of Gad and Manasséh, had a war against the Hagarites, the Jethrites, and the people of Naphthi and of Nodab, in which the Israelites had the advantage. 1 Chr. v. 19. But the time and the other particulars of this war are unknown.

NODATES, a name given by Sir Isaac Newton to a kind of hyperbola, which, by turning round, decussates or crosses itself.

NODDY. See STERNA.

NODE, a tumour arising on the bones, and usually proceeding from some venereal cause; being much the same: with what is otherwise called excoriis.

NODES, in astronomy, the two points where the orbit of a planet intersects the ecliptic.

Such are the two points C and D; of which the node C, where the planet ascends northward above the plane of the ecliptic, is called the ascending node, or the dragon's head, and is marked thus Q. The other node D, where the planet descends to the south, is called the descending node, or the dragon's tail, marked thus Q.

The line CD, wherein the two circles CEDF and CDGH intersect, is called the line of nodes. It appears from observation, that the line of the nodes of all the planets constantly changes its place, and shifts its situation from east to west, contrary to the order of the signs; and that the line of the moon's nodes, by a retrograde motion, finishes its circulation in the compass of 19 years; after which time, either of the nodes having receded from any point of the ecliptic, returns to the same again; and when the moon is in the node, she is also seen in the ecliptic. If the line of nodes were immovable, that is, if it had no other motion than that whereby it is carried round the sun, it would always look to the same point of the ecliptic, or would keep parallel to itself, as the axis of the earth does.

From what hath been said, it is evident, that the moon can never be observed precisely in the ecliptic, but twice in every period; that is, when the nodes enter the signs. When she is at her greatest distance from the nodes, viz. in the points E, F, she is said to be in her limits.

The moon must be in or near one of the nodes, when there is an eclipse of the sun or moon.

To make the foregoing account of the motion of the moon's nodes still clearer, let the plane of the sun's orbit still nearer the ecliptic, S the sun, T the centre of the earth, L the moon in her orbit DN d n. Na is the line of the nodes passing between the quadrature Q and the moon's place L, in her last quarter. Let now LP, or any part LS, represent the excess of the sun's action at T; and this being resolved into the force LR, perpendicular to the plane of the moon's orbit, and PR parallel to it, it is the former only that has any effect to alter the position of the orbit, and in this it is wholly exerted. Its effect is twofold: 1. It diminishes its inclination by a motion which we may conceive as performed round the diameter Dd, to which L T is perpendicular. 2. Being compounded with the moon's tangential motion at L, it gives it an intermediate direction Ll, through which and the centre a plane being drawn, must meet the ecliptic nearer the conjunction C than before.

NODUS, or node, in dialling, a certain point or pole in the gnomon of a dial, by the shadow or light whereof either the hour of the day in dials without furniture, or the parallels of the sun's declination, and his place in the ecliptic, &c. in dials with furniture, are shown. See DIALING.

NOEOMAGUS LEXUSIORUM, (Ptol.) thought to be the Civitas Leucuorium of the lower age. Now Lifieux, a city in Normandy. Another of the Tricesfini; a town of Gallia Narbonensis; thought to be S. Pol de Trois Chateaux, six miles to the west of Nyons in Dauphine.

NOETIANS, in church history, Christian heretics in
in the third century, followers of Noetus, a philosopher of Ephesus, who pretended that he was another Moses sent by God, and that his brother was a new Aaron. His hereby confessed in affirming that there was but one person in the Godhead; and that the Word and the Holy Spirit were but external denominations given to God in consequence of different operations; that, as Creator, he is called Father; as Incarnate, Son; and as defending on the apostles, Holy Ghost.

NOL, a very ancient city, formerly populous and flourishing, situated in a plain to the north-east of Vesuvius in Campania, said to be built by the Chaldaeans, (Julius, Silius Italicus); according to others, by the Tuscans. At this place Hannibal met with the first check by Marcellus. Veipsian added the appellation Augustus Colonia, (Frontinus). At this place, or in its neighbourhood, Augustus is said to have expired. It is also said that bells were first invented there in the beginning of the 5th century; hence their Latin names Nola or Campana. It retains its old name to this day, but it hath vastly fallen short of its ancient splendor. A town of the kingdom of Naples. L. Long. 15. N. Lat. 41.5.

NOLANA, in botany: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 41st order, Alpersfolia. The corolla is campanulated; the style situated between the germs; the seeds are bilocular, and resemble berries.

NOLLE PROSEQUI, is where a plaintiff in an action does not declare in a reasonable time; in which case it is usual for the defendant's attorney to enter a rule for the plaintiff to declare, after which a non prosequi may be entered. A non prosequi is deemed a voluntary confession, that the plaintiff has no cause of action; and therefore if a plaintiff enters his non prosequi, he shall be amerced; and if an informer cause the same to be entered, the defendant shall have costs.

NOLLET (Jean Antoine), a deacon, licentiate in theology, preceptor to the Enfons de France for physics and natural history, regius professor of physics in the college of Navarre, member of the academy of sciences at Paris, of the royal society of London, of the institution of Bologna, and of the academy of sciences of Erfurt; was born at Pimbré, in the diocese of Noyon, on the 17th of November 1700, of respectable but not wealthy parents. To make up the want of riches, they determined to give their son a good education. They sent him to the college of Clermont in Beauvais, and afterwards to Beauvais, there to finish his introductory studies. The prospects which he made in the different classes, determined them to send him to study philosophy at Paris. Thenceforward they intended him for the clerical order; and they considered the strictness and purity of his morals, together with his unwearied application to study, as sufficient proofs of his vocation. The young Nollet yielded without reluctance to the wishes of his parents. As soon as he was capable of showing an inclination for anything, he had discovered a taste for physics; but this was not become his ruling passion; he therefore sacrificed it to the study of scholastic divinity, to which he wholly dedicated himself during his time of probation in 1728. No sooner had he been invested with the deaconship, than he solicited and obtained a licence to preach. This new occupation, however, did not make him entirely lose sight of those studies which had first engaged his attention. They infinitively began to occupy a greater portion of his time, which was now more equally divided between theology and the sciences. The latter, however, prevailed; and thenceforth he entered into the study of physics with an ardour which was only increased by that kind of privation to which he had been long subject. He was received into the society of arts, established in Paris under the patronage of the late count de Clermont. In 1730, the Abbé Nollet was engaged in a work conjointly with Beaumur and du Fay of the academy of sciences. In 1734, he went to London in company with Mr. du Fay, du Hamel, and de Jussieu. His merit procured him a place in the royal society without any solicitation. Two years after, he went to Holland, where he formed an intimate connection with Delaiguilers, Graevenfæde, and Mitchel-tenbroek. On his return to Paris, he resumed the concern of experimental physics which he had begun in 1735, and which he continued till 1760. These courses of physics first suggested the idea of particular courts in other branches of science, such as in chemistry, anatomy, natural history, &c. In 1738, the count de Maurepas prevailed on the cardinal Fleury to establish a public class for experimental physics; and the Abbé Nollet was appointed the first professor. In the beginning of the year 1739, he was admitted a member of the royal academy of sciences; and in the month of April following, the king of Sardinia intending to establish a professorship of physics at Turin, invited the Abbé Nollet into his dominions. From thence he travelled into Italy. In 1744, he was honoured with an invitation from Verailles, to infruct the dauphin in experimental philosophy; the king and royal family were often present at his lectures. The qualities as well of his understanding as of his heart gained him the esteem and confidence of his pupils. Going one day in state to Paris, he caused intimation to be made that he was to dine at the Thulleries. M. Nollet having gone thither to pay his court, the dauphin no sooner perceived him, than he had the goodness to say, "Binet has the advantage of me, he has been at your house." Till the period of his death, this prince showed marks of the strongest attachment and favour for this ingenious philosopher. He would have wished that he had been a little more attentive to the improvement of his fortune. He prevailed upon him to go and pay court to a man in power, whose patronage might have been of service to him. The Abbé Nollet accordingly waited upon the placeman, and made him a present of his works. "I never read any works of that kind," said the patron coldly, and casting a look at the volumes before him. "Sir (replied the Abbé), will you all with them to remain in your antechamber? There perhaps may be found men of genius who will read them with pleasure." In the month of April 1749, he made a grand tour into Italy, being sent thither for the purpose of making observations. At Turin, Venice, and Bologna, the Abbé Nollet appeared as a deputy from the philosophers of the reign of Europe. During his short stay in Italy, the wonders of electricity were not the only object of his researches;
Nollet II

month of Saint Maurice, which he did not think proper to profess for the royal college of Navarre, and appointed the cation, having founded a class of experimental physics, by the discoveries with which he has enriched every branch of this science, but of the royal academy of sciences. Among those who were by no means abundant, on account of its unhealthy situation. W. Long. 78. 35. N. Lat. 9. 43.

NOMBRIL. Point, in heraldry, is the next below the chief, or the very center of the escutcheon.

NOME, or NAME, in algebra, denotes any quantity with a sign prefixed or added to it, whereby it is connected with some other quantity, upon which the whole becomes a binomial, trinomial, or the like. See Algebra.

NOMENCLATOR, in Roman antiquity, was usually a slave who attended upon persons that flood candidates for offices, and prompted or suggested to them the names of all the citizens they met, that they might court them and call them by their names, which among that people was the highest piece of civility.

Nomenclators, among the botanical authors, are those who have employed their labors about settling and adjusting the right names, synonyms, and etymologies of names, in regard to the whole vegetable world.

NOMENCLATURE, NOMENCLATURA, a catalogue of several of the more usual words in any language, with their significations, compiled in order to facilitate the use of such words to those who are to learn the tongue: such are our Latin, Greek, French, &c. Nomenclatures.

The chemical nomenclature has within these few years undergone a total change: we have given a table exhibiting these new names facing page 598 of Volume IV. At that time we were not convinced of the propriety of the new theory, nor was it possible to foresee that it would so soon obtain the approbation of the literary world. True philosophy requires, however, that we should readily change our opinions when we see sufficient grounds, for 

NOMEN, a name given, in antiquity, to several nations whose whole occupation was to feed and tend their flocks; and who had no fixed place to abide in, but were continually moving according to the conveniences of pasturage. The word comes from the Greek *nóm, nóm, nóm,* "a place.

The most celebrated among the Nomades were those of Africa, who inhabited between Africa, properly so called, to the eal, and Mauritania to the west. They are also called *Nomades, Nomadis.* Sallust says, they were a colony of Perians brought into Africa with Hercules.

The Nomades of Asia inhabited the coasts of the Caspian Sea. —The Nomades of Scythia were the inhabitants of Little Tartary; who still retain the ancient manner of living.

NOMARCHA, in antiquity, the governor or commander of a nome, or nomos. —Egypt was anciently divided into several regions or quarters, called *nomes,* from the Greek *néo,nóm,* taken in the sense of a division; and the officer who had the administration of each *nóm,* or nomos, from the king was called *nomarch,* from *ném, nomarch,* "commander.

NOMBRE-DOS, a town of Mexico, in the province of Darien, a little to the eastward of Porto-Bello. It was formerly a famous place; but it is now divided into two equal parts below the fide, the first of these divisions is the nombril, and the lower the base.

NOME, or NAME, in algebra, denotes any quantity with a sign prefixed or added to it, whereby it is connected with some other quantity, upon which the whole becomes a binomial, trinomial, or the like. See Algebra.

NOMENCLATOR, in Roman antiquity, was usually a slave who attended upon persons that flood candidates for offices, and prompted or suggested to them the names of all the citizens they met, that they might court them and call them by their names, which among that people was the highest piece of civility.

Nomenclators, among the botanical authors, are those who have employed their labors about settling and adjusting the right names, synonyms, and etymologies of names, in regard to the whole vegetable world.

NOMENCLATURE, NOMENCLATURA, a catalogue of several of the more usual words in any language, with their significations, compiled in order to facilitate the use of such words to those who are to learn the tongue: such are our Latin, Greek, French, &c. Nomenclatures.

The chemical nomenclature has within these few years undergone a total change: we have given a table exhibiting these new names facing page 598 of Volume IV. At that time we were not convinced of the propriety of the new theory, nor was it possible to foresee that it would so soon obtain the approbation of the literary world. True philosophy requires, however, that we should readily change our opinions when we see sufficient grounds, for to every human. In consequence of Lavolier's fyltem being become now so universally adopted, it becomes necessary for us to explain his principles at more length than was thought proper before. This we think our duty, and it therefore shall be our endeavour, in some part of the work, to introduce a sufficient analysis of the celebrated and now almost universally adopted fyltem.

NOMENEX, a town in Germany, in the duchy of Lorraine, situated on the river Seille, 15 miles north of Nancy.

NOMINALS, or NOMINALISTS, a sect of school-philosophers, the disciples and followers of Ockam, or Ocham, an English cordelier, in the 14th century. They were great dealers in words, whence they were vulgarly denominated Word-sellers; but had the denomination of Nominalists, because, in opposition to the Realists, they maintained, that words, and not things, were the object of dialectics.

This sect had its first rise towards the end of the 11th century, and pretended to follow Porphyry and Aristotle; but it was not till Ocham's time that they bore the name. The chief of this sect, in the 11th century, was a person called John, who, on account of his logical futility, was called the sophist; and his principal disciples were Robert of Paris, Rofcclin of Compeigne, and Arnoul of Laon. At the beginning, the nominals had the upper hand: but the realists, though greatly divided among themselves, were supported
N O N [ 9 5 ]

Ported by men of great abilities; such as Albertus Magnus, T. Aquinas, and Duns Scotus. The nominalists came thereby to disperse; till William Occam, in the 14th century, again revived it, and filled France and Germany with the flame of disputatation. Having joined the party of the Franciscan monks, who heretofore opposed John XXII. that pope himself, and his successors after him, no means were used to extirpate the philosophy of the nominalists, which was deemed highly prejudicial to the interests of the church; and hence it was, that, in the year 1339, the university of Paris, by a public edict, solemnly condemned and prohibited the philosophy of Occam, which was that of the nominalists. The consequence was, that the nominalists flourished more than ever. In the 15th century, the controversy was continued with more vigour and animosity than before; and the disputants were not content with using merely the force of eloquence, but had frequently recourse to more hostile and dangerous weapons: and battles were the consequence of a philosophical question, which neither side understood. In most places, however, the realists maintained a manifest superiority over the nominalists. While the famous Germon, and the most eminent of his disciples were living, the nominalists were in high esteem and credit in the university of Paris. But upon the death of these patrons, the face of things was much changed to their disadvantage. In the year 1473, Louis XI. by the influence of his confessor, the bishop of Avranches, issued out a severe edict against the doctrines of the nominalists, and ordered all their writings to be seized and secured, that they might not be read by the people: but the same monarch mitigated this statute shortly after it was issued, and permitted some of the books they had already seized to be restored to their former authority. The nominalists were the founders of the university of Leipsic; and there are many yet abroad who pique themselves on being nominalists.

The nominalists, with the Stoics, admit the formal conceptions or ideas of things, as the subject and foundation of universality; but to this they add significations, which represent them, after the same universal manner, and without any distinction, a great variety of single things alike in genus and species.

Whence it is that they are called nominalists; as pretending, that to become learned, it is not enough to have just ideas of things, but it is likewise required to know the proper names of the genera and species of things, and to be able to express them clearly and precisely, without confusion or ambiguity.

NOMINATIVE, in grammar, the first case of nouns which are declinable. The simple position, or laying down of a noun, or name, is called the nominative case; yet it is not so properly a case, as the matter or ground whence the other cases are to be formed, by the several changes and inflections given to this first termination. Its chief use is to be placed in discourse before all verbs, as the subject of the proposition or affirmation.

NONA, a city of Dalmatia, remarkable at present only for its ruins, which might furnish abundant materials to gratify the curiosity of antiquaries; but indeed they are so buried by repeated devastations, to which that unhappy city has been exposed, that rarely any vestige of them appears above ground. I went thither (says Fortis in his Travels), in hopes of finding something worthy of notice, but was disappointed. Nothing is to be seen that indicates that grandeur of the Roman times; neither are there any remains of barbarous magnificence, to put one in mind of the ages in which the kings of the Croat Slav had their residence there. It lies on a small island, surrounded by a harbour, which in former times was capabte of receiving large ships; but is now become a fetid pool by means of a little muddy river that falls into it, after a course of about six miles through the rich abandoned fields of that diocese. The ancient inhabitants turned this water into another channel, and made it run through the valley of Draufich into the sea; and the remains of the bank raised by them for that purpose are still to be seen. Notwithstanding, however, the depopulation of this diocese, and the dreary situation of Nona in particular, the new inhabitants have not lost courage; and animated by the privileges granted to them by this most serene republic, are endeavouring to bring the population and agriculture once more into a flourishing state. Proper drains for the water would not only render that rich territory habitable, but moreover very fertile; and the brackish marsh that surrounds the walls of Nona is well calculated to supply a considerable quantity of fish, especially eels. The government generously granted the in-gentile to private persons, who already draw no inconsiderable advantage from the fishing; and did they but adopt better methods, they might every year fetch many thousand of eels, which would greatly answer our internal commerce, and save at least a part of the money that goes out of the country for foreign fish.

The left of the city of Nona, the walls of some ancient ruinous buildings appear; which probably in ancient times were situated on the main land, though now surrounded by water. The sea forms a narrow channel in this place, which is easily fordable, and, at low water, the smallest boat can scarcely pass."

NONAGE, in law, generally signifies all the time a person continues under the age of 21; but in a special sense, it is all the time that a person is under the age of 14.

NON-CAPTAINAGE, a prominent on the west coast of Africa, opposite to the Canary islands. W. Long. 12. 0. N. Lat. 44° 28'.

NONCONFORMISTS, those who refuse to join the established worship. Nonconformists, in England, are of two sorts. First, such as abstain themselves from divine worship in the established church through total irreligion, and attend the service of no other persuasion. These, by the statute 1 Eliz. c. 2. 23. Eliz. c. 1. and 3. Jac. I. c. 4, forfeit one sitting to the poor every Lord's-day they so abstain themselves, and 20l. to the king if they continue such default for a month together. And if they keep any inmate thus irreligiously disposed in their houses, they forfeit 10l. per month.

The second species of nonconformists are those who offend through a mistaken or perverse zeal. Such were
were esteemed, by the English laws enacted since the time of the Reformation, to be Papists and Protestant dissenters: both of which were supposed to be equally schismatics, if not communicating with the national church; with this difference, that the Papists divided from it upon material, though erroneous, reasons; but many of the dissenters upon matters of indifference, or, in other words, for no reason at all. Yet certainly (says Sir William Blackstone) our ancestors were mistaken in their plans of compulsion and intolerance. The sin of schism, as such, is by no means the object of temporal coercion and punishment. If through weakness of intellect, through misdirected piety, through perseverance in acerbity of temper, or (which is often the case) through a prospect of peculiar advantage in herding with a party, men quarrel with the ecclesiastical establishment, the civil magistrate has nothing to do with it; unless their tenets and practice are such as threaten ruin or disturbance to the state. He is bound indeed to protect the established church; and if this can be better secured, all persecution for diversity of opinions, however ridiculous or absurd they may be, is contrary to every principle of sound policy and civil freedom. The names and subordination of the clergy, the posture of devotion, the materials and images; nay, even their principles did not also extend to a subversion of the church of England, from the penalties of certain statutes, commonly called the Toleration-act; which declares, that neither the laws above mentioned, nor the statutes 1 Eliz. c. 2. 6 14. 3. Jac. I. c. 4. 5. nor any other penal laws made against Popish recusants (except the first acts) shall extend to any dissenters, other than Papists and such as deny the Trinity: provided, 1. That they take the oaths of allegiance and supremacy, and be fined for all the oaths and ceremonies of Popery; 2. That they repair to some congregation certified to and registred in the court of the bishop or archdeacon, or at the county-seions. 3. That the doors of such meeting-house shall be unlocked, unbarred, and unbolted; in default of which, the persons meeting there shall be liable to all the penalties of the former acts. Differing teachers, in order to be exempted from the penalties of the statutes 15 & 14. Car. II. c. 4. 17. Car. II. c. 2. and 22. Car. II. c. 1. are also to subscribe the articles of religion mentioned in the statute 15 Eliz.
ance of the same; they may not keep or teach any school, under pain of perpetual imprisonment; and, if they willingly pay or hear mass, they forfeit the one 200, the other 100 marks, and each shall suffer a year's imprisonment. Thus much for persons who, from the misfortune of family prejudices, or otherwise, have conceived an unhappy attachment to the Romish church from their infancy, and publicly profess its errors. But if any evil inducement is used to rivet these errors upon them; if any person sends another abroad to be educated in the Popish religion, or to reside in any religious house abroad for that purpose, or contributes to their maintenance when there; both the sender, the sent, and the contributor, are disabled to sue in law or equity, to be executor or administratrix to any person, to take any legacy or deed of gift, and to bear any goods and chattels, and by the same means, the estate.

And where these errors are also aggravated by apoc- tacy or perversion; where a person is reconciled to the see of Rome, or procures others to be reconciled, the offence amounts to high treason.

2. Popish recusants, convicted in a court of law of not attending the service of the church of England, are subject to the following disabilities, penalties, and forfeitures, over and above those before mentioned. They are considered as persons excommunicated; they can hold no office or employment; they must not keep arms in their houses, but the same may be seized by the justices of the peace, for the use of arms.

3. No marriage or burial of such recusant, or baptism of his child shall be had otherwise than by the minister of the church of England, under other severe penalties. A married woman, when recusant, shall forfeit two thirds of her dower or jointure, may not be executrix or administratrix to her husband, nor have any part of his goods; and during the coverture may be kept in prison, unless her husband redeems her, at the rate of 101. a month, or the third part of all his lands. And lastly, as a femme-covert recusant may be imprisoned, so all others must, within three months after conviction, either submit and renounce their errors, or, if required to do so by the justices, must abjure and renounce the realm: and if they do not depart, or if they return without the king's licence, they shall be guilty of felony, and suffer death as felons without benefit of clergy. There is also an inferior species of recusancy, (refuting to make the declaration against Popery enjoined by statute 30 Car. II. § 2. when tendered by the proper magistrate;) which, if the party refudes within ten miles of London, makes him an absolute recusant convicted; or, if at a greater distance, suffices him from having any seat in parliament, keeping arms in his house, or any horse above the value of 101. 3. Popish priests are in a still more dangerous condition. By statute 1 & 12 W. III. c 4. Popish priests, or bishops, celebrating mass or exercising any part of their functions in England, except in the houses of ambassadors, are liable to perpetual imprisonment. And by the statute 27 Eliz. c. 2. any Popish priest, born in the dominions of the crown of England, who shall come over either from beyond sea (unless driven by storms of weather and carrying only a reasonable time) or shall be in England three days without conforming and taking the oaths, is guilty of high treason; and all persons harbouring him are guilty of felony without the benefit of clergy.

This is a short summary of the laws against the Papists; of which the president Montesquieu observes, that they are so rigorous, though not professedly of the singular kind, that they do all the hurt that can possibly be done in cold blood. But in answer to this, it may be observed (what foreigners who only judge from our statute-book are not fully apprized of), that these laws are seldom exerted to their utmost rigour: and indeed, if they were, it would be very difficult to execute them. For they are rather to be accounted for from their history, and the urgency of the times which produced them, than to be approved (upon a cool review) as a standing system of law. The refi lifes machinations of the Jesuits during the reign of Elizabeth, the turbulence and uneasiness of the Papists under the new religious establishment, and the boldness of their hopes and wishes for the succession of the queen of Scots, obliged the parliament to counteract this dangerous spirit by laws of a great and then perhaps necessary severity. The powder-treason, in the succeeding reign, struck a panic into James I. which operated in different ways: it occasioned the enacting of new laws against the Papists; but deterring him from putting them in execution. The intrigues of queen Henrietta in the reign of Charles I. the project of a Popish successor in that of Char. II. the affaillation-plot in the reign of king William, and the avowed claim of a Popish pretender to the crown in subsequent reigns, will account for the extention of these penalties at those several periods of our history. But now that all just fears of a pretender may be said to have vanished, and the power and influence of the pope has become feeble, ridiculous, and depicable, not only in Britain, but in almost every kingdom of Europe; and as in fact the British Catholics loyally disclaim the dangerous principles ascribed to them; they See their the British legislature, giving way to that liberality of the British project, becoming the dangerous principles ascribed to them The Popists. 1788, in the Maga- zines or Annual Register for that year.

The power given to the king, or other relation, being a Protestant, to take possession of the father's or other relation's estate, during the life of the real proprietor. —And the debarring Papists from the power of acquiring any legal property by purchase. —In proposing the repeal of these penalties, it was observed, That, besides that some of them had now ceased to be necessary, others were at all times a disgrace to humanity. The imprisonment of a Popish priests for life, only for officiating in the services of his religion, was horrible in its nature: And although the mildness of government had hitherto softened the rigour of the law in the practice, it was to be remembered that the Roman Ca-
Non-Suit.

And magistrates and judicial powers were of necessity bound to enforce all the shameful penalties of the act. Others of these penalties held out the most powerful temptations for the commission of acts of depravity, at the very thought of which our nature recoils with horror. They seemed calculated to loosen all the bands of society; to dissolve all civil, moral, and religious obligations and duties, to poison the sources of domestic felicity, and to annihilate every principle of honour. The encouragement given to children to lay their hands upon the estates of their parents, and the restriction which debarres any man from the honest acquisition of property, need only to be mentioned to excite indignation in an enlightened age.

In order the better to secure the English established church against perils from non-conformists of all denominations, infidels, Turks, Jews, heretics, papists, and sectaries, there are, however, two bulwarks erected; called the corporation and tell acts: By the former of which, no person can be legally elected to any office relating to the government of any city or corporation unless, within a twelvemonth before, he has received the sacrament of the Lord's supper according to the rites of the church of England; and he is also enjoined to take the oaths of allegiance and supremacy at the same time that he takes the oath of office; or, in default of either of these requisites, such election shall be void. The other, called the tell act, directs all officers civil and military to take the oaths and make the declaration against transubstantiation, in any of the king's courts at Westminster, or at the quarter-seelfions, within fix kalender months after their admission; and also within the same time to receive the sacrament of the Lord's Supper, according to the usage of the church of England, in some public church immediately after divine service and sermon, and to deliver into court a certificate thereof signed by the minister and church-warden, and also to prove the same by two credible witnesses; upon forfeiture of 500L and disability to hold the said office. And of much the same nature with these is the statute 7 Jac. I. c. 2, which permits no person to be naturalized or restored in blood, but such as undergo a like test: which test having been removed in 1753, in favour of the Jews, was the next feission of parliament restored again with some precipitation.

Non-Naturals, in medicine, so called because by their abuse they become the caufes of diseases.

Physicians have divided the non-naturals into fix classes, viz. the air, meats and drinks, sleep and waking, motion and rest, the passions of the mind, the emotions and excretions. See Medicine, phaffin.

Non Obstant (notwithstanding,) a clause frequent in statutes and letters patent, importing a licence from the king to do a thing, which at common law might be lawfully done, but being restrained by act of parliament cannot be done without such licence.

Non Pros. See Nolle Prosequi.

Non Suit, signifies the dropping of a suit or action, or a renouncing thereof by the plaintiff or defendant: which happens most commonly upon the discovery of some error in the plaintiff's proceedings when the cause is so far proceeded in, that the jury is ready at the bar to deliver in their verdict.

Nones, (Nones) in the Roman kalender, the fifth day of the months January, February, April, June, August, September, November, and December; and the seventh of March, May, July, and October. March, May, July, and October, had fix days in their nones; because thefe alone, in the ancient constitution of the year by Numa, had 31 days a piece; the reft having only 29, and February 30: but when Caesar reformed the year, and made other months contain 31 days he did not allow them fix days of nones.

Nonjurors, those who refused to take the oaths to government, and who were in confquence under certain incapacities, and liable to certain severe penalties. It can scarcely be said that there are any nonjurors now in the kingdom; and it is well known that all penalties have been removed both from Papists and Protestants, formerly of that denomination, as well in Scotland as in England. The members of the Episcopal church of Scotland have long been denominated Nonjurors; but perhaps they are now called so improperly, as the ground of their difference from the establishment is more on account of ecclesiastical than political principles.

Nonius (Peter), in Spanish Nunez, a learned Portuguese, and one of the ablest mathematicians of the 16th century, was born at Alcacer. He was preceptor to Don Henry, king Emmanuel's son, and taught the mathematics in the university of Coimbra. He published the following works, by which he gained great reputation: 1. De arte navigandi. 2. Annotationes in theoriam planetarum Purbachit: which are greatly esteemed. 3. A treatise De Crepufculis. 4. A treatise on algebra. It is observed in Forcetiere's dictionary, that Peter Nonius, in 1530, first invented the angles of 45 degrees made in every meridian, and that he called them rhumbs in his language, and calculated them by spherical triangles. Nonius died in 1577, aged 80.

Nonius, the name which was not many years ago given to the common device for subdividing the area of quadrants and other astronomic instruments, from the persuasion that it was invented by Nonius or Nunez, of whom some account has been given in the preceding article. The generality of astronomers of the present age, transferring the honour of the invention from Nunez to Peter Vernier, a native of Franche Comte, have called this method of division by his name. (See VERNIER). Mr Adams, however in his Geometrical and Geographical Essays, has lately shown that Clevis the Jeluit may dispute the invention with them both. The truth seems to be, that Nunez started the idea, Clevius improved it, and Vernier carried it to its present state of perfection. The method of Nunez, described in his treatise De Crepufculis, printed at Lyon 1542, consists in describing within the same quadrant 45 concentric circles, dividing the outermost into 90 equal parts, the next within into 89, the next into 88, &c. till the innermost was divided into 46 only. On a quadrant thus divided the plumb line or index must crofs one or other of the circles very near a point of division; whence, by computation, the degrees
degrees and minutes of the arch might be easily ascertained. This method is also described by Nunez in his treatise De arte atque ratione navigandi, where he would fain persuade himself, that it was not unknown to Ptolomey. But as the degrees are thus divided very unequally, and as it is very difficult to attain exactness in the division, especially when the numbers into which the arches are to be divided are incommo-

posite (of which there are no less than nine), the method of diagonals, first published by Thomas Digges, Esq; in a treatise intitled Alear fuit folo mathematici, printed at London in 1573; and said to be invented by one Richard Chenelder, was subtilized in its father. Nunius's method was, however, improved at different times and by different persons; and it must be acknowledged, that if Vernier saw either the original or any of the improvements (and there can be little doubt of his having seen them all), his merit is only that of having applied to an useful practical purpose the specu-

cative invention of another person.

Nunius (Marcellus), a grammarians and peripate-
tic philosopher, born at Tivoli, wrote a treatise, intituled De proprietate hercumin. This author is only valuable for his giving fragments of ancient authors that are nowhere else to be found. The above treatise was printed at Paris in 1614, with notes.

'Lonius, or Nunius (Lewis), a learned physi-

cian of Antwerp in the 17th century, wrote several works which are esteemed; the principal of which are 1. An excellent treatise intitled Ichthyographia, seu de Piscium eou. 2. Historia; which is of great use in understanding the ancient geography of Spain. 3. A commentary on the medallions of Greece, and those of Julius Cesar, Augustus, and Tiberius, in folio; it contains G-litzius's two words on the same subjed. 4. A commentary on Golzius's account of Greece, the islands, &c. 5. Poems, &c.

Nunius, a Greek poet of the 4th century, and native of Panopilis in Egypt, was the author of an heroic poem in 48 books, intitled Dionysiacum, and a paraphrase in verse of St John's Gospel, which may serve as a commentary upon it.

Nonula, in the Italian music, denotes a quick time, peculiar to jigs. This species of time is other-

wise called the mesure of nine times, which requires two

falls of the hand, and one rise. There are three sorts of nonula. 1. Nonula di semi minimo, or dupla femiqua-

varia, thus marked 1, where nine crotches are to be in the bar, of which four make a semi-breve in common time, i. e. in the down stroke fix, but three up: it is usually beat adagio. 2. Nonula di creòne, or

 semifara, marked thus $, wherein nine quavers make a bar instead of eight in common time; i. e. fix down and three up: it is beat presto. 3. No-

nula di femi cre o e saper noti parimenti nona, thus distinguished $i, in which nine semi-quavers are contained in a bar, whereof sixteen are required in common time, fix down, and three up: it is ordinarily beat presto. Beside these, there are two other spec-

ies of nonula, for which see Triplie.

Nootka-sound, or it was called by Captain Cook, King George's Sound, lies in N. Lat. 49. 33.

W. Long. 15. 12. It is an entrance or strait to a vast inland sea on the west coast of North America, and is said to resemble the Baltic or Mediterranean in Europe. Upon the flat coast the land is tolerably high

and level; but within the found it rises into steep hills, which have an uniform appearance. The trees of which the woods are composed, are the Canadian pine, white-cypress, and two or three other sorts of pine. In general, the trees grow here with great vigour, and are

of a large size. About the rocks and borders of the woods were seen some strawberry plants and raspberry, currant, and gooseberry bushes, all in a flourishing state. The principal animals seen here were racoons, martens, and squirrels. Birds are far from being numerical, and those that are to be found are remarkably shy, owing perhaps to their being continually disturbed by the native; either to eat them, or to becom-

polished of their feathers to be worn as ornaments. The quarenhuleos, thugs, and gulls, were seen off the coast; and the two last were also frequent in the sound. Though the variety of fish is not very great, yet they are in great quantities than bird. The principal forts are the common herring, a silver colour-

ed bream, and another of a brown colour. Captain Cook and Doctor King, who visited this place, con-

 sider it as an excellent shelter for ships; and in the account of a Voyage to the Pacific Ocean, they give some directions for falling into it. These and other matters of that kind we shall not trouble our readers with; and perhaps the generality of them will be better pleased with the following extract from Mearns's Voyages to the North-west Coast of America.

"The people of the Nootka nation are, in general, robust and well proportioned; their faces are large and full, their cheeks high and prominent, with small black eyes; their noses are broad and flat, their lips thick, and they have generally very fine teeth, and of the most brilliant whiteness.

"The manner in which the children of Nootka are treated, when young, is not more extraordinary from its strange, and, as it should appear, total inutility, as from its agreement with the customs of the Chinese and Tartars, to whom this practice gives these people a considerable resemblance. The head of the infant is bound by the mother with a kind of flicet of several folds, as low down as the eyes, in order to give it a certain form, which, at this tender age, it is capable of receiving. It might be supposed, that such a tight drawn ligature must cause considerable pain to the child; but we never observed that any of the infants, in such a state of preparation for sugar-loaf heads, suffered any visible pain or inconvenience.

"Though the custom of compressing the head in this manner gives them an unpleasant appearance, by drawing up the eye-brows, and sometimes producing the disagreeable effect of squinting, as well as of flattening the nose and dilating the nostrils, they are by no means an ill looking race of people. They have all the cuftom, which is known to prevail in to many Indian nations, of plucking out the beard by the roots, on its first appearance; and, as it continues to sprout, to keep it down by the same practice. It is one of the domestic employments assigned to their wives, to watch this appearance of manhood, and to eradicate the hairs as they come forth; which they do in a very dexterous manner with their fingers, and without giving the least pain in the operation. Some of them, however, though we saw but very few of this disposition, when they advance in years and become infirm, suffer their beards to grow without interruption. But, notwithstanding..."
flanding they have so great an aversion to the hair of their chin, that of the head is an object of their attentive vanity: it is strong, black, and glossy, grows to a considerable length, and is either tied in a kind of knot on the top of their heads, or suffered to hang down their backs in flowing negligence.

"In their exterior form they have not the symmetry or elegance which is found in many other Indian nations — Their limbs, though stout and athletic, are crooked and ill-shaped; their skin, when cleansed of filth and ochre, is white; and they have neither men nor women, when in a state of cleanliness (which, however, is long, black, and ochre, is white; and we have seen some of the

All reports concerning Nootka Sound agree in characterizing the inhabitants as a very indolent race of people." — Indolent, however, as they are, it is a custom of a very unusual, and we should imagine cruel, kind prevail among them: for, together with many other articles which they exposed to sale to Captain Cook's ships, they brought human skulls and hands (part of the flesh still remaining on them), which they acknowledged they had been feeding on; and some of them, we are told, had evident marks of the fire.

From hence it is too apparent, that the horrid practice of devouring their enemies exists here as well as at New Zealand and other South seas-lands: and hence, too, appears what men of even the best natural dispositions will be, if left entirely to the freedom of their own will, without law to control or religion to instruct them. As there are but two villages of the Sound inhabited, the number of people cannot be many; perhaps they are about 2000 in all. Our limits prevent us from being so minute as we could wish to be, respecting the form of their houses and their manner of building them; of their furniture, decorations, and other things of that kind: we can therefore only refer those who will with further information on this subject to Cook and other voyagers and travellers, &c.

The employment of the men is chiefly fishing, &c. whilst the women manufacture their garments. Their ingenuity in this and in the mechanic art is far from being inconsiderable; and in the imitative arts their skill is very great. "On these subjects, however, we cannot enlarge: we have in general made it our business and it certainly is our duty, to dwell, where it can be done, on the manners or religion of the inhabitants of the several places which come under our notice; and they who know the utility of this in developing the philosophy of the human mind, the most important of all sciences, will not blame our intentions, even if they should not approve of the execution. In Cook's Voyages before referred to, we find the following observations on the religion and language of the inhabitants of Nootka Sound.

"Little knowledge we can be supposed to have acquired of the political and religious institutions established among these people. We discovered, however, that there were such men as chiefs, distinguished by the title of Aekwek, to whom the others are, in some degree, subordinate. But the authority of each of these great men seems to extend no farther than to his own family, who acknowledge him as their head. As they were not all elderly men, it is possible this title may be hereditary.

"Nothing that we saw could give us any insight into their notions of religion, except the figures already mentioned, called Klumma. These, perhaps, were idols; but as the word Aekwek was frequently mentioned when they spoke of them, we may suppose them to be the images of some of their ancestors, whose memories they venerate. This, however, is all conjecture; for we could receive no information concerning them; knowing little more of their language than to enable us to ask the names of things, and being incapable of holding any conversation with the natives relative to their traditions or their institutions.

"Their language is neither harsh nor disagreeable, farther than proceeds from their pronouncing the k and h with less softness than we do. As to the composition of their language, we are enabled to say but little. It may, however, be inferred from their flow and distinct method of speaking, that it has few prepositions or conjunctions, and is defective of even a single interjection to express surprise or admiration. The affinity it may bear to other languages, we have not been able sufficiently to trace, not having proper specimens to compare it with; but from the few Mexican words we have procured, there is an obvious agreement throughout the language, in the frequent termination of the words in i, ti, or z.

"The word wakalib was frequently in the mouths of the people of Nootka. It seemed to express approbation, applause, and friendship. Whenever they appeared to be pleased or satisfied at any sight or occurrence, they would call out wakalib! wakalib! — It is worthy of remark, that as these people do essentially differ from the natives of the islands in the Pacific Ocean, in their persons, customs, and language, we cannot suppose their respective progenitors to have belonged to the same tribe, when they emigrated into those places where we now find their descendants."

We cannot finish this article without taking notice of a circumstance, which at the time made a great noise in Europe, and which it is probable will find a place in the future histories of the contending countries.

A small association of British merchants resident in the East Indies had, early in the year 1786, formed the project of opening a trade to this part of the world, for the purpose of supplying the Chinese market with furs. The principal point towards which these expeditions were directed, was Port Nootka, or King George's Sound; and the adventurers, being in some degree satisfied with their traffic, took measures
Norpal

Plate

in the year 1788, to secure to themselves a permanent settlement; at the same time that the shipping employed in this expedition was generally two, and never exceeded the amount of four, small vessels. The Spaniards conceived some jealousy of the intrusion of the English into a part of the world which they had long been desirous to regard as their exclusive property; and accordingly a Spanish frigate of 26 guns was dispatched from the province of Mexico, for the purpose of putting an end to this commerce. The Spanish frigate arrived in May 1789, and captured two English vessels in the following July, at the same time taking possession of the little settlement which had been formed upon the craft. Such, in short, is the circumstance which was likely to involve the parties in an expensive war. Happily, however, for both countries, and perhaps for Europe, the matter was at length, after being discussed, at the same time, the whole article having extended perhaps to more than a sufficient length.

Nopal, Raqette, or Indian fig; plants so named by the Indians from which the cochineal is collected in Mexico. Thee plants bear fruits which resemble our figs; tinge the urine of those who eat them; and probably communicate to the cochineal the property which makes it useful to the dyer. The Indians of Mexico cultivate the nopal near their habitations, and low, as it were, the insect which affords the cochineal. They make small nets of moss or fine herbs; put twelve or fourteen cochineals into each net; place three or four of these nets on each leaf of the nopal; and fasten them there by the prickles of the plant. In the course of a few days, thousands of small insects eat them out, and from themselves upon the parts of the leaf which are left sheltered and afford the most nourishment. The cochineals are collected several times in the course of the year, and are deprived of life by scalding them, or by putting them into an oven. See Cochineal.

Nopalkochuetzalli, or Nopalcochuetzalli, the prickly pear of Mexico, and common over all the West Indies. See Cactus.

Noph. See Memphis.

Norbury, a town in England, in Staffordshire, on the south-west side of Eccleshall. Here is a fortifying echo, which, taken 440 yards north-east from the manor-house, near a little bank under a wood-side, repeats in a full day 10 or 11 syllables very distinctly, or 12 or 13, if spoken very quick. It is remarked that the banks of the Black Meer, in this parish, grow forward every year over the surface of the water, at the rate of three or four yards every seven years.

Norden (Frederic Lewis), an ingenious traveller and naval officer in the Danish service, was born at Gluckstadt in Holstein in the year 1708. He was well skilled in mathematics, ship-building, and especially in architecture; and in 1732 obtained a pension to enable him to travel for the purpose of studying the construction of ships, particularly the galleys and other rowing vessels used in the Mediterranean. He spent near three years in Italy; and Christian VI. being desirous of obtaining a circumstantial account of Egypt, Mr Norden at Florence received an order to extend his travels to that country. How he acquitted himself in this commission, appears from his Travels into Egypt and Nubia, printed at Copenhagen in folio, 1756; and which were soon after translated into English by Dr Peter Templeman. In the war between England and Spain, Mr Norden, then a captain in the Danish navy, attended Count Ulric Adolphus, a fleet captain, to England; and they went out volunteers under Sir John Norris, and afterwards under Sir Chaloner Ogle. During his stay in London, Mr Norden was made a fellow of the royal society, and gave the public drawings of some ruins and colossal statues at Thebes in Egypt, with an account of the same in a letter to the Royal Society, in 1741. His health at this time was declining; and taking a tour to France, he died at Paris in 1742.

Nordheim, a town in Germany, in the Hanover quarter. Of the four larger towns of this principality, it is the third in order. It is situated on the Rhume, which runs into the Leine. It contains 500 houses, and beside a secularized Lutheran abbey, has one parish-church, and some charitable foundations, and also enjoys some manufactures.

Nores (Jaffon de), a scholar, poet, and philosopher, was born at Nicofia in Cyprus. He left his fortune when the Turks made themselves masters of that island in 1570. He retired to Padua; where he acquired great reputation by teaching moral philosophy. His character had that cast of severity which is often the consequence of scholastic habits. He was one of those men who discuss every thing without being capable of feeling anything. The Paynth, Piso of Guarini made its appearance; and pastoral became a fashionable species of reading throughout all Italy. Nores, who did not relish works of this kind, attacked the production of Guarini; who entirely confuted him in a little piece printed at Ferrara in 1586. Nores made a reply two years after; and the poet was preparing an answer still more fierce than the former, when his antagonist died of grief occasioned by the banishment of his only son for having killed a Venetian in a duel. He left behind him a great many works, some in Italian, and others in Latin. The chief of his Italian works are, 1. The Poetical, Padua, 1588, 4to; this edition is rare. 2. A Treatise on Republics, 1578, 4to; which he forms on the model of that of the Venetians, his masters. 3. A Treatise on the World and its Parts, Venice, 1571, 8vo. 4. Introduction to three books of Arilote's Rhetoric, Venice, 1584, 4to, valuable. 5. A treatise on what Comedy, Tragedy, and Epic Poetry may receive from Moral Philosophy. His Latin works are, 1. Infeftation in Philosophiam Ciceronis, Padua, 1576, 8vo. 2. Brevis et diversa simia praeseptorum de arte divina, ex libris Ciceronis collecta, Venice, 1553, 8vo. A good work. 3. De Constitutione partium huius et civilis philosophiae, 4to. 4. Interpretatio in arvum positum Horatii, 8vo. In all his works we remark great perspicuity and accuracy, profound erudition, happy expressions, an elevated, and sometimes forcible style.—His son, Peter Nores, successively secretary to several cardinals, at once a man of letters and a man of business, left behind him different manuscripts; among others, the life of Paul IV. in Italian.

Norfolk, a county of England, so called from
Norfolk. its northern situation in respect of Suffolk, is bounded on the east and north by the German ocean; on the south by Suffolk, from which it is parted by the rivers Waveney, and the Lefier Oufe; and on the west it is separated from Cambridgehire by the Greater Oufe, and from a small part of Lincolnshire by the Wythes. According to Templeman, it extends in length 57 miles, in breadth 35, and 140 in circumference. It contains an area of 1426 square miles, one city, 32 market-towns, 711 villages, according to the book of rates, 175000 and 2360000 inhabitants, as some have it, and 283000, according to others. It is divided into 31 hundreds, 164 vicarages, and 660 parishes.

The air differs in different parts of the country according to the soil, which in some places is marshy, especially on the sea coast, and there the air is foggy and unwholesome; in others it is clayey and chalky, poor, lean, and sandy, and there the air is good. The country is almost all champaign, except in some places, where rise gentle hills. The marsh-lands yield rich pasture for cattle; the clay-grounds peats, rye, and barley; and the sandy-heaths feed flocks of large sheep, of which some villages are said to feed 4000 or 5000. These heaths abound also in rabbits of a silver-grey colour. Wallingham is noted for producing the best flaxon. Great quantities of mackarel and herring are caught upon the coasts of this county, the former in the spring, and the latter in September; and how originally formed, like many other small islands, by the eruption of volcanic matter from the bed of the sea, must doubtless have contained a volcano. This conclusion is formed from the vast quantity of pumice-stone which is scattered in all parts of it, and mixed with the soil. The crater, or at least some traces of its former existence, will probably be found at the summit of a small mountain, which rises near the middle of the island. To this mountain the commandant has given the name of Mount Pitt. The island is exceedingly well watered. At or near Mount Pitt rises a strong and copious stream, which flowing through a very fine valley, divides itself into several branches, each of which retains sufficient force to be used in turning mills; and in various parts of the island springs have been discovered.

The climate is pure, salubrious, and delightful, preferred from oppressive heats by constant breezes from the sea, and of to mild a temperature throughout the winter, that vegetation continues there without interruption, one crop succeeding another. Refreshing flowers from time to time maintain verdure: not indeed of grass, for none has yet been seen upon the island; but of the trees, shrubs, and other vegetables, which in all parts grow abundantly. On the leaves of these, and of some kinds in particular, the sheep, hogs, and goats, not only live, but thrive and fatten very much. To the salubrity of the air every individual in this little colony can bear ample testimony, from the uninterrupted state of good health which has been in general enjoyed.

When our settlers landed, there was not a single acre clear of wood in the island, and the trees were so bound together by that kind of creeping shrub called supple jack, interwoven in all directions, as to render it very difficult to penetrate far among them. The commandant, small as his numbers were at first, by indefatigable activity soon caused a space to be cleared sufficient for the requisite accommodations, and for the production of excellent vegetables of all kinds in the greatest abundance. When the last accounts arrived, three acres of barley were in a very thriving state, and ground was prepared to receive rice and Indian corn. In the wheat field there had been a disappointment, the grain that was sown having been so much injured by the weevil as to be unfit for vegetation. But the people were all at that time in commodious houses; and, according to the declarations of Mr King himself, in his letters to Governor Philip, there was not a doubt that this colony would be in a situation to support itself entirely without assistance in less than four years; and with very little in the intermediate time. Even two years would be more than sufficient for this purpose, could a proper supply of black cattle be sent.

"Fifth
Norfolk.

"Fifths are caught in great plenty; and in the proper season very fine turtle. The woods are inhabited by innumerable tribes of birds, many of them very gay in plumage. The most useful are pigeons, which are very numerous; and a bird not unlike the Guinea fowl, except in colour (being chiefly white), both of which were at first so tame as to suffer themselves to be taken by hand. Of plants that afford vegetables for the table, the chief are cabbage palm, the wild plantain, the fern tree, a kind of wild spainage, and a tree which produces diminutive fruit, bearing some resemblance to a currant. This, it is hoped, by transplanting and care, will be much improved in size and flavour.

"But the productions which give the greatest importance to Norfolk Island are the pines and the flax plant; the former rilling to a fine and perfection unknown in other places, and promising the most valuable supply of masts and spars for our navy in the East Indies; the latter not less estimable for the purposes of making sail cloth, cordage, and even the finest manufactures, growing in great plenty, and with flesh luxuriance as to attain the height of eight feet. The pines measure frequently 160, or even 180 feet in height, and are sometimes 9 or 10 feet in diameter at the bottom of the trunk. They rile to about 80 feet without a branch; the wood is said to be of the best quality, almost as light as that of the best Norway masts; and the turpentine obtained from it is remarkable for purity and whiteness. The fern tree is found also of a great height for its species, measuring from 70 to 80 feet, and affords excellent food for the sheep and other small cattle. A plant producing pepper, the bucket is at the present moment to be of the size, and perhaps the most valuable; and specimens have been sent to England in order to ascertain this important point."

NORWICH-Bound, according to the account of Captain George Dixon, is fit for them. 57° 5' north latitude, and 185° 50' east longitude. It is a very extensive place, but how far it stretches to the northward is not known. There may possibly be a passage through to the Bay of Islands, but neither is this certain. The shore, in common with the rest of the coast, abounds with pines: there is also great quantities of the witch hazel. There are various kinds of flowering trees and shrubs, wild goose-berries, currants and raspberries; wild parsley is found here in great plenty, and it eats excellently either as a salad or boiled amongst soup. The parsnip, or wild lily root, grows also in great plenty and perfection. There are a very few wild geese or ducks here, and they are shy and difficult of approach.

NORHAM, a town of England, in the county of Northumberland, on the river Tweed, near the mouth of the Till, under the castle, which was ancietly erected on the steep rock mounted round, for the better security against the incursions of the Scotch moors troopers. It is of great antiquity; and its old church has lately received repairs, and been made a decent place of worship. Antiquities have been discovered here. The church had the privilege of a fantery. The castle has been frequently honoured with the presence of sovereigns, particularly Edward I. Here received the oath of treaty from John Balliol of Scotland. It has been a formidable structure, a great part of which is in ruins; the size of which, with its domes, consisted of 1030 acres.

NORIA, an hydraulic machine much used in Spain. It consists of a vertical wheel of 20 feet diameter, on the circumference of which are fixed a number of little boxes or square buckets, for the purpose of raising the water out of the well, communicating with the canal below, and to empty it into a reservoir above, placed by the side of the wheel. The buckets have a lateral orifice to receive and to discharge the water. The axis of this wheel is embraced by four small beams, crofting each other at right angles, tapering at the extremities, and forming eight little arms. This wheel is near the centre of the horse walk, contiguous to the vertical axis, into the top of which the horse-beam is fixed; but near the bottom it is embraced by four little beams, forming eight arms similar to those above described, on the axis of the water wheel. As the mule which they use goes round, these horizontal arms, supplying the place of cogs, take hold, each in succession, of those arms which are fixed on the axis of the water wheel, and keep it in rotation.

This machine, than which nothing can be cheaper, throws up a great quantity of water; yet undoubtedly it has two defects; the first is, that part of the water runs out of the buckets and falls back into the well after it has been raised nearly to the level of the reservoir: the second is, that a considerable proportion of the water to be discharged is raised higher than the reservoir, and falls into it only at the moment when the bucket is at the highest point of the circle, and ready to descend.

Both these defects might be remedied with ease, by leaving these square buckets open at one end, making them swing on a pivot fixed a little above their centre of gravity, and placing the trough of the reservoir in such a portion of the wheel that their progress whilet perpendicular; make them turn upon their pivot, and do discharge their contents.

From the reservoir the water is conveyed by channels to every part of the garden; these have divisions and sub-divisions or beds, some large, others very small, separated from each other by little channels, into which a boy with his shovel or his hoe directs the water, first into the main distant trenches, and successively to all the rest, till all the beds and trenches have been either covered or filled with water.

Mr Townsend, from whom we have taken the above account, thinks, that on account of the extreme simplicity of this machine, it is an invention of the most remote antiquity. By means of it the inhabitants every morning draw as much water from the well, as will serve through the day, and in the evening distribute it to every quarter according to the nature of their crops. The reservoirs into which they raise the water are about 20, 30, or even 40 feet square, and three feet high above the surface of the ground, with a stone cap on the wall, declining to the water for the women to wash and beat their cloths upon.

Our limits preclude us from following Mr Townseed further in the description of a particular noria used at Barcelona; which he conceives to be the original chain.
pump, or at least its parent. He compares it with similar instruments, and shows its advantages and disadvantages.

Noricum (A. Ptolemy, Tacitus); a Roman province, situated between the Danube on the north, and thus separated from ancient Germany; the Alps Norice on the south; the river Xerus on the west, which separates it from Vindelicia; and Mons Cetius on the east, which divides it from Panonia. Now containing a great part of Austria, all Saltsburgh, Stiria, and Carinthia. It was anciently a kingdom under its own kings (Cesar, Velleius, Sueto-nius). Notiis the people, subdued by Tiberius under Augustus, as allies of the Pannonii (Dio, Vellius). Tacitus reckons Noricum among those provinces which were governed by procurators, officers sent by the emperors to receive and dispose of the public revenue according to order. It was divided into two provinces, but at what time uncertain; supposed as low down as Diocletian and Constantin, viz. the Noricum Ripense, running along the south side of the Danube; and the Noricum Mediterraneum, extending towards the Alps. How far each of these extended in breadth does not appear; all the account we have of the matter being from Sextus Rufus, and the Notitia Imperii Occidentalis. An ancient country famous for its iron and steel (Horace), as is Stiria at this day, a part of Noricum. A climate cold and more sparingly fruitful (Solinus).

Norin, a river which rises in a corner of the Venetian confines, that runs between the rugged marble hills, and is left entirely to itself from its very sources; hence a vast tract of land is overflowed by it, and encumbered with reeds, willows, and wild eders. A small space of ground only remains dry between the roots of the hills and the marsh at a place called Prad, and that is all covered with pieces of ancient hewn stones, fragments of inscriptions, columns, and capitals, and bafi-reliefs of the best age, worn and deformed by time, and the barbarism of the northern people, who begun on that side to destroy Narona. The inhabitants, who go often to cut reeds in the marsh, affert, that the vestiges of that large city may still be seen under water. It appears to have been extended over the plain a great way, and undoubtedly it was three miles in length at the foot of the hills. The ancient road is now under water; and it is necessary to ascend a very steep road, in order to pass the point of a craggy hill, on which probably before the Roman times those fortificac ions were erected that cost Venetius so much labour.

Noris (Henry), cardinal, who was a great ornament of the order of the monks of St. Augustine, was descended from the president Jafon, or James de Noris, and born at Verona 1631. He was carefully educated by his father Alexander Noris, originally of Ireland, and well known by his History of Germany. He discovered from his infancy an excellent understanding, great vivacity, and a quick apprehension. His father instructed him in the rudiments of grammar, and procured an able professor of Verona, called Maffi, to be his preceptor. At 15 he was admitted a penitent in the Jefuits college at Rimini, where he studied philosophy; after which he applied himself to the writings of the fathers of the church, particularly those of St. Augustine: and taking the habit in the convent of the Augustine monks of Rimini, he distinguished himself among that fraternity in a short time by his erudition; inasmuch, that as soon as he was out of his novitiate or time of probation, the general of the order sent for him to Rome, in order to give him an opportunity of improving himself in the more solid branches of learning. He did not disappoint his superior's expectations. He gave himself entirely to his studies, and spent whole days, and even nights, in the library of the Angelicus of St. Augustine. His constant course was to flick to his books 14 hours a day; and this course he continued till he became a cardinal. By this means he became qualified to instruct others; and on this errand he was sent first to Pezaro, and thence to peroufa, where he took his degree of doctor of divinity; after which proceeding to Padua, he applied himself to finish his History of Pelagianism. He had begun it at Rome at the age of 26; and having completed his design, the book was printed at Padua, and published in 1673. The great duke of Tuscany invited him the following year to that city, made him his chaplain, and professor of ecclesiastical history in the university of Pisa, which his highness had founded with that view.

In his history he set forth and defended the condemnation pronounced, in the eighth general council, against Origen and Mopisci, the first authors of the Pelagian errors; he also added An Account of the Schism of Aquitaine, and a Vindication of the Books written by St. Augustine against the Pelagians and Semi-Pelagians. The work had procured him a great reputation, but met with several antagonists, to whom he published proper answers; the dispute grew warm, and was carried before the sovereign tribunal of the inquisition. There the history was examined with the utmost rigour, and the author dismissed without the least censure. It was reprinted twice afterwards, and Mr. Noris honoured by Pope Clement X. with the title of Qualificator of the Holy Office. Notwithstanding this, the charge was renewed against the Pelagian History, and it was dilated afire before the inquisition in 1676: but it came out again with the fame success as at first. Mr Noris was now suffered to remain in peace for sixteen years, and taught ecclesiastical history at Pisa, without any molestation, till he was called to Rome by Innocent XII. who made him under-librarian of the Vatican in 1692. This post was the way to a cardinal's hat; his accusers therefore took fresh hire, and published several new pieces against him. Hence the Pope appointed some learned divines, who had the character of having taken neither side, to re-examine Father Noris's books, and make their report of them. Their testimony was so advantageous to the author, that his holiness made him counsellor of the inquisition. Yet neither did this hinder one of his adversaries, the most formidable on account of his erudition, to rise up against him, and attack him warmly, under the assumed title of a Scrupulous Doctor of the Sorbonne. Noris tried to remove these scruples in a work which appeared in 1695, under the title of An Historical Disputation concerning one of the Trinity that suffered in the flesh; wherein, having justified the monks of Scythia, who made use of that expression, he vindicated himself also from the imputation of having attained the Pope's infallibility,
Norfolk of having abused Vincentius Lirincenis, and other bishops of Gaul, as favourers of Semi-pelagianism, and of having himself gone into the errors of the bishop of Ypres.

His answers to all these statements were so much to the satisfaction of the Pope, that at length his holiness honoured him with the purple in 1695. After this, he was in all the congregations, and employed in the most important affairs; so that he had little time to spend in his study, a thing of which he frequently complained to his friends. Upon the death of cardinal Cafanati, he was made chief library-keeper of the Vatican in 1700; and two years afterwards nominated, among others, to reform the calendar: but he died at Rome in 1704 of a dropsy. He was one of the most learned men in the last century; his writings abound with erudition, and are very elegantly finished. He was a member of the academy; whence he assumed the name of Erucrates Agereticus. His works are numerous, and were published at Verona, in 1729 and 1730, in five volumes folio.

NORKOPING, a town of Sweden, in the province of East Gothland, in east longitude 15° 30', latitude 58° 20'. Its name signifies "the northern market" in the Swedish language. It stands on the banks of a large river called Motala, which coming from the lake Vinter, falls a little lower into a gulf called Brauskau. It is the largest and most populous town in Sweden, next to Stockholm, conveniently situated near the sea on a navigable river, which brings large vessels up to the middle of the town. There are some handsome streets, and the houses in general are neatly built. Some of the churches are worth seeing; but the greatest curiosity is the famous copper mines, where there is a vast number of people constantly at work. In this article the town carries on a very good trade; as also in several other manufactures, as leather, steel, and guns, which they make the best in Sweden.

It covers a large space of ground, being ten miles in circumference; but the houses are small and scattered, and the inhabitants do not exceed 10,000. The river Motala flows through the town, forms a series of cataracts, and is divided into the four principal streams, which encircle several rocky islands, covered with houfes and manufactories. At the extremity of the town it is navigable for small vessels. Several manufactories are established in the town; 55 fabrics of cloth, which employ 1500 men; 3 sugar-houses; 1 of snuff; 50 mills for grinding corn, which is exported in large quantities; and a brass foundry. A salmon-fishery gives employment and riches to many of the inhabitants.

NORMANDY, a province of France, bounded on the north by the English channel; on the east by Picardy and the Isle of France; on the south by Perche and Maine, and one part of Bretagne; and on the west by the ocean. It is about 155 miles in length, 85 in breadth, and 600 in circumference. It is one of the most fertile, and brings in the largest revenue of the kingdom. It abounds in all things except wine, but they supply that defect by cyder and perry. There are vast meadows, fat pastures, and the sea yields plenty of fish. It contains iron, copper, and a great number of rivers and harbours. It carries on a great trade, is very populous, and comprehends a vast number of towns and villages. It is divided into the Upper and Lower; the Upper borders upon Picardy, and the Lower upon Bretagne. It contains seven dioceses or bishoprics, Rouen, Bayeux, Avranches, Evreux, See, Lilleux, and Coutances, in which they compute 4189 parishes, and 80 abbeys. The inhabitants are ingenious, and capable of understanding arts and sciences, but they are chiefly fond of law. The Normans, a people of Denmark and Norway, having entered France under Rollo, Charles the Simple ceded this country to them in 912, which from that time was called Normandy, and contains about 8200 square miles. Its chief city is Rouen. Rollo was the first duke, and held it as a fief of the crown of France, and several of his successors after him, till William, the seventh duke, conquered England in 1066: from which time it became a province of England, till it was left in the reign of King John, and reunitcd to the crown of France; but the English still keep the islands on the coasts of Normandy.

The principal rivers are the Seine, the Eure, the Aure, the Iton, the Dive, the Andelle, the Rillé, the Touque, the Drôme, and the Orne: among the seaports, the principal are those of Dieppe, Havre, Honfleur, Cherbourg, and Granville. Rouen is the principal city.

NORMANS, a fierce warlike people of Norway, Denmark, and other parts of Scandinavia. They at different times over-ran and ravaged most countries in Europe: to the respective histories of those countries we therefore refer for a fuller account of them, as it is impossible to enlarge upon particulars in this place without repeating what has been already laid, or may be said, in different parts of the work.

NORMAN CHARACTERS, a species of writing introduced into England by William I. From some old manuscripts the Norman writing appears to have been composed of letters nearly Lombardic. In regal grants, charters, public instruments, and law proceedings, this character was used with very little variation from the reign of the Conqueror to that of Edward III. See Writing.

NORRIS, or NOS. See Noris.

NORRIS (John), a learned English divine and Platonick philosopher, was born in 1657 at Collingborne-Kington, in Wiltshire, of which place his father Mr John Norris was then minister. He bred his son first at Winchester school, and afterwards sent him to Exeter college in Oxford, where he was admitted in 1676; but was elected fellow of All Souls in 1680, soon after he had taken his degree of bachelor of arts. From his first application to philosophy, Plato became his favourite author; by degrees he grew deeply enamoured with the beauties of that divine writer, as he thought him; and took an early occasion to communicate his ideal happiness to the public, by printing an English translation of a Rhapsody, under the title of The Picture of Love unwound, in 1682. He commenced master of arts in 1684, and the same year opened a correspondence with that learned mystick divine Dr Henry More of Christ's college in Cambridge. He had also a correspondence with the learned lady Matham, Dr Cundworth's daughter, and the ingenious Mrs Attell. He resided at his college, and had been...
in holy orders five years, when he was presented to the rectory of Newton St Loy, in Somersetshire, 1689; upon which occasion he married and resigned his fellowship. In 1691, his distinguished merit procured him the rectory of Bemerton, near Sarum. This living, upwards of 200 l. a year, came very reasonably to his growing family; and with the more acceptable, for the efficacy of the parochial duty, which gave him leisure to make an addition to his revenues by the fruits of his genius: the activity of which produced a large harvest, that continued increasing till 1710. But this activity seems to have become fatal to him; for towards the latter end of his life, he grew very infirm, music. He was afterwards made the king's solicitor.

In 1691, his household orders required a rectory, upon which occasion he married and resigned his family, upwards of 200 l. a-year, came very reasonably to his growing family; and with the more acceptable, for the efficacy of the parochial duty, which gave him leisure to make an addition to his revenues by the fruits of his genius: the activity of which produced a large harvest, that continued increasing till 1710. But this activity seems to have become fatal to him; for towards the latter end of his life, he grew very infirm, music. He was afterwards made the king's solicitor.

In 1691, his household orders required a rectory, upon which occasion he married and resigned his family, upwards of 200 l. a-year, came very reasonably to his growing family; and with the more acceptable, for the efficacy of the parochial duty, which gave him leisure to make an addition to his revenues by the fruits of his genius: the activity of which produced a large harvest, that continued increasing till 1710. But this activity seems to have become fatal to him; for towards the latter end of his life, he grew very infirm, music. He was afterwards made the king's solicitor.
The republican spirit of the Americans, his administration will not only stand marked in the page of history with an immense waste of public treasure, but it will appear bejewelled with the kindred blood of thousands of British subjects. To the very last moment he spoke in the senate, however he defended that war; and said, he was then, as he was formerly, prepared to meet the minutest investigation as to his conduct in that business; which nothing but the unforeseen intervention of France could have prevented from being crowned with success. His lordship was one of the firmest and most ardent supporters of the constitution in church and state. He died on the 6th of August 1792. His recollection he retained to his last moments; his family except lord North, who came within a few minutes afterwards, were assembled round his bed, and he took leave of them individually. Their grief did not suffer them to leave the room for some time after the event; and lady Caroline Douglas was at last forced from it. Even Dr Warren, who must have strengthened the habit of a man that can operate against nature to endure such scenes, ran from this, convulsed with sorrow. If any extent of sympathy can lessen affliction, this family may find such relief; for perhaps no man was ever more generally beloved by all who had access to him than the earl of Guilford.

We may form an opinion of the estimation the celebrated university of Oxford entertained of their chancellor while living by the very great honour they paid to his remains. About five o'clock in the afternoon of the 15th, the great bell at St Mary's church at Oxford rang out, which was a signal that the funeral procession had arrived in the environs of that city. The officers of the university, and the whole body of resident students, were previously assembled in Magdalen College, in order to pay homage, tribute to the memory of their deceased chancellor. They joined the procession at Magdalen Bridge, and paraded on foot before the hearse up the high-street to Carfax; from thence down the corn market to St Giles's church at the town's end in a most solemn manner. Here they halted and opening to the north and south, the hearse and other carriages passed through the whole university being uncovered. The hearse and attendants were proceed to Banbury, where his Lordship's remains were deposited in the family vault.

North-West Passage, the most northerly promontory in Europe, on the coast of Norway. E. Long. 21° 0'. N. Lat. 78° 0'.

North-West Ferry, a small village, on the north side of the Firth of Forth, at the Queen's-Ferry passage. There was here formerly a chapel, served by the monks of Dunfermline, and endowed by Robert 1. Near it are large granite quarries, which partly supply London with paving-stones, and employ many vessels for the conveyance. The granite (Mr Pennant says) lies in perpendicular strata, and above is a reddish earth, filled with micaceous friable nodules.

Northard, a cape or promontory of Kent in the isle of Thanet, four miles east of Margate. Between this and the South-Foreland are the Downs, through which all ships pass that are bound to or from the west. E. Long. 1° 25'. N. Lat. 51° 25'.

North-West Passage, a passage to the Pacific Ocean through Hudson's Bay or Davis's Straits, and which hath been frequently attempted without success; notwithstanding which, many people are still of opinion that it is practicable.

The idea of a passage to the East Indies by the north pole, or through some opening near to it, was suggested as early as the year 1527. The person who had the honour to conceive this idea was Robert Thorne a merchant of Bristol, who addressed two papers on the subject, the one to the king Henry VIII., the other to Dr Ley, ambassador from that monarch to the emperor Charles V. To remove any objection to the undertaking which might be drawn from the supposed danger, he inflicts, in his address to the king, upon the great advantages of constant day-light in the polar seas, and the probability of the climate being in those regions temperate during the summer months. In the paper addresed to Dr Ley, he observes that cosmographers may as probably be mistaken in the opinion which they entertain of the polar regions being impassable from extreme cold, as it has been found they were in supposing the countries under the line to be uninhabitable from excessive heat. The possibility of the passage was, in consequence of these addresses, very generally supposed; and in 1557, Sir Martin Frobisher failed to 62° north latitude, where he discovered the straits which have since bore his name. In 1577, Barne, in a book intitled the Regimen of the Sea, mentions a north-west passage as one of the five ways to Cathay; and dwells on the mildness of the climate, which, from the constant prevalence of the sun during summer, he imagines must be found near the pole. In 1578, George Belt, a gentleman who had been with Sir Martin Frobisher in his voyages of discovery, wrote a very ingenious discourse to prove all parts of the world habitable. It does not, however, appear that any voyage was undertaken, for the express purpose of attempting to fall to India in a north-west direction, till the year 1607, when Henry Hudson was sent at the expense of some merchants in London, to discover a passage by the north pole to Japan and China. He failed from Gravelend on the 18th of May, and on the 21st of June fell in with the land to the westward, in latitude 73°, which he named Hold-with-hope. On the 27th he discovered Spitsbergen, and met with much ice. The highest latitude in which he made an observation was 80° 27'. See Hudson.

In March 1609, Jones Poole was sent by Sir Thomas Smith, and the rest of the Muscovy company, to make further discoveries towards the north pole. After great severity of weather, and much difficulty from ice, he made the south part of Spitsbergen on the 16th of May, and sailing along and sounding the coast, he made many accurate discoveries; but was not in that voyage able to proceed beyond 79° 50'. He was again employed (1611), in a small veal called the Elizabeth, to attempt the north-west passage; but after surmounting numberless difficulties, and penetrating to 80° of latitude, he left his ship at Spitsbergen. Two voyages, equally unsuccessful, were made in 1614 and 1615, by Baffin and Fotherby; the latter of whom concludes the account of his discoveries and dangers, with exhorting the company which employed him not to adventure more than 150 or 200 pounds at most on yearly voyages to these seas.

Hitherto nothing had been done in this great undertaking but by private adventurers, fitted out for the
the double purpose of discovery and present advantage; and the polar regions were suffered to remain unexplored in that direction, from the year 1615 till 1773, when the earl of Sandwich, in consequence of an application which had been made to him by the Royal Society, laid before his majesty a proposal for an expedition to try how far navigation is practicable towards the north pole. Upon receiving this proposal, his majesty was pleased to direct that the voyage should be immediately undertaken, with every assistance that could contribute to its success. Accordingly, the Racehorse and Carcass bombs were fitted out for the purpose, and the command of the expedition given to Captain Phipps, now Lord Mulgrave. His Lordship’s instructions were to proceed up to the pole, or as far towards it as possible, and as nearly upon a meridian as the ice or other obstructions should admit; and during the course of the voyage, to make full observations of every kind as might be useful to navigation, or tend to the promotion of Natural knowledge. A very accurate account of this voyage was published by his Lordship in 1774. He had by exerting all the powers of a skillful and intrepid seaman, forced his way, on the 18th of August, to 80° 37’; but could proceed no farther, as he was there opposed by one continued plain of smooth unbroken ice, bounded only by the horizon.

Many other attempts have been made to discover this passage, by failing along the western coast of America; but hitherto none of them has been crowned with success. So early as 1578, Sir Francis Drake assailed queen Elizabeth that he had failed some leagues up the straits of Anian (see Anian), and discovered New Albion, to the north of California; but the strait is now known to have no existence; and Draké’s real discoveries were not improved. In 1630, King Cha. I. sent captain Luke Fox in one of his pinnaces to attempt the passage; but of his proceedings we know nothing, but that he reached port Nelson in Hudfon’s bay, where he found some remains of former navigators. Next year captain James was fitted out by the merchants of Britol for the same purpose. James was one of the ablest navigators that ever failed from England or any other country; and his voyages to the north were printed in 1633. After all the experiments he had made, he concluded that there was no such passage; or if there be, he affirmed that the discovery of it would not be attended with those advantages which are commonly expected. His reasons, however, for these opinions have been answered, and many subsequent attempts have been made to perform what he thought impossible. The arguments for a north-west passage were so plausible, that, in 1744, an act of Parliament was passed to encourage the discovery of it. Among many others, captain Cook attempted the discovery in vain, and thence adopted James’s opinion. See Cook’s Discoveries, p. 103.) This celebrated navigator, after having proceeded northwards to the western extremity of America, and ascertained the proximity of the two great continents of Asia and America, returned to the Sandwich islands, firmly persuaded of the impracticability of a passage in that hemisphere from the Atlantic into the Pacific Ocean, either by an eastern or a western course.

Later voyagers, however, have pretended to detect some errors in Cook’s discoveries; and the author of North-east small tract, intitled An authentic Statement of all the Facts relative to Northe-Sound, goes a great way to make the discovery not yet hopeless. In his account of the expedition under the direction of Melf’s Etches, he says, that “one of the first discoveries made by these ships was, that what was by the immortal Cook laid down as a continuation of the north-west continent of America, and lying between the northern latitudes of 48 and 57°, is on the contrary an extensive cluster of unexplored islands inhabited by numerous tribes of friendly Indians, with whom a regular connection was formed.”

These islands they discovered, contrary to the affe­tion of captain Cook, to conceal the opening of a vast inland sea, or archipelago, in all probability equal to the Mediterranean or Baltic seas, and dividing the great northern continent of America. The Princep’s Royal penetrated some hundred leagues among them, in a north-east course, to within 200 leagues of Hudfon’s house, but had not an opportunity to explore the extreme termination of that archipelago, their commerical concerns obliging them to return to the China market; but the commanders had the strongest reasons to believe, had time favoured their survey, that they should have been able to discover the long-wished for passage between the Atlantic and South Sea. They conceived, that should neither the inland arm of the sea through which the Princeps Royal penetrated, nor a large strait named Sir Charles Middleton’s, about three degrees to the southward, be found to reach across the continent, yet that the land barrier must be very inconsiderable; and that at the extremity of this bay a practicable passage, either by rivers or lakes, will, by perseverance, be found terminating towards Hudfon’s bay.

Upon the whole, however, it appears to us extremely doubtful whether there be such a passage; but it is much more likely to be discovered, if discovered at all, by the progressive advances of mercantile enterprise, than by any immediate expedition undertaken for that purpose.

North-East Passage, a passage to the East Indies along the northern coasts of Asia, which, like the former, hath frequently been attempted, but hitherto without success. The first attempt was made in 1553 by Sir Hugh Willoughby, who commanded three ships. He departed from the Thames and failed to the North Cape, where one of his ships left him, and returned home. The other two ships being separated, Sir Hugh proceeded farther northwards, and discovered that part of Greenland which the Dutch have since called Spitzburg; but the severity of the cold obliging him to return to the southward, he was forced, by bad weather, into the river Arzina, in Mu­covite Lapland, where, not being able to come out, he was found the next spring frozen to death, with all his ship’s company; having the notes of his voyage and his last will lying before him, whereby it appeared that he lived till January. But Richard Chancel­lor, in the third ship, with better success, in the mean­while entered Wardhuys, where he waited some time for his companions to no purpose; uncertain whether they were lost, or driven farther by tirs of weather. He held a council on what he should do; whether to return
return, or pursue his voyage. Whatever danger might be in the air, every one agreed to it, that they might not seem to have less courage than their captain. They therefore set sail, and in a few days found themselves in a sea where they could no longer perceive any night. This ship, wandering about, entered soon after into a large bay or gulf. Here they anchor, in sight of land; and while they were examining the coast, they discovered a fishing boat. Chancellor getting into his floop, went towards it; but the fishermen took to flight. He followed, and, overtaking them, showed them such civilities as conciliated their affections to him; and they carried him to the place where now is the famous port of St Michael the Archangel. These people immediately spread through all the coasts an account of the arrival of those strangers; and people came from several parts to fee them, and ask them questions. They, in their turn, examined the others, and found that the country they were in, was Ruffia, governed by the mighty Emperor John Baflilowitz. Chancellor from Archangel travelled on sledges to the Czar at Moscow: from whom, overjoyed at the prospect of opening a maritime commerce with Europe, he obtained privileges for the English merchants, and letters to King Edward VI. who was not, however, alive to receive them.

In 1585, Mr John Davis in two barks discovered Cape Defolation, which is supposed to be part of Greenland; and two years after advanced as far as Lat 72°, where he discovered the strait which still bears his name. To enumerate all the attempts which have been made to discover a north-eaft passage, would swell the article to very little purpose. The English, Dutch, and Danes, have all attempted it without success. The last voyage from England for this purpose was made in 1676, under the patronage of the duke of York. That unfortunate prince, who was on all occasions earl of the promotion of commerce, and the Lord Berkeley, &c. fitted out a ship commanded by Captain Wood, for an attempt once more to find a north-eaft passage to India, accompanied with a ship of the king's. They were encouraged to this attempt, after it had been so long deferred, by several new reports and reafonings; some of which seem not to have been very well grounded.---As.

1. On the coast of Corea, near Japan, whales had been found with English and Dutch harpoons sticking in them. This is no infallible proof that ships could get thither by a north-eaft passage, although whales might.

2. That, 20 years before, some Dutchmen had failed within one degree of the north pole, and found it temperate weather there; and that therefore William Barents, the Dutch navigator who wintered at Nova Zembla in the year 1596, should have failed further to the north before turning eastward; in which case, said they, he would not have found so much obstruction from the ice.

3. That two Dutch ships had lately failed 300 leagues to the eastward of Nova Zembla; but their East India company had filled that design, as against their interest—and such like other airy reports. But this attempt proved very unfortunate. They doubled the North Cape, and came among much ice and drift wood, in 76° of north latitude, fleeing to the coast of Nova Zembla, where the king's ship struck upon the rocks, and was soon beat to pieces; and Captain Wood returned home with an opinion, "that such a passage was utterly impracticable, and that Nova Zembla is a part of the continent of Greenland."

These passages, however, are not yet deemed impracticable by all. The Count de Buffon holds it for certain, that there is a passage from Europe to China by the north sea. The reason why it has been so often attempted in vain, he thinks, is, that fear prevented the undertaking it in a large distance from land, and from approaching the pole, which they probably imagined to be an immense rock. Hence he affirms, that if any farther attempts be made to find a passage to China and Japan by the north seas, it will be necessary to keep at a distance from the land and the ice; to steer directly towards the pole; and to explore the most open seas, where unquestionably, says he, there is little or no ice. This opinion has been lately revived by the Hon. Daines Barrington, who says, that if the passage be attempted by the pole itself, he has very little doubt of its being accomplished. See North Pots.

NORTHAMPTON, a town in England, capital of a county of the same name, situated in W. Long. c. 55. N. Lat. 52. 15. According to Camden, it was formerly called North-afton, from its situation to the north of the river Nen, called recently Aftona, by which and another leffer river it is almost inclosed. Dr Gibbon says, that the ancient Saxon annals called both it and Southampton simply Hamton; and afterwards, to distinguish them, called the one from its situation, Southampton, and the other Northampton; but never North aftenon. Though it does not appear to be a place of very great antiquity, nor to have emerged from obscurity till after the conquest, it has sent members to parliament since the reign of Edward I. and being in the heart of the kingdom, several parliaments have been held at it. There was also a castle, and a church dedicated to St Andrew, built by Simon de Sande Licio, commonly called Sandon, the first earl of Northampton of that name. It is said to have been burnt down during the Danish depredations; but in the reign of St Edward it appears to have been a considerable place. It was besieged by the barons in their war with King John; at which time that military work called Hauhhil, is supposed to have been raised. In the time of Henry III., it sided with the barons, when it was besieged and taken by the king. Here the bloody battle was fought in which Henry VI., was taken prisoner. It was entirely consumed by a most dreadful fire in 1675; yet, by the help of liberal contributions from all parts of the country, it hath so recovered itself, that it is now one of the neatest and best-built towns of the kingdom. Among the public buildings, which are all lofty, the most remarkable are the church called All Hallowes (which stands at the meeting of four spacious streets), the inns and alehouse, and the George-Inn, which belongs to the poor of the town. A country-hospital or infirmary has been lately built here, after the manner of those of Bath, London, Bristol, &c. It has a considerable manufacture of flaces and stockings; and its fairs are noted for horses both for draught and race.
NOR [110]

besides, it is a great thoroughfare for the north and west roads. It was formerly walled, and had seven churches within and two without. The horse market is reckoned to exceed all others in the kingdom, it being deemed the centre of all its horse markets and horse-fairs, both for saddle and harness, and the chief rendezvous of the jockeys both from York and London. Its principal manufacture is shoes, of which great numbers are sent beyond sea; and the next to that, stockings and lace, as we have hinted at above. It is the richer and more populous, by being a thoroughfare both in the north and west roads; but, being 80 miles from the sea, it can have no commerce by navigation. The walls of this town were above two miles in compass. It is supposed to contain about 10,033 houses, and 5,200 inhabitants. It had formerly a nunnery in the neighbouring meadows, with several other monasteries; and of its very old cattle on the west side of the town, a small part of the ruins are still to be seen. Some discontented scholars came hither from Oxford and Cambridge, about the end of the reign of Henry III. and, with the king's leave, prosecuted their studies here academically for three years; during which there was the face of an university, till it was put a stop to by express prohibition, because it was a damage to both universities. The public horse-races are on a neighbouring down, called Peg-Legs. In and about the town are abundance of cherry-gardens. Within half a mile of the town is one of the crofts erected by King Edward I. in memory of his queen Eleanor, whose corpse was reeved there in its way to Westminster. On the north side of the river, near that crofs, many Roman coins have been ploughed up. At Guilfborough, north west of Northampton, are to be seen the vestiges of a Roman camp, the situation of which is the more remarkable, as lying between the Nen and the Avon, the only paths from the north to the four parts of England not intercepted by any river. This camp was secured only by a single intrenchment, which was, however, very broad and deep.

NORTHAMPTONSHIRE, a county of England, is situated in the very heart of the kingdom: bounded on the east by the counties of Bedford and Huntingdon; on the south by those of Buckingham and Oxford; on the west by Warwickshire; and on the north by the counties of Leicester, Rutland, and Lincoln, which are separated from it by the Iffer Avon, and the Welland. Its greatest length is about 50 miles, its greatest breadth about 20, and its circumference about 130. It contains 330 parishes. There are in it one city, 11 market-towns, 25,000 houses, and 150,000 inhabitants. Nine members are returned to parliament for this county, viz. two knights for the shire, two for the city of Peterborough, two for each of the towns of Northampton and Brookley, and one for Higham Ferrers. It lies in the Midland circuit, and in the diocese of Peterborough. As this country is dry, well cultivated, free from marshes, except the fens about Peterborough, in the centre of the kingdom, and of course at a distance from the sea, it enjoys a very pure and wholesome air. In consequence of this it is very populous, and so full of towns and churches that 30 spires or steeples may be seen in many places at once view; and even in the fens, the inhabitants seem to enjoy a good state of health, and to be little affected by the water which frequently overflows their grounds, especially in winter, but is never suffered to remain long upon it. Its soil is exceeding fertile both in corn and pasture; but it labours under a scarcity of fuel, as it doth not produce much wood, and, by lying at a distance from the sea, cannot be easily supplied with coal. Its commodities besides corn, are sheep, wool, black cattle, and silk-petre; and its manufactures are ferges, tammies, slannahons, boots, and shoes. Besides many leffer brooks and streams, it is well watered by the rivers Nen, Welland, Ouse, and Leam; the three first of which are large, and for the most part navigable.

NORTHAMPTON, a county of North America, in Virginia, forming the south part of the peninsula on the eastern coast of Virginia.

NORTH rocks, (otherwise called St Patrick's rocks, from a feat of lone amongst them called St Patrick's chair, whence the rocks have taken this second name; situated in the harbour of Donaghadee, in the county of Down, and province of Ulster, in Ireland. From north to south they are about two thirds of a league between which is clean good ground. But care must be taken of the south rock, on which many ships have perished; for it is overflowed by every tide, and no crew can save their lives if the wind blows high. This rock stands a full mile from the shore.

NORTH SEA. See North-Sea.

NORTHERN LIGHTS, the same with aurora borealis, under which article we have given a copious account of this phenomenon, and of the supposed causes of it. Natural science, however, does not arrive at perfection at once, and it is well if it does so after trials repeated for years with care and accuracy. How far the causes that have been assigned for this appearance will account for it, or whether they will be able to remove all difficulties, it is not for us to determine; but it is the part of philosophers to hear all fides, and to attend with patient avidity to every hypothesis, rejecting or receiving as reason, after the most careful investigation, shall seem to favour the one side or the other. Wishing to lay before our readers every thing important either in science or in literature, we cannot let pass the opportunity which the present article affords us, of mentioning an hypothesis which Dr Stearns, an American, formed, about the year 1788, to account for the appearances called aurora borealis; and aurora australis. For this last, see AURORA BOREALIS, n° 3.

Doctor Stearns supposes that these phenomena originate from aqueous, nitrous, fulphureous, bituminous, and other exhalations, from the flames of various kinds of earths or other minerals, vegetables, animals, fires, volcanoes, &c. These, he thinks, become rarefied, and being charged with fluid, become specifically lighter than the circumambient air: hence, of course, they ascend; and being elevated to the upper regions of the air and driven by the winds from warmer to colder climates, the cold makes them combine and stiffen. When they are afterwards agitated by different currents of air, they sparkle and erackle like the hairs of cats and other animals when stiffened with cold. This coruscation in quite cold atmospheres,
spheres, and in those which are more temperate, appears in different positions in the horizon, zenith, or otherwise, according to the situation of the spectator, and the position of the elevated exhalations. The difference of colours the Doctor supposes to arise from the different qualities of the articles combined, those of the most inflammable nature shining with the greatest lustre.

The Doctor likewise tries to account for these lights not appearing, or but seldom appearing, in ancient times. The atmosphere, he thinks, was not impregnated with materials proper to produce them. He imagines that the increased consumption of fuel, in land, which are inexhaustible, enrich the proprietors and profit the merchants; and profecuted.

Northumberland raises a good number of excellent fountains: its climate, like that of Kent, is moister; and the difference of colours the pears in different positions in the horizon, zenith, or German

mountainous country in the neighbourhood of the sea, especially the Tweed, in which a great number of grain; and great part of it is laid out to plunder by banditti.

the two rivers Tweed and the who propounded to the two small

NORTHUMBERLAND, the most northerly county of England, and formerly a dillitent kingdom, is bounded on the north and west by the river Tweed, which divides it from Scotland, the Cheviot-hills, and part of Cumberland; washed on the east by the German Ocean; and separated from Durham on the south by the rivers Tyne and Derwent. This county, which gives the title of duke to a nobleman who married the daughter of Algernon duke of Somerset, whose mother was heiress of the Percy family, extends about 66 miles in length from north to south, and about 47 in breadth from east to west. It is remarkably populous, containing 12 market-towns, 280 villages, and 400 parishes. The face of the country, especially towards the west, is roughened with huge mountains, the most remarkable of which are the Cheviot-hills, and the high ridge called Riding-hall; but the lands are level towards the sea-fide and the borders of Durham. The climate, like that of every other mountainous country, in the neighbourhood of the sea, is moist and disagreeable: the air, however, is pure and healthful, as being well ventilated by the breezes and fresh gales of wind; and in winter mitigated by the warm vapours from the two seas, the Irish and the German Ocean, between which it is situated. The soil varies in different parts of the county. Among the hills it is barren; though it affords good pasture for sheep, which cover those mountains. The low country, when properly cultivated, produces plenty of wheat, and all sorts of grain; and great part of it is laid out in meadow-lands and rich enclosures. Northumberland is well watered with many rivers, rivulets, and fountains: its greatest rivers are the Tweed and the Tyne. The Tyne is composed of two streams called South and North Tyne: the first rises on the verge of Cumberland, near Allon-Moor; enters Northumberland, running north to Haltwhistle; then bends easterly, and receiving the two small rivers East and West Alston, unites above Hexham with the other branch, taking its rise at a mountain called Fowell-head in the western part of the county, thence called Tine-deale; it swelled in its course by the little river Shele; joins the Read near Billingham; and running in a direct line to the fouth-east, is united with the southern Tyne, forming a large river that washes Newcastle, and falls into the German Ocean near Tynemouth.

In all probability the mountains of Northumberland contain lead-ore and other mineralized metals in their bowels, as they in all respects resemble those parts of Wales and Scotland where lead mines have been found and prosecuted. Perhaps the inhabitants are diverted from inquiries of this nature, by the certain profits and constant employment they enjoy in working the coal-pits, with which this county abounds. The city of London, and the greatest part of England, are supplied with fuel from these flows of Northumberland, which are inexhaustible, enrich the proprietors, and employ an incredible number of hands and shipping. About 658,850 chaldrons are annually shipped for London.

There are no natural woods of any consequence in this county; but many plantations belonging to the Earls of Berners and Parkinson, which gives the title of Duke to the holders of the respective estates. The hills and mountains abound with a variety of game, such as red deer, foxes, hares, rabbits, heathcock, grouse, partridge, quail, plover, teal, and woodcock: indeed, this is counted one of the best sporting counties in Great Britain. The sea and rivers are well stocked with fish; especially the Tweed, in which a vast number of salmon is caught and carried to London, where being pickled, they are conveyed by sea to London, and sold under the name of Newcastle Salmon.

The Northumbrians were anciently distinguished as a savage, barbarous people, addicted to cruelty, and inured to rapine. The truth is, before the union of the two crowns of England and Scotland, the borderers on each side were extremely licentious and ungovernable, trained up to war from their infancy, and habituated to plunder by the mutual incursions made into each kingdom; incursions which neither treaty nor treachery could totally prevent. People of a pacific disposition, who proposed to earn their livelihood by agriculture, would not on any terms remain in a country exposed to the first violence of a bold and desperate enemy; therefore the lands lay uncultivated, and in a great measure defecrated by every body but lawless adventurers, who subsisted by theft and rapine. There was a tract 50 miles in length and 6 in breadth, between Berwick and Carlisle, known by the name of the Debated Land, to which both nations laid claim, though it belonged to neither; and this was occupied by a set of banditti who plundered on each side, and what they stole in one kingdom, they sold openly in the other:
of Marches or borders in each kingdom; and these offices were always conferred on noblemen of the first character for influence, valour, and integrity. The English border was divided into three marches, called the east, west, and middle marches: the gentlemen of the country were constituted deputy-wardens, who held marches courts, regulated the watches, disciplined the militia, and took measures for assembling them in arms at the first alarm: but in the time of peace between the two nations, they were chiefly employed in suppressing the insolence and rapine of the borderers. For all these purposes they were chiefly employed in the lands, and the reformation of the inhabitants. Some Courts were held at the most remarkable towns, and a considerable part of the taxes were collected here. The first march extended from the Tyne to the Trent; the second from the Trent to the Dee; and the third from the Dee to the Solway Firth. The inhabitants of these marches were chiefly engaged in agriculture, and manufactured woollen stuffs for the English market, and in making the Liv-erpo'ol-earth.—

2

In the town of Chester, long noted for its rock salt and brine pits. The salt itself extends about five miles in a north-south direction. It is about 700 feet deep at the highest point, and 600 feet deep at the lowest. The brine is about 90 feet deep. The salt is excavated by means of a canal, which is about 12 feet wide and 18 feet deep. The salt is worked in a series of galleries, which are about 30 feet wide and 30 feet high. The brine is collected in large basins, and is then evaporated to form a salt of excellent quality. The salt is worked by the use of steam power, and the brine is evaporated by means of steam engines. The town of Chester is the largest producer of salt in England, and the production of salt is one of the chief industrial activities of the town. The town is also noted for its wool industry, which is one of the oldest and most important in England. The wool is produced on the surrounding farms, and is then processed in the many wool mills that can be found in the town. Chester is also noted for its rich history, and is home to many important historical sites, including the Chester Castle, the Chester Cathedral, and the Chester Racecourse. The town is also a popular tourist destination, and attracts many visitors each year. In addition to its industrial and historical attractions, Chester is also renowned for its excellent shopping, and is home to many high-end shops and boutiques. The town is also noted for its excellent food, and is known for its many restaurants and cafes. Chester is a fascinating and charming town, and is well worth a visit.
Norway is divided into the four governments of Aggerhus, Bergen, Drontheim, and Wardhus, besides that of Balhus, which is now subject to Sweden. The province of Aggerhus comprehends the south-east part of Norway extending in length about 300 miles. Its chief towns are Christiana, the see of a bishop, suffragan to the metropolitan see of Drontheim, where the sovereign court of justice is held, in presence of the viceroy and the governor of the province; Aggerhus, about 15 miles to the south-west of Christiana; Frederiksholm or Frederickstadt, in the siege of which Charles XII. of Sweden lost his life; Saltsberg, Tonberg, Alleen, Hammar, and Hollen.

The government of Bergen lies in the most fotherly and weftely part of Norway, including the city of the same name, which is an episcopal see, and a place of considerable trade; and Staff-hanger, situated in the bay of Dückenhor, about 80 miles to the southward of Bergen. The third province, called Drontheim or Trontheim, extends about 500 miles along the coast; and is but thinly peopled. The chief town of Drontheim, seated on a little gulf at the mouth of the river Nider, is the only metropolitan see in Norway; and carries on a considerable trade in mats, deals, tar, copper, and iron. Leetirand, Stronden, Scordale, Opdal, Romidael, and Solendael, are likewise places of some traffic. The northern division of Drontheim, called the sub-government of Salten, comprehends the town of Melanger and Scheen. The province of Wardhus, extending to the North Cape, and including the islands, is divided into two parts; namely, Finnmark and Norwegian Lapland. The chief town, which is very inconsiderable, stands upon an island called Ward, from whence the place and the government derive their name. The province of Balhus, though now yielded to the Swedes, is reckoned part of Norway, being a narrow track of land, about 90 miles in length, lying on the coast of the Catgatte.

The great chain of Norway mountains, running from north to south, called indifferently Radfeld, Studefeld, Skarsfeld, and Scoreberg, is known in different parts by other appellations; such as Doresfeld, Lamferd, Sagenfeld, Filefeld, Halvol, Hardangerfeld, Jockelfeld, Pyllefeld, Hiekfeld, and Hangfeld. The height and breadth of this extensive chain likewise vary in different parts. To pass the mountain Hardanger, a man must travel about 70 English miles, whereas Filefeld may be about 50 over. This last rises about two miles and a half in perpendicular height; but Doresfeld is counted the highest mountain of Norway, if not of Europe. The river Dirivone winds along the side of it in a serpentine course, so as to be met nine times by those who travel the winter-road to the other side of the chain. The bridges are thrown over roaring cataracts, and but indifferently fastened to the steep rocks on either side; so that the whole exhibits a very dreadful appearance, sufficient to deter the traveller from hazarding such a dangerous passage; for which reason, people generally choose the road over Filefeld, which is much more tedious. This, however, is the post-road used by the king's carriages. The way is disfigured by rocks fixed at the distance of 200 paces from each other, that, in snowy or dark weather, the traveller may not be bewildered.
For the convenience of refreshing, there are two mountain-slotes or houses maintained on Filefild, as well as upon other mountains, at the expense of the public, and furnished with fire, light, and kitchen utensils. Nothing can be more dismal and dreary than these mountains covered with eternal snow, where neither house, tree, nor living creature is to be seen, but here and there a solitary rein-deer, and perchance a few wandering Laplanders.

In travelling from Sweden to Nordenfields, there is only one way of avoiding this chain of mountains; and that is, where it is interrupted by a long deep valley, extending from Romfild to Galbrandifild. In the year 1612, a body of 1000 Scots, commanded by Sinclair, and sent over as auxiliaries, to the Swedes, were put to the sword in this defile, by the peasants of Guildbrand, who never give quarter.

Besides this chain, there is a great number of detached mountains over all the country, that form valleys and ridges, inhabited by the peasants. Some of these are of incredible height, and others exhibit very remarkable appearances. In failing up Joering Creek on the left hand, the sight is adorned with a group of mountains, resembling the prospect of a city, with old Gothic towers and edifices. In the parish of Oerkong is the high mountain Skophorn, the top of which represents the figure of a fortification, with regular walls and battlements. In the district of Hilgeland appears a very high range of mountains, with seven pinnacles or crests, known by the appellation of the Seven Sibiers, discernible a great way off at sea. To the southward of this range, though in the same district, rises the famous mountain Torghatten, so called because the summit resembles a man's head with a hat on, under which appears a single eye, formed by an aperture through the mountain, 150 ells high, and 3000 ells in length. The sun may be seen through this surprising cavity, which is passable by the foot of travellers. On the top of the mountain we find a reservoir of water, as large as a moderate fish-pond; in the lower part is a cavern, through which a line 400 fathoms in length, being let down, did not reach the bottom. At Heroy in Sundmoor is another cavern called Dolfen, supposed to reach under the sea to Scotland; which, however, is no more than an idle tradition. In the year 1750, two clergymen entered this subterranean cavity, and proceeded a considerable way, until they heard the sea dashing over their heads; the passage was as wide and high as an ordinary church, the sides perpendicular, and the roof vaulted. They defended one flight of natural stairs; but arriving at another, they were afraid to penetrate farther; they had gone so far, however, that two candles were consumed in their progress and return. A cavern of a very curious nature, serving as a conduit to a stream of water, penetrates through the sides of the mountain Limur. In the district of Rake, in the neighbourhood of Frederichkall, are three cavities in a rock; one of which is so deep, that a small stone dropped down, does not reach the bottom in less than two minutes; and then the sound it produces is pleasant and melodious, not unlike the sound of a bell.

The vaft mountains and rugged rocks that deform the face of this country are productive of numberless inconveniences. They admit of little arable ground; they render the country in some parts impassable, and every where difficult to travellers; they afford shelter to wild beasts, which come from their lurking holes, and make terrible havoc among the flocks of cattle: they expel the sheep and goats, as well as the peasants, to daily accidents of falling over precipices: they occasion sudden torrents, and falls of snow, which descend with incredible impetuosity, and often sweep away the labours of the husbandman; and they are subject to dreadful dislocations, by which huge rocks are rent from their sides, and, hurling down, overwhelm the plains below with inevitable ruin. The peasants frequently build their houses on the edge of a steep precipice, to which they must climb by ladders, at the hazard of their lives; and when a person dies, the corpse must be let down with ropes, before it can be laid in the coffin. In winter the mail is often drawn up the sides of steep mountains. Even in the king's road, travellers are exposed to the frequent risks of falling over those dreadful rocks; for they are obliged to pass over narrow pathways, without rails or riling on the sides, either shored up with rotten posts, or suspended by iron bolts fastened in the mountains. In the narrow pass of Naeroe is a remarkable way of the kind, which above 600 years ago, the famous king Surre caused to be made for the passage of his cavalry; and even this would have been found impassable by any other horses than those of Norway, which are used to climb the rocks like goats. Another very difficult and dangerous road is that between Shogfstad and Vang in Volders, along the side of a steep mountain, in some places so narrow, that if two travellers on horseback should meet in the night, they would find it impracticable either to pass each other, or turn back. In such a case their lives could not be saved, unless one of them should alight, and throw his horse headlong into the lake below, and then cling to the rock, until the other could pass. When a sheep or goat makes a false step to the projection of a rock from whence it can neither ascend nor descend, the owner hazards his own life to preserve that of the animal. He directs himself to be lowered down from the top of the mountain, sitting on a crofs stick, tied to the end of a long rope; and when he arrives at the place where the creature flounders, he falls it to the same cord, and it is drawn up with himself. Perhaps the other end of the rope is held by one person only; and there are some instances in which the affistant has been dragged down by the weight of his friend, so that both have perished. When either man or beast has had the misfortune to fall over very high precipices, they have not only been suffocated by the repercussion of the air, but their bodies have been always burnt before they reached the ground. Sometimes entire crefts of rocks, many fathoms in length and breadth, have fallen down at once, creating such a violent agitation of the air, as seemed a prelude to the world's dissolution. At Steenbroe in Lærdal, a stupendous mass, larger than any caille in the universe, appears to have been severed and tumbled from the mountain in large, sharp, and ragged fragments, through which the river roars with hideous bellowing. In the year 1731, a promontory on Sundmoor, called Rommersfield, that hung
The remarkable rivers of Norway are these: The Nied, issuing from Tydalen, on the borders of Sweden, runs westward into the lake Selboe; and afterwards, turning to the northward, falls by the city of Drontheim, to which it anciently gave the name of Nilræs and Nidaros: Sule Ely, that depending from Sulafielde, runs with a rapid course through Nordale into the sea; Gulen, which rises near Sifarsfield in the north; and running 20 leagues westward, through Aales, Hotalaeal, Sten, and Melhuus. discharges itself into the sea, about a league to the west of Drontheim. In the year 1384, this river burnt itself under ground: from whence it again burnt forth with such violence, that the earth and rocks thrown up by the eruption filled the valley, and formed a dam; which, however, was soon broken and washed away by the force of the water. Divers churches, 48 farm-houses, with 250 persons, were destroyed on this occasion. Osteroen, a large river, taking its rise from the mountain Adjey, runs about 30 leagues through Seterdale and Else, and dimerbogues itself into the catarract of Wiland. The river Syre rises near the mountain Lang, and winds its course through the vale of Syre, into the lake of Lunde in the diocese of Christiantan; thence it continues its way to the sea, into which it discharges itself through a narrow strait formed by two rocks. This alteration augments its impetuousity, so that it shoots like an arrow into the sea, in which it produces a very great agitation. Nil and Sheen are two considerable rivers, issuing out of Tillemark. Their water-falls have been diverted, with infinite labour, by canals and passageways cut through the rocks, for the convenience of floating down the timber. Tyreford, or Drammen, is in the neighbourhood of Honifolle, joined by two rivers from Oedale and Hadeland, and dimerbogues itself into the sea near Bragmef. Loven rises in the highest part of Nummedal, and runs through Conberg to the sea near Laurwig. Glamen is the largest river of Norway, distinguished by the name of Star-Elsin, or the great river. It derives its origin from the mountain Dolfe, from whence it winds all along the plains of Oterdale and Soloe; then joins the Verme, another considerable river rising out of Mooe and Gulbranddale. These being joined, traverfs the lake Oeyeren; and thence issuing, run on to Sarp near Frederikstadt.

Narway abounds with fresh-water lakes; the principal of which are, Ryivand in Nordland, Snaafen, Selboe, the Greater and Leffer Mooe, Sliarovand, Sperdille, Rand, Veltin, Saren, Modum, Lund, Nor-foe, Huidfoe, Faritvand, and Oeyevand: all these are well stocked with fish, and navigable for large vessels. Wars have been formerly carried on upon these inland seas; in some of which are small floating islands, or parcels of earth, with trees on them, separated from the main land, and probably recovered in compact masses by the roots of trees, shrubs, and grafts, interwoven in the soil. In the year 1702, the family of Borgs, near Frederikstadt, being a noble edifice, with lofty towers and battlements, suddenly sunk into an abyss 100 fathoms deep, which was instantaneously filled by a piece of water 300 ells in length and about half as broad. Fourteen persons, with 200 head of cattle, perished in this catastrophe, which was occasioned by the river Glamen precipitating itself down a water-fall near Sarp, and undermining the foundation. Of all the water-falls in Norway this of Sarp is the most dangerous for its height and rapidity. The current drives 17 miles; and roars with such violence, that the water, being dashed and comminuted among the rocks, flies in the form of rain, where a beautiful rainbow may be always seen when the sun shines. In ancient times this catarract was made use of for the execution of traitors and other malefactors; they were thrown down alive, that they might be dashed in pieces on the points of rocks, and die in a dreadful commotion, analogous to those they had endeavoured to excite in the community.

Great part of Norway is covered with forests of wood, which constitute the principal article of commerce in this country. They chiefly consist of fir and pine, for which great sums are received from foreigners, who export an immense number of masts, beams, planks, and boards. Besides, an incredible quantity is consumed at home, in building houses, ships, bridges, piles, moles, and fences; so that the vast demand for charcoal to the foundaries, and fuel for domestic uses. Nay, in some places, the trees are felled for no other purpose but to clear the ground, and to be burned into ashes for manure. A good quantity of timber is yearly exported to Scotland and Spain; but this is inconsiderable when compared to the vast exports from Drammen, Frederikshall or Frederikstadt, Christiantania, Sken, Arendal, Christiantan, Christiantania, and Drontheim. The masts and large beams are floated down the rivers, and the reft is divided into boards at saw-mills. These works supply a vast number of families with a comfortable subsistence. A tenth part of all sawed timber belongs to his Danish majesty, and makes a considerable branch of his revenue. The forests in Norway are so vast and thick, that the people seem to think there can never be a scarcity of wood, especially as the soil is peculiarly adapted for the production of timber: they therefore destroy it with a wanton hand; in much that more wood rots in Norway than is burned in the whole kingdom of Denmark. The best timber grows in the provinces of Sultan, Helleland, Romdahl, Gulbranddale, Oterdale, Soloe, Valders, Hallingdale, Sognsford, Tadmark, and the lordship of Nedene.

The climate of Norway is very different in different parts of the kingdom. At Bergen the winter is so moderate, that the seas are always open and practicable both to mariners and fishermen, except in creeks and bays, that reach far up into the country towards Fieldfield, when the keen north easter wind blows from the land. On the easterly shore of Norway from the shores of Sweden to Fieldfield, the cold generally sets in about the middle of October with great severity, and lasts till the middle of April; during which interval the waters are frozen to a very considerable
The cold is still more intense in that part of Norway called *Finnmark*, situated in the frigid zone near the polar circle. But if the winter is generally cold, the summer is often excessively hot, in Norway. The rays of the sun are reverberated from the sides of the mountains so as to render the weather close and sultry in the valleys; besides, the sun's absence below the horizon is so short, that the atmosphere and mountains have not time to cool. The heat is so great that vegetation is remarkably quick. Barley is sown, grows, ripens, and is reaped, in the space of six weeks or two months—The longest day at Bergen consists of 19 hours; the sun rising at half an hour after nine, and setting at three in the afternoon. In the beginning of the year the daylight increases with remarkable celerity; and at the approach of winter, decreases in the same proportion. In summer one may read and write at midnight by the light of the sky. Christlun V. while he resided at Drontheim, used to sup at midnight without candles. In the district of Troms, at the extremity of Norway, the sun is continually in view at midsummer. It is seen to circulate day and night round the north pole, contracting its orbit, and then gradually enlarging it, until at length it leaves the horizon. In the depth of winter, therefore, it is for some weeks invisible; and all the light perceived at noon is a faint glimmering for about an hour and an half, proceeding from the reflection of the sun's rays from the highest mountains. But the inhabitants of these provinces are supplied with other lights that enable them to follow their employments in the open air. The sky being generally serene, the moonshine is remarkably bright, and, being reflected from the mountains, illuminates the valleys. They are also supplied by the Aurora Borealis, which is very frequent in the northern parts of Europe.

The air of Norway is generally pure and salubrious. On the sea-coasts, indeed, it is rendered moist by vapours and exhalations: but in the midland parts of the country, towards the mountains, the climate is so dry, that meal may be kept for many years without being worm-eaten or damaged in the least. The inhabitants have no idea of sickness, except what is occasioned by excesses. It is said, that in the vale of Gulbrand the inhabitants live to such extreme old age, that they become weary of life, and cause themselves to be removed to a less salubrious climate, whereby they may have a chance of dying the sooner. In consumptions, however, the moist air on the sea-side is found to be most agreeable to the lungs in respiration. Norway, being a mountainous country intersected by creeks, abounding with lakes, rivers, and snow, must be subject to frequent rains; and from sudden thaws the inhabitants are sometimes exposed to terrible disasters. Vail make of snow falling from precipices, overcomes men, cattle, boats, houses, may, even whole villages. About two centuries ago, a whole parish was covered and destroyed by an immense mass of snow; and several domestic utensils, as scythes, knives, and barses, have been at different times brought to light by a rivulet that runs under the snow, which has been gradually hardened and increased by repeated frosts and annual accretions.

The winds that chiefly prevail on the western coast are those that blow from the south; whereas, on the other side of Fife, the winds that produce and continue the hard frosts are always northerly. In the summer, there is a kind of regular trade-wind on the coast of Bergen. In the forenoon the sea begins to be cooled with a westerly breeze, which continues till midnight. Then the land breeze begins from the east, and blows till about ten in the morning. The coast is likewise subject to sudden squalls and storms. Hurricanes sometimes rise at sea; and in these latitudes the phenomenon called a *water-fog* is not uncommon. One of these in the neighbourhood of Ferro is said to have sucked up with the water some laths of herrings, which were afterwards dropped on Kolter, a mountain 1200 feet high.

The fresh-water of Norway is not very light or pure; but on the contrary is generally turbid, and deposits a sediment of adventitious matter, being sometimes impregnated with ochre, and particles of iron. Nevertheless it is agreeable to the table, and remarkably salubrious; as appears from the good health of the common people, who drink little or no other liquor.

The soil of Norway varies in different places according to the situation of rock or valley. The mountains here, as in every other country, are bare and barren; but the earth washed down from them by the rain enriches and fertilizes the valleys. In these the soil generally consists of black mould, sand, loam, chalk, and gravel, lying over one another in unequal strata, and sometimes in three or four successions; the mould that lies uppermost is very fine and mellow, and fit to nourish all sorts of vegetables. There is also clay found in different parts of this kingdom, of which the inhabitants begin to make earthen ware; but bricks and tiles are not used in building. The climate of the country is so warm that many places deformed by large swamps and marshes, very dangerous to the traveller. Near Leefoe in the diocese of Christiand, a wooden cauway is extended near a mile over a morass; and if a horse or any other animal should make a false step, he will sink at once into the abyss, never to rise again.

In a cold country like Norway, roughened with rocks and mountains, interfered with bogs, and covered with forests, we cannot expect to find agriculture in perfection. The ploughed lands, in respect to mountains, woods, meadows, and wafes, do not exceed
Norway. the proportion of 1 to 80; so that the whole country does not produce corn to maintain above 1/2 the number of its inhabitants. The peasants are discouraged from the practice of husbandry by the frequency of accidents that seem peculiar to the climate. Even in the fruitful provinces of Guldbrandsfæde, Otterdale, and Soloer, as well as in other places, when the corn appears in the most flourishing condition, the whole hope of the harvest is sometimes destroyed in one night by sudden frosts that nip the blade and extinguish the vegetation. The kingdom is more over visited by some unfavourable years, in which the sun seems to have loft his genial power; the vegetables are stunted; the trees look and bloom, yet bear no fruit; and the grain, though it ripens, will yet produce nothing but empty ears and straw. This calamity, however, rarely occurs; and in general the cultivated parts of Norway yield plentiful crops of excellent rye, barley, and oats. The most fruitful provinces are Nordland, Tunderbarre, and Numedale, in the diocese of Drothiem; Sogniford, and Vaas, in that of Bergen; Sodder, Rystul, Redbydelag, and the lordship of Nedenes, in the diocese of Christin, and Hedemark in the diocese of Aggerhus; Hadeland, Totten, Romerige, Ringerige, and Guldbrandsfæde: these territories not only produce grain enough for their own consumption, but likewise support their neighbours, and even supply part of Sweden. Peas are likewise propagated in this country, together with wheat, buck-wheat, hops, hemp, and flax, but not to any considerable advantage. The meadows are well sowed with purlage for sheep and cattle, and the fields are productive of those vegetables which are common in other northern countries. Within these 50 years the people of Norway have bestowed some attention on the culture of gardens, which in former times was so neglected, that the cities and towns were supplied with leeks, cabbage, and roots, from England and Holland. At present, however, the Norwegians raise their own culinary roots and vegetables, which thrive there as well as in other parts of the kingdom; such as the hagbar, a kind of fleshy; an infusion of which in wine makes a pleasant cooling liquor; juniper berries, currants red and white, field-bar or fun berries, raspberries, gooseberries, blackberries, strawberries, &c. with many other species that seem to be natives of Norway and Sweden. Among these are the treenuts, the produce of the myrtillus repens, red and sweet, found in the firing in perfection under the snow, and much relished by the reindeer; crakebeer, resembling bilberries, deemed a powerful antiscorbutic; age-beer, larger and blacker than bilberries, of a pleasant acid, ripened by cold, and used as cherries for an infusion in wine; and finally tylte-beer, a red pleasant berry growing on a short stem, with leaves like those of box: they are plucked off by hand, and sent to Denmark to be preferred for the table, where they are eaten by way of defert.

Of the trees that grow wild in Norway, the principal are the fir and the pine. The firf tree yields an annual revenue of 1,000,000 of rix-dollars, if we include the advantages resulting from the saw-mills and the malt; one of which lath has been known to sell for 200 rix-dollars. The red fir-tree, which grows on the mountains, is so rich in turpentine as to be almost incorruptible. Some of the houses belonging to the Norwegian peasants, built of this timber, are supposed to be above 400 years old. In Guldbrandsfæde the house is said to be seen standing in which king Olaf lodged five nights above 700 years ago, when he travelled round the kingdom to convert the people to the Christian faith. Even 100 years after the trunk of the fir-tree has been cut down, the peasants balm the roots for tar, which is a very profitable commodity. In the fens, the reift of the fir-tree, is by nature transformed into a substance which may be called Norway frankincense. The buds or pine-apples of this tree, boiled in stale beer, make an excellent medicine for the fcurvy; left unpleasant to the taste, though as efficacious, as tar-water. The pine-tree is more tall and beautiful than the fir, though inferior to it in strength and quality; for which reason the planks of it are sold at an inferior price, and the peasants waste it without remorse. Norway likewise produces some ferefts of oak, which is found to be excellent for ship-building. Here also grow plenty of elm-trees; the bark of which, being powdered, is boiled up with other food to fatten hogs, and even mixed by the poor among their meal: also the ash, from which the peasants distil a balm used in certain
certain disorders, and which is used both externally and internally. Many other fruits throve in this country, an enumeration of which would prove too tedious. Hazels grow here in such abundance, that 100 tons of the nuts are annually exported from Bergen alone.

A great diversity of stones is found in Norway, some of which are of a surprizing figure. Several mountains consist chiefly of a brown pebble, which decays with age; next, it forms diluvial silt, and drops into the sea, and the cement being thus loosened, a terrible disintegration ensues. In some places the grey and black pebbles are intermixed with iron, copper, lead, silver, and gold. The ground in certain districts is covered with the fragments of rocks that have been precipitated from the summits of mountains, and broken by their fall into innumerable shivers. Between 20 and 30 years ago, in the neighbourhood of Bergen, a man was suddenly overwhelmed with such a mass, which formed a kind of vault around him. In this dreadful tomb he remained alive for several weeks. By his loud cries the place of his confinement was discovered: but it was impossible to remove the huge stones by which he was inclosed. All that his friends could do for him was, to lower down meat together with some detached pieces by his loud cries the place of his confinement was discovered. All that his friends could do for him was, to lower down meat together with some detached pieces. The lead found mixed in the silver ore is an article of small importance in Norway; yet some mines of this metal have been lately opened in the district of Solber by the proprietors of the copper work of Oudal. A vitriol work has been begun near Kongberg: the mines yield great plenty of sulphur; which, however, the Norwegians will not take the trouble to melt and separate, because immense quantities are found at a cheaper rate in the island of Iceland. Alum is found between the flate flake near Christiana in such plenty, that works have been set up for refining this mineral, though they have not yet brought it to any degree of transparency. His Danish majesty has established salt works in the peninsula of Valeo, about six English miles from Tonberg, where this mineral is extracted in large quantities from the sea-water.

Besides the animals common to other countries, Norway is said to contain many of the uncommon and dubious kind; such as the kraken, merman, sea-serpent, &c. See these articles.

Many Danilb, Englilb, Scotch, Dutch, and German families have now settled in Norway: and indeed form no inconsiderable part of the trading people: but the original inhabitants are the descendants of those fierce Normanni, who harassed almost all the coasts of Europe with piratical armaments in the 8th, 9th, and 10th centuries.

"Our first certain knowledge of the inhabitants of this country (says Pennant) was from the defolate and deserted nation they brought on the southern nations by their zoological invasions. Their country had before that period the name of Norway, and the inhabitants of this country copper-mines have been discovered, but the principal, and perhaps the richest in all Europe, is at Roraa, about 100 English miles from Drontheim. This work yields annually about 1,000 chips pounds of pure copper; the foundries belonging to it consume yearly about 14,000 loads of coal, and 500 fathoms of wood. The next in importance is the copper-work at Lykken, about 20 miles from Drontheim. A third work is carried on at the village of Noyken, at the distance of 30 miles from the same place; and here the copper ore precipitates the copper from its menhir, by means of iron. There are a fourth copper-work at Silve, about 30 miles distant from Drontheim, though the least considerable of the four. Other copper-mines of less note are worked in different parts of the kingdom. Iron is still in greater plenty, and was the first metal wrought in this country. Many hundred thousand quintals are annually exported, chiefly in bars, and part of it in ingots, pots, kettles, and cannon: the national profit arising from this metal is estimated at 300,000 rix dollars. There is a species called moor-iron, found in large lumps among the morasses: of this the peasants make their own domestic tools and utensils, such as knives, sickles, and axes. The lead found in the silver-ore is an article of small importance in Norway; yet some mines of this metal have been lately opened in the district of Solber by the proprietors of the copper work of Oudal. A vitriol work has been begun near Kongberg: the mines yield great plenty of sulphur; which, however, the Norwegians will not take the trouble to melt and separate, because immense quantities are found at a cheaper rate in the island of Iceland. His Danish majesty has established salt works in the peninsula of Valeo, about six English miles from Tonberg, where this mineral is extracted in large quantities from the sea-water.

Belides the animals common to other countries, Norway is said to contain many of the uncommon and dubious kind; such as the kraken, merman, sea-serpent, &c. See these articles.

people. Great Britain and Ireland were ravaged by the Norwegians; a title which included other adjacent people. Norway was a subject of England, and under their leader Canute the Great they went up the Seine as far as Paris, burnt the town, and forced its weak monarch to purchase their absence at the price of fourteen thousand marks. There was no time lost; they plundered and carried their exactions through the Mediterranean to Italy, and even into Sicily. They used narrow vessels, like their ancestors the Srones; and, besides oars, added the improvement of two sails; and utilized them with salted provisions, biscuit, cheese, and beer. Their ships were of a small size; but in after times they were large enough to hold 100 or 120 men. But the multitude of vessels was amazing. The fleet of Harold Blaftand consisted of 700. A hundred thousand of their savages have at once failed from Scandinavia, so justly styled Officina gentium, et cœtus velut vagina nationum. Probably necessity, more than ambition, caused them to discharge their country of its exuberant numbers. Multitudes were destroyed; but multitudes remained, and peoples more favourable climates.

Their king, Olaus, was a convert to Christianity in 1094. Bernard an Englishman had the honour of baptizing him, when Olaus happened to touch at one of the Scilly islands. He plundered with great spirit during several years; and in 1066 received the crown of martyrdom from his pagan subjects. But religious zeal first gave the rest of Europe a knowledge of their country and the sweets of its commerce. The Hanse towns poured in their millions, and reaped a temporal harvest. By the year 1204, the merchants obtained from the wife price Hane every encouragement to commerce; and by that means introduced wealth and civilization into his barren kingdom. England by her intercourse cherished the advantages resulting from an intercourse with Norway, and Bergen was the emporium. Henry III. in 1217, entered into a league with its monarch Haquin; by which both princes stipulated for free access for their subjects into their respective kingdoms, free trade, and security to their persons. In 1269, Henry entered into another treaty with Magnus; in which it was agreed, that no goods should be exported from either kingdom except they had been paid for; and there is, beside, a humane provision on both sides, for the security of the persons and effects of the subjects who should suffer, shipwreck on their several coasts.

The inhabitants now speak the same language that is used in Denmark, though their original tongue is the dialect now spoken in Iceland. They profess the Lutheran religion, under an archbishop established at Dratein, with four suffragans; namely of Bergen, Stedanger, Hamme, and Christiania. By the union of Calmar, the two kingdoms of Norway and Denmark were united under one monarch, and then the people of both nations enjoyed considerable privileges; but the Danish government soon became absolute; and Norway was ruled despotsically by a vice-regent, who reeded in the capital, and presided in the supreme court, to which appeals were made from the subordinate courts of judicature. A great change has, however, taken place since the present amiable and accomplished prince of Denmark had part of the government, and more may be expected from his virtue and affability when the power shall come wholly into his own hands.

The Norwegians are generally well-formed, tall, sturdy, and robust, brave, hardy, honest, hospitable, and ingenious; yet savage, rash, quarrelsome, and litigious. The same character will nearly suit the inhabitants of every mountainous country in the northern climates. Their women are well-shaped, tall, comely, remarkably fair, and obliging. The nobility of Norway have been chiefly removed by the kings of Denmark, in order to prevent faction and opposition to the court; or are long ago degenerated into the rank of peasants; some families, however, have been lately raised to that dignity. Every freeholder in Norway enjoys the right of primogeniture and power of redemption; and it is very usual for a peasant inheriting the same house which had been possessed 400 years by his ancestors. The adels gads, or freehold, cannot be alienated by sale or otherwise from the right heir, called adels mand: if he is not able to redeem the estate, he declares his incapacity every tenth year at the festivities; and if he, or his heirs to the third generation, should acquire wealth enough for that purpose, the possessor for ten years must resign his possession.

The mountaineers acquire surprizing strength and dexterity by hard living, cold, laborious exercise, climbing rocks, floating on the snow, and handling arms, which they carry from their youth to defend themselves against the wild beasts of the forest. Those who dwell in the maritime parts of Norway exercise the employments of fishing and navigation, and become expert mariners. The peasants of Norway never employ any handicraftsmen for necessaries to themselves and families: they are their own batters, shoemakers, tailors, tanners, weavers, carpenters, smiths, and joiners: they are even expert at ship-building; and some of them make excellent violins. But their general turn is for carving in wood, which they execute in a surprizing manner with a common knife of their own forging. They are taught in their youth to wrestle, ride, swim, skate, climb, shoot, and forge iron. Their amusements consist in making verses, blowing the horn, or playing upon a kind of guitar, and the violin: this last kind of music they perform even at funerals. The Norwegians have evinced their valour and fidelity in a thousand different instances. The country was always disturbed by intestine quarrels, which raged from generation to generation. Even the farmers stand upon their puds, and challenge one another to single combat with their knives. On such occasions they hook themselves together by their bolts, and fight until one of them is killed or mortally wounded. At weddings and public feasts they drink to intoxication, quarrel, fight, and murder generally ends. The very common people are likewise passionate, ambitious of glory, and independence, and vain of their pedigree. The nobility and merchants of Norway bear fortunately; but the peasant lives with the utmost temperance and frugality, except at festivities.
Norway.

festivals: his common bread is made of oatmeal, rolled into broad thin cakes, like those used in Scotland. In time of scarcity, they boil, dry, and grind the bark of the fir trees into a kind of flour which they mix with oat meal; the bark of the elm-tree is used in the same manner. In those parts where a fishery is carried on, they knead the roots of cod with their oatmeal. Of these last, mixed with barley-meal, they make hardy-pudding and soup, enriched with a pickled hering or salted mackarel. Fresh fish they have in plenty on the sea-coast. They hunt and eat grouse, partridge, hare, red deer, and rein-deer. They kill cows, sheep, and goats, for their winter stock: these they pickle, or smoke, or dry for use. They make cheese of their milk, and a liquor called firen from their four whey: this they commonly drink mixed with water; but they provide a store of strong ale for Christmas, weddings, christenings, and other entertainments. From their temperance and exercise, joined to their gravity. Nothing is more common than to see a hearty

Norwegian turned of twenty, when joined, exceeded 800 years. Nevertheless, the Norwegians are subject to various diseases; such as the scab, the leprosy, the scurvy, the catarrh, the rheumatism, gout, and epilepsy. The nature of the ground does not admit of much improvement in agriculture; nevertheless, the farmers are not deficient in industry and skill to drain marshes, and render the ground arable and fit for pasture. Many are employed in grazing and breeding cattle: but a much greater number is engaged in felling wood, floating timber, burning charcoal, and extruding tar from the roots of the trees which have been cut down; in the silver, copper, and iron-mines; in the navigation and fishery. A considerable number of people earn a comfortable livelihood by hunting, fishing, and bird-catching. Every individual is at liberty to pursue the game, especially in the mountains and commons: therefore every peasant is expert in the use of fire-arms; and they are excellent marksmen among the mountains, who make use of the bow to kill those animals, whose skins, being valuable, would be damaged by the shot of fire-arms.

Norway can produce above 14,000 excellent soldiers. The army of this country amounts to 30,000 effective men; and the annual revenue exceeds 800,000 rix-dollars.

Norwegian, in zoology. See Mus.

NORWICH, the capital of the county of Norfolk in England, situated in E. Long. 1. 26. N. Lat. 52. 40. It is supposed to have had its name, which signifies "a cattle to the north," from its situation in respect of Calton, the ancient Venta Icenorum, three or four miles to the south of it, out of whose ruins it seems to have risen. In its infancy, in the reign of Etheldred, it was plundered and burnt by Sweyn the Dane, when he invaded England with a great army. Afterwards it recovered; and in the reign of Edward
the Confessor was a considerable place, having 1320 burghers. But it suffered again much in the reign of William I. by being the seat of a civil war, which Ralph earl of the East Angles raised against that king. So much was it impaired by the siege it then underwent, that there were scarce 560 burghers left in it, as appears from Doomslay-book. From that time forward it began by little and little elecified off, and by a licence from Pope Paschal, declared it the mother-church of Norfolk and Suffolk. After this, as Malmsbury has it, it became a town famous for manufac-
derize and the number of inhabitants. Yet it was miserably harried in the reign of Henry II. by Hugh Bigod earl of Norfolk, who was an adherent of Henry's son, called the junior king. In the time of Edward I. it was walled round by the citizens, who had presented a petition to parliament for liberty to do it. Henry VI. allowed them instead of balliffs, which they had before, to elect a mayor yearly, and made the city a county of itself. In the year 1448, near 58,000 persons were carried off by the plague; and in 1505, the city was almost consumed by fire. For the flourishing state to which the city is now arrived, they are much indebted to the Flemings, who fled hither from Thetford in the reign of Henry Rufus in 1066; and built a beautiful cathedral, of which he himself laid the first stone, from this inscrip-
tion, Dominus Herbertus papst primum lapidem, in nomine Patris, Filii, & Spiritus Sancti, Amen, i. e. "Lord (Bishop) Herbert laid the first stone, in the name of the Father, Son, and Holy Ghost!" and by a licence from Pope Paschal, declared it the mother-
church of Norfolk and Suffolk. After this, as Malmsbury has it, it became a town famous for manufac-
derize and the number of inhabitants. Yet it was miserably harried in the reign of Henry II. by Hugh Bigod earl of Norfolk, who was an adherent of Henry's son, called the junior king. derize and the number of inhabitants. Yet it was miserably harria
The city of Norwich has long been famous for its manufactures; which are not, in the opinion of some at present in so flourishing a state as formerly. In addition to the manufacture of camblets, druggets, and, harassed, it is also remarkable for baize, ferges, slashons, stockings, and woollen cloths.

The inhabitants of Norwich are generally so employed in their manufactures within doors, that the city has the appearance of being deserted, except on Sundays and holidays, when the streets swarm with people.

Caflor, near Norwich, was the Venta Icenorum, or capital city of the Iceni, the broken walls of which contain a square of about 30 acres. In those walls may be perceived the remains of four gates and a tower. Several Roman urns, coins, and other relics of antiquity, have been found at this place.

NOSE, the organ of smell. See ANATOMY, t. 140. The uses of the nose are, its giving us the sense of smelling; its serving in the great office of respiration, and in modelling the voice; in receiving the abundant humours from the eyes, and in adding to the beauty of the face.

The nose was by the Augurs particularly attended to in forming conjectures concerning future good or ill successes. The tinging of the right or left side of it, for instance, was thought to have different significations as it happened to different sexes, or persons in different conditions.

In Tartary the greatest beauties are those who have the least noses. Ruybrock mentions the wife of the great Jenghiz Khan as a celebrated beauty, because she had only two holes for a nose. The Crim-Tartars break the noses of their children while young, as thinking it a great piece of folly to have their noses stand before their eyes. In most other countries, China excepted, great noses are an honour.

In what the beauty of the nose consists, different nations have different opinions; and the following reflections of Sir Joshua Reynolds on this subject, are perhaps the most philosophical account of the beauty of form that is to be found in any language. "I suppose (says Sir Joshua) it will be easily granted, that no man can judge whether any animal be beautiful in its kind, or deformed, who has only seen one of that species; that is as conclusive in regard to the human figure; so that if a man born blind was to recover his sight, and the most beautiful woman was brought before him, he could not determine whether she was half-handome or not; nor, if the most beautiful and most deformed were produced, could he any better determine to which he should give the preference, having seen only those two. To dizziness of beauty, then, implies the having seen many individuals of that species. If it is asked, how is more skill acquired by the observation of greater numbers? I answer, that, in consequence of having seen many, the power is acquired even without looking at it, of distinquishing between accidental blemishes and eccentricities, which are continually varying the surface of Nature's works, and the invariable general form which Nature most frequently produces, and always seems to intend in her productions.

Thus amongst the Blades of grass or leaves of the fame tree, though no two can be found exactly alike, yet the general form is invariable: a naturalist, before he chose one as a sample, would examine many, line, if he took the first that occurred, it might have, by accident or otherwise, such a form as that it would scarce be known to belong to that species; he feels, as the painter does, the most beautiful, that is, the most general form of nature.

"Every species of the animal as well as the vegetable creation may be said to have a fixed or determinate form, towards which nature is continually inclining, like various lines terminating in the centre; or it may be compared to pendulums vibrating in different directions over one central point; and as they all cross the centre, though only one path through any other point, so it will be found that perfect beauty is often produced by nature than deformity; I do not mean than deformity in general, but than any one kind of deformity. To instance in a particular part of a feature: the line that forms the ridge of the nose is beautiful when it is straight; this then is the central form, which is oftener found than either concave, convex, or any other irregular form that shall be proposed. As we are then more accustomed to beauty than deformity we may conclude that to be the reason why we approve and admire it, as we approve and admire customs and fashions of dress for no other reason than that we are used to them; so that though habit and custom cannot be said to be the cause of beauty, it is certainly the cause of our liking it; and I have no doubt, but that if we were more used to deformity than beauty, deformity would then lose the idea now annexed to it, and take that of beauty; as if the whole world should agree that yes and no should change their meanings, yes would then deny, and no would affirm.

"Whoever undertakes to proceed further in this argument, and endeavours to fix a general criterion of beauty respecting different species, or to show why one species is more beautiful than another, it will be required from him first to prove that one species is really more beautiful than another. That we prefer one to the other, and with language, and with custom, is granted; but it does not follow from thence that we think it a more beautiful form; for we have no criterion of form by which to determine our judgment. He who says a swan is more beautiful than a dove, means little more than that he has more pleasure in seeing a swan than a dove, either from the flatlines of its motions, or its being a more rare bird: and he who gives the preference to the dove, does it from some affection of ideas of innocence that he always annexes to the dove: but if he pretends to defend the preference he gives to one or the other, by endeavouring to prove that this more beautiful form proceeds from a particular gradation of magnitude, undulation of a curve, or direction of a line, or whatever other conceit of his imagination he shall fix on as a criterion of form, he will be continually contradicting himself, and find at last that the great mother of nature will not be subjected to such narrow rules. Among the various reasons why we prefer one part of her works to another, the most general, I believe, is habit and custom; custom makes, in a certain sense, white black, and black white; it is custom alone determines our preference of the colour of the Europeans to the Ethiopians.
The importance of a comprehensive and accurate nosology has been long and generally allowed. Bagloë, Boerhaave, Gorter, Gaukies, and Sydenham, have expressed their desire of a work of this kind, the great object of which is to fix pathognomonics to every disease; or in which all diseases are disposed into certain classes, orders, and genera, founded on distinctions taken from the symptoms only, without regard to remote or proximate causes.

Under the article Medicine, we have mentioned some of the most accurate nosological arrangements; and have here only to add, that, in 1776, Dr Sagar, at Iglaw in Moravia, published a Systema Morborum Symptomaticum, octavo, which is an useful abridgment of the work of M. Sauvages, with some alterations and additions. See Medicine, n° 123.

A writer in the Gentleman's Magazine gives this account of it: "The substance in question is not infrequent in England, nor in all other parts of Europe, after rains, both in spring and autumn. Very large spots of it are seen in gravelly foils, and particularly on the tops of hills, and on open downs, and often it is found on gravel-walks.

"It is met with in some of the old authors, under the name of nothoch, as in Paracelsus and others; and the alchemists fancied there was something wonderful in it, and that it would afford a menstrum for gold. Nothoch is said to be a word synonymous to Fasculum alecjius filles, vel potius ejus repurgatione dejectum quid in terram floo aeris; fragmentum nimbi; as this substance was believed to fall from the sky with the meteors that we often see, and call falling stars. Hence the country people in Sweden have called it sky-fall; and in England it is known by the name of witches butter, in common with some of the gelatinous liverworts.

"Paracelsus, Helmont, and others, ranked it, with the tormentil, or manna, and thought it dropped, as that did, from heaven. It is described, and the chemical analysis thereof given, by M. Geoffroy, in the Paris Memoirs for 1708, and is there said to yield, besides an acid phlegm, a portion of concrete volatile salt and some fixed salt. The distilled water from it was believed by some to possess singular virtues, in allaying pains of the joints; but there is certainly no room to attribute any extraordinary qualities to it.

"Since the days of Paracelsus it has been considered as a vegetable production; but the botanists have had difficulty to assign its place or genus in their several systems. Our own countryman, Dr Merret, seems to have been among the first authors who ranked it among vegetables, and he calls it Lichen bunclis, Lichen intumescens, fictitata ex oeferus (Pin. page 71.) Others have retained it among the plants of that genus to this day: as does the celebrated Dr Haller, in his Historia Stirp. Helvetica, who calls it Lichen gelatinosus, Placenta, nodule a laciniae crispati, granulosi, n° 2041 as there are several of the liverworts that have a gelatious texture and appearance; though they differ much from the nothoch, in not being instantly dried up. It was put into Ray's Synopsys, by Dr Dillenius, under the name of Ulva terrae-firiris pinguis et fugus, p. 64. but he afterwards changed that name for remeza, in his Historia Muscorum, where he calls it tremella terrae-firiris sumula pinguis et fugas, p. 52. tab. 10. f. 14. and reduces the classes to the same genus. Micheli, an Italian botanist, summed for his attention to the Cryptogamia class of plants, makes it a fungus, as Magnol and Dr Morrison had done before him, and describes and figures it in his nova..."
NOS [ 124 ]

Niska ter-re friend gelatinosa, membranacea, vulgaris, p. 126., t. 67.

He describes the seeds as lying in the form of little rings of heads, coiled up within the plant, or rather in the folds thereof, and only to be discovered by the microscope. Linnaeus mentions it, first under the name of Bytus gelatinosa fugax terrestris, in his Flora Lapponica, n° 530; but he afterwards adopted Dillenius's term, though he does not make it a laver. Linnaeus has called it, in all his subsequent works, tre-mella (notto) plicata, undulata, under which name it stands in his Species Plantarum, p. 1157, and in Hudson's Flora Anglica, p. 463, as also in a numerous list of other authors who follow his system.

Another writer in the same work gives this account of it. "This substance is very rarely seen between the middle of April and the month of October. It is most frequently to be found on the high pasture lands, where the ground is inclined to wet, and on the moors and commons in the north of England. The time we always meet with it, is after a very wet night, when the air in the morning suddenly clears up, and a sharp frost ensues. The frogs that then happen to be out are immediately seized by the froth, and turned into this jelly-like substance. For as I have had occasion sometimes to go out very early, I have found several parts of the frog not yet dissolved among the jelly, such as feet, legs, and thighs; yet in a little time afterwards the change was fully completed. The quantity of jelly produced from one single frog is almost beyond belief, even to five or six times its bulk when in its natural state."

"I communicated this discovery to an acquaintance, who has since had frequent opportunities of observing and examining this production; and we are fully assured, that, whatever opinion the learned may have of it, certainly proceeds from the abovementioned cause wherever found."

"Most people that I have conversed with on the subject are of opinion that this jelly falls from the stars, or out of the higher regions of the air; which notion, however absurd, many are credulous enough to believe."

Naturalists had for some years begun to doubt whether these gelatinous substances were of a vegetable or animal nature, and that the different appearances they put on are owing to various circumstancies, viz. the different birds that feed on frogs, the quantity they devour at a time, and the state of digestion before they are voided.

NOSTRADAMUS (Michael), an able physician and a celebrated astrologer, was a Provencal, and descended of a noble family, and born Dec. 14. 1503, at St Remy, in the diocese of Avignon. By his grandfather he was initiated in the study of the mathematics. He afterwards completed his course of humanity and philosophy at Avignon; and, going thence to Montpellier, he there applied himself to physics, till being forced away by the plague in 1525, he took his route towards Toulouse, and passed on till he came to Bourdeaux. This course held him five years; during which he undertook the cure of all such patients as were willing to put themselves under his care. After this he returned to Montpellier, and was created doctor of his faculty in 1529, and then revisited the same places where he had practised physic before. At Agen he contracted an acquaintance with Julius Caesar Scaliger, which induced him to make some stay in that town, and there he entered into matrimony; but having buried his wife, and two children which she brought him, he quitted Agen after a residence of about four years. He returned into Provence, and fixed himself first at Marsilles; but his friends having provided an advantageous match for him at Salon, he transported himself thither in 1544. In 1546, Aix being afflicted with the plague, he went thither at the solicitation of the inhabitants, and was of great service; particularly by a powder of his own invention: so that the town in gratitude gave him a considerable pension for several years after the contagion ceased. Returning afterwards to Salon, he became a recluse, and made use of his..."
his leisure to apply himself to his studies. He had a long time followed the trade of a conjurer occasionally; and now he began to think himself inspired, and miraculously illuminated with a prospect into futurity. As fast as theft illuminations had discovered to him any future event, he entered it in writing, in simple prose, but by enigmatical sentences, as he declared himself; but revising them afterwards, he thought the sentences would appear more respectable, and would favour more of a prophetic spirit if they were expressed in verse. This opinion determined him to throw them all into quatrains, and he afterwards ranged them into centuries. When this was done he heititated about making them public, till reflecting that the time of many events which he had foretold was very near at hand, he determined to print them. This he did with a dedication addressed to his son Cesar, an infant only some months old, in the form of a letter or preface, dated March 1, 1555. This first edition, which is included in seven centuries, was printed by Rigault at Lyons. He prefixed his name in Latin, but gave to his son Cesar the name as it is pronounced, Notradame.

The public were divided in their sentiments of this work: many looked upon the author as a simple visionary or a fool; while he was accused of the black art, or black magic, by others, and treated as an impious person, who held a commerce with the devil, at the same time there were not wanting such, and those in great numbers, who believed him to be really and truly endowed with the supernatural gift of prophecy. Lastly, some were found who remained in suspense, and refrained from giving any judgment at all upon the point. However, Henry II. and queen Catharine of Medicis his mother, were resolved to see our prophet; and, receiving orders to that effect, he presently repaired to Paris. He was very graciously received at court: and, besides the extraordinary respect that was paid to him, received a present of 200 crowns. He was sent afterwards to Blois, to make a visit to his majesty's children there, and report what he should be able to discover concerning their destinies. No doubt he exerted himself to the utmost on the occasion; but what his sentence was is not known: however, it is certain, he returned to Salon loaded with honour and prefects. Animated with so much success, he augmented his work from 300 quatrains to the number of a complete milliade, and published it with a dedication to the king in 1558. That prince dying the next year of a wound which he received as is well known, at a tournament, the book of our prophet was immediately consulted; and in the 35th quatrain of the first century this unfortunate event was found predicted in the following verse:

Le lion jeune le vieux fur montée,
En champ bellicque par sanguinar duel,
Dans cage d'or les jeux fut croire,
Deux statues une fois mourir, mort crièlle.

So remarkable a prediction added new wings to his fame, and he was honoured flortlyafter with a visit from Emanuel duke of Savoy and the princes Margaret of France his confort. From this time Notradamus found himself even over-burdened with visitors, and his fame made every day new acquisitions. Ch. IX, coming to Salon, was eager above all things to have a fight of him. Notradamus, who then was in waiting as one of the retinue of the magistrates, being instantly prefented to his majesty, complained of the little esteem his countrymen had for him; whereas, the monarch publicly declared, that he should hold the enemies of Notradamus, to be his enemies, and desired to see his children. Nor did that prince's favour stop here; in passing, not long after, through the city of Arles, he sent for Notradamus, presented him with a purse of 200 crowns, together with a brevet, confiting him his physician in ordinary, with the same appointment as the rest. But our prophet enjoyed these honours only for the space of sixteen months, for he died July 2. 1566, at Salon. Besides his "Centuries," we have the following compositions of his: A Treatise of fardemans & de fentours, 1552.—A Book of Fingular Receipts, pour entretenir la fante du corps, 1559.—A piece des confuitures, 1557.—A French Translation of the Latin of Galen's Paraphrafs, exhorting Mendolus to study, especially to that of physic. 1552. Some years before his death, he published a small instruction for husbandmen, showing the belt feotions for their feveral labours, which he intituled, The Almanac of Notradamus. Lastiy after his death there came out The eleventh and twelfh Centuries of his Quatrains, added to the former ten, which had been printed three times in two separate parts. It is only in these first editions that our author's Centuries are found without alterations, additions, &c. It is to this work that the following diitich of Stephen Jodolle alludes:

Notra damus cum falsa damus, nam fallere noflrum eff.
Et cum falsa damus, nil nisi Notra damus.

NOSTRE (Andrew Le), comptroller of the buildings of the French king, and designer of his gardens, distinguished himself by carrying the art of laying out gardens to great perfection. He was born at Paris in 1631; and was near 40 years of age when M. Fouquet, superintendant of the finances, gave him an opportunity of becoming known by the fine gardens of Vaux-le-Vicomte. He was afterwards employed by Louis XIV. at Verailles, Triannon, St. Germain, &c. and discovered an admirable taste in all his works. In 1678 he went to Rome, with the permission of the French king, to improve his skill: but he found nothing there comparable to what he himself had done. Pope Innocent XI. resolved to see Le Nofdre, and gave him a pretty long audience; at the conclusion of which Le Nofdre said, "I have seen the two greatest men in the world, your holiness, and the king my master." There is a great difference, answered the pope: "The king is a great victorious prince; and I am a poor priest, the fervant of the fervants of God." Le Nofdre, charmed with this answer, and forgetting he was with, clapped the pope on the shoulder, saying, "Reverend father you look extremely well, and will live to bury all the sacred college." The pope laughed at his prediction. Le Nofdre, charmed more and more at the goodness of the sovereign pontiff, and the singular effeem he shewed for the king, threw his armes about the pope's neck and killed him. It was his custom to behave in the same manner to all who spoke in praise of Louis XIV. and his
NOT [ 126 ] NOT

antiquis, explains many of the characters used by the short-hand writers; and there is a dictionary of them set forth by Janus Gruterus. See STENOGRAPHY.

NOTARIUS, persons employed by the Romans to take, by note, trials and pleadings in their courts of judicature, or to write as amanuenses from the mouth of an author. These notarii were of servile condition. Under the reign of Justinian, they were formed into a college or corporate body. Notarii were also appointed to attend the prefects, to transcribe for them. There were likewise notarii domestici, who were employed in keeping the accounts of the Roman nobility; and when the empire became Christian, there were notaries for ecclesiastical affairs, who attested the acts of archbishops, bishops, and other spiritual dignitaries.

We find ecclesiastical notaries at Rome, under Pope Julius IV. and in the church of Antioch, about the year 370. From these notaries are derived the office of chancellor to the bishops; afterwards almost every advocate was admitted a notary.

NOTARY (NOTARIUS), signifies a person, usually some scrivener, who takes notes, or frames short draughts, of contracts, obligations, charter-parties, or other writings. At present we call him a notary public, who publicly attests deeds or writings, in order to make them authentic in another nation; but he is principally employed in business concerning merchants; as making protests of bills of exchange, &c. And noting a bill, is where he goes to take notice of a merchant's refusal to accept or pay the same.

NOTATION, in arithmetic and algebra, the method of expressing numbers or quantities by signs or characters appropriated for that purpose. See ARITHMETIC and ALGEBRA.

NOTES, in music, characters which mark the sounds, i.e. the elevations and fallings of the voice, and the swiftness and slowness of its motions.

Note is likewise used for a mark made in a book or writing, where there occurs something remarkable and worthy of particular notice: as also for an observation or explication of some passage in an author added in the margin, at the bottom of the page, or elsewhere, in which sense it stands contradistinguished to text.

Note is also a minute, or short writing, containing some article of business; in which sense we say, promissory note, note of hand, bank-note, &c.

NOTHUS, signifies spurius, or bajatus; whence it is figuratively applied by physicians to such diseases as, though in respect of a similitude of symptoms, &c. they have the fame denomination as some others, yet are of a different origin, seat, or the like, from the same.

NOTUS, a Persian prince, and grandfather to Darius Codomannus. He is worthy of being mentioned only as he was progenitor to that sovereign whose overthrow conterted upon Alexander the title of Great.

NOTION, a word, which in common language is considered as of the same import with idea. This, however, is improper. Notion comprehends the meaning of idea, but it denotes much more. We have a notion of spirit, of power, of solidity; but of these things we can have no ideas. Ideas are reliefs of sensation; but there are objects of knowledge which fall under the cognizance of no sense; of these objects, however, we may have very distinct notions either direct or relative. See METAPHYSICS, p. 11.
NOTITIA, in literary history, a book that gives an account of a particular country, city, or other place: such is the Notitia Imperii Romani, Notitia Romae Antiqua, &c.

NOTO, an ancient, large, and handsome town of Sicily, and capital of the Val-di-Noto. It was entirely ruined by an earthquake in 1693; but the inhabitants built another town at some distance from it, which they call Noto Nuovo. E. Long. 14. o. N. Lat. 36. 50.

Noto (Val-di), one of the three valleys or provinces into which Sicily is divided; and it lies between the sea, Val-di-Demona, and Val-di-Mazzara. Noto is the capital town.

NOTIONECTA, the boat-fly; a genus of insects belonging to the order of hemiptera. Barbut gives the following character of this genus. "The rostrum is inflected: the antennæ are shorter than the thorax; the four wings, which are coriaceous from their base to their middle, are folded together crossed-wise; the hind feet are hairy, and formed for swimming. To which may be added, that the tarfi are composed of two articulations, and all the six feet are equally formed for swimming. The abdomen terminated by four little horns or appendices." He also describes the notionecta glauca, Linn. a' i. in these words. "This insect has a head somewhat round, of which the eyes seem to take up the greatest part. Those eyes are brown and very large, the rest of the head being yellow. In the fore part it has a sharp trunk that projects, and is inflected between the fore feet. On the sides are seen the antennæ, very small, yellowish, and that spring from under the head. The thorax, which is broad, short, and smooth, is yellow on the fore and black on the back part. The scutellum is large, of a rough black, and as it were nappy. The elytra, rather large, and crossed over each other, are a mixture of brown and yellow, not unlike the colour of rust, which makes it look cloudy. The under part of the body is brown; and at the extremity of the abdomen are to be seen a few hairs. The feet, fix in number, are of a light brown, the two hindermost having on the leg and tarsoi hairs that give them the shape of fins, nor are they terminated by nails. The four anterior ones are somewhat flat, and serve the animal to swim with; but at their extremity they have nails and no hairs. This insect is seen in stagnant waters, where it swims on its back, and presents its abdomen upwards; for which reason it has been called by the Greek name of notionecta. The hinder feet, longer than the rest, serve it as paddles. It is very nimble, and dives down when you go to take hold of it; after which, it rises again to the surface of the water. It must be cautiously handled if one would avoid being pricked by it, for the point of its rostrum is exceeding sharp, and it stings very painful, but it goes off in a few minutes. The larva very much resembles the perfect insect." Such is the account that Mr Barbut gives of this beautiful nimble little creature, which we thought it our duty to lay before our readers, as this gentleman seems to have been particularly attentive to the subject. To this account, however, we shall add the following. Its legs are long; when taken out of the water it hops: it is very common in the ponds of water in Hyde-park, and in several other places about London. It is of a very particular form, being flattish at the belly, and rising to a ridge on the middle of the back; so that when it swims, which is almost always on the back, its body has much theresemblance of a boat in figure, and whence its vulgar name. It is eight lines long, three broad, and two and a half thick. The belly is jointed, frillated, and, as Barbut observes, hairy. Nature has provided it with an offensive weapon resembling a sting, which it thrusts out when hurt from a large opening at the tail. The head is large and hard. The eyes of nearly a triangular form. The nose is a long, green, hollow proboscis, ending in a hard and sharp point, which in its natural posture remains under the belly, and reaches to the middle pair of legs. The outer pair of its wings are of a pale flesh-colour, with spots of a dead white; these are long, narrow, and somewhat transparent: they terminate in a roundish point, and perfectly cover the whole body. The triangular piece which stands between the top of the wings is hard, and perfectly black; the inner wings are broader and shorter than the outer ones; they are thin and perfectly transparent, and are of a pale pearl colour. The hinder pair being greatly longer than the rest, they serve as oars; and nature has tufted them with hair at the end for that purpose. This creature mostly lives in the water, where it preys on small insects, killing them and sucking their juices with its proboscis, in the manner of the water scorpion and many other aquatic insects; and it feizes its prey violently, and darts with incredible swifness to a considerable distance after it.

Though it generally lives in the water, it sometimes, however, crawls out in good weather; and drying its wings by exposing them in the sun, takes flight, and becomes an inhabitant of the air, not to be known for the same creature, unless to those who had accurately observed it before; when tried of flying, or in danger of an enemy, it immediately plunges into the water. We are told that there are 14 species of it, seven of which are common in Europe in waters, &c.

NOTTEBURG, a town of Russia, in the province of Ingria, seated on an island in the lake Ladoga, at the place where the river Nieva proceeds from this lake. It is strong, has a good citadel, and was capital of the province before Peterburg was built. E. Long. 31. 40. N. Lat. 60. 0.

NOTTINGHAMSHIRE, a county of England, bounded on the east by Lincolnshire, on the south and south by Leicestershire, on the west by Derbyshire, and on the north, and north-west by Yorkshire. It extends in length 48 miles, 25 in breadth, and 110 in compass; containing 560,000 acres, 8 hundreds, 9 market-towns, 168 parishes, 450 villages, about 174,500 houses, and 95,000 inhabitants. No county in England enjoys a pleasanter and healthier air. As for the soil, it is the widest in the county parishes of the county. Towards the west, where lies the forest of Sherwood, it is sandy; and therefore that part of the county is called by the inhabitants the Sand: but the south and east parts, watered by the Trent and the rivulets that fall into it, are clayey; and for that reason are called by the inhabitants the Clay. The latter is fruitful both in corn and pasture; but the former produces little besides wood, coal, and some lead. The county has a variety of commodities and manufactures, as wool, leather, tallow,
low, butter, cheese, coal, marl, cattle, malt, liquors, stockings, glass, earthen-wares, and strong ale. The principal rivers are the Trent and Idle. The Trent, whose name is supposed to be derived from the French or Latin word signifying thirty, either because it receives thirty smaller rivers, or has thirty different forts of fish in it, is inferior to no river in England, but the Severn, Thames, and Humber. It enters the county on the fourth-well, and passes through it to the north-east, where it enters Lincolnshire, and after a long course falls at last into the Humber. The Idle rises in Sherwood-forest; and after traversing the northern part of the county, falls into the Trent upon the borders of Yorkshire and Lincolnshire.

The spacious forest of Sherwood lies in the west part of the county, and indeed takes up the greatest part of it. It was formerly so thick, that it was hardly passable; but now it is much thinner. It feeds an infinite number of deer, and fanges; and has some towns in it, of which Mansfield is the chief. It abounds in coal, and a road lies through it for thirty miles together. Since the reign of King Edward I., the nobility and gentry have had grants of it. It was governed by a great number of officers under the late earl of Chesterfield, chief-forester; whose ancestor, Sir John Stanhope, had a grant of it, with liberty to destroy and kill at pleasure, referring only an hundred deer in the whole walk. The duke of Newcastle is now steward and keeper. The principal town is NOTTINGHAM, which gives name to the county. It is a handsome town, and a county of itself by charter. The name is derived from the Saxon word Snoutingham, which signifies caves, from the caves and apartments anciently dug in the rocks on which the town stands. These, being soft, easily yield to the spade and pick-axe; whence the townsmen have excellent cellars for the vast quantities of malt liquors made here, and rent, as well as their malt, to most parts of England. The situation of the town is very pleasant, having meadows on one hand, and hills of a gentle, easy ascent on the other. It is well supplied with fuel, both wood and coal, from the forest; and with fish by the Trent, which runs about a mile to the south, and has been made navigable for barges: so that they receive by it not only great quantities of cheese from Warwickshire and Staffordshire; but all their heavy goods from the Humber, and even from Hull. Over the Trent is a flately plane-bridge of 19 arches, where the river is very large and deep, having received the addition of the Dove, the Derwent, the Irwafh, and the Severn, three of them great rivers of themselves, which fall into it after its passing by Barton in Staffordshire.

The town is of great antiquity, and it had formerly a strong castle, in which the Danes, in the time of the heptarchy, held out a siege against Ruthred king of Mercia, Alfred, and Ethelred his brother, king of the West Saxons.

Soon after the conquest, William either repaired this fortress or built a new one on the same spot, in the second year of his reign, probably to secure a retreat on his expedition against Edwin Earl of Chester and Morcar Earl of Northumberland, who had revolted. He committed the custody of it to William Peverell, his natural son, who has by some been considered as the founder. It stands on a steep rock, at the foot of which runs the river Leen.

Deering, in his history of Nottingham, seems very justly to explode the story of the place called Mortimer’s-hole, having been made as a hiding-place for him; and from his description of it, shows that it was meant as a private passage to the caflle, to relieve it with men or provisions in a siege. He says that it is one continued stair-case, without any room, or even a place to sit down on. It was by this passage that Edward III. got into the caflle and surprized Mortimer and the queen; and from hence, and his being carried away through it, it has its name. Edward IV. greatly enlarged the caflle but did not live to complete the buildings he begun. Richard III. finished them.

It was granted by James I. to Francis Earl of Rutland, who pulled down many of the buildings; but it was still of so much strength, that Charles I. in 1642, pitched on it as the place for beginning his operations of war. He set up his standard, first on the walls of the caflle, but in two or three days removed it to a close on the north-side of the caflle, without the wall, on a round spot; after which it was for many years called Standard close, and since, from the name of one who rented it, Neville’s close. Where the standard was fixed, there stood a post for a considerable time. It is a common error that it was erected on a place called Derry-mount, a little further north than the close just mentioned; this is an artificial hill raised on purpose for a wind-mill, which formerly was there. The caflle was afterwards fequestrated by the parliament, and the trees in the park cut down.

This caflle was too strong that it was never taken by storm. After the civil war, Cromwell ordered it to be demolished. On the restoration, the duke of Buckingham, whose mother was daughter and heir of this Francis Earl of Rutland, had it restored to him, and sold it to William Cavendish, marquis and afterwards duke of Newcastle. In 1664 he began the present building, but died in 1676, when the work was not far advanced. However, he had the buildings of it so much at heart, that he left the revenue of a considerate estate to be applied to that purpose, and it was finished by Henry his son. The expense was about 14,000l. It is one of the seats of the present duke of Newcastle.

In the park, well of the caflle, and facing the river Leen, are some remains of an ancient building (if it may be so called) cut and framed in the rock. Dr Stukely gives it, as he does most things, to the Britons. Many other ancient excavations have been found in other parts of the rocks.

The frames for knitting stockings were invented by one William Lea of this county, about the beginning of the last century; but he not meeting with the encouragement he expected (a cafe too common with the first inventors of the most useful arts), went with several of his workmen to France, on the invitation of Henry IV. The death of that king, and the troubles which ensued, prevented attention being given to the work. Lea died there, and most of his men returned to England. Other attempts were made to steal the trade, without better success, and it has flourished here ever since, and is now carried on to a very considerable extent.
extant. It is noted for its horse-races on a fine course on the north side of the town. The corporation is governed by a mayor, recorder, six aldermen, two coroners, two sheriffs, two chamberlains, and twenty-four common-councilmen, eighteen of the senior-council, and six of the junior, a bell-bearer, and two pinders, one for the fields and the other for the meadows. The town being within the jurisdiction of the forest, the former of these pinders is town-woodward, and attends the forest courts. It has three

Novatur.
Novation or Innovation, in the civil law, denotes the change of one kind of obligation for another; as when a promise is accepted instead of a written obligation.

NOVATUS, a priest of Carthage, in the third century, who, to avoid being punished for a crime, joined with the deacon, named Felicissimus, against St. Cyprian. He went to Rome in 255; and there found Novatian, who had acquired great reputation by his eloquence, but who murmured at his not being raised to the see of Rome in preference to Cornelius. Novatian contracted a friendship with him; and afterwards promoted the detestable confection of Novatian to the see of Rome. This irregular confection produced a very great schism: Novatus also maintained, that the church had not the power to receive those to communion who have fallen into idolatry.

NOVEL, a fictitious narrative in prose, which professes to exhibit the natural workings of the human heart, the happiness and misery of private life, and, above all, the nature of the affection called Love, and the consequence of indulging it in certain circumstances.

The novel sprung out of the old romance, and has been cenured for insipidity, as its parent was for extravagance. (See Romance.) That the greater part of those absurd things, which, under this title, are daily issuing from the press, deserve all the contempt with which they can be treated, is a position which we feel not ourselves inclined to controvert; but we cannot admit that any species of writing is in itself insipid, merely because numbers have attempted it without success. The heroic poems of Blackmore are universally known to be contemptible performances; and if we had before us all the heroic poetry that has ever been written, how many thousands of volumes should we have as much as either Prince Arthur, King Arthur, Eliza, or Alfred? Yet no critic has hitherto dared to maintain, that heroic poetry is an insipid species of writing.

But the novel objections have been urged of more importance than its insipidity. It has been often affirmed with learned solemnity, that the perusal of novels tends to corrupt the youth of both sexes; to produce effeminacy in men and extravagant notions of the happiness of love in women; that it diverts the minds of the former from more serious and useful studies, and expels the latter to the arts of seduction. That there are too many novels to which this objection is applicable in its full force, is a fact which we are afraid cannot be denied; but when it is admitted, let not these performances be again accused of insipidity: for were they insipid, they could have no such consequences. It is by laying fast hold of the heart that they lead it astray. That a novel might be written so as to interest the heart in behalf of virtue, as much as any one has ever warped it to the side of vice, is a truth which no man will ever venture to call in question who has any knowledge of human nature; and therefore we are decidedly of opinion, that there may be novels worthy at once of the perusal of inexperienced youth and hoary wisdom. A critic, by no means too indulgent to works of fancy, and among whose failings laxity of morals has never been numbered, thus expresses himself on the subject of novel writing:—"These familiar histories may perhaps be made of a greater use than the solemnities of professed morality, and convey the knowledge of vice and virtue with more efficacy than axioms and definitions. But if the power of example is so great as to take possession of the memory by a kind of violence, and produce effects almost without the intervention of the will, care ought to be taken, that, when the choice is unrestrained, the best examples only should be exhibited; and that what is likely to operate strongly, should not be mihleievous or uncertain in its effects."

We have said, that the novel professes above all things to exhibit the nature of love and its consequences. Whether this be essential to such performances may perhaps be reasonably questioned: but it has been made an important part of the drama in most novels, and we think, with great propriety. It is the object of the novelist to give a true picture of life, diversified only by accidents that daily happen in the world, and influenced by passions and qualities which are really to be found in conversing with mankind. To accomplish this object, he conceives a hero or heroine, whom he places in a certain rank of life, endued with certain qualities of body and mind, and conducts, through many vicissitudes of fortune, either to the summit of happiness or to the abyss of misery, according to the passion which he wishes to excite in his readers. In the modern novel, this hero or heroine is never placed on a throne, or buried in a cottage; because to the monarch and the cottager no difficulties occur which can deeply interest the majority of readers. But among the virtuous part of the intermediate orders of society, that affection which we call love seldom fails, at some period of life, to take possession of the hearts of both sexes; and wherever it has place, it must be productive of happiness or of misery. In the proper management of this passion confines much of the difficulty of the novel-writer. He must exhibit this hero as feeling all the pangs and pleasures of love, at some times animated with hope, and sometimes ready to sink into despair, but always exerting himself to obtain the gratification of his wishes. In doing this, care should be taken, either that he never transgress the laws of virtue, or at least that he never transgress them with impunity.

"It is justly considered as the greatest excellence of art to imitate nature: but it is necessary to distinguish those parts of nature which are most proper for imitation; greater care is still required in representing life, which is so often discoloured by passion or deformed by wickedness. If the world be promiscuously described, I cannot perceive (says the great critic already quoted) of what use it can be to read the account; or why it may not be as safe to turn the eye immediately upon mankind, as upon a mirror which shows all that presents itself without discrimination. It is therefore not a sufficient vindication of a character, that it is drawn as it appears: for many characters,
N O V

A French critic, speaking of this character, says, "By choosing the last of life to die, to escape from love, to escape from life to love, to escape from love to life, and to combine all these in a person of high birth and amable person, Richardçon's".

His pride, his gaiety, his drollery, charm and amuse me; his genius confounds me and makes me smile; his wickedness makes me laugh, and stimulates me; but at the same time I admire as much as I detest him." Surely this is not the character which ought to be presented to the inexperienced and ardent mind.

The most perfect characters which we present recollect any novel are Richardson's Clarissa and Fielding's Allworthy. The virtues of the former are perhaps tinctured with moral pedantry, if we may use the expression; and the latter suffered himself to be long imposed upon by the arts of the hypocrite and the philosophical coxcomb; but without some defects they would not be human virtues, and therefore no objects of human imitation. Clarissa is an excellent character: she has as much perfection as can be expected in woman, whilst the exhibits, at the same time, some obvious defects.

As it is the object of the novelist to interest the heart, and to communicate instruction through the medium of pleasure, his work, like a tragedy or comedy, should be one, exhibiting a hero or heroine whose successes every incident should contribute to forward or to retard. In this respect no work of fancy has ever surpassed the Tom Jones of Fielding. It is constructed upon principles of the soundest criticism, and contains not a single event which does not in some way contribute towards the winding up of the piece. A living author, deeply read in Grecian literature, and far from being prejudiced in behalf of any modern, has been heard to say, that had Aretine seen Tom Jones, he would have pronounced it a poem perfect in its kind.

Against this sentence another critic of name has entered his protest, and strenuously maintained that nothing can be a poem which is not written in verse. We shall judge of the truth of this conclusion by comparing it with the principles from which it is deduced. Having laid down as a maxim invariable, that "the end of poetry is pleasure, to which use itself must be subservient," he very justly infers from this idea, that "poetry should neglect no advantage that fairly offers itself, of appearing in such a dress or mode of language as is most taking and agreeable to us. It follows (he says), from the fame idea of the end, which poetry would accomplish, that not only rhythm, but numbers properly so called, is essential to it, and that it cannot obtain its own purpose unless it be clothed in verse." He then proceeds to ask, "What, from this conclusion, are we to think of those novels or romances, as they are called, which have been so current of late throughout all Europe? As they propose pleasure for their end, and prostitute it, besides, in the way of fiction, though without metrical numbers, and generally indeed in harsh and rugged prose, one easily sees what their pretensions are, and under what idea they are ambitious to be received. Yet as they are wholly deficient of measured sounds (to say nothing of their other numberless defects), they can at most be considered but as daily, imperfect, and abortive poems: whether spawned from the dramatic or narrative species, it may be hard to say.
Unfinished things, one knows not what to call.

Their generation's so equivocal.

However, such as they are, those novelties have been generally well received; some for the real merit of their execution; others, for their amusing subjects: all of them, for the gratification they afford, or at least promise, to a vitiated, pallid, and sickly imagination, that lies diseased of learned minds, and fure prognostic of expiring letters. But whatever may be the temporary fascin of these things (for they vanish as fast as they are produced), good sense will acknowledge no work of art but such as is composed according to the laws of its kind."

Of this severe critic the author himself has given us what amounts to a complete confirmation. He tells us, that the ancients looked for so much force and spirit of expression in whatever they dignified with the name of poem, as sometimes to make a question "whether comedy were rightly referred to this class, because it differed only in measure from mere prose? Their doubt (he justly adds) might have been spared or at least resolved, if they had considered that comedy adopts as much of this force and spirit of words as is consistent with the nature and dignity of that pleasure which it pretends to give: For the name of poem will belong to every composition whose primary end is to please, provided it be so constructed as to afford all the pleasure which its kind or fort will permit."

If this decision be just, and we readily admit it, a well composed novel is intitled to the appellation of a poem though it be written in prose and in a style not remarkable for elevation. The business of the novelist is to interest the heart by a display of the incidents of common life. In doing this, he must exhibit scences that are probable, and record speeches that are natural. He is not at liberty to invent, but only to select, objects, and to call from the mass of mankind those individuals upon which the attention ought most to be employed. The more closely he adheres to this rule, the more deeply does he interest us in his narrative; because every reader feels at once that it is possible he may at some time or other be in circumstances nearly resembling those of the hero of the tale. But the business of life is not transacted in pompous language, and the speeches of real lives made in verse either rhimed or blank. Were Tom Jones or Clarissa Harlowe to be translated into verse, we shall venture to assert that they would quickly lose their hold of the public mind; because the hero and heroine would then appear in a light which every heart must feel to be unnatural.

It is well observed by Johnson, that the task of the novel writer "requires, together with that learning which is to be gained from books, that experience which can never be attained by solitary diligence, but must arise from general convers and accurate observation of the living world. Their performances have, as Horace expresses it, plus oneri quantum variae minus, little indulgence, and therefore more difficulty. They are engaged in portraits of which every one knows the original, and can detect any deviation from exactness of resemblance. Other writings are safe, except from the malice of learning, but these are in danger from every common reader; as the slipper ill executed, was cenured by a shoemaker who happened to drop in his way at the Venus of Appelles." It is in thus faithfully copying nature that the excellence of Fielding consists. No man was ever better acquainted with the shades which diversify characters, and none ever made his personages act and speak more like real men and women in the particular circumstances which he describes.

But the fear of not being approved as a just copier of human manners, is not the most important concern that an author of this class ought to have before him. Novels are written chiefly to the young, the ignorant, and the idle, to whom they serve as lectures of conduct and introduction into life. In every such work, it should therefore be carefully calculated, that virtue is the highest proof of understanding, and the only solid basis of greatness; and that vice is the natural consequence of narrow thoughts; that it begins in mistake, and ends in ignominy: and since love must be introduced, it should be represented as leading to wretchedness, whenever it is separated from duty or from prudence."

Novel, in the civil law, a term used for the constitutions of several emperors, more particularly those of Julianus. They were called novels, either from their producing a great alteration in the face of the ancient law, or because they were made on new cases, and after the revival, of the ancient code.

NOVELTY, or Newness. Of all the circumstances that raise emotions, not excepting beauty, nor even greatness, says Lord Kames', novelty hath the most powerful influence. A new object produces instantaneously an emotion termed wonder, which totally occupies the mind, and for a time excludes all other objects. Conversation among the vulgar never is more interesting than when it turns upon strange objects and extraordinary events. Men tear themselves from their native country in search of things rare and new; and novelty converts into a pleasure the fatigue and even perils of travelling. To what caufe shall we ascribe these singular appearances? To curiosity undoubtedly; a principle implanted in human nature for a purpose extremely beneficial, that of acquiring knowledge; and the emotion of wonder raised by new and strange objects, inflames our curiosity to know more of such objects. This emotion is different from admiration; novelty, wherever found, whether in a quality or action, is the cause of wonder; admiration is directed to the perfon who performs any thing wonderful.

During infancy, every new object is probably the occasion of wonder, in some degree; because, during infancy, every object at first sight is strange as well as new: but as objects are rendered familiar by custom, we cease by degrees to wonder at new appearances, if they have any resemblance to what we are acquainted with; for a thing must be singular as well as new to raise our wonder. To save multiplying words, we would be understood to comprehend both circumstances when we hereafter, talk of novelty.

In an ordinary train of perceptions where one thing introduces another, not a single object makes its appearance unexpectedly: the mind thus prepared for the reception of its objects, admits them one after another without perturbation. But when a thing breaks in unexpectedly, and without the preparation of any
Novelty. connection, it raises emotion, known by the name of surprife. That emotions may be produced by the most familiar object, as when one unexpectedly meets a friend who was reported to be dead; or a man in high life, lately a beggar. On the other hand, a new object, however strange, will not produce the emotion, if the spectator be prepared for the fight; an elephant in India will not surprize a traveller who goes to see one; and yet its novelty will raise his wonder: an Indian in Britain would be much surprized to tumble upon an elephant feeding at large in the open fields; but the creature itself, to which he was accustomed, would not raise his wonder.

Surprize thus in several respects differs from wonder, unexpectedness is the cause of the former emotion; novelty is the cause of the latter. Nor differ they less in their nature and circumstances, as will be explained by and by. With relation to one circumstance they perfectly agree; which is, the shortness of their duration: the instantaneous production of these emotions in perfection, may contribute to that effect, in conformity to a general law. That things soon decay which soon come to perfection; the violence of the emotions, may also contribute; for an ardent emotion, which is not susceptible of increase, cannot have a long course. But their short duration is occasioned chiefly by that of their causes: we are soon reconciled to an object, however unexpected; and novelty soon degenerates into familiarity.

Whether these emotions be pleasant or painful, is not a clear point. It may appear strange, that our own feelings, and their capital qualities should afford any matter for a doubt: but when we are engrossed by any emotion, there is no place for speculation; and when sufficiently calm for speculation, it is not easy to recall the emotion with accuracy. New objects are sometimes terrible, sometimes delightful: the terror which a tyger inspires is greatest at first, and wears off gradually by familiarity; on the other hand, even women will acknowledge that it is novelty which pleads the most in a new fashion. It would be rash however to conclude, that wonder is in itself neither pleasant nor painful, but that it assumes either quality according to circumstances. An object, it is true, that hath a threatening appearance, adds to our terror by its novelty; but from that experiment it doth not follow, that novelty is in itself disagreeable; for it is perfectly consistent that we be delighted with an object in one view, and terrified with it in another. A river in flood swelling over its banks, is a grand and delightful object; and yet it may produce no small degree of fear when we attempt to cross it: courage and magnanimity are agreeable; and yet when we view these qualities in an enemy, they serve to increase our terror. In the same manner, novelty may produce two effects clearly distinguishable from each other: it may directly and in itself, be agreeable, and it may have an opposite effect indirectly, which is to inspire terror; for when a new object appears in any degree dangerous, our ignorance of its powers and faculties affords ample scope for the imagination to dress it in the most frightful colours. The first sight of a lion, for example, may at the same instant produce two opposite feelings, the pleasant emotions of wonder, and painful passion of terror: the novelty of the object produces the former directly, and contributes to the latter indirectly. Thus, when the subject is analysed, we find that the power which novelty hath indirectly to inflame terror, is perfectly consistent with its being in every circumstance agreeable. The matter may be put in the clearest light, by adding the following circumstance. If a lion be first seen from a place of safety, the spectator is altogether agreeable without the least mixture of terror. If, again, the first sight puts us within reach of that dangerous animal, our terror may be too great as quite to exclude any sense of novelty. But this fact proves not that wonder is painful: it proves only, that wonder may be excluded by a more powerful passion. Every man may be made certain from his own experience, that wonder raised by a new object that is inoffensive, is always pleasant; and with respect to offensive objects, it appears, from the foregoing deduction, that the same must hold as long as the spectator can attend to the novelty.

Whether surprize be in itself pleasant or painful, is a question not less intricate than the former. It is certain that surprize inflames our joy when unexpectedly we meet with an old friend, and not less our terror when we stumble upon any thing noxious. To clear that question, the first thing to be remarked is, that in some instances an unexpected object overpowers the mind, so as to produce a momentary stupefaction: where the object is dangerous, or appears so, the sudden alarm it gives, without preparation, is apt totally to unhinge the mind, and for a moment to suspend all its faculties, even thought itself; in which state a man is quite helpless; and if he move at all, is as like to run upon the danger as from it. Surprize carried to such a height, cannot be either pleasant or painful; because the mind, during such momentary stupefaction, is in a good measure, if not totally, insensible.

If we then inquire for the character of this emotion, it must be where the unexpected object or event produces less violent effects. And while the mind remains sensible of pleasure and pain, is it not natural to suppose, that surprize, like wonder, should have an invariable character? It would appear however, that surprize has no invariable character, but assumes that of the object which raft it. Wonder being an emotion invariably raised by novelty, and being distinguishable from all other emotions, ought naturally to possess one constant character. The unexpectable appearance of an object, seems not equally intitled to produce an emotion distinguishable from the emotion, pleasant or painful, that is produced by the object in its ordinary appearance: the effect it ought naturally to have, is only to swell that emotion, by making it more pleasant or more painful than it commonly is. And that conjecture is confirmed by experience, as well as by language which is built upon experience: when a man meets a friend unexpectedly, he is said to be agreeably surprized; and when he meets an enemy unexpectedly, he is said to be disagreeably surprized. It appears, then, that the sole effect of surprize is to swell the emotion raised by the object. And that effect can be clearly explained: a tis of connected perceptions glide gently into the mind, and produce no perturbation; but an object breaking in unexpectedly, founds an alarm, roules the mind out of its calm state, and directs...
Novelty.

its whole attention to the object, which, if agreeable, becomes doubly so. Several circumstances concur to produce that effect: on the one hand, the agitation of the mind and its keen attention prepare it in the most effectual manner for receiving a deep impression; on the other hand, the object, by its sudden and unforeseen appearance, makes an impression not gradually as expected objects do, but as at one stroke with its whole force. The circumstances are precisely similar where the object is in itself disagreeable (A).

The pleasure of novelty is easily distinguished from that of variety: to produce the latter, a plurality of objects is necessary; the former arises from a circumstance found in a single object. Again, where objects, whether coaxent or in succession, are sufficiently diversified, the pleasure of variety is complete, though every single object of the train be familiar; but the pleasure of novelty, directly opposed to familiarity, requires no diversification.

There are different degrees of novelty, and its effects are in proportion. The lowest degree is found in objects surveyed a second time after a long interval; and that in this case an object takes on some appearance of novelty, is certain from experience: a large building of many parts variously adorned, or an extensive field embellished with trees, lakes, temples, statues, and other ornaments, will appear new often than once: the memory of an object so complex is soon lost, of its parts at least, or of their arrangement. But experience teaches, that, even without any decay of remembrance, absence alone will give an air of novelty to a once familiar object: which is not surprising, because familiarity wears off gradually by absence: thus a person with whom we have been intimate, returning after a long interval, appears like a new acquaintance. And distance of place contributes to this appearance, not less than distance of time: a friend, for example, after a short absence in a remote country, has the same air of novelty as if he had returned after a longer interval from a place nearer home:

the mind forms a connection between him and the remote country, and belittles upon him the singularity of the objects he has seen. For the same reason, when two things equally new and singular are presented, the spectator balances between them; but when told that one of them is the product of a distant quarter of the world, he no longer hesitates, but clings to it as the more singular; hence the preference given to foreign luxuries, and to foreign curiosities, which appear rare in proportion to their original distance.

The next degree of novelty, mounting upward, is found in objects of which we have some information at second hand; for description, though it contribute to familiarity, cannot altogether remove the appearance of novelty when the object itself is presented: the first sight of a lion occasions some wonder, after a thorough acquaintance with the correct pictures and statues of that animal.

A new object that bears some distant resemblance to a known species, is an instance of a second degree of novelty: a strong resemblance among individuals of the same species, prevents almost entirely the effect of novelty, unless distance of place or some other circumstance concur; but where the resemblance is faint, some degree of wonder is felt, and the emotion rises in proportion to the faintness of the resemblance.

The highest degree of wonder arises from unknown objects that have no analogy to any species we are acquainted with. Shakespeare in a simile introduces that species of novelty:

As glorious to the sight
As is a winged messenger from heaven
Unto the white up-turned wond'ring eye
Of mortals, that fall back to gaze on him
When he bestrides the lazy-pacing clouds
And falls upon the bosom of the air.

Romeo and Juliet.

One example of that species of novelty deserves peculiar attention; and that is, when an object altogether new is seen by one person only, and but once.

These

(A) What the Marechal Saxe terms le cœur humain, is no other than fear occasioned by surprise. It is owing to that cause that an ambush is generally so destructive: intelligence of it beforehand renders it perfectly harmless. The Marechal gives from Caesar's Commentaries two examples of what he calls le cœur humain. At the siege of Amiens by the Gauls, Caesar came up with his army, which did not exceed 7000 men; and began to entrench himself in such a hurry, that the barbarians, judging him to be afraid, attacked his encroachments with great spirit. During the time they were filling up the ditch, he fled out with his cohorts, and by attacking them unexpectedly struck a panic that made them fly with precipitation, not a single man offering to make a stand. At the siege of Aleia, the Gauls infinitely superior in number attacked the Roman lines of circumvallation, in order to raise the siege. Caesar ordered a body of his men to march out silently, and to attack them on the one flank, while he with another body did the same on the other flank. The surprise of being attacked when they expected a defence only, put the Gauls into disorder, and gave an easy victory to Caesar.

A third may be added not less memorable. In the year 846, an obstinate battle was fought between Xamire king of Leon and Abdoulrahaman the Moorish king of Spain. After a very long conflict, the night only prevented the Arabians from obtaining a complete victory. The King of Leon, taking advantage of the darkness, retreated to a neighbouring hill, leaving the Arabians masters of the field of battle. Next morning, perceiving that he could not maintain his place for want of provisions, nor be able to draw off his men in the face of a victorious army, he ranged his men in order of battle, and, without losing a moment, marched to attack the enemy, resolving to conquer or die. The Arabians, astonished to be attacked by those who were conquered the night before, loft all heart: fear succeeded to astonishment, the panic was universal, and they all turned their backs without almoat drawing a sword.
Novelty.

These circumstances heighten remarkably the emotion: the singularity of the spectator concurs with the singularity of the object, to inflame wonder to its highest pitch.

In explaining the effects of novelty, the place a being occupies in the scale of existence, is a circumstance that must not be omitted. Novelty in the individuals of a low class is perceived with indifference, or with a very light emotion: thus a pebble, however singular in its appearance, scarce moves our wonder. The emotion rises with the rank of the object; and, other circumstances being equal, is strongest in the highest order of existence; a strange object affects us more than a strange vegetable; and a strange quadruped more than a strange insect.

However natural novelty may be, it is a matter of experience, that those who relish it the most are careful to conceal its influence. Love of novelty, it is true, prevails in children, in idlers, and in men of shallow understanding: and yet, after all, why should one be ashamed of indulging a natural propensity? A distinction will afford a satisfactory answer. No man is ashamed of curiosity when it is indulged to acquire knowledge. But to prefer any thing, merely because it is new, shows a mean taste which one ought to be ashamed of: vanity is commonly concurred in by the society, and the party-coloured man, though above his companions in a public theatre, thinking they would admire him, was called a Hallambe, a dunce.

One final cause of wonder, hinted above, is, that this emotion is intended to stimulate our curiosity. Another, somewhat different, is, to prepare the mind for receiving deep impressions of new objects. An acquaintance with the various things that may affect us, and with their properties, is essential to our well-being; nor will a flight or superficial acquaintance be sufficient; they ought to be so deeply engraved on the mind, as to be ready for use upon every occasion. Now, in order to a deep impression, it is wisely contrived, that things should be introduced to our acquaintance with a certain pomp and solemnity productive of a vivid emotion. When the impression is once fairly made, the emotion of novelty being no longer necessary, vanishes almost instantaneously; never to return, unless where the impression happens to be obliterated by length of time or other means; in which case the second introduction hath nearly the same solemnity with the first.

Designing wisdom is no more eligible than in this part of the human frame. If new objects did not affect us in a very peculiar manner, their impressions would be so slight as scarce to be of any use in life; on the other hand, did objects continue to affect us as deeply as at first, the mind would be totally engulfed with them, and have no room left either for action or reflection.

The final cause of surprise is still more evident than of novelty. Self-love makes us vigilant to attentive to self-preservation; but self-love which operates by means of reason and reflection, and impels not the mind to any particular object or from it, is a principle too cool for a sudden emergency; an object breaking unexpectedly, affords no time for deliberation; and in that case the agitation of surprise comes in seasonably to relieve the soul into action: surprise gives the alarm; and if there be any appearance of danger, our whole force is instantaneously summoned to shun or to prevent it.

NOVELLARA, a handsome town of Italy, and capital of a small district of the same name, with a hand-made castle, where their sovereign resides. E. Long. 10. 37. N. Lat. 45, 50.

NOVEMVIRI, nine magistrates of Athens, whose government lasted but for one year. The first of whom was called archon, or prince; the second baiilus, or king; the third polemarchus, or general of the army: the other six were called thesmathetes, or lawyers. They took an oath to observe the laws; and in case of failure, obliged themselves to hew upon the commonwealth a statute of gold as big as themselves. Those who discharged their office with honour, were received into the number of the senators of Areopagus.

NOVI, a town of Italy, in the territory of Genoa, on the confines of the Milanese. It was taken by the Piedmontese in 1746. E. Long. 8. 48. N. Lat. 44. 47.

Novocr, Bazar, a considerable town of Turky in Europe, and in Servia, near the river Oredco. E. Long. 20. 24. N. Lat. 43. 25.

NOVICE, a person not yet skilled or experienced in an art or profession.

In the ancient Roman militia, novicii, or noviti, were the young raw soldiers distinguished by this appellation from the veterans.

In the ancient orders of knighthood, there were novices or clerks in arms, who went through a kind of apprenticeship ere they were admitted knights. — See Knight.

Novice is more particularly used in monasteries for a religious yet in his, or her, year of probation, and who has not yet made the vows.

In some convents, the sub prior has the direction of the novices. In nunneries, the novices wear a white veil; the rest a black one.

NOVICIATE, a year of probation appointed for trial of religious, whether or not they have a vocation, and the necessary qualities for living up to the rule; the observation whereof they are to bind themselves.
selves to by vow. The novieiate lasts a year at least; in some houses more. It is esteemed the bed of the civil death of a novice, who expires to the world by profession.

NOVIGRAD, a small but strong town of Upper Hungary, capital of a county of the same name, with a good castle, seated on a mountain near the Danube.

E. Long. 18. 10. N. Lat. 40. 50.

NOVIJARD, a small but strong town of Dalmatia, with a castle, and subject to the Turks; seated on a lake of the same name, near the gulf of Venice.

E. Long. 16. 45. N. Lat. 44. 30.

NOVIGRAD, a very strong place of Servia, subject to the Turks; seated near the Danube.

E. Long. 26. 5. N. Lat. 45. 5.

NOVIODUNUM (César), a town of the Áedui, commodiously seated on the Liguris: the Noviodunum of the Aureli Diablintes, in Gallia Celta, (Antonine); called Noviodunum (Tolomey), and Noviodunum Rotrudum by the moderns. Noviodunum of Perche.—A third of the Bituriges, (César): Now Noves for Bairanion; a village 15 miles to the north of Bourges, towards Orleans.—A fourth, of Musia, Inferior, (Tolomey); situated on the Ile; now Nivora, in Beifarabin.—A fifth, of Pannonia Superior, (Antonine): now Gürfild in Carinthia.—A sixth, Noviodunum Subfionum, the same with Augufla Subfionum.—A seventh, Noviodunum of the Veromandui in Gallia Belgica, (César): now Novan in the Isle of France, on the borders of Picardy.

NOUN, see Grammer, no 7.; and chapter tll in toto.

NOVOGOROD WELICKI, or Great Novgorod, according to Mr Coxe, is one of the most ancient cities in Russia. It was formerly called Great Novgorod, to distinguish it from other Russian towns of a similar appellation; and now presents to the attentive and intelligent traveller a striking instance of fallen grandeur. According to Nisbor, the earliest of the Russian historian, it was built at the same time with Kiev, namely, in the middle of the 9th century, by a Scalian ord, who, according to Procopius, issued from the banks of the Volga. Its antiquity is clearly proved by a passage in the Gothic historian Jornandes, in which it is called Civitas Nova, or new town. We have little insight into its history before the 9th century, when Ruric the first great- duke of Russia reduced it, and made it the metropolis of his vast dominion. The year subsequent to his death, which happened in 879, the se of government was removed, under his son Igor, then an infant, to Kiev; and Novgorod continued, for above a century, under the jurisdiction of governors nominated by the great dukes, until in 970, when Svatoslav, the son of Igor, created his third son Vladimir duke of Novgorod; the latter, succeeding his father in the throne of Russia, ceded the town to his son Yaroslav, who in 1036 granted to the inhabitants very considerable privileges, that laid the foundation of that extraordinary degree of liberty, which they afterwards gradually obtained. From this period Novgorod was for a long time governed by its own dukes; these sovereigns were at first subordinate to the great-dukes, who resided at Kiev and Volodymir; but afterwards, as the town increased in population and wealth, they gradually usurped an absolute independency. Its independency, however, was not perpetual. It continued, indeed, in a flourishing state until the middle of the 15th century: but the great-dukes of Russia, whose ancestors had reigned over this town, and who still retained the title of dukes of Novgorod, having transferred their residence from Kiev to Volodymir, and afterwards to Moscow, laid claim to its feudal sovereignty; a demand which the inhabitants sometimes put off by composition, sometimes by resistance, but were sometimes compelled to acknowledge. At length, however, the great-duke became absolute sovereign of Novgorod, though the onalienable forms of government were still preserved. It even then, however, continued to be the largest and most commercial city of Russia; a proof of which we have as late as the year 1554, from the following description of Richard Chancellor, who passed through it in 1554, in his way to Moscow. "Next unto Moscow, the city of Novgorod is esteemed the chief of Russia, for although it be in majesty inferior to it, yet in greatness it goeth beyond it. It is the chiefest and greatest mart town of all Muscovy; and all the emperor's feet is not there, but at Moscow, yet the commodiousness of the river, falling into that gulf which is called Sinus Finnicus, whereby it is well frequented by merchants, makes it more famous than Moscow itself." An idea of its population during this period, when compared with its present declined state, is manifest from the facts, that in 1708 above 15,000 persons died of an epidemic disorder; more than double the number of its present inhabitants. In its most flourishing condition it contained at least 400,000 souls. Its ruin was brought on by Ivan Valievitch II. and completed by the foundation of Peterburgh. The present town is surrounded by a rampart of earth, with a range of old towers at regular distances, forming a circumference of scarcely a mile and an half; and even this inconsiderable circle includes much open space, and many houses are not inhabited. As Novgorod was built after the manner of the ancient towns of this country in the Asiatic style, this rampart, like that of the Semlainsgorod at Moscow, probably included several interior circles. Without it was a vast extensive suburb, which reached to the distance of six miles, and included within its circuit all the convents and churches, the ancient ducal palace and other structures, that now make a splendid but solitary appearance, as they lie scattered in the adjacent plain.

Novgorod stretches on both sides of the Volkof, a beautiful river of considerable depth and rapidity, and somewhat broader than the Thames at Windsor. This river separates the town into two divisions, the trading part, and the quarter of St Sophia, which are united by means of a bridge, partly wooden and partly brick.

NOVOGOROD WELICKI, a province of Moscow, bounded on the north by Lugria; on the salt by part of the duchy of Belozero, and that of Tocra, which also bounds it on the south, with the province of Rzeva; and on the west by Pleiscow. It is full of lakes and forests;
NOY [137] NUB

Novgorod forests; however, there are some places which produce corn, flax hemp, honey, and wax.

Novgorod Sertka, a strong town of the Russian empire, and capital of a province of Siberia of the same name, situated on the river Dubica, in E. Long. 53° 20', N. Lat. 52° 30'.

NOVGORODECK, a town of Lithuania, and capital of a palatinate of the same name. It is a large place, and situated in a vall plain, in E. Long. 25° 30', N. Lat. 53° 45'.

NOURISHMENT. See Nutrition. Nourishment of Vegetables. See Agriculture, Part I. Sect. 1. and 2. and Plants; also the article Composts.

NOWED, in heraldry, signifies "knotted," from the Latin nodatus, being applied to the tails of such creatures as are very long, and sometimes represented in coat armour as tied up in a knot.

NOX (fulf. hist.), one of the most ancient deities among the heathens, daughter of Chaos. From her union with her brother Erebus, she gave birth to the Day and the Light. She was also the mother of the Parcae, Hesperides, Dreams of Dicord, Death, Momus, Fraud, &c. She is called by some of the poets the mother of all things, of gods as well as of men; and she was worshipped with great solemnity by the ancients. She had a famous statue in Diana's temple at Ephesus. It was usual to offer her a black sheep, as she was the mother of the Furies. The cock was also offered to her, as that bird proclaims the mother of the Furies. The cock yeller is called by one of the deities that the length of the trunk, &c. is called by another of the deities that the length of the trunk, &c.

She gave birth to the mother of the Furies. The cock yeller is called by one of the deities that the length of the trunk, &c.

NOYON is a town in France, situated on the declivity of a hill of an easy descent, on the rivulet Voré, which at a quarter of a league's distance falls into the Oyé, in the Isle of France, in E. Long. 49° 58', about 66 miles north-east of Paris. It is an ancient place, being the noviodunum Belgarum of the Latins. It is a pretty large city, and is well situated for inland trade, which consists here in wheat and oats, which they send to Paris. They have also manufactories of linen, cloths, lawns, and tanned leather. There are eight parishes in it, two abbeys, and several monasteries of both sexes. It is the site of a bishop suffragan to the metropolitan of Rheims; he has the title of count and peer of France, and his income is said to amount to about 15,000 livres per annum. The principal buildings are the episcopal palace, a cloister where the canons of the cathedral dwell, and the town house. The latter is regularly built in a large square, in the middle of which there is a fountain, where the water conveyed to it from a neighbouring mountain, runs continually through three conduits, and is received in a large basin built of very hard stone. They have also many other fountains, several market-places, and two public gardens. Noyon is particularly remark-
common, their worship is chiefly paid to the moon, while they pay no attention to the sun either rising or setting, advancing to the meridian or receding from it. It is an old observation, that the worship of every people is tinctured by their natural dispositions; and this is verified in the Nuba. “That their worship is performed with pleasure and satisfaction is obvious (says our author) every night that the moon shines. Coming out from the darkenss of their huts, they say a few words upon seeing her brightness, and testify great joy, by motions of their feet and hands, at the first appearance of the new moon.” This is just what we should have expected from their gentleness and hospitality. They worship likewise a tree and a stone: but our author could never discover what tree or stone, only he learned that neither of them exist in Senmaar, but in the country where the Nuba are born. Such of them as are natives of the villages where he saw them, became, like their masters, nominal Mahometans. The religion of the idolatrous worship of their ancestors, and are much under the influence of their priests, from fear rather than from affection. They are immediately fond of swine’s flesh, and maintain great herds of small hogs, marked with black and white spots. Few of the Nuba advance higher than to be soldiers and officers in their own corps; and the Mek maintains about 12,000 of them near Senmaar to keep the Arabs in subjection. In a climate so violent as that which they inhabit, there is very little need of fuel; and it is happy for them that such is the case, for in the whole country there is not a single tree, nor turf, nor any thing resembling it. They do not, however, “eat their meat raw like the Abyssinians; but with the stalk of the dora or millet, and the dung of camels, they make ovens under ground, in which they roast their hogs whole, in a very cleanly manner, keeping the skins on till they are perfectly baked. They have neither flint nor fleel with which to light their fires at first; but do it in a manner still more expedient, by means of two flicks, brought together, we are led to think, from Senmaar, and there picked out of the river when flooded. They make a small hole in one of these flicks, and point the other at the ground, in a horizontal position, they apply the point of the latter to the hole; and, turning the perpendicular flick between their hands, as we do a chocolate mill, both flicks take fire and flame in a moment; so perfectly dry and prepared to take fire is every thing there on the surface of the earth”

NUBECULA, LITTLE CLOUD, in medicine, a term sometimes used for a dish of the eye, wherein objects appear as through a cloud or mist.

The nubecula seems to arise from certain gross particles detained in the pores of the cornea, or swimming in the aqueous humour, and thus intercepting the rays of light.

NUBECULA, OR NUB, is also used for what we otherwise call albugo. See Albugo.

Nubea is used likewise for a matter, in form of a cloud, suspended in the middle of the urine.

NUBIA, a kingdom of Africa, bounded on the north by Egypt, on the east by the Red Sea and part of Abyssinia, on the west by the kingdoms of Tagua, Gaoga, and the desert of Gerham. The river Nile runs through it; on the banks of which, and thos of the other rivers, it is pretty fruitful, but in other places barren, sandy, and in want of water. To the west of the Nile is the desert of Bahouda, which is five days journey over, being the usual road from Egypt to Abyssinia. Money is of no use in this country in the way of trade, it being all carried on by way of exchange. Their bread and drink is made of a small round seed, called doda or jeff, which is very ill tasted. Their houses have mud walls being very low and covered with reeds. The habit of the better sort is a vault without sleeves; and they have no coverings for their heads, legs, and feet. The common people wrap a piece of linen cloth about them, and the children go quite naked. They are a stupid debauched sort of people, having neither modesty, civility nor religion, though they profess to be Mahometans. - The productions of this country are gold, elephants, teeth, ivory, and sandal wood; and they send a great many fables into Egypt. The principal towns known to the Europeans are Dangola and Senmaar.

It is famous for a race of horses the most powerful and docile in the world. These animals are generally about 16 hands high; and by Mr Bruce, who has given the most scientific account of them, they are said to be the breed which was introduced into Nubia at the Saracen conquest, and has been preserved unmixéd to this day. Our author represents this as a much nobler animal than the Arabian horse. “What figure (says he) the Nubian horse would make in the point of fleetness is very doubtful, his make being fo different that neither the Egyptians nor the Europeans are Dangola and Senmaar.

Our author says that the Nubia are born. Hence great per­

One will pay much regard to this legendary tale, or be­lieve that the strength and beauty of this breed of horses is owing to any virtue communicated to the first of them by the prophet and his apostles. Mr Bruce accounts for their excellence upon rational principles: “The best horses of the Arabian breed are found (he says) in the tribe of Mowelli and Amnay, which is about 36° north latitude. Dangala, which is in 25° latitude, seemed to him to be the centre of excellence for this noble animal.” Hence he infers that the bounds in which the horse is in greatest perfection, are between the 20th and 36th degrees of latitude, and between 30 degrees of longitude east from Greenwich.
Greenwich and the banks of the Euphrates. If to the effects of climate we add the manner of feeding the Nubian hordes, we shall perhaps have the true cause of their superiority over all others. "They are kept fat upon dora, and suffered to eat nothing green but the short roots of grass that are to be found by the side of the Nile, after the fun has withered it. This is dug out where it is covered with earth and appears blanched, and laid in small heaps once a day on the ground before them."

Nubian Desert, a vast tract of barren rocks and burning sands, extending from Syene in Upper Egypt to Geon the capital of Berber in Nubia. As Syene is in latitude 24° 0' 30" north, and Geon in latitude 17° 57' 22", the length of this desert from north to south is 6° 3' 23", or upwards of 420 English miles. Its breadth from east to west has not, as far as we know, been precisely ascertained. Through this horrid region, where nothing is to be seen which has the breath of life, must all travellers pass from Semna to Egypt; in danger every moment of perishing by thirst, suffocated by a hot and poisonous wind, or cut in pieces by troops of wandering Arabs. The last European of whom we have heard that made the journey and lived to give an account of it, is Mr Bruce; and the person must have neither taste nor sensibility who can read unmoved his manly narrative.

No single traveller, nor even a caravan, can enter with safety into this desert, but under the protection of a Hybeor; whose title and office are thus explained by Mr Bruce: "A Hybeor is a guide, from the Arabic word Hubbar, which signifies to inform, instruct, or direct, because they are used to do this office to the caravans travelling through the desert in all directions. They are men of great consideration, knowing perfectly the situation and properties of all kinds of water to be met with on the route, the distances of wells, whether occupied by enemies or not; and if so, the way to avoid them with the least inconvenience. It is also necessary that they should know the places occupied by the Smoom, and the seasons of its blowing (see Smoom), as well as those occupied by moving fands." "Under the conduct of one of these men, Mr Bruce, with infinite fortitude and address, passed through the desert in the year 1772, furmouning dangers at which one shudders in his closet. Of these the following, which we shall give in the nervous language of the author, may serve as an instance.

"We were here (at a place called Wadis al Haboh) at once surprized and terrified by a sight fully one of the most magnificent in the world. In that vast expanse of desert, from W. and to N. W. of us, we saw a number of prodigious pillars of sand at different distances, at times moving with great celerity, at others standing on with a majestic slowness. At intervals we thought they were coming in a very few minutes to overwhelm us; and small quantities of sand did actually more than once reach us. Again, they would retreat so as to be almost out of sight; their tops reaching to the very clouds. There the tops often separated from the bodies; and these once disjointed, dispersed in the air, and did not appear more. Sometimes they were broken in the middle as if by a large cannon shot. About noon they began to advance with considerable swiftness upon us, the wind being very strong at north. Eleven of them ranged alongside of us about the distance of three miles. The greatest diameter of the largest appeared to me at that distance as if it would measure 10 feet. They retired from us with a wind at S. E. leaving an impression on my mind to which I can give no name; tho' surely one ingredient in it was fear, with a considerable degree of wonder and astonishment."

If it be true, as the author of A Philosophical Inquiry into the Origin of our Ideas of the Sublime and Beautiful affirms, that "the passion raised by the sublime is astonishment, and that astonishment is that state of the soul in which all its motions are suspended with some degree of horror," surely a more sublime spectacle was never presented to mortal eyes, than that which was on this occasion presented to Mr Bruce. It must have been awfully majestic; but few, we believe, would choose the pleasure of contemplating such a scene of magnificence at the hazard of that dreadful death with which at every moment it threatened our traveller and his attendants. He, indeed, had firmness of mind to stand still and admire it; but his companions shrieked out; while some of them exclaimed that it was the day of judgment, and others that it was hell or the world set on fire. But for a more particular account of this phenomenon, as well as of the nature of the desert and the proper way of passing it, we must refer to the work from which this short sketch is taken.*

NUCLEUS, in general, denotes the kernel of a nut, Travels, or even any seed enclosed within a husk. The term nucleus is also used for the body of a comet, otherwise called its head.

NUCTA, a dew, which falling in Egypt about St John's day, is by the superstitious natives of the country considered as miraculous, and the peculiar gift of that saint. Its effects are indeed so beneficial, that this belief is little surprising among a people so totally ignorant of natural causes as the modern Egyptians; for it is acknowledged, by the most enlightened travellers, to stop the plague, and announce a speedy and plentiful inundation of the country. These effects are thus rationally accounted for by Mr Bruce.

"In February and March, the sun is on its approach to the zenith of one extremity of Egypt, and of course has a very considerable influence upon the other. The Nile having now fallen low, the water in certain old cisterns, which, though they still exist, are suffered to accumulate all the filth of the river, becomes putrid, and the river itself has lost all its finer and volatile parts by the continued action of a vertical sun; so that instead of being subject to evaporation, it grows daily more and more inclined to putrefaction. About St John's day it receives a plentiful mixture of the fresh and fallen rain from Ethiopia, which dilutes and refrehes the almost corrupted river, and the fun near at hand exerts its influence upon the water, which is now become light enough to be exhaled, tho' it has still with it a mixture of the corrupted fluid. It is in February, March, or April only, that the plague begins in Egypt." Our philosophical traveller does not believe it an endemical disease; but affirms very sufficient reasons for thinking that it comes from Constantinople with merchandise or with passengers at the very time of the year when the air, by the long abstinence of
The author could learn upon every person, though that they could not have got such universality died of it after that period; but of influence of the thousands that were handled, bought, put and worn, without any apprehension of danger, and without a single accident being known to have happened to any one poiffessed of this happy confidence.

NUDITIES, in painting and sculpture, those parts of an human figure which are not covered with any drapery; or those parts where the daughter Pompo, a illustrious Sabine, lived in familiarity with her husband, who was of the Sabine, that Numa lived in familiarity with the nymph Egeria. Upon the death of Romulus both the senate and people strongly solicited him to be their king. They dispatched Julius Proculeus and Varilius Volusia, two senators of distinction, to acquaint Numa with their resolution, and make him an offer of the kingdom. The Sabine philosopher rejected at first their proposal; but being at last prevailed upon by the arguments and entreaties of the deputies, joined with those of his father and of Marcus his near relative, he yielded; and having offered sacrifices to the gods, set out for Rome, where he was received by all ranks of people with loud roars of joy. Spurius Vettius, the interrex for the day, having attended the conic, he was elected in due form, and the election was unanimously confirmed by the senate.

The beginning of his reign was popular; and he dismissed the 300 body-guards which his predecessor had kept around his person, and observed, that he did not distrust a people who had compelled him to reign over them. He was not, like Romulus, fond of war and military expeditions, but he applied himself to tame the ferocity of his subjects, to inculcate in their minds a reverence for the Deity, and to quell their divisions by dividing all the citizens into different classes. He established different orders of priests, and taught the Romans not to worship the Deity by images: and from his example no graven or painted statues appeared in the temples or sanctuaries of Rome for the space of 120 years. He encouraged the report that was spread of his paying regular visits to the nymph Egeria, and made use of her name to give sanction to the laws and institutions which he had introduced. He established the college of the vestals, and told the Romans that the safety of the empire depended upon the preservation of the sacred angles or shield, which as was generally believed, had dropped from heaven. He dedicated a temple to Janus, which during his whole reign, remained shut as a mark of peace and tranquillity at Rome. After a reign of 42 years, in which he had given every possible encouragement to the useful arts, and in which he had cultivated peace. Numa died in the year of Rome 82. Not only the Romans, but also the neighbouring nations, were eager to pay their last offices to a monarch whom they revered for his abilities, moderation, and humanity. He forbade his body to be burnt according to the custom of the Romans; but he ordered it to be buried near mount Janiculum, with many of the books which he had written. These books were accidentally found by one of the Romans, about 400 years after his death; and as they contained nothing new or interesting, but merely reasons why he had made innovations in the form of worship and in the religion of the Romans, they were burnt by order of the senate. He left behind him one daughter called Pomilia, who married Numa Marcus, and became the mother of Ancus Marcus the fourth king of Rome. Some say that he had also four sons; but this opinion is ill-founded. The principal laws of king Numa, mentioned by different authors, are, that the gods should be worshipped with corn and a salted cake. That whoever knowingly killed a free man, should be held as a paificide. That no harlot should touch the altar of Juno; and if she did, that she should sacrifice an ewe-lamb to that goddess, with difhallowed hair. That whoever removed a landmark should be put to death. That wine should not be poured on a funeral pile, &c.

NUMANTIA, a very noble city, the ornament of the Iberian Spain, (Florus); celebrated for the long war of 20 years which it maintained against the Romans. The baseness and injustice of the Romans during this war was truly disgraceful to them, and altogether unworthy of a great and powerful people. The inhabitants obtained some advantages over the Roman forces, till Scipio Africanus was empowered to finish the war and to see the destruction of Numantia. He began the siege with an army of 60,000 men, and was bravely opposed by the besieged, who were no more than 4000 men able to bear arms. Both armies behaved with uncommon valour, and the courage of the Numantines was soon changed into despair and fury.
Their provisions began to fail, and they fed upon the flesh of their horses, and afterwards on that of their dead companions, and at last they were obliged to draw lots to kill and devour one another. The melancholy situation of their affairs obliged them to surrender to the Roman general. Scipio demanded them to deliver themselves up on the morrow; they refused, and when a longer time had been granted to their petitions, they retired and set fire to their houses and destroyed themselves, so that not even one remained to adorn the triumph of the conqueror. Some historians, however, deny that; and assert, that a number of Numantines delivered themselves into Scipio's hands, and that so of them were drawn in triumph at Rome, and the rest fold as slaves. The fall of Numantia was more glorious than that of Carthage or Corinth, though the place was much inferior to them. It was taken by the Romans, A. U. C. 629; and the conqueror obtained the surname of Numanticus.

NUMBER, an assemblage of several units, or things of the same kind. See Arithmetic, and Metaphysics, n° 205—208.

Number, says Malcolm, is either abstract or aplicate: Abstract, when referred to things in general, without attending to their particular properties; and aplicate, when considered as the number of a particular sort of things, as yards, trees, or the like.

When particular things are mentioned, there is always something more considered than barely their numbers; so that what is true of numbers in the abstract, or when nothing but the number of things is considered, will not be true when the question is limited to particular things: for instance, the number two is less than three; yet two yards is a greater quantity than three inches: and the reason is, because regard must be had to their different natures as well as number, whenever things of a different species are considered; for though we can compare the number of such things abstractedly, yet we cannot compare them in any applicable sense. And this difference is necessary to be considered, because upon it the true sense, and the possibility or impossibility, of some questions depend.

Number is unlimited in respect of increase; because we can never conceive a number so great as till there is a greater. However in respect of decrease, it is limited; unity being the first and least number, below which therefore it cannot descend.

Kinds and distinctions of Numbers. Mathematicians, considering numbers under a great many relations, have established the following distinctions.

Broken numbers are the same with fractions.

Cardinal numbers are those which signify the quantity of units, as 1, 2, 3, 4, &c. whereas ordinal numbers are those which express order, as 1st, 2nd, 3rd, &c.

Compound number, one divisible by some other number besides unity; as 12, which is divisible by 2, 3, 4, and 6. Numbers, as 12 and 15, which have some common measure besides unity, are said to be compound numbers among themselves.

Cubic number is the product of a square number by its root: such is 27, as being the product of the square number 9 by its root 3. All cubic numbers, whose root is less than 6, being divided by 6, the remainder is the root itself: thus 27 + 6 leaves the remainder 3, its root; 216, the cube of 6, being divided by 6, leaves no remainder; 14, the cube of 2, leaves a remainder 1, which added to 6, is the cube root; and 512, the cube of 8, divided by 6, leaves a remainder 2, which added to 6, is the cube root. Hence the remainders of the divisions of the cubes above 216, divided by 6, being added to 6, always gives the root of the cube so divided till that remainder be 5, and consequently 1, the cube-root of the number divided. But the cubic numbers above this being divided by 6, there remains nothing, the cube root being 12. Thus the remainders of the higher cubes are to be added to 12 and not to 6, till you come to 18, when the remainder of the division must be added to 18; and so on ad infinitum.

Determinate number is that referred to some given unit, as a ternary or three; whereas an indeterminate one is that referred to unity in general, and is called quantity.

Homogeneous numbers are those referred to the same unit; as those referred to different units are termed heterogenous.

Whole numbers are otherwise called integers.

Rational number is one commensurable with unity; as a number, incommensurable with unity, is termed irrational, or a surd.

In the same manner, a rational whole number is that whereof unity is an aliquot part; a rational broken number, that equal to some aliquot part of unity; and a rational mixed number, that consisting of a whole number and a broken one.

Even number, that which may be divided into two equal parts without any fraction, as 6, 12, &c. The sum, difference, and product, of any number of even numbers, is always an even number.

An evenly even number, is that which may be measured, or divided, without any remainder, by another even number, as 4 by 2.

An unevenly even number, when a number may be equally divided by an uneven number, as 20 by 5.

Uneven number, that which exceeds an even number, at least by unity, or which cannot be divided into two equal parts, as 3, 5, &c.

The sum or difference of two uneven numbers makes an even number; but the product of two uneven ones makes an uneven number.

If an even number be added to an uneven one, or if the one be subtracted from the other, in the former case the sum, in the latter the difference, is an uneven number; but the product of an even and uneven number is even.

The sum of any even number of uneven numbers is an even number; and the sum of any uneven number of uneven numbers is an uneven number.

Primitive or prime numbers are those divisible only by unity, as 5, 7, &c. And prime numbers among themselves, are those which have no common measure besides unity, as 12 and 19.

Perfect number, that whose aliquot parts added together make the whole number, as 6, 28; the aliquot parts of 6 being 1, 2, and 3; and those of 28, being 14, 7, 4, 2, 1; = 28.

Imperfect numbers, those whose aliquot parts added together make neither more or less than the whole.
And these are distinguished into abundant and defective: an insinuate in the former case is 12, whose aliquot parts 6, 4, 3, 2, 1, make 16; and in the latter case 16, whose aliquot parts 8, 4, 2, and 1, make but 15.

The main number, that arising from the multiplication of two numbers, as 6, which is the product of 3 by 2; and these numbers are called the sides of the plane triangle.

Square number is the product of any number multiplied by itself; thus 4, which is the factum of 2 by 2, is a square number.

Even square number added to its root makes an even number.

Polyhedral or polygonal numbers, the sums of arithmetical progressions beginning with unity; these, where the common difference is 1, are called triangular numbers; where 2, square numbers; where 3, pentagonal numbers; where 4, hexagonal numbers; where 5, heptagonal numbers, &c.

Pyramidal numbers, the sums of polygonal numbers, collected after the same manner as the polygons themselves, and not gathered out of arithmetical progressions, are called first pyramidal numbers; the sums of the first pyramids are called second pyramids, &c.

If they arise out of triangular numbers, they are called triangular pyramidal numbers; if out of pentagons, second pentagonal pyramidal numbers.

From the manner of summing up polygonal numbers, it is easy to conceive how the prime pyramidal numbers are found, viz. \((a-2)^2+3(a-5)\)

6

expresses all the prime pyramids.

The number nine has a very curious property, its aliquot parts 1, 3, and 9, the rest being defective. Thefe numbers are fanciful derivations.

The Jewish cabalists, the Grecian conjurors, and the Roman augurs, had a great veneration for particular numbers, and the result of particular combinations of them. Thus three, four, fix, seven, nine, ten, are full of divine mysteries, and of great efficacy.

Golden Number. See Chronology, no. 27.

Numbers, in poetry, oratory, &c. are certain measures, proportions, or cadences, which render a verse, period, or song, agreeable to the ear.

Poetical numbers confit in a certain harmony in the order, quantities, &c. of the feet and syllables, which make the piece musical to the ear, and fit for differing, for which all the verses of the ancients were intended. See Poetry.—It is of these numbers Virgil speaks in his ninth Eclogue, when he makes Lyceidas say, Numeros memini, ferabo tenebros; meaning, that although he had forgot the words of the verfe, yet he remembered the feet and measure of which they were composed.

Rhetorical or profaic numbers are a fort of simple unaffected harmony, less glaring than that of verse, but such as is perceived and affects the mind with pleasure.

The numbers are that by which the style is said to be easy, free, round, flowing, &c. Numbers are things absolutely necessary in all writing, and even in all speech. Hence Aristotle, Tully, Quintilian, &c. lay down abundance of rules as to the best manner of intermixing dactyles, spondees, anapests, &c. in order to have the numbers perfect. The substance of what they have said, is reducible to what follows.

1. The style becomes numerous by the alternate disposition and temperature of long and short syllables, so as that the multitude of short ones neither render it too halffy, nor that of long ones too flow and languid; sometimes, indeed, long and short syllables are thrown together defignedly without any fuch mixture, to paint the flownees or celerity of any thing by that of the numbers; as in these verfs of Virgil:

Ili inter fefé magnae vi brahsia sollunt;

and

Racit iter liquidum, colora neque commovet arat.

2. The style becomes numerous by the intermixing words of one, two, or more syllables; whereas the TOO frequent repetition of monosyllables renders the style pitiful and grating. 3. It contributes greatly to the numerosness of a period, to have it cleaved by magnificent and well-founded words. 4. The numbers depend not only on the nobleness of the words in the clofe, but of those in the whole tenor of the period. 5. To have the period flow easily and equally, the harfh concurrence of letters and words is to be flutely avoided, particularly the frequent meeting of rough confonants; the beginning the first syllable of a word with the laft of the preceding; the frequent repetition of the fame letter or syllable; and the frequent ufe of the like ending words. Lastly, the utmost care is to be taken lest, in aiming at oratorial num-

bers,
NUMERAL LETTERS, those letters of the alphabet which are generally used for figures; as I, one; V, five; X, ten; L, fifty; C, a hundred; D, five hundred; M, a thousand, &c.

It is not agreed how the Roman numerals originally received their value. It has been supposed, as we have observed in the end of the article Numbers, that the Romans used M, to denote 1000, because it is the first letter of mille, which is Latin for thousand; and C to denote 100, because it is the first letter of centum, which is Latin for hundred. It has also been supposed, that D, being formed by dividing the old M in the middle, was therefore appointed to stand for 500, that is, half as much as the M stood for when it was whole; and that L, being half a C, was, for the same reason, used to denominate 50. But what reason is there to suppose, that 1000 and 100 were the numbers which letters were first used to express? And what reason can be assigned why D, the first letter in the Latin word decem, ten, should not rather have been chosen to stand for that number, than for 500, because it had a rude resemblance to half an M? But if these questions could be satisfactorily answered, there are other numeral letters which have never yet been accounted for at all. These considerations render it probable that the Romans did not, in their original intention, use letters to express numbers at all; the most natural account of the matter seems to be this:

The Romans probably put down a single stroke, I, for one, as is still the practice of those who score on a slate or with chalk: this stroke, I, they doubled, trebled, and quadrupled, to express 2, 3, and 4: thus, II. III. IIII. So far they could easily number the strokes with a glance of the eye. But they presently found, that if more were added, it would soon be necessary to tell the strokes one by one: for this reason, when they came to 5, they expressed it by joining two strokes together in an acute angle thus, V; which will appear the more probable, if it be considered that the progression of the Roman numbers is from 5 to 5, i.e. from the fingers on one hand to the fingers on the other.—Ovid has touched upon the original of this in his Fasti, lib. iii. and在他的 lib. 1. has made the same remark.

After they had made this acute angle V, for five, they added the single strokes to it to the number of 4, thus, VI. VII. VIII. VIIII. and then as the strokes could not be further multiplied without confusion, they doubled their acute angle, by prolonging the two lines beyond their interconnexion thus, X, to denote two fives, or ten. After this they doubled, trebled, and quadrupled, this double acute angle thus, XX. XXX. XXXX. they then, for the same reason which induced them first to make a single and then to double it, joined two single strokes in another form, and instead of an acute angle, made a right angle, L, to denote fifty. When this 50 was doubled, they then doubled the right angle thus, D, to denote 100, and having numbered this double right angle four times, thus, C; when they came to the fifth number, as before, they reverted it, and put a single stroke before it thus, J, to denote 500; and when this 500 was doubled, then they also doubled their double right angle, letting two double right angles opposite to each other, with a single stroke between them, thus, F, to denote 1000: when this note for 1000 had been four times repeated, then they put down [ ] for 5000, [ ] [ ] [ ] for 10,000, and [ ] [ ] [ ] [ ] for 50,000, [ ] [ ] [ ] [ ] [ ] for 100,000, [ ] [ ] for 500,000, and [ ] [ ] [ ] [ ] for one million.

That the Romans did not originally write M for 1000, and C for 100, but square characters, as they are written above, we are explicity informed by Paulus Manutius; but the corners of the angles being cut off by the transcribers for dispatch, these figures were gradually brought into what are now numeral letters. When the corners of [ ] were made round, it stood thus ( ), which is so near the Gothic m, that it soon deviated into that letter; so ( ) having the corner made round, it stood thus ( ) and then easily deviated into D. ( ) also became a plain C by the same means; the single rectangle which denoted 50, was, without alteration, a capital L; the double acute angle was an X; the single acute angle a V consonant; and a plain single stroke, the letter I, and thus these seven letters, M, D, C, L, X, V, I, became numerals.

NUMERAL CHARACTERS of the Arabs, are those figures which are now used in all the operations of arithmetic in every nation of Europe. We have elsewhere shown that the Arabs derived the use of them most probably from India; (See Arithmetic, No. 5.) This opinion, however, though very generally received, has been controverted with some ingenuity. A writer in the Gentleman’s Magazine, at a period when that miscellany was in its highest reputation, thus endeavoured to prove that the Arabs derived their notations from the Greeks. “I maintain (says he) that the Indians received their numeral characters from the Arabsians, and the Arabians from the Greeks, as from them they derived all their learning, which in some things they improved, but for the most part have altered. The numerical figures which they received from the Greeks are proofs of this alteration; which is so great, that without particular attention one can scarce discover in them the vestiges of their origin. But when we compare them carefully, and without prejudice, we find in them manifest traces of the Greek figures. The Greek numerical figures were no other than the letters of their alphabet. A small stroke was the mark of unity. The B, being abridged of its two extremities, produced the 2. If you incline the 9 a little on its left side, and cut off its foot, and make the left horn round towards the left side, you will produce a 3; the A makes the 4, by raising
NUMERATION, or Notation, in arithmetic, the art of expressing in characters, any number proposed in words, or of expressing in words, any number proposed in characters. See Arithmetic, No. 7.

NUMERICAL, Numerous, or Numeral, something belonging to numbers; as numerical algebra is that which makes use of numbers, instead of letters of the alphabet. Also numerical difference is that by which one man is distinguished from another. Hence a thing is said to be numerically the same, when it is so in the strictest sense of the word.

NUMIDIA, in mythology, a genus belonging to the order of gallines. On each side of the head there is a kind of coloured fishy horn; and the beak is furnished with cera near the nostrils. The species called meleagris, or Guinea hen, is a native of Africa. It is larger than a common hen. Its body is flopped like that of a partridge, and its colour is all over a dark grey, very beautifully spotted with small white specks; there is a black ring round the neck; its head is reddish, and it is blue under the eyes. They naturally herd together in large numbers, and breed up their young in common; the females taking care of the broods of others, as well as of their own. Barbut informs us, that in Guinea they go in flocks of 200 or 300, perch on trees, and feed on worms and grasshoppers; that they are run down and taken by dogs; and that their flesh is tender and sweet, generally white, though sometimes black. They breed very well with us. Mr. Latham observes, "that the native place of this bird is, without doubt, Africa, and that it is the meleagen of old authors. It is supposed originally to have come from Nubia, and was esteemed in the Roman banquets. It has been met with in flocks of two or three hundred by various travellers. Dampier found them in numbers in the island of Mayo; and Forster speaks of them as numerous at St. Jago; but they have been transported into the West Indies and America, and are now in a wild state in those places as well as domesticated."

The white-breasted one is a mere variety, of which there are many: it is mostly found in Jamaica. The grey, or numida mitrata, is a different and not a common species: it inhabits Madagascar and Guinea. Pallas seems to think that it may be the bird mentioned by Columella, as differing from the common one; and will account for Pliny's having thought the numida and meleagris to be different birds. The third species which Mr. Latham mentions is the crested, or numida cristata. This species likewise inhabits Africa. Perhaps it may have some relation to the crested fort which Maregraves mentions to have seen, and which came from Sierra Leon. This had a kind of membranous collar about the neck, of a bluish ash-colour, and had a large roundish black crest.

Buffon, who describes it at great length, calls it la pintade. Linnaeus and Gmel. call it Numida meleagris; &c. Ray and Will call it galbus and galina Guineensis, &c. Mr. Pennant contends, and seems to prove, that the pintades had been early introduced into Britain, at least prior to the year 1277. But they seem to have been much neglected on account of the difficulty of rearing them; for they occur not in the ancient bills of fare. They have a double caruncle at the chaps, and no fold at the throat.

NUMIDIA, an ancient kingdom of Africa, bounded on the north by the Mediterranean Sea; on the south by Geutilia, or part of Libya Interior; on the west by the Mulucha, a river which separated it from Mauritania; and on the east by the Tufca, another river which bounded it in common with Africa Propria. Dr. Shaw has rendered it probable, that the river which formerly went under the dominations of Malobis, Malobous, Mulucha, and Melobath, is the same with that now called Mullodiah by the Algerines; in which cafe, the kingdom of Numidia must have extended upwards of 500 miles in length; its breadth, however, cannot be so well ascertained; but supposing it to have been the same with that of the present kingdom of Algiers, in the narrowest part it must have been at least 40 miles broad, and in the widest upwards of 100.

Ancient Africa is divided into two districts; one inhabited by the Maffyli, and the other by Mefefily; the latter being also called in after times Mauritania Cefariensis, and the former Numidia Propria. The country of the Maffyli, or, as some call it, Terra Metaguina, was separated from the proper territory of Carthage by its eastern boundary the river Tufta, and from the kingdom of the Mefefyli, or Mauritania Cesariensis, by the river Ampaga. It seems to correspond with that part of the province of Constantinople lying between the Zaine and the Wed al Kibeer, which is above 130 miles long, and more than 100 broad. The sea-coast of
Numidia

of this province is for the most part mountainous and rocky, answering to the appellation given to it by Abulfeda, viz. El Edwan, the high or lofty. It is far from being equal in extent to the ancient country of the Maffyli, which, Strabo informs us, was yet inferior to the country of the Maffyli. Its capital was Cirta, a place of very considerable note among the ancients.

The most celebrated Antiquarians agree, that the tract, extending from the isthmus of Suez to the lake Tritonis, was chiefly peopled by the descendants of Mizraim, and that the poorness of his brother Put, or Phut, spread themselves all over the country between that lake and the Atlantic ocean. To this notion Herodotus gives great countenance: for he tells us, that the Libyan Nomades, whose territories to the west were bounded by the Triton, agreed in their customs and manners with the Egyptians; but that the African, from that river to the Atlantic ocean, differed in almost all points from them. Ptolemy mentions a city called Pthia near Atragum; and Pliny, a river of Mauritania Tingitana, known by the name of Fut, or Phut; and the district adjacent to this river was called Regia Plantea, which plainly alludes to the name of Phut. That word signifies scattered, or dispersed, which very well agrees with what Mela and Strabo relate of the ancient Numidians; so that we may without any figure, admit the aborigines of this country to have been the descendants of Phut.

The history of Numidia, during many of the early ages, is buried in oblivion. It is probable, however, that as the Phoenicians were masters of a great part of the country, those transactions had been recorded, and generally known to the Carthaginians. King Jarbas probably reigned here as well as in Africa Propria, if not in Mauritania, and other parts of Libya, when Dido began to build Byrsa. It appears from Justin, that about the age of Herodotus, the people of this country were called both Libani or Libian, and Numidians. Justin likewise intimates, that about this time the Carthaginians vanquished both the Moors or Mauritaniats and Numidians; in consequence of which they were excused from paying the tribute which had hitherto been demanded of them.

After the conclusion of the first Punic war, the African troops carried on a bloody contest against their masters the Carthaginians; and the most active in this rebellion, according to Diodorus Sicius, were a part of the Numidian nation named Mocatanians. This fact incensed the Carthaginians, that after Hamilcar had either killed or taken prisoners all the mercenaries, he sent a large detachment to ravage the country of those Numidians. The commandant of that detachment executed his orders with the utmost cruelty, plundering the district in a terrible manner, and crucifying all the prisoners without distinction that fell into his hands. This filled the rest with such indignation and resentment, that both they and their posterity ever afterwards bore an implacable hatred to the Carthaginians.

In the time of the second Punic war, Syphax king of the Maffyli entered into an alliance with the Romans, and gave the Carthaginians a considerable defeat. This induced Gala, king of the Maffyli, to conclude a treaty with the Carthaginians, in consequence of which his son Masmith marched at the head of a powerful army to give Syphax battle. The contest ended in favour of Masmith; 30,000 of the Maffyli were put to the sword, and Syphax driven into Mauritania; and the like had success attended Syphax in another engagement, where his troops were entirely defeated and dispersed.

Gala dying whilst his son Masmith was acting at the head of the Numidian troops sent to the assistance of the Carthaginians in Spain, his brother Defalles, according to the established rules of succession in Numidia, took possession of the Maffylian throne. That prince dying soon after his accession, Capua his eldest son succeeded him. But he did not long enjoy his high dignity; for one Mezetulus, a parricide of the royal blood, but an enemy to the family of Gala, found means to excite a great part of his subjects to revolt. A battle from took place between him and Capua; in which the latter was slain with many of the nobility, and his army entirely defeated. But though Mezetulus thus became possessed of the sovereignty, he did not think proper to assume the title of king, but styled himself guardian to Lacumaces, the surviving son of Defalles, whom he charged with the royal title.

To support himself in his usurpation, he married the dowager of Defalles, who was Hannibal's niece, and consequently of the most powerful family in Carthage. In order to attain the fame end, he sent embassowers to Syphax, to conclude a treaty of alliance with him. In the mean time Masmith, receiving advice of his uncle's death, of his cousin's daughter, and of Mezetulus's usurpation, immediately passed over to Africa, and went to the court of Bocchor king of Mauritania, to solicit succours. Bocchor, sensible of the great injustice done Masmith, gave him a body of 4000 Moors to escort him to his dominions. His subjects having been apprised of his approach, joined him upon the frontiers with a party of 500 men. The Moors, in pursuance of their orders, returned home, as soon as Masmith reached the confines of his kingdom. Notwithstanding which, and the small body then declared for him having accidentally met Lacumaces at Thapfus with an army going to implore Syphax's affiance, he drove him into the town, which he carried by assault, after a violent resistance. However, Lacumaces, with many of his men, found means to escape to Syphax. The fame of this exploit gained Masmith great credit, informuch that the Numidians flocked to him from all parts, and amongst the rest, many of his father Gala's veterans, who preffed him to make a speedy and vigorous pufli for his hereditary dominions. Lacumaces having joined Mezetulus with a reinforcement of Maffylians, which he had prevailed upon Syphax to lend to the assistance of his ally, the usurper advanced at the head of a numerous army to offer Masmith battle; which that prince, though much inferior in numbers, did not decline. Hereupon an engagement ensued; which, notwithstanding the inequality of numbers, ended in the defeat of Lacumaces. The immediate consequence of this victory of Masmith was a quiet and peaceable possession of his kingdom; Mezetulus and Lacumaces, with a few that attended them, flying into the territories of Carthage. However, being apprehensive that
he should be obliged to sustain a war against Syphax, he offered to treat Lacumaces with as many marks of distinction as his father Gala had Defaces, provided that prince would put himself under his protection. He also promised Mezentius pardon, and a reinstitution of all the effects forfeited by his treaflagable conduct, if he would make his submission to him. Both of them readily complied with the proposal, and immediately returned home; so that the tranquillity and repose of Numidia would have been settled upon a solid and lasting foundation, had not this been prevented by Aedrulbal, who was then at Syphax's court. He intimated to that prince, who was disposed to live amicably with his neighbours, "That he was greatly mistaken, if he imagined Mafinissa would be satisfied with his hereditary dominions. That he was a prince of much greater capacity and ambition, than either his father Gala, his uncle Defaces, or any of his family. That he had discovered in Spain marks of a most rare and uncommon merit. And that, in fine unless his rising flame was extinguished before it came to too great a head, both the Mafylians and Carthaginian states would be infallibly consumed by it. Syphax, alarmed by these suggestions, with great vanity fixed in himself obliged to fly to a place of safety; and having fortified himself in a cave, where he was supported by the robberies of the two horsemen that had made their escape with him. But having cured his wound by the application of some medicinal herbs he boldly began to advance towards his own frontiers, giving out publicly that he intended once more to take possession of his kingdom. In his march he was joined by about 40 horse; and, soon after his arrival amongst the Mafyli, so many people flocked to him from all parts, that out of them he formed an army of 6000 foot and 4000 horse. With these forces, he not only reinstated himself in the possession of his dominions, but likewise laid waste the borders of the Mafyli and Carthagiens. To the terror of Syphax, that he immediately assembled a body of troops and encamped very commodiously upon a ridge of mountains between Cirta and Hippo. His army he commanded in person; and detached his son Vermina, with a considerable force, to make a compass, and attack the enemy in the rear. In pursuance of his orders, Vermina set out in the beginning of the night, and took post in the place appointed him, without being discovered by the enemy. In the mean time Syphax decamped, and advanced towards the Mafyli, in order to give them battle. When he had possessed himself of a rising ground that led to their camp, and concluded that his son Vermina must have formed the ambuscade behind them, he began the fight. Mafinissa being advantageously posted, and his soldiers distinguishing themselves in an extraordinary manner, the dispute was long and bloody. But Vermina unexpectedly falling upon their rear, and by this means obliging them to divide their forces, which were scarce able before to oppose the main body under Syphax, they were soon thrown into confusion, and forced to betake themselves to a precipitate flight. All the avenues being blocked up, partly by Syphax and partly by his son, such a dreadful slaughter was made of the unhappy Mafyli, that only Mafinissa himself, with 60 horse, escaped to the Leifer Syrtes. Here he remained, betwixt the confines of the Carthaginian and Garamantes, till the arrival of Lælius and the Roman fleet on the coast of Africa. What happened immediately after this junction with the Romans, belongs to the article Rome. It will be sufficient therefore in this place to observe, that, by the assistance of Lælius, Mafinissa at last reduced Syphax's kingdom. According to Zonarism, Mafinissa and Scipio, before the memorable battle of Zama, by a stratagem deprived of some advantageou. polts; which, with a solar eclipse happening during the heat of the action, and not a little intemidating the Carthaginian troops, greatly contributed to the victory the Romans obtained. At the conclusion therefore of the second Punic war, he was amply rewarded.
Numidia, warded by the Romans for the important services he had done them. As for Syphax, after the loss of his dominions, he was kept in confinement for some time at Alba; from whence being removed in order to grace Scipio's triumph, he died at Tibur in his way to Rome. Zonaras adds, that his corpse was decently interred; that all the Numidian prisoners were released; and that Vermina, by the assistance of the Romans, took peacable possession of his father's throne. However, part of the Masmalaonian kingdom had been before annexed to Masinissa's dominions, in order to reward that prince for his singular fidelity and close attachment to the Romans.

This seems to be countenanced by the epitomizer of Livy, who gives us sufficiently to understand, that Syphax's family, for a considerable time after the conclusion of the second Punic war, reigned in one part of Numidia. For he intimates, that Archobazarzes, Syphax's grandson, and probably Vermina's son, hovered with a powerful army of Numidians upon the Carthaginian frontiers a few years before the beginning of the third Punic war. This he seems to have done, either in order to cover them, or to enable the Carthaginians to make an irruption into Masinissa's territories. Cato, however, pretended that these forces, in conjunction with those of Carthage, had a design to invade the Roman dominions, which he urged as a reason to induce the confcript fathers to pass under the yoke, and to conspire against the Carthaginian prince, than to exhibit to our readers view some points of his history.

Of this famous prince, than to exhibit to our readers view some points of his history, Plutarch from the African republic.

By drawing a line of circumvallation around the Carthaginian army under Afdurbaal, posted upon an eminence, Masinissa cut off all manner of supplies from them; which introduced both the plague and famine into their camp. As the body of Numidian troops employed in this blockade was not near so numerous as the Carthaginian forces, it is evident, that the line here mentioned must have been extremely strong, and consequently the effect of great labour and art. The Carthaginians, finding themselves reduced to the last extremity, concluded a peace upon the following terms, which Masinissa dictated to them: 1. That they should deliver up all defectors. 2. That they should recall their exiles, who had taken refuge in his dominions. 3. That they should pay him 5000 talents of silver within the space of 90 years. 4. That their soldiers should pass under the jugum, each of them carrying off only a single garment. As Masinissa himself, though between 80 and 90 years of age, conducted the whole enterprise, he must have been extremely well versed in fortification, and other branches of the military art. His understanding likewise he must have retained to the last. This happened a short time before the beginning of the third Punic war. See CARTHAGE.

Soon after, the consuls landed an army in Africa, in order to lay siege to Carthage, without imparting to Masinissa their design. This not a little chagrined him, but it was contrary to the former practice of the Romans; who in the preceding war had communicated their intentions to him, and consulted him on all occasions. When, therefore the consuls applied to him for the body of his troops to act in concert with their forces, he made answer, "That they should have reimbursement from him when they flood in need of it." It could not but be provoking to him to consider, that after he had extremely weakened the Carthaginians, and even brought them to the brink of ruin, his pretended imperious friends should come to reap the fruits of his victory, without giving him the least intelligence of it.

However, his mind soon returned to its natural bias, which was in favour of the Romans. Finding his end approaching, he sent to Æmilianus, then a tribune in the Roman army, to defire a visit from him. What he proposed by this visit, was to invest him with full powers to dispose of his kingdom and estate as he should think proper, for the benefit of his children. The high idea he had entertained of that young hero's abilities and integrity, together with his gratitude and affection for the family into which he was adopted, induced him to take this step. But believing that death would not permit him to have a personal conference with Æmilianus upon this subject, he informed his wife and children in his last moments, that he had empowered him to dispose of an absolute manner of all his possessions, and to divide his kingdom amongst his sons. To which he subjoined, "I require, that whatever Æmilianus may decree, shall be executed as punctually as if I myself had appointed it by my will." Having uttered these words, he expired, at about 90 years of age.

This prince, during his youth, had met with strange reverses of fortune. However, says Appian, being supported by the Divine protection, he enjoyed an uninterrupted course of prosperity for a long series of years. His kingdom extended from Mauritania to the western confines of Cyrenaica; from whence it appears, that he was one of the most powerful princes of Africa. Many of the inhabitants of this vast tract he civilized in a wonderful manner, teaching them to cultivate their soil, and to reap those natural advantages which the fertility of some parts of their country offered them. He was of a more robust habit of body than any of his contemporaries, being blessed with the greatest health and vigour; which was double in his extreme temperance, and the toils he incessantly sustained. We are informed by Polybius, that sometimes he stood upon the same spot of ground from morning till evening, without the least motion, and at others continued as long in a sitting posture. He would remain on horseback for several days and nights together, without being sensible of the least fatigue. Nothing can better evince the strength of his constitution, than his youngest son, named Stemba, Segmenta, or Stembaus, who was but four years old at his decease. Though 90 years of age, he performed all the exercises used by young men, and always rode without a saddle. Pliny tells us, that he reigned above 60 years. He was an able commander, and much facilitated the reduction of Carthage. Plutarch from Polybius observes, that the day after a great victory won over
NUM

NUM

Maelin was seen sitting at the door of his tent, eating a piece of brown bread. Suicis relates, that to the left he could mount his horse without any affluence. According to Appian, he left a numerous well-disciplined army, and an immense quantity of wealth, behind him.

Maelin, before his death, gave his ring to his eldest son Micipia; but left the distribution of all his other effects and possessions amongst his children entirely to Æmilianus. Of 54 sons that survived him, only three were legitimate, to wit, Micipia, Gulufa, and Maftanabal. Æmilianus, arriving at Cirta after he had expired, divided his kingdom, or rather the government of it, amongst these three; though to the others he gave considerable possessions. To Micipia, who was a prince of a pacific disposition, and the eldest son, he assigned Cirta, the metropolis, for the place of his residence, in exclusion of the others. Gulufa, the next to him, being a prince of a military genius, had the command of the army, and the transacting of all affairs relating to peace or war committed to his care. And Maftanabal, the youngest, had the administration of justice, an employment suitable to his education, allotted him. They enjoyed in common the name of Æmilianus with the royal title. After he had made these wise dispositions, that young nobleman departed from Cirta, taking with him a body of Numidian troops, under the conduct of Gulufa, to reinforce the Roman army that was then acting against the Carthaginians.

Maftanabal and Gulufa died soon after their father; as appears from the express testimony of Sallust. We find nothing more remarkable of those princes, besides what has been already related, than that the latter continued to affilt the Romans in the third Punic war, and that the former was pretty well verified in the Greek language. Micipia therefore became sole possessed of the kingdom of Numidia. In his reign, and under the consulship of M. Plautius Hypsens and M. Fulvius Flaccus, according to Cato, a great part of Africa was covered with locusts, which destroyed all the produce of the earth, and even devoured dry wood. But at last they were all carried by the wind into the African sea, out of which being thrown in vast heaps upon the shore, a plague ensued, which swept away an infinite number of animals of all kinds. In Numidia only 800,000 men perished, and in Africa Propria 200,000; amongst the rest 30,000 Roman soldiers quartered in and about Ulic a for the defence of the last provinces. At Utica, in particular, the mortality raged to such a degree, that 700 dead bodies were carried out of cemeteries in a day. Micipia had two sons, Acherbal and Hiempiel, whom he educated in his palace, together with his nephew Jugurtha. That young prince was the son of Maftanabal; but his mother having been only a concubine, Micipia had taken no great notice of him. However, Micipia considering him as a prince of the blood, took as much care of him as he did of his own children.

Jugurtha possessed several eminent qualities, which gained him universal esteem. He was very handsome, endued with great strength of body, and adorned with the finest intellectual endowments. He did not devote himself, as young men commonly do, to a life of luxury and pleasure. He used to exercise himself, with persons of his age, in running, riding, hurling the javelin, and other manly exercises, fitted to the martial genius of the Numidians; and though he purfued all his fellow sportsmen, there was not one of them but loved him. The chase was his only delight; but it was what of lions and other savage beasts. Sallust, to finish his character, tells us, that he excelled in all things, and spoke very little of himself.

So conspicuous an assemblage of fine talents and perfections, at first charmed Micipia, who thought them an ornament to his kingdom. However, he soon began to reflect, that he was considerably advanced in years, and his children in their infancy; that mankind naturally thirsted after power, and that nothing was capable of making men run greater lengths than a vicious and unlimited ambition. These reflections soon excited his jealousy, and determined him to expose Jugurtha to a variety of dangers, some of which, he entertained hopes, might prove fatal to him. In order to this, he gave him the command of a body of forces which he sent to affift the Romans, who were at that time besieging Numantia in Spain. But Jugurtha, by his admirable conduct, not only escaped all those dangers, but likewise won the esteem of the whole army, and the friendship of Scipio, who sent him a high character of him to his uncle Micipia. However, that general gave him some prudent advice in relation to his future conduct; observing, no doubt, in him certain sparks of ambition, which, if lighted into flame, he apprehended might one day be productive of the most fatal consequences.

Jugurtha being about to go to Spain, and Sallust being at that time besieging Numantia in Spain, Sallust was desirous to find out some method of taking him off privately; but his popularity amongst the Numidians obliged that prince to lay aside all thoughts of this nature. After his return from Spain the whole nation almost adored him. The heroic bravery he had shown there, his undaunted courage, joined to the utmost calmness of mind, which enabled him to preserve a just medium between a timorous foresight and an impetuous rashness, a circumstance rarely to be met with in persons of his age, and above all the advantageous testimonials of his conduct given by Scipio, attracted an universal esteem. Nay, Micipia himself, charmed with the high idea the Roman general had entertained of his merit, changed his behaviour towards him; reserving, if possible, to win his affection by kindness. He therefore adopted him, and declared him joint heir with his two sons to the crown. Finding, some few years afterwards, that his end approached, he sent for all three to his bed-side; where, in the presence of the whole court, he declared Jugurtha to recollect with what extreme tenderness he had treated him, and consequently to consider how well he had deferred at his hands. He then intreated him to protect his children on all occasions; who being before related to him by the ties of blood, were now by their father’s bounty become his brethren. In order to fix him the more firmly in their interest, he likewise complimented him upon his bravery, address, and consummate prudence. He further intimated, that neither arms nor treasures constitute the strength of a kingdom; but friends, who are neither won by arms nor gold, but by real services, and an inviolable fidelity. “Now where (continued he)
he) can we find better friends than in brothers? And how can that man who becomes an enemy to his relations, repose any confidence in, or depend upon strangers?" Then addressing himself to Adherbal and Hiempfal, "And you (said he) I enjoin always to pay the highest reverence to Jugurtha. Endeavour to imitate, and if possible surpase, his exalted merit, that the world may not hereafter observe Micipsa's adopted son to have reflected greater glory upon his memory than his own children." Soon after, Micipsa, who, according to Diodorus, was a prince of an amiable character, expired. Though Jugurtha did not believe the king to speak his real sentiments with regard to him, yet he seemed extremely pleased with so gracious a speech, and made him an answer suitable to the occasion. However, that prince at the same time was determined within himself to put into execution the scheme he had formed at the siege of Numantia, which was suggested to him by some factious and abandoned Roman officers, with whom he there contracted an acquaintance. The purport of this scheme was, that he should extort the crown by force from his two cousins, as soon as their father's eyes were closed; which they influnated might easily be effected by his own valour, and the venality of the Romans. Accordingly, a short time after the old king's death, he found means to affaiUnate Hiempfal in the city of Thirmida where his treasures were deposited, and drive Adherbal out of his dominions. That unhappy prince found himself obliged to fly to Rome, where he endeavoured to engage the confcript fathers to ecpoue his quarrel; but, notwithstanding the justice of his cause, they had not virtue enough effectually to support him. Jugurtha's ambassadors, by distributing vast sums of money amongst the senators, brought them so far over, that a majority palliated his inhuman proceedings. This encouraged those ministers to declare, that Hiempfal had been killed by the Numidians on account of his excessive cruelty; that Adherbal was the aggressor in the late troubles; and that he was only chagrined because he could not make that havoc among his countrymen he would willingly have done. They therefore intreated the senate to form a judgment of Jugurtha's behaviour in Africa from his conduct at Numantia, rather than from the suggestions of his enemies. Upon which, by far the greatest part of the senate discovered themselves prejudiced in his favour. A few, however, that were not lost to honour, nor abandoned to corruption, insifted upon bringing him to condign punishment. But as they could not prevail, he had the best part of Numidia allotted him, and Adherbal was forced to rest satisfied with the other.

Jugurtha finding now by experience that every thing was venal at Rome, as his friends at Numantia had before informed him, thought he might pursue his towering projects without any obstruction from that quarter. He therefore, immediately after the last division of Micipsa's dominions, threw off the mask, and attacked his cousin by open force. As Adherbal was a prince of a pacific disposition, and almost in all respects the reverse of Jugurtha, he was by no means a match for him. The latter therefore pillaged the former's territories, forsook several of his fortresses, and over-ran a good part of his kingdom without opposition. Adherbal, depending on the friendship of the Romans, which his father in his last moments affured him would be a stronger support to him than all the troops and treasures in the universe, dispatched deputies to Rome to complain of these hostilities. But whilst he lost his time in sending thicker fruitless deputations, Jugurtha overthrew him in a pitched battle, and soon after put him up in Cirta. During the siege of this city, a Roman commission arrived there, in order to persuade both parties to an accommodation; but finding Jugurtha untractable, the commissioners returned home without so much as conferring with Adherbal. A second deputation, composed of senators of the highest distinction, with Æmilius Scaurus, president of the senate, at their head, landed some time after at Utica, and summoned Jugurtha to appear before them. That prince at first seemed to be under dreadful apprehensions, especially as Scaurus reproached him with his enormous crimes, and threatened him with the resentment of the Romans if he did not immediately raise the siege of Cirta. However, the Numidian, by his address, and the irresistible power of gold, as was afterwards felt at Rome, so mollified Scaurus, that he left Adherbal at his mercy. In fine, Jugurtha had left Cirta surrendered to him, upon condition only that he should spare the life of Adherbal. But the merciless tyrant, in violation of the laws of nature and humanity as well as the capitulation, when he had got possession of the town, ordered him to be put to a most cruel death. The merchants likewise, and all the Numidians in the place capable of bearing arms, he caused without distinction to be put to the sword.

Every person at Rome inspired with any sentiments of humanity, was struck with horror at the news of this tragical event. However, all the venal senators, still concurred with Jugurtha's ministers in palliating his enormous crimes. Notwithstanding which, the people, excited thereto by Caius Memmius their tribune, who bitterly inveighed against the venality of the senate, resolved not to let so flagrant an instance of villainy go unpunished. This disposition in them induced the confcript fathers likewise to declare their intention to chastise Jugurtha. In order to this, an army was levied to invade Numidia, and the command of it given to the confid Calpurnius Beflia, a person of good abilities, but rendered unfit for the expedition he was to go upon by his intangible avarice. Jugurtha being informed of the great preparations making at Rome to attack his dominions, sent his son thither to avert the impending storm. The young prince was plentifully supplied with money, which he had orders to distribute liberally amongst the leading men. But Beflia, proposing to himself great advantages from an invasion of Numidia, defeated all his intrigues, and, got a decree passed, ordering him and his attendants to depart Italy in ten days, unless they were come to deliver up the king himself, and all his territories, to the republic by way of dedication. Which decree being notified to them, they returned without so much as having entered the gates of Rome; and the confid soon after landed with a powerful army in Africa. For some time he carried on the war there very briskly, reduced several strong holds, and took many Numidians prisoners. But upon the arrival of Scaurus, a peace was granted Jugurtha upon advantageous terms.

That...
That prince coming from Vaca, the place of his residence, to the Roman camp, in order to confer with Beflia and Scaurus, and the preliminaries of the treaty being immediately after settled between them in private conferences, every body at Rome was convinced that the prince of the senate and the conful had to their avantage sacrificed the republic. The indignation therefore of the people in general displayed itself in the strongest manner. Memmius also fired them with his speeches. It was therefore resolved to dispatch the praetor Caflus, a person they could confide in, to Numidia, to prevail upon Jugurtha to come to Rome, that they might learn from the king himself which of their generals and senators had been seduced by the pernicious influence of corruption. Upon his arrival there, he found means to bribe one Babius Salca, a man of great authority amongst the plebeians, but of inatiable avarice, by whose assistance he escaped with impunity. Nay, by the efficacy of gold, he not only eluded all the endeavours of the people of Rome to bring him to justice, but likewise enabled Bominus, one of his attendants, to get Mafhea, an illegitimate son of Micia, affiliated in the streets of Rome. That young prince was advised by many Romans of probity, well-willers to the family of Micia, to apply for the kingdom of Numidia; which coming to Jugurtha's ears, he prevented the application by this execrable step. However, he was obliged to leave Italy immediately.

Jugurtha had hence set foot in Africa, when he received advice that the senate had annulled the shameful peace concluded with him by Beflia and Scaurus. Soon after, the conful Albinus transported a Roman army into Numidia, flattering himself with the hopes of reducing Jugurtha to reason before the expiration of his confulate. In this, however, he found himself deceived, for that crafty prince, by various artifices fo amased and impoied upon Albinus, that nothing of moment happened that campaign. This rendered him strongly suspected of having betrayed his country, after the example of his predecessors. His brother Aulus, who succeeded him in the command of the army, was still more unsuccessful; for after rising from before Suthul, where the king's treasures were deposited, he marched his forces into a defile out of which he found it impossible to extricate himself. He therefore was obliged to submit to the ignominious ceremony of passing under the jugum, with all his men, and to quit Numidia entirely in ten days time, in order to deliver his troops from immediate destruction. The avaricious disposition of the Roman commander had prompted him to besiege Suthul, the possession of which place he imagined would make him master of all the wealth of Jugurtha, and consequently paved the way to such a scandalous treaty. However, this was declared void as soon as known at Rome, as being concluded without the authority of the people. The Roman troops retired into Africa Prupria, which they had now reduced into the form of a Roman province, and there took up their winter quarters.

In the mean time Caius Mamilius Limetatus, tribune of the people, excited the plebeians to inquire into the conduct of those persons by whom assistance Jugurtha had found means to elude all the decrees of the senate. This put the body of the people into a great ferment; which occasioned a prosecution of the guilty senators, that was carried on, for some time, with the utmost heat and violence. Lucius Metellus the conful, during these transactions, had Numidia affigned him for his province, and consequently was appointed general of the army defined to act against Jugurtha. As he perfectly disregarded wealth, the Numidian found him superior to all his temptations; which was a great mortification to him. To this he joined all the other virtues which constitute the great captain; so that Jugurtha found him in all respects inaccessible. That prince therefore was now forced to regulate his conduct according to the motions of Metellus, with the greatest caution; and to exert his utmost bravery, in order to compensate for that hitherto so favourable expedient which now began to fail him. Marius, Metellus's lieutenant, being like wise a person of uncommon merit, the Romans reduced Vaca, a large opulent city, and the most celebrated mart in Numidia. They also defeated Jugurtha in a pitched battle; overthrew Bominus, one of his generals, upon the banks of the Muthullus; and, in fine, forced the Numidian monarch to take shelter in a place rendered almost inaccessible by the rocks and woods with which it was covered. However, Jugurtha signalized himself in a surprizing manner, exhibiting all that could be expected from the courage, abilities, and attention of a confummate general, to whom despair administers fresh strength, and suggests new lights. But his troops could not make head against the Romans; they were again warred by Marius, though they obliged Metellus to raise the siege of Zama. Jugurtha therefore, finding his country every where ravaged, his most opulent cities plundered, his fortresses reduced, his towns burnt, vast numbers of his subjects put to the sword and taken prisoners, began to think seriously of coming to an accommodation with the Romans. His favourite Bominus, in whom he repofed the highest confidence, prayed but who had been gained over to the enemy by Metellus, observing this disposition, found it no difficult matter to persuade him to deliver up his elephants, money, arms, horses, and defeclers, in whom the main strength of his army consisted, into the hands of the Romans. Some of these last, in order to avoid the punishment due to their crime, retired to Bocchus king of Mauritania, and lifted in his service. But Metellus ordering him to repair to Tifidium, a city of Numidia, there to receive farther directions, and he refusing a compliance with that order, hostilities were renewed with greater fury than ever. Fortune now seemed to declare in favour of Jugurtha; he retook Vaca, and massacred all the Roman garrison, except Turpilus the commandant. However, soon after, a Roman legion frized again upon it, and treated the inhabitants with the utmost severity. About this time, one of Micia's sons, named Gauola, whom Micia in his will had appointed to succeed to the crown in case his two legitimate sons and Jugurtha died without issue, wrote to the senate in favour of Marius, who was then endeavouring to supplant Metellus. That prince having his understanding impaired by a declining state of health, fell a more easy prey to the base and infamous adulation of Marius. The Roman soothing his vanity, assured him, that as he was the next heir to the crown, he might depend upon being fixed.
A conspiracy against him.

Numidia.

fixed upon the Numidian throne, as soon as Jugurtha was either killed or taken; and that this must in a short time happen, when once he appeared at the head of the Roman army with an unlimited commission. Soon after, Bomilcar and Nubisalfa formed a design to assassinate Jugurtha, at the instigation of Metellus; but this being detected, Bomilcar and most of his accomplices suffered death. The plot however had such an effect upon Jugurtha, that he enjoyed afterwards no tranquillity or repose. He suspected perfons of all denominations, Numidians as well as foreigners, of some black designs against him. Perpetual terrors fated brooding over his mind; infomuch that he never got a wink of sleep but by stealth, and often changed his bed in a low plebian manner. Starting from his sleep, he would frequently snatch his sword, and break out into the most doleful cries: So strongly was he haunted by a spirit of fear, jealousy, and distraction!

Jugurtha having destroyed great numbers of his friends on suspicion of their having been concerned in the late conspiracy, and many more of them defecting to the Romans and Bocchus king of Mauritania, he found himself, in a manner, destitute of counsellors, generals, and all perfons capable of affisting him in carrying on the war. This threw him into a deep melancholy, which rendered him dissatisfied with every thing, and made him fatigue his troops with a variety of contradictory motions. Sometimes he would advance with great celerity against the enemy, and at others retreat with no small swiftness from them. Then he resumed his former courage; but soon after despair of either of the value or fidelity of the forces under his command. All his movements therefore proved unsuccessful, and at last he was forced by Metellus to a battle. That part of the Numidian army which Jugurtha commanded, behaved with some resolution; but the other fled at the first onset. The Romans therefore entirely defeated them, took all their standards, and made a few of them prisoners. But few of them were slain in the action; since, as Sallust observes, the Numidians trusted more to their heels than to their arms for safety in this engagement.

Metellus pursued Jugurtha and his fugitives to Thala. His march to this place being through vall deferts, was extremely tedious and difficult. But being supplied with leathern bottles and wooden vessels of all sizes taken from the huts of the Numidians, who were filled with water brought by the natives, who had submitted to him, he advanced towards that city. He had no sooner begun his march, than a most copious shower of rain, a thing very uncommon in those deserts, proved a great and favourable refreshment to his troops. This so animated them, that upon their arrival before Thala, they attacked the town with such vigour, that Jugurtha, with his family, and treasures deposited therein, thought proper to abandon it. After a brave defence, it was reduced; the garrison consisting of Roman deferters, setting fire to the king's palace, and consuming themselves, together with every thing valuable to them, in the flames. Jugurtha being now reduced to great extremities, retired into Gaetulia, where he formed a confiderable corps. From thence he advanced to the confines of Mauritania; and engaged Bocchus king of that country, who had married his daughter, to enter into an alliance with him. In consequence of which, having reinforced his Gaetulian troops with a powerful body of Mauritians, he turned the tables upon Metellus, and obliged him to keep close within his entrenchments. Sallust informs us, that Jugurtha bribed Bocchus's ministers to influence that prince in his favour; and that having obtained an audience, he intimated, that, should Numidia be subdued, Mauritania must be involved in its ruin, especially as the Romans seemed to have vowed the destruction of all the thrones in the universe. In support of what he advanced, he produced several instances very apposite to the point in view. However, the same author seems to intimate, that Bocchus was determined to affift Jugurtha against his enemies by the flight the Romans had formerly shown him. That prince, at the first breaking out of the war, had sent ambassadors to Rome, to propose an offensive and defensive alliance to the republic; which, though of the utmost consequence to it at that juncture, a few of the most venal and infamous senators, who were abandoned to corruption, prevented from taking effect. This undoubtedly wrought more powerfully upon Bocchus in favour of Jugurtha, than the relation he stood to him: For both the Moors and Numidians adapted the number of their wives to their circumstances, so that some had 10, 20, &c. to their share; their kings therefore were unlimited in this particular, and of course all degrees of affinity resulting to them from marriage had little force. It is observable, that the polterity of those ancient nations have the same custom prevailing amongst them at this day.

Such was the situation of affairs in Numidia, when Marius Metellus received advice of the promotion of Marius succeeded to the confidulate. But, notwithstanding this injurious treatment, he generously endeavoured to draw off Bocchus from Jugurtha, though this would facilitate the reduction of Numidia for his rival. To this end ambassadors were dispatched to the Mauritanian court, who intimated to Bocchus, “That it would be highly imprudent to come to a rupture with the Romans without any cause at all; and that he must know, that if the Romans therefore, would grant his request, he would not run the hazard of losing his dominions by embroiling himself with other states, when he could easily avoid this; that it was much easier to begin a war than to end it, which it was in the power of the victor alone to do; that, in fine, he would by so means confult the interest of his subjects if he followed the desperate fortunes of Jugurtha.” To which Bocchus replied, “That for his part there was nothing he wished for more than peace; but that he could not help pitying the deplorable condition of Jugurtha; that if the Romans, therefore, would grant him the unfortnate prince the fame terms they had offered him, he would bring about an accommodation.” Metellus let the Mauritanian monarch know, that it was not in his power to comply with what he desired. However, he took care to keep up a private negotiation with him till he kneweful Marius's arrival. By this conduct he served two wise ends. First, he prevented thereby Bocchus from coming to a general action with his troops;
Jugurtha, being informed that Marius, with a numerous army, was landed at Utica, advised Bocchus to retire, with part of the troops, to some place of difficult access, whilst he himself took post upon another inaccessible spot with the remaining corps. By this measure, he hoped the Romans would be obliged to divide their forces, and consequently be more exposed to his attacks. He likewise imagined, that seeing no formidable body appear, they would believe the enemy in no condition to make head against them; which might occasion a relaxation of discipline, the usual attendant of a too great security, and consequently produce some good effect. However, he was disappointed in both these views. For Marius, far from suffering a relaxation of discipline to take place, trained up his troops, which consisted chiefly of new levies, in so perfect a manner, that they were soon equal in goodness to any consular army that ever appeared in the field. He also cut off great numbers of the Getulian marauders, defeated many of Jugurtha's parties, and had like to have taken that prince himself near the city of Cirta. These advantages, though not of any great importance, intimidated he imagined, might be of no small service, either to himself or his successors, in the future prosecution of the war.

Jugurtha's condition was desolate, and not of any great importance, intimidated he imagined, might be of no

He gained a great advantage over Jugurtha.
In consequence of the indignity Cæsar had offered to Juba, and the disposition it had occasioned, that prince set on one of his generals to treat with him and Pompey. By a stratagem he drew Curius, one of his lieutenants, into a general action, which it was his interest at that time to have avoided. He caused it to be given out all over Africa Propria and Numidia, that he was retired into some remote country at a great distance from the Roman territories. This coming to Curio's ears, who was then besieging Utica, it hindered him from taking the necessary precautions against a surprise. Soon after, the Roman general receiving intelligence that a small body of Numidians was approaching his camp, he put himself at the head of his forces in order to attack them, and, for fear they should escape, began his march in the night, looking upon himself as sure of victory. Some of their advanced posts he surprised asleep, and cut them to pieces; which still further animated him. In short, about day-break he came up with the Numidians, whom he attacked with great bravery, though his men were then failing, and vastly fatigued by their forced and precipitate march. In the mean time, Juba, who, immediately after the propagation of the rumour above-mentioned, had taken care to march privately, with the main body of the Numidian army, to support the detachment sent before to decoy Curio, advanced to the relief of his men. The Romans had met with a great resistance before he appeared; so that he easily broke them, killed Curio, with a great part of his troops, upon the spot, purified the rest to their camp, which he plundered, and took many of them prisoners. Most of the fugitives, who endeavoured to make their escape on board the ships in the port of Utica, were either slain by the pursuers, or drowned. The remainder fell into the hands of Varus, who would have saved them; but Juba, who arrogated to himself the honour of this victory, ordered most of them to be put to the sword.

This victory infused new life and vigour into the Juba over the Pompeian faction, who thereupon conferred great honours upon Juba, and gave him the title of king of all Numidia. But Cæsar and his adherents declared him an enemy to the state of Rome, adjudging to Bocchus and Bogud, two African princes entirely in their interest, the sovereignty of his dominions. Juba afterwards, uniting his forces with those of Scipio, reduced Cæsar to great extremities, and would in all probability have totally ruined him, had he not been relieved by Publius Sittius. That general, having formed a confederate and consulting Roman exiles, and Mauritanian troops sent him by Bocchus, according to Dio, or, as Cæsar will have it, Bogud, made an irruption into Getaulia and Numidia, whilst Juba was employed in Africa Propria. As he ravaged those countries in a dreadful manner, Juba immediately returned with the belt part of his army, to prevent them from utter destruction. However, Cæsar knowing his horse to be afraid of the enemy's elephants did not think proper to attack Scipio in the absence of the Numidian, till his own elephants, and a fresh reinforcement of troops, hourly expected, arrived from
NUMMUS, the son of Procas king of Alba, and the brother of Amulius. Procas before his death made him and Amulius joint heirs to the crown, on condition of their reigning annually by turns; but Amulius getting possession of the throne, excluded Numitor, whose son Lausus he ordered to be put to death, and obliged Rhea Sylvia, Numitor's only daughter, to become a veil. This prince's becoming pregnant declared that she was with child by the good Mars; and afterwards brought forth Romulus, who at length killed Amulius, and restored Numitor to the throne, 754 B.C. See RHEA and ROMULUS.

NUMMUS, a piece of money otherwise called sestertius.

NUN, the son of Eliashab, and father of Joshua, of the tribe of Ephraim. The Greeks gave him the name of Nauc instead of Num. This man is known in sacred history only by being the father of Joshua.

Num, a woman in several Christian countries, who devotes herself, in a cloister or nunnerly, to a religious life. See the article MONK.

There were women, in the ancient Christian church, who made public profession of virginity, before the monastic life was known in the world, as appears from the writings of Cyprian and Tertullian. These, for distinction's sake, are sometimes called ecclesiastical virgins, and were commonly enrolled in the canon or matricula of the church. They differed from the monastic virgin chiefly in this, that they lived privately in their fathers' houses, whereas the others lived in communities: but their profession of virginity was not so strict as to make it criminal in them to marry afterwards, if they thought fit. As to the consecration of virgins, it had some things peculiar in it; it was usually performed publicly in the church by the bishop. The virgin made a public profession of her resolution, and then the bishop put upon her the accustomed habit of sacred virgins. One part of this habit was a veil, called the faticum velamen; another was a kind of mitre or coronet worn upon the head. At present, when a woman is to be made a nun, the habit, veil, and ring of the candidate are carried to the altar; and she herself accompanied by her nearest relations, is conducted to the bishop, who, after mass and an anthem, (the subject of which is, "that she ought to have her lamp lighted, because the bridegroom is coming to meet her"), pronounces the blessing: then she rises up, and the bishop consecrates the new habit, sprinkling it with holy water. When the candidate has put on her religious habit, the presents herself before the bishop, and, on her knees, Asciella Chrisii jam, &c.; then she receives the veil, and afterwards the ring, by which she is married to Christ; and finally, the crown of virginity. When she is crowned, an anathema is denounced against all who shall attempt to make her break her vows. In some few instances, perhaps, it may have happened that nunneries, monasteries, &c. may have been useful as well to morality and religion as to literature: in the gross, however, they have been highly prejudicial; and however well they might be supposed to do when viewed in theory, in fact they are unnatural and impious. It was purely far from the intention of Providence to exclude youth, and beauty in a cloistered ruin, or to deny them the innocent enjoyment of their years and sex.
Nuncio, or Nuntio, an ambassador from the pope to some Catholic prince or state, or a person who attends on the pope's behalf at a congress, or an ambassadress of several ambassadors.

NUNCUPATIVE, in the schools, something that is only nominal, or has no existence but in name.

NUNCUPATIVE Will or Testament, a will made verbally, and not put in writing. See the articles Will and Testament.

NUDINA, a goddes among the ancient heathens, supposed to have the care of the purification of infants. And because male infants were purified nine days after their birth, her name is derived from nine, or the ninth, though female-infants were purified the eighth day; which purification was called iustration by the Romans.

NUNDINALS, Nundinalia, a name which the Romans gave to the eight first letters of the alphabet used in their calendar.

This series of letters, A, B, C, D, E, F, G, H, I, is placed and repeated successively from the first to the last day of the year: one of these always expressed the market-days, or the assemblies called nundine quae nundinae, because they returned every nine days. The country people, after working eight days successively, came to town the ninth, to sell their several commodities, and to inform themselves of what related to religion and government. Thus the nundinal day being under A on the first, ninth, seventeenth, and twenty-fifth days of January, &c. the letter D will be the nundinal letter of the year following. These nundinals bear a very great resemblance to the dominical letters, which return every eight days, as the nundinal day nine.

NUDINOCOMAR, a Rajah in Bengal, and head of the Bramins, who, in 1775, was condemned to an ignominious death by English laws newly introduced in an English court of justice newly established, for a forgery charge to have been committed by him many years before. That he was guilty of the deed cannot be questioned; but there was surely something hard in condemning a man by an ex post facto law. He bore his fate with the utmost fortitude, in the full confidence that his soul would soon be reunited to the universal spirit whence it had sprung. See Metaphysics, Part III. Ch. iv. Of the Immortality of the Soul.

Monte Nuovo, in the environs of Naples, blocks up the valley of Averno. This mountain (Mr Swinburne tells us) arose in the year 1538, for after repeated quakings the earth burst asunder, and made way for a deluge of hot ashes and flames, which rising extremely high, and darkening the atmosphere, fell down again and formed a circular mound four miles in circumference, and 1000 feet high, with a large cup in the middle. The wind rising afterwards, wafted the lighter particles over the country, blasted vegetation, and killed the animals who grazed; the consequence was, that the place was deserted, till Don Pedro de Toledo, viceroy of Naples, encouraged the inhabitants by example and otherwife to return.

Part of Monte Nuovo is cultivated, but the larger portion of its deciduity is wildly overgrown with prickly-broom, and rank weeds that emit a very fidal fulphureus smell. The water is shallow; its inside clad with shrubs, and the little area at the bottom planted with fig and mulberry trees; a most striking specimen of the amazing vicissitudes that take place in this extraordinary country. I saw no traces of Java or melted matter, but few stones within.

Near the foot of this mountain the fubterraneous fires acted with fuch immediate power, that even the land at the bottom of the sea is heated to an intolerable degree.

NUPTIAL RITES, the ceremonies attending the solemnization of marriage, which are different in different ages and countries. We cannot omit here a custom which was practiced by the Romans on these occasions; which was this: Immediately after the chief ceremonies were over, the new-married man threw nuts about the room for the boys to scramble for. Various reasons have been assigned for it; but that which most generally prevails, and seems to be the most just, is, that by this act the bridegroom signified his resolution to abandon trifles, and commence a sober course of life; whence nucibus veliciti in this fene became a proverb. They might also be an emblem of fertility.

The ancient Greeks had a person to conduct the bride from her own to the bridegroom's house; and hence he was called by the Greeks Nymphagogi, which term was afterwards used both by the Romans and the Jews.

NUREMBERG, an imperial city of Germany, capital of a territory of the same name, situated in E. Long. 11°, N. Lat. 47. 30. It stands on the Regnitz, over which it has several bridges, both of wood and stone, at the bottom of a hill, 60 miles from Augsburg, 37 from Munich, 46 from Wurtzburg, and 50 from Ratibbon; and is thought by some to be the Segodumum, and by others the Caflrium Noricum, of the ancients.

The city has derived its name from the hill, upon which stands this castle, called in Latin, Caflrium Noricum, round which the city was begun to be built, and where the emperors formerly lodged; and here they lodge till, when they pass by that city. They there preserve, as precious relics, the crown, sceptre, cloths, buffkins, and other ornaments of Charlemagne (a), which were also the emperor Leopold, when he went thither after his election, to receive the homage of the city. The small river Regnitz, which runs through it, and those of Rednitz and Schwarza, which pass by its walls, furnish the inhabitants, besides other advantages, with the means of making all sorts of stuffs, dyes, and other manufactures (b).
It is a large and well-built town, but not very populous. Its fortifications are a double wall, flanked with towers mounting cannon, and a deep ditch. The magistrates, and most of the inhabitants, are Lutherans. There are a great many churches and chapels in it. In that of St. Sebald is a brass monument of the saint; and a picture representing the creation of the world, by the celebrated Albert Durer, who was a native of the town; but the finest church in the town is that of St. Giles. In that of the Holy Ghost are kept most of the jewels of the empire, together with the pretended spear with which our Saviour's side was pierced, a thorn of his crown, and a piece of the manger wherein he was laid. Here are also a great many hospitals, one in particular for foundlings, and another for pilgrims; with a gymnasium, an anatomical theatre, a granary, a fine public library, the old imperial fortress or castle; some remains of the old citadel of the burgraves of Nuremberg, several Latin schools, an academy of painting, a well furnished arsenal, a Teutonic house in which the Roman-catholic service is tolerated, and a mint. Mr. Keyser says there are upwards of 500 streets in it, about 140 fountains, 16 churches, 44 religious houses, 12 bridges, 10 market-places, and 25,000 inhabitants; and that its territories, besides the capital and four other towns, contain above 500 villages, and about 160 mills on the Regnitz. The trade of this city, though upon the decline, is still very great, many of its manufactures being still exported to all parts of the world; among which may be reckoned a great variety of curious toys in ivory, wood, and metal, already mentioned. The city has also distinguished itself in the arts of painting and engraving. When the emperor Henry VI. allied at a tournament in Nuremberg, he raised 38 burghers to the degree of nobility, the descendants of whom are called patricians, and have the government of the city entirely in their hands; the whole council, except eight members of companies, who are summoned only on extraordinary occasions, confiding them. Among the fine brass cannon in the arsenal, is one that is charged at the breach, and may be fired eight times in a minute; and two that carry balls of eighty pounds. The city keeps, in time of peace, of 100 men, but, in time of war, of 185; two troops of cuirassiers, each consisting of 85 men; and two companies of invalids. There are also 24 companies of burghers, well armed and disciplined. On the new bridge, which is said to have cost 100,000 guilders, are two pyramids, on the top of one of which is a dove with an olive branch in her bill, and on the other an imperial black eagle. Mufic also flourishes greatly in Nuremberg; and those who delight in mechanic arts and manufactures cannot any where better gratify their curiosity. As an imperial city, it has a fest and voice at the diets of the empire and circle, paying to the chamber of Wetzlar 812 rix dollars each term. The territory belonging to the city is pretty large, containing, besides two considerable forests of pine, called the Stibald and Lawrence foresis, several towns and villages.

We have mentioned already that certain families called patricians, to the exclusion of the refi, possess the offices of the senate. They are composed of 42 persons (c), over which two castellans, or perpetual feudalities, preside, the first of whom has his residence in the castle. These castellans assemble sometimes in the castle, with five or six of the chief members, to hold a secret council (d). And, as this city glories in being one of the first which embraced Lutheranism, it preserves the privilege of that in civil matters, not admitting any catholics to the magistracy or freedom of the town; the catholics there having the liberty only of remaining under the protection of the refi, and performing their religious worship in a commandery of Maltes, and this but at certain hours, not to disturb the Lutherans, who likewise assemble there, although in possession of all the other churches.

This city is particularly noted for its antiquity, grandeur, fortifications, its triple walls of hewn stones, its large and deep moat, its fine houses, large churches, its wide streets, always clean, and for its curious and large library, its magazine stored with every thing proper for its defence.

NURSERY. In gardening, is a piece of land set apart for raising and propagating all sorts of trees and plants to supply the garden and other plantations.

NURSING OF CHILDREN. See LACTACIO.

The following observations are said to be the result of long experience. A child, when it comes into the world, is almost a round ball; it is the nurse's part to form nature, in bringing it to a proper shape. The child should be laid (the first month upon a thin matra, rather longer than itself, which the nurse will keep upon her lap, that the child may always lie straight, and only fit up as the nurse plants the matra, to set a child quite upright before the end of the first month, hurts the eyes, by making the white part of the eye appear below the upper eye-lid. Afterwards the nurse will begin to set it up and dance it by degrees. The child must be kept as dry as possible.

The clothing should be very light, and not much longer than the child, that the legs may be got at with ease, in order to have them often rubbed in the day.

Workmen, very ingenious in making several kinds of toys of wood, which are carried through all the fairs of Germany, and from thence through all Europe. These toys are called Nuremberges; and they have so great a sale, that it even exceeds description. This employment affords a livelihood to the greatest part of the inhabitants of the city; and they make a very considerable profit from this traffic.

(c) Of these 42 persons, there are only 24 chosen from the patrician families; the other eight are taken from among the burghers, and make in a manner a small separate body.

(d) This secret council is composed of seven principal chiefs of the republic, and for that reason is called the Senate.
NURSING. day with a warm hand or flannel, and in particular the inside of them.

Rubbing a child all over takes off surf, and makes the blood circulate. The one hand should be rubbed with the hands one way, and the other the other way, night and morning at least.

The ankle-bones and inside of the knees should be rubbed twice a day; this will strengthen those parts, and make the child stretch its knees and keep them flat, which is the foundation of an erect and graceful person.

A nurse ought to keep a child as little in her arms as possible, lest the legs should be cramped, and the toes turned inwards. Let her always keep the child's legs loose. The oftener the posture is varied, the better.

Toiling a child about, and exercising it in the open air in fine weather, is of the greatest service. In cities, children are not to be kept in hot rooms, but to have as much air as possible.

Want of exercise is the cause of large heads, weak and knotted joints, a contracted breath, which occasions coughs and stuffed lungs, an ill-shaped person, and waddling gait, besides a numerous train of ill habits.

The child's flesh is to be kept perfectly clean, by constantly washing its limbs, and likewise its neck and ears; beginning with warm water, till by degrees it will not only bear, but like to be washed with cold.

Riding early in the morning is good for all children, provided they awake of themselves, which they generally do; but they are never to be waked out of their sleep, and as soon as possible to be brought to regular sleeps in the day.

When laid in bed or cradle, their legs are always to be laid straight.

Children, till they are two or three years old must never be suffered to walk long enough at a time to be weary.

Girls might be trained to the proper management of children if a premium were given in free-schools, workhouses, &c. to those that brought up the finest child to one year old.

If the mother cannot fuckle the child, get a wholesome, cheerful woman, with young milk, who has been used to tend young children. After the first six months, small broths, and innocent foods of any kind, may do as well as living wholly upon milk.

A principal thing to be always attended to is, to give young children constant exercise, and to keep them in a proper posture.

With regard to the child's dress in the day, let it be a shirt; a petticoat of fine flannel, two or three inches longer than the child's feet, with a dainty top (commonly called a bodice-coat, to tie behind, over that a surcingle made of fine buckram, two inches broad, covered over with satin or fine tucker, with a ribbon fastened to it to tie it on, which answers every purpose of flays, and has none of their inconveniences. Over this put a robe, or a flip and frock, or whatever you like best; provided it is fastened behind, and not much longer than the child's feet, that their motions may be freely observed.

Two caps are to be put on the head, till the child has got most of its teeth.

The child's dress for the night may be a shirt, a blanket to tie on, and a thin gown to tie over the blanket.

NUSANCE, or NUISANCE, in law, a thing done to the annoyance of another.

Nuisances are either public or private.—A public nuisance is an offence against the public in general, either by doing what tends to the annoyance of all the king's subjects, or by neglecting to do what the common good requires: in which case, all annoyances and injuries to streets, highways, bridges, and large rivers, as also disorderly alcohous, bawdy-houses, gaming-houses, stages for rope-dancers, &c. are held to be common nuisances.—A private nuisance is, when only one person or family is annoyed by the doing of any thing; as where a person stops up the light of another's house, or builds in such a manner that the rain falls from his house upon his neighbour's.

Nut, among botanists, denotes a PERICARPium of an extraordinary hardness, including a kernel or seed.

NUTATION, in astronomy, a kind of tremulous motion of the axis of the earth, whereby, in each annual revolution, it is twice inclined to the ecliptic, and as often returns to its former position.

"This bird (says Buffon) is distinguished from the corvidæ, jays and magpies by the shape of its bill, which is straighter, blunter, and composed of two unequal pieces. Its instinct is also different; for it prefers the residence of high mountains, and its disposition is not so much tinctured with cunning and suspicion."

"They live upon hazel-nuts, acorns, wild berries, the kernels of pine-tops, and even on insects."

"Besides the brilliancy of the plumage, the nutcracker is remarkable for the triangular white spots, which are spread over its whole body, except the head. These spots are smaller on the upper part, and broader on the breast; their effect is the greater, as they are contrasted with the brown ground."

"These birds are most attached, as I have observed above, to mountainous situations. They are common in Austria, Savoy, Lorraine, Switzerland, the Bergamasque, in Austria, in the mountains which are covered with forests of pines. They also occur in Sweden, though only in the southern parts of that country. The people in Germany call them Turkey birds, Italian birds, African birds; which language means no more than that they are foreign."

"Though the nutcrackers are not birds of passage, they fly sometimes from the mountains to the plains. Frisch says, that flocks of them are often observed to accompany other birds into different parts of Germany, especially where there are pine forests. But in 1754, great sights of them entered France, particularly Burgundy, where there are few pines; they were so fatigued on their arrival, that they suffered themselves to be caught by the hand."

"We cannot find in writers of natural history any details with regard to their laying, their incubation, the training of their young, the duration of their life, &c.
NUT

NUTMAG. & c. for they haunt inaccessible spots, where they enjoy undisturbed safety and felicity.

NUTHATCH, in ornithology. See Sitta, its generic name. In this place we shall only extract from Buffon an account of two species of foreign birds related to the nuthatch.

1. The great hook-nosed nuthatch.—"It is the largest of the known nuthatches; its bill, though pretty short, is inflated at the middle, and a little hooked at the end; the nostrils are round; the quills of the tail and of the wings edged with orange on a brown ground; the throat white; the head and back gray; the under side of the body whitish. Such are the principal properties of the bird. It was observed by Sloane in Jamaica.

"Its total length is about seven inches and a half; the bill, eight lines and one third; the upper mandible a little protuberant near the middle; the mid toe, eight lines and one third; the alar extent, eleven inches and a quarter; the tail about twenty-three lines."

2. The spotted or Surinam nuthatch.—"This is another American nuthatch, with a hooked bill; but differs from the preceding in size, plumage, and climate: it inhabits Dutch Guiana.

"The upper side of the head and of the body is of a dull ash colour; the superior coverts of the wings of the same colour, but terminated with white; the throat white; the breast and all the under side of the body cinnereous, and more dilute than the upper side, with white streaks scattered on the breast and sides, which forms a sort of speckling; the bill and legs brown.

"Total length, about six inches; the bill, an inch; the tarsus, seven lines and a half; the mid toe, eight or nine lines, and longer than the hind toe, whose nail is the strongest; the tail, about eighteen lines, consisting of twelve nearly equal quills, and exceeds the wings thirteen or fourteen lines."

PLATE CXLVIII.

NUTMAG. See Myristica, its generic name.

The tree which produces this fruit was formerly thought to grow only in the Banda Islands. It is now chiefly known in the Loudon's Magazine for January 1751, upon what appeared at that time to be good grounds, that it was likely to be produced in the West Indies. An English planter said he had seen some trees in Jamaica, and the governor on inquiry found it so, and that they agreed exactly with the description given of those in the Spice Islands in the East Indies. This account, which was given in the Gentleman's Magazine for January 1751, we have never seen confirmed; and therefore we suppose that the expectations formed were either frustrated or premature: however, it is certain, as we have observed under the generic name, that a wild species of it grows at Tobago. To avoid repetition, or the appearance of prolixity, we must refer those who wish for farther information respecting the trade in this article to M. P. Sonnerat's account of a voyage to the Spice Islands and New Guinea, which was printed at Paris in 1775, Nutmeg.

It will not, however, we trust, be deemed improper nor beseide our purpose, if we lay before our readers the following account of the dangerous consequences of using this article to excess. It was given by Dr Jacob Schmidius, published in the Gentleman's Magazine for 1767.

"A gentleman of Lower Silesia, about thirty-six years old, of a good constitution, and who enjoyed a good state of health, having felt, during some days, some cholic pains, took it in his head, by way of remedy, to eat four nutmegs, which weighed all together two ounces, and he drank, in eating them, some flaggles of beer; which he had no sooner done, but he was seized with a great heat, a violent pain in the head, a vertigo and delirium, and was instantly deprived of the use of sight, speech, and of all his senses. He was put to bed, where he remained two days and two nights; his body was oppressed with languor, always drowsy, yet without being able to sleep. The third day he was in that lethargic state, which is called coma vigilis, with a weak and intermitting pulse Cephalic remedies, cordials, and among others the spirit of cephalic vitriol, and the essence of catechol, were administered in good spirit of sal-ammoniac. The fourth day he recovered a little, but had absolutely lost his memory, so as not to remember the least thing he had done in his life. A continued fever then came on, accompanied by an obstinate watchfulness; a palpitation of the heart seemed to be the forerunner of other symptoms, and he was finally struck with a palsy in all his limbs.

"At the expiration of eight days, he recovered the use of reason, and fared, that during the first four days of his illness, he seemed to himself to have constantly a thick veil before his eyes, and that a great number of sparks and flashes continually issued from it. All the bad symptoms of this malady yielded at last successively to the continued use of remedies suited to his condition; and in three months time he was perfectly recovered, but he was particularly indebted for his cure to mercurial and ammoniacal remedies.

"According to chemical principles, it might perhaps be said, that the aromatic and oily fluid contained in nutmeg, of which this patient had taken too large a dose, had immediately excited so great an agitation in the humour, and so rapid a motion in the animal spirits, as in some measure to partake of the nature of fire, and that a vicious and narcotic sulphur, which refides likewise in the nutmeg, though in a less sensible manner, being carried at the same time into the maws of blood, by suddenly fixing the animal spirits, and intercepting their course in the nerves, had afterwards caused the fuper in the limbs, the aphony, and the palsy. But I leave others to explain these phenomena; my only view, by communicating this observation, being to shew that the immoderate use of nutmeg may be attended with very great danger."

NUTRITION, in the animal economy, is the repairing the continual loss which the different parts of the body undergo. The motion of the parts of the body,
body, the friction of these parts with each other, and especially the action of the air, would destroy the body entirely; if the lofs was not repaired by a proper diet, containing nutritious juices; which being digested in the stomach, and afterwards converted into chyle, mix with the blood, and are distributed through the whole body for its nutrition.

In young persons, the nutritious juices, not only serve to repair the parts that are damaged, but also to increase them, which is called growth.

In grown persons, the cuticle is everywhere constantly desquamating, and again renewing; and in the same manner the parts rubbed off or otherwise separated from the fleasy parts of the body, are soon supplied with new flesh; a wound heals, and an emaciated person grows plump and fat.

Buffon, in order to account for nutrition, supposes the body of an animal or vegetable to be a kind of mould, in which the matter necessary to its nutrition is modelled and assimilated to the whole. But (continues he) of what nature is this matter which an animal or vegetable assimilates to its own substance? What power is it that communicates to this matter the activity and motion necessary to penetrate this mould? and, if such a force exist, would it not be by a similar force that the internal mould itself might be reproduced?

As to the first question, he supposes that there exist in nature an infinite number of living organic parts, and that all organized bodies consist of such organic parts; that their production无人 nature nothing, since their existence is constant and invariable; that they unfold in the animal or vegetable as substances, is an organic matter of the same nature with that of the animal or vegetable, which consequently may augment its volume without changing its form or altering the quality of the substance in the mould.

As to the second question: There exist (says he) in nature certain powers, as that of gravity, that have no affinity with the external qualities of the body, but act upon the most intimate parts, and penetrate them throughout, and which can never fall under the observation of our senses.

And as to the third question, he answers, that the internal mould itself is reproduced, not only by a similar power, but it is plain that it is the very same power that causes the unfolding and reproduction thereof: for it is sufficient (proceeds he), that in an organized body that unfolds itself, there be some part similar to the whole, in order that this part may one day become itself an organized body, altogether like that of which it is actually a part.

Nux Yonag, a flat, compressed round fruit, about the breadth of a shilling, brought from the East Indies. It is found to be a certain poison for dogs, cats, &c. and it is not to be doubted that it would also prove fatal to mankind. Its surface is not much corrugated; and its texture is firm like horn, and of a pale greyish brown colour. It is said to be used as a specific against the bite of a species of water-snake. It is considerably bitter and deleterious; but has been used in doses from five to ten grains twice a-day or fo, in intermittent, particularly obilinate quanta, and in contangious dysentery. The Jeechwaia Jaa, is a tree of the same kind producing sourish fruit, the seeds of which are improperly called St Ignatius's beans. These, as also the herbs or roots of some such trees, called lignum cubiftrum or ftalcwared, are very narcotic bitters like the nux venetica.

Nuyts (Peter), a native of Holland, and a leading character in that extraordinary transaction which happened between the Japanese and the Dutch about the year 1628. In 1627 Nuyts arrived in Batavia from Holland, and was in the same year appointed ambassador to the Emperor of Japan by the governor and council of Batavia.

He repaired to that empire in 1628; and being a man of a hasty disposition, and extremely vain, he believed it practicable to put upon the natives for an ambassador from the king of Holland. Upon his assuming this title he was much more honourably received, cared for, and respected, than former ministers had been. But he was soon detected, repri­manded, and reproached in the severest manner, sent back to the port, and ordered to return to Batavia with all the circumstances of disgrace imaginable; notwithstanding which, his interest was so great, that, instead of being punished as he deserved, he was immediately afterwards promoted to the government of the island of Formosa, of which he took possession the year following.

He entered upon the administration of affairs in that island with the same disposition that he had shown while ambassador, and with the most implacable resentment against the Japanese; neither was it long before an opportunity offered, as he thought, of revenging himself to the full. Two large Japanese ships, with upwards of five hundred men on board, came into the port; upon which he took it into his head to disarm and unrig them, in the same manner as the Dutch vessels are treated at Japan. The Japanese did all they could to defend themselves from this ill usage; but at last, for want of water, they were forced to submit. Governor Nuyts went still farther. When they had finished their affairs at Formosa, and were desirous to proceed according to their instructions, to China, he put them off with fair words and fine promises till the monsoon was over. They began then to be very impatient, and desired to have their cannon and sails restored, that they might return home; but the governor had recourse to new artifices, and, by a series of false promises, endeavoured to hinder them from making use of the featon proper for that voyage.

The Japanese, however, soon perceived his design; and at length, by a bold attempt, accomplished what by fair means and humble entreaty they could not obtain; for, by a daring and well concerted effort, they took him prisoner, and made him and one of the council sign a treaty for securing their liberty, free departure, and indemnity which was afterwards ratified by the whole council. Nuyts was first confined in Batavia, and afterwards delived at the Japanese, notwithstanding the most earnest entreaties on his part to be tried, and even to suffer any kind of death where he was, rather than to be sent to Japan. He was sent there, however, in 1632. He was submitted,
submitting to the mercy or discretion of the emperors; and the consequence was, that, though imprisoned, he was well used, and could go anywhere, provided his guards were with him, which was more than he could possibly have expected. He now looked for nothing but the continuance of his confinement for life. On a particular occasion, however, i.e. at the funeral of the emperor's father, at the request of the Dutch he was set free, and returned again to Batavia, to the surprise of that people, who, however, adopted ever after a very different conduct with respect to the Japanese.

Nuzzer, or Nuzzerannah; a present or offering from an inferior to a superior. In Hindostan no man ever approaches his superior for the first time on business without an offering of at least a gold or silver rupee in his right hand; if which not taken, it is a mark of disfavour. Nuzzzerannah is also used for the sum paid to the government to an acknowledgment for a grant of lands or any public office.

Nycthemeron, among the ancients, signified the whole natural day, or day and night, consisting of 24 hours, or 24 equal parts. This way of considering the day was particularly adopted by the Jews, and seems to owe its origin to that expression of Moses, in the first chapter of Genesis, "the evening and the morning were the first day."—Before the Jews had introduced the Greek language into their discourse, they used to signify this space of time by the simple expression of a night and a day.

It is proper here to observe, that all the eastern countries reckoned any part of a day of 24 hours for a whole day: and say a thing that was done on the third or seventh day, &c. from that last mentioned, was one after three or seven days. And the Hebrews, having no word which exactly answers to the Greek nycthemeron, signifying "a natural day of 24 hours," the night and day, or day and night, for it. So that to say a thing happened after three days and three nights, was with them, the same as to say it happened after three days, or on the third day. This, being remembered, will explain what is meant by the Son of Man's being three days and three nights in the heart of the earth.

Nyctanthes, Arabian Jasmine: A genus of the monogynia order, belonging to the diandria class of plants; and in the natural method ranking with the 44th order, Saffiariae. The corolla and calyx are obovate; the perianthium discolored. There are five species; the most remarkable of which are, 1. The Arbor tritis, or sorrowful tree. This tree, or shrub, the pataxicum of the Bramins, grows naturally in sandy places in India, particularly in the islands of Ceylon and Java, where it is produced in great abundance, and attains the height of 18 or 20 feet. It rifes with a four-cornered stem, bearing leaves that are oval, and taper to a point. They stand opposite, on short footstalks; are of a shining brownish-green on the upper side, a more vivid green on the under, and of a taste that is aromatic and somewhat bitter. From the middle-rib, on the under surface of the leaves proceed on both sides a number of coffins, or smaller ribs, which run nearly to the margin, and mark the surface with the impression of their arched furrows. The flowers, which are white and highly odoriferous, having a sweet delectable smell emulating the best honey, consist of one petal deeply divided into eight parts, which are narrower towards the stalk and dilated towards the summit. They stand upon footstalks, which emerge from the origin of the leaves; are rigid, obliquely raised towards the top, grow opposite in pairs, and are divided into three short leaf branches, each of which supports five flowers placed side by side, without partial footstalks. The fruit is dry, capsular, membranaceous, and compressed.

It is generally ascertained of this plant, that the flowers open in the evening, and fall off the succeeding day. Fabricius and Paludanus, however, redist the assertion, by affirming, from actual observation that this effect is found to take place only in such flowers as are immediately under the influence of the solar rays. Grimmius remarks in his Labaratory Cyclopinum, that the flowers of this tree afford a fragrant water, which is cordial, refreshing, and frequently employed with success in inflammations of the eyes. The tube of the flower, when dried, has the smell of saffron; and, being pounded and mixed with sanders-wood, is used by the natives of the Malabar coast for imparting a grateful fragrance to their bodies, which they rub or anoint with the mixture.

2. The Zambae, noted, like the other species, for the fragrancy of its flowers, is a native likevise of India; and is cultivated in our flowers, where it generally rises with a twining stem to the height of 18 or 20 feet. The leaves are opposite, simple, and entire; but in different parts of the plant assume different forms; the lower leaves being heart-shaped and blunt; the upper, oval and sharp. The flowers are white, inexpressibly fragrant, and generally appear with us in the warm summer-months. Strong loam is its proper soil. There is a variety of these species with a double flower, which is much larger and more fragrant than the former.

Nyctastragoni, among the ancients, were officers appointed to prevent fires in the night, or to give alarm and call assistance when a fire broke out. At Rome they had the command of the watch, and were called noturni trismquiri, from their office and number.

Nycticorax, in ornithology, the night raven; a species of Aresia.

Nye (Philip), an English non-conformist, a native of Sufset, descended of a genteel family there, was born about 1596. After a proper foundation at the grammar-school, he was sent to Oxford and entered a commissary of Brazen-Nose college in 1611, whence he removed in a little time to Magdalen-hall, under a puritanical tutor. He took the degrees in arts in 1619 and 1622, about which time he entered into holy orders, and was, some time in 1620, curate of St Michael's church in Cornhill, London. Refolving, however, to reject the constitution of the church of England, he became obnoxious to all the censures of the episcopal court; to avoid which he went, with others of his persuasion, to Holland, in 1633. He continued for the most part as Arnheim, in Culerland, till 1640; when, the power of the parliament beginning to prevail over the king, he returned home, and was soon after made minister of Kimborton in Huntingdonshire, by Edward Lord Kimbolton, then earl of Manchester. In 1643, he was appointed one of the
Nye, assembly of divines, and became a great champion of the Presbyterians, and a zealous affier of the solemn league and covenant; and having married the daughter of Stephen Marshall, was sent with his father-in-law into Scotland the same year, to expedite the taking of their covenant. Accordingly, he harangued that people, in some speeches on the occasion; in which he told them, among other things, that they were entered into such a covenant and league as would never be forgotten by them and their posterity, and both would have occasion to remember it with joy; that it was such an oath, for matter, perons, and other circumstances, that the like had not been in any age, sufficiently warranted both by human and divine story: for, as God did swear for the salvation of men and kingdoms, so kingdoms must now swear for the preservation and salvation of kingdoms, to establish a Saviour Jesus Christ in England, &c. After his return, both houses of parliament took the covenant the same year; at which time he preached a sermon in defence of it, showing its warrant from scripture, and was rewarded for his good service with the rectory of Acton near London, in the room of Dr. Daniel Featley, who was ejected from it. Not long after, however, Nye began to dislike the proceedings of the said assembly of divines, and differed from them, opposing the discipline intended to be set up by them; and, closing with the Independents when they became the reigning faction, he paid his court to the grandees of the army, who often made use of his counsel. In December 1647 he was sent by them, with Stephen Marshall, to the king at Carlashock-castle, in the Isle of Wight, in attendance upon the commissioners then appointed to carry the four deposing votes, as they are now called, viz. 1. To acknowledge the war raised against him to be just; 2. To abolish episcopacy; 3. To settle the power of the militia in persons nominated by the two houses; 4. To sacrifice all those that had adhered to him: for which service they were rewarded with no less than 500 l. a piece. Nye was also employed about that time by the same masters to get subscriptions from the apprentices in London, &c. against a personal treaty with the king, while the citizens of that metropolis were petitioning for one. April the next year, he was employed, as well as Marshall and Joseph Caryl, by the Independents, to invite the secured and excluded members to fit in the house again, but without success. In 1653 he was appointed one of the triers for the approbation of public preachers; in which office he not only procured his son to be clerk, but, with the affiance of his father-in-law, obtained for himself a living of 400 l. a year. In 1654, he was joined with Dr. Lazarus Seaman, Samuel Clark, Richard Vines, Obadiah Sedgwick, Joseph Caryl, &c. as an assiant to the commissioners appointed by parliament to erect such as were then called scandalous and ignorant ministers and schoolmasters in the city of London. After Charles II's restoration in 1660, it was debated by the healing parliament, for several hours together, whether he and John Goodwin should be excepted for life; but the result was, that if Philip Nye, clerk, should after the 1st of September, in the same year, 1660, accept or exercise any office, ecclesiastical, civil, or military, he should, to all intents and purposes in law, stand as if he had been totally excepted for life. November 1662 he was vehemently suspected to be engaged in Tongue's plot: but the suspicion was never proved. He died in the parish of St. Michael's, Cornhill, London, in Sept. 27, 1672, and was buried in the upper vault of the said church. Wood says he was a dangerous and seditions person, a politic pulpit-driver of indepenency, an infatiable effuient after riches, and what not, to raise a family, and to heap up wealth.

NYLAND, a province of Finland in Sweden, lying on the gulf of Finland, to the west of the province of Barcla. NYL-GHAU, in zoology, of the genus Bos, a native of the anterior parts of India. "It seems (says Bewick in his Hist. of Quadr.) to be of a middle nature between the cow and the deer, and carries the appearance of both in its form. In size, it is as much smaller than the one, as it is larger than the other: its body, horns, and tail, are not unlike those of a bull; and the head, neck, and legs, are similar to those of a deer. The colour in general is ash or grey, from a mixture of black hairs and white: all along the ridge or edge of the neck, the hair is blacker, longer, and more erect, making a short, thin, and upright mane, reaching down to the hump. Its horns are seven inches long, six inches round at the root, tapering by degrees, and terminating in a blunt point: the ears are large and beautiful, seven inches in length, and spread to a considerable breadth: they are white on the edge and on the inside, except where two black bands mark the hollow of the ear with a zebra-like variety. The height of this animal at the shoulder is four feet one inch; behind the loins, it only measures four feet.

"The female differs considerably from the male both in height and thickness, being much smaller; in shape and colour, very much resembling a deer; and has no horns. She has four nipples, and is supposed to go nine months with young: She commonly has one at a birth, but sometimes two.

"Several of this species were brought to this country in the year 1767, which continued to breed annually for some years after. Dr. Hunter who had one of them in his cullody for some time, describes it as a harmless and gentle animal: that it seemed pleased with every kind of familiarity, always licked the hand that either stroked or fed it, and never once attempted to use its horns offensively. It seemed to have much dependence on its organs of smell, and stuffed keenly whenever any peril came in sight. It did so likewise when food or drink was brought to it; and would not take the bread which was offered, if the hand that presented it happened to smell of turpentine.

"Its manner of fighting is remarkable, and is described thus. Two of the males at Lord Clive's, being put into an inclosure, were observed, while they were at some distance from each other, to prepare for the attack, by falling down upon their knees; they then shuffled towards each other, keeping still upon their knees; and at the distance of a few yards they made a spring, and darted against each other with great force.

"The following anecdote will serve to show, that during the rutting season, these animals are fierce and vicious, and not to be depended upon. A labouring man, without knowing that the animal was near him, went up to the outside of the inclosure; the nyI ghan, with
Nymph.

the quickness of lightning, darted against the wood
work with such violence, that he broke it to pieces, and
broke off one of his horns close to the root. The
death of the animal, which happened soon after, was
supposed to be owing to the injury he sustained by the
blow.

"Bernier says that it is the favourite amusement
of the Mogul emperor to hunt the Nyly-gahu; and that
he kills them in great numbers, and distributes quar-
ters of them to his omrals; which shows that they
are esteemed good and delicious food.

"The Nyly-gahu is frequently brought from the in-
terior parts of Asia, as a rare and valuable present to
the sabbahs and other great men at our settlements in
India.

"It remains to be considered, whether this rare ani-
mall might not be propagated with success in this coun-
try. That it will breed here is evident from experi-
ence; and if it should prove docile enough to be easily
trained to labour, its great swiftness and considerable
strength might be applied to the most valuable pur-
puses."

Nymph, in mythology, an appellation given to
certain inferior goddesses, inhabiting the mountains,
winds, waters, &c. said to be the daughters of Oc-
anus and Tethys. All the universe was represented as
full of these nymphs, who are distinguished into fe-
veral ranks or classes. The general division of them
is into celestial and terrestrial; the former of which
were called urania, and were supposed to be intelli-
gences that governed the heavenly bodies or spheres.
The terrestrial nymphs, called epigeiti, presided over
the several parts of the inferior world; and were
分裂 into those of the water and those of the earth.
The nymphs of the water were the oceanides, or
nymphs of the ocean; the nereids, the nymphs of the
sea; the naiads and sphyriades, the nymphs of the
fountains; and the limnades, the nymphs of the lakes.
The nymphs of the earth were the oreades, or nymphs
of the mountains; the napae, nymphs of the meadows;
and the degatis and hamadryads, who were nymphs of
the forests and groves. Besides these, we have with
nymphs who took their names from particular coun-
tries, rivers, &c. as the citheraonides, so called from
mount Citheron in Boeotia: the dionyssides, from Do-
dona: hyakinthides, from the Tiber, &c.—Goats were
sometimes sacrificed to the nymphs, but their con-
stant offerings were milk, oil, honey, and wine.

We have the following account of nymphs in Chand-
ler's Greece. They were suppos'd to enjoy longevity,
but not to be immortal. They were believed to delight
in springs and fountains. They are described as sleekets,
and as dreaded by the country people. They were
susceptible of passion. The arguments, it is related,
landing on the shore of the Propontis to dine in their
way to Colchis, sent Hylas, a boy, for water, who,
discovered a lovely fountain, in which the nymphs Eu-
ica, Malis, and Nychaia were preparing to dance;
and these seeing him were enamoured, and, seizing him
by the hand as he was filling his vase, pulled him in.
The deities, their copartners in the cave, are such as
prefigured with them over rural and pastoral affaires.

"The old Athenians were ever ready to cry out, A
god! or a goddess! The tyrant Piseutritus entered the
city in a chariot with a tall woman drested in armour
like Minerva, and regnied the Acropolis,

which he had been forced to abandon, by this frightful
the people worshipping, and believing her to be the
deity whom she represented. The nymphs, it was the
popular persuasion, occasionally appeared; and nym-
pholepsy is characterized as a frenzy, which arose
from having beheld them. Superstition dispensed the
mind to adopt delusion for reality, and gave to a
fancied vision the efficacy of full conviction. The foun-
dation was perhaps no more than an indirect, partial,
or obscure view of some harmless girl, which had ap-
proached the fountain on a like errand with Hylas,
or was retiring after she had filled her earthen pitcher.

"Among the sacred caves on record, one on mount
Ida in Crete was the property of Jupiter, and one by
Lebadea in Boeotia of Trophonius. Both these were
oracular, and the latter bore some resemblance to that
we have described. It was formed by art, and the mouth
surrounded with a wall. The definent to the landing-
place was by a light and narrow ladder, occasionally
applied and removed. It was fastened on a mountain
above a grove; and they related that a swarm of
bees conducted the perfon by whom it was first dis-
covered. But the common owners of caves were the
nymphs, and these were sometimes local. On Cithe-
pron in Boeotia, many of the inhabitants were possessed
by nymphs called Spraggutides, whose cave, once also
oracular, was on a summit of the mountain. Their
dwellings had generally a well or spring of water; the
former often a collection of moisture condened or ex-
uding from the roof and sides; and this, in many in-
fiances, being pregnant with fomy particles, concreted,
and marked its passage by incrustation, the ground-
work in all ages and countries of idle tales framed or
adopted by superstitious and credulous people.

"A cave in Paphlagonia was farmed to the nymphs
who inhabited the mountains about Heraclea. It was
long and wide, and pervaded by cold water, clear as
crystal. There also we were seen bowls of stone, and
nymphs and their webs and diaphanies, and curious work,
exciting admiration. The poet who has described this
grotto, deferves not to be regarded, as servilely copying
Homer; he may justly claim to rank as an original to-
pographer.

"The piety of Archidamus furnished a retreat for the
nymphs, where they might find shelter and provision,
if distressed; whether the sun parched up their trees,
or Jupiter enthroned in clouds upon the mountains-top
feared them with his red lightning and terrible thun-
der, pouring down a deluge of rain, or brightening the
fummits with his frow."

Nymph, among naturals, that state of winged
insects between their living in the form of a worm and
their appearing in the winged or most perfect state.
The eggs of insects are first hatched into a kind of
worms or maggots; which afterwards pass into the
nymph state, surrounded with shells or cases of their
own skins: so that, in reality, these nymphs are only
the embryo insects, wrapped up in this covering; from
whence they at last get loose, though not without great
difficulty.

During this nymph-flate the creature loses its motion.
Swammerdam calls it nympha aurelpa, or simply aurelpa;
and others give it the name of chrysalis, a term of the
like import. See the article Chrysalis.

Nymph-Bank, situate about 10 leagues off the coast
of the county of Waterford, and province of Munster
NYMPHAEA, in Ireland, is a great fishing place, and at leagues
S. S. E. from the head of Dungravan. It abounds with cod, ling, flanks, bream, whiting, and
other fish; which was discovered by Mr. Doyle, who
on July 15, 1736, failed to it in company with seven
men, on board the Nymph, a small vessel of about 12
guns. This place is well adapted for a fishing company,
the great public advantages of which must be
very evident.

NYMPHAEA, in anatomy, two membranaceous parts,
situated on each side the rima. They are of a red co-
lar, and cavernous structure, somewhat resembling
the wattles under a cock's throat. They are some-
times smaller, sometimes larger; and are contiguous
to the prepatorium of the clitoris, and joined to the in-
terior side of the labia.

NYMPHAEA, the water-lily; a genus of the
monogynia order, belonging to the pannonia class
of plants; and in the natural method ranking under the
54th order, Miscellanea. The corolla is polyteta-
loous; the calyx tetraphyllous or pentaphyllous; the
berry multilocular and truncated. There are four
species; of which the most remarkable are, 1. 2. The
lutea and alba, or yellow and white water-lilies; both of
which are natives of Britain, growing in lakes and
ditches. Linnaeus tells us, that twine are fond of the
leaves and roots of the former; and that the smoke
of it will drive away crickets and butterflies, or cock-
roaches, out of houses. The root of the second has an
aromatic and bitter taste, like those of most aqua-
tic plants that run deep into the mud. The High-
landers make a dye with it of a dark chestnut-colour.

3. The lotus, with heart-shaped toothed leaves, a plant
thought to be peculiar to Egypt, is thus mentioned
by Herodotus: "When the river Nile is become
full, and all the grounds round it are a perfect sea,
there grows a vast quantity of lilies, which the Egyp-
tians call lotus, in the water. After they have cut
them, they dry them in the sun; then, having parched
the feed within the lotus, which is moist like the
poppy, they make bread of it, baking it with fire.
The root also of the lotus is eatable, easily becoming
sweet, being round, and of the size of an apple." M.
Savary mentions it as growing in the rivulets and
on the sides of the lakes; and that there are two forts
or varieties of the plant the one with a white, the
other with a bluish flower. "The calyx (he says)
blows like a large tulip, and diffuses a sweet smell,
referring that of the lily. The first species produces
a round root like that of a potato; and the inhabi-
tants of the banks of the lake Menzall feed upon it.
The rivulets in the environs of Damietta are covered
with this majestic flower, which rises upwards of two
feet above the water. 4. In the east and West In-
dies grows a species of this plant, named nymphaea
by the inhabitants of Ceylon. The leaves which reit
upon the surface of the water are smooth, undivided,
perfectly round, thick, target-shaped, and about one
foot and a half in diameter. The foot-flalk of the
leaves is prickly; and infected, not in their bafe, or
margin, as in mott plants, but in the centre of the
lower diff or surface. From this centre, upon the
upper surface, lies, like rays, a great number of large
ribs or nerves, which towards the circumference are
divided and subdivided into a small number of very
minute parts. The flowers are large, flesh coloured,
and consist of numerous petals, disposed, as in the
other species of water-lily, in two or more rows.
The feed-vessel is shaped like a top, being broad and cir-
cular above, narrow and almost pointed below. It is
divided into several distinct cells, which form for many
large round holes upon the surface of the fruit; each
containing a single seed. — With the flower of this
plant, which is furred among the heathens, they adorn
the altars of their temples; they paint their gods fit-
ing upon it; and make use of such pictures to an-
imate the minds of the pious on their deathbed, and
to raise their affections to heaven. The seed, which
are used as a pot-herb, are of a wonderful length.
The root is very long, extends itself transversely, is
of the thickness of a man's arm, jointed and fibrous,
with long intervals between the joint. The fibres
surround the joints in verticillt or whirls. 5. A spe-
cies of nymphaea, called by the Chinese lon i:sa and
nymphaea, is highly extolled in that country for its
excellent virtues, and ranked by their physicians among
these plants which are employed in the composition of
the liquor of immortality. The seeds are there eaten as
we eat fig rolls in Europe; they are more delicate
when they are green, but harder of digestion; they
are preferred in many different ways with sugar. The
root of this plant is also admitted by the Chinese
to their tables, in whatever manner it be prepared, it
is equally wholesome. Great quantities of it are
picked with salt and vinegar, and excellent soup with
water and milk. The leaves of the nymphaea are much
used for wrapping up fruits, figs, salt provisions, &c.
When dry, the Chinefe mix them with their smoking tobacco, to render it
fetter and milder.

The high veneration in which the nymphaea was
held by the Egyptians, is fully known; and at this hour
it is equally venerated by the Hindoos. Sir William
Jones, in speaking of brimba, Vishnou, and Shiva, as
emblematical representations of the Deity, says,
"The first operations of these three powers are
evidently described in the different Fournas by a
number of allegories; and from them we may
deduce the Ionian philosophy of primeval water, the doctrine
of the mundane egg, and the veneration paid to the
nymphaea or lotus, which was anciently revered in
Egypt, as it is at present in Hindoos, Tibet, and
Nepal. The Tibetans are far too embibish their
temple and altars with it; and a native of Nepal
made profforations before it, on entering my Study
where the fine plant and beautiful flowers lay for ex-
namination."

NYMPHAEA (amongst the ancients) doubtful what
structures they were; some take them to have been
grottos, deriving their name from the statues of the
nymphae of which they were adorned; but that they
were considerable works appears from their being ex-
ecuted by the emperors Ammian, Victor, Capitolineus;
or by the city prefects. In an inscription, the term
is written nymphaon. None of all these nymphaeas has
laid down to our time. Some years since, indeed a
square building of marble was discovered between
Naples and Vesuvius, with only one entrance, and
some steps that went down to it. On the right hand as

X 2

you
you enter towards the head, there is a fountain of the purest water; along which, by way of guard as it were, is laid a naked Arethusa of the whitest marble; the bottom or ground is of variegated marble, and encompassed with a canal fed by the water from the fountain: the walls are set round with shells and pebbles of various colours; by the setting of which, as by so many strokes in a picture, are expressed the 12 months of the year, and the four political virtues; also the rape of Proserpine; Pan playing on his reed, and fothing his flock: besides the representations of nymphs swimming, falling, and wantoning on fishes, &c.

It seems pretty evident that the nymphae were public baths; for at the same time that they were furniished with pleasing grottos, they were also supplied with cooling fountains, by which they were rendered exceedingly delightful, and drew great numbers of people to frequent them. Silence seems to have been a particular requisite there, as appears by this inscription, Nymphis lati, liceo, tace. That building between Naples and Vesuvius mentioned above, was certainly one of these nymphae.

NYMPHÆUM, (Plutarch); the name of a sacred place, near Apollonia in Lylycum, sending forth continually fire in detached fumes from a green valley and verdant meadows. Dio Cassius adds, that the fire neither burns up nor parches the earth, but that herbs and trees grow and thrive near it, and therefore the place is called nymphaeum; near which was an oracle of such a nature, that the fire, to show that the wish was granted, confirmed the frankincense thrown into it; but repelled it, in case the defire was commonly called nymphs swimming, falling, and wantoning on fishes, &c.

Its mention has the fame features as the poets ascribe to the satyr. He was interrogated by Sylla and by his interpreters; but his articulations were unintelligible, and the Roman spurned from him a creature which seemed to partake of the nature of a beast more than that of a man.

NYMPHÆUM, in antiquity, a public hall magnificently decorated, for entertainments, &c. and where those who wanted convenience at home held their marriage-feasts; whence the name.

NYMPHIDIUS (Sabinus), a person of mean defeat, but appointed by Nero 'colleague of Tigelinus in the command of the prætorian guards. About the time, however, that the German legions revolted from this despotic prince, he was also betrayed by Nymphidius and abandoned by his guards.

Nymphidius began now to entertain thoughts of seizing the sovereignty himself. However, he did not immediately declare his ambitious views; but pretending to espouse the cause of Galba, affured the guards that Nero was fled, and promised them such sums as neither Galba nor any other was able to discharge. This promise secured for the present the empire to Galba, ocasioned afterwards the loss of it, and finally, produced the destruction of Nymphidius and the guards themselves. After Nero's death, however, and on the acknowledgment of Galba as emperor, he renewed his ambition; and having by his immense largesses gained the affections of the prætorian guards, and perfuading himself that Galba, by reason of his infirmities and old age, would never reach the capital, usurped all the authority at Rome. Presuming upon his interest, he obliged Tigellinus, who commanded jointly with him, the prætorian guards, to resign his commission. He made several magnificent and expensive entertainments, inviting such as had been confuls or had commanded armies, distributed large sums among the people, and with shows and other diversions, which he daily exhibited, gained to great an interest with all ranks, that he already looked upon himself as sovereign. The female dread-}

NYON, a confiderable town of Switzerland, in the eanto of Bern, and capital of a bailiwick of the fame name, with a castle. It stands delightfully upon the edge of the lake of Geneva, in the very point where it begins to widen, and in a most charming country commonly called Pays de Vaud. It was formerly called Colonia Eugubina Notedanum; and as a proof of its antiquity, several Roman inscriptions, and other ancient remains have been frequently discovered in the outskirts of the town. E. Long. 5. 10. N. Lat. 46. 24.

NYSSA, or Nyssa (anc. gog.), a town of Ethiopia; at the south of Egypt. Some place it in Arabia. This city, with another of the same name in India, was sacred to the God Bacchus, who was educated there by the nymphs of the place, and who received the name of Dionysus, which seems to be compounded of Nyss, the name of his father, and that of the place of his education. The god made this place the seat of his empire, and the capital of the conquered nations of the east. According to some geographers, there were no less than ten places of this name. One of these was famous on the coast of Eubea for its vines, which grew in such an uncommon manner, that if a twig was planted in the ground in the morning, it immediately produced grapes which were full ripe in the evening. A city of Thrace: another seated on the top of Mount Parnassus, and sacred to Bacchus.

NYSLLOT, a strong town of Rufina, in Livonia, with a castle, seated on the river Narva, among large marshes. E. Long. 26. 55. N. Lat. 61. 46.

NYSSA, in botany: a genus of the order of dicelia, belonging to the polygama class of plants; and in the natural method ranking under the 12th order, Holaraceæ. The hermaphrodite calyx is quinquepartite; there is no corolla; the flamina are five; there is one pistil; the fruit a plum inferior. The male calyx is quinquepartite, no corolla, and ten famina.
The entire leaved tupelo tree, in its native soil and climate, grows to near 20 feet high; in this country its size varies according to the nature of the soil or situation. In a moist rich earth, well sheltered, it comes near to 20 feet; in others, that are less so, it makes flower progress, and in the end is proportionally lower. The branches are not very numerous, and it rises with a regular trunk, at the top of which they generally grow. The leaves are of a lanceolated figure, and of a fine light green colour. They end in acute points and are very ornamental, of a thickish constirue, soft, grow alternately on pretty long footstalks, and often retain their verdure late in the autumn. The flowers, which are not very ornamental, are produced from the sides of the branches, growing sometimes singly, sometimes many together, on a footstalk. They are of a greenish colour; and, in the countries where they naturally grow, are succeeded by oval drupes, inclining oval, acute, furrowed nuts. In England they seldom produce fruit.

The serrated leaved tupelo tree grows usually nearly 90 feet in height; and divides into branches near the top like the other. The leaves are oblong, pointed, of a light green colour and come out without order on long footstalks. The flowers come out from the wings of the leaves on long footstalks. They are small, of a greenish-colour; and are succeeded by oval drupes, containing sharp pointed nuts, about the size of a French olive.

The propagation of these trees is from seeds, which come from America. As soon as they arrive, they should be sown in large pots of light sandy earth an inch deep. The gardener (no plants come up the first spring), after this work is done, should plunge his pots up to their rims in the natural ground; and if it be a moist place, it will be the better. Weeding must be observed during the summer, and a few furze bushes should be pricked round the pot; in November, which will prevent the ground from freezing, and forward the coming up of the seed. In the next spring, the pots should be plunged into an hot-bed, and after that the seeds will soon appear. As much air as possible, and watering, should be afforded them; and they must be hardened soon, to be set out. The pots should then be plunged to their rims again, in the natural mould; where they are to remain till October. Watering must be given them; and they should also be shaded in the heat of the day. In October, they must be housed, with other greenhouse plants, or else set under a hot-bed-frame, or some other cover, during winter. The third spring they should be taken out of the larger pots, and each planted in a smaller, in which their growth may be assisted by a gentle heat in a bed; but if they are planted up to the rims in a moist place, and shaded in dry weather, they will grow very well. Though by this time they should have become hardy, yet it will be proper to shelter them the winter following in bad weather. They will require little more care during their stay in the pots, which may be either two, three, or more years, if they are large enough; when in spring they may be turned out, with the mould, into the places where they are to remain, which ought always to be moist and properly sheltered.

NYU-CHE, or Kin, an empire which arose in eastern Tartary in the beginning of the 13th century, from the founder of this empire the late Chinese emperor Kang-hi said that his family was descended. See China and Tartary.

O.

The 14th letter and fourth vowel of our alphabet; pronounced as in the words nof, ryes, etc.

The sound of this letter is often so soft as to require it double, and that chiefly in the middle of words; as goos, reproof, &c. And in some words this o is pronounced like a short as in flood, blood, &c.

As a numeral, o was sometimes used for 11 among the ancients; and with a diphthong over it thus, ẞ, for 11,000.

In the notes of the ancients, O. CON. is read opus, constitution; O. C. Q. opera conjilique; O. D. M. operis, donum munis; and O. L. O. opus locatum.

The Greeks had two O's; viz. omicron, ϐ, and omega, ω; the first pronounced on the tip of the lips with a sharper sound, the second in the middle of the mouth, with a fuller sound, equal to o in our language. The long and short pronunciation of our O are equivalent to the two Greek ones; the first, as in suppose; the second, as in obey.

O is usually denoted long by a servile a subjunct; as mane; or by e at the end of the syllable, as bone; when these vowels are not used, it is generally short.

Among the Irish, the letter O, at the beginning of the name of a family, is a character of dignity annexed to great houses. Thus in the History of Ireland, we frequently meet with the O Neill O Carolis, &c. considerable houses in that island.

Camden observes, that it is the custom of the lords of Ireland to prefix an O to their name, to distinguish them from the commonalty.

The ancients used O as a mark of triple time; from a notion that the ternary, or number 3, was the most perfect of numbers, and therefore properly expressed by a circle the most perfect of figures.

It is not, strictly speaking, the letter O, but the figure
OAK

The oak has been long known by the title of monarch of the woods, and very justly. It was well known, often very elegantly described, by the ancient poets. The following description from Virgil is exquisite:

Virg. "Veli uniforme validam cum robore quercum
Alpini Borae, nume bino, num fataibus ilia
erue inter fc cantant; it fridera, alite
Conferunt terram concius, flitisse frondes:
Ipsa heret fopulite: et quantum vortice ad auras
Athurios, tumultum radice: Tanara tendit.

Enn. iv. 441.

A s'oth's aerial Alps sublimely spread,
Some aged oak uprears his rever'd head;
This way and that the furious tempests blow,
To lay the monarch of the mountains low;
The'd imperial plant, though nodding at the ground,
Though all his scatter'd honours frowr the ground;
Safe in his strength, and seated on the rock,
In naked majesty defies the shock;
High as the head shoots winging to the skies,
So deep the root in hell's foundation lies.

PITT.

The ancient druids had a most profound veneration for oak trees. Pliny * says, that "the druids (as the Gauls call their magicians or wise men) held nothing so sacred as the mistletoe, and the tree on which it grows, provided it be an oak. They make choice of oak groves in preference to all others, and perform no rites without oak-leaves, so that they seem to have the name of druids from thence, if we derive their name from the Greek," &c. (See Druids—definition, and n° 11.) Maximus Tyrius says the Celtæ or Gauls worshipped Jupiter under the figure of a lofty oak (A).

This useful tree grows to such a surprising magnitude, that there are not many well authenticated instances of them in our own country, they would certainly appear difficult of belief. In the 18th volume of the Gentleman's Magazine we have the dimensions of a leaf twelve inches in length and seven in breadth, and all the leaves of the same tree were equally large. On the estate of Woodhall, purchased in 1775 by Sir Thomas Rumbold, bart., late governor of Madras, an oak was felled which fell for 45 l. and measured 24 feet round. We are told of one in Millwood forest, near Chaddesley, which was in full verdure in winter, getting its leaves again after the autumn ones fell off. In Hunter's Evelyn's Sylva, we have an account of a very remarkable oak at Greendale; which Gough, in his edition of Camden, thus minutely describes: "The Greendale oak, with a road cut thro' its stem bears one green branch. Such branches as have been cut or broken off are guarded from wet by lead. The diameter of this tree at the top, whence the branches issue, is 15 feet 2 inches; at the surface of the ground 11 feet; circumference there 35 feet; height of the trunk 533; height of the arch 15, width 6. Mr Evelyn mentions several more oaks of extraordinary size in Worksbop park."

In the Gentleman's Magazine for 1773 we have an account of one differing very essentially from the common one; it is frequent about St Thomas in Devonshire, and is in that county called Luxcombe oak, from one William Luxcombe who successfully cultivated it near Exeter. It grows as straight and handsome as its leaves are evergreen, and its wood as hard as that of the common oak. Its growth is so quick, as to exceed in 20 or 30 years the altitude and girth of the common oak at 100. It is cultivated in various places; Cornwall, Somersetshire, &c.

M. du Hamel du Monceau, of the royal academy of Sciences at Paris (who wrote a treatise on husbandry), gave an account in the year 1749 of an oak which he had kept in water eight years, and which yielded fine leaves every spring. The tree had, he says, four or five branches; the largest 16 or 20 lines round, and more than 18 inches long. It thrives more in the two first years than it would have done in the belt earth, it afterwards lost its vigour, and rather decayed; which he attributed to a defect in the roots rather than to want of aliment.

M. de Buffon made some experiments on oak trees; the result of which is recorded in the Gentleman's Magazine, 1764. He had compared barked with unbarked trees: and proves, we think with success, from a variety of trials, that timber barked and dried standing, is always heavier and considerably stronger than timber kept in its bark.

The bark of oak trees was formerly thought to be extremely useful in vegetation. One load (Mr Mills in his treatise on husbandry informs us) of oak-bark, laid in a heap and rotted, after the tanners have used it for dressing of leather, will do more service to stiff cold land, and its effects will last longer, than two loads of the richest dung; but this has been frequently controverted. (See Oak-Leaves.)

The bark, in medicine, is also a strong astringent; and hence stands recommended in hemorrhages, alvine fluxes, and other preternatural or immediate secretions; and in thefe it is sometimes attended with good effects. Some have alleged, that by the use of this bark every purpose can be answered which may be obtained from Peruvian bark. But after several very fair

(A) Camden informs us of a tradition (which, like most other traditions of this nature, seems to be founded in ignorance and fostered by credulity) respecting an oak near Malwood castle, where Rufus was killed, viz. that it buckled on Christmas-day, and withered before night. This tree, the same tradition reports to have been that against which Tyril's arrow glanced.
Oak.

Fair trials, we have by no means found this to be the case. Besides the bark, the buds, the acorns, and their cups are used; as also the galls, which are excrescences caused by insects on the oaks of the eastern counties, of which there are divers sorts; some perfectly round and smooth, some rougher with small protuberances, but all generally having a round hole in them. All the parts of the oak are styptic, binding, and useful in all kinds of fluxes and bleedings, either inward or outward. The bark is frequently used in gargoyrifs, for the relaxation of the uvula, and for sore mouths and throats: it is also used in refrigerent ointments, against the prolapsus uteri or anus. The acorns, beaten to powder, are frequently taken by the vulgar for pains in the side. The only way by which they are used is, to rub them in the hands, and then to beinger them in the ears, as they will not pass down the windpipe. Besides these, Mr. Speechly says, it was his custom to fumble the leaves round with charcoal, huddled, or any thing else, to keep them from being blown about the garden in windy weather. In this place they tread them well, and water them in a place where they happen to have been brought in dry. The heap is made of the leaves, and covered over with old mats, or any thing else, to prevent the upper leaves from being blown away. In a few days the heap will come to a strong heat. For the first year or two in which he used these leaves, our author did not continue them in the heap longer than ten days or a fortnight; but by this method of management they lasted so much when brought to the dry, as if perfectly was but from soon roasted, and he afterwards found, that it was proper to let them remain for six weeks in the heaps before they are brought to the hot-houfes. In getting them into the pine-pots, if they appear dry, they are to be watered, and again trodden down exceedingly well, in layers, till the pots are quite full. The whole is then covered with tan-bark, to the thickness of two inches, and well trodden down, till the surface becomes smooth and even. On this the pine-pots are to be placed in the manner they are to stand, beginning with the middle row first, and filling up the spaces between the pots with tan. In this manner we are to proceed to the next row, till the whole be felled; and this operation is performed in the same manner as when tan only is used. The leaves require no further trouble through the whole season; as they will retain a constant and regular heat for 12 months without stirring or turning; and our author informs us, that if he may judge from their appearance when taken out (being always entire and perfect), it is probable they would continue their heat through a second year; but, as an annual supply of leaves is easily obtained, the experiment is hardly worth making. After this, the pines will have no occasion to be moved, but at flated times of their management, viz. at the shifting them in their pots, &c. when at each time a little fresh tan should be added to make up the deficiency arising from the settling of the beds; but this will be inconsiderable, as the leaves do not settle much after their long southing. During the first two years of our author's practice he did not use any tan, but plunged the pine-pots into the leaves, and just covered the surface of the beds, when finished, with a little saw-dust, to give it a neatness. This method, however, was attended with one inconvenience; for by the caking of the leaves they shrunk from the sides of the pots, whereby they became exposed to the air, and at the same time the heat of the beds was permitted to escape.

"Many powerful reasons (says Mr Speechly) may be given why oak-leaves are preferable to tanner's bark."

1. They always heat regularly; for during the whole time that I have used them, which is near seven years, I never once knew of their heating with violence; and this is so frequently the case with tan, that I affirm, and indeed it is well known to every person conversant in the management of the hot-houses, that pines suffer more from this one circumstance, than all the other accidents put together, insects excepted. When this accident happens near the time of their fruiting, the effect is soon seen in the fruit, which is exceedingly small and ill-shaped. Sometimes there will be little or no fruit at all; therefore gardeners who make use of tan only for their pines, should be most particularly careful to avoid an over-heat at that critical juncture,—the time of showing the fruit.

2. The heat of oak-leaves is constant; whereas tanner's bark generally turns cold in a very short time after its furious heat is gone off. This obliges the gardener to give it frequent turnings in order to promote its heating. These frequent turnings, not to mention the expense, are attended with the worst consequences; for by the continual moving of the pots backwards and forwards, the pines are exposed to the extremes of heat and cold, whereby their growth is considerably retarded; whereas, when leaves are used, the pines will have no occasion to be moved but at the times of potting, &c. The pines have one peculiar advantage in this undisturbed situation; their roots grow through the bottoms of the pots, and mix among the leaves in a surprizing manner. From the vigour of the plants when in this situation, it is highly probable that the leaves, even in this state, afford them an uncommon and agreeable nourishment.

3. There is a saving in point of expense; which is no inconsiderable object in places where tan cannot be had but from a great distance.

4. The last ground of preference is, that decayed leaves make good manure; whereas rotten tan is experimentally found to be of no value. I have often tried it both on sand and clay, and on wet and dry land; and never could discover, in any of my experiments, that it deserved the name of a manure; whereas, decayed leaves are the richest, and of all others the most proper manure for a garden. Leaves mixed with dung make excellent hot-beds; and I find that beds compounded in this manner, preserve their heat much longer than when made entirely with dung; and in both,
both cafes, the application of leaves will be a considerable saving of dung, which is a circumstance on many accounts agreeable.

Oak-Leaf-Galls. These are of several kinds; the remarkable species called the mushroom gall is never found on any other vegetable substance but these leaves; and beside this there are a great number of other kinds.

The double gall of these leaves is very singular, because the generality of productions of this kind affect only one side of a leaf or branch, and grow all one way; whereas this kind of gall extends itself both ways, and is seen on each side of the leaf, in form of two protuberances, opposite the one to the other. These are of differently irregular shapes, but their natural figure seems that of two cones, with broad bases, and very obtuse points, though sometimes they are round, or very nearly so.

These make their first appearance on the leaf in April, and remain on it till June or longer. They are an auburn green, but afterwards yellowish, and are softer to the touch than many other of the productions of this kind; they are usually above the size of a large pea, but sometimes they grow to the size of a nut. When opened, they are found to be of that kind which are inhabited each by one insect only, and each contain one cavity. The cavity in this is, however, larger than in any other gall of the size, or even in many others of three times the size; the sides of it being very little thicker than the substance of the leaf.

It is not easy to ascertain the origin of the several species of flies which are at times seen in this manner to come out of the same species of galls. It seems the common course of nature, that only one species of insect forms one kind of gall; yet it may be, that two or three kinds may give origin to the same kind.

There is, however, another occasion of our seeing different species come out of different galls of the same kind; and this is the effect of the enemies of the proper inhabitants.

It might appear that the parent fly, when she had formed a gall for the habitation of her worm offspring, had placed it in an impregnable fortress; but this is not the case; for it frequently happens, that a fly, as small perhaps as that which gave origin to the gall, produces a worm which is of the carnivorous kind, as the other feeds on vegetable juices. This little fly, well knowing that where there is one of these protuberances on a leaf, there is a tender and defenceless insect within, pierces the sides of the gall, and deposits her egg within it. This, when it hatches into a worm, feeds upon the proper inhabitant; and finally, after devouring it, paves into the chrysalis state, and thence appears in the form of its parent fly, and is then making its way out of the gall, in the place of the proper inhabitant.

On opening these leaf galls, which are properly the habitation only of one animal, it is common to find two, the stronger preying upon the body of the other, and sucking its juices as it does those of the leaf; often it is found wholly employed in devouring its offending neighbour at once: this is probably the cause when its time of eating is nearly over; and, in fact, when we find the gall inhabited by only one insect, or containing only one chrysalis, as it ought in its natural state to do, as we are never certain that this is the proper inhabitant, it may be one of these destroyers who has eaten up the other, and supplied its place.

See Aphids and Oak Puceron.

Oak Saw-dust is now found to answer the purposes of tanning as well, at least, as the bark. See Tanning.

Oak of Jerusalem. See Chenopodium.

Oakham, Ockham, or Oakum, in sea-language, denotes the matter of old ropes untwisted and pulled out into loose hemp, in order to be used in caulking the seams, tree-nails, and bends of a ship, for stopping or preventing leaks.

OAKHAMPTON, a town of Devonshire, which sends two members to parliament; situated in W. Long 4, 5, N. Lat. 50, 48.

Oannes, a being in Chaldean mythology, represented as half a man and half a fish. According to Berosus and other fabulous writers, this monster was the civilizer of the Chaldeans; to whom he taught a system of jurisprudence so perfect as to be incapable of improvement. In discharging the duties of his office, he spent the day on dry land, but retired every night into the ocean or the river. See Mythology, p. 25.

Oar, a long piece of timber, flat at one end and round or square at the other; and which being applied to the side of a floating vessel, serves to make it advance upon the water.

That part of the oar which is out of the vessel, and which enters into the water, is called the blade, or any flat plate; and that which is within board is termed the loom, whose extremity being small enough to be grasped by the rowers, or persons managing the oars, is called the handle.

To pull the boat or vessel forwards by means of this instrument, the rowers turn their backs forward, and, dipping the blade of the oar in the water, pull the handle forward so that the blade at the same time may move a little in the water; but since the blade cannot be moved, without striking the water, this impulse is the same as if the water were to strike the blade from the stern towards the head; the vessel is therefore necessarily moved according to this direction. Hence it follows, that the will advance with the greater rapidity, by as much as the oar strikes the water more forcibly. Thus it is evident, that an oar acts upon the side of a boat or vessel like a lever of the second class, whose fulcrum is the station upon which the oar rests on the boat's gunnel. In large vessels, this station is usually called the row-port; but in lights and boats it is always termed the row-lock.

Oaristus, or Caristys, a term in the Greek poetry, signifying a dialogue between a husband and his wife; such as that in the fifth book of the Iliad between Hector and Andromache.

Scaiger observes, that the caristus is not properly any particular little poem, or entire piece of poetry; but always a part of a great one. He adds, that the passage now cited in Homer is the only proper caristus extant in the ancient poets.

Oat, in botany. See Aveia.

Under the word Aveia it was observed, that the native place of the common oat, cultivated in our fields,
the only account of it, in its natural state, which we then had, is in Anson's Voyage; and that the report of such an author respecting facts in natural history is not intitled to implicit credit. We had not then seen the Travels of Mr Bruce, whose botanical knowledge is very superior to that of most voyagers, or we should have mentioned his account of the plants which he found growing wild in Arooffi, a small territory in Abyssinia, not far from the source of the Nile: (see Note.) "Wild oats (says he) grow up here spontaneously to a prodigious height and size, capable often of concealing both the horse and his rider, and some of the stalks being little less than an inch in circumference. They have, when ripe, the appearance of small corn. The inhabitants make no sort of use of this grain in any period of its growth; the uppermost thin husk of it is beautifully variegated with a changeable purple colour; the taff is perfectly good. I often made the meal in cakes in remembrance of Scotland." Our author informs us, that the Abyssinians could never be brought to relish these cakes, which they said were bitter, burnt their stomachs, and made them thirsty. He is, however, decidedly of opinion, that the wild oat of Arooffi is the oat in its original state; and that it has degenerated every where in Europe. From the facts which he states, this opinion seems to be well founded.

OATH, an affirmation or promise, accompanied with an invocation of God to witness what we say, and with an imprecation of his vengeance, or a renunciation of his favour, if we affirm be false, or what we promise be not performed (a).

The laws of all civilized states have required the security of an oath for evidence given in a court of justice, and in other occasions of high importance (b); and the Christian religion utterly prohibits swearing, except when oaths are required by legal authority. Indeed no serious and reflecting thief, whether he admit the truth of revelation or not, can look upon swearing on trivial occasions as anything else than a sin of a very heinous nature. To call upon that infinite and omnipotent Being, who created and sustains the universe, to witness all the importunities of idle conversation, of which great part is commonly uttered at random, betrays a spirit to profane, that nothing short of experience could make us believe it possible for a creature endowed with reason and reflection to be habitually guilty of a practice so impious. No man can plead in extenuation of this crime, that he is tempted to swear by the importunity of any appetite or passion implanted in the human breast: for the utterance of a profane oath communicates no pleasure, and removes no uneasiness; it neither elevates the speaker, nor depresses the hearer.

Quakers and Moravians,royzed by these considerations, and by the sense which they put upon certain texts of Scripture, refuse to swear upon any occasion, even at the requisition of a magistrate, and in a court of justice. These scruples are groundless; and seem to proceed from an incapacity to distinguish between the proper use and abuse of swearing. It is unquestionably impious to call upon God to witness importunities, or to use his tremendous name as a mere expletive in conversation; but it by no means follows, that we may not piously call upon him to witness truths of importance, or invoke his name with reverence and solemnity. No individual could, without gross profaneness, pray for a thousand times more wealth than he may ever have occasion to use; but it was never thought profane to pray "day by day for our daily bread, for rain from heaven, and fruitful seasons." If it be lawful to ask of God these earthly blessings, because he alone can bestow them; it cannot securely be unlawful, where the lives or properties of our neighbours, or the security of government is concerned, to invoke him with reverence to witness the truth of our assertions, or the sincerity of our intentions; because of our truth in many cases, and of our sincerity in all, none but he can be the witness.

The text of Scripture upon which the Quakers chiefly rest their argument for the unlawfulness of all swearing under the Gofpel, is our Saviour's prohibition

(a) The word oath is a corruption of the Saxon oth. It is often in England called a corporal oath, because, in the days of perry, the perfon swore over the boit or corpus Chrifti.

(b) The various oaths required by different nations at different times, and the various forms, &c. of imposing them, is a subject of very considerable extent and curiosity: An account of them does not fall within the plan of the present article; it would indeed extend it to an undue length; we cannot, however, omit observing, what is doubtless very remarkable, that the grand impostor Mohammed taught the Molemis, that their oaths might be dissolved. This wonderful doctrine is contained in the 66th chapter of the Koran; which, to free himself from his premit and oath to Hafsa his spouse, he pretended was revealed. What the use of oaths is in such circumstances, or what security they afford for performance, it is difficult to ascertain.

It is also very remarkable, that an oath restraining marriages was the cause of the first divorce at Rome. The circumstance happened about the year of the city 523, Polthirmius Albinus and Spurius Carvilius being coniuges. The consuls of this year observing the population declining, and imagining it proceeded from interred marriages and promiscuous cohabitation, obliged all the citizens to swear, that they would not marry with any other view than that of populating the republic. It raised, however, many scruples, and occasioned many domestic ruptures. Among the rest one Carvilius Ruga, a man of dissimulation, imagined that he was bound by his oath to divorce his wife, whom he passionately loved, because she was barren; which was the first instance of a divorce at Rome from its foundation, though the marriage-laws of the kings allowed it; it afterwards, however, became shamefully frequent. This is also a striking instance of the great attention paid to oaths among the Romans; it is remarked indeed by all writers, that they paid a most profound respect to them; and on that we know they founded their hopes of success in war.
In my prayers, and by the earth, by Jerusalem, or by their own heads, was the form of a judicial oath in use among the Jews. On the contrary, we are told by Maimonides, that "if any man swear by heaven or by earth, yet this is not an oath" which surely he could not have said, had such been the forms of judicial swearing. Indeed they could not have admitted such forms into their courts without expressly violating the law of Moses, who commands them to "Fear the Lord (Jehovah) their God, to serve him, and to swear by his name." But the Jews, as every one knows, had such a reverence for the name Jehovah, that they would not pronounce it on light occasions, and therefore could not swear by that name in common conversation. Hence, to gratify their propensity to common swearing, they invented such oaths as, by heaven, by earth, by Jehovah, by the life of thy head, &c. and by this contrivance they thought to avoid the guilt of profaning the name Jehovah. This, however, is seen to be contrary to the Catholic church; for either had no meaning, or were in fact, as our Saviour justly argues, oaths by that God whose creatures they were; so that the Jew who swore them was still guilty of profanation towards the very Jehovah whose name his superstition would not permit him to profane. But what puts it beyond all doubt that the use of judicial oaths is not wholly prohibited, even by such a form of a judicial oath as, by heaven, by earth, and by the life of thy head, &c. is the conduct of our Saviour himself as well as of his apostle St. Paul. When Jesus was simply asked by the high priest, what it was which certain false witnesses testified against him; we are told by the evangelists, that "he held his peace:" but being adjured by the living God to declare whether he was the Christ, the Son of God, or not, he immediately answered the high priest, without objecting to the oath (for such it was) upon which he was examined. "St. Paul, in his Epistle to the Romans, says, "God is my witness, that without ceasing, I make mention of you in my prayers; and to the Corinthians, still more strongly, "I call God for a record upon my soul, that, to spare you, I came not as yet to Corinth." Both these expressions are of the nature of oaths; and the author of the Epistle to the Hebrews speaks of the custom of swearing judicially without any mark of superstition or disapprobation; "Men verily swear by the greater; and an oath, for confirmation, is to an end all thralles." But though a nation has an undoubted right to require the security of an oath upon occasions of real importance, we do not belittle to say, that in our opinion, it is something worse than bad policy to multiply oaths, and to hold out to the people temptations to perjure themselves. The security which an oath affords, depends entirely upon the reverence which attaches to it in the mind of him by whom it is given; but that reverence is much weakened by the frequency of oaths, and by the careless manner in which they are too often administered. An excellent moralist observes, with truth, that "the levity and frequency with which oaths are administered, has brought about a general inattention to the obligation of them, which both in a religious and political view is much to be lamented; and it merits (continues he) public consideration, whether the requiring of oaths on so many frivolous occasions, especially in the customs, and in the qualifications for petty offices, has any other effect than to make them cheap in the minds of the people. A pound of tea cannot travel regularly from the flip to the consumer without collating half a dozen oaths at least; and the same security for the due discharge of his office, namely that of an oath, is required from a church-warden and an archdeacon, from a petty constable and the chief justice of England. Let the law continue its own functions, if they be thought requisite; but let it spare the solemnity of an oath: and where it is necessary, from the want of something better to depend upon, to accept a man's own word or own account, let it annex to perjury penalties proportioned to the public consequence of the offence." That these pernicious consequences of frequent oaths are not felt only in England, we have the evidence of another respectable writer, whose acuteness well qualified him to observe, whilst his station in society furnished him with the best opportunities of observing, the effect of repeated swearing upon the morals of Scotchmen. "Cuttinhouse oaths (says Lord Kames*) are become so familiar among us, as to be swallowed without a wary face; and is it certain that bribery and perjury in electing parliament-members are not approved of by the same cool face? Men creep on to vice by degrees. Perjury, in order to support a friend, has become customary of late years; witness fictitious qualifications in the electors of parliament-men, which are made effectual by perjury: yet such is the degeneracy of the present times (c), that no man is the worse thought of upon that account. We must not flatter ourselves, that the poison will reach no farther: a man who boggles not at perjury to serve a friend, will in time become such an adept, as to commit perjury in order to ruin a friend which he becomes an enemy to." Besides the frequency of oaths, we have mentioned the irreverent manner in which they are too often administered as one of the causes which make them cheap in the estimation of the people. In this view, the form of the oath, and the circumstances with which it is required to be taken, are of considerable importance. (c) Such was the case when his Lordship wrote. Some decisions of the house of peers, however, have since that period changed mens opinions respecting the legality of these votes and the innocence of the means by which they were made effectual. It is to be hoped that such a reformation will soon be made of the laws by which elections are regulated in Scotland, as will render the temptations to perjury less numerous than they have hitherto been.
The forms of oaths in Christian countries (says Mr. Paley) are very different; but in none I believe were contrived either to convey the meaning or to impress the obligation of an oath, than in England. In that country the juror, after repeating the promise or affirmation which the oath is intended to confirm, adds, 'fo help me God,' or more frequently the substancce of the oath is repeated to the juror by the officer or magistrate who administers it; adding in the conclusion, 'fo help you God.' The energy of the sentence resides in the particle 'fo,' i.e. 'hence,' 'upon condition of my speaking the truth, or performing this promise, may God help me, and not otherwise.' The juror, whilst he hears or repeats the words of the oath, holds his right hand upon a Bible, or other book containing the four gospels. The conclusion of the oath sometimes runs, 'ita me Deus adjuravit, et haec famina evangelica,' or 'fo help me God, and the contents of this book;' which last clause forms a connection between the words and action of the juror, which before was wanting. The juror then seals the book."

This obscure and elliptical form, the excellent author justly observes, is ill calculated to impress the juror with reverence: and he seems to think that any preference due to the form of judicial oaths in Scotland. In that country the juror holds up his right hand towards heaven, and swears by Almighty God, and as he shall answer to God at the great day of judgment, "that he will tell the truth, the whole truth, and nothing but the truth, so far as he knows, or it shall be asked of him." This if administered with dignity and reverence, is an oath sufficiently solemn and well calculated to have the proper effect upon the mind of the juror, as it brings immediately into his view the Author of his being and the awful day of final retribution when every man shall receive the things done in his body according to that he hath done, whether it be good or evil. But when the magistrate, as is too often the case, repeats this solemn invocation without rising from his seat at the name of the supreme Being, and in a tone of carelessness which may convey to the ignorant juror an opinion that he has himself no serious belief that there ever will be a great day of judgment, the form, however excellent, makes not its full impression.

But let us suppose an oath to be administered with the greatest dignity and reverence, the words of the promise itself appear to us by no means unexceptionable. In a trial on life and death we should be glad to know what this oath binds the witness to declare. Is he to tell all that he knows touching the matter in question? or only all that shall be asked of him? If he be obliged, in virtue of his oath, to tell all that he knows, the clause — "or it shall be asked of you" is superfluous and calculated to mislead. If he be bound to tell nothing more of the truth than what shall be asked of him, the word or shall be changed into and; he should swear "to tell the truth, &c. so far as he knows, and it shall be asked of him." The court, we believe, considers the witness as bound to declare every thing which he knows touching the matter in question. The greater part of witnesses, on the other hand consider themselves as bound no farther by their oath than to give true answers to such questions as shall be asked of them. They would do well, however, to remember, that as oaths are designed for the security of the public, they must be interpreted in the sense in which the public understands them, otherwise they afford no security. But the sense of the public is the law; and as it belongs to the court to declare what the mind of the law is, the witness, who has any doubt concerning the extent of the obligation imposed on him by the words of his oath, should apply to the court for a solution of that doubt, which will be a fair guarantee to him respecting the evidence which he is to give. Should the court, in resolving the doubts of a witness, give an opinion concerning the sense of any other part of the oath contrary to what he apprehends to be the design of the law in imposing it, he is bound to disregard such opinion; because it is only where he himself is doubtful that the court has a right to interfere, and because in all moral questions men must be finally determined by their own judgment and conscience.

There is one case, and but one, in which, whatever sense be put upon the words of the oath, no witness is obliged to declare the whole truth. It is when such declaration would tend to accuse himself of some legal crime; for as the laws of Scotland and England constrain no man to become his own accuser, they must be considered as imposing the oath of testimony with this tacit reservation. "The exception, however, must be confined to legal crimes. A point of honour, of delicacy, or of reputation, may make a witness backward to disclose some circumstances with which he is acquainted; but is no excuse for concealment, unless it could be shewn, that the law which imposes the oath, intended to allow this indulgence to such motives. The exception is also withdrawn by compact between the magistrate and the witness, when an accomplice is admitted to give evidence against the partners of his crime." But these are a fort of witnesses to whom a sensible jury will always listen with a very cautious ear.

Oaths are either afferatory or promissory. Afferatory oaths are required both to confirm our veracity in evidence, and to give security to the public that we believe certain propositions conceived to be of public importance. An oath in evidence binds the juror to declare what he knows to be true, and nothing but what he knows to be true. An oath required to assure the public of our belief in the truth of any proposition, cannot, without the guilt of perjury, be taken by any man, who, at the time of swearing, has the slightest doubt whether the proposition be really true. Such an oath, however, though it unquestionably requires the sincerity of the juror's belief at the time when it is given, cannot oblige him to continue in that belief as long as he may live; for belief is not in any man's power: it is the necessary consequence of evidence, which compels the silent of the mind according as it appears to preponderate on the one side or on the other. No man, therefore, can be justly accused of perjury for holding opinions contrary to those which he may formerly have sworn to believe; because his belief at the time of emitting his oath may have been the necessary result of the evidence which then appeared before him; and his change of opinion may have resulted with the same necessity from superior evidence.
OATHLAW, the name of a parish in Angus, about two miles from Forfar, chiefly remarkable for the remains of a Roman camp called Battle-dykes (vulgarly Black dykes), which is about a mile west of the church.

OBADIAH, or the Prophecy of Obadiah, a canonical book of the Old Testament, which is contained in one single chapter; and is partly an invective against the cruelty of the Edomites, who mocked and derided the children of Israel as they passed into captivity; and with other enemies, their conquerors, invaded and oppressed those strangers, and divided the spoils amongst themselves; and partly a prediction of the deliverance of Israel, and of the vitory and triumph of the whole church over her enemies.

Obadiah, the prophet, is believed to have been the same with the governor of Ahab's house, mentioned in the first book of Kings, (xviii. 3, &c.) who hid and fed the hundred prophets whom Jezebel would have destroyed; and some say, that he was that Obadiah whom Jofiah made overseer of the works of the temple, (2 Chron. xxxiv. 12.) The truth is, that when he lived or prophesied is wholly uncertain: though most writers make him cotemporary with Hosea, Amos, and Joel.

Obadiah, a valiant man of David's army, who came to join him in the wilderness, with several others of the tribe of Gad, (1 Chron. xii. 9.)

This was also the name of one of those whom king Jehoshaphat sent into the cities of Judah to instruct the people in their religion, (2 Chron. xvii. 7.) It was also the name of one of the principal men of Judah, who signed the covenant that Nehemiah renewed with the Lord, (Nehem. x. 5.)

OBED-EDOM, son of Jeduthun, a Levite, (1 Chr. xvi. 38.) and father of Shemaiah, Jezobad, Joah, Sacar, Nathaneel, Ammiel, Ifchacher, and Peulthai. He had a numerous family, says the scripture, (1 Chr. xxvi. 4.) because the Lord blessed him; and this is the occasion of this blessing. When David transferred the ark of the covenant to the city of Jerusalem, Uz­zah having rashly laid hands on the ark, which he thought to be in danger of falling, was smitten of God, and died upon the spot. David, terrified at this accident, durst not remove the ark into the place he had provided for it in his own house, but set it up in the house of Obed-edom, which was near the place where Uz­zah had been struck dead. But the preference of the ark not only created no temporary misfortune to the family of this Levite, but on the contrary the Lord heaped upon him all sorts of blessings which encouraged David some months after to remove it to the place he had appointed for it. Afterwards Obed-edom and his sons were assigned to be keepers of the doors of the temple, (1 Chron. xv. 18, 21.) In the second book of Samuel, (vi. 10.) Obed-edom is called the Gittite, probably because he was of Gath­rin­dum, a city of the Levites beyond Jordan, (Jos. xii. 24, 25.)

OBELEISK, in architecture, a truncated, quadrangular, and slender pyramid, raised as an ornament, and frequently charged either with inscriptions or hieroglyphics.

Obelisks appear to be of very great antiquity, and to be first raised to transmit to posterity precepts of philosophy, which were cut in hieroglyphical characters: afterwards they were used to immortalize the great actions of heroes, and the memory of persons beloved. The first obelisk mentioned in history was that of Rameses king of Egypt, in the time of the Trojan war, which was 40 cubits high. Phius, another king of Egypt, raised one of 55 cubits; and Ptolemy Phil­adelphus, another of 88 cubits, in memory of Ares­nis­cus. Augustus erected one at Rome in the Campus Martius, which served to mark the hours on an horizontal dial, drawn on the pavement. They were called by the Egyptians priests the fingers of the sun, because they were made in Egypt also to serve as stiles or gnomons to mark the hours on the ground. The Arabs still call them Pharaon's wedies: whilst the Italians call them augugia, and the French aiguilles.

The famous obelisks called the devil's arrows, now reduced to three, the fourth having been taken down in the last century, stand about half a mile from the town of Borough-Bridge to the south west, in three fields, separated by a lane, 200 feet asunder, nearly on high ground sloping every way. Mr Drake urges
many arguments for their Roman antiquity, and plainly proves them to be natural and brought from Plumptonian quarries about five miles off, or from Jekly 16 miles off. The crosses in the town, 12 feet high, is of the same kind of stone. The carvermost or highest is 22 feet and an half high by 4 broad and 4½ in girth; the second 21½ by 5½; the third 16½ by 6¼. Strukley's measures differ. The flutes are cut in the stone but not through: the tallest stands alone, and leans to the south. But and Struclley affirm them to be British monuments, originally hewn square. Dr Gale supposed that they were Mercury's, whose head, and inscriptions but in a MS note in his Antoninus, he acknowledges that he was misinformed, and that there was no cavity to receive a bull.

On the north side of Penrith in the church-yard are two square obelisks, of a single stone each, 11 or 12 feet high, about 12 inches diameter, and 12 by 8 at the sides, the highest about 18 inches diameter, with something like a transverse piece to each, and mortised into a round base. They are 4 feet alder, and between them is a grave inclosed between four mitered stones of unequal lengths of five, six, and four and an half, and two feet high, having on the outside rude carving, and the tops notched. This is called the Giant's grave, and attributed to Sir Ewan Caffierius, who is said to have been as tall as one of the columns, and capable of reaching his arms from one to the other, to have destroyed robbers and wild bears in Englewood forest, and to have had an hermitage hereabouts called Sir Hugh's parlor; but the conjectures respecting them are so various and contradictory, that our readers will readily excuse our enlarging on them.

A little to the west of these is a stone called the Giant's thumb, six feet high, 14 inches at the base contracted to 10, which is no more than a rude cross, such as is at Langtown in Cumberland and elsewhere; the circle of the cross 18 inches diameter.

M. Powelrod, in the memoirs of the Academy of Inscriptions, gives a very curious account of some celebrated Egyptian obelisks. We cannot afford room to follow him; but those who wish for further information on the subject, and who are not possessed of the original, will find a very good account of them in the Gentleman's Magazine for June 1748.

OBJECT, in philosophy, something apprehended or presented to the mind by sensation or imagination. See METAPHYSICS, Part I. C. 1. Sect. II.

OBJECT-GLASS of a Telescope, or Microscope: the glass placed at the end of the tube which is next the object. See OPTICS and MICROSCOPY.

OBJECTION, something urged to overthrow a position, or a doctrine raised against an allegation or proposition of a person we are disputing with.

OBJECTIVE, is used in the 3d. s. in speaking of a thing which exists no otherwise than as an object known. The existence of such a thing is said to be objective.

OBIT, (Lat.) signifies a funeral sedemity, or office for the dead, most commonly performed when the corpse lies in the church uninterred: Also the anniversary office, (2 Cor. 5; 1 Dyer 313.) The anniversary of any person's death was called the obit; and to observe such day with prayers and alms, or other commemoration, was the keeping of the obit. In religious houses they had a regisiter, wherein they entered the obits or obitual days of their founders and benefactors; which was thence termed the obituary. The tenure of obit or chantry lands is taken away and extinct by 1 Edw. VI. c. 14. and 15 Car. II. c. 9.

OBLATI, in church-history, were secular persons, who devoted themselves and their estates to some monastery, into which they were admitted as a kind of lay-brothers. The form of their admission was putting the bell-ropes of the church round their necks, as a mark of fervitude. They wore a religious habit, but different from that of the monks.

OBLIGATION, in general, denotes any act whereby a person becomes bound to another to do something; as to pay a sum of money, be surety, or the like.

Obligations are of three kinds, viz. natural, civil, and mixed. Natural obligations are entirely founded on natural equity; civil obligation on civil authority alone, without any foundation in natural equity; and mixed obligations are those which, being founded on natural equity, are further enforced by a civil authority.

In a legal sense, obligation signifies a bond, wherein is contained a penalty, with a condition annexed for the payment of money, &c. The difference between it and a bill is, that the latter is generally without a penalty or condition, though it may be made obligatory: and obligations are sometimes by matter of record, as statutes and recognizances. See the article BOND.

Moral Obligation. See Moral Philosophy, p. 58, &c.

OBLIQUE, in geometry, something slanting, or that diviates from the perpendicular. Thus an oblique angle is either an acute or obtuse one, i.e. any angle except a right one.

Obligue Cases, in grammar, are all the cases except the nominative. See GRAMMAR.

OBLIGE LINE, that which, falling on another line, makes oblique angles with it, viz. one acute, and the other obtuse.

Obligue Planes, in dialling, are those which decline from the zenith, or incline towards the horizon. See DIAL.

Obligue Sailing, in navigation, is when a ship falls upon some rhumb between the four cardinal points, making an oblique angle with the meridian; in which case the continually changes both latitude and longitude. See NAVIGATION, chap. 8.

OBLIQUUS, in anatomy, a name given to several muscles, particularly in the head, eyes, and abdomen. See ANATOMY, Table of the muscles.

OBLONG, in general, denotes a figure that is longer than broad: such is a parallelogram.

OBOLARIA, in botany: A genus of the angiospermous order, belonging to the gymnosperms class of plants; and in the natural method ranking under the 20th order, Poacina. The calyx is bisected: the corolla, campanulate and quadridit: the capsule unilocular, livalved, and polysemente; the stamina rising from the divisions of the corolla.

OBOLUS, an ancient silver money of Athens, the sixth part of a drachma: worth somewhat more than a penny.
penny-farthling Stirling.—The word comes from the Greek σπιτ or σπιτ, “spit or brooch,” either because it bore such an impression; or because, according to Euthubius, it was in form thereof. But those now in the cabinets of the antiquaries are round. Osobus, in medicine, is used for a weight of ten grains, or half a scruple.

Obotus, an encampment of the Hebrews in the wilderness. From Puseon they went to Oboth, and from Oboth to Je-abarim, (Numb. xxxi. 10, xxxii. 43.) Ptolemy speaks of a city called Oboda, or Ebdos, in Arabia Petraea, which is the same as Oboth. Pliny and the geographer Stephanus mentions it also. Stephanus makes it belong to the Nabathaeans, and Pliny to the Helmodaeans, a people of Arabia. It was at Oboth that they worshipped the god Obodos, which Tertullian joins with Dufares, another god or king of the country.

Obrecht (Ulie), a learned German, born of a noble family at Strabburg in 1646, where he filled the chairs of civil law and history with great distinction. He was of the Protestant religion; but when Louis XIV. made himself master of Straburg, and went there with his court, he was prevailed on to change; and accordingly abjured in 1684, and put his instrument into the bands of Bishop of Meaux. The next year the king nominated him to preside in his history. There he spent twenty years in observing the stars; the result is his catalogue.

1. The Paris observatory, built by the order of Louis XIV. in the Faubourg of St Jacques. It is a very singular, but withal a very magnificent building, the design of Monfieur Perault; it is 80 feet high; and at top is a terrace. The difference in longitude between this and the Greenwich observatory is 2° 20′.

2. Tycho Brahe's observatory, which was in the little island Ween, or Scarlet island, between the coasts of Schonen and Zealand in the Baltic. It was erected and furnished with instruments at his own expense, and called by him Uraniborg. Here he spent several years in observing the stars; the result is his catalogue.

3. Pekin observatory. Father Le Compte describes a very magnificent observatory, erected and furnished by the late emperor of China, in his capital, at the intercession of some Jesuit missionaries, principally Father Verbeust, whom he made his chief observer. The instruments are exceedingly large; but the division less accurate, and the contrivance in some respects less commodious, than that of the Europeans. The chief are, An armillary zodiacal sphere of fix feet diameter; an equinoctial sphere of fix feet diameter; an azimuthal horizon of fix feet diameter; a large quadrant fix feet radius; a sextant eight feet radius; and a celestial globe fix feet diameter.

Observatories, as they are very useful, and indeed absolutely necessary for astronomers, so they have become far more common than they were. There is a very excellent one now at Oxford, built by the trustees of Dr Radcliffe, at the expense of nearly 30,000 l. At Cambridge, there is as yet no public observatory. Over the great gate of Trinity College, indeed there is one which is called Sir Isaac Newton’s, because this great philosopher had used it; but it is gone to decay. It were well if the university would repair and preserve it in memory of that truly great man. In St John’s, too, there is a small one. The late ingenious Mr Cotes had used to give lectures in Sir Isaac Newton’s on experimental philosophy. There are several very good ones in the Scotch universities; and there is an excellent one lately erected at Dublin.

5. Bramins observatory at Benares. Of this Sir Robert Barker gives the following account (Phil. Trans. Vol. LXVII. p. 598.) “Benares in the East Indies, one of the principal seminaries of the Bramins or priests of the original Gentoo of Hindoostan, continues still to be the place of resort of that sect of people; and there are many public charities, hospitals, and pagodas, where some thousands of them now reside. Having frequently heard that the ancient Bramins had a knowledge of astronomy, and being confirmed in this by their information of an approaching eclipse both of the sun and moon, I made inquiry, when at that place in the year 1772, among the principal Bramins, to endeavour to get some information relative to the manner in which they were acquainted of an approaching eclipse. The most intelligent that I could meet with, however, gave me but little satisfaction. I was told, that these matters were confined to a few, who were in possession of certain books and records; some containing the mysteries...

Observation.

series of their religion; and others the tables of astronomical observations, written in the Sanscrit language, which few understood but themselves: that they would take me to a place which had been

in the Shandrit language, which few understood but themselves: that they would take me to a place which had been

condemned for the purpose of making such observations as I was in my letter, and from whence they supposed the learned Brahmans made the rs. I was then

condemned to an ancient building of stone, the lower part of which, in its present situation, was converted

into a stable for horses, and a receptacle for lumber; but, by the number of court-yards and apartments, it

appeared that it must once have been an edifice for the use of some public body of people. We entered

this building, and went up a stair-case to the top of a part of it, near to the river Ganges, that led to a

large terrace, where, to my surprise, I saw a

instrument has been completed, at the

point. In the

original position; and I saw that the line of the gnomon,

that, by applying the eye to a small iron ring of

an inch diameter at one end, the light is carried through

three others of the same dimension, to the extremity

at the other end, distant 38 feet 8 inches, without

obstruction: such is the firmness and art with which this

instrument has been executed. This performance is

the more wonderful and extraordinary when compared

with the works of the architects of Mahaballin at this
day, who are not under the immediate direction of an

European mechanic; but arts appear to have declined

equally with science in the east.

 Lieutenant colonel Archibald Campbell, at that
time chief engineer in the East India Company's
service at Bengal, made a perspicuous drawing of
the whole of the apparatus that could be brought within
his eye at one view; but I lament he could not re-

present some very large quadrants, whole radii were
about twenty feet, they being on the side from whence
he took his drawing. Their description however is,
that they are exact circles of different radii; the largest of which I judged to be 20 feet, construted very exactly on the sides of stone-walls, built perpendicular, and situated, I suppose, in the meridian of the place: a brass pin is fixed at the

centre or angle of the quadrant, from whence, the

Brahmin informed me, they stretched a wire to the

circumference when an observation was to be made;

from which it occurred to me, the observer must have

moved his eye up or down the circumference, by means

of a ladder or some other contrivance, to raise and

lower himself, until he had discovered the altitude of

any of the heavenly bodies in their passage over

the meridian, so expressed on the arcs of their quadrants:

these arcs were very exactly divided into nine large

sections; each of which again into ten, making ninety

lesser divisions or degrees; and these into twenty,

expressing three minutes each, of about two-tenths

of an inch in diameter; so that it is probable they had

some method of dividing these into more minute

divisions at the time of observation.

"My time would only permit me to take down the

particular dimensions of the most capital instrument,

or the greater equinoctial sundial, represented by

figure a, which appears to be an instrument to expres-

solar time by the shadow of a gnomon upon two

quadrants, one situated to the east, and the other to

the west of it; and indeed the chief part of their instru-

ments at this place appear to be constructed for the

same purpose, except the quadrants, and a brass in-

strument will be described hereafter.

"Figure a is another instrument for the purpose

of determining the exact hour of the day by the sha-

dow of a gnomon, which stands perpendicular to, and

in the centre of, a flat circular stone, supported in an

oblique situation by means of four upright stones and

crofs-piece; so that the shadow of the gnomon, which

is a perpendicular iron-rod, is thrown upon the divi-

sion of the circle described on the face of the flat cir-

cular stone.

"Figure c is a brass circle, about two feet diam-
ter, moving vertically upon two piers between two

tone pillars, having an index or hand turning round

everally on the centre of this circle, which is

divided into 360 parts; but these are no counter

divisions on the index to subdivide those on the circle.

This instrument appears to be made for taking the

angle of a star at setting or rising, or for taking the

azimuth or amplitude of the sun at rising or setting.

"The use of the instrument, figure d, I was at a loss
to account for. It consists of two circular walls: the

cuts of which is about 70 feet diameter, and eight

feet high; the wall within about half that height,

and appears intended for a place to stand on to ob-

serve the division on the upper circle of the outer

wall, rather than for any other purpose: and yet both

circles are divided into 360 degrees, each degree be-

ing subdivided into twenty lesser divisions, the same

as the quadrants. There is a door way to pass into

the inner circle, and a pillar in the centre, of the same

height with the lower circle, having a hole in it, being

the centre of both circles, and seems to be a socket

for an iron rod to be placed perpendicular into it.

The divisions on these, as well as all the other ins-

truments, will bear a fine examination with a pair of

compasses.

"Figure e is a smaller equinoctial sundial, con-

structed upon the same principle as the large one.

I cannot quit this subject without observing,

that the Brahmans, without the assistance of optical

glases,
OBY [ 176 ] OCC

OBY, or Oby, a large and famous river of Afiatic Russia, which issues from the Altai lake (called by the Russians Tcheli Ogra), in latitude 52 degrees, and longitude 105 degrees. Its name signifies Great; and accordingly in Russia it is often styled the Great River. The Calmucks and Tartars call it Uman. Its stream is very large and smooth, its current being usually slow; and it is in general between two and three hundred fathoms broad; though in some places it is much wider. It affords plenty of fish, and is navigable almost to the lake from which it springs. After a long winding course through a vast tract of land, in which it forms several islands, it empties itself into the sea, having a bay, which, extending near 40 miles further, joins the Sea of Japan in latitude 53 30, and longitude 90. The springs from which this river rises, are not very copious; but it receives in its course the waters of a great number of considerable streams. Of these, the Tom and the Irty are the most considerable; the Tom falls into it in Lat. 50, and the Irty in Lat. 61, and Long. 86. The exact course of this river was unknown, till the country was surveyed by the Russians; who have given us tolerable maps of it, and of all Siberia. The Oby forms the boundary between Europe and Asia, and its course is upwards of 2000 miles in length.

OCCIDENT, in geography, the westward quarter of the horizon; or that part of the horizon where the eclipste, or the sun therein, descends into the lower hemisphere; in contradistinction to orient. Hence we use the word accidental for any thing belonging to the west; as accidental benefit, accidental pearl, &c.

OCCIPITAL, in anatomy, a term applied to the parts of the occiput, or back part of the skull.

OCCULT, something hidden, secret, or invisible. The occult sciences are magic, necromancy, cabal, &c. Occult qualities, in philosophy, were those qualities of body or spirit which baffled the investigation of philosophers, and for which they were unable to give any reason: unwilling however to acknowledge their ignorance, they deceived themselves, and the vulgar by an empty title, calling what they did not know occult.

OCCULTATION, in astronomy, the time a star or planet is hid from our sight, by the interposition of the body of the moon or some other planet.

OCCUPANCY, in law, is the taking possession of those things which before belonged to nobody. This Black's true special ground and foundation of all property, or of holding those things in sevency, which by the law of nature, unqualified by that of society, were common to all mankind. But, when once it was agreed that every thing capable of ownership should have an owner, natural reason suggested, that he who could first declare his intention of appropriating any thing to his own use, and, in consequence of such his intention, actually took it into possession, should thereby gain the absolute property of it, according to that rule of the law of nations, recognized by the laws of Rome, quod nullius est, id retine natura occupant condidit.

The right of occupancy, so far as it concerns real property, hath been confined by the laws of England within a very narrow compass; and was extended only to a single instance; namely, where a man was tenant pour aures, &c., or had an estate granted to himlonely (without mentioning his heirs) for the life of another man, and died during the life of ceflay que vie, or him by whole life it was held; in this case, he that could first enter on the land, might lawfully retain the possession so long as ceflay que vie lived by right of occupancy.

This seems to have been recurring to first principles, and calling in the law of nature to ascertain the property of the land, when left without a legal owner. For did it not revert to the grantee, who had parted with all his interest, so long as ceflay que vie lived; it did
Occupancy. did not escheat to the lord of the fee; for all escheats must be of the absolute entire fee, and not of any particular estate carved out of it, much less of a minute remainder as this: it did not belong to the grantee; for he was dead: it did not descend to his heirs; for there were no words of inheritance in the grant; nor could it vest in his executors; for no executors could succeed to a freehold. Belonging therefore to nobody, like the hereditas jacens of the Romans, the law left it open to be seized and appropriated by the first person that could enter upon it, during the life of egena que vice, under the name of an occupant. But there was no right of occupancy allowed, where the king had the reversion of lands: for the reverfioner had an equal right with any other man to enter upon the vacant possession; and where the king’s title and a subject’s interfere, the king’s shall always be preferred. Against the king therefore there could be no prior occupant, because nullum tempus occupatur regi.

And, even in the case of a subject, had the estate pour auire vie granted to a man and his heirs during the life of egena que vice, there the heir might, and still may, enter and hold possession, and is called in law a special occupant; as having a special exclusive right, by the terms of the original grant, to enter upon and occupy this hereditas jacens, during the residue of the estate granted: though some have thought him called with no very great propriety; and that such estate is rather a definable freehold. But the title of common occupancy is now reduced almost to nothing by two statutes; the one, 29 Car. II. c. 3. which enacted, that where there is no special occupant, in whom the estate may vest, the tenant pour auire vit may divide it by will, or it shall go to the executors, and be affets in their hands for payment of debts: the other that of 14 Geo. II. c. 20. which enacted, that it shall vest not only in the executors, but, in case the tenant dies intestate, in the administrators also; and go in course of a distribution like a chattel interest. By these two statutes the title of common occupancy is utterly extinct and abolished; though that of special occupancy by the heir at law, continues to this day: such heir being held to succeed to the ancestor’s estate, not by descent, for then he must take an estate of inheritance, but as an occupant, specially marked out and appointed by the original grant. The doctrine of common occupancy may, however, be usefully remembered on the following account, amongst others: That, as by the common law no occupancy could be of incorporeal hereditaments, as of rents, tithes, advowsons, commons, or the like (because, with respect to them, there could be no actual entry made, or corporeal feisin had; and therefore by the death of the grantee pour auire vit a grant of such hereditaments was entirely determined): fo now, it is apprehended, notwithstanding these stipulations, such grant would be determined likewise; and the hereditaments could not be devisable, nor vest in the executors, nor go in a course of distribution. For the statutes must not be confined so as to create any new estate, or to keep that alive which by the common law was determined, and thereby to defeat the grantees’ reversion; but merely to dispose of an interest in being, to which by law there was no owner, and which therefore was left open to the first occupant. When there is a refidue

left, the statutes give it to the executors, &c. instead of the first occupant: but they will not create a residue on purpose to give it to the execution. They only mean to provide an appointed instead of a caerus, a certain instead of an uncertain, owner, of lands or which before were nobody’s, and thereby to supply this caerus nullius, and render the disposition of the law, in all respects entirely uniform: this being the only instance wherein a title to a real estate could ever be acquired by occupancy.

For there can be no other case devised, wherein there is not some owner of the land appointed by the law. In the case of a sole corporation, as a parson of a church, when he dies or resigns, though there be no actual owner of the land till a successor be appointed, yet there is a legal, potential, ownership, subsisting in contemplation of law; and when the successor is appointed, his appointment shall have a retrospective and relation backwards, so as to intitle him to all the profits from the intestine that the vacancy commenced.

And, in all other instances, when the tenant dies intestate, and no other owner of the lands is to be found in the common course of descent, there the law vests an ownership in the king, or in the subordinate lord of the fee, by escheat.

So also, in some cases, where the laws of other nations give a right by occupancy, as in lands newly created, by the rising of an island in a river, or by the allusion or dereliction of the sea; in these instances, the law of England assigns them an immediate owner. For Bredon tells us, that if an island arise in the middle of a river, it belongs to those who have lands on each side thereof; but if it be nearer to one bank than the other, it belongs only to him who is proprietor of the nearest shore: which is agreeable to, and probably copied from, the civil law. Yet this seems only to be reasonable, where the soil of the river is equally divided between the owners of the opposite shores: for if the whole soil is the freehold of any one man, as must be whenever a several fishery is claimed, there it seems just (and so is the usual practice) that the iflets, or little islands, arising in any part of the river, shall be the property of him who owns the piscary and the soil. However, in case a new island rise in the sea, though the civil law gives it to the first occupant, yet the law of England gives it to the king. And as to the lands gained from the sea, either by alluvion, by the washing up of sand and earth, so as to make terra firma; or by dereliction, as when the sea shrinks back below the usual water-mark: in these cases the law is held to be, that if this gain be by little and little, by small and imperceptible degrees, it shall go to the owner of the land adjoining. For de minimis non curat lex: and, besides, these owners being often liers by the breaking in of the sea, or at charges to keep it out, this possible gain is therefore a reciprocal consideration for such possible charge or loss. But if the allusion or dereliction be sudden and considerable, in this case it belongs to the king: for, as the king is lord of the sea, and so owner of the soil while it is covered with water, it is but reasonable he should have the soil when the water has left it dry. So that the quantity of ground gained, and the time during which it is gained, are what make it either the king’s or the subject’s property. In the same manner,
OCEANUS, in Pagan mythology, the son of Cerys and Terra, the husband of Theiss, and the father of the rivers and fountains, called Oceanides. The ancients called him the Father of all things, imagining that he was produced by Humidity, which, according to Thales, was the first principle from which every thing was produced. Homer represents Juno visiting him at the remotest limits of the earth, and acknowledging him and Theiss as the parents of the gods. He was represented with the bull's head, as an emblem of the rage and bellowing of the ocean when agitated by a storm.

According to Homer, he was the father even of all the gods, and on that account he received frequent visits from them. He is often, indeed almost always, represented as an old man with a long flowing beard, and sitting upon the waves of the sea. He often holds a pike in his hand, while ships under sail appear at a distance, or a sea monster flounders near him. Oceanus prefided over every part of the sea, and even the rivers were subjected to his power. The ancients were superstitious in their worship of him, and revered with great solemnity a deity to whose care they entrusted themselves when going on any voyage.

OCelia, a woman who prefided over the sacred rites of Vesta for 57 years with the greatest fidelity. She died in the reign of Tiberius, and the daughter of Domitian succeeded her.

Ocellus the Lucanian, an ancient Greek philosopher of the school of Pythagoras, who lived before Plato. His work ulla et parvis or "The Univerfe," is the only piece of his which is come down entire to us; and was written originally in the Doric dialect, but was translated by another hand into the Attic. William Christian, and after him Lewis Nogaroila, translated this work into Latin; and we have several editions of it, both in Greek and Latin.

Ocellot, the Mexican cat. See Felis.

Oceloxochitl, or Tyger-flower, in botany: A large Mexican plant, composed of three pointed petals, red, but towards the middle of a mixed white and yellow, representing in some degree the spots of that wild animal from which it takes its name. The plant has leaves also resembling those of the iris, and a bulbous root. See plate CCCXLIX.

Ochinus (Bernadin) a celebrated Italian, was born at Seine in 1487, and first became a Cordelier; but he quickly returned into the world, applied himself to the study of physic, and acquired the esteem of cardinal Julius de Medicis, afterwards Pope Clement VII. At length, again changing his mind, he refused...
med his monk's habit in a penitential mood; and not content with this, but aiming at higher perfection, he embraced in 1534, the reformed sect of the Capuchins. He practised, with a most rigorous exactness, all the rules of the order; and, being then in its infancy, he contributed so much to improve and enlarge, that some writers have called him the founder of it. He was certainly made vicar-general of it, and became in the highest degree eminent for his pulpit eloquence. He delivered his sermons with so much grace and politeness, and spoke so copiously, that he ravished his audience wherever he was; never indeed was a man more successful or more applauded. His extraordinary merit procured him the favour of Pope Paul III. who, it is said, made him his father confessor and preacher.

He was thus the darling both of prince and people; when, falling into the company of one John Valde a Spaniard, who had imbibed Luther's doctrine in Germany, he became a profylete. He was then at Naples, and began to preach in favour of Protestantism; which being observed, he was summoned to appear at Rome; and was in his way thither when he met at Florence Ochinus, the public minister of an Italian church which was gainst the popes power, and they both agreed to withdraw to themselves in the dress of soldiers; and proceeding thence to Ferrara, where he disguised himself in the dress of a soldier; and proceeding thence to Geneva, arrived there in 1542, and married a woman of Lucca. He did act, however, settle there, but went to Augsburg, where he published some sermons.

In 1547 he was invited, together with Peter Martyr, into England by Archbishop Cranmer, that he might have their joint affiliation in carrying on the reformation. They arrived in December; and going to Lambeth, were kindly received by Cranmer. They were entertained there for some time; and Ochinus, as well as Martyr, was made a prebendary of Canterbury. He laboured heartily in the conduct of the reformation; and his dialogue upon the unjust usurped primacy of the bishop of Rome, was translated into Latin by Pontius bishop of Winchelsea, and published in 1549. But upon the death of Edward VI. being forced as well as Martyr to leave England, they retired to Strasbourg, where they arrived in 1553. From this city Ochinus went to Basil; and was invited thence in 1555 to Zurich, to be minister of an Italian church which was gathering there. This church consisted of some refugees from Locarno, one of the four bailiwicks which the Switzers poise in Italy: they being hindered from the public exercise of the reformed religion by the opposition of the Popish cantons. Ochinus had no difficulty to subcribe the articles of faith agreed upon by the church of Zurich, and met in that city with Bullinger, who proved a very good friend to him. He governed this Italian church till 1553, when he was banished thence by the magistrates of the town for publishing some dialogues wherein he defended the doctrine of monogamy. From Zurich he went to Basal; but not being suffered to stay there, he fled in great distress into Moravia, where he fell in with the Socinians, and joined them. Stanislaus Lubienietz, the great patron of this sect, gives the following account of his last days in his Hist. Reformat. P. D. Ochinus, says he, retired into Moravia, and into Poland, and even there he was not out of the reach of Calvin's letters. He returned into Moravia after king Sigismund's edict; who in 1564 punished with banishment all those that were called Trithelit, Athelast, &c. Some gentlemen endeavoured to keep him in Poland; but he answered, that men must obey the magistrates, and that he would obey them, even were he to die among the wolves in the woods. During his travels, he fell sick of the plague at Pinccklow, and received there all possible offices of kindness from one of the brethren, named Philippovius. His daughter and two sons, whom he carried along with him, died of the plague; but he had buried his wife before he had left Zurich. As for himself, he continued his journey to Moravia, and within three weeks died at Skalow, in 1564, aged 77.

His character is variously represented by different authors, as was to be expected; for men like him have all manner of things, good and bad, said and written of them, by somebody or other. Bayle says, that the confession he made publicly, on the change of his religion, is remarkable. He acknowledged, in a preface, that if he could have continued, without danger of his life, to preach the truth, after the manner he had preached it for some years, he would never have hid down the habit of his order; but as he did not find within himself that courage which is requisite to undergo martyrdom, he took sanctuary in a Protestant country. His writings are numerous but not bulky.

OCHLOCRAZY, that form of government wherein, in the populace have the chief administration of affairs.

OCHNA, in botany: A genus of the monogynia order, belonging to the polyandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is pentametopous: the calyx pentamphylous; the berries monospermous, and affixed to a large roundish receptacle.

OCHRE, in natural history, a genus of earths, slightly coherent, and composed of fine, smooth, soft, argillaceous particles, rough to the touch, and readily dispersible in water. Oches are of various colours, as red, blue, yellow, brown, green, &c.

OCHROMA, in botany: A genus of the pentandria order, belonging to the monodelphus class of plants; and in the natural method ranking under the 37th order, Columnifereae. The corolla consists of six petals, three of which are external, and the other three internal; the anthers unite and form a spiral pillar round the stile; the capsule is long, and has five loculi, and contain a number of black round seeds. Of this there is only one species, viz. the ochroma lagoopus, the downy or corkwood. This tree is frequent in Jamaica; is of speedy growth, and rises to about 25 or 30 feet. The flowers are large and yellow. The capsules are about five inches long, round,

(1) According to Wood, Athen. Oxon. but it reds solely on his authority, so far as we know.
Ockham, a king of Persia, son of Artaxerxes. He was cruel and avaricious; and in order to strengthen himself on his throne, he murdered all his brothers and sisters. His subjects revolted; but he reduced them to obedience, and added Egypt to his other dominions. Bagas his favorite eunuch poisoned him for the infults he had offered to Apis the god of the Egyptians; and he gave his flesh to be eaten by cats, and made handles for knives with his bones. It seems to be not a little remarkable, that all those monsters who disgraced humanity by their crimes, and funk themselves below the level of brutes, have met with condign punishment; and this in general seems true, whether we refer to ancient or modern times.—A man of Cyzicus, who was killed by the Argonauts.—A prince of Persia, who refused to visit his native country for fear of giving every woman a piece of gold.—A river of India or of Babrians.—A king of Persia: He exchanged this name for that of Darius Nothus. See Persia.

Ockham, Occam, or Ockham (William of), was a celebrated scholastic divine in the 14th century, of the order of Cordeliers. He was a native of England, and disciple to the famous Duns Scotus. He was head of the Nominalists; and acquired so much celebrity, as to be denominated the Invincible Doctor.

At the request of Michael de Cefena, general of his order, he became a party-man with Lewis of Rivières, who was an avowed enemy of the church of Rome; and he really wrote vigorously against pope John XXII. and his successors. Trenchus informs us, that he used to say to Lewis, "My Lord, let your sword defend me, and my pen shall be always ready to support you." He treated Charles and Clement in a book he wrote against them with gross futility.

This, however, was a bold, dangerous, and imprudent step, and cannot well be defended on any proper principle. The effect of it, as might be expected, was an accusation against him and Cefena. They were charged with maintaining, that neither Christ nor his apostles had any possessions at all, either in common or as private property. This doctrine gave rise to that pleasant question called the bread of the Cordeliers; and confuted in determining, whether the dominion of things consumed in the use, such as bread and wine, belonged to them, or only the simple use of them, without the dominion? Their rule not permitting them, to have anything as property, Pope Nicolas III. who had been of their order, devised a method to enrich them, without breaking their rule. To this end he made an ordinance, that they should have only the usufruct of the estates which should be given to them, and that the soil and fund of all such donations should belong to the Roman church at large. By this means he gave them the possession of an almost infinite number of estates, in the name of the church of Rome; but on this account, Pope Nicolas's bull was revoked by John XXII. who condemned the use without the dominion, by his Extra.rogantia ad Condtjonem. He also condemned, by another Extra.rogantia commenditer, the doctrine about the possession of estates by Christ and his apostles. Ockham and Cefena were also excommunicated, because they had departed from Avignon without the pope's licence, and had written against him. Ockham, however, was absolved, as is said, from this censure before he died, which was about the year 1347.

We have several pieces of his, which are written with considerable wit and subtilty. The reformed church sometimes makes use of his reasoning against the church of Rome. Melchior Goldaft printed, in his treatise upon monarchy, 413 questions of Ockham. His works are mentioned by many authors.

Ockley (Simon), a learned orientalist, was born at Exeter in 1678, and educated at Queen's college, Cambridge, where he distinguished himself by his intents application to literature. At the usual time he took the degrees in arts, and that of bachelor in divinity; but marrying very young, was precluded from a fellowship in his college, and this occasioned his being afterwards involved in many difficulties. In 1705 he was prenticed to the vicarage of Swaseley in Cambridgeshire; and in 1711 he was chosen Arabic professor of the university. He was perfect master of the Arabic and other oriental tongues: the learned Religion said of him, "Viv, si quis alius harum literarum perfusurus." Afterwards, however, he had the misfortune to be confined for some time in Cambridge castle for debt. The above preferments, notwithstanding, he enjoyed till his death, which happened on the 9th of August 1720. He wrote, 1. Introductio ad Linguas Orientales. 2. The history of the present Jews throughout the world; translated from the Italian of Leo Modena, a Venetian rabbi. 3. The improvement of human reason, exhibited in the life of Hai Ebn Yorkdhan, translated from the Arabic. 4. An account of South-west Barbary, containing what is most remarkable in the kingdoms of Fez and Morocco; written by a person who had been a slave there a considerable time, and translated from his manuscript. 5. The history of the Saracens, collected from the most authentic Arabic authors, in 2 vols 8vo. He was not only well skilled in the learned languages, but also in the modern, as French, Spanish, Italian, &c.

Ocras, a vicious vegetable substance well known in the West Indies, where it is used to thicken soup, and for other purposes.

Ocrisia (Fab. fict.), the wife of Corniculus, was one of the attendants of Tanagui the wife of Tarquinius Priscus. As she was throwing into the flames for offerings some of the meats that were served on the table of Tarquin, the suddenly faw, as is reported, in the fire what Ovid calls aliant formam vivit. She informed the queen of it; and when by her command she had approached near it, she conceived a son who was named Servius Tullius, and was educated in the king's family. He afterwards succeeded to the va
Some suppose that Vulcan had assumed that form which was presented to the eyes of Octavia, and that this god was the father of the fifth king of Rome.

OCTAERIS, a cycle or term of eight years, in the Grecian chronology, at the conclusion of which three entire lunar months were added. This cycle was in use till Meteor's invention of the golden number or cycle of 19 years.

OCTAGONAL, or OCTAGON, in geometry, is a figure of eight sides and angles; and this, when all the sides and angles are equal, is called a regular octagon, or one that may be inscribed in a circle.

OCTAHEDRON, or OCTAHEDRON, in geometry, one of the five regular bodies, consisting of eight equal and equilateral triangles.

OCTANDRIA (οκτάδρια, "eight," and ἄριος, a "man, or husband," the 8th clas in Linnaeus's sexual system, consisting of plants with hermaphroditic flowers, which are furnished with eight stamens, or male organs of generation. See BOTANY, p. 430.

OCTANT, or OCTILE, in astronomy, that aspect of two planets, wherein they are distant an eighth part of a circle, or 45° from each other.

OCTAPLAX, in matters of sacred literature, denotes a polyglot bible, consisting of eight columns, and as many different versions of the sacred text; viz. the original Hebrew both in Hebrew and Greek characters, Greek versions, &c.

OCTAVE, in music. See INTERVAL.

OCTAVIA, daughter of Caius Octavius and sister to Augustus Caesar. See the following article. She was one of the most illustrious ladies of ancient Rome; her virtues and her beauty were equally conspicuous. Prideaux says she was much handier than Cleopatra. She married Claudius Marcellus, and after his death M. Antony. Her marriage with Antony was a political match, to reconcile her brother and him together. Antony proved for some time attentive to her; but when he had seen Cleopatra, he neglected and despised her; and when he attempted to withdraw him from this illegal amour by going to meet him at Athens, she was rebuked and totally banished from his presence. This affront was highly resented by her brother; and though Octavia endeavoured to pacify him by palliating Antony's behaviour, yet he resolved to revenge her wrongs by arms. After the battle of Actium and the death of Antony, Octavia, forgetful of her own injuries, took into her house all the children of her husband, and treated them with extraordinary tenderness. Marcellus, her son by her first husband, was married to a niece of Augustus, and openly intended as a successor to his uncle. His sudden death plunged all the family into the greatest grief. Virgilius, whom Augustus patronized, undertook of himself to pay a melancholy tribute to the memory of a young man whom Rome had looked upon as her future father and patron. He was desired to repeat his composition in the presence of the emperor and his sisters. Octavia burst into tears even when the poet began; but when he mentioned Tu Marcellus Octavius, et alia, she swooned away. This tender and pathetic encomium upon the merit and the virtues of young Marcellus the liberally rewarded, and Virgilius received 10,000 talents, according to some L. 728: 2: 5, for every one of the verses. Octavia had two daughters by Antony, Antonia Major and Antonia Minor. The elder married L. Domitian Aemilius, by whom she had Cn. Domitius, who was the father of the Emperor Nero by Agrippina the daughter of Germanicus, and Antonia Minor, who was as beautiful as her mother, married Drusus the son of Tiberius, by whom she had Germanicus and Claudius, who reigned before Nero. The death of Marcellus constantly preyed upon the mind of Octavia, who died of grief or melancholy, about 11 years before the Christian era. Her brother paid great regard to her memory, and pronounced her funeral oration himself. The Roman people also showed their regard for her virtues, by wishing to pay her divine honours.—A daughter of the emperor Claudius by Messalina. She was betrothed to Silanus, but by the intrigues of Agrippina, she was married to the Emperor Nero in the 16th year of his age. She was soon after divorced under pretence of barrenness; and the emperor married Poppaea, who exercised her enmity upon Octavia by procuring her to be banished into Campania. She was afterwards recalled by the people; but Poppaea, who was determined on her ruin, caused her again to be banished to an island, where she was ordered to kill herself by opening her veins. Her head was cut off and carried to Poppaea.

OCTAVIANUS, or OCTAVIUS Cæsar, was nephew of Julius Caesar the dictator, being the son of Accia his brother by Octavia a senator, and afterwards became the second emperor of Rome. He was born in the year of the city 691, during the consulship of Cicero. His uncle Julius Cæsar adopted him, and left him the greatest share of his fortune. When he was but 20 years of age, he was raised to the consulship. His youth and inexperience were ridiculed by his enemies; notwithstanding which obstacle, his prudence and valour raised his consequence. He made war against his opponents on pretence of avenging the affillation of his uncle. He engaged in five civil wars with great success, viz. The wars of Mutina, Perusia, Filippic, Sicily, and Actium: the first and last of which were against M. Antony: the second against L. Antony brother of the triumvir; the third was against Brutus and Cassius; and the fourth against Sext. Pompey, son of Pompey the Great. He united his forces with Antony's at the battle of Philippi; and had he not been supported by the activity and bravery of his colleague, he would doubtless have been totally ruined in that engagement. In his triumvirate with Antony and Lepidus, he obtained the western parts of the Roman empire; and, like his other colleagues, more firmly to establish his power, he proscribed his enemies and cut them off. The triumvirate lasted for 10 years. He had given his sister Octavia in marriage to Antony, to make their alliance more lasting; but when Cleopatra had charmed this unfortunate man, Octavia was repudiated. Augustus immediately took up arms to avenge the wrongs of his sister; but perhaps more

more eagerly to remove a man whose power and ex-
sistence kept him in continual fear and constant de-
pendence. Both parties met at Ægium to decide the
fate of Rome. Antony was supported by all the
power of the east, and Augustus by Italy. Cleopa-
tria fled from the battle with 60 ships, and her flight
ruined the interest of Antony, who followed her into
Egypt. The conqueror soon after went into Egypt, he
like Cæsar besieged Alexandria, and honoured with a
magnificent funeral his unfortunate colleague and the cele-
brated queen, whom the fear of being led in the victor's
triumph at Rome had driven to commit suicide. Af-
fter he had established peace all over the world, he shut
the gates of the the temple of Janus, A. U. C. 753. He
was twice determined to lay down the supreme power
immediately after the victory obtained over Antony,
and on account of his ill health; but his two faithful
friends Mecenas and Agrippa dissuaded him, and
contended, that if he did he would leave it to be the
greatest of his age, after he theazgl. The

OCTOSTYLE, in the ancient architecture, is the
face of an edifice adorned with eight columns.

OCULUS, the eye, in anatomy. See there, no 142.

OCYCLUS Beli, in natural history, one of the semi-

crystals of a greenish white colour, variegated

with yellow and with a black central nucleus: it

is of a roundish form, and its variegations very beauti-
fically represent the pupil and iris of the eye; whence

the name.

OCYXUS Mundii, or Lapis Mutabilis. See HYD-

ROPHAKES.

OCYNYMUM, basil; a genus of the gymnospermae
order, belonging to thedidynamia class of plants; and

in the natural method ranking under the 42d order, Ver-
ticulata. The upper lip of the calyx is orbiculated,

the inferior one quadriangled; the corolla is repulsi-

ated, with one lip quadriangled, the other undivided; the

ter filaments send out a reflected proces at the base.

There are eight species, all of them natives of warm

climates, rising from six inches to two feet in height,

and have a strong aromatic smell, resembling that of
cloves. One of the species is used in the kitchen, par-

ticularly by the French cooks, who make great use of

it in their soups and sauces. This rises about ten

inches high, sending out branches by pairs opposite,

from the bottom; the flanks and branches are four-

cornered; the leaves are oval, spear-shaped, ending in

acute points, and are indented on their edges; the

whole plant is hairy, and has a strong scent of cloves
too powerful for most persons, but to some it is very

good agreeable. These plants are propagated by seeds,

and will thrive in this country in the open air, and will even

ripen their seeds if placed in a stove or airy glass-cabinet.

OCZAKOW, or Oczakoff, a Town of Turkey in

Europe, and capital of Sanjock of the same name,
inhabited by Tartars. During a late war, here was a

Turkish garrison of 20,000 men. However, it was ta-

ken by the Russians in 1737, and all those that resisted

were put to the sword. The Russians themselves left

18,000
O C Z A K O W 18,000 men in the assault. The Turks returned the same year with 70,000 men to retake it; but were obliged to retire, after the loss of 20,000. In 1758, the Russians withdrew their garrison, and demolished the fortifications. It is seated on the river Bog, to the west of the Niemer, or rather where they both unite and fall into the Black Sea. It is 42 miles south-west of Bialagrod, and 150 north by east of Constantinople. It has been lately a subject of great contest between the Russians and Turks. The affair is fresh in our readers' memories; but the following more particular account of the place, will not, we trust, be unacceptable to our readers. It is called by the Turks Dneaf Cremenets, is seated at the mouth of the Niemer into the Black Sea, 120 miles from Bender, to the south-east. The river is here above a mile broad. Either the Turkish galleys retire which guard the mouth of the river, to prevent the Cossacks from pirating upon the Black Sea. Here is no port, but good anchorage. It is defended by a castle, surrounded with walls 25 feet high; those of the town are much lower. There are about 2000 people at Oczakow. Below the castle are two towns or suburbs, situated on the declivity of a hill, which on the other side has nothing but precipices. To the south of these towns is another small castle, where is some artillery to prevent vessels from coming up the river. Here is also a tower, in which are always some Turks upon the watch to discover from afar any of the Cossacks at sea, and give notice of them to the galleys by a signal. The city is inhabited by Tartars though garrisoned by Turks. E. Long. 30° 50'. N. Lat. 46° 50'.

Oczakow is in the Turkish seraglio, signifies a class, or chamber. The grand signior's pages are under the command of the kilardgi-bachi, and serve in the grand fignonier's bed-chamber, which, besides their other exercises, are under the command of the kirargi-bachi, and serve in the pantry and fruitery. The fourth consists only of 24, who are under the command of the khazineda-bachi, and have charge of the treasure in the grand signior's apartment, which they never enter with cloaths that have pockets. The fifth is called kas odas or privy-chamber; and is composed of only 45 pages who attend in the prince's chamber. Every night eight of these pages keep guard in the grand signior's bed-chamber, while he sleeps: they take care that the light, which is constantly kept in the room, does not glare in his eyes, lest it should awake him: and if they find him disturbed with troublesome dreams, they cause him to be awaked by one of their agas.

Ozakow, or Oddabashi, an officer in the Turkish soldiery, equivalent to a serjeant or corporal among us. The common soldiery and janizaries, called oldasha, after having served a certain term of years, are always preferred and made biquelars; and of biquelars in time become odobachis, i. e. corporals of companies, or chiefs of certain divisions, whose number is not fixed: being sometimes ten, and sometimes twenty. Their pay is six doubles per month; and they are distinguished by a large felt, a foot broad and above a foot long, hanging on the back, with two long offich feathers.

ODE, in poetry, a song, or composition proper to be sung. See Poetry.

Oded, a prophet of the Lord, who was at Samaria, when the Israelites, of the ten tribes returned from the war, with their king Pekah, together with 200,000 of the people of Judah, captives, he went out to meet them, and said, "You have kept that the Lord God of your fathers was in wrath against Judah; he has therefore delivered them into your hands, and you have slain them inhumanly, so that your cruelty has ascended up into heaven; and more than this, you would make slaves of the children of Judah, who are your brethren, and would add this sin to the many others you have committed: therefore, hear the counsel that I give you; send back these captives, left the Lord should pour out his fury upon you." Oded having done speaking, some of the chiefs of Samaria concurred in him, and by their remonstrances prevailed with the Israelites to set the captives at liberty (2 Chron. xxviii.) See Ahaz.

The enlargement of the captives being obtained, the principal men of Samaria took care of them, gave them cloaths and food and other necessaries. After which they furnished them with horses, because the greatest part of them were so tired and exhausted that they were not able to walk. Thus they conducted them to Jericho, which was in the confines of the land of Judah. This is all that is come to our knowledge concerning the prophet Oded.

ODENSE, the capital of the isle of Funen, a place of such high antiquity, that some Danish writers derive its foundation and name from Oden, the god and hero of the Gothic nations. "Its name certainly occurs (says Mr Cox) in the earliest ages of the Danish history; and it was a town of great note long before Copenhagen existed. Odense stands upon a small river, not navigable, and about two miles from the bay of Stegebrand. Many of the houses are ancient, bearing dates about the middle of the 16th century; but part is newly built: it contains about 5200 inhabitants, who carry on some commerce, exporting chiefly grain and leather; the latter is much esteemed, and its goodness is supposed to arise from a certain property in the river water, in which it is soaked for tanning. The Danish cavalry are supplied from thence with the greatest part of their leather accoutrements."

"Odense is the seat of a bishop, which was founded by Harald Blaatsand in 980, and is the richest in Denmark next to Copenhagen. It has a school, endowed by the celebrated Margaret of Valdemar, in which a certain number of scholars, from six to 16 years of age, are instructed gratis; they live and board in the town, and each receives a yearly pension; other scholarships have been also founded by private persons. The whole number amounted to 70. There is also a gymnasium, instituted by Christian IV. for the admission of students at the age of 16. This seminary was
ODENATUS, a celebrated prince of Palmyra. He very early incurred himself to bear fatigues, and by hunting leopards, and wild beasts, accustomed himself to the labours of a military life. He was a faithful friend to the Romans; and when Aurelian had been taken prisoner by Sapor king of Persia, Odenatus warmly interested himself in his escape, and solicited his release, by writing to the conqueror, and by sending him presents. The king of Persia was offended at this liberty of Odenatus, he tore the epistle out of his hand, and ordered the presents that were offered to be thrown into a river; and in order to punish Odenatus, who had the impudence, as he called it, to pay homage to fo great a monarch as himself, he commanded him one Mimer, whom he had offended at that liberty of Odenatus, to tore the coroposing out of his hand. Having subdued Denmark, and on the changing himself into the shape of a bear, a wild bull, or a lion, and amidst ranks of enemies committing the most horrible devastation, without receiving any wound himself.

Dr Henry gives this account of him: "Odin is believed to have been the name of the one true God among the first colonies who came from the east and ten, vol. ii. people Germany and Scandinavia, and among their posterity for several ages. But at length a mighty conqueror, the leader of a new army of adventurers from the east, over-ran the north of Europe, ered a great empire, affirmed the name of Odin, and claimed the honours which had been formerly paid to that deity. From thenceforward this defiled mortal, under the name of Odin or Woden, became the chief object of the idolatrous worship of the Saxons and Danes in this island, as well as of many other nations. Having been a mighty and successful warrior, he was believed to be the god of war, who gave victory, and revived
revived courage in the conflict. Having civilized, in some measure, the countries which he conquered, and introduced arts formerly unknown, he was also worshiped as the god of arts and artists. In a word to this Odin his devoted worshippers impiously ascribed all the attributes which belong only to the true God; to him, they built magnificent temples, offered many sacrifices, and consecrated the fourth day of the week, which is still called by his name in England and in all the other countries where he was formerly worshiped. Notwithstanding all this, the founders of all the kingdoms of the Anglo-Saxon heptarchy pretended to be descended from Oodin, and some of them at the distance only of a few generations.

Odin's Fire. We have this account of it in Gough's Camb. len., "In Evie parish, in the Orkneys, near the sea are some rocks, which frequently in the night appear on fire: and the church of St Michael there was often seen full of lights, called fires sent by Odin to guard their tombs, but now ceased. This my be a meteor, or some inflammable matter on the cliffs, as at Charmouth, Dorset."

ODINUS, a celebrated hero of antiquity, who flourished about 70 years before the Christian era, in the northern parts of ancient Germany, or in the modern kingdom of Denmark. He was at the same time a priest, a soldier, a poet, a monarch, and a victor. He imposed upon the credulity of his suppliant countrymen, and made them believe that he could raise the dead, and that he was acquainted with futurity. When he had extended his power, and increased his fame by conquest and by artifice, he determined to die in a different way from other men. He assembled his friends, and with the sharp point of a lance he made in his body nine different wounds in the form of a circle; and when expiring he declared that he was going to Scythia, where he would become an immortal god. He added, that he would prepare bliss and felicity for his James, when he had the authority, and with his own power, to order the destruction of his country and nation. This was the origin of the custom of the Scyths, who, when they engaged in battle, and they entreated him to receive their souls of such as fell in war.

De Odio et Aitia. See False Imprisonment.

The writ de odio et aitia was anciently used to be directed to the sheriff, commanding him to inquire whether a prisoner charged with murder was committed upon just cause of supplication, or merely propter odio et aitia, for hatred and ill will; and if upon the inquisition due cause of supplication did not then appear, then there ensued another writ for the sheriff to admit him to bail. This writ, according to Bruton, ought not to be denied to any man: it being expressly ordered to be made out gratis, without any denial, by magna charta, c. 26. and statute Wilm. 2. 13. Edw. I. c. 19. but the statute of Gloucester, 6 Edw. 1. c. 9. restrained it in the case of killing by mischief or self-defence, and the statute 26 Edw. III. c. 9. abolished it in all cases whatsoever, but as the stat. 42 Ed. III. c. 1. repeated all statutes then in being, contrary to the great charter, Sir Edward Coke is of opinion that the writ de odio et aitia was thereby revived. See Habees Corpus. Vol. XIII.
Odyssey. before his countrymen the adventures of a prince who had been obliged to forfake his native country, and to head an army of his subjects in a foreign expedition; and he artfully contrives, without interrupting the narrative, to make the reader acquainted with the fate of the country in the absence of its sovereign. The chief having gloriously finished the enterprise in which he was engaged, was returning with his army; but in spite of all his eagers he was detained on the way by tempests for several years, and cast upon several countries differing from each other in manners and in government. In these dangers his companions, not strictly obeying his orders, perished through their own fault. In the mean time the grandees of his country abuse the freedom which his absence gave them: consume his estate; injure themselves in every species of violence, from a persuasion that he would never return. In this they were disappointed. He returns; and discovering himself to them, accepts one of them for his queen; and indulges himself with every species of violence, from a ruthless personage to his son and some others who had maintained his absence. He was disappointed. He returns, and discovering himself only to his son and some others who had maintained his absence, he is an eye-witness of the infolence of his enemies, punishes them according to their deserts, and restores to his illand tranquillity and repose to which it had been a stranger during the many years of his absence.

Such is the fable of the Odyssey, in which there is no opportunity of displaing that vigour and sublimity which characterize the Iliad. "It defends from the dignity of gods and heroes, and warlike achievements; but in recollection we have more pleasing pictures of ancient manners. Instead of that ferocity which reigns in the other poem, this presents us with the most amiable images of hospitality and humanity; entertains us with many a wonderful adventure; and instructs us by such a confant vein of morality and virtue which runs through the poem," sometimes in precepts, and always in the conduct of the hero, that we should not wonder if Greece, which gave the appellation of wife to men who uttered flinge sentences of truth, had given to Homer the title of the father of virtue, for introducing into his work such a number of moral maxims. As a poem, however, the Odyssey has its faults. The last twelve books are tedious and languid; and we are disappointed by the calm behaviour of Penelope upon the discovery of her long lost husband.

Oeconomics, the art of managing the affairs of a family or community; and hence the person who takes care of the revenues and other affairs of churches, monasteries, and the like, is termed econosmus.

OECONOMY, denotes the prudent conduct, or discreet and frugal management, whether of a man's own estate or that of another.

Animal Oeconomy, comprehends the various operations of nature in the generation, nutrition, and preservation of animals. The doctrine of the animal econosmus is nearly connected with physiology, which explains the several parts of the human body, their structure, use, &c. See Anatomy and Medicine.

OECEUMENICAL, signifies the same with general or universal; as oecumenical council, bishop, &c.

Oedema, or Phlegmatic Tumour, in medicine and surgery, a sort of tumour attended with paleness and cold, yielding little resistance, retaining the print of the finger when pressed with it, and accompanied with little or no pain.

This tumour obtains no certain situation in any particular part of the body, since the head, eye lids, hands, and sometimes part, sometimes the whole body, is afflicted with it. When the last mentioned is the case, the patient is said to be troubled with a cachexy, lycophlegmatism, or dropy. But if any particular part is more subject to this disorder than another, it is certainly the feet, which are at that time called fowelled or edematous feet.

Oederia, in botany: A genus of the polygymia segregata order, belonging to the fyn geniea class of plants. The calyces are multifloros: the corollets tubular, hermaphrodite, and one or two feminine ones ligulate; the receptacle is caffy; the pappus with numerous cћaff.

Odipus, the unfortunate king of Thebes, whose history is partly fabulous, flourished about 1266 B.C. It is said he was given by his father to a shepherd, who was ordered to put him to death, in order to prevent the misfortunes with which he was threatened by an oracle. But the shepherd, being unwilling to kill him with his own hands, tied him by the feet to a tree, that he might be devoured by wild beasts. The infant was however found in this situation by another shepherd named Phorbas, who carried him to Polybus king of Corinth; where the queen, having no children, educated him with as much care as if he had been her own son. When he was grown up, he was informed that he was not the son of Polybus; on which, by order of the oracle, he went to seek for his father in Phocis; but scarce was he arrived in that country, when he met his father on the road, and killed him without knowing him. A short time after, having delivered the country from the monster called the Syrinx, he married Jocasta, without knowing that she was his mother, and had four children by her; but afterwards, being informed of his incest, he quit the throne, and, thinking himself unworthy of the light, put out his eyes. Etocles and Polynices, who were celebrated amongst the Greeks, were born of this incestuous marriage.

Oegwa, a town on the gold coast of Africa, standing, according to Artus, on the brow of an eminence, raling itself by a gentle ascent to a considerable height, and defended by rocks, against which the waves beat with the utmost violence, the noise of which is heard at a great distance.

Barbot affirms, that Oegwa contains above 500 houses, disjoined by narrow crooked streets; and that from the sea it has the appearance of an amphitheatre. Des Marchais reduces the number of houses to 200, in the centre of which stands a large square building, the repository of their gold-dust and other commodities. The houses are built of earth and clay, but convenient, and well furnished with chairs, stools, mats, carpets, earthen pots, and even looking-glasses, which last they purchase from the Europeans. No part of the coast is better provided with all kinds of eatables, which are sent in from the adjacent cantons, and fold in public markets. Every thing is bought and fold with gold-dust, which is the sandard of all other commodities, and brought hither in greatest abundance.
OEN

dance from all quarters of Fetu, Abrambo, Atlant, and Mandingo. 'Tis gold is sold by weight, and the quantity determined by nice scales, made in the country before it was frequented by the Europeans: a proof that those negroes are not wholly ignorant of the more refined principles of mechanics. Next to gold, the chief commerce of the place consists in the sale of fish, of which there is much of both the Fetiche, Abrambo, and Mandingo. Gold, the chief commodity, is sold by weight, and the quantity determined by nice scales, made in the country before it was frequented by the Europeans: a proof that those negroes are not wholly ignorant of the more refined principles of mechanics. The negroes have the dexterity of making their advantage of those seasons, which oblige others to discontinue their labours, by throwing their lines with the same success in turbid waters as in calm weather.

OELAND, an island of Sweden, seated on the Baltic sea, between the continent of Gothland and the isle of Gotland. It lies between 56° and 57° of north latitude, and between 17° and 18° of east longitude. It is about 60 miles in length, and 15 in breadth; having a wholesome air, and a fertile soil, with rising hills, and several cattles. It has no town of any great note.

OENANTHE, WATER DROPWORT: A genus of the digynia order, belonging to the plantae claus of plants; and in the natural method ranking under the 45th order, Umbellatae. The florets are dilorm; those of the dic femile and bunne; the fruit crowned with the calyx. There are five species; of which the most remarkable are the creocate or hemlock dropwort, growing frequently on the banks of ditches, rivers, and lakes in many parts of Britain. The root and leaves of this plant are a strong poison; several persons have perished by eating it through mistake, either for water-parfnips or for celery, which last it resembles pretty much in its leaves. So exceedingly deleterious is this plant, that Mr Lightfoot tells us he has heard the late Mr Christopher d'Ehret, the celebrated botanist painter, say, that while he was drawing it, the smell or effluvia only rendered him so giddy, that he was several times obliged to quit the room and walk out in the fresh air to recover himself; but recollecting at last what might be the probable cause of his repeated illnese, he opened the door and windows of the room, and the free air then enabled him to finish his work without any more returns of the giddiness. Mr Lightfoot informs us, that he has given a spofhul of the juice of this plant to a dog, but without any other effect than that of making him very sick and stupid. In about an hour he recovered; and our author has seen a goat eat it with impunity. To such of the human species as have unfortunately eat any part of this plant, a vomit is the most approved remedy.

Lobel calls this vegetable oenanth: aquatica clavis fis.

civ. It grows in great plenty all over Pembrokehire, and is called by the inhabitants five fingered root: it is much used by them in cataplains for the felon or worst kind of whitlow. They eat some parts of it, but carefully avoid the roots or stalks. These are indeed of a most pernicious nature, and never fail to prove instantly fatal, unless a proper remedy is applied. The following instance, in addition to what has been said, of the effects of this plant on man, is given in the Gentleman's Magazine for July 1747.

Three French prisoners being in the fields near the town of Pembroke, dug up a large quantity of a plant with its roots (which they took to be wild celery) to eat with their bread and butter for dinner. After washing it, while yet in the field, they all three eat, or rather only tasted, of the roots.

As they were entering the town, one of them was seized with convulsions. The other two ran and sent for a surgeon, who endeavoured first to bleed, and then to vomit him; but in vain, and he died presently.

Ignorant of the cause of their comrade's death, and of their own danger, they gave of these roots to eight other prisoners, who all ate some of them with their dinner.

A few minutes after, the two who gathered the plants were seized in the same manner as the first: of which one died: The other was bled, and an emetic with great difficulty forced down, on account of his jaws being set. This operating, he recovered; was some time much affected with a diuresis in his head, though not fick, or in the least disordered in his stomach. The other eight, being bled and vomited immediately, were soon well.

This vegetable is so extremely like celery, and therefore, as in the above case, so apt to be mistaken for it, that it cannot be enough guarded against by all who have a proper regard for themselves. In the plate (See Plate CCCXLVIII.), X is the shape of the root. a, The part cut off from the stalk. b, A branch taken from the bottom of the stalk, where the leaves are largest, c, A top branch with the umbels of flowers. d, An anterior view of the flower in its natural size. e, A posterior view of the same. g, The anterior appearance of the flower through a microscope. h, The posterior view of the same, i, A view of the rudiments of the fruit after the decay of the flower. j, The same magnified. * The shape of a leaf of celery. b, A leaf of parsley. These two are printed, to prevent any unhappy mistake in eating the poisonous plant instead of either. We have added to the figures of this dangerous plant these leaves of celery and parsley, which, as we have said, it greatly resembles, in order to show our readers how careful they ought to be in cafe of an accident because of its similarity.

OENKEJE, in botany, a species of Iris. See Iris.

OENOPTÈ, in Grecian antiquity, a kind of censors at Athens, who regulated entertainments, and took care that none drank too much nor too little.

OENOS, in ornithology, the name used by authors for the black-dove, or wood-pigeon, called also by some vigno, somewhat larger than the common pigeon, but of the same shape and general colour. Its neck is of a fine changeable hue, as differently opposed to the light; and its breast, shoulders, and wings, are of
OENOTHRIA, an ancient name of Italy; so called from the Oenotrias, (Virgil); inhabiting between Pa­rum and Tarentum, (Ovid). Originally Arcadians, (Dionysius Halicarnassius), who came under the con­duct of Oenotrus son of Lycaon, 17 generations before the war of Troy, or 459 years, at 27 years each generation, and gave name to the people. Cato de­scends the name from Oenotrus, king of the Sabines and Etruscans; but Varro from Oenotrus king of the La­tins; and Servius from the Greek name for wine, for which Italy was famous; of which opinion is Strabo.

OENOTRIDES (Strabo, Pliny) two small islands in the Tufcan sea, over-against Velia, a town of Lu­cania, called Poniia and Icfa; now Penna and Isca on the coast of the Principato Citra, or to the west of Naples. So called from the Oenotrias, an ancient people of Italy.

OSEL, an island of the Baltic sea, at the en­trance of the gulf of Livonia. It is about 70 miles in length, and 50 in breadth, and contains 10 parishes. It is defended by the fortresses of Airenburg and Sonneburg. It lies between 20° and 24° of east longi­tude, and between 58° and 59° of north latitude.

OESOPHAGUS, in anatomy, the Gula, or Gul­let, is a membraneous canal, reaching from the fa­cues to the thorax, and conveying into it the food ta­ken in at the mouth. See Anatomy, n° 52.

OESTRUS, in zoology, a genus of insects be­longing to the order of diptera. It has no mouth; mouth; but three punctures, without trunk or beak; Anten­nae tapering, proceeding from a lenticular joint. There are five species.

1. Bosris, the breeze or gaudy.—Thorax yellow, with a black transverse line between the wings: Ab­domen tawny, with fine black transverse lines; last segment black: Wings white, with a brown trans­verse line, and three brown spots. Size of the large blue fly. Deposits its eggs under the skin on the backs of oxen, where the maggots, hatched from the eggs, lodge the whole winter, to the great torment. See Botfly.

2. The hamorrhoidalis.—Body long, black, covered with tawny hair; middle of the thorax less hairy; wings immaculate; antennae very short: Length half an inch. Deposits its eggs in the rectum of horses, and occasions great torment. See Botfly.

3. Ovis, the grey fly.—Spotted with black; front pale-yellow; legs brownish; wings with short black veins: length half an inch. Breeds in the front sinews of sheep, where the maggots, hatched from the eggs, lodge the whole winter, viviparously. See bots.

4. The norai.—Body black; but the head thorax, and abdomen, covered with pale red hair, except the first segment of the latter, which is covered with white hair; the wings immaculate. Breeds in the fauces of horses, entering by their nose.

5. The tarandi.—Thorax yellow; with a black line between the wings, which are immaculate: Abdomen tawny, last segment black. Infeits the back of the reindeer, so as greatly to retard the breed. The rein-deer of Lapland are obliged every year to fly to the Alpine mountains, to escape the pursuit of these insects.

OENOTRIA, an ancient name of Italy; so called from the Oenotrias, (Virgil); inhabiting between Pa­rum and Tarentum, (Ovid). Originally Arcadians, (Dionysius Halicarnassius), who came under the con­duct of Oenotrus son of Lycaon, 17 generations before the war of Troy, or 459 years, at 27 years each generation, and gave name to the people. The rein-deer of Lapland are obliged every year to fly to the Alpine mountains, to escape the pursuit of these insects.

OENOTHRIA, a fine purplish hue, or red wine colour, from whence it has its name vinoza. Its legs are red, and feathered a little below the joint.

OENOTHERA, tree-primrose: A genus of the monoeyous order, belonging to the oenandra class of plants; and in the natural method ranking under the 17th order, Calycanthus. The calyx is quadri­fid; the petal's four; the capsule cylindric beneath; the seeds naked. There are seven species; the most remarkable of which are,

1. The Biennis, or common biennial tree-primrose. It hath a long, thick, deeply-furking root: crowned by a long, thick, deeply-furking root: crowned by

2. Octovalvis, or oftovalved, smooth, biennial tree-primrose, hath upright, firm, somewhat hairy stems, rising a yard high; oblong, spear-shaped, pointed, plane, smooth leaves; and at the axillae, from the middle upwards, large bright yellow flowers.

3. The fruticoso, or shrubby, narrow-leaved, peren­nial tree-primrose, hath long thick roots; upright under-shrubby like red stems, two or three feet high; spear-shaped, lightly-indented leaves; and at the axillae pedunculated clusters of yellow flowers, succeeded by pedicellated, acute-angled capsules.

4. The pumilla, or low perennial tree-primrose, hath fibrous roots, crowned with many oval, spear shaped, close fitting leaves; slender herbaceous stems from 10 to 12 inches long; garnished with spear shaped, blunt, smooth leaves, having very short foot stalks; and at the axillae smallish bright yellow flowers, succeeded by acute angled capsules.

All these plants flower very profusely in June and July, coming out almost half the length of the stalks from the axillae; and as the stalk advances in stature new flowers are produced, succeeding those below; in which order the plants continue flowering from about midsummer till October: each flower is moderately large and conspicuous, consisting of four plane petals, which with the calyx forms a very long tube below, and spreading above, generally expand most towards the evening; and are succeeded by plenty of seed in autumn for propagation.

These plants are exotics from America; but are all very hardy, proper in any common soil and situation, and have been long in the English gardens especially the three first sorts; but the onothera biennis, is the most commonly known.

The first and second species are biennial, and the third and fourth are perennial in root.

They are proper to be employed as plants of orna­ment for embellishing the pleasure-garden; they may be placed anywhere, and will effect a very agreeable variety three or four months with their plentiful blow of flowers.

The biennial kinds must be raised annually from seed, for they totally perish after they have flowered. But the perennials, once raised, continue for years by the root.

The propagation of all sorts is by seed, and the perennial alfo by parting the roots.

insects; yet a fourth part of their number perish by them at two years old; the rest are emaciated, and have their skins spoiled. It is one of the most curious genera of insects. They are distinguished into several species, by reason of the different places wherein they deposit their eggs. Some, instructed by nature that their eggs cannot be hatched but under the skins of living creatures, such as bulls, cows, rein-deer, flocks, and camels, fix upon them at the instant of laying their eggs. From the hinder part of their body issues a whirled of wonderful structure. It is a fowy cylinder, composed of four tubes, which draw out like the pieces of a flying-gale; the last is armed with three hooks, and is the gublet with which the oenrit bore through the tough hides of horned cattle. The animal seems to experience no pain from the puncture, unless the insect, plunging too deep, attacks some nerve fibre; in which case, the beast runs about, and becomes furious. The eggs being hatched, the grub feeds on the matter of the wound. The place of its abode forms upon the body of the quadrupeds a bunch sometimes above an inch high. When full-grown, the larva breaks through the tumor, and slides down to the ground; for doing which it takes the cool of the morning, that it may neither be overpowered by the heat of the day, nor chilled by the cold of the night: it then digs itself a burrow, into which it retires. Its skin grows hard, and turns to a very solid shell. There it is transformed to a chrysalis, and afterwards to a winged insect. Nature has provided for every exigence. The shell wherein the oenrit is inclosed, is of so strong a texture that it could not make its way out, if at one of the ends there were not a small valve, fastened only by a very flight filament. The first push the oenrit makes, the door gives way and the prifon opens. The insect wings its way to woods and places frequented by cattle.

OETA (anc. geog.), a mountain of Thessaly, extending from Thermopylae westward to the Sinus Ambracius, and in some measure cutting at right angles the mountainous country stretching out between Parnassus to the south, and Pindus to the north. At Thermopylae it is very rough and high, rising and receding in sharp and steep rocks, affording a narrow passage between it and the sea from Thessaly to Locris (Strabo), with two paths over it; one above Trachis, very steep and high: the other through the country of the Eunianes, much easier and readier for travellers; by this it was that Leonidas was attacked in rear by the Persians (Pausanias). Here Hercules laid himself on the funeral pile (Silenus Italicus, Ovid); the spot thence called Pyra (Livy), who says, that the extreme mountains to the east are called Oeta, and hence the poets allege, that day, night, sun, and stars, arose from Oeta (Seneca, Statius, Silenus Italicus, Catullus, Virgil's Cales)—circumstances which show the height of this mountain.

OETING, a town of Germany, in Upper Bavaria, under the jurisdiction of Burkhausen. It is divided into the upper and lower town, and seated on the river Inn, eight miles west of Burkhausen. E. Long. 12° 58'. N. Lat. 48° 31'. There is a great resort of pilgrims to the old chapel.

Oeting, or Oetingen, a town of Germany, in the circle of Swabia, and capital of a county of the same name seated on the river Wirnitz. E. Long. 10° 45'. N. Lat. 48° 52'.

Oeting, a county of Germany, in the circle of Swabia, bounded on the north and east by Franconia; on the south by the duchy of Neuburg; and on the west by that of Wirtemberg. It is about 40 miles from east to west, and 20 from north to south.

OFFA's dyke, an entrenchment cut up by Offa, a Saxon king, to defend England against the incursions of the Welsh. It runs through Hertfordshire, Shropshire, Montgomeryshire, Denbighshire, and Flintshire.

OFFANTO, a river of Italy in the kingdom of Naples. It rises in the Apennine mountains, in the Farther Principato; and passing by Conza, and Monte Verde, it afterwards separates the Capitanata from the Basilicata and the Terra di Bari, and then it falls into the gulph of Venice, near Salpe.

OFFENCE, in law, an act committed against the law, or omitted where the law requires it.

OFFERINGS. The Hebrews had several kinds of offerings which they presented at the temple. Some were free-will offerings, and others were of obligation. The first-fruits, the tenth, the sin-offerings, were obligation; the peace offerings, vows, offerings of wine, oil, bread, salt, and other things, which were made to the temple or to the ministers of the Lord, were offerings of devotion. The Hebrews called all offerings in general carbon. But the offerings of bread, salt, fruits, and liquors, as wine and oil, which were presented to the temple, they called mincha. The sacrifices are not properly offerings, and are not commonly included under that name. See CORBAN and SACRIFICE.

The offerings of grain, meal, bread, cakes, fruits, wine, salt, and oil, were common in the temple. Some times these offerings were alone, and sometimes they accompanied the sacrifices. Honey was never offered with the sacrifices; but it might be offered alone in the quality of first fruits. Now these were the rules that were observed in the presenting of those offerings, called in Hebrew mincha, or koron mincha; in the Septuagint, offringes of sacrifices; and the same by St Jerom, oblationes sacrificij; but by our translators, meat offerings (Lev. ii. 1 &c.). There were five sorts of these offerings: 1. Fine flour, or meal. 2. Cakes of several sorts, baked in an oven. 3. Cakes baked upon a plate. 4. Another sort of cakes, baked upon a gridiron, or plate with holes in it. 5. The first fruits of the new corn, which were offered either pure and without mixture, or roasted or parched in the ear, or out of the ear.

The cakes were kneaded with oil olive, or fried with oil in a pan, or only dipped in oil after they were baked. The bread offered to be presented upon the altar, was to be without leaven; for leaven was never offered upon the altar, nor with the sacrifices. But they might make presents of common bread to the priests and ministers of the temple. See CAKE, &c.

The offerings now mentioned were appointed on account of the poorer folk, who could not go to the charge of sacrificing animals. And even those that offered living victims were not excused from giving meal, wine, and salt, which was to go along with the greater sacrifices. And also those that offered only oblations of bread or of meal, offered also oil, in case, salt,
O F F  [ 190 ]  O F F

Offerings, salt, and wine, which were in a manner the seafonings of it. The priest in waiting received the offerings from the hand of him that offered them; laid a part of them upon the altar, and reserved the rest for his own subsistence: this was his right as minister of the Lord. Nothing was burnt quite up but the incense, of which the priest kept back nothing for his own share.

When an Israelite offered a loaf to the priest, or a whole cake, the priest broke the loaf or the cake into two parts, setting that part aside that he referred to himself, and broke the other into crumbs; poured oil upon it, salt, wine, and incense; and spread the whole upon the fire of the altar. If these offerings were accompanied by an animal for a sacrifice, it was all thrown upon the victim, to be consumed along with it.

If these offerings were the ears of new corn, either of wheat or barley, these ears were parched at the fire or in the flame, and rubbed in the hand, and then offered to the priest in a vessel; over which he put oil, incense, wine, and salt, and then burnt it upon the altar, after having taken as much of it as of right belonged to himself.

The greatest part of these offerings were voluntary, and of pure devotion. But when an animal was offered in sacrifice, they were not at liberty to omit these offerings. Every thing was to be supplied that was to accompany the sacrifice, and which served as a seafoning to the victim. There are some cafes in which the law requires only offerings of corn, or bread; for example, when they offered the first-fruits of their harvest, whether they were offered solemnly by the whole nation, or by the devotion of private persons.

As to the quantity of meal, oil, wine, or salt, which was to go along with the sacrifice, we cannot easily fix that the law had determined it. Generally the priest threw an handful of meal or crumbs upon the fire of the altar, with wine, oil, and salt in proportion, and all the incense. All the rest belonged to him, the quantity depended upon the liberality of the offerer.

We observe in more places than one, that Moses appointed an Aaroun, or the tenth part of an ephah of meal, for those that had not wherewithal to offer the libation. Fetter receird offered in sacrifice, they were not at liberty to omit it.

OFFICIAL, in the canon law, an ecclesiastical judge, appointed by a bishop, and with charge of the spiritual jurisdiction of the diocese.

OFFICIAL, is also a deputy appointed by an archdeacon as his assistant, who acts as judge in the archdeacon's court.

OFFICIAL, in pharmacy, an appellation given to such medicines, whether simple or compound, as are required to be constantly kept in the apothecaries' shops. The official simples are appointed, in Britain, by the college of physicians; and the manner of making the compositions directed in their dispensatory. See PHARMACY.

OFFING, or OFFIN, in the sea-language, that part of the sea a good distance from shore, where there is deep water, and no need of a pilot to conduct the ship; thus, if a ship from shore be seen falling out to seaward, they say, the lands for the offing; and if a ship, having the shore near her, has another a good way without her, or towards the sea, they say, that ship is in the offing.

OFF-SETS, in gardening, are the young shoots that spring from the roots of plants; which being carefully separated, and planted in a proper soil, serve to propagate the species.

OFF-SETS, in surveying, are perpendiculars let fall, and marked from the situation lines to the hedge, fence, or extremity of an inclosure.

OGEE, or O. G. in architecture, a moulding consisting of two members, the one concave and the other convex; or of a round and hollow, like an ogee. See ARCHITECTURE.

OGHAM, a particular kind of polygonography, or writing in cypher professed by the Irish; of which there were three kinds; The Irish was composed of certain lines and marks, which derived their power from their situation and position, as they stand in relation to one principal line, over or under which they are placed, or through which they are drawn; the principal line is horizontal, and serves, for a rule or guide, whose upper part is called the left, and the under side the right; above, under, and through which line the characters or marks are drawn, which stand in the place of vowels, consonants, diptonghs, and triphongs. Some authors have doubted the existence of this species of writing in cypher, called Ogham among the Irish; but these doubts are perhaps ill-founded; for several MSS. in this character still exist, from which Mr Alli has given a plate of them.

OGILBY (John), an eminent writer, was born in or near Edinburgh; about the 17th of November, 1600. His father having spent his estates and being prisoner in the King's Bench for debt, could contribute but little to his education; however, he obtained some knowledge in the Latin grammar, and afterwards so much money as to procure his father's discharge from prison, and to bind himself an apprentice to a dancing-master in London; when, by his dexterity in his profession, and his compliant behaviour to his master's scholars, he obtained money to buy out the remainder of his time and to set up for himself. But being afterwards appointed to dance in the duke of Buckingham's great mask, he by a false step strained a vein in the inside of his leg, which occasioned his being ever after somewhat lame. When Thomas Earl of Strafford was made lord lieutenant of Ireland, he was entertained as a dancing-master in his family, and made one of the earl's troop of guards; at which time he composed a humorous piece called the Character of a Trooper. He was soon after appointed master of the revels in Ireland, and built a theatre at Dublin. About the time of the conclusion of the war in England, he left Ireland, and, being shipwrecked, came to London in a melancholy condition; but soon after walked to Cambridge, where, being assisted by several scholars, he became to complete a master of the Latin tongue, that in 1649 he published a translation of Virgil. He soon after learned Greek; and in 1660 published, in folio, a translation of Homer's Iliad, with Annotations. About two years after he went into Ireland, where he was made master of the revels by patent. He then built another theatre in Dublin, which cost him about 1000l. He published at London, in folio, a translation of Homer's Odyssey, with Annotations; and afterwards wrote two heroic poems, intitled the Ephesian Matron, and the Roman Saver. He next composed the Carolics, an epic poem, in 12 books, in honour of king Charles I. But this was entirely lost in the fire of London; when Mr Ogilby's house in White Friars was burnt down, and his whole fortune, except to the value of five pounds, destroyed. He, however, soon procured his house to be rebuilt, set up a printing-office within it, was appointed his majesty's cosmographer and geographic printer, and printed several great works translated or collected by himself and his assistants, particularly his Atlas. He died in 1676.

OGIVE, in architecture, an arch or branch of a Gothic vault; which, instead of being circular, pales diagonally from one angle to another, and forms a crock with the other arches. The middle, where the ogives cross each other, is called the key; being cut in form of a rose, or a cil de lampre. The members or mouldings of the ogives are called nervs, branches, or reins; and the arches which separate the ogives, double arches.

OGYES, king of the Thebans, or, according to others, of Ogygia and Aetna, afterwards called Ecotia and Africa. He is recorded to have been the first founder of Thebes and Eleusina. The famous deluge happened in his time, in which, some say he perished with all his subjects, 1796 B. C.

OGYIA (Homer), the island of Calypso; placed by Pliny in the Sinus Scylaceus, in the Ionian Sea, opposite to the promontory Lacunum; by Mela in the Strait of Sicily, calling it Eae; or others place at the promontory Circeum, and call it the island of Circe.

Ogygia, the ancient name of Thebes in Boeotia; so called from Ogyges, an ancient king, under whom
OIL [ 192 ]

OIL

Oil happened a great deluge, 100 years before the first Olympic.

OITIO, a river of North America, called by the French the Beautiful River, has its source between the Alleghany mountains and the lake Erie; and running south west through a most delightful country, and also receiving many smaller rivers in its passage, at length falls into the Mississippi, in about 37 degrees of latitude. The French had several forts on or near it; but the whole country through which it flows was ceded by the peace of 1763 to the British.

O HETEROA, one of the South Sea islands lately discovered, is situated in W. Long. 150. 47. S. Lat. 22. 27. It is neither fertile nor populous; nor has it an harbour or anchorage fit for shipping, and the disposition of the people is hostile to such as visit them.

OIL, in natural history, an unctuous inflammable substance, drawn from several natural bodies, as animal and vegetable substances.

Animal oils are their fats, which are originally vegetable oils; all animal substances yield them, together with their volatile fats, in distillation.

Vegetable oils are obtained by expression, infusion, and distillation.

The oils by expression are obtained from the seed, leaves, fruit, and bark of plants; thus, the seed of mustard, and of the sunflower, almonds, nuts, beech-mast, &c. afford a copious oil by expression; and the leaves of rosemary, mint, rue, wormwood, thyme, fage, &c. the berries of juniper, olives, Indian cloves, nutmeg, mace, &c. the barks of cinnamon, fassafras, and clove, yield a considerable proportion of essential oil by distillation.

The method or procuring oils by expression is very simple: thus, if either sweet or bitter almonds, that are fresh, be pounded in a mortar, the oil may be forced out with a press, not heated; and in the same manner should the oil be pressed from linseed and mustard. The avoiding the use of heat, in preparing these oils intended for internal medicinal use, is of great importance, as heat gives them a very prejudicial rancidness.

This method holds of all those vegetable matters that contain a copious oil, in a loose manner, or in certain cavities or receptacles: the sides whereof being broken, or squeezed, makes them let go the oil they contain; and thus the seet or oil of lemon-pee, orange-pee, citron-pee, &c. may be readily obtained by prefire, without the use of fire. But how far this method of obtaining oils may be applied to advantage, seems not hitherto considered. It has been commonly applied to almonds, olives, linseed, rape-seed, beech-mast, ben-nuts, walnuts, bay-berries, mace, nutmeg, &c. but not, that we know of, to juniper berries, cherry-nuts, Indian cloves, pine-apples, &c. many other substances that might be enumerated, both of foreign and domestic growth. It has, however, been of late successfully applied to mustard-seed, so as to extract a curious gold-coloured oil, leaving a cake behind, fit for making the common table mustard.

Certain dry matters, as well as moit ones, may be made to afford oils by expression, by grinding them into a meal, which being suspended to receive the volatil

As to the treatment of oils obtained by expression, they would be suffered to depurate themselves by standing in a moderately cool place, to separate from their water, and deposit their faces; from both which they ought to be carefully freed. And if they are not thus rendered sufficiently pure, they may be washed well with fresh water, then thoroughly separated from it again by the separating glass, whereby they will be rendered bright and clear.

The next class of oils are those made by infusion, or decoction, wherein the virtues of some herb or flower are drawn out in the oil; as the oils of roses, chamomile, hypericum, alder, &c. However, these require to be differently treated: thus, for the scented flowers, particularly roses, infusion does not; because much boiling would exhale their more fragrant parts: but oils impregnated with green herbs, as those of chamomile and alder, require long boiling, before they receive the green colour desired. And, in general, no oils will bear to be boiled any longer than there remains some aqueous humidity, without turning black.

There are many compound oils prepared in the same manner, viz. by boiling and infusion, and then draining off the oil for use.

The same contrivance has likewise its use in making essences for the service of the perfumer; not only where essential oils cannot be well obtained in sufficient quantities, but also where they are too dear. The essential oil of jasmine flowers, honeysuckles, sweet-briar, damask-roses, lilies of the valley, &c. are either extremely dear, or scarcely obtainable by distillation; and, in some of them, the odorous matter is so subtle, as almost to be lost in the operation. But if these flowers are barely infused in fine oil of nuts, or oil of ben, drawn without heat, and kept in a cool place, their subtle odorous matter will thus pass into the oil, and richly impregnate it with their flavour. And these essences may be rendered still more perfect by draining off the oil at first put on, and letting it stand again, without heat, upon fresh flowers, repeating the operation twice or thrice.

Oils or fats may likewise be obtained, by boiling and expression, from certain animal-substances; for the membranes which contain the fat, being chopped small, and set in a pan over the fire, become fit for the canvas bag, and, by pressure, afford a large quantity of fat; as we see in the art of chandlery, which thus extracting the oily matter, leaves a cake behind, commonly called greaves.

As to the essential oils of vegetables, they are obtained by distillation with an alembic and a large refractory. Water must be added to the materials, in sufficient quantity, to prevent their burning; and they should be macerated or digested in that water, a little time before distillation. The oil comes over with the water; and either swells on the top, or sinks to the bottom, according as it is specifically heavier or lighter than the water.

This process is applicable to the distilling of the essential oils from flowers, leaves, berries, roots, woods, gums,
OIL

[ 193 ]

gums, and balsams, with a slight alteration of circumstances, as by longer digestion, brrier distillation, &c., according to the tenacity and hardiness of the subject, the ponderosity of the oil, &c.

Essential oils may be divided into two classes, according to their different specific gravity; some floating upon water, and others readily sinking to the bottom. Thus, the essential oils of cloves, cinnamon, and fiafras, readily sink, whereas those of lavender, marjoram, mint, &c., swim, in water: the heaviest of these essential oils is, perhaps, that of citron peel, which even sinks in fluids of wine; and the heaviest seems to be oil of fiafras.

For obtaining the full quantity of the more ponderous oils from camom m, cloves, fiafras, &c., it is proper to reduce the subjects to powder, to digest this powder for some days in a warm place, with thrice its quantity of soft river-water, made very saline by the addition of sea salt, or sharp with oil of vitriol; to use the strained decoction, or liquor left behind in the still, instead of common water, for fresh digestion; to use for the same purpose the water of the second running, after being cleared off its oil: not to distil too large a quantity of these subjects at once; to leave a considerable part of the still, or about one fourth, empty; to use a brisk fire, or a strong boiling heat, at the fire, but to slacken it afterwards. To have a low still-head with a proper internal ledge and current leading to the nofe of the warm; and, finally, to cohabit the water, or pour back the liquor of the second running upon the matter in the still, repeating this once or twice.

The directions here laid down for obtaining the ponderous oils to advantage, are easily transferred to the obtaining of the lighter; so that we need not dwell particularly upon them.

Many of the essential oils being dear, it is a very common practice to adulterate or debase them several ways, so as to render them cheaper both to the feller and the buyer. The several ways seem reducible to three general kinds, each of which has its proper method of detection, viz. 1. With expressed oils. 2. With alcohol. And, 3. with cheaper essential oils.

If an essential oil be adulterated with an expressed oil, it is easy to discover the fraud; by adding a little spirits of wine to a few drops of the suspected essential oil, and shaking them together; for the spirit will dissolve all the oil that is essential, or procured by distillation, and leave all the expressed oil that was mixed with it, untouched.

If an essential oil be adulterated with alcohol, or rectified spirit of wine, it may be done in any proportion, up to that of an equal quantity, without being easily discoverable either by the smell or taste: the way to discover this fraud, is to put a few drops of the oil into a glass of fair water; and if the oil be adulterated with spirit, the water will immediately turn milky, and, by continuing to shake the glass, the whole quantity of spirit will be absorbed by the water, and leave the oil pure at top.

Finally, if an essential oil be adulterated by a cheaper essential oil, this is commonly done very artfully; the method is to put fir-wood, turpentine, or oil of turpentine, into the still, along with the kegs to be distilled for their oil, such as rosemary, lavender, or gum, &c., and by this means the oil of turpentine distilled from these ingredients comes over in great quantity, and intimately blended with the oil of the genuine ingredient. The oils thus adulterated always discover themselves in time, by their own flavour being overpowered by the turpentine smell; but the ready way to detect the fraud, is to drum a piece of paper, or paper, in the oils, and hold it before the fire; for thus the grateful flavour of the plant will fly off, and leave the naked turpentine-scent behind.

The virtues of oils, being the same with those of the substances from whence they are obtained, may be learned under their several articles, to which we refer.

We have this account of different oils in the island of Madagascar in the Universal History.

Oils are of different sorts; the most common are those of menach-tanehal, menach signifying oil, menachil, menach-chouvan, menach-maforat, menach-yowrave, menach-apacopou, menach-vintang, and menach-arame. Menach-tanehal is drawn from a particular plant, called, in the language of the country, tanetehteh, and known in Europe by the name of palma Chiffri, or Rucinis. Menachil is an oil from the feed of same, which they call vuancuze; a great quantity whereof is made in the valley of Amboute. Menach-chouuvau is drawn from a fruit of the size of an almond, extremely good in liquors or meats. Menach-maforat is drawn from nuts, the fruit of the tree which produces dragon’s blood. Menach-yowrave is drawn from a fruit named fowf. Menach-apacopou is squeezed from the fruit apacopou, extremely poisonous. Menach-vintang is an oil from large acorns, or mast. Menach-arame is drawn from nuts, the fruit of the tree from which the gum tacamahaca is produced.

Rock Oil. See Petroleum.

Essential Oil of Roses. See Roses.

Ointment, in pharmacy. See Unguent.

Okeham, the capital of Rutlandshire, in England, seated in a rich and pleasant valley, called the vale of Catnus. It is pretty well built, has a good church, a free-school, and an hospital. W. Long. o. 45. N. Lat. 52. 40.

Olaus Magnus. See Magnus.

Okra, See Hibiscus.

Olad, in botany; A genus of the monogynia order, belonging to the triandra class of plums; and in the natural method ranking with those of which the order is doubtful. The calyx is entire; the corolla funnel-shaped and triad; the nectarium tetraphylous.

Old Age. See Longevity. Many methods have been proposed for lengthening life, and rendering old age comfortable. Cornaro’s Treatise on this subject is known to every body, and needs not be quoted. To some of our readers the following, etc.

B b
Old resolutions will perhaps be new, and may certainly be useful.

The old men should refute, except the reasons for a change be invincible, to live and to die is the public profession of the religion in which they were born and bred. To avoid all profane talk and intricate debates on sacred topics. To endeavour to get the better of the intrusions of indolence of mind and body, those certain harbingers of enfeebling age. Rather than to nod in company, or to indulge religion, "the detestable, old and new. To admit every cheerful ray of light, like the dead belong to a world of their own. To live for memory, for the day. To overcome by the sovereign balm of life, though the nerve of competition, or to be in another's way. To avoid being jollied too much in the street, being overcome by the noise of the carriages, and not to be carried even by curiosity itself into a large crowd. To strive to embody that dignified sentiment, "to write injuries in dust, but kindness in heaven." Not to give the reins to constitutional impatience, for it is apt to hurry on the first expirations into the incredulity of swearing. To recollect, that he who can keep his own temper may be master, of another's. If one cannot be a Rebe, in bearing and forbearance, on every trying occasion, yet it may not be impossible to pull the check string against the moroseness of spleen or the impetuosity of petulances. Anger is a short madness. Not to fall in love, now on the precipice of threescore, nor expect to be fallen in love with. A connection between summer and winter is an improper one. Love, like fire, is a good servant, but a bad master. Love is death, when the animal spirits are gone. To continue to love as few vacant hours upon one's hands as possible, that idleness, the mother of crimes and vices, may not pay its visit. To be always doing of something, and to have something to do. To fill up one's time, and to have a good deal to fill up; for time is the materials that life is made of. If one is not able by situation, or through the necessity of raising the supplies within the year, or by habit (for virtue itself is but habit), to do much ostentations good, yet to do as little harm as possible, to make the belt and the most of every thing. Not to indulge too much in the luxury of the table, nor yet to underlive the constitution. The gout, rheumatism, and dropsy, in the language of the Spectator, seem to be hovering over the dishes. Wine, the great purveyor of pleasure, and the second in rank among the venereal, offers his service, when love takes his leave. It is natural to catch hold of every help, when the spirits begin to drop. Love and wine are good cordials, but are not proper for the beverage of common use. Refuse not to go to bed on a full meal. A light flipper and a good conscience are the belt receipts for a good night's rest, and the parents of undisturbing dreams. Not to be enervated by the flatulence of ten. Let the second or third morning's thought be to consider of the employment for the day: and one of the last at night to inquire what has been done in the course of it. Not to let one's tongue run at the expense of truth, Nor to be too communicative nor unreserved. A close tongue, with an open countenance, are the false passports through the journey of the world. To correct the error of too much talking, and restrain the narrativeness of the approaching climacteric. To take the good-natured side in conversation. However, not to praise everybody, for that is to praise no body. Not to be inquisitive, and eager to know secrets, nor to be thought to have a head full of other people's affairs. Not to make an enemy, nor to lose a friend. To aim at the esteem of the public, and to leave a good name behind. Not to be singular in dress, in behaviour, in notions, or expressions of one's thoughts. Never to give bad advice, and to strive not to let a bad example. Seldom to give advice till asked, for it appears like giving something that is superfluous to one's self. Not to like or dislike too much at first sight. Not to wonder, for all wonder is ignorance that possession falls short of expectation. The longing of twenty years may be disappointed in the unanswerd gratification of a single hour. Whilst we are wishing, we see the belt side; after we have taken possession, the worst. Resolved to attend to the arguments on both sides, and to hear every body against every body. The mind ought not to be made up, but upon the best evidence. To be affedtionate to relations, which is a kind of self-love, in preference to all other acquaintances. But not to omit paying the commanding respect to merit, which is superior to all the accidental chains of kindred. Not to debilitate the mind by new and future compositions. Like the spider, it may spin itself to death, the mind, like the field, must have its fallow season. The leisure of the pen has created honourable acquaintance, and pleas'd all it has wished to please. To resolve not to be too free of promises, for performances are sometimes very difficult things. Not to be too much alone, nor to read, nor meditate, or talk too much on points that may awaken tender sensations, and be too pathetic for the soul. To enjoy the present, not to be made too unhappy by reflection on the past, nor to be oppressed by invincible gloom on the
the future. To give and receive comfort, those necessary arms to a disrelished mind. To be constantly thankful to Providence for the plenty hitherto bestowed, which has preferred one from the dependence on party, persons, and opinions, and kept one out of debt. The appearance of a happy situation, and opportunities of tainting many worldly felicities (for content has seldom perverted itself into discontent), has induced many to conclude, that one must be pleased with one's lot in life; and it occasions many to look with the eye of innocent envy. To resolve more than ever to shun every public flattery and responsibility of conduct.

To be satisfied with being master of one's self, one's habits, now a second nature, and one's time. Determined, not to solicit, unless trampled upon by fortune, to live and die in the harness of trade, or a profession.

To take care that pity (humanity is not here meant) does not find out one in the endurance of any calamity. When pity is within call, contempt is not far off. Not to wish to have a greater hold of life, nor to quit that hold. The possible tenure of existence is of too short polisheon for the long night that is to succeed; therefore not a moment to be lost. Not to lose fight, even for a single day, of these good and proverbial doctors—diet —merryman—and quiet. Resolved to remember and to recommend, towards tranquillity and longevity, the three oral maxims of Sir Hans Sloane—"Never to quarrel with one's self—one's wife—or one's prince." Lastly, not to put one's self too much in the power of the elements, those great enemies to the human frame; namely, the fun—the wind—the rain—and the night air.

OLD Man of the Mountains. See Assassin.

OLDCASTLE (Sir John), called the Good Lord Cobham, was born in the reign of Edward III, and was the first author as well as the first martyr among the English nobility: he obtained his peerage by marrying the heiress of that Lord Cobham who with so much virtue and patriotism opposed the tyranny of Richard II. By his means the famous statute against provisors was revived, and guarded against by severer penalties; he was one of the leaders of the reforming party; was at great expense in procuring and dispersing copies of Wickliffe's writings among the people, as well as by maintaining a number of his disciples as itinerant preachers. In the reign of Henry V. he was accused of heresy; the growth of which was attributed to his influence. Being a dominec in the king's court, the king delayed his prosecution that he might reason with him himself; but not being able to reclaim him to the church of Rome, he in great displeasure refigned him to its censure. He was apprehended and condemned for heresy; but escaping from the tower, lay concealed for four years in Wales, until the rumour of a pretended conspiracy was raised against him, and a price set upon his head: he was at last seized, and executed in St. Giles's Fields: being hung alive in chains upon a gallows, and burned by a fire placed underneath. He wrote "Twelve Conclusions, addressed to the Parliament of England."

OLDENBURG, a title of the royal house of Denmark. The origin of this illustrious family, we are told, is this.

On the death of Christoper king of Denmark, Sc. in 1448, without issue, there was a great content about the succession; and a variety of factions were raised, Oldenburg, particularly in Sweden and Norway, for the promotion of different persons, and various animosities and numerous discord were excited by the several parties, in order each to obtain their own ends.

As soon as these intrigues were known in Denmark, the senate resolved to proceed to the election of a king; for it did not appear expedient to commit the government of affairs to the queen-dowager, at a time when they had every thing to fear from the two neighbouring crowns. At this time a lord of great weight, property, and ambition, sought the queen in marriage, the more easily to pave his way to the throne. This is a fact mentioned by Fontaines and Meurinus, though neither takes notice of his name. But as for a great number of years there was no precedent for electing a king out of the body of nobility, though agreeable to law, the queen entered into the views of the senate, and declared the would give her hand to no prince who should not be judged deserving of the crown by the supreme council of the nation.

The advantages which would have accrued from annexing the duchy of Slewick and Holstein to the crown, made the senate first call their eyes on Adolphus. This matter required no long deliberation; all saw the conveniences resulting from such an union, and gave their assent. Immediately an embassy was dispatched with the offer to Adolphus; but that prince considering the good of his subjects, whose interest would have been absorbed in the superior weight of Denmark, declined it, with a moderation and disinterestedness altogether uncommon among princes. However, that he might not be wanting in respect to the senate, he proposed to them his nephew Christian, second son to Theodoric, count of Oldenburg, a prince bred up at the court of Adolphus from his infancy. The proposition was so agreeable to the senate, that without lapse of time, the ambassadors were sent to Theodoric, to demand either of his sons he should pitch upon for their king. Theodoric's answer to the ambassadors was remarkable: "I have three sons, says he, of very opposite qualities. One is passionately fond of pleasure and women; another breathes nothing but war, without regarding the justice of the cause; but the third is moderate in his disposition, prefers peace to the din of arms, yet fluids unrivalled in valour, generosity, and magnanimity." He said he painted these characters for the senate's information, desiring they would choose which of the young princes they believed would render the kingdom happy. It was a matter which would admit of no hesitation: with one voice the senate declared for that prince whose panegyric the father had so warmly drawn; and under these happy auspices commenced the origin of the grandeur of the house of Oldenburg, at this day seated on the throne of Denmark.

OLDENBURG (Henry), a learned German gentleman in the 17th century, was descended from the noble family of his name, who were earls of the county of Oldenburg, in the north part of Westphalia, for many generations. He was born in the duchy of Bremen in the Lower Saxony; and during the long English parliament in King Charles I.'s time, was appointed confid for his countrymen, at London, after the usurpation of Cromwell: but being discharged of
OLD [ 196 ]

Oldenburg continued to publish the Translations, as before, to n° xxxvi. June 25, 1677. After which the publication was discontinued till the January following, when it was again resumed by his successor in the secretary's office, Mr Nehemiah Grew, who carried it on till the end of February 1678. Our author dying at his house at Charleton, near Greenwich in Kent, in the month of August that year, was interred there.

OLDENLANDIA, in botany: A genus of the tetrandria monogynia class. Its characters are these: The emplacement of the flower is permanent, sitting upon the germ; the flower has four oval petals, which form the perianth, and four stamens, terminated by small summits; it has a roundish germen, situated under the flower, crowned by an indented stigma; the germen afterwards turns to a globular capsule, with two cells filled with small seeds. We have but one species of this plant in the English gardens; but Linnaeus enumerates six.

OLDHAM (John), an eminent English poet in the 17th century, son of a non-conformist minister, was educated under his father, and then sent to Edmund-hall in Oxford. He became usher to the free-school at Croydon in Surry; where he received a visit from the ears of Rochester and Doriet, Sir Charles Sedley, and other persons of distinction, merely upon the reputation of some verses of his which they had seen in manuscript. He was tutor to several gentlemen's sons successively, and having saved a small sum of money, came to London, and became a perfect ventary to the bottle, being an agreeable companion. He was quickly found out here by the noblemen who had visited him at Croydon, who brought him acquainted with Mr Dryden. He lived mostly with the earl of Kingston at Holme-Pierpoint in Nottinghshire, where he died of the small-pox in 1665, in the 40th year of his age. His acquaintance with learned authors appears by his satires against the Jesuits, in which there is as much learning as wit discovered. Mr Dryden esteemed him highly. His works are printed in 2 vols 12mo. They chiefly consist of satires, odes, translations, paraphrases of Horace and other authors, elegiac verses, imitations, parodies, familiar epistles, &c.

OLD-HEAD, situated in the county of Cork, and province of Munster, four miles south of Kinsale, in the barony of Courties, Ireland: it is a promontory, running far into the sea, on which is a light-house for the convenience of shipping. A mile from its extremity is an ancient castle of the lords of Kinsale, built from one side of the isle towards the other, which de­fended all the lands towards the head; this place was formerly called Dunearnna, and was the old seat of the Irish kings. The island, by the working of the sea, was quite penetrated through, so as to form a tu­pendous arch, under which boats might pass from one bay to the other. Among the rocks of this coast there are aviaries of good hawks, also the sea-eagle or osprey built their nests and brooded there.

OLDMIXON (John), was descended from an ancient family in Somersetshire: he was a violent part­y-writer and malevolent critic, who would fearlessly have been remembered, if Pope, in remembrance of his abuse, had not condemned him to immortality in his Dunciad. His party-writings procured him a place in the revenue at Liverpool, where he died at an advanced age in the year 1745. Besides his fugitive temporary pieces, he wrote a history of the Stuarts in folio; a Critical History of England, 2 vols. 8vo; a volume of Poems, some dramatic pieces, &c. none of them worthy of notice; his principal talent being that of falsifying history.

OLD-WIFE, or Wreath. See Labrus.

OLD-WIFE Fifth. See Balistes.

OLD-WOMAN'S ISLAND, a narrow slip of land, about two miles long, separated from Bombay in the East Indies by an arm of the sea, which, however, is passable at low water. It is termed a promontory in a small eminence, on which a look-out house is kept for vessels. Near the middle are three tombs kept constantly white, as land-marks into the harbour. From the end of the island a dangerous ledge of rocks shoots forth, which are not very easily cleared. It produces only pasture for a few cattle.

OLEA, in botany, the olive-tree: A genus of the monogynia order, belonging to the diandria class of plants; and in the natural method ranking under the 44th order, Sapéria. The corolla is quadridid, with the segments nearly ovate. The fruit is a monoferm­mous plum.

There are three species of the olean. 1. The Euro­pea, or common olive-tree, rides with upright solid limbs, bearing numerously on every side, 20 or 30 feet high; spear-shaped, stiff, opposite leaves, two or three inches long, and half an inch or more broad; and at the axillae small clusters of white flowers, suc­ceeded by oval fruit.

This species is the principal sort cultivated for its fruit: the varieties of which are numerous, varying in size, colour, and quality.
It is a native of the southern warm parts of Europe, and is cultivated in great quantities in the south of France, Italy and Portugal, for the fruit to make the olive oil, which is in so great repute, and is transported to all parts, to the great advantage of those countries where the trees grow in the open ground: the green fruit is also in much esteem for pickling, of which we may see plenty in the shops.

2. The capensis, or cape box-leaved olive, takes with fluffy leaves, branching numerously from the bottom, six or seven feet high: small, oval thick, light, shining leaves; and at the axils small clusters of whitish flowers; succeeded by small fruit of inferior value.

3. *Olea odoratissima*. (Indian name, gurja : Japanese name, Shiso Ren, or Sju Ren) is first described by Thunberg, bullis fruticos, fo ita enzforovus, essibibas, farinis jupendius. (See Plate CCCL.) The flower of the *Olea odoratissima* is by some said to give the fine flavour to the green tea; but Thunberg attributes the said flavour to the *Cemella turgida*.

Olive-trees are easily propagated by shoots; which, when care has been taken to ingraft them properly, bear fruit in the space of eight or ten years. Those kinds of olive trees which produce the purest oil, and bear the greatest quantity of fruit, are ingrafted on the stocks of inferior kinds.

Different names are assigned by the French to the different varieties of the olive tree: and of these they reckon 19 whilst in Florence are cultivated no fewer than 32.

Olive shoots are ingrafted when in flower. If the operation has been delayed, and the tree bears fruit, it is thought sufficient to take of a ring of bark, two fingers breadth in extent, above the highest graft. In that case the branches do not decay the first year; they afford nourishment to the fruit, and are not lopped off till the following spring. Olive trees are commonly planted in the form of a quincunx, and in rows at a considerable distance from one another. Between the rows it is usual to plant vines, or to sow some kind of grain. It is observed that olives, like many other fruit-trees, bear well only once in two years.

The whole art of drolling these trees consists in removing the superfluous wood: for it is remarked, that trees loaded with too much wood produce neither so much fruit nor of so good a quality.

Their propagation in England is commonly by layers. The laying is performed on the young branches in spring. Give plenty of water all summer, and they will sometimes be rooted and fit for potting off in autumn; but sometimes they require two or three times to be rooted in fall: however, when they are properly rooted, take them off early in autumn, and put them separately; give them water, and place them in the shade till they have taken fresh root: and in October remove them into the green-house, &c.

Thore you intend to plant in the open ground, as before suggested, should be kept in pots, in order to have occasional shelter of a garden-frame two or three years, till they have acquired some size, and are hardened to the full air; then transplant them into a warm border against a wall: mull their roots in winter, and mat their tops in rainy weather.

Olives have an acid, bitter, extremely disagreeable taste: pickled (as we receive them from abroad) they prove less disagreeable. The Lucena olives, which are smaller than the others, have the weakest taste; the Spanish, or larger, the strongest; the Provence which are of a middling size, are generally the most esteemed.

When olives are intended for preservation, they are gathered before they are ripe. The art of preparing them consists in removing their bitterness, in preserving them green, and in improving them with a brine of aromatized salt, which gives them an agreeable taste. For this purpose different methods are employed. Formerly they used a mixture of a pound of quicklime, with six pounds of newly lifted wood ashes; but of late, instead of the ashes, they employed nothing but a lye. This, it is alleged, softens the olives, makes them more agreeable to the taste, and less hurtful to the constitution. In some parts of Provence, after the olives have lain some time in the brine, they remove them, take out the kernel, and put in a copper in its place. These olives they prefer in excellent oil; and when thus prepared, they strongly stimulate the appetite in winter. Olives perfectly ripe are soft and of a dark-red colour. They are then eaten without any preparation, excepting only a scattering of pepper, salt, and oil; for they are extremely tart, bitter, and corrosive.

The oil is undoubtedly that part of the produce of olive-trees which is of greatest value. The quality of it depends on the nature of the soil where the trees grow, on the kind of olive from which it is expressed, on the care which is taken in the gathering and pressing of the fruit, and likewise on the separation of the part to be extracted. Unripe olives give an intolerable bitterness to the oil; when they are over ripe, the oil has an unguinous taste; it is therefore of importance to choose the true point of maturity. When the situation is favourable, those species of olives are cultivated which yield fine oils; otherwise, they cultivate such species of trees as bear a great quantity of fruit, and they extract oil from it, for the use of soaperies, and for lamps.

They gather the olives about the months of November or December. It is best to put them as soon as possible into baskets, or into bags made of wool or hair, and to press them immediately, in order to extract a fine oil. Those who make oil only for soap, let them remain in heaps for some time in their foreshores; when afterwards pressed, they yield a much greater quantity of oil. Those even who extract oil to be used in food, sometimes allow them to ferment in heaps, that they may have more oil; but this is extremely hurtful to the quality of the oil, and is the reason why fine oil is so very rare. M. Duhamel recommends not to mix found olives with those in which a fermentation has already begun, and still less, if such as are putrid: in both cases, the oil which is extracted is of a bad quality, and unfit for preservation. In order to have the oil in its purity, we must allow it to deposit its sediment, and then pour it off into another vessel. The oil extracted from the pulp only of olives is the most perfect which can be obtained, and will keep for several years; but that which
is extracted from the kernel only, or from the nut, or from the whole olive ground in the common way in public mills has always more or fewer defects, loses its limpidity in a certain time, and is very apt to become rancid. Care must be taken likewise to keep the oil in proper vessels well shut. After all, in the course of time, olive-oil loses its qualities, becomes disagreeable to the taste and smell, diminishes in fluidity, and at length thickens considerably.

The refuse of the first pressing, when squeezed a second time, yields an oil, but thicker and less pure than the former. What remains after the second pressing, when mixed with a little water and placed in a pan over the fire, produces by pressure a third oil, but of a very inferior quality. What remains after all the oil is expressed, is termed grignon, and is of no farther use but as fuel.

The sediment, or facets, of new oil, we name after the ancients, amuria: it is an excellent remedy in rheumatic affections. In Paris the wax used for shoes is commonly made of the dregs of defecated oil and smoke-black.

Oil of olives is an ingredient in the composition of a great many balms,ointments, plasters, mollifying and relaxing liniments. It is of an emollient and solvent nature; mitigates gripes of the colic, and the pains accompanying dysentery; and is one of the best remedies when one has chanced to swallow corrosive poisons; but it by no means prevents the fatal accidents which ensue from the bite of a snake, as has been pretended. It is an effectual cure, as M. Bourgeois tells us, for the flogging of wasps, bees, and other insects. A bandage soaked in the oil is immediately applied to the flogging, and a cure is obtained without any inflammation or swelling.

Olive oil is of no use in painting; because it never dries completely. The balm is made of it, mixed with Alicant salt-wort and quicklime.

Great drought, as well as much rain, is extremely injurious to the tree of olives. This fruit is much exposed to the attacks of a worm peculiar to itself, and which injures it so much, that after the olives are gathered the produce of the oil extracted from them is diminished one half.

The wood of the olive tree is beautifully veined, and has a pretty agreeable smell: it is in great esteem with cabinet-makers, on account of the fine polish which it affumnes. It is of a refrinous nature, and consequently excellent for burning.

As the laurel branch is the symbol of glory, so the olive-branch covered with leaves has from the most ancient times been the emblem of concord, the symbol of friendship and peace.

The leaves of olive trees have an astringent quality. Many people use them in making gargles for inflammations of the throat.

These plants in this country must be kept principally in pots for moving to the shelter of a green-house in winter; for they are too tender to prosper well in the open ground in this climate; though sometimes they are planted against a warm south wall, and sheltered occasionally from frost in winter, by mulching the roots, and matting their tops: whereby they may be preserved, and will sometimes produce fruit for picking: a very severe winter, however, often kills or greatly injures their young branches; therefore let the principal part of olives be put in rich earth, and placed among the green house shrubs, and managed as others of that kind.

These trees are often sent over from Italy to the Italian warehouses in London, along with orange-trees, &c. where pretty large plants may be purchased reasonably, which should be managed as directed for orange trees that are imported from the same country.

Oleaginous, something that partakes of the nature of oil, or out of which oil may be expressed.

Oleander, or Rose Bay, Nerium: A genus of the pentandria monogynia class. Its characters are these: The empanell of the flower is permanent, and cut into five acute segments; the flower has one funnel-shaped petal, cut into five broad obtuse segments, which are oblique; it hath a nectarium, terminating the tube, which is torn into hairy segments: it hath five short awl-shaped lamina within the tube; it hath an oblong germen, which is bifid, with scarce any style, crowned by fingle fligma; the germen afterwards turns to two long, taper, acute-pointed pods, filled with oblong seeds lying over each other like the scales of a fish, and crowned with down. There are four species.

These plants are generally propagated by layers in this country; for although they will take root from cuttings, yet that being an uncertain method, the other is generally preferred; and as the plants are very apt to produce suckers or shoots from their roots, those are best adapted for laying; for the old branches will not put out roots: when these are laid down, they should be set at a joint, in the same manner as is practised in laying of carnations. There are two or three plants which are equal to them either to the fight or smell, for their scent is very like that of the flowers of the white thorn; and the bunches of flowers will be very large if the plants are strong.

It is called Nerium from μελί, "humid," because it grows in humid places. The plant itself has a force which is inapplicable; for its juice excites so great and violent an inflammation, as immediately to put a stop to deglutition: and if it be received into the stomach, that part is rendered incapable of retaining any thing; the pernicious drug exerting its force, and purging both upwards and downwards.

Nerium in qualities refembles the apocynum. See Apocynum. But when handled and examined upon an empty stomach, in a close chamber, it causes a numbness coming by degrees, with a pain in the head; which shows that something poisonous belongs even to the smell, though there is no danger if it be received in the open air, as may be found upon trial. Antidotes against its poisons are vinegar and all acids.

Olearius (Adam), minifter to the duke of Holstein, and secretary to the embassy sent in 1633 to the great duke of Muscovy and to the king of Peru. He spent six years in this employment; and, on his return, published a relation of his journeys, with maps and figures, at Stewec, 1656, in folio. He wrote an Abridgment of the Chronicles of Holstein from 1498 to 1663; and was appointed librarian to the duke of Holstein, in which capacity he probably died. Help has the character of an able mathematician, an adept of
OLEARIUS, the son of Godfrey Olearius, D.B. superintendent of Halle in Saxony, was born there in 1639. He became professor of Greek at Leipzig; and showed his abilities in that language by 52 exercises on the dominical epistles, and upon those parts of the epistles in the New Testament which are read in the public exercises, and which among the Lutherans are the subject of part of their sermon. He deciphered the most important parts in the university, and among other dignities was ten times rector of it. His learning and industry were displayed in 106 theological disputations, 61 in philosophy, some programs upon difficult points, several speeches and theological counsels; which make two thick volumes; besides his Moral Theology, his introduction to Theology, which treats of cafes of confidence, and his Hermetic a Saca. He lived to a good old age, dying in 1713. His eldest son of his own name was a man of genius and learning, a professor in the same university, who published several works, but died young of a consumption before his father.

OLECRANUM, or Olecranon, in anatomy, the protuberance of the ulna, which prevents the joint of the elbow from being bent back beyond a certain length. See Anatomy, p. 51.

OLENEUS, a Greek poet, older than Orpheus, came from Xantie, a city of Lydia. He composed several hymns, which were sung in the island of Delos upon festival days. Olemsus is said to have been one of the founders of the oracle at Delphi; to have been the first who filled at that place the office of priest of Apollo; and to have given responses in verse: but the truth of these assertions is very doubtful.

OLERON, an island of France, on the coast of Annis and Saintonge, about five miles from the continent. It is 12 miles in length and five in breadth; and is very fertile, containing about 12,000 inhabitants, who are excellent farmers. It is defended by a castle, which is well fortified; and there is a lighthouse placed there for the direction of ships. It is 14 miles south-east of Rochelle. W. Long. 1° 26. N. Lat. 46° 10'.

Sea-Laws of Oleron, certain laws relating to maritime affairs, made in the time of Richard I., when he was at the island of Oleron. These laws being accounted the most excellent sea-laws in the world, are recorded in the black book of the admiralry. See S. I'.

OELEUM PARME CHRISTI, commonly called caustica, is extracted from the kernel of the fruit produced by the Ricinus Africanus. (See Ricinus.) This oil has been much used as a purgative in medicine. It acts gently on the bowels, with little or no irritation. By many physicians it has been deemed a sovereign remedy in bilious, calculous, and nephritic complaints; but its taste is extremely nauseous, and, when frequently used, it is apt to relax the tone of the bowels. It is recommended to be given in clysters; and Dr. Cuvane of Bath affirms, that when children cannot be made to swallow any medicine, if the navel and hypochondria be rubbed with this oil, it will produce one or two physical stools. He adds, that it is given in small draughts, or by clysters, or by embrocation, it is an excellent and wonderful vermifuge.

OLFATORY nerves. See Anatomy, p. 136 and 143.

OlgA, queen of Igor, the second monarch of Russia, who flourished about the year 880, having succeed her father Russ, who died in 878. Olga was born in Pilecow, and was of the belt family in that city. She bore him one son, called Sweatplamo. Igor being murdered by the Drewswites, or Dronians, Olga avenged his death. She went afterwards, for what reason we know not, to Constantinople, where she was baptized, and received the name of Helena.

The emperor John Zimithes was her godfather, and fell in love with her as we are told; but she, alleging their spiritual alliance, refused to marry him. Her example made some impression upon her subjects, a good number of whom became converts to Christianity; but none upon her son, who reigned for a long time after her death, which happened at Pereaflaw, in the 80th year of her age, 14 years after her baptism. The Russians to this day rank her among their saints, and commemorate her festival on the 11th of July.

OLIBANUM, in pharmacy, a gummy resin the product of the juniperus lynce (Lin.), brought from Turkey and the East Indies, usually in drops or tears like those of mastic, but larger; of a pale yellowish, and sometimes reddish, colour; a moderately warm pungent taste, and a strong, not very agreeable smell. This drug has received many different appellations, according to its different appearances; the single tears are called simply olbanum, or thus; when two are joined together, they have been called thus mastodium, and when very large, thus feminine; sometimes four or five, about the bigness of fibres, are found adhering to a piece of the bark of the tree which exuded from; these have been named thus cortisium: the finer powder which runs off from the tears in the carriage, misa buris; and the coarser powder, wanna buris. This drug is not however, in any of its states, what is now called thus or frankinzen in the thopus. See the article Thus.

Olibanum consists of about equal parts of a gummy and resinous substance: the first soluble in water, the other in rectified spirit. With regard to its virtues, abundance have been attributed to it, particularly in disorders of the head and breast, in hemoptysis, and in divine and uterine fluxes: but its real effects in these cases are far from answering the promises of the recommenders. Riverius is said to have had large experience of the good effects of this drug in pleurisy, officially epidemic ones: he directs a scooped apple to be filled with a dram of olibanum, then covered and roasted under the ashes; this is to be taken for a day, three ounces of cardiac water after it, and the patient covered up warm in bed; in a short time, he says, either a plentiful sweat, or a gentle diarrhoea ensues, which carry off the disease. Godfrey informs us, that he has frequently made use of this medicine after vaccination, with good success; but acknowledges that it has sometimes failed.

OLIGADRA, in natural history, the name of a genus of crystals composed of very few layers, as the name expresses. The word is compounded of ole, the Greek name for wax, and drá, a layer.
OLI

OLIGARCHY, a form of government wherein the administration of affairs is confined to a few hands.

OLIO, or Ologio, a favourite dish, or food, composed of a great variety of ingredients; chiefly found on Spanish tables.

The forms of olives are various. To give a notion of the strange assemblage, we shall add one from an approved author.

Take rump of beef, neat's tongues boiled and dried, and Bologna sausages; boil them together, and after boiling two hours, add mutton, pork, venison, and bacon, cut in bits; as also, turnips, carrots, onions, and cabbage, borago, endive, marigolds, forest, and spinach; then spices, as saffron, cloves, mace, nutmeg, &c. This done, in another pot put a turkey, or goose, with capons, pheasants, pigeons, and ducks, partridges, teal, and tuck-doves, snipes, quails, and larks, and boil them in water and salt. In a third vessel, prepare a sauce of white wine, strong broth, butter, bottoms of artichokes, and chefnutes, with cauliflowers, bread, marrow, yolks of eggs, mace, and saffron. Lastly, difh the olio, by first laying out the beef and veal, then the venison, mutton, tongues, and sausages, and the roots over all; then the largest fowls, then the smallest, and last pour on the sauce.

OLISIPO, (Pliny, Antonine, Inscriptions) a town of Lusitania, situated on the north side of the frith of the Tagus; of such antiquity, that Solinus thought it was built by Ulysses; and Mela, probably to favour this opinion, writes, according to the common copies, Ulyfsea; both of them perhaps deceived by similarity of sound. It was a municipality, with the surname Felicius Julia, a privilege granted by the munificence of Augustus, (Inscriptions, Pliny). Now Lisbon, capital of Portugal, situated on the north bank of the Tagus, distant about ten miles from its mouth. See Lisbon.

OLIVAREZ, (Count de), by name Don Gaspar de Gazmán, favourite and minister to Don Philip IV. of Spain, about 1620; a man of great parts and boundless ambition. Philip no sooner became king, than he became the subject of this his favourite. The king had abilities, it is true, but they lay dormant; and whilst he spent his time in little inactivity, the whole government was under the direction of Olivarez. The court's management, indeed was sufficiently dexterous in accomplishing his own designs; for by the bent framed excuses, and on the most plausible pretences, he removed all such as he thought friend in his way; nor did he stop there, but sometimes perfected his rivals even to death, of which Don Rodrigo Calderona was a melancholy instance, an instance which at the time excited universal compassion. This minister, in short, had a genius of no common kind; added to which, he had a disposition which spurred all control.

He had perfected the late ministry for their pusilla

ity in the management of affairs; he therefore thought it necessary, and it was certainly prudent, to pursue new measures. His self-sufficiency, though unbounded, was concealed under the veil of assumed modesty, and he was careful to make it appear that he was wholly taken up with the things of his own province. His polities were perhaps, of a refined but not of a useful tendency; for his imprudence, or his wrong notions on the subject, made him renew a war with Holland, contrary to the universal opinion of the council and the people. By the same imprudence, or by something worse, he provoked England, and obliged her to endeavour to humble the pride and lessen the authority of the house of Austria. Thus far he had been of little service to his country, having only provoked the retribution of the most powerful states, particularly England, France, Holland, &c. to conspire for its ruin. It is remarkable that Olivarez notwithstanding this, never lost his credit; and indeed things so turned about in the end, that though Spain for a whole year was put to the severest trials, it acquired a degree of fame which sufficiently, in the general opinion, overbalanced some little loss. Olivarez was particularly fortunate in making the peace; in which transaction he gained a very considerable advantage over Richieu, so that things appeared to be still in a very favourable train. Fortune, however, was not always quite so indulgent to the schemes of this minister; he again drew Spain into a war with Mantua, contrary to the sentiments of the wisest men, from which it is justly dated its declension if not its ruin.

On the whole, Olivarez seems to have been always averse to peace; and with such a relish of disposition, it is undoubtedly wonderful that he held his place so long and with so few complaints as he did.

It was certainly owing to his ambition and obliquity, that an almost general war was excited about the year 1627, and which, as we have said, proved so fatal to Spain. So averse, indeed, does he appear to have been to peace, that he used every means in his power to prevent the restoration of it in Italy; and for this very purpose he sent Feria into Milan, whom he knew to be a man of such a temper and abilities as suited his purposes; for he was naturally averse to quiet. He endeavoured to break the alliances of the duke of Mantua by various stratagems; but they did not succeed: the schemes of Olivarez and the intrigues of Feria being totally defeated. Our minister had soon after this another cause of mortification, on Richieu's being created a duke and peer of France, and unsanimously admitted among the Venetian nobility; which could not fail to be a severe stroke on Olivarez, who considered him as his implacable enemy.

The people at length began to see and to be displeased with his conduct; and with reason, had they known it all, for it was in many inferences cruel and detestable. Indeed the differences which at that time had so long subsisted between France and Spain were the effect of the private animosity between him and Richieu. Things, however, so turned about, and Spain was so unusually successful, that the faults of the minister were overlooked for the time; but this unexpected good fortune had no other effect than that of making
The revolt of the Catalans, whom he wished to deprive of their privileges, was the next consequence of his folly: he had privately employed the Marquis de los Velez to extinguish this rebellion; but the cruelty of the measures used for this purpose only inflamed it the more. The revolution of Portugal, another difastrous event, was also the result of his obstinacy and rigour.

This series of ill-fortune, which ought to have opened the eyes of the Catholic king and his ministers, seemed to infatuate both. The great secret by which Olivarez had governed his master was being the companion, or at least the confidant, of his pleasures. While he affected to deceive the world with a pious appearance of religion and piety, he was not only immersed in vice himself, but encouraged and promoted it in his prince, to the scandal of his subjects, and the prejudice of his affairs. At this time, of all others the most improver, Olivarez produced a ballest of his, hitherto called flatter; he had taken so little care of this son, that, not able to subdivide in Spain, he had paved over to the Indies, where, in every flations, he had scarce got bread. On him he now bestowed the name of Don Enrique de Gazman; and, bringing him with great pomp and splendor to court, either flattered or forced theconfiable of Caille to give him his daughter; in consideration of which alliance he was to devote upon his duchy of St Lucar. In the beginning of his administration, by some accident or other, he preferred to the king a memorial, in relation to an affair upon which his majesty had already received one from Don Balthasar de Zuiga; upon comparing them, they contradicted each other flatly. The king ordered a perfon of great quality to inquire thoroughly into this business; in consequence of which Don Balthasar's memorial appeared to be the truth, and that of Olivarez the reverse of it. The king was very angry; but the counsellor regained his favour, by procuring for him the fair address Cadereona. By this woman he had a fon of whom no great notice was taken; but now, to obscure the folly of the Conde Duke, this youth, scarce in the 14th year of his age, was produced, with the title of Don Juan of Asturias, and declared generalissimo of the army against Portugal; while the heir apparent to the crown, Don Balthasar, was left under the tuition, or rather in the custody, of the countess of Olivarez; at which conduct the queen was chagrined, the people enraged, and the world in general astonished.

His schemes now began to be entirely broken and defeated every where and in every kind; he fell under the displeasure of the queen, the emperor, the grandees, and the people all at once, and experienced the disgrace he had long merited. His ill fortune, which came upon him with force of a torrent, did not, however, wholly overpower him; he was indeed obliged to conceal himself, in order to avoid the rage of the populace; but he had still confidence enough to offer an apology for his conduct, which paused no inconsiderable share of wit and humour, well tempered with spirit and merrily reasoning. It was not, however, of any confecution to him; for he was benighted to Toro, where, worn out by infirmities, or overcome by despair, he ended his days about the year 1645.

Olive, in botany. See Olea.

Olive-preb. In order to obtain the olive oil, the olives are first bruised in a rough trough, under a miffion, rolling perpendicularly over them; and when sufficiently mashed, put into the mays, or trough, m, of an olive-preb, where a are the upright beams, or checks; b, the female, and e, the male screw; f, the board on which the screw presses; g, cubical piece of wood, called a block; h, the peel, a circular board, to be put under the block. By turning the screw, all the liquor is pressed out of the mashed olives, and is called virgin oil; after which, hot water being poured upon the remainder in the press, a scarper oil is obtained. Olive oil keeps only about a year, after which it degenerates.

Olive-colour, a yellow mingled with black.

Olive (Peter John), was born in France and died in 1297, in the fiftieth year of his age. In his youth, he wrote a book in praise of the Virgin Mary, which was condemned during the pontificate of Nicholas III, as containing fame things too extravagant. He afterwards was frequently accursed by the brothers of his order, whose resentment he had drawn upon himself by his severe reproofs of their luxury, and his endeavours to recall them to the poverty and rigour of their first institution. After his death his body was dug up, he was condemned as a heretic, and his writings were burnt, and remained prohibited till the time of Sixtus IV, who having ordered them to be examined, declared they contained nothing expressly contrary to the Catholic faith. The propositions condemned by John are mentioned by Emmericus, in his Directory of the Inquisition, under twenty-two heads. The chief of them are, "That the Pope was the mythical antichrift; that St Francis was the angel in the Revelations faid to have the mark of the living God, and that his rule was the true gospel; that the perfect state of the church began with St Francis; and that Christ and his apostles had no property either in common or in particular, but only the use of what they enjoyed."
OLIVET, or Mount of Olives (anc. geogr.), was preferred in the closet of queen Caroline at Kensington; and a capital painting of his wife is in the pos-

session of the duchess of Portland. He died in 1660.

OLIVET, or Mount of Olives (anc. geogr.), was founded to the east of the city of Jerusalem, and part-

ed from the city only by the brook Kidron, and by the valley of Jehoshaphat, which stretches out from the north to the south. It was upon this mount that So-

lomon built temples to the gods of the Ammonites (1 Kings xi. 7.) and of the Moabites, out of com-

plaisance to his wives, who were natives of these na-

tions. Hence it is that the Mount of Olives is called the Mountain of corruption (2 Kings xxiii. 13.) Jo-

sephus, says, that this mountain is at the distance of five fadias, or furlongs, from Jerusalem, which make 625 geometrical paces, or the length of a Sæbath-

day's journey, says St Luke (Acts i. 12.) The Mount of Olives had three summits, or was com posed of three several mountains ranged one after another from north to south. The middle summit is that from whence our Saviour ascended into heaven. It was upon that towards the south that Solomon built temples to his idols. The summit which is most to the north is distant two furlongs from the middlemost. This is the highest of the three, and is commonly called Calpe.

In the time of King Uzziah, the Mount of Olives was so flattered by an earthquake, that half of the earth that was on the western side fell down, and roll'd four furlongs or 500 paces from thence, towards the mountain which was opposite to it on the east: so that the earth blocked up the highways, and covered the king's gardens.

Mr Maundrell tells us, that he and his company going out of Jerusalem at St Stephen's gate, and crost-

ing the valley of Jehoshaphat, began immediately to ascend the mountain; that being got above two-thirds of the way up, they came to certain grottoes cut with intricate windings and caverns under ground, which were called the sepulchres of the prophets: that a little higher up were twelve arched vaults under ground standing side by side, and built in memory of the apostles, who are said to have compiled their creed in this place; that forty paces higher they came to the place where it is said to have uttered his prophecy concerning the final destruction of Jerusalem; and a little on the right hand, to another where he is said to have dictated a second time the Lord's prayer to his disciples; that somewhat higher is the cave of a saint called Pelagia; a little above that a pillar, de-

oting the place where an angel gave the Blessed Virgin three days warning of her death; and at the top of all, the place of our Blessed Lord's ascension.

OLIVETAN (Robert), related to the famous Cal-

vin, printed at Neufchatel in 1535, in folio, a version of the Bible into French, the first which had been translated from the original Hebrew and Greek. It is written in an uncout and barbarous style, and is far from being faithful. The characters in which it is printed are Gothic, and the language of it is no less so. It is valued only because it is rare to be found.

Calvin is thought to have had a very considerable share in this translation. Olivetan survived his publication but a short time; for he was poisoned at Rome the year after, of which his translation is alleged to have been the cause. Olivetan's Bible, revised by John Cal-

vin and N. Malinger, was reprinted at Geneva, in 1540, in quarto. This edition is full rarer than the former. It is called the Bible de l'Epée, because the printer, had a fudge for his sign.

OLIVIER (Claude Matthieu), advocate of the par-

tliament of Ais, was born at Marille in 1701, and ap-

peared at the bar with eclat. He had a chief hand in

the establishment of the academy of Marielles, and was one of its original members, he possesses a quick and lively genius. A few hours retirement from society and from his pleasures were frequently sufficient to enable him to speak and write, even on important causes; but his works commonly bore marks of haste. Given to excess in every thing, he would employ a fortnight in the studying the Code and the Digest, or in storing his mind with the beauties of Demothenes, Homer, Cicero, or Bofuet; and then abandon himself for another fort-

night, frequently a whole month, to a life of frivolity and dissipation. He died in 1756, at the age of 35.

He published 1. L'Histoire de Philippe roi de Male-
doine, et pere d Alexandre le Grand, 2 vols. 12mo. No

writer has so ably handled the history of the age of Philip, the interelts of the different nations of Greece, and their manners and customs; but the conduct of the work is extremely defective. The digressions are too frequent, and often tedious. The style is in no respect suitable to a history. It is in general dry, uncon-

nected, and like the style of a dissertation. Some-
times, however, we find in it passages full of fire and beauty, and turns of expression truly original. A dif-

ease of the brain, with which he was attacked, and un-
der which he laboured several years, prevented him from putting his last hand to the work. 2. Mémoire sur les secours donnés aux Romains par les Marcellins pendant la 2e Guerre Punique. 3. Mémoire sur les secours donnés aux Romains par les Marcellins durant la Guerre contre les Gaulois.

OLMUTZ, a town in Germany, in Moravia, with a bichop's see, and a famous university. The public

buildings are very handsome, particularly the Jesuits' college. It is a populous, trading, and very strong

place; and yet it was taken, with the whole garrison,

by the king of Prussia in 1744. In July 1758 he bes-

iegled it again; and when he had almost taken the place where he was obliged to raise the siege, to go and meet the Russian army. It is seated on the river Mo-

ruve. E. Long. 17. 35. N. Lat. 49. 30.

OLOCENTROS, in natural history, a name given by the old Greeks to a small animal of the spider kind, whose bite was accounted mortal. It is the same with the folipupa, so called from its ftring, or biting most violently, in places, or seafons, where the sun had the most power, as Africa, &c. The name f5pupa, was a corrupt way of writing that word; and this seems also a false way of writing the word beloncentros, which signifies the same as folipupa.

OLYMPIA (Malachini Donna), a woman of a very uncommon character. She flourished about the middle of the last century. She was father in law to Pope Innocent X. and had the address to acquire an unlimited power over this vain, weak and injudicious ecclesiastic. Her son Camillo was promoted to the car-

dinalate, under the title of Pamphilii; but falling in love with the Prince's Roffana a beautiful young widow, he laid aside his hat, and married. The crime, it was one, was scemned by the Romans in general at least vu-

nal.
The pope, however, was displeased; and Olympia procured their banishment, being afraid lest her daughter-in-law should lessen her authority in the court. This authority, equally natural and usurped by her, she either by the means of a friend of the court, or procured neither honour nor popularity on her being made a spectacle of in the hands of this assuming woman, who, observing her infirmities daily increasing, redoubled her avarice, dispos ing of benefices to the highest bidders in all parts of Italy. She was again, however, in hazard of being displaced by a new favourite, viz. the Cardinal de Retz; and had not the pope’s diliberation prevented it, it would in all probability quickly have taken place.

During his last illness he received nothing but from the hands of Donna Olympia, who was at great pains to prolong his life, watched continually at his bedside, and prevented the ambassadors or others from disturbing him with discourses upon business. She is said, during the last ten days of his life, when he continued without the use of reason, to have amassed about half a million of crowns. She did not find the succeeding pope (Alexander VII.) easy to be played upon by his weak predecessor; a number of memorials were sent in against her, and his holiness was well disposed to attend to them: he ordered her to retire from Rome, and at the same time began to examine witnesses respecting her conduct. She was cut off, however, before the trial was finished, by the plague, which, in 1656, afflicted Rome and its neighbourhood. Her estate was not confiscated as was generally expected; and the prince Pamphilio was allowed to succeed her. The pope only referred for his own relations about a million of crowns.

Olympia (anc. geogr.), with the surname Pifatus (Strabo); so called from the territory of Pisa in Elis; described by Strabo, “as the temple of Jupiter Olympus, before which stands a grove of wild olive-trees, in which is the stadium, or foot-course, so called because the eighth part of a mile; and by which the Alpheus, coming down from Arcadia, runs.” Olympia, however, was famous, not merely for the temple of Jupiter, but also for a temple of Juno, 63 feet long with columns round it of the Doric order; and a Metronion or temple of the mother of the gods, a large Doric edifice; with holy treasuries. These, and the porticoes, a gymnasium, prytaneum, and many more buildings, chiefly in the enclo ser, with the houses of the priests and other inhabitants, made Olympia no inconsiderable place. The stadium was in the grove of wild olive-trees, before the great temple; and near it was the hippodrome or course for the races of horses and chariots. The Alpheus flowed by from Arcadia with a copious and very pleasant stream, which was received on the coast by the Sicilian sea.

The temple of Jupiter was of the Doric order, 63 feet high to the pediment, 95 wide, and 230 long; the cell encompassed with columns. It was erected with the country-stone; the roof, not of earth baked, but of Pentelic marble; the slabs disposed as tiles; the way to it up a winding staircase. The two pediments were enriched with sculpture; and one had over the central flat of Victory gilded, and underneath a votive
OLY [ 204 ] OLY

Olympia. buckler of gold. At each corner was a gilded vase: Above the columns were fixed 21 gilded bucklers, offered at the conclusion of the Achaean war by the Roman general Mummius. The gates in the two fronts were of brass, and over them were carved the labours of Hercules. Within the cell were double colonnades, between which was the approach to the image.

The Jupiter of Olympia was accounted alone sufficient to immortalize its maker, Phidias. It was of ivory and gold, the head crowned with olive. In the right hand was a statue of Victory; in the left a flowered sceptre, composed of various metals, on which was an eagle. The sandals were of gold, as also the veilment, which was curiously embossed with lilies and animals. The throne was gold inlaid with ebony and ivory, and flubbed with jewels, intermixed with paintings and exquisite figures in relief. The pillars between the feet contributed to its support. Before it were walls, serving as a fence, decorated principally with the exploits of Hercules; the portion opposite to the door of a blue colour. It was the office of a family descended from Phaidas, called Phadrante or the polifers, to keep the work bright and clean. The veil or curtain was cloth rich with the purple dye of Phoenicia and with Assyrian embroidery, an offering of King Antiochus, and was let down from above by loosing the strings. The image impressed on the spectator an opinion that it was higher and wider than it measured. Its magnitude was such, that though the temple was very large, the artift seemed to have erred in the proportions. The god, sitting, nearly touched the ceiling with his head; suggesting an idea, that if he were to rise up, he would destroy the roof. A part of the pavement before it was of black marble, enclosed in a rim of Parian or white, where they poured oil to preserve the ivory.

The altar of Jupiter Olympius was of great antiquity, and composed of ashes from the thighs of the victims, which were carried up and consumed on the top with wood of the white-poplar-tree. The ashes also of the pythaeum, in which a perpetual fire was kept on a hearth, were removed annually on a fixed day, and stored on it, being first mingled with water from the Alpheus. The cement, it was affirmed, could be made with Ashes only; and therefore this river was much respected, and esteemed the most friendly of all to the god. On each side of the altar were stone steps. Its height was 22 feet. Girls and women, when allowed to be at Olympia, were suffered to ascend the basement, which was 125 feet in circumference. The people of Elis sacrificed daily, and private persons as often as they chose.

Religion flourished at Olympia, and many deities were worshipped besides Jupiter. Pausanias has enumerated above 60 altars of various shapes and kinds. One to the unknown god stood by the great altar. The people of Elis offered on all these monthly; laying on them boughs of olive; burning incense, and wheat mixed with honey; and pouring libations of such liquors as the ritual prescribed. At the latter ceremony sometimes a form of prayer was used, and they sung hymns composed in the Doric dialect.

Olympia was situated on an eminence, between two mountains called Ossa and Olympus. Though its ancient splendor is gone, the place reminds the traveller of what it once was. It is in the Marsa, being now a small place called Longinio, 50 miles south of Le- panto, in E. Long. 22° 5. N. Lat. 37° 40'.

OLYMPIAD, the space of four years, whereby the Greeks reckoned time.—The first Olympiad fell, according to the accurate and learned computation of some of the moderns, exactly 776 years before the first year of Christ; or 775 before the year of his birth, in the year of the Julian period 538, and 22 years before the building of the city of Rome. The games were exhibited at the time of the full moon next after the summer solstice; therefore the Olympiads were of unequal length, because the time of the full moon differs 11 days every year, and for that reason they sometimes began the next day after the solstice, and at other times four weeks after. The computation by Olympiads ceased, as some suppose, after the 364th, in the year 440 of the Christian era. It was universally adopted not only by the Greeks, but by many of the neighbouring countries; though full the Pythian games served as an epoch to the people of Delphi and to the Boeotians; the Numean games to the Argives and Arcadians; and the Ithmian to the Corinthians and the inhabitants of the Peloponnesian Íthmus. To the Olympiad's history is much indebted. They have served to fix the time of many momentous events; and indeed before this method of computing time was observed, every page of history is mostly fabulous, and filled with obscurity and contradiction, and no true chronological account can be properly established and maintained with certainty.

OLYMPIAS, a celebrated woman, who was daughter of a king of Epirus, and who married Philip king of Macedonia, by whom she had Alexander the Great. Her haughtiness, and more probably her infidelity, obliged Philip to repudiate her, and to marry Cleopatra, the niece of King Attalus. Olympics was of theodic of this injury, and Alexander showed his disapprobation of his father's measures, by retiring from the council to his mother. The murder of Philip, which soon followed this disgrace, and which some have attributed to the intrigues of Olympics, was productive of the greatest extravagances. The queen paid the greatest honour to her husband's murderer. She gathered his mangled limbs, placed a crown of gold on his head, and laid his ashes near those of Philip. The administration of Alexander, who had succeeded his father was in some instances offensive to Olympics; but when the ambition of her son was concerned, the did not venture to declare publicly that Alexander was not the son of Philip, but that he was the offspring of an enormous serpent who had supernaturally introduced himself into her bed. When Alexander was dead, Olympics seized the government of Macedonia; and, to establish her usurpation, the cruelly put to death Arûsæus, with his wife Eury- dice, as also Nicanor the brother of Callander, with 100 leading men of Macedon, who were impoverished to her interest. Such barbarities did not long remain unpunished: Callander befought her in Pydna, where she had retired with the remains of her family, and she was obliged to surrender after an obdurate siege. The conqueror ordered her to be accursed, and to be put to death. A body of 200 soldiers were ordered to put the bloody commands into execution, but the splen-
OLYMPIC GAMES, were solemn games among the ancient Greeks, so called from Olympian Jupiter, to whom they were dedicated; and by some said to be first instituted by him, after his victory over the sons of Titan; others ascribe their institution to Hercules, not the son of Alcmena, but one of much greater antiquity; others to Pelops; and others to Hercules the son of Alcmena. By whomsoever they were instituted, we know that at a period rather early, they had fallen into disuse. The wars which prevailed among the Greeks, for a while, totally interrupted the religious ceremonies and exhibitions with which they had been accustomed to honour the common gods and heroes: but the Olympic games were restored on the following occasion. Amidst the calamities which afflicted or threatened Peloponnesus, Iphitus, a descendent of Oxylos, to whom the province of Eleia had fallen in the general partition of the peninsula, applied to the Delphic oracle. The priests of Apollo, ever disposed to favour the views of kings and legislators, answered agreeably to his wish, that the festivals annually celebrated at Olympia, on the Alpheus, must be renewed, and an armistice proclaimed for all the states willing to partake of them, and desirous to avert the vengeance of heaven. Fortified by this authority, and assisted by the advice of Lycurgus, Iphitus took measures, not only for restoring the Olympic solemnity, but for rendering it perpetual. The injunction of the oracle was speedily diffused through the remotest parts of Greece by the numerous votaries who frequented the sacred shrine. The armistice was proclaimed in Peloponnesus, and preparations were made in Eleia for exhibiting shows and performing sacrifices. In the heroic ages, feats of bodily strength and address were defined to the honour of deceased warriors; hymns and sacrifices were reserved for the gods; but the flexible texture of Grecian superstition, easily confounding the expressions of respectful gratitude and pious veneration, enabled Iphitus to unite both in his new institution.

The festival, which lasted five days began and ended with a sacrifice to Olympian Jove. The intermediate time was chiefly filled up by the gymnastic exercitaces, in which all freemen of Grecian extraction were invited to contend, provided they had been born in lawful wedlock, and had lived untaught by any infamous immoral law. The preparation for this part of the entertainment was made in the gymnasion of Eleia, a spacious edifice, surrounded by a double range of pillars, with an open area in the middle. Adjoining were various apartments, containing baths, and other conveniences for the combatants. The neighbouring country was gradually adorned with porticoes, shady walks and groves, interpenetrated with seats and benches; the whole originally defined to relieve the fatigue and anxiety of the candidates for Olympic fame; and frequented, in later times, by sophists and philosophers, who were fond to contemplate wisdom, and communicate knowledge, in those delightful retreats. The order of the athletic exercitaces, or combats, was established by Lycurgus, and corre-

sponded almost exactly to that described by Homer, in the 23d book of the Iliad, and eighth of the Odyssey. Iphitus, we are told, appointed the other ceremories and entertainments; settled the regular return of the festival at the end of every fourth year, in the month of July; and gave to the whole solemnity that form and arrangement, which it preserved with little variation above a thousand years; a period exceeding the duration of the most famous kingdoms and republics of antiquity. Among the benefactors of Olympia, at a much later period, was reckoned Herod, who was afterwards king of Judea. Seeing, on his way to Rome, the games neglected or dwindling into insignificance from the poverty of the Eleans, he displayed vast munificence as president, and provided an ample revenue for their future support and dignity.

The care and management of the Olympics belonged for the most part to the Eleans; who on that account enjoyed their possessions without molestation, or fear of war or violence. They appointed a certain number of judges, who were to take care that those who offered themselves as competitors should perform their preparatory exercises; and those judges, during the solemnity, fat naked, having before them a crown of victory, formed of wild olive, which was presented to whomsoever they adjudged it. Those who were conquerors were called Olympionices, and were loaded with honours by their countrymen. At these games women were not allowed to be present; and if any woman was found, during the solemnity, to have passed the river Alpheus, she was to be thrown headlong from a rock. This however was sometimes neglected; for we find not only women present at the celebration, but also some among the combatants, and some rewarded with the crown. The preparations for their festivals were great. No person was permitted to enter the lists if he had not regularly exercised himself ten months before the celebration at the public gymnasion of Elia. No unfair dealings were allowed; whoever attempted to bribe his adversary was subjected to a severe fine; and even the father and relations were obliged to swear that they would have recourse to no artifice which might decide the victory in favour of their friends. No criminals, nor such as were connected with impious and guilty persons, were suffered to present themselves as combatants. The wrestlers were appointed by lot. Some little balls perforated with a letter were thrown into a silver urn, and such as drew the same letter were obliged to contend one with another. He who had an odd letter remained the last; and he often had the advantage, as he was to encounter the last who had obtained the superiority over his adversary. In these games were exhibited running, leaping, wrestling, boxing, and the throwing of the stone, which was called altogether pugilism, or quinquerium. Besides these, there were horse and chariot races, and also contentions in poetry, eloquence, and the fine arts. The only reward that the conqueror obtained was a crown of olive. This, as some suppose, was in memory of the labours of Hercules, which were accomplished for the universal good of mankind, and for which the hero claimed no other reward but the consciousness of having been the friend of mankind. So small and trifling a reward stimulated courage and virtue, and was the source of greater
Olympic games were observed every fifth year, or, to speak with greater exactness, after a revolution of four years, and in the first month of the fifth year, and they continued for five successive days. As they were the most ancient and most solemn of all the festivals of the Greeks, it will not appear wonderful that they drew so many people, not only inhabitants of Greece, but of the neighbouring islands and countries.

Such is the account of Grecian writers, who have, doubtless, often ascribed to positive imitation many inventions and usages naturally resulting from the progressive manners of society. When we come to examine the Elean games in their more improved state, together with the innumerable imitations of them in other provinces of Greece, there will occur reasons for believing that many regulations, referred by an early solution to the legislative wisdom of Iphitus or Lycurgus were introduced by time or accident, continued through custom, improved by repeated trials, and confirmed by a sense of their utility. Yet such an institution as the Olympiad, even in its least perfect form, must have been attended with manifest advantages to society. It is sufficient barely to mention the suspension of hostilities which took place not only during the celebration of the festival, but a considerable time both before and after it. Confident as a religious ceremony, at which the whole Grecian name was invited, and even enjoined, to assist, it was well adapted to facilitate intercourse, to promote knowledge, to soften prejudice, and to halt the progress of civilization and humanity. Greece, and particularly Peloponnesus, was the centre from which the adventurous spirit of its inhabitants had diffused innumerable colonies through the surrounding nations. To these widely separated communities, which, notwithstanding their common origin, seemed to have lost all connection and correspondence, the Olympiad served as a common bond of alliance and point of reunion. The celebrity of this festival continually attracted to it the characters most distinguished for genius and enterprise, whose name would have otherwise been unknown and lost in the bounds of its extent of Grecian territory. The remote inhabitants, not only of European Greece, but of Asia and Africa, being assembled to the worship of common gods, were formed to the sense of a general interest, and excited to the pursuit of national honour and prosperity. Strangers of similar dispositions might confirm in Elis the sacred and indelible ties of hospitality. If their communities were endangered by any barbarous power, they might here solicit alms from their Grecian brethren. On other occasions they might explain the benefits which, in peace or war, their respective countries were best qualified to communicate. And the Olympic festival might thus serve the purpose of resident ambassadors, and other institutions alike unknown to antiquity.

OLYMPUS, the name of several mountains. One bounding Bithynia on the south. Another in the island of Cyprus, on whose top was a temple of Venus which women were not permitted either to enter or to see (Strabo).—A third Olympus of Galatia (Livy).—A fourth, of Lyca, with a noble cognominal town, near the sea-coast (Strabo, Cicero), extinct in Pliny’s time, there remaining only a citadel; the town was destroyed by P. Servilius Taurus (Florus), having been the retreat of pirates. From this mountain there was an extensive prospect of Lyca, Pamphylia, and Pisidia (Strabo).—A fifth, Olympus of Myia (Pomponius Lathron); whence named Olympena, anciently Minor; one of the highest mountains, and named Myius (Theophrastus); situated on the Propontis, and thence extending more inland. A sixth, on the north of Thrace, or on the confines of Macedonia; famous for the site of the giants (Virgil), Horace, Seneca); reckoned the highest in the whole world, and to exceed the flight of birds (Apuleius), which is the reason of its being called kea, than which nothing is higher: the severity and calamities which reign there are celebrated by Homer, Lucan, and Claudian.

OLYRA, in botany: A genus of the triandria order, belonging to the nectia class of plants; and in the natural method ranking under the fourth order, Gramineae. The male calyx is a biforous and arilicated glume; the corolla a bearded glume; the female calyx is an uniforous, palealous, and ovate glume; the style is bifid, and the seed cartilaginous.

OMAR (Abd Al Khattab) successor of Abu Beer. The Mahommedan imposture, like every other falsehood of its kind, copies after the truth as far as was thought convenient or proper; and miracles being the grand proof of revelation, it was to be expected that all pretences to that should assume at least the appearances of them. Few systems of faith are more absurd than Mohammed’s; yet, though he disclaimed miracles, it was supported, as we are told by latter writers, by a variety of them, which, however unfortunately for the creed they were contrived to support, are too trifling, absurd, and contradictory, to deserve the slightest attention.

They tell us, but upon grounds too vague and indeterminate to command belief, that Omar was miraculously converted to this faith; a man he is reported to have been, before this event, truly respectable, and in particular a violent opponent of the Arabian prophet. Mohammed, it seems, felt this opposition and regretted it; he therefore, with the fervour, and, as it happened, with the success of a true prophet, according to his followers account prayed for the conversion of this his dangerous antagonist. Omar, it is said, had no sooner read the 20th chapter of the Koran than he was convinced: upon which he instantly repaired to Mohammed and his followers, and declared his conversion. It is said, that at one time he intended to murder...
murder the prophet; and various causes are assigned for the prevention of this shocking piece of sacrilege. After his wonderful conversion, the Mohammedan writers inform us that he was surnamed Al Faruk, or the "diviner"; because, they say, when a certain M.流程 was condemned by Mohammed for his iniquitous treatment of a Jew, and appealed afterwards from the sentence of the prophet to Omar, he cut him in two with his scimitar, for not acquiescing in the decision of s upriot a judge: which circumstance when Mahm med heard, he gave him the surname of Al Faruk or "the divider;" because, by this action, he had shown himself capable of perfectly distinguishing between truth and falsehood. Al Kodai affirms, that 39 of Omar's adherents followed his example the same day he professed himself a votary of Mohammed. The conversion of Hamza and Omar Ebn Al Khattab happened in the year preceding the first flight of the Mo llems into Ethiopia, or the fourth year of Mohammed's mission according to Abulכס. He was unquestionably a great acquisition to the prophet, and enabled him to carry on his schemes to far more purpose than he could have possibly done without him. He discharged every public office, and was incumbered by the legal and pontifical dignity. The title first affixed to him was the khalif of the khalif of the apostle of God; or in other words the successor of the successor of Mohammed: but the Arabs considering that this title, by the addition to be annexed to it at the accession of every future khalif, would be too long, they, by universal consent, substituted him the emperor of the believers. Which illustrious title, at this juncture conferred on Omar, descended afterwards to all the successors of that prince. Our readers will not expect us to follow the khalif with minute exactness through the transfigurations of his reign. This would indeed swell our article beyond all proportion. We shall therefore confine ourselves to some of the leading facts.

His arms appear to have been particularly successful; the Persians conquered, and Jerusalem submitted to his power; nor does he appear to have been checked in a single instance. In consequence, however, of his successes, an attempt was made to affiance him. The fact is thus related: Walthek Ebn Mofafer, a resolute young Arab, was procured by the king of Ghafan, and sent to Medina for this very purpose. Some time after his arrival, observing Omar to fall asleep under a tree on which he had placed himself, so as not to be discovered by any person, he drew his dagger, and was upon the point of stabbing him, when, lifting up his eyes, he saw a lion walking round about him, and licking his feet. Nor did the lion cease to guard the khalif till he awoke; but then instantly went away. This phenomenon struck Walthek with a profound reverence for Omar, whom he now revered as the peculiar care of heaven. He therefore came down from the tree, on which the lion had forced him to remain, kissed the khalif's hand, confessed his crime, and embraced the Mohammedan religion; being so strongly affected with the wonderful deliverance he had been an eye-witness of. His life, however, was at length ended by assassination; for about two years after the conclusion of the Mohawandian war, in which the Arabs probably still farther extended their conquests, though no account of their military operations during that period has reached us, that is, in the 23d year of the Hegira, according to Abu Jaafar Al Tabari, the khalif Omar Ebn Al Khattab was affianced by a Persian slave; of which horrid fact the Arab writers have handed down the following particulars: Abu Lulua, a Persian of the Magian faith, whose name was Firuz, one of Al Mohgueira Ebn Al Shaaban's slaves, was obliged by his master to pay daily two dirhems, in conformity to the Mohammedan custom, for the free exercise of his religion. Firuz refuting this treatment, complained of it to the khalif, and desired that some part at least of the tribute exacted of him might be remitted; but this favour being refused by Omar, the Persian threatened his desirouf; when he soon after effects, by stabbing him twice in the belly with a dagger, whilst he was in the mosque at Medina performing his morning devotions. The Arabs then pretend that the villain had embraced his hands in the blood of their sovereign, immediately rushed upon him; but he made so desperate a defence, that he wounded 13 of the affidants, and five of them mortally. At last, one of the khalif's attendants threw his veil over him, and seized him; upon which he stabbed himself, and soon after expired. According to Theophanes, this Firuz was an apostate or renegade, and consequently had before embraced the Mohammedan religion; but this assertion is by no means probable; because, on his becoming a convert to Islamim, he must have been manumitted by his master, and on his relapsing into Magism, he would have been put to death by the khalif's order: neither of which particulars are consistent with the information relating to the Arab historians, and even by our Greek chronographer himself. Omar languished three days, and then died, in the month of Dhu'al-hajjah, and the 23d year of the Hegira, which began in the year of the Lord 643. Authors are not agreed with regard to the duration of his khalifate. The Arab historians, whom we are inclined to follow, say that he reigned between 10 and 11 years. Theophanes affirms, that he was murdered in the 14th year of his khalifate, and Dionysius Telemacon extends the length of his reign to 12 complete years. Only one of the wounds given him by Firuz was mortal, and that he received under his navel. At his death he was 63 years old; which, as we are told by an Arab author, was the age of Mohammed himself, Abu Beer, and Ayesh, one of the prophet's wives, when they died. When Omar fell in the mosque, Ab'dulrahman Ebn Abb, one of Mohammed's first converts, supplied his place during the remainder of the service; and three days before his death, Sa'id Ebn Tarib, at his command, officiated for him. His body was interred in Ayesh's apartment, near that of the prophet Mohammed. We are informed by Ettychius, that during his khalifate he performed the pilgrimage to Mecca nine times. His extensive conquests made the Moslem empire one of the most powerful and formidable monarchies in the world. His disposition is represented to us, with evident partiality, as
as one of the best possible, and his temperance has always been highly extended.

OMBRE, a city of ancient Egypt, afterwards called Abydos and Abydes, was the capital of one of the countries in which that empire was divided, and is remarkable, in the annals of idolatry, for the hatred of its inhabitants to the religion of their neighbours the citizens of Tanis.

The genius of paganism was so complying with respect to the objects of religious worship, that although each nation, each city, and almost every family, had its own peculiar god, we know not a single instance out of Egypt, of one tribe of pagans persecuting another for worshipping gods different from theirs. The Jews and Christians were indeed persecuted by the Romans, not however for worshipping the true God, but because, together with them, they would not worship Jupiter, Juno, and all the rabble of heathen divinities.

The reason of the almost universal toleration of idolaters to one another, and of the intolerance of all to the Jews and Christians, is very obvious. Not a single pagan, a very few philosophers perhaps excepted, ever thought of paying his adoration to the Supreme and self-existent Being; but to inferior divinities, to whom it was supposed that the care of particular persons, families, cities, and nations was confided by the God of the universe. The consequence was, that, as no person denied the divinity of his neighbour's object of worship, an intercommunity of gods was everywhere admitted, and all joined occasionally in adoring the gods of the various nations. By the Jews and Christians this communion was rejected as in the highest degree impious; and it could not well be maintained between the citizens of Ombi and those of Tanis.

That brutes were worshipped in Egypt is universally known (See Polytheism); and Diodorus the Sican informs us in a passage quoted by Eusebius, that the cities and nomes of Egypt being at one time prone to rebellion, and to enter into conspiracies against monarchical government, one of their most powerful kings contrived to introduce into the neighbouring nomes the worship of different animals, so that while each reverence the deity which itself held sacred, and despised that which its neighbours had consecrated, they could hardly be brought to join cordially in one common design to the disturbance of the government.

In this distribution of gods he conferred upon Ombi the crocodile, and upon Tanis the mortal enemy of that monster, the ibex. The consequence of which was, that while the Ombites worshipped the crocodile, the Tanitrites took every opportunity of slandering him, and much that, according to Strabo, the very voice of an inhabitant of Tanis put the crocodile to flight. This, we confess, is a very improbable fact; but it is certain that the mutual hatred of those cities, on account of their hostile gods, rose to such a height, that whenever the inhabitants of the one were engaged in the more solemn rites of their religion, those of the other were not to embrace the opportunity of setting fire to their houses, and rending them in every injury that their power to inflict. And, what may, to a superficial thinker, appear extraordinary, though it will excite no wonder in the breast of him who has studied mankind, this animosity continued between the inhabitants of the two cities long after the crocodile and ibex were lost their divinity.

The conduct of the Egyptian monarch was admirably calculated for preventing the nation from combining against the government; and it extended its influence over the whole kingdom. Diodorus informs us that he assigned to each nome an animal to worship, which was hated, killed, and sometimes fed upon by the inhabitants of the neighbouring nome; and we know upon higher authority than his, that the Israelites could not offer sacrifices in Egypt, because the bullock was deemed sacred over the whole country.

OMBRE, a celebrated game at cards, borrowed from the Spaniards, and played by two, by three, or by five persons, but generally by three. When three play at this game, nine cards are dealt to each party; the whole ombre pack being only 40; because the eight, nine, and ten are thrown out of the pack. There are two sorts of counters for flukes, the greater and the lesser; the last having the same proportion to the other as a penny to a halfpenny; of the greater counters each man takes one for the game; and of the lesser for putting the hand, when eldest; and for every card taken in. As to the order and value of the cards, the ace of spades, called spadille, is always the highest trump, in whatsoever suit the trump be; the manille, or black ace, is the second; and the jack, or ace of clubs, is always the third: the next in order is the king, the queen, the knave, the fix, the five, four, and three. Of the back there are 11 trumps; of the red, 12. The least small cards of the red are always the best, and the most of the black; except the deuce and red jacks, both of which are called the manille, and are always second when the red is a trump. The red ace, when a trump, enters into the fourth place, and is called pino, otherwise it is only called an ace. The three principal cards are called matadores; which have this privilege, that they are not obliged to attend an inferior trump when it leads; but for want of a small trump, the person may renounce his trump, and play any other card, and when these are all in the same hand, the others pay three of the greater counters a-piece; and with these three for a condonation, he may count as many matadores as he has cards in an uninterrupted series of trumps; for all which the others are to pay one counter a-piece. He who hath the first hand is called ombro, and has his choice of playing the game, of naming the trump, and of taking in as many and as few cards as he pleases; and after him the second, &c. But if he does not make the trump before he looks on the cards he has taken in, any other may prevent him, by naming what trump he pleases. He that has the first hand should neither take in nor play, unless he has at least three sure tricks in his hand. For, as he wins the game who wins most tricks, he that can win five of the nine has a sure game; which is also the case if he wins four, and can divide the tricks as that one person may win two, and the other three.

If a person plays without discarding or changing any cards, this is called playing sans prudence; and if another wins more tricks than he, he is said to have carry. The over-fights in the course of the game are called
OME

OME, is a word which, in its proper sense, signifies a sign or indication of some future event taken from the language of a person speaking without any intent to prophecy. Hence Tully says, "Lythagerot noifolum voce operum runa, fed ceim hor-ne minum, quae veient eunius;" or the Lythagerotae attend to the discours not only of gods, but also of men, which they call omen. "This sort of omen was supposed to depend much upon the will of the person concerned in the event; whence the phrase accept omen, arripuit omen. Such were the original omens; but they were afterwards derived from things as well as from words. Thus Paterculus, speaking of the head of Sulpius on the rostrum, says, it was 2tum omen invia nitis propritiones, "the omen of an impending proscriptio," Suetonius says of Augulius, that he believed implicitly in certain omens; and that, si multa fihi caelestum perperam, ac sufficit pro destro inducere, ut dirum, "if his shoes were improperly put on in the morning, especially if the left shoe was put upon his right foot, he held it for a bad omen." Omen was used in a still larger sense, to signify an angry; as in the following line of Tully: "Sic aquila clarum firmavit Jupiter omen?" Thus Jove confirmed the bright omen of the eagle." It was lastly used, in the most generic sense, of all, for a portent or prodigy, as in the third book of the Æneas, where a myrtle torn up by Æneas dropped blood. Upon this appearance, says the hero,

— Mift frigida horror
Membra quatis, gelidualque corf formidine fanguis.

And the same thing being repeated upon his breaking a branch from another tree, he prayed to the gods to avert the omen.

Multa movens animo Nymphas venerabat agetres, Gradivunque patrem, Geticae qui praedit arvis, Rite secundarent vilis, enulique levarent (A).

These portentous or supernatural omens were either external or internal. Of the former sort were those showers of blood so frequently occurring in the Roman history, which were much of the same nature with this adventure of Æneas, which he calls monstra deum. Of the second sort were those sudden confirmations, which, feizing upon men without any visible cause, were imputed to the agency of the god Per, and hence called panic fears. But indeed there was

D d

hardly

(A) Instead of translating these short quotations, we shall here give Dryden's version of the whole of this portentous adventure, as we are persuaded that the mere English reader, who alone can with a translation, be glad to have the fullest account of the bleeding myrtle, together with its effects on the mind of the hero. It is as follows:

Not far, a rising hillock flood in view:
Sharp myrtles on the sides and corners grew.
There, while I went to crop the sylvan scenes,
And shade our altar with their leafy greens,
I pull'd a plant (with horror I relate
A prodigy of strange, and full of fate:
The tender fibres roll; and from the wound
Black bloody drops distill'd upon the ground.
Mute and amaz'd, my hair with terror flood;

Fain shrink my fines, and congeal'd my blood.
Mann'd once again, another plant I try;
That other gulph'd with the same fanguine dye.
Then, fearing guilt for some offence unknown,
With prayers and vows the Dryad I stone,
With all the fiders of the woods, and mott
The God of arms, who rules the Thracian cash;
That they, or he, these omens would aver,
Release our fears, and better signs impart.
hardly any thing, however trivial, from which the ancients did not draw omens. That it should have been thought a direful omen when any thing befel the temples, altars, or statues of the gods, need excite no wonder; but that the meeting of a eunucon, a negro, a bitch with whelps, or a snake lying in the road, should have been looked upon as portending bad fortune is a deplorable instance of human weaknecfs, and of the pernicious influence of superflition on the mind.

It is more than probable that this practice of making ordinary events ominous of good or bad fortune took its rise in Egypt, the parent country of almost every superflition of paganism; but wherever it may have arisen, it spread itself over the whole inhabited globe, and at this day prevails in a greater or lesser degree among the vulgar of all nations.

In England, it is reckoned a good omen, or a sign of future happiness, if the fun fhines on a couple coming out of the church after having been married. It is also esteemed a good sign if it rains whilst a corpse is burying:

Happy is the bride that the fun fhines on;  
Happy is the corpele that the rain rains on.

To break a looking-glass is extremely unlucky; the party to whom it belongs will lose his best friend.

If, going a journey on businesf, a few crofs the road, you will probably meet with a disappointment, if not a bodily accident before you return home. To avert this, you must endeavour to prevent her crossing you; and if that cannot be done, you must ride round on fresh ground. If the fow is attended with her litter of pigs, it is lucky, and denotes a feluccfsful journey.

It is unlucky to see, firft one magpie, and then more; but to see two, denotes marriage or merriment; three a feluccfsful journey; four, an unexpected piece of good news; five, you will shortly be in a great company. To kill a magpie, will certainly be punished with some terrible misfortune.

If, in a family, the youngest daughter should be married before her elder sisters, they must all dance at her wedding without shoes: this will counteract their ill luck, and procure them husbands.

If you meet a funeral poadition, or one pastles by you, always take off your hat: this keeps all evil fpirits attending the body in good humour.

If, in eating, you miss your mouth, and the viettals fall, it is very unlucky, and denotes approaching fickness.

It is lucky to put on a focking the wrong fide outward; changing it alters the luck.

When a perfon goes out to transact any important businesfs, it is lucky to throw an old shoe after him.

It is unlucky to present a knife, scissors, razor, or any sharp or cutting instrument, to one's mistref or friend, as they are apt to cut love and friendship. To avoid the ill effects of this, a pin, a farthing, or some trifling recompence, must be taken. To find a knife or razor, denotes ill luck and disappointment to the party.

In the Highlands of Scotland, it is thought unlucky if a perfon falling out upon a journey stumble over the threshold, or be obliged to return for any thing forgotten. If a sportman fee any perfon stepping over his gun or fishing-rod, he expects but little success in that day's diversion. Sweating is also deemed ominous. If one fneeze when making a bed, a little of the straw or heath is taken out and thrown into the fire, that nothing may disturb the rest of the perfon who is to sleep in the bed. Among the fame people, success in any enterprize is believed to depend greatly upon the firft creature that presents itself after the enterprize is undertaken. Thus, upon going to shoot, it is reckoned lucky to meet a hare, but very unfortunate to fee a hare if the efcape; and upon meeting any creature deemed unlucky, the belt means of averting the omen is to roll a ftone towards it. The Greeks attributed the fame efficacy to the rolling of a ftone, though they greatly preferred killing the ominous animal, that the evil portended might fall on its own head.

The motions and appearances of the clouds were not long ago confidered as certain signs by which the skilful Highlander might attain to the knowledge of futurity. On the evening before new-year's-day, if a black cloud appeared in any part of the horizon, it was thought to prognoficate a plague, a famine, or the death of some great man in that part of the country over which it should appear to fit; and in order to avert the place threatened by the omen, the motions of this cloud were often watched through the whole night, if it happened to continue fo long visible above the horizon.

By the believers in this superflition there are days, as well as words and events, which are deemed ominous of good or bad fortune. The firft day of every quarter, midsummer, and new-year's day, are reckoned the moft fortunate days in the year for accomplishing any de SIGN. In the Ile of Mull, ploughing, fowing, and reaping, are always begun on Tuesday, though the moft favourable weather for these purposes be in this way frequently loft. That day of the week on which the third of May falls, is deemed unlucky throughout the whole year. In Morven, none will upon any account dig peat or turf for fuel on Friday; and it is reckoned unlucky to number the people or cattle belonging to any family, and doubly so if the number be taken on Friday. The age of the moon is also much attended to by the vulgar Highlanders. It is alleged, that during the increafe things have a tendency to grow and fick together; and hence, in the Ile of Skye, fences, which are there made of turf, are built only at that time; whilst turf or peats for fuel are never, even in the moft favourable weather, either made or stacked up but while the moon is in its wane. An opinion prevails in fome places, that if a house take fire during the increafe of the moon, the family to which it belongs will prosper in the world; but that if the fire happen while the moon is in the decreafe, the family will from that time decline in its circumstances, and sink into poverty.

In attributing such influence to the moon, the superflitious Highlanders have the honour to agree with the philofophic Virgil, who in his Georgics gives the following sage inftstructions to the husbandman:

\[\text{Ipsa} \]
From this coincidence of the superstitious practices of the Roman poet with that of the natives of Mull and Morven, we are strongly inclined to adopt the hypothesis of the gentry among us, that the Druids were paid to pretended omens, not only in the highlands, but also in the low country of Scotland; and indeed, when we consider the prevalence of Druidism handed down by the Spaniards, and the fact that the Druids were a relic of Druidism handed down by the Romans, we are led to believe that the Druids were acquainted with the doctrine of Pythagoras as it was known elsewhere (see Druids); that Virgil was not stranger to the Pythagorean philosophy; that Pythagoras and his followers were addicted to the dotations of Magic which has been made apparent in that article; and therefore it appears to us probable at least, that the attention paid to pretended omens, not only in the highlands, but also in the low country of Scotland, and indeed among the natives of Europe, is a remnant of one of the many superstitions which the Druids imposed upon their deluded followers. That it is contrary to every principle of sound philosophy, all philosophers will readily acknowledge: and whoever has studied the writings of St. Paul must be convinced that it is inconsistent with the spirit of genuine Christianity.

OMENTUM, or EPILOGUE, the Caeli, in anatomy, a membranaceous part, usually furnished with a large quantity of fat; being placed under the peritoneum, and immediately above the intestines. See Anatomy, n° 90.

OMER, in Jewish antiquity. See CORSUS.

St. OMER'S, a strong, fortified, large, and populous town of France, in Artois, and capital of a considerable bailiwch, with a castle and a bishop's seat. It is a fortress of considerable importance, and surrounded on one side with a large morass; and about it there are many fuites, which serve to carry the water off when it is overflowed; and in the midst of the morass there is a fort of floating islands covered with verdure and trees. The cathedral is a handsome structure; and there are other fine buildings, with a rich Benedictine abbey. The French became masters of this place in 1679. It is situated on the river Aa, and on the side of a hill, eight miles north-west of Aire, and 153 north of Paris. E. Long. 2° 20'. N. Lat. 54° 45'.

OMOA, a Spanish town and fortress on the south side of the bay of Honduras, N. Lat. 15° 50'. W. Long. 89° 50' from London. It is the key to the bay; and such is the depth of the water, that ships of any burden may ride in the harbour with safety. It is a place of the utmost importance to Spain, as the regilder ships to and from Guatemala are sent to it in the time of war. The town was first established in 1751, under the command of Don Joseph Antonio de Palmo. At that period the inhabitants were about 20 white men, 60 mulattoes and free negroes, and 200 slaves to the king of Spain; and the military force consisted of about 30 soldiers, besides officers. The fort was originally composed of sand confined in boarded cofiers, and faced with hail-burnt bricks. It was defended by 12 fine brads 24-pounders mounted, four or five iron guns of different bores, and some field-pieces. The Spaniards, sensible of the importance of the place, afterwards fortified it at an incredible expense, the stone of which the walls are built having been raised from the sea, and brought from the distance of 20 leagues. The outworks were not completely finished in the year 1779, though 1000 men had then been employed upon them for 20 years.

Towards the end of that year an expedition was undertaken against this fortress, in consequence of one formed by the Spaniards against the British log-wood cutters in the bay of Honduras and on the Mosquito fiore. The latter, finding themselves hard pressed by their enemies, applied to general Dalling governor of Jamaica for assistance; who accordingly sent a detachment to their relief under Captain Dalrymple, with necessary supplies of arms, ammunition, and artillery. Before their arrival, however, the Spaniards had taken possession of St. George's Key, the chief settlement of the British in these parts, which they plundered and took a number of prisoners, being joined by a body of their countrymen, retake it, and forced the enemy to retire. In the mean time Captain Dalrymple, who had been informed of the loss of the place, was hastening to the relief of the inhabitants, and in his way fell in with Admiral Parker, who was in quest of some regilder ships; but which, retreating into the harbour of Omoa, were too strongly protected by the fort there to be attacked by sea. As the Spaniards, however, had now been compelled to abandon St. George's Key, it was proposed to unite the British forces by sea and land, and to attempt the conquest of this fortress. As the force under Captain Dalrymple was too incomconsiderable to attempt the fort by land, it was augmented by the marines of the squadron, and a strong party of the seafers; though, after all, it did not exceed the number of the garrison who opposed them.

The troops were landed at about nine miles distance from the fort in the dusk of the evening, with a design to march directly forward; but in order to surprize and carry it by escalade in the night-time. No roads, however, being found, they were obliged to explore their way through narrow foot-paths, morasses, and over mountains to be met with precipices, that they were obliged, in order to avoid them, to make use of
In a short time, however, without impediments the Spaniards were quickly routed and driven into the town; from whence they continued to fire upon the British, it was found necessary to set fire to it, tho' very much against the inclination of the assailants. An engagement ensued, in which the Spaniards were completely routed and driven into the town, though they continued to fire upon the British. It was found necessary to send fire to it, the very much against the inclination of the assailants.

In the mean time the squadron took the opportunity while the town was in flames, to come into the bay, and approach the fort with an intention to batter it; but the garrison returned their fire so briskly, that no impression could be made by that of the squadron, which was detained by want of wind from approaching sufficiently near. The troops then, being masters of the ground adjacent to the fort, erected several batteries in such situations as were most proper for annoying it: but though they carried on their operations with great vigour, it was full found that heavier artillery than any they possessed would be requisite, the walls being no less than 18 feet in thickness; in consequence of which they resolved still to attempt the place by escalade.

The attempt was made on the 21st of October, early in the morning. The troops entered the ditch, which fortunately for them happened to be dry, and fixed their scaling ladders against the walls, which were near 30 feet high. Twofeamen mounted first; and, with admirable courage and presence of mind, fimbod by the ladder which they had mounted, to guard it till others ascended; and boldly presented their pieces against a large party drawn up to receive them, though they prudently retained their fire till their comrades came up.

The squadron, now drawing near, kept up a heavy and continual fire upon the fort, while the Spaniards were struck with such fury of the excessive celerity and boldness of the assailants, that they remained motionless and unable to oppose their enemies, notwithstanding the exhortation and example of their officers. From this panic they never recovered, while the seamen and soldiers, continued to scale the wall with greater rapidity. The Spanish, now being the conquerors, were able to make an effort to defend themselves. About 400 of them escaped over the walls on the opposite side of the fort; the remainder surrendered at discretion.

The whole of this transaction reflected the highest honour both on the conduct and courage of the British, and an instance of heroism is related in a British sailor to which history affords nothing superior. This man, having scaled the walls, and armed himself with a cutlass in each hand. Thus armed he met with a Spanish officer unarmed, and just routed from sleep. The generous tar scorned to take advantage of his condition, and therefore presented him with one of his own cutlasses, saying, "You are now on a footing with me!" The officer, however, was too much struck with admiration at his conduct to accept the offer, and took care to make the circumstance sufficiently known.

The value of the booty taken on this occasion amounted to three millions of dollars, but the loss most sensibly felt by the Spaniards was that of 250 quintals of quick silver, a commodity indispensably necessary in extracting the precious metals from their ores. They offered therefore to ransom it at any price; but though the retention of it was far from affording a profit equal to that offered by the Spaniards, the British commanders absolutely refused to part with it, on account of the advantages the enemy would derive from having the metal in their possession. For the same reason they refused to accept of any ransom for the fort though the governor offered to lay down 500,000 dollars for it. The Spanish military and the inhabitants were treated with the utmost humanity; their personal effects remaining untouched; and this generosity must have appeared to greater advantage, when compared with the behaviour of their own countrymen at Honduras, where the British were treated with remarkable severity. The church plate and ornaments were restored on condition that the terms of capitulation should be faithfully kept.

In a short time, however, it appeared that it would have been better to have accepted of a ransom for the fort, as from circumstances at that time it could not be retained in the possession of Britain. A garrison was indeed left for its defence on the departure of the British squadron; but as it was very inconsiderable, on account of the small number of men that could be spared, the Spaniards quickly determined to make an attempt to regain the fort. For this purpose a body of 2000 men were collected, who invested it on the 27th of November. The British defended it with the utmost bravery; keeping up a constant fire upon the enemy, and obliging them to retire for shelter and take up their quarters behind a hill. Here they made preparations for an assault, in which their numbers left the success, as they supposed, by no means dubious. The garrison was therefore summoned to surrender, with a promise of the honours of war and a safe conveyance to Great Britain; denouncing at the same time, the utmost vengeance in case of refusal; which being refused, the necessary preparations were made for an escalade.

The condition of the garrison was now such as could afford very little hope of being able to make any effective resistance. They were but 80 in number, most of whom were become incapable of duty either from illness or excessive fatigues; and they were now also obliged to make one central answer for five men filling his place, and challenging as many times. There was no surgeon to attend the sick and wounded; nor had they even any water but what came from a dip of war that lay abreast of the fort. In this desperate situation, they resolved, notwithstanding the menace of the Spanish commander, to render the place as unserviceable as they could. For this purpose they spiked up all the guns; destroying the stores and ammunition that could not be carried off; they even locked the gates of the fort, after which they embarked without the loss of a single man. All this was performed in defiance of the large force that besieged them; and the exploit, when duly considered, must appear not less of a matter of astonishment than the extraordinary manner in which the fort had been taken, the officer who commanded in this remarkable retreat, was Captain Hulke of the navy.

OMOPHAGIA, an ancient Greek festival, in honour of Bacchus, surnamed Omophages, i.e. eater of raw flesh. This festival was observed in the same manner with the other festivals of Bacchus, in which they consul.
counterfeited madness. What was peculiar to it, was, that the worthi-plea used to eat the entrails of goats, raw and bloody, in imitation of the god who was supposed to do the same thing.

Omphacine-nit, a vicious brown juice extracted from green olives. With this oil the ancient Athletes, when going to wrestle, anointed themselves; and when that gymnastic exercise was over, they rolled themselves in the sand, which, mixing with the oil and ointment on their bodies, constituted the friuljatis to highly excelled in the cure of several diseases. This precious medicine was carefully scraped off the body of the Athlete with a kind of instrument somewhat like a comb, which was called friulis; and such was the demand for the preparations, that they were a very lucrative article of trade.

Omphale (fab. hist.), a queen of Lydia, daughter of Jardamus. She married Tmolus, who at his death left her mistress of his kingdom. Omphale had been informer of the great exploits of Hercules, and wished to see a illustrious hero. Her wish was soon gratified. After the murder of Eurytus, Hercules fell sick, and was ordered to be sold as a slave, that he might recover his health and the right use of his senses. Mercury was commissioned to tell him, and Omphale bought him, and restored him to liberty. The hero became enamoured of his mistress, and the queen favoured his passion, and had a son by him, whom she called Ageus, and others Lamen. From this son were descended Gyges and Croesus; but this opinion is different from the account which makes these Lydian monarchs spring from Alceus, a son of Hercules, by one of the female servants of Omphale. Hercules is represented by the poets as to desperately enamoured of the queen, that to conciliate her eflence, he spins by her fide among her women, while the covers herself with the lion's skin, and arms herself with the club of the hero, and often strikes him with her fandoms, for the uncouth manner in which he holds the ditaft, &c. Their fondness was mutual. As they once travelled together, they came to a groto on mount Tmolus, where the queen dressed herself in the habit of her lover, and obliged him to appear in a female garment. After they had dined, they both retired to rest in different rooms, as a sacrifice on the morrow to Bacchus required. In the night Simon, or rather Pan, who was enamoured of Omphale, introduced himself into the cave. He went to the bed of the queen, but the lion's skin concealed him that it was the dros of Hercules; and therefore he repaired to the bed of Hercules, in hopes to find there the object of his affections. The female dros of Hercules deceived him, and he laid himself down by his side. The hero was awakened, and kicked the intruder into the middle of the cave. The noise awoke Omphale, and Faunus was discovered lying on the ground, greatly disapponted and ashamed.

Omphalea, in botany: A genus of the triandra order, belonging to the monoeica clafs of plants; and in the natural method ranking with those of which the order is doubtful. The male calyx is tetraphyllous; there is no corolla; the receptacle, into which the anther are sunk, is ovate. The female calyx and corolla are as in the mal; the stigma tririd; the capsular carnos and trilocular, with one seed.

Omphalomesenteric, in anatomy. All the ophalomesenteric tubes are wrapped up in at least two coats or membranes; most of them have a third, called allantoides, or urinary.

Some, as the dog, cat, hare, &c. have a fourth, which has two blood-vessels, viz. a vein and an artery, called omphalo-nec mesentery, because passing along the linting to the navel, and terminating in the mesentery, which, on the ling of the ovum, is the umbilical cord.

Omale, a man of the first rank in the Mogul empire; a nobleman. It is the plural of the Arabic awar.

On, (anc. geog.), a city of Egyəpt faced to the sun, and by the Greeks, on that account called Heliospolis. (See Heliospolis.) It was remarkable for the wisdom and learning of its priestdom, and for the spacious buildings in which they cultivated the studies of philosophy and astronomy. The priests of On were esteemed more noble than all the other priests of Egypt. They were always privileged to enter and minister at the temple of the priest of On, and were highly esteemed in their profession.

Omrah, a man of the first rank in the Mogul empire; a nobleman. It is the plural of the Arabic awar.

On, (anc. geog.), a city of Egypt, sacred to the sun, and by the Greeks, on that account called Heliospolis. (See Heliospolis.) It was remarkable for the wisdom and learning of its priestdom, and for the spacious buildings in which they cultivated the studies of philosophy and astronomy. ONA | 214 |

ONA, or Onania, has been manifested to have been committed by Onan, and punished in him with death.

This practice, however common, hath among all nations been reckoned a very great crime. In scripture, besides the instance of Onan above-mentioned, we find self-polluters termed eminently, unclean, filthy, and abominable. Even the heathens, who had not the advantage of revelation, were of the same opinion, as appears from the following lines of Martial.

_Hoc nihil effe putas! feculsi eft, michi crede; sed ingens
Quantum viso animo concepti! seiu tuo._

You think 'tis nothing! 'tis a crime, believe!
A crime so great you scarcely can conceive.

Dr Tiffot has published a treatise on the pernicious effects of this shameful practice, which appears to be no less baneful to the mind than to the body. He begins with observing, that by the continual waste of the human body, ailments are required for our support. These ailments however, require certain preparations in the body itself; and when by any means we become so altered that these preparations cannot be effected, the best ailments then prove insufficient for the support of the body.

Of all the causes by which this morbid alteration is brought on, none is more common than too copious evacuations; and of all evacuations, that cess. It is also to be observed, that though excess in natural venery is productive of very dangerous disorders, yet an equal evacuation by self-pollution, which is unatural way, is productive of others still more to be dreaded. The consequences enumerated by Dr Tiffot are as follow:

1. All the intellectual faculties are weakened: the memory fails; the ideas are confused, and the patient sometimes even falls into a flight degree of insanity. They are continually under a kind of inward restlessness, and feel a constant anguish. They are subject to giddiness; all the senses, especially those of seeing and hearing, grow weaker and weaker, and they are subject to frightful dreams.

2. The strength entirely fails, and the growth in young persons is considerably checked. Some are afflicted with almost continual watching; and others do so almost perpetually. Almost all of them become hypochondriac or hysterical, and are afflicted with all the evils which attend these disorders. Some have been known to spit calculus matter; and others are afflicted with coughs, flow fevers, and consumptions.

3. The patients are afflicted with the most acute pains in different parts of the body, as the head, breast, stomach, and intestines; while some complain of an obtuse sensation of pain all over the body on the slightest impression.

4. There are not only to be seen pimples on the face, which are one of the most common symptoms; but even blisters, or supplicative pustules, appear on the face, nose, breast and thighs, and sometimes delirious excrecences arise on the forehead.

5. The organs of generation are also affected: and the semen is evacuated on the slightest irritation, even that of going to stool. Numbers are afflicted with an habitual gonorrhoea, which entirely destroys the vigour of the constitution, and the matter of it resembles a fetid fannah. Others are affected with painful pimples, dyuries, stranguries, and heat of urine, with painful tumours in the testicles, penis, bladder, and spermatic cord; and impotence in a greater or less degree is the never-failing consequence of this detestable vice.

6. The functions of the intestines are sometimes totally destroyed, and some patients complain of colitiveness, others of diarrhoea, piles, and the running of a fetid matter from the fundament.

With regard to the cure, the first step is to leave off those practices which have occasioned the disease; which our author afferts it no easy matter; as, according to him, the soul itself becomes polluted, and can dwell on no other idea; or if it does, the irritability of the parts of generation themselves quickly recall ideas of the same kind. This irritability is no doubt much more to be dreaded than any pollution the soul can have received; and by removing it, there will be no occasion for exhortations to discontinue the practice. The principal means for diminishing this irritability are, in the first place, to avoid all stimulating, acid, and spiced meats. A low diet, however, is improper, because it would further reduce the body, already too much emaciated. The food should therefore be nutritive, but plain, and should consist of flesh rather roasted than boiled, rich broths, &c. It is certain, however, that as these foods contribute to restore the strength of the body, the stimulus on the organs of generation will be proportionately increased by the semen which is constantly secreted, and which will now be in larger quantity than ever in healthy persons, owing to the great evacuations of it which have preceded.

Some part of the semen is gradually absorbed by the lymphatics; in consequence of which, the remainder becomes thick, acid, and very stimulating. To remedy this, exercise is to be used, and that not only for pleasure, but till it is attended with a very considerable degree of fatigue. The sleep also must be no more than is barely sufficient to repair the fatigues occasioned by the exercise, or other employment; for an excess in sleep is as bad as idleness or stimulating foods. Excess in wine or intoxicating liquors is also to be avoided; or rather such liquors ought never to be tasted, unless as a medicine to restore the exhausted spirit, and to all this ought to be joined the Peruvian bark, which hath this admirable property, that, with little or no stimulus, it restores the tone of the fyltem, and invigorates the body in a manner incredible to those who have not observed its effects. If these directions are followed, the patient may almost certainly expect a recovery, provided any degree of vital strength remains; and those who desire a life of celibacy on a moral account, will find them much more effectual than all the vows of chastity they can make.

ONA and ONCE. See Felis, vi. and iv.

ONEHOURA and ONEEHOW, two small islands of that cluster which was discovered by Captain Cook, and by him called the Sandwich Islands. (See Sandwich Islands.) Onehoura is very small and its chief produce is yams. Oneehow is considerably larger, being about ten miles over. It is remarkable for the great quantity of excellent yams which it produces, and for a sweet root called tee or tea, which is generally...
Ily about the thickness of a man's wrist, though sometimes much larger. This root, which the natives commonly bake previous to bringing it to market, is of a wet clammy nature, and with proper management makes excellent beer.

ONEGA, a river and lake of the Ruffian empire, between Mucovice Carelia, the territory of Cargopol, and Swedifh Carelia. It is 100 miles in length and 40 in breadth, having a communication with the lake Ladoga, and consequently with Petersburg. The river has its source in Cargopol, and gives its name to a county full of woods.

ONEGA, a sea-port town of Italy, in the territory of Genoa, with the title of a principality; but it belongs to the king of Sardinia, as well as the province, which abounds in olive-trees, fruit and wine. It has often been taken and retaken in the wars of Italy; which is no wonder, as it is an open place. The French and Spaniards had possession of it in 1744, but were driven out by the Piedmontese; however, they returned next winter, and again made themselves masters of it. E. Long. 7°. 51. N. Lat. 43°. 58.

ONEIROCRITICA, the art of interpreting dreams: or a method of foretelling future events by means of dreams. See Dream, Divination, &c. — The word is formed from the Greek ονειροκρίτης, "dream." and προφήτης, "prophecy," "judgment." — Some call it oni occurred, and derive it from κρίνω, and προφήτης, "I prophesy, I command.

It appears from several passages of scripture, that there was, under the Jewish dispensation, such a thing as foretelling future events by dreams; but then there was a particular gift or revelation required for that purpose.

Hence it has been inferred, that dreams are really significative, and do forebode something to come; and all that is wanting among us is the oni occurred, or the art of knowing what: yet it is the opinion of many, that dreams are mere chimerae; bearing indeed some relation to what has passed, but none to what is to come. — As to the case: of Joseph, it was possible for God, who knew all things, to discover to him what was in the womb of fate; and to introduce that, he might take the occasion of a dream.

ONEIROCRITICS, a title given to interpreters of dreams, or those who judge of events from the circumstances of dreams.

There is no great regard to be had to those Greek books called oni occurred; nor do we know why the patriarch of Constantinople, and others, should amuse themselves with writing on so pitiful a subject.

Rigault has given us a collection of the Greek and Latin works of this kind, one attributed to Alarmpice, another to Niceratus, patriarch of Constantinople; to which are added the treatises of Artemidorus and Achmet. — But the books themselves are little else than reviviscences; a kind of waking dreams, to explain and account for sleeping ones.

The secret of oni occurred, according to them all, consists in the relation supposed to be between the dream and the thing signified; but they are far from keeping to the relations of agreement and similitude; and frequently have recourse to others of diffimilitude and contrariety. Concerning oni occurred and oni occurred, the unlearned reader will find much information in Warburton’s Divine Legation of Moabs, and the books to which he refers.

ONESIÆ thermae, were, according to Strabo, excellent baths, and fotaly waters, at the foot of the Pyrenees in Aquitania. Near the river Aterus stands at this day the town Bagneres, famous for its waters, which appear to be the Onesie of Strabo: situated in the county of Bigorre in Gallicy, near the river Adour.

ONIÆ oppidum and Templum, (Josephus); so called from Onias, the high-priest of the Jews in Egypt; who built a temple in imitation of that at Jerusalem, by permission of the king of Egypt, on the spot where stood the temple of Diana Argelitis Leontopolis: it was encompassed with a brick-wall and had a large tower like that at Jerusalem. (Josephus;) it was the metropolis of the Nomos Helopolites, (Ptolemy;) because in Strabo’s time Helopolis was fallen to decay.

ONGLEE, in heraldry, an appellation given to the talons or claws of buffal or birds, when borne of a different colour from that of the body of the animal.

ONION, See Allium, p. 5.—Onions, leeks, and garlic are all of the same genus; and in their recent state are acrid, but harmless to the human body. When, by age or climate, this acrimony is too great, we do not use them as food. In Spain, the garlic being equally mild with the onion is used as common food. By the ordinary culinary preparation their acrimony is diffipated, and a remarkably mild subtility remains, promising much nutriment, which those who can digest them raw will certainly obtain. Though sometimes suffered as food, yet they are on that account used in medicine, uniting the two qualities of pectorals, viz: on the account of their acrimony, being in their recent state expectorant; in their boiled state, on account of their mucilage, demulcent, provided the quantity taken be sufficient. Some of late, in this country have found in leeks a form:ferous quality: but this is not yet confirmed by a sufficient number of experiments. — Besides the three above-mentioned, there are several others belonging to the same tribe, which we use as condiment; but only the leek and onion as diet. In its recent state, the onion is the most acrid: in its boiled state, the leek retains its acrimony more tenaciously. On account of this, and some difference of texture, the onion is more easily digested and more universally used than the leek; being more easily broken down, and more generally agreeable.

ONISCUS, in zoology, a genus of insects belonging to the order of aptera. It has 14 legs, bristly feelers, and an oval body. There are 15 species; of which the most remarkable are,

1. The estonius, or sea wood-louse, is white; yes black; convex above, beneath flat, margin acute; Antennæ 4; Four kind pair of legs largest, hairy, Body of 10 segments. Lengts ½ line. Found on the coast. It accompanies the herring, and is an enemy well known to our fishermen: these insects will frequently eat up a whole fillet while it hangs in the net.

2. Oniscus aquaticus, is of an aften colour, and tolerably smooth. Its body is composed of seven articulations, exclusive of the head and tail; which last part
is much larger than the other segments, round at the extremity, and from which issue two appendices, each divided into two threads. This insect has that in common with some sea-anemone, but differs from them by the sea ones having ten segments. This has seven legs on each side; the last of which gradually increase in length, and are constantly larger than the forefoot. The antennae have but three long articulations, the last of which is much longer than the rest. This insect is found in pools, small rivulets, and especially in spring time.

3. Astius, still ps., or easulodes, is oval; the tail obsolete, with two undivided bifilae; various as to colour; length, 5 lines. Their use in medicine is well known.

4. Calus armadillo is broad, very glossy, and smooth; its colour is black, with a small portion of white on the edge of the segment, which colour often varies; but still the insect is glossy and smooth. Its body is composed of ten segments, besides the head and tail. Of the ten segments, the first seven are broad, and the last three short. The first of these three appears divided in the middle, which is broader than the rest, into three more. These last short segments, with that of the tail, form the extremity of the animal's body, which is round, without any appendix, and constitutes the specific character of this insect. It has fourteen feet, seven on each side. This oniscus, when touched, rolls itself up into a ball, bringing its head and tail together like the animal called armadillo, and neither antenna nor feet are seen; it might be taken for a round, shining pearl. This oniscus is found in woods.

Onkelos, named the Prophyle, a famous Rabbi of the first century, and the author of the Chaldee Targum on the Pentateuch. He flourished in the time of Jesus Christ, according to the Jewish writers; who all agree that he was, at least in some part of his life, contemporary with Jonathan ben Uzziel, author of the second Targum upon the prophets. Dean Prideaux thinks he was the elder of the two, for several reasons: the chief of which is the purity of the style in his Targum, therein coming nearest to that part of Daniel and Ezra which is in Chaldee, and is the truest standard of that language, and consequently is the most ancient; since that language, as well as others, was in a constant flux, and continued deviating in every age from the original; nor does there seem to be any reason why Jonathan ben Uzziel, when he undertook his Targum, should pass over the law, and begin with the prophet, but that he found Onkelos, had done this work before him, and with a success which he could not exceed.

Azaries, the author of a book intitled Novum Examin., or the Light of the eyes, tells us, that Onkelos was a prophet in the time of Hillel and Sannai, and lived to see Jonathan ben Uzziel one of the prime scholars of Hillel. These three doctors flourished 12 years before Christ, according to the chronology of Gauz; who adds, that Onkelos was contemporary with Gamaliel the elder, St Paul's master, who was the grandfoss of Hillel; who lived 28 years after Christ, and did not die till 18 years before the destruction of Jerusalem. However, the fame Gauz, by his calculation, places Onkelos 100 years after Christ; and to adjust his opinion with that of Azaries, extends the life of Onkelos to a great length. The Talmudists, tell us that he assisted at the funeral of Gamaliel, and was at profigious expense to make it most magnificent. Dean Prideaux observes, that the Targum of Onkelos is rather a version than a paraphrase; since it renders the Hebrew text word for word, and for the most part accurately and exactly, and is by much the best of all the Targums; and being set to the same musical notes with the Hebrew text, it is thereby made capable of being read in the same tune with it in their public assemblies. From the excellency and accuracy of Onkelos's Targum, the dean also concludes him to have been a native Jew, since, without being bred up from his birth in the Jewish religion and learning, and long exercised in all the rites and doxologies of the Jewish religion and learning, and long exercised in all the rites and doxologies and prayers of that religion, he could not have been fitted for that learned work which he performed; and that the representing him as a prophet seems to have proceeded from the error of taking him to have been the true of Akillas, or Aquila, of Pontus, author of the Greek Targum or version of the prophets and Hagiography, who was indeed a Jewish prophet.

Onkotomny, in surgery, the opening of a tumour or abscess. See Surgery.

Onuclea, in botany: A genus of the natural order of flics, belonging to the cryptogama class of plants. The spike is flat, and turned to each side, with quinquaversal fructifications.

Onomancia, or rather Onomatia, a branch of divination, which foretels the good or bad fortune of a man, from the letters in his name. See the article Divination, and Name.

From much the same principle the young Romans toasted their names as often as there were letters in their names; hence Martial says,

Neeia fes coelis, fepens fusinae ubatur,

Onomatopoemia, in grammar and rhetoric, a figure where words are formed to resemble the sound made by the things signified: as the buzz of bees, the cackling of hens, &c. Reembonances of this kind are often fancied when they are not real, though, no doubt, there are in every language some words of which the sound is very like to that which these words are employed to express. Yet, to the mortification of grammarians and rhetoricians, conjunctions, which have been jully pronounced in parts of speech, are the only sounds uttered by men that are wholly natural, and these are fewer than is commonly supposed. See Grammar and Language.

Ononis, in botany: A genus of the decandria order, belonging to the diadelpia class of plants. The calyx is quinquepartite, with the segments linear; the vexillum frilled; the legumen turgid and sellole; the filamentous without a filum.

Onopordum, in botany: A genus of the polygama class of plants; and in the natural method ranking under the
The word in the Greek language signifies only the Osiris-like poets making this stone to have been formed by the Parce from a piece of Venus's nails, cut off by Cupid with one of his arrows.

Ono! anuer. The receptacle is honey-combed; the scales of the calyx mucronated or pointed.

Ocosa, a Greek author and Platonic philosopher, who wrote Commentaries on Plato's politics, which are lost: but his name is particularly famous for a treatise entitled Λέξεις Στρατευμάτων. "Of the duty and virtues of the general of an army," which has been translated into Latin, Italian, Spanish, and French. The time when he lived is not precisely known: but is imagined to be in the reign of Emperor Claudius.

Onosander, in botany: A genus of the monocotyledon order, belonging to the pentandria class of plants; and in the natural method ranking under the 41st order, Alphifolica. The corolla is campanulated, with the throat porous; there are four petals.

Ontario, a lake of North America, in the country of the Iroquois, 180 miles in length and 60 in breadth. There are many rivers that run into it; and from it the great river St Lawrence proceeds. It communicates with Lake Erie by a river 33 miles in length, which is the remarkable cataract of Niagara.

Ontology, see Metaphysics, p. 3.

Onuphrius Panvinus, a learned Italian of the order of hermits of St Augustin, was born of a noble family at Verona, in 1529; and, being trained to literature, became so indefatigable in his studies, that he spent whole days and nights in reading the ancients: which made Manutius fyle him Helio Antiquitatis. His first performance was a Chronicle of the Popes and Cardinals, which was printed without his knowledge at Venice in 1557; and some time after, more correctly by himself. He afterwards continued Plutarch's Lives of the Popes, from Sextus IV. to Pius V. and subjoined annotations to the lives Plutarch had written. He also wrote four pieces upon Roman Antiquities, which are printed in Gravelius's Collection. He died in his 35th year, in 1568.

Onycomancy, or as some write it, Onynamcy, is a kind of divination by means of the nails of the fingers. — The word is formed from the Greek onyx, "nail," and μυστήριον "divination."

The ancient practice was to rub the nails of a youth with oil and foot, or wax; and to hold up the nails thus smeared against the sun. — Upon them were supposed to appear figures or characters, which showed the thing required.

Onyx, in natural history, one of the semi-precious gems, with variously coloured zones, but none red; being composed of crystal, debated by a small druse of earth; and made up either of a number of flat plates or of a series of coats surrounding a central nucleus, and separated from each other by veins of a different colour, resembling zones or belts.

We have four species of this gem. 1. A bluish-white one, with broad white zones. 2. A very pure onyx, with snow-white veins. 3. The jasperony, or horn-onyx, with green zones. 4. The brown onyx, with bluish white zones.

The ancients attributed wonderful properties to the onyx, and imagined that if worn on the finger it acted as a charm: they have also recommended it as an astringent; but at present no regard is paid to it.
Naturally he was of a rough and disagreeable temper, which occasioned him to lose the love of his disciples and his friends; and among the number, he totally forfeited the esteem of Rubens, his best pupil. Jordaens was the only friend to the savage humour of his master, but it appears probable, that he only condescended to endure his morose behaviour, out of affection to the daughter of Van Oort, to whom Jordaens was afterwards married.

In his style of painting, however, he neglected nature, and was entirely a mannerist; nor did he seem to have any regard to painting as a fine art, but merely as an art that might be the means of making him rich. In his time, his composition was agreeable and his design correct; but in his latter time, his works had nothing to recommend them, except the freedom of handling, and the goodness of his works had nothing to recommend them, except the freedom of handling, and the goodness of his colouring; yet, with all his defects, he was accounted a good painter. Rubens used to say, that Van Oort would have surpassed all his contemporaries, if he had been Rome, and formed his taste by studying after the best models. He painted a great number of designs for the altars of churches in Flanders, which have much merit in several parts; and they are still beheld with pleasure by good judges.

OOST, a kiln for drying hops after they are picked, as the account is confirmed to us by Mr. Travis, who had an opportunity of examining one of the same species.

Newcastle, September 12. On Saturday last was thrown upon the sands at Blyth, a very rare and beautiful fish, weighing between 70 and 80 pounds, shaped like the sea-bream. The length was three feet and an half; the breadth from back to belly almost two feet; but the thicknesses from side to side not above four inches.

The mouth small for the size of the fish, forming a square opening, and without any teeth in the jaws. The tongue thick, resembling that of a man, and rough and thick set with beards or prickles, pointing backwards, so that any thing might pass down, but could not easily return back; therefore these might serve instead of teeth to retain its prey. The eyes remarkably large, covered with a membrane, and shining with a glare of gold. The cover of the gills like the salmon.

The body diminishes very small to the tail, which is forked, and expands 12 inches: the gill fins are broad, about eight inches long, and play horizontally; a little behind their insertion the back fin takes its original, where it is about seven inches high, but slopes away very suddenly, running down very near the tail, and at its termination becomes a little broader; the belly fins are very strong, and placed near the middle of the body: a narrow fin also runs from the anus to the tail.

All.

Plate CCLI.

(a) I at writers seem with more propriety to have ranked it under the genus Zeus, to which we have already referred.
OPAL, in natural history, a species of the chro- 

flaces genus of gems.—This species of precious stone is generally esteemed the most beautiful of all the flinty tribe, which appears to be owing to its changeable appearance when viewed by reflection.—The form of the opal is that of a pebble, like the agate, with which authors in general have classed it, from a supposed resemblance, of which there appears no sort of proof. On the contrary, Bergman’s analysis points it out to be of a very different nature from the genus of flints, of which the agate is a species; magnesia constituting a large part of its composition, and not entering at all into that of the agate, if we are to judge from the analysis of the parent species or flint, there being none yet published of agate. The specific gravity of the opal is likewise extremely different from that of the agate. Wallerius tells us that its specific gravity is upwards of 2.4. It loses its colour and transparency in the fire, and in other respects is affected by it in the very same manner as quartz or flint would be. It may be melted with borax, but not without great difficulty. The species are,

1. The opal of Nonnius. This appears olive-coloured by reflection, and then opaque; but when held between the eye and the light, it is found to be transparent, and appears of a beautiful ruby colour. Bocce De Boot, author of the Complex Jewell, considers it as the most precious sort of opal, and indeed the most wonderful of this kind of nature’s works: he gives a lofty encomium upon it, chiefly from Pliny, who called this opal pedetes. This species of opal is the sanguin of India, and nonnius of the ancients and modern Europeans, from the Roman senator Nonnius, possessor of the famous opal of Rome, worth 20,000 solidi, who preferred banishment to parting with it to Anthony. An opal answering exactly to Pliny’s description of the nonnius was discovered about 30 or 35 years ago in the ruins of Alexandria, and purchased for a trifle by the French consul Lironcourt, from his dragman Roboly. The duke de Nivernois, when ambassador in London in 1763, was in possession of the very stone. The next in esteem and value is the Iris opal, of a glitzy white colour, but when looked through it appears of a flame-colour, as the nonnius does of a ruby.

Wallerius indeed is of opinion that the opal found in Alexandria was not that of Nonnius mentioned by Pliny; and adds, that it was by many supposed to be only a counterfeit piece of glass or paté. There is another of the same species in Sweden, which by reflection appears of a brownish colour, but by refraction is red with violet veins.

2. The white opal, having its ground of a white glass-like complexion, from whence green, yellow, bluish, and purple rays are thrown out; but when held against the light it appears of a reddish or rather flame-colour. Wallerius, in his Mineralogy, says, that this white opal answers the description of it given by Pliny much better than the olive coloured one above described. There are two varieties of it: 1. The oriental opal, showing many colours. Engelsrhom informs us, that he has obtained a fine piece of a white agate from the East Indies, of a yellowish brown and pale blue, or rather milky-colour, with a shining brightness, exactly like that of the milky opals already mentioned; and some other specimens near Turin in Piedmont, where they are called bar-fard-agates, a name which, in his opinion, is extremely proper for them, as they agree with the agates in almost every respect except hardness: this, however, has been controverted.—Sometimes the opal is surrounded with a white crust, like common flints in the strata of chalk; which crust has likewise the same properties as the flint when this last mentioned substance has been previously freed from the adherent chalk; viz. 1. It does not dissolve in nitrous acid. 2. It is not fusible per se. 3. It melts pretty easily with borax, but without any efficacy, contrary to what is observed in calcareous substances; for that borax will dissolve about three quarters of its own bulk of this substance, though with difficulty, especially towards the end of the operation; but the glafs becomes quite clear and colourless, instead of becoming white and opaque, as is the case with calcareous substances. This oriental stone is found in the island of Ceylon, where it is called the elementary stone. The Indians put as high a value on it as on the diamond. There is another kind of oriental opal much valued, generally called the flaming opal, because it changes its colours, as if sparks of fire escaped from it in parallel lines.

3. The bluish and semitransparent opal is less valued by those who are conversant in gems than the others, on account of its being supposed more easily imitable by art. M. Magellan, however, informs us, that not only this, but several other kinds of opals are easily imitable by art; several compositions of glafs being met with which show very different colours by reflection and by refraction. A curious ancient one of this kind is to be seen in the royal abbey of St. Denis near Paris, which is green on the outside, but shows a fine ruby-colour when held between the eye and the light. Our author has also seen some glafs pates made in London by Edward Delaval, Esq; and others by Mr More secretary to the society of Arts, which appeared of a yellow-brown or other colour by reflection; but when held against the light transmitted a fine blue, purple, or red colour, like the sapphires, rubies, garnets, and other precious stones.—Wallerius gives directions for making these pates; and M. Magellan informs us, that he by chance discovered that the red glafs of Kamackel, when over-melted, or burnt in a common fire, produces a similar effect, transmitting one colour by refraction and another by reflection. The fine imitations of the true white opals, which Pliny says were made by the Indians, have, in our author’s opinion, hitherto baffled the art of the moderns.

*E 2* The...
The fangenon or nonnius opal is found in the East Indies; the Iris, in Ceylon; the milky opal, at Elbenstock and Fryberg; the bluish or moss common and least esteemed, in Hungary, Silesia, Saxony, &c.; the olive and bottle coloured cat's eye, in Ceylon; the inferior in different countries of Europe. Mr. Born mentions what he calls an aventurine cat's eye, of a fleth colour and transparent, possessing the curious structure of the aventurine, viz. composed of little plates like scales, with a metallic splendour, which reflect the rays of light like the opal. This stone we suspect to be that which has led authors to class the aventurine with the opal, although it is in fact a fine opaque quartz. Rufis produces the opal at the rivulet Katicha, near the city of Krafnaik, in the Altai mountains in Siberia. The cat's eye is found in Mount Caucasus, and is often confounded with the opal, though improperly. See Asteria. The oculus mundi (see Hydropathes) has a very intimate connection with opal, being generally found in beds over it, and being regarded by some naturalists as the same stone in a state of decomposition by the action of the air. Rufis produces this stone in the Altai mountains, where the opals are found.

No method of estimating the opal is given by authors that we know of. But those of uncommon beauty and size are sold for very large sums.

The late Leopold II. emperor of Germany, was in possession of an oriental stone, sometimes described as a cat's eye, and sometimes as an opal, of one inch diameter, and which was valued at a great price. Prince Potemkin, the Russian general, purchased for 1000 ducats a stone of the same kind, said to have been taken by the famous Nadir Shah from the head of a Gentoo idol, of which it made one of the eyes. By what circuitous road it found its way to Potemkin, we have not been informed; but with many other gems it disappeared from the tent of the Persian conqueror when he was assassinated.

Opals are commonly found in detached pieces, in an envelope of a different kind of stone, from the size of a pin-head to that of a walnut. Beautiful opals of this last size are extremely rare; so that it is difficult to find an opal sufficiently perfect and large to be completely possessed of all its beauties; this renders it so precious, and makes it almost impossible to determine its value. They have agreed, however, to value a beautiful oriental opal at double the price of a sapphire of the same size.

It is very remarkable, that all the beautiful colours of the opal may entirely change or disappear when the stone is divided into pieces. This phenomenon, which has been demonstrated more than once by experience, leads us to think that all the sparkling play of the opal is owing to the refraction of the rays of the sun from the surface of the stone, which is naturally formed to produce this refraction.

OPALIA, in antiquity, feasts celebrated at Rome in honour of the Goddess Opa. Varro says they were held on the 19th of December, which was one of the days of the saturnalia: these two feasts were celebrated in the same month, because Saturn and Opa were husband and wife: the vows offered to the goddess were made sitting on the ground.

OPERA, a dramatic composition set to music, and sung on the stage, accompanied with musical instruments, and enriched with magnificent dresses, machines, and other decorations.—This species of drama is of modern invention. In its present state it was not known even in Italy before the beginning of the last century; and at its introduction into England, a century afterwards, it divided the wise, the silly, and musicians of the age. By those who were esteemed the best judges of the art, the English language was considered as too rough and inharmonious for the music of the opera; and, on the other hand, critics, whose taste was formed on the basis of common sense, looked upon a drama in a foreign and unknown tongue as the greatest of all absurdities. Many of them, however, pleased for operas in the English language; and it is well known that Addison, who was one of the opponents of the Italian opera on the London stage, wrote in his native tongue the opera of Rosamond. This is confessedly a beautiful poem; but, in the opinion of Dr. Burney, it adds nothing to Addison's fame, as it shows his total ignorance of the first principles of music, and of course his unfitness for the task he had undertaken.

In questions respecting the fine arts there is no appeal from the general taste; and therefore, as the French opera, which is in the language of the country where it is acted, has always been admired by persons of liberal education, it doubtless has merit considered as a drama; but how the dramas of this kind which are composed in Italian should find admirers in England, among persons who understand not a word of the language, is to us a matter of astonishment. The music of them may deserve and command the admiration of every one who has an ear; and the action of the figures may be perfectly suitable to the subject represented; but of this it is certain the majority of the audience can be no judges.

Even when the language is thoroughly understood, we should imagine, that, to make an opera agreeable to good taste, much would depend upon the choice of the subject; for it is surely absurd to have perfons of all ranks, and on every occasion, perpetually accompanied with the regular responses of symphony. To hear Caesar, Scipio, or Macbeth, when forming plans to ensure victory, or hatching plots of treachery and murder, talking in recitative and keeping time with fiddles, would surely disgust every person whose taste had not all evaporated in sound; but when the subject represented naturally admits of music in real life, we can suppose an opera to afford to persons of taste one of the most exquisite and refined entertainments of which human nature is capable. For a further account of the opera, see Music, p. 394, 425, 444, and Poetry, p. 133, &c.

OPERATION, in general, the act of exerting or exercising some power or faculty, upon which an effect follows.

OPERATION, in surgery and medicine, denotes a methodical action of the hand on the human body, in order to re-establish health.

OPHIDIUM, a genus of fishes belonging to the order of apodes. The principal characters of this genus are the following. The head is somewhat naked;
Ophidium. The teeth are in the jaws, palate, and fauces; the body long; the fins of the back, tail and anus, confounded in one; no fin on the under part of the body; and the eyes covered by the common skin. Of this genus there are several species, of which the most curious is the *Ophidium barbatum* of Linnaeus, thus described by Dr. Brownet in the 7th volume of the Philosophical Transactions.

"The scales of the ophidium (says he) are irregularly placed and dispersed over the whole body. Their form is sometimes round, sometimes nearly oval; they are larger near the head, and in the lower part of the body; but are hardly to be distinguished near the tail. They adhere to the body by means of a particular transparent skin, which is in general very thin, but somewhat thicker near the neck, and extended loofely over the whole head; this skin is very easily destroyed, after which the scales falling, the body appears spotted (fig. 1.). When you look at them with the naked eye (fig. 2.) they appear as covered with very small grains; but viewed through a microscope (fig. 3.) the middle of them appears more elevated than the margin; and from the centre to the margin, close by each other, there are many lines or rays formed by small scales placed upon one another, like tiles upon a roof, the superior being always the nearer to the centre. This sort of scales, which may be called umbonate, are fastened to the body by very small velvets which are inserted in their middle; they are to be seen on the body only, not on the head nor the fins."

The anatomy of this fish comprehends some very remarkable circumstances, which our author thinks, were never observed, in any other species. When the skin is drawn off, there appears a thin membrane of a silver colour, which covers the muscles. The muscles being removed, we find the peritoneum, which lines the abdominal cavity, and is adherent to the swimming bladder by some elongations. It is of a silvery hue, with some very small black points. The ventricle is not to be distinguished from the intestines by any other mark but by its size; its form is oblong; it is extended almost to the mus, from whence the intestinal duct has a retrograde course, and then descends again, having a little dilatation near the anus. On the vertebræ next the anus on one side of the peritoneum is a kind of cavity of an oblong form, containing a reddish viscus, which he takes to be the kidney.

The first vertebræ from the head has nothing very remarkable in its structure. The second has on each side an elongated and sharp apophysis, to the apex of which is annexed a small ligament. The third is very flat, and has on each side a kind of triangular and sharp apophysis, to which adheres a ligament as to the second. The fourth is remarkable in having a sharp apophysis on each side, articulated with the body of the vertebræ; and under each of them is another articulated apophysis, flat, thick, roundish at its extremities, and forked at its base (fig. 5.). The fifth, which is strongly adherent to the former, has in its middle a bird processes. The sixth has in its middle a flatish elevation, sharp on each side. Between the extremity of the larger apophysis of the fourth vertebræ is a bone, or rather a hard cartilage, which bears the figure of a kidney (fig. 6.) Its convexity being turned towards the body of the vertebræ: its position is parallel to the bodies of the vertebræ; its motion is half circular; one of its parts, oes. the lowest, being in the cavity of the swimming bladder, to which it adheres by a thin membrane, so that no air can escape at that part. It is covered by membranes, which adhere strongly to its middle; in this part are fastened the two ligaments of the apophysis of the second, and third vertebræ, of which we spoke before, and which are of a great tensity. In the same point are fastened also two ligaments, each of which belongs to an oblong muscle parallel to each other, and fixed to the bones of the lowest and posterior part of the head (fig. 4.)

All this apparatus is certainly subervient to the purpose of swimming; but it is very remarkable, that if these parts are necessary to some animal function, they should not be found in all the individuals; "for I have seen (says our author) two, of which the vertebræ were not different from the vertebræ of the other species: which difference depends, perhaps, on the difference of sex. I am inclined to believe so; but, the generation in this fish seems to be no less mysterious than that of the eel: I could never distinguish a male from a female in this species."

This fish commonly grows to the size of eight or nine inches. It is to be found in all the Mediterranean sea, and in great plenty in the Adriatic; its flesh is not of a good taste, rather coarse, as is that of all the species of fishes which have no ventral fins, are obliged to make great efforts in swimming, and have consequently the muscles harder.

**Ophioglossum**,adder's tongue: A genus, of the natural order of filices, belonging to the cryptogamia class of plants. The spike is articulated, flat, and turned to the two sides; with the articuli or joints, opening acrois. There are seven species; of which the only remarkable one is the vulgatum, or common adder's tongue, which is a native of several places of Britain, growing in meadows and moist pastures. The country-people make an ointment of the fresh leaves, and use it as a vulnerary to green wounds; which is a very ancient application, recommended by Matthiolus, Tragus, and others.

**Ophiomancy**, in antiquity, the art of making predictions from serpents. Thus Calchas, on seeing the pest devour eight sparrows with their dam, foretold the duration of the siege of Troy; and the seven coils of a serpent that was seen on Anchises's tomb, were interpreted to mean the seven years that 

**Ophiorniza**, in botany: A genus of the monocotylium order, belonging to the pantendra class of plants; and in the natural method ranking under the 47th order, Stellate. The corolla is funnel-shaped; the capsule twin, bilocular, and polymorphous. There are two species; the most remarkable of which is the Asificatum, or true ligum culobrunum. The root of this is known in the East Indies to be a specific against the poison of the most dreadful animal called the hooded serpent. There is a treatise in Annon. Acad. tom. iv. upon this subject, wherein the author of John. And. Darius undertakes, from the description of such authors as had seen it upon the spot, to ascertain the plant from which the genuine root is taken. It appears in this account, that it had puzzled the Euro-
European physicians; and what had been sold in the shops for it, is the root of a very different plant, and of a poisonous nature.

The true root is called *mungus,* for the following reason. — There is a kind of weasel in the East Indies, called *mungula* by the natives, *mungo* by the Portuguese, and *muncas* by the Dutch. This animal pursues the hooded serpent, as the cat does the mouse with us. As soon as the serpent appears, the weasel attacks him; and if the chances to be bit by him, he immediately runs to find a certain vegetable, upon eating which he returns and renews the fight. — The Indians are of opinion that this plant is the *mungos.*

That celebrated traveller and convert, the order is doubtful. The hermaphrodite *muncascis* is the prec principally threes

The time of the voyage from Ezion-gaber to that place and Tarshith and return. To establish this important fact, our author observes, that the fleet or ships for Sofala, putting in June from Ezion-gaber (see *Ezion-gaber*), would run down before the northern monsoon to Mocha (see *Mocha*); here, not the monsoon, but the direction of the gulf changes; and the violence of the south-westers, which then reign in the Indian ocean, make themselves at times felt even in Mocha roads. The vessel therefore comes to anchor in the harbour of Mocha; and here she waits for moderate weather and a fair wind, which carries her out of the straits of Babelmandeb, through the few leagues where the wind is variable.

Her course from this is nearly south-west, and she meets at Cape Gardefan a strong south-wester that blows directly in her teeth. Being obliged to return into the gulf, she makes this for a trade wind; because she is not able to make her voyage to Mocha but by the summer monsoon, which carries her no farther than the straits of Babelmandeb, and then leaves her in the face of a contrary wind, a strong current to the northward, and violent swell.

The attempting this voyage with fails, in these circumstances, was absolutely impossible, as their vessels went only before the wind; if it was performed at all, it must have been by oars; and great havoc and loss of men must have been the consequence of the several trials.

At last, philosophy and observation, together with the unwearyed perseverance of man bent upon his own views and interest, removed these difficulties, and allowed the mariners of the Arabian gulf, and the periodical winds, which in the beginning they looked upon as invincible barriers to the trading of Sofala, when once understood, were the very means of performing this voyage safely and expeditiously.

The vessel trading to Sofala failed from the bottom of the Arabian gulf in summer, with the monsoon at north, which carried her to Mocha. There the monsoon failed her by the change of the direction of the gulf. The south-west winds, which blow without Cape Gardefan in the Indian ocean, forced themselves round the cape so as to be felt in the road of Mocha, and made it uneasy riding there. But the soon changed, the weather became moderate, and the vessel, supposing the month of August, was safe at anchor.
anchor under cape Gardesano, where was the port which, many years afterwards, was called Promontorium Aromatum. Here the ship was obliged to stay all November, because all the summer months the wind south of the cape was a strong south-westerly, as hath been before said, directly in the teeth of the voyage to Sofala. But this time was not lost; part of the goods bought to be ready for the return was ivory, frankincense, and myrrh; and the ship was then at the principal mart for these.

Our author supposes, that in November the vessel failed with the wind at north-east, with which she would soon have made her voyage; but off the coast of Melinda, in the beginning of December, she there met an anomalous monsoon at south west, in our days first observed by Dr. Halley, which cut off her voyage to Sofala and obliged her to put into the small harbour of Mocha, near Melinda, but nearer still to Tarshih, which we find here by accident, and which we think a strong corroboration that we are right as to the rest of the voyage. In the annals of Abyssinia, it is said that Amida Sion, making war upon that coast in the 14th century, in a list of the rebellious Moerish valets, mentions the chief of Tarshih as one of them, in the very situation where we have now placed him.

Solomon's vessel, then, was obliged to stay at Tarshih till the month of April of the second year. In May, the wind set in at north-east, and probably carried her that same month to Sofala. At the same time she spent at Tarshih was not lost, for part of her cargo was to be brought from that place; and the probably bought, bespoke, or left it there. From May of the second year, to the end of that monsoon in October, the vessel could not fair; the wind was north-east. But this time, far from being lost, was necessary to the traders for getting in their cargo, which we shall suppose was ready for them.

The ship fails, on her return, in the month of November of the second year, with the monsoon south-west, which in a very few weeks would have carried her into the Arabian gulf. But off Mocha, near Melinda and Tarshih, she met the north-east monsoon, and was obliged to go into that port and stay there till the end of that monsoon; after which a fierce gale came to her relief in May of the third year. With the May monsoon she ran to Mocha within the straits, and was there confined by the summer monsoon blowing up the Arabian gulf from Suez, and meeting her. Here she lay till that monsoon, which in summer blows northwesterly from Suez, changed to a south-east one in October or November, and that very easily brought her up into the Eolian gulf, the middle or end of December of the third year. She had no need of more time to complete her voyage, and it was not possible she could do it in the next.

Such is a very short and imperfect abstract of our author's reasons for placing Ophir in Sofala. If it excite the curiosity of our readers to consult his work, it will answer the purpose for which we have made it.

We are now to give another ingenious conjecture, concerning the situation of Ophir and Tarshih, with which we have been favoured by Dr. Doig, the learned author of Letters on the Savage State, addressed to Lord Kames.

This ingenious writer holds that Ophir was somewhere on the west coast of Africa, and that Tarshih was the ancient Bética in Spain. His essay is not yet published; but he authorizes us to give the following abstract of it: "The first time that Ophir, or rather Aser, occurs in scripture, is in Gen. x. 29, where the sacred historian, enumerating the sons of Joktan, mentions Aser as one of them." According to his account, the descendants of those 13 brothers settled all in a contiguous situation, from Melita (the Mocha of the moderns) to Sepharah, a mountain of the east. Moses, as every one knows, denominates countries, and the inhabitants of countries, from the patriarch of whom those inhabitants descended. In describing the course of one of the branches of the river of parid, the fame Moses informs us that it encompassed the whole land of Havilah, &c. which abounded with fine gold, balsam, and the onyx stone; and this land had its name from Havilah the 12th son of the patriarch Joktan. Ophir or Aser was Havilah's immediate elder brother; and of course the descendants of the former, in all probability, fixed their habitation in the neighbourhood of those of the latter. If, then, the land of Havilah abounded with gold and precious stones, the land of Ophir undoubtedly produced the very same articles.

Here we then, the original Ophir, here we found the primary gold of Ophir, and here lay the Ophir mentioned in Job xii. 4. But as navigation was not the Ophir of Solomon; mention of which is only to which the fleets of Solomon and Hiram went to meet the return of their triennial voyages. That several countries on the north-east coast of Africa abounded with gold long after the era of Job, is evident from the testimony of Herodotus, Strabo, Diodorus Siculus, Ptolemy, Pomponius Mela, &c.; and that in these countries the Ophir of Solomon could not be situated, is plain, because his ships in the same voyage touched at Tarshih, which lay in a very different quarter.

The Abyssinian traveller has placed this regio aurifera in Sofala on the eastern coast of Africa, nearly opposite to the island of Madagascar. This hypothesis, I have current an hundred years before he was born; but I am persuaded (lays our author) that it is not tenable. The Ophir of Solomon, in whatever part of Africa it lay, must have been well known, prior to his reign, both to the Phenicians and the Edomites. These people navigated that monarch's fleet, and therefore could be no strangers to the port whither they were bound. That it was in Africa is certain; and that it was on the west coast of that immense peninsula, will appear more than probable, when we have ascertained the situation of Tarshih, and the usual course of Phenician navigation. To these objects, therefore, we shall now direct our enquiries.

"Javan, the fourth son of the patriarch Japhet, discovering had four sons, Elishah, Tarshish, Kittim, and Dodan, that of him or Rodanim; among whose descendants were the islands of the Gentiles divided. The city of Tarshish on the coast of Cilicia, at once ascertains the region colonized by the descendants of Tarshih. But as much depends."
depends upon determining the position of this country, I shall endeavour (says the Doctor) to fix it with all possible precision.

"In the first place, I must beg leave to observe, that there is not a single passage in any ancient author, sacred or profane, that so much as alludes to any city, district, canton, or country, of the name of Tarshish in the eastern parts of the world. The descendants of Javan, of whom Tarshish was one, are agreed on all hands to have extended their settlements towards the north-west, i.e. into Asia Minor, Italy, and Spain. The inhabitants of Tarshish are every where in scripture said to be addicted to navigation and commerce, in which they seem to have been connected with the Phoenicians and Phenicians, who were always said by 7. Isai. 10. to have inhabited the isles of the sea. Indeed, in Hebrew geography, all the countries toward the north and west, which were divided from Judæa by the sea, were called the isles of the sea. Thus Isaiah:

'The burden of Tyrus. Howl ye ships of Tarshish, it is laid waste, for that there is no house, no entering in: from the land Chittim it is revealed unto them. Be still ye inhabitants of the isles, thou whom the merchants of Zidon, that pass over the sea, have replenished.'

The land of Chittim (or Zidon, that pass over the sea, and are connected with the Tyrians and Phenicians) was one of the most renowned places of commerce; and if so, they would undoubtedly furnish, that the silver fold by the merchants of Tarshish was the product of that country. When this mistake came to be discovered they very naturally transferred the name Tarshish from the country of the merchants to that of the articles of one which they imported. Let us now, says our author, see if we cannot find out where that country was. It has been already shown, by quotations from Isaiah and Ezekiel, that the merchants of Tarshish traded in the markets of Tyre with silver, iron, lead, and tin. To these authorities, we shall add another from Jeremiah: "Silver (says that prophet) spread into plates is brought from Tarshish." But in source continues our learned dissertator, all those commodities were found in the greatest abundance. All the ancient authors who describe that region dwell with repletion on its silver mines. This fact is too generally known to need to be supported by authorities. Spain was then the region which furnished Solomon's traders with the immense mass of silver he is said to have imported. This was, one might say, the modern Tarshish; and indeed both Josephus and Eusebius are positive that the province of Tarshish actually peopled that country. It was an early opinion, as it certainly was, the Jews would of course denominate Spain from the purport in question.

"I have shown above, that the inhabitants of Tarshish were chiefly connected with the Kittim or Grecians: I shall here produce an authority which will prove to a demonstration that the Kittim had extended their commerce into that part of Africa now called Barbary."

"The Prophet Ezekiel (xxviii. 6.) describing the splendour and magnificence of Tyre, tells us, 'that the company of the Affhurra, made her steps of ivory, brought from the isles of Kittim.' In the first place, I must observe, that there is probably a small error in the orthography of the word Affhirum. This term is every where in scripture transliterated Affhirum, which
which translation is certainly just. But how the Af-
fyrians could export ivory from the isles of Kittim,
and fashion it into benches for the Tyrian Mariners,
is, in my opinion, a problem of no easy solution.
The fact is, APhurim should be Asherim, that is, the
company of the men of Asher. The tribe of Asher ob-
tained its inheritance in the neighbourhood of Tyre;
(see Josh. ix. 28.) "And Hebron, and Rehob, and
Hammon and Canah, unto Zidon the great." The
companies of the tribe of the Asherites then, and not
the APhurim, were the people who manufactured
the benches in question.

"Be that as it may, the ivory of which these imple-
ments were formed was imported from the isles of
Kittim, that is, from Greece and its neighbourhood.
These isles, it is certain, never produced ivory. They
must therefore have imported it from some other
country; but no other country, to which the Greeks
and their neighbours could have extended their com-
merce, except the north of Africa, produced that
commodity. The conclusion then is, that the maritime
states of Asia Minor, Greece, and probably the He-
trucans on the west coast of Italy, carried on a gain-
ful commerce with Spain and barbary at a very early
period.

"We have now seen that the original Tarfihh on the
coast of Asia Minor did not produce the metals im-
ported by Solomon's fleet; that no Tarfihh is to be
found in the eastern parts of the globe; that the Tar-
fish we are in quest of was undoubtedly situated
somewhere on the coast of Judea: we have shown that
the mercantile people of Asia Minor, Greece, and
probably of Italy, actually imported some of those ar-
ticles from the coast of Africa; we have hazarded a con-
jecture, that Spain was the modern Tarfishh, and that
very country from which Solomon imported his sil-
ver, and the Tyrians their silver, iron, tin, and lead.
Let us now make a trial whether we cannot exhibit
some internal proofs in support of the hypothesis we
have above adopted.

"The ancients divided Spain into three parts, Bae-
tica, Lusitania, and Tarvacosenis. Baeotica is the
modern Andalusia. It stretched along the Fretum
Heracleum, or Straits of Gibraltar, to the mouth of
Guadalquivir. This region is thought by some to
have been the Elyfan fields of the poets. The river
Baeotis, which divides it, is called Tarccifus, by Aris-
otle, Stathorus, Strabo, Paudianis, Steph. Byzant,
and Avianus. Here too we have a city and a lale of
the same name. But Tarccifus is positively the very
same with Tarfishh. The Phoenicians, by changing
shin into thaw, made it Tarfish. The Greeks manufac-
tured the zell, by changing Tarfish into Tarris, and in pro-
cesses of time into transs. That the Phoenicians
actually changed shin into thaw is certain; for Plu-
tarch tells us in the life of Sylfa, that in their lan-
guage ox was called thor, which is, no doubt, the
name with the Hebrew shor.

"From this deduction, it appears highly probable at
least, that the Spanih Baeotis was originally called
Tarfishh. Indeed this similarity of names has operat-
ed so powerfully on the learned Bochart, and on some
other moderns of no mean figure, that they have po-
fitively affirmed, as Josephus had done before them,
that the patriarch Tarfishh actually settled in that
country. This I should think not altogether prob-
able; but that his descendants who settled on the
coast of Asia Minor colonized Baeotis, and carried on
an uninterrupted commerce to that country, along
with the Phoenicians, for many centuries after it was
peopled, and that from the circumstances above nar-
rated, it was denominated Tarfishh, are facts too pal-
pable to admit of contradiction.

"Let us now see whether this Baeotis, where I have
endeavoured to fix the situation of the Tarfishh of the
scriptures, was actually furnished with those articles
of commerce which are said to have been imported
from that country. To enlarge on this topic would be al-
together superfluous. Diodorus Siculus, Strabo, Po-
ybius, Pliny, Solinus, and, in one word, all the
Greek and Roman historians who have mentioned
that region, have unanimously exhibited it as the na-
tive land of silfer, iron, and tin: to these, contrary to
the opinions of the celebrated modern traveller, they
likewise add gold in very large quantities."

Our author having thus ascertained the situation of
Tarfishh, proceeds to prove, by a mass of evidence too
large for our infertion, that the Edomites and Ty-
rans had doubled the cape, and almost encompassed
Africa, long before the era of Solomon. Then refer-
ing to 1 Kings, chap. ix. and x. 2 Chron. viii. ix.
2 Kings xxii. and 2 Chron. xx. he observes, that from
these authorities it appears indubitable, that the fleets
of Solomon and Hiram sailed from Ezion-geber; that the voyages to Ophir and Tarfishh were ex-
actly the same, performed at one and the same time,
by the very same fleet; which must necessarily have en-
compassed the peninsula of Africa before it could ar-
rive at the country of Tarfishh. This being the cafe,
the traders might easily enough collect the gold on
the coast of Guinea, or on what is now vulgarly
called the Gold Coast. The ivory they might readily
enough procure on the Barbary coast, opposite to
Tarfishh. In Africa, too, they might hunt apes,
monkeys, baboons, &c.; and peacocks, or rather par-
rrots, and parroquets, they might furprise in the forefis
which abounded on the coast. In Spain, silver, iron,
lead, and tin, were, one may say, the native produce
of the soil. Even at this early period, the Phoenician
navigators had discovered the Caspiterides, or Scilly
islands and Cornwall; and from that region, in com-
pany with the merchants, may have supplied them
with that rare commodity.

"I have supposed that the navy of Solomon and Hi-
ram collected their gold in the course of their voyage
somewhere on the coast of Africa, beyond the Cape,
for the following reasons: Had they found the golden
fleece at Sofala (a), or any part of the coast of Afri-
ca, they would have chosen to return and unlade at
Eloth or Ezion-geber, rather than pursue a long and
dangerous course, quite round Africa, to Tarfishh; to
which last country they might have shaped their
course.

(a) That Sofala opposite to the island of Madagascar
was Ophir, was an ancient conjecture. See Bochart-
Upon the whole, I conclude, that the original Ophir, which is really Aufr or Aufr, was situated on the south of Arabia Felix, between Sheba and Havilah, whose laft was encompassed by one of the branches of the river of Paradise: that the name Ophir, i.e. Aufr, was, in consequence of its resemblance, in process of time transferred to a region on the coast of Africa; and that from it first After and then Africa was denominated: that the primitive Tarshish was Cilicia, and that the Jews applied this name to all the commercial states on the coast of Asia Minor, and perhaps of Italy, there being strong presumptions that the Tyrians were colonists from Tarshish; that the Phcenics, and perhaps some other regions of Spain, being planted with colonies from Tarshish, likewise acquired the name of Tarshish; that the Tyrians were strictly connected with the merchants of Tarshish in their commercial enterprizes; that Tarshish was certainly situated westward from Judea, Phoenicia, &c.; that no other country in the western quarters produced the commodities imported by the two kings, except Spain and the opposite coasts; that this country, in those ages, produced not only silver, iron, tin, and lead, but likewise gold in great abundance; that the merchants of Kittim imported ivory, of which the Athenians made benches for the Tyrians; which commodity they must have purchased on the coast of Barbary, where the Jews and Phcenicians would find the same article; that Tarshish being situated in Spain; it was impossible for a fleet failing from Eloth or Ozen-geber, to arrive at that country without encompassing Africa; Ophir situated that of course, the fleet in question did actually enter on the compafs that continent; that the Ophir of Solomon and must have been situated somewhere on the coast of Africa, to the west of the Cape, because from it the course to Tarshish was more eligible than to return the same way back to Ezion-geber.

Our author supports this conclusion by many other arguments and authorities, which the limits preferred us will not permit us to detail; but perhaps the article might be deemed incomplete, if we did not show how he obviates an objection that will readily occur to his theory. “If the original Ophir was seated on the coast of Arabia Felix, and the modern region of the same name on the west coast of Africa, it may be made a question, how the latter country came to be denominated from the former? Nothing (says our author) can be more easy than to answer this question. The practice of adapting the name of an ancient country to a newly discovered one, resembling the other in appearance, situation, in figure, in dilance, in the nature of the climate, productions, &c. has ever been so common, that to produce instances would be altogether superfluous. The newly discovered region on the coast of Africa abounded with the same species of commodities by which the original one was distinguished; and, of course, the name of the latter was annexed to the former.”

Whether Mr Bruce’s hypothesis or Dr Doig’s, respecting the long disputed situation of Solomon’s Ophir, be the true one, it is not for us to decide. Both are plausible.
5. The jnabilis or jnabil-archis, hath two roundish bulbous roots, crowned with oblong leaves; erect leafy stalks, from six to ten or twelve inches high, terminated by spikes or jnabil-shaped greenish flowers, having the lip of the nektarium almost five-lobed. This wonderful species exhibits flowers in different varieties, that represent singular figures of flies, bees, and other insects; and are of different colours in the varieties.

6. The Rnteris, or mullky-ophry, hath a roundish bulbous root; crowned with three or four oblong leaves; an erect naked stalk, six inches high; terminated by a loose spike of yellowish, mullky-scented flowers.

All these six species of ophry flower in summer, at different times in different sorts, from May until July; and in most of the sorts exhibit a singularly curious appearance. The plants are all perennial in root, which are of the bulbous flabby kind, from which the flower-stalks rise annually in spring, and decay in autumn; at which period is the proper time for removing the roots from one place to another. They all grow wild in Britain, &c. are residents of woods, bogs, marshy grounds, sterile pastures, chalky soils, and the like places, where they flourish and display their singular flowers in great abundance, from which places they are introduced into gardens for variety; and having procured some plants at the proper season, and planted them in soils and situations somewhat similar to that where they naturally grow, the roots will abide for several years and flower annually.

As to their propagation, it may be tried by seed in a shady border, as soon as it is ripe; likewise by offsets from the root, though they multiply sparingly in gardens; however, roots of some standing may be examined at the proper season, and any offsets separated and planted in proper places.

Ophry, a genus of the monogyria order, belonging to the orchis class of plants. The involucrum is bivalvular and triflorous; the corolla tetrapetalous above; the berry uniculour.

Ophry, in botany: A genus of the monogyria order, belonging to the orchis class of plants. The involucrum is bivalvular and triflorous; the corolla tetrapetalous above; the berry uniculour.

Ophry, in natural history, a sort of variegated marble, of a dusky-green ground, sprinkled with spots of a lighter green, otherwise called jnabil. See the article Marble.

Ophry, in church-history, Christian heretics, so called both from the veneration they had for the serpent that tempted Eve, and the worship they paid to Jesus Christ, and that he taught men the knowledge of good and evil. They distinguished between jnabil and jnabil: Jesus, they said, was born of the Virgin, but Christ came down from heaven to be united with him; Jesus, was crucified, but Christ had left him to return to heaven. They distinguished the God of the Jews, whom they termed jnabil-archis, from the supreme God: to the former they ascribed the body, to the latter the soul of men. They had a live serpent, which they kept in a kind of cage; at certain times they opened the cage-door, and called the serpent: the animal came out, and mounting upon the table, twined itself about some leaves of bread; this bread they broke and distributed it to the company, who all killed the serpent: this they called the Eucharist.

Ophry, a genus of the orchis order belonging to the gynandria class of plants; and in the natural method ranking under the 7th order, Orchideae. The nektarium is a little carinated below. The species are numerous, but the most remarkable are the following:

1. The ovata, ovul-leaved ophry, or common tay-blade, hath a bulbous, fibrated root; crowned by two oval, broad, obtuse, veined, opposite leaves; an erect, succulent, green stalk; six to eight inches high, naked above, and terminated by a loose spike of greenish flowers, having the lip of the nektarium bifid. The flowers of this species resemble the figure of gnats.

2. The spiralis, spirul archis, or triple ladies-tresses, hath bulbous, oblong, aggregated roots; crowned by a cluster of oval, pointed, ribbed leaves; erect simple stalks, half a foot high; terminated by long spikes of white odoriferous flowers, hanging to one side, having the lip of the nektarium entire and crenated.

3. The nidus-avis, or bird's-nest, hath a bulbous, fibrated, clustered root; upright, thick, succulent stalks, a foot high, sheathed by the leaves, and terminated by loose spikes of pale-brown flowers; having the lip of the nektarium bifid.

4. The antropophora, man-shaped ophry, or man-archis, hath a roundish bulbous root, crowned with three or four oblong leaves; upright thick stalks, riling a foot and a half high; adorned with narrow leaves, and terminated by loose spikes of greenish flowers, representing the figure of a naked man; the lip of the nektarium linear tetraptite, with the middle segment long-stif and bifid. There is a variety with brownish flowers tinged with green.
but it does not produce science like rigid demonstration. The fact is not doubted, but those who have it on report do not know it to be true, as they know the truth of propositions intuitively or demonstrably certain. When one or two men relate a story including many circumstances to a third person, and another comes who positively contradicts it either in whole or in part, he to whom those jarring testimonies are given, weighs all the circumstances in his own mind, balances the one against the other, and lends an affent more or less wavering, to that side on which the evidence appears to preponderate. This assent is his opinion respecting the facts of which he has received such different accounts.

Opinions are often formed of events not yet in being. Were an officer from the combined armies, which are just now besieging Valenciennes, to come into the room where we are writing, and tell us that those armies are in good health and high spirits; that every shot which they fire upon the fortress produces some effect; and that they have plenty of excellent provisions, whilst the besieged are perishing by hunger; we should absolutely believe every fact which he had told us upon the evidence of his testimony; but we could only be of opinion that the garrisons must soon surrender. In forming opinions of this kind, upon which, in a great measure depend, our success in any pursuit, every circumstance should be carefully attended to, and our judgments guided by former experience. Truth is a thing of such importance to man, that he should always pursue the best methods of attaining it; and when the object eludes all his researches, he should remedy the disappointment, by attaching himself to that which has the strongest resemblance to it; and that which most resembles truth is called probability, as the judgment which is formed of it is termed opinion. See Probability.

OPITTS, or OPITUS (Martin), a celebrated German poet, born at Breilaw in 1507. He acquired great fame by his Latin, and more by his German poems; and, retiring to Dantzic, wrote a history of the ancient Daci: he died of the plague in 1639.

Opits (Henry), a learned Lutheran divine, born at Altenburgh in Misnia in 1642. He was professor of theology and of the oriental languages at Kiel, where he acquired great reputation by a variety of excellent works concerning oriental literature and Hebrew antiquities. He died in 1712.

Opium, in the materia medica, is an infusilated juice, partly of the resinous and partly of the gummy kind, brought to us in cakes from eight ounces to a pound weight. It is very heavy, of a dense texture, and not perfectly dry; but, in general, easily receives an impregnation from the finger: its colour is a brownish-yellow, so very dark and dusky that at first it appears black: it has a dead and faint smell, and its taste is very bitter and acid. It is to be chosen moderately firm and not too soft; its smell and taste should be very strong, and care is to be taken that there be no dirty or foamy matter in it.

Opium is the juice of the papaver album, or white poppy, with which the fields of Asia Minor are in many places sown, as ours are with corn. When the heads are near ripening, they wound them with an instrument that has five edges, which, on being stuck into the head makes at once five long cuts in it; and from these wounds the opium flows, and is next day taken off by a person who goes round the field, and put up in a vessel which he carries fastened to his girdle; at the same time that this opium is collected, the opposite side of the poppy-head is wounded, and the opium collected from it the next day. They differing, however, the produce of the first wounds from that of the succeeding ones; for the first juice afforded by the plant is greatly superior to what is obtained afterwards. After they have collected the opium, they moisten it with a small quantity of water or honey, and work it a long time upon a flat, hard, and smooth board, with a thick and strong instrument of the same wood, till it becomes of the confidence of pitch; and then work it up with their hands, and form it into cakes or rolls for sale.

Opium at present is in great esteem, and is one of the most valuable of all the simple medicines. In its effects on the animal system, it is the most extraordinary, - it is the most extraordinary nature. It touches the nerves as if it were by magic and irresistible power, and heals the most danger out of forgetfulness; even in opposition to the determination of the philosopher or physiologist, approved of its narcotic effect.

The modification of matter is infinite; and who shall truly say by what peculiar or specific configuration of its parts, opium, even in the quantity of a single grain, administered to the human body, shall alluvate the most raging pain, and procure profound sleep? The action of matter upon matter, thus exemplified in the effect of opium on the animal system, is not less astonishing and incomprehensible, than that of spirit upon matter or the agency of mind on the motive powers of the body.

The first effects of opium are like those of a strong stimulating cordial, but are soon succeeded by universal languor or irresistible propensity to sleep, attended with dreams of the most rapturous and enthusiastic kind. After these contrary effects are over, which are generally terminated by a profuse sweat, the body becomes cold and torpid; the mind pensive and desponding; the head is affected with stupidity, and the stomach with sicknens and nausea.

It is not our business, neither is it in our power, to reconcile that diversity of opinion which has lately prevailed concerning the manner in which opium produces its effects; or to determine whether it acts simply on the brain and nerves, or, according to the experiments of Fontana, on the mass of blood only.

Opium is the most sovereign remedy in the materia medica, for eating pain and procuring sleep, and also the most certain antispasmodic yet known; but, like other powerful medicines, becomes highly noxious to the human constitution, and even mortal, when improperly administered. Its liberal and long continued use has been observed greatly to injure the brain and nerves, and to diminish their influence on the vital organs of the body. By its first effects, which are exhilarating, it excites a kind of temporary delirium, which dissipates and exhausts the spirits; and, by its subsequent narcotic power occasions confusion of ideas and loss of memory, attended with nausea, giddines, headach,
headach, and convulsion of the bowels; in a word, it seems to suspend or diminish all the natural secretions and excretions of the body, that of perspiration only excepted.

Those who take opium to excess become enervated and soon look old; when deprived of it, they are faint, and experience the languor and dejection of spirits common to such as drink spirituous liquors in excess; to the bad effects of which it is similar, since, like those, they are not easily removed without a repetition of the dose.

By the indiscriminate use of that preparation of opium called GSVrey's cordial, many children are yearly cut off; for it is frequently given dose after dose, without moderation, by ignorant women and mercenary nurses, to silence the cries of infants and lull them to sleep, by which they are at last rendered stupid, inactive, and rickety.

Opium is universally known to be used as a luxury in various parts, especially amongst the hard-labouring people at Surat, and especially the porters, who take great quantities of this drug, which, they pretend, enables them to work, and carry heavier burdens than they otherwise could do. Some of these, our author assures us, will take more than an ounce at a time without detriment. Many people in opulent circumstances follow the same custom, but with very different motives. Some use it merely for the sake of the pleasing delirium it occasions; others for venereal purposes, as by this means they can lengthen the amorous congress as much as they please, though they thus are certain to bring on an absolute impotency and premature old age at last. For this purpose it is usually taken in milk; and when they have a mind to check or put an end to its operation, they swallow a spoonful or two of lime juice, or any similar acid.

Before these effects of opium, it is said by the Indians to have a very singular one in bringing on a seeming heaviness of the head and sleepiness of the eye, at the same time that it really produces great watchfulness. It is also considered as a great inspirer of courage, or rather insensibility to danger; so that the commanders make no scruple of allowing large quantities of it to the soldiers when they are going to battle or engaged in any hazardous enterprise.

The belt opium in the world is said to come from Patna on the river Ganges, where, at least, the greatest traffic of it is made, and from whence it is exported all over India; though in some parts, especially on the Malay coast, it is prohibited under pain of death, on account of the madness, and murders consequent upon that madness, which are occasioned by it; notwithstanding which severe prohibition, however, it is plentifully smuggled into all these countries. The soil about the Ganges is accounted best for producing the finest kind of opium; of which the following remarkable instances are related. A nabob of these parts having invited an English factory to an entertainment, a young gentleman, a writer in the company's service, sauntering about the garden, plucked a poppy and sucked the head of it. In consequence of this he fell into a profound sleep; of which the nabob being apprised, and likewise informed of the particular bed out of which he had taken the flower, expressed his sorrow; acquainting his friends at the same time that the poison was too strong to admit of any remedy; which accordingly proved true, and the unfortunate gentleman never awaked.”

Opium applied externally is emollient, relaxing, and diffusent, and greatly promotes suppuration: if long kept upon the skin, it takes off the hair, and always occasions an itching in it; sometimes it excretes it, and raises little blisters, if applied to a tender part. Sometimes, on external application, it allays pain, and even occasions sleep: but it must by no means be applied to the head, especially to the future of the skull; for it has been known to have the most terrible effects in this application, and even to bring on death itself.

It appears, too, from some curious experiments made by Dr. Leight, to act as the most powerful of all styptics. “Having laid bare the crural artery of a rabbit (says the Doctor), I divided it, when the blood instantly flew out with considerable velocity; some of a strong solution was then applied to the divided artery, the ends of which in a short space of time contracted and the hemorrhage ceased. The same experiment was performed on the brachial artery with like success.”

The effects of a strong solution of opium upon the heart, appears from the same experiments to be very extraordinary. “I opened the thorax of a rabbit (says the Doctor), and by diffusion placed the heart in full view; the aorta was then divided, and the animal bled till it expired. After the heart had remained motionless ten minutes, and every appearance of life had ceased for the same length of time, I poured on the heart a quantity of my strong solution; it was instantly thrown into motion, which continued two minutes: I then added more of the solution, and the action was again renewed. By thus repeating my applications, the motions of the heart were supported more than ten minutes. I afterwards opened the thorax of a rabbit, and, without doing any injury to the large blood-vessels, placed the heart in view. A quantity of my strong solution was then applied to it, which so accelerated the motions as to render it impossible to number them: by renewing the application, these were continued for some considerable time. The surface of the heart now appeared uncommonly red, and continued so some time.”

Opium contains gum, resin, essential oil, salt, and earthy matter; but its narcotic or vomifferous power has been experimentally found to refuse in its essential oil.

OPOBALSAMUM, in the materia medica. Opoponum, or balm of Gilead. See AMYRIS.

Mr. Bruce, the celebrated traveller, whom we have frequently had occasion to introduce to our readers with that praise to which we think his labours have fully entitled him, employs several pages of his Appendix in ascertaining the antiquity and native foil of the balsam-tree, with other particulars of that nature; after which he gives us the following account of the opoponum, or juice flowing from it: “At first when it is received into the bottle or vase from the wound from whence it issues, it is of a light, yellow colour, apparently turbid, in which there is a whitish cah, which I apprehend are the globules of air that pervade the whole of it in its first state of fermentation; it then appears very light upon shaking. As it settles and cools, it turns clear, and loses that milkiness which..."
myrrh; and he is the more confirmed in his opinion, this it appears that the opocalpafum mentioned by

stuffs

Mr Bruce says, he saw

in a Mahometan village a

large tree, which was fo

covered with knots and balls of gum on the upper part

of the trunk and on the large branches, that it had a

moniftrous appearance. From some inquiries which

he made on this subject, he found that certain mer-

chants had brought this tree from the country of the

good myrrh, which is Trogloydityra (for it does not

grow in Arabia), and that they had planted it for the

fake of its gum; with which thefe Muftufmen itch

the blue fuffs of Surat, which they receive damaged

from Mocha, in order to barren them with the Ga-

r and the Abyssinians. This tree is called fafa, and

Mr Bruce declares that he has feen it completely

covered with beautiful crimson flowers of a very uncom-

mon ftucture. The fame traveller observes, that the Opocalpa-

fafa gum is well calculated, both on account of its

abundance and its colour, to augment the quantity of

myrrh; and he is the more confirmed in his opinion,
because every thing leads him to think that no other

gumniferous tree, polished of the fame properties

with the fafa, grows in the myrrh country. In short,

he thinks it almost beyond a doubt that the gum of the

fafa-tree is the Opocalpafum; and he fuppofes

Galen miftaken in attributing any fatal property to the

drug, and that many were believed to be killed by it, whole death might, perhaps, with more juftice, have

been placed to the account of the physician. Mr

Bruce adds, that though the Trogoldtites of the myrrh

country are at premnt more ignorant than formerly,

they are nevertheless well acquainted with the pro-

perties of their simples; and that while they wish to

incrcafe the fale of their commodities, they would

never mix with them a poison which muft necelfarily

caufe death. In this we accede to his opinion; but

we must differ from him when he fays, that no gum

or reen with which we are acquainted is a mortal poi-

fon; the favages of bothhemifpheres are acquainted

with but too many of them. The gum of the fafa-

tree, according to Mr Bruce, if of a clofe smooth

gran, of a brown dull colour, but sometimes very

transparent; it fwellis and becomes white in water;

it has a great reemblance in its properties to gum tra-

gamth, and may be eaten with all fafety. From all

this it appears that the opocalpafum mentioned by

Pliny is not the fafa gum defcribed by Mr Bruce.

OPOPPANAX, in the materia medica, is a gum-

rein of a tolerably firm texture, ufually brought to us

in loose granules or drops, and fometimes in large

mofes, formed of a number of thefe connected by a

quantity of matter of the fame kind; but these are

ufually loaded with extraneous matter, and are greatly

inferior to the pure loofe kind. The drops or gran-

ules of the fine opopanax are on the outside of a

brownih red colour, and of a dulky yellowish or

whitih colour within: they are of a fomewhat unctu-

ous appearance, smooth on the surface; and are to be

chofen in clear pieces, of a frong smell and acid

taff.

This gummy ftufance is obtained from the roots

of an umbelliferous plant, which grows spontaneou-

ly in the warmer countries, and bears the colds of this.

The juice is brought from Turkey and the East In-

dies; and its virtues are thofe of an attenuating and

afpeint medicine. Boerhaave frequently employed it,

along with ammoniacum and galbanum, in hypocon-

driacal disorders, obftructions of the abdominal vice-

ra, and fuppressions of the menftrual evacuations from a

fuggifhhood of mucous humours, and a want of due

ealciy of the solids: with these intentions it is an

ufeful ingredient in the pilula gummosae and compo-

nd powder of myrrh of the London pharmacopoeia, but it

is not employed in any composition of the Edinburgh.

It may be given by itself in the dose of a ferup, or

half a dram: a whole dram proves in many conflu-

tions gently purgative: also dipes flatulencies, is

good in affitans, in inverteate coughs, and in dior-

ders of the head and nerves.

Doctor Woodville, in his Medical Botany, gives the

following account of this vegetable. "It is of the
dignia order, and peniandria claf of plants: the root is

perennial,

OPOSIUM, in zoology. See Didelphis.

OPPENHEIM, a town of Germany, in the lower Palatinate of the Rhine, and capital of a bailiwick of the same name; seated on the declivity of a hill near the Rhine. E. Long. 8° 20'. N. Lat. 49° 48'.

OPPIANUS, a poet and grammarian of Anazarba in Cilicia, in the second century. He composed a poem of hunting, and another of fishing, for which Antoninus Caracalla gave him as many golden crowns as there were verses in his poems; they were hence called Oppian's golden verses. He died in the 30th year of his age.

ÓPPILATION, in medicine, the act of obstructing or flapping up the passage of the body, by redundant or pessant humours. This word is chiefly used for obstructions in the lower belly.

OPTATIVE mood, in grammar, that which serves to express an ardent desire or wish for something.

In most languages, except the Greek, the optative is only expressed by prefixing to the subjunctive an adverb of wishing; as utinam, in Latin; plus à Dieu, in French; and would to God, in English.

OPTIC ANGLE, the angle which the optic axes of both eyes make with one another, as they tend to meet at some distance before the eyes.

OPTIC AXIS, the axis of the eye, or a line going through the middle of the pupil and the centre of the eye.

OPTICS,

THAT science which treats of the element of light, and the various phenomena of vision.

HISTORY.

§ 1. Discoveries concerning the Light.

The element of light has occupied much of the attention of thinking men ever since the phenomena of nature have been the objects of rational investigation. The discoveries that have from time to time been made concerning it, are so fully inferred under the article LIGHT, that there is little room for any further addition here. The nature of that subtle element is indeed very little known; as yet, notwithstanding all the endeavours of philosophers; and whatever is said with regard to it, whether we suppose it to consist of an infinity of small particles propagated by a repulsive power from the luminous body, or whether we suppose it to consist in the vibrations of a subtle fluid, there are prodigious difficulties, almost, if not totally insuperable, which will attend the explanation of its phenomena. In many parts of this work the identity of light and of the electric fluid is ascertained; this, however, doth not in the least interfere with the phenomena of optics; all of which are guided by the same invariable laws, whether we suppose light to be a vibration of that fluid, or any thing else. We shall therefore proceed to,

§ 2. Discoveries concerning the Refraction of Light.

We find that the ancients, though they made very few optical experiments, nevertheless knew, that when light passed through mediums of different densities, it the fluid did not move forward in a straight line, but was bent, or refracted, out of its course. This was probably suggested to them by the appearance of a straight flick partly immersed in water; and we find many accounts concerning this and other optical appearances in Aristotle; to which, however, his answers are insignificant. Archimedes is even said to have written a treatise concerning the appearance of a ring or circle under water, and therefore could not have been ignorant.

Oriental the common phenomena of refraction. But the ancients were not only acquainted with these more ordinary appearances of refraction, but knew also the production of colours by refracted light. Seneca says, that if the light of the sun shines through an angular piece of glass, it will show all the colours of the rainbow. These colours, however, he says, are false, such as are seen in a pigeon's neck when it changes its position; and of the same nature he says, is a specular, which, without having any colour of its own, assumes that of any other body. It appears also, that the ancients did not understand the magnifying power of glasses filled with water, though they do not seem to have known any thing of the reason of this power; and the ancient engravers are supposed to have made use of a glass globe filled with water to magnify their figures, and thereby to work to more advantage. That the power of transparent bodies of a spherical form in magnifying or burning was not wholly unknown to the ancients, is further probable from certain gems preferred in the cabinets of the curious, which are supposed to have belonged to the Druids. They are made of rock-crystal of various forms, amongst which are found some that are lenticular and others that are spherical; and though they are not sufficiently wrought to perform their office as well as they might have done if they had been more judiciously executed, yet it is hardly possible that their effect, in magnifying at least, could have escaped the notice of those who had often occasion to handle them; if indeed, in the spherical or lenticular form, they were not solely intended for the purposes of burning. One of these, of the spherical kind, of about an inch and an half diameter, is preserved among the fossils given to the university of Cambridge by Dr Woodward.

The first treatise of any note written on the subject of optics, was by the celebrated astronomer Claudius Ptolomeus, who lived about the middle of the second century. The treatise is lost; but from the accounts of others we find that he treated of astronomical refractions. Though refraction in general had been observed very early, it is possible that it might not have occurred to any philosopher much before his time, that the light of the sun, moon, and stars, must undergo a similar refraction in consequence of falling obliquely upon the glass atmosphere that surrounds the earth; and that they must, by that means, be turned out of their rectilinear course, so as to cause those luminaries to appear higher in the heavens than they would otherwise do. The first astronomers were not aware that the intervals between stars appear less near the horizon than near the meridian; and, on this account, they must have been much embarrassed in their observations. But it is evident that Ptolomeus was aware of this circumstance, by the caution that he gives to allow something for it, upon every recurrence to ancient observations.

This philosopher also advances a very sensible hypothesis to account for the remarkably greater apparent size of the sun and moon when seen near the horizon. The mind, he says, judges of the size of objects by means of a pre-conceived idea of their distance from us: and this distance is fancied to be greater when a number of objects are interposed between the eye and the body we are viewing; which is the case when we see the heavenly bodies near the horizon. In his Almagest, however, he ascribes this appearance to a refraction of the rays by vapours, which actually enlarge the angle under which the luminaries appear; just as the angle is enlarged by which an object is seen from under water.

In the 12th century, the nature of refraction was largely considered by Alhazen an Arabian writer; in so much that, having made experiments upon it at the common surface between air and water, and glass, water and glass or crystal; and, being prepossessed with the ancient opinion of crystalline orbs in the regions Discoveries above the atmosphere, he even suspected a refraction there also, and fancied he could prove it by astronomic observations. This author deduces from hence several properties of atmospheric refraction, as that it increases the altitudes of all objects in the heavens; and he first advanced, that the stars are sometimes seen above the horizon by means of refraction, when they are really below it. This observation was confirmed by Vitello, B. Waltherus, and especially by the excellent observations of Tycho Brahe. Alhazen observed, that refraction contracts the vertical diameters and distances of the heavenly bodies, and that it is the cause of the twinkling of the stars. But we do not find that either he, or his follower Vitello knew any of its just quantity. Indeed it is too small to be determined except by very accurate instruments, and therefore we hear little more of it till about the year 1500; at which time great attention was paid to it by Bernard Walther, Martin, and others, chiefly by Tycho Brahe.

Alhazen supposed that the refraction of the atmosphere did not depend upon the vapours in it, as was probably the opinion of philosophers before his time, but on the different transparency; by which, as Monastica conjectures, he meant the density of the gross air contiguous to the earth, and the ether or the subtle air that lies beyond it. In examining the effects of refraction, he endeavours to prove that it is so far from being the cause of the heavenly bodies appearing larger near the horizon, that it would make them appear less; two stars, he says, appearing nearer together in the horizon, than near the meridian. This phenomenon he ranks among optical deceptions. We judge of distance, he says, by comparing the angle under which objects appear, with their supposed distance; so that if these angles be nearly equal, and the distance of one object be conceived greater than that of the other, it will be imagined to be larger. And the sky near the horizon, he says, is always imagined to be further from us than any other part of the concave surface. Roger Bacon ascribes this account of the horizontal moon to Ptolomey; and as such it is examined, and objected to by B. Porta.

In the writings of this Bacon, whose genius perhaps equalled that of his great name-fake Lord Verulam, we find the first distinct account of the magnifying power of glasses; and it is not improbable, that what he wrote upon this subject gave rise to that most useful invention of spectacles. For he says, that if an object be applied close to the base of the larger segment of a sphere of glass, it will appear magnified. He also treats of the appearance of an object through a globe, and says that he was the first who observed the refraction of rays into it.
History.

In 1279, Vitello, a native of Poland, published a treatise on optics, containing all that was valuable in Alhazen, and digested in a much more intelligible and methodical manner. He observes, that light is always lost by refraction, in conformance of which the objects seen by refracted light always appear less luminous; but he does not pretend to estimate the quantity of this loss. He reduced into a table the results of his experiments on the refractive powers of air, water, and glass, corresponding to different angles of incidence. In his account of the horizontal moon he agrees exactly with Alhazen; observing, that in the horizon he seems to touch the earth, and appears much more distant from us than in the zenith, on account of the intermediate space containing a greater variety of objects upon the visible surface of the earth. He ascribes the twinkling of the stars to the motion of the air in which the light is refracted; and to illustrate this hypothesis, he observes, that they twinkle still more when viewed in water put in motion. He also shows, that refraction is necessary as well as reflection, to form the rainbow; because the body which the rays fall upon is a transparent substance, at the surface of which one part of the light is always reflected and another refracted. But he seems to consider refraction as serving only to condense the light, and thereby enabling it to make a stronger impression upon the eye. This writer also makes some ingenious attempts to explain refraction, or to ascertain the law of it. He also considers the fact of glass spheres, and the apparent size of objects seen through them; though upon these subjects he is not at all exact. It is sufficient indeed to show the rate of knowledge, or rather of ignorance, at that time, to observe, that both Vitello, and his master Alhazen, endeavored to account for objects appearing larger when they are seen under water by the circular figure of its surface; since, being fluid, it conforms to the figure of the earth.

Contemporary with Vitello was Roger Bacon, a man of very extensive genius, and who wrote upon almost every branch of science; yet in this branch he does not seem to have made any considerable advances beyond what Alhazen had done before him. Even some of the wildest and most absurd of the opinions of the ancients have had the sanction of his authority. He does not hesitate to asent to an opinion adopted by many of the ancients, and indeed by most philosophers till his time, that visual rays proceed from the eye; giving this reason for it, that every thing in nature is qualified to discharge its proper functions by its own powers, in the same manner as the sun and other celestial bodies. In his Specula Mathematica, he added some observations on the refraction of the light of the stars; the apparent size of objects; the extraordinary size of the sun and moon in the horizon; but in all this he is not very exact, and advances but little. In his Opus Majus he demonstrates, that if a transparent body interposed between the eye and an object, be convex towards the eye, the object will appear magnified. This observation, however, he certainly had from Alhazen; the only difference between them is, that Bacon prefers the smaller segment of a sphere, and Alhazen the larger, in which the latter certainly was right.

From this time to that of the revival of learning in Europe, we have no farther treatise on the subject of refraction, or indeed on any other part of optics. One of Maurolycus, teacher of mathematics at Medina. In a treatise, De Luminis et Umbrae, published in 1575, he demonstrates that the crystalline humour of the eye is a lens that collects the rays of light issuing from the objects, and throws them upon the retina where is the focus of each pencil. From this principle he discovered the reason why some people were short-sighted and others long-sighted; and why the former are relieved by concave, and the others by convex glasses.

About the same time that Maurolycus made such discoveries towards the discovery of the nature of vision, of B. Porta-Johannes Baptista Porta at Naples discovered the camera obscura, which throws still more light on the same subject. His house was constantly resorted to by all the ingenious persons of Naples, whom he formed into what he called an academy of secrets; each member being obliged to contribute something that was not generally known, and might be useful. By this means he was furnished with materials for his Magia Naturalis, which contains his account of the camera obscura, and the first edition of which was published, as he informs us, when he was not quite 15 years old. He also gave the first hint of the magic lantern; which Kircher afterwards followed and improved. His experiments with the camera obscura convinced him, that vision is performed by the intromission of something into the eye, and not by visual rays proceeding from the eye, as had been formerly imagined; and he was the first who fully satisfied himself and others upon this subject. Indeed the resemblance between experiments with the camera obscura and the manner in which vision is performed in the eye, was so striking as to escape the observation of a less ingenious person. But when he says that the eye is a camera obscura, and the pupil the hole in the window-blind, he was so far mistaken as to suppose that it was the crystalline humour that corresponds to the wall which receives the images; nor was it discovered till the year 1604, that this office is performed by the retina. He makes a variety of just observations concerning vision; and particularly explains several cases in which we imagine things to be without the eye, when the appearances are occasioned by some affection of the eye itself, or some motion within the eye. He observes also, that, in certain circumstances, vision, will be afflicted by convex or concave glasses; and he seems also to have made some small advances towards the discovery of telescopes. He takes notice, that a round and flat surface plunged into water, will appear hollow as well as magnified to an eye perpendicularly over it; and he very well explains by a figure the manner in which it is done.

All this time, however, the great problem concerning the measuring of refractions had remained unsolved. Alhazen and Vitello, indeed, had attempted it; but failed, by attempting to measure the angle itself instead of its sine. At last it was discovered by Snellius professor of mathematics at Leyden. This philosopher, however, did not perfectly understand his own discovery, nor did he live to publish any account of it himself. It was afterwards explained by professor Hortenius both publicly and privately by
At a meeting of the Royal Society, Aug. 31.

Descartes undertook to explain the cause of refraction by the revolution of forces, on the principles of mechanics. In consequence of this, he was obliged to suppose that light passes with more ease through a denser medium, than through a rare one. The truth of this explanation was first questioned by M. Fermat, counsellor to the parliament of Thoulon, and an able mathematician. He alleged, contrary to the opinion of Descartes, that light suffers more resistance in water than air, and more in glass than in water; and he maintained, that the resistance of different mediums with respect to light is in proportion to their densities. M. Leibnitz adopted the same general idea; and these gentlemen argued upon the subject in the following manner.

Nay, say they, accomplishes her ends by the shortest methods. Light therefore ought to pass from one point to another, either by the shortest road, or that in which the least time is required. But it is plain that the line in which light passes, when it falls obliquely upon a denser medium, is not the most direct or the shortest; so that it must be that in which the least time is spent. And whereas it is demonstrable, that light falling obliquely upon a denser medium (in order to take up the least time possible in passing from a point in one medium to a point in the other) must be refracted in such a manner, that the sines of the angles of incidence and refraction must be to one another, as the different facilities with which light is transmitted in those mediums; it follows, that since light approaches the perpendicular when it passes obliquely from air into water, so that the sine of the angle of refraction is less than that of the angle of incidence, the facility with which water suffers light to pass through it is less than that of the air; so that light meets with more refinance in water than air.

Arguments of this kind could not give satisfaction; and a little time showed the fallacy of the hypothesis. At a meeting of the Royal Society, Aug. 31. 1664, an experiment for measuring the refraction of common water was made with a new instrument which they had prepared for that purpose; and the angle of incidence being 40 degrees, that of refraction was found to be 30. About this time also we find the first mention for mediums not refracting the light in an exact proportion to their densities. For Mr Boyle, in a letter to Mr Oldenburg, Dated Nov. 3. 1664, observes, that in spirit-of-wine, the proportion of the sines of the angles of incidence to the sines of the angles of refraction was nearly the same as 4 to 3; and that, as spirit-of-wine occasions a greater refraction than common water, so oil of turpentine, which is lighter than spirit-of-wine, produces not only a greater refraction than common water, but a much greater than salt water. And at a meeting held Nov. 9. the same year, Dr Hooke (who had been ordered to prosecute the experiment) brought in an account of one that he had made with pure and clear salad oil, which was found to have produced a much greater refraction than any liquor which he had then tried; the angle of refraction that answered to an angle of incidence of 30° being found no less than 40° 30', and the angle of refraction that answered to an angle of incidence of 20° being 29° 47'.—M. de la Hire also made several experiments to ascertain the refractive power of oil with respect to that of water and air; and found the sine of the angle of incidence to that of refraction to be as 60 to 42; which, he observes, is a little nearer to that of glass than to that of water, though oil is much lighter than water, and glass much heavier.

The members of the Royal Society finding that the refraction of salt water exceeded that of fresh, purposed the experiment farther with solutions of vitriol, falt-petre, and alum, in water; when they found the refraction of the solution of vitriol and falt-petre a little more, but that of alum a little less, than common water.

Dr Hooke made an experiment before the Royal Society, Feb. 11. 1663, which clearly proves that ice refracts the light less than water; which he took to be a good argument that the lightness of ice, which causes it to swim in water, is not caused only by the small bubbles which are visible in it, but that it arises from the uniform constitution or general texture of the whole mass. M. de la Hire also took a good deal of pains to determine whether, as was then the common opinion, the refractive power of ice and water were the same; and he found, as Dr Hooke had done before, that ice refracts less than water.

By a most accurate and elaborate experiment made in the year 1668, in which a ray of light was transmitted through a Torricellian vacuum, Mr Lowthorp found, that the refractive power of air is to that of water as 36 to 34,400. He concludes his account of the experiment with observing, that the refractive power of bodies is not proportional to the density, at least not to the gravity, of the refracting medium.

For the refractive power of glass to that of air, it is as 55 to 34, whereas its gravity is as 87 to 34; that is, the squares of their refractive powers are very nearly as their respective gravities. And there are some fluids, which, though they are lighter than water, yet have a greater power of refraction. Thus the refractive power of spirit-of-wine, according to Dr Hooke's experiment, is to that of water as 33 to 34, and its gravity reciprocally as 33 to 36, or 36%. But the refractive powers of air and water seem to observe the simple proportion of their gravities directly. And if this should be confirmed by succeeding experiments, it is probable, he says, that the refractive powers of the atmosphere are every where, and at all heights above the earth, proportioned to its density and expansion; and then it would be no difficult matter to trace the light through it, so as to terminate the shadow of the earth, and, together with proper experiments for measuring the quantity of light illuminating an opaque body, to examine at what distances the moon must be from the earth to suffer eclipses of the observed durations.
Caffini the younger happened to be present when Mr. Lowthorp made the above-mentioned experiment before the Royal Society; and upon his return home, having made a report of it to the members of the Royal Academy of Sciences, those gentlemen endeavored to repeat the experiment in 1700; but they did not succeed.—For, as they said, beams of light passed through the vacuum without suffering any refraction. The Royal Society being informed of this, were disposed that it might be put past dispute, by repeated and well-attested trials; and ordered Mr. Haukibee to make an instrument for the purpose, by the direction of Dr. Halley. It consisted of a strong brass prism, two sides of which had sockets to receive two plane glasses, whereby the air in the prism might either be exhausted or condensed. The prism had also a mercurial gage fixed to it, to discover the density of the contained air; and was contrived to turn upon its axis, in order to make the refractions equal on each side when it was fixed to the end of a telescope. The refracting angle was near 64°; and the length of the telescope was about 10 feet, having a fine hair in its focus. The event of this accurate experiment was as follows:

Having chosen a proper and very distinct erect object, whose distance was 2588 feet, June 15. O. S. 1708, in the morning, the barometer being then at 29-73, and the thermometer at 60, they first exhausted the prism, and then applying it to the telescope, the horizontal hair in the focus covered a mark on the object distinctly seen through the vacuum, the two glasses being equally inclined to the visual ray. Then admitting the air into the prism, the object was seen to rise above the hair gradually as the air entered, and in the end the hair was observed to hide a mark 10 inches below the former mark. This they often repeated, and with the same success.

After this they applied the condensing engine to the prism; and having forced in another atmosphere, so that the density of the included air was double to that of the outward, they again placed it before the telescope, and, letting out the air, the object which before seemed to rise, appeared gradually to descend, and the hair at length rested on an object higher than before by the same interval of 10 inches. This experiment they likewise frequently repeated without any variation in the event.

They then forced in another atmosphere; and upon discharging the condensed air, the object was seen near 21 inches lower than before.

Now the radius in this case being 2588 feet, 104 inches will subtend an angle of one minute and 8 seconds, and the angle of incidence of the visual ray being 32 degrees (because the angle of the glass planes was 64°), it follows from the known laws of refraction, that as the sine of 39° is to that of 31°, 59', 26" differing from 32° by 34' the half of 1', 8"; so is the sine of any other incidence, to the sine of its angle of refraction; and so is radius, or 1000000, to 999736; which, therefore, is the proportion between the sine of incidence in vacuo and the sine of refraction from thence into common air.

It appears, by these experiments, that the refractive power of the air is proportional to its density. And since the density of the atmosphere is as its weight directly, and its heat inversely, the ratio of its density, at any given time, may be had by comparing the heights of the barometer and thermometer; and hence he concludes that this will also be the ratio of the refraction of the air. But Dr. Smith observes, that, before we can depend upon the accuracy of this conclusion, we ought to examine whether heat and cold alone may not alter the refractive power of air, while its density continues the same. This, he says, may be tried, by heating the condensed or rarefied air, that up in the prism, just before it is fixed to the telescope, and by observing whether the air in its focus will continue to cover the same mark all the while that the air is cooling.

The French academicians, being informed of the result of the above-mentioned experiment, employed M. Delisle the younger to repeat their former experiment with more care; and he presently found, that their operators had never made any vacuum at all, there being chinks in their instrument, through which the air had infiltrated itself. He therefore annexed a gage to his instrument, by which means he was sure of his vacuum; and then the result of the experiment was the same with that in England. The refraction was always in proportion to the density of the air, excepting when the mercury was very low, and consequently the air very rare; in which case the whole quantity being very small, he could not perceive much difference in them. Comparing, however, the refractive power of the atmosphere, observed at Paris, with the result of his experiment, he found, that the best vacuum he could make was far short of that of the ethereal regions above the atmosphere.

Dr. Hooke first suggested the thought of making allowance for the effect of the refraction of light, in passing from the higher and rarer, to the lower and denser regions of the atmosphere, in the computed height of mountains. To this he attributes the different opinions of authors concerning the height of several very high hills. He could not account for the appearance of the Peak of Teneriff, and several very high mountains, at so great a distance as that at which they are actually seen, but upon the supposition of the curvature of the visual ray, that is made by its passing obliquely through a medium of such different density, from the top of them to the eye, very far distant in the horizon. All calculations of the height of mountains that are made upon the supposition that the rays of light come from the tops of them, to our eyes, in straight lines, must, he says, be very erroneous.

Dr. Hooke gives a very good account of the twinkling of the stars; ascribing it to the irregular and unequal refraction of the rays of light, which is also the reason why the limbs of the sun, moon, and planets appear to wave or dance. And that there is such an unequal distribution of the parts of the atmosphere, he says, is manifest from the different degrees of heat and cold in the air. This, he says, will be evident by looking upon distant objects, over a piece of hot glass, which cannot be supposed to throw out any kind of exhalation from itself, as well as through ascending streams of water.

About this time Grimaldi first observed that the coloured image of the sun refracted through a prism is always
always oblong, and that colours proceed from refraction. — The way in which he first discovered this was by Vitellio's experiment abovementioned, in which a piece of white paper placed at the bottom of a glafs vessel filled with water, and exposed to the lights of the sun, appears coloured. However, he observed, in that case the two surfaces of the refracting medium were exactly parallel to each other, no colours were produced. But of the true cause of those colours, viz. the different refrangibility of the rays of light, he had not the least suspicion. This discovery was reserved for Sir Isaac Newton, and which occurred to him in the year 1666. At that time he was amusing himself with this, the oblong figure of the coloured spectrum first struck him. He was surprized at the great disproportion between its length and breadth; the former being about five times the measure of the latter. He could hardly think that any difference in the thickness of the glass, or in the composition of it, could have such an influence on the light. However, in order not to conclude anything without a proof, he proceeded to examine the effects of these circumstances, and particularly tried what would be the consequence of transmitting the light through parts of the glass that were of different thicknesses, or through holes in the window-shutter of different sizes; or by setting the prism on the outside of the shutter, so that the light might pass through it, and be refracted before it was terminated by the hole.

He then suspected that these colours might arise from the light being dilated by some unevenness in the glass, or some other accidental irregularity; and to try this, he took another prism, like the former, and placed it in such a manner, as that the light, passing through them both, might be refracted contrarywise, and so be returned by the latter into the same course from which it had been diverted by the former. In this manner he thought that the regular effects of the first prism would be destroyed by the second; but that the irregular ones would be augmented by the multiplicity of refractions. The event was, that the light, which by the first prism was diffused into an oblong form, was by the second reduced into a circular one, with as much regularity as if it had not passed through either of them.

At last, after various experiments and conjectures, he hit upon what he calls the experimentum crucis, and which completed this great discovery. He took two boards, and placed one of them close behind the prism at the windows, so that the light might pass through a small hole made in it for the purpose, and fall on the other board, which he placed at the distance of about 12 feet; having first made a small hole in it also, for some of that incident light to pass through. He then placed another prism behind the first board, so that the light which was transmitted through both the boards might pass through that also, and be again refracted before it arrived at the wall. This being done, he took the first prism in his hand, and turned it about its axis, so much as to make the several parts of the image, cast on the second board, successively to pass through the hole in it, that he might observe to what places on the wall the second prism would refract them; and he saw, by the change of these places, that the light tending to that end of the image, towards which the refraction of the first prism was made, did, in the second prism, suffer a refraction considerably greater than the light which tended to the other end. The true cause, therefore, of the length of the image was discovered to be no other, than that light is not similar, or homogenous; but that it consists of rays, some of which are more refrangible than others: so that, without any difference in their incidence on the same medium, some of them shall be more refracted than others; and therefore, that, according to their particular degrees of refrangibility, they will be transmitted through the prism to different parts of the opposite wall.

Since it appears from these experiments that different rays of light have different degrees of refrangibility, it necessarily follows, that the rules laid down by preceding philosophers concerning the refractive power of water, glass, &c. must be limited to the middle kind of rays. Sir Isaac, however, proves that the fine of the incidence of every kind of light, considered apart, is to its fine of refraction in a given ratio. This he deduces, both by experiment, and by reasoning geometrically, from the supposition that bodies refract the light by acting upon its rays in lines perpendicular to their surfaces.

The most import discovery with regard to refraction, Mr Dolland's discovery of the method of correcting the faults of refracting telescopes arising from the different refrangibility of the rays, and which had been generally thought impossible to be removed. Notwithstanding the great discovery of Sir Isaac Newton concerning the different refrangibility of the rays of light, he had no idea but that they were all affected in the same proportion by every medium, so that the refrangibility of the extreme rays might be determined if that of the mean ones was given. From this it would follow, as Mr Dolland observes, that equal and contrary refrangibility must only destroy each other, but that the divergency of the colours from one refraction would likewise be corrected by the other, and that there could be no possibility of producing any such thing as refraction which would not be affected by the different refrangibility of light; or, in other words, that however a ray of light might be refracted backwards and forwards by different mediums, as water, glass, &c. provided it was so done, that the emergent ray should be parallel to the incident one, it would ever after be white; and consequently, if it should come out inclined to the incident, it would diverge, and ever after be coloured; and from this it was natural to infer, that all spherical object-glasses of telescopes must be equally affected by the different refrangibility of light, in proportion to their apertures, of whatever materials they may be formed.

For this reason, Sir Isaac Newton, and all other philosophers and opticians, had despaired of bringing refracting telescopes to any great degree of perfection, without making them of an immoderate and very inconvenient length. They therefore applied themselves chiefly to the improvement of the reflecting telescope; and the business of refraction was dropped till about
about the year 1747, when M. Euler, improving up
on a hint of Sir Isaac Newton's, formed a scheme of
making object-glasses of two materials, of different re
fractions: hoping, that by this difference, the re
fractions would balance one another, and thereby
prevent the dispersion of the rays that is occasioned by
the difference of refractionability. These object-glasses
were comprised of two lenses of glass with water be
tween them. This memoir of M. Euler excited the
attention of Mr Dollond. He carefully went over all
M. Euler's calculations, substituting for his hypotheti
cal laws of refraction those which had been actually
ascertained by the experiments of Newton; and found,
that, after this necessary sublimation, it followed from
M. Euler's own principles, that there could be no
union of the foci of all kinds of colours, but in a lens
infinitely large.

M. Euler did not mean to controvert the experi
ments of Newton: but he said, that they were not con
trary to his hypothesis, but in so small a degree as
might be neglected; and affirmed, that, if they were
admitted in all their extent, it would be impossible to
correct the difference of refrangibility occasioned by
the transmigration of the rays from one medium into
another of different density; a correction which he
thought was very possible, since he supposed it to be
actually affected in the structure of the eye, which in
his opinion was made to consist of different mediums
for that very purpose. To this kind of reasoning Mr
Dollond made no reply, but by appealing to the ex
periments of Newton and the great circumspection
with which it was known that he conducted all his
inquiries.

In this state of the controversy, the friends of M.
Clairaut engaged him to attend to it; and it appeared
to him, that, since the experiments of Newton
cited by Mr Dollond could not be questioned, the speculations of M. Euler were more ingenious than
useful.

The same paper of M. Euler was also particularly
noticed by M. Klingensferna of Sweden, who gave a
considerable degree of attention to the subject, and
discovered, that, from Newton's own principles, the
result of the 8th experiment of the second book of his
Optics could not answer his description of it.

He found, he says, that when light goes out of air
through several contiguous refracting mediums, as
through water and glass, and thence goes out again
into air, whether the refracting surfaces be parallel or
inclined to one another, that lights as often as by con
trary refractions it is so corrected as to emerge in lines
parallel to those in which it was incident, continues
ever after to be white; but if the emergent rays be
inclined to the incident, the whiteness of the emergin
light will, by degrees, in passing on from the place of
emergence, become tinged at its edges with colours.
This he tried by refracting light with prisms of glass,
placed within a prismatic vessel of water.

By theorems deduced from this experiment he in
fers, that the refractions of the rays of every sort, made
out of any medium into air, are known by having the
refraction of the rays of any one sort; and also that
the refraction out of one medium into another is found
as often as we have the refractions out of them both
into any third medium.

On the contrary, the Swedish philosopher observes,
that, in this experiment, the rays of light, after pas
sing through the water and the glass, though they
come out parallel to the incident rays, will be col
oured; but that the smaller the glass prism is, the
nearer will the ref salt of it approach to Newton's de
scription.

This paper of M. Klingensferna being communi
cated to Sir Dollond by M. Maillet, made him enter
tain doubts concerning Newton's report, and deter
mined him to have recourse to experiment.

He therefore cemented together two plates of pa
rallel glass at their edges, so as to form a prismatic
vessel, when stopped at the ends of bases; and the
glasses being turned downwards, he placed in it a glass
prism, with one of its edges upwards, and filled up the
vacancy with clear water; so that the refraction of the
prism was contrived to be contrary to that of the wa
ter, in order that a ray of light, transmitted through
both these refracting mediums, might be affected by
the difference only between the two refractions. As he
found the water to refract more or less than the glass
prism, he diminished or increased the angle between
the glass plates, till he found the two contrary refractions to be equal; which he discovered by viewing an
object through this double prism. For when it appeared
neither raised nor depressed, he was satisfied that the
refractions were equal, and that the emergent rays
were parallel to the incident.

Now, according to the prevailing opinion, he ob
serves, the object should have appeared through this
double prism in its natural colours; for if the differ
ence of refrangibility had been in all respects equal in
the two equal refractions, they would have refected
each other. But this experiment fully proved the fal
lacy of the received opinion, by showing the diver
gency of the light by the glass prism to be about
double of that by the water; for the image of the ob
ject, though not at all refacted, was yet as much in
fected with prismatic colours, as if it had been seen
through a glass wedge only, whose refracting angle
was near 30 degrees.

This experiment is the very same with that of Sir
Isaac Newton's abovementioned, notwithstanding the
result was so remarkably different; but Mr Dollond
assures us, that he used all possible precaution and
care in his process; and he kept his apparatus by
him, that he might evince the truth of what he said,
every time he should be properly required to do it.

He plainly saw, however, that if the refracting
angle of the water vessel could have been doubled by
sufficient increase, the divergence of the coloured rays
would have been greatly diminished, or entirely re
fected; and that there would have been a very great re
fraction without colour, as he had already produced a
great disinfecting without refraction: but the incon
venience of so large an angle as that of the prismatic
vessel must have been, to bring the light to an equal
divergence with that of the glass prism whose angle
was about 60 degrees, made it necessary to try some
experiments of the same kind with smaller angles.

Accordingly, he got a wedge of plate glass, the
gle of which was only nine degrees; and using it in
the same circumstances, he increased the angle of the
water.
water wedge, in which it was placed, till the divergence of the light by the water was equal to that by the glass; that is, till the image of the object, though considerably refracted by the excess of the refraction of the water, appeared nevertheless quite free from any colours proceeding from the different refrangibility of the light; and, as near as he could then measure, the refraction by the water was about \(1/4\) of that by the glass. He acknowledges, indeed, that he was not very exact in taking the measurements, because his business was not at that time to determine the exact proportions, so much as to show that the divergence of the colours, by different substances, was by no means very probable of being found in different kinds of glass, especially as the first glases, made nearly alike in that respect, made much better light than others; and as no satisfactory cause had been assigned for such difference, he thought there was great reason to presume that it might be owing to the different divergence of the light in the same refractions.

As these experiments clearly proved, that different substances made the light to diverge very differently in proportion to their general refractive power, Mr Dollond began to suspect that such variety might possibly be found in different kinds of glass, especially as experience had already shown that some of the kinds made much better object-glasses in the usual way than others; and as no satisfactory cause had been assigned for such difference, he thought there was great reason to presume that it might be owing to the different divergence of the light in the same refractions.

His next business, therefore, was to grind wedges of different kinds of glass, and apply them together; so that the refractions might be made in contrary directions, in order to discover, as in the abovementioned experiments, whether the refraction and the divergence of the colours would vanish together. But a considerable time elapsed before he could set about that work: for though he was determined to try it at his leisure, for satisfying his own curiosity, he did not expect to meet with a difference sufficient to give room for any great improvement of telescopes, so that it was not till the latter end of the year 1757 that he undertook it; but his first trials convinced him that the business deserved his utmost attention and application.

He discovered a difference far beyond his hopes in the refractive qualities of different kinds of glass, with respect to the divergence of colours. The yellow or straw-colour foreign glass, commonly called Venice glass; and the English crown glass, proved to be very nearly alike in that respect; though, in general, the crown glass seemed to make the light diverge the less of the two. The common English plate glass made the light diverge more; and the white crystall, or English flint glass, most of all.

It was now his business to examine the particular qualities of every kind of glass that he could come at, not to amuse himself with conjectures about the cause of this difference, but to fix upon two sorts in which it should be the greatest; and he soon found these to be the crown glass and the white flint glass. He therefore ground one wedge of white flint, of about 25 degrees; and another of crown glass, of about 29 degrees; which refracted nearly alike, but their power of making the colours diverge was very different. He then ground several others of crown glass to different angles, till he got one which was equal, with respect to the divergence of the light, to that in the white flint-glass; for when they were put together, so as to refract in contrary directions, the refracted light was entirely free from colours. Then measuring the refraction of each wedge with these different angles, he found that of the white glass to be to that of the crown glass nearly as two to three: and this proportion held very nearly in all small angles; so that any two wedges made in this proportion, and applied together, so as to refract in a contrary direction, would refract the light without any diffraction of the rays.

In a letter to M. Clairaunt, Mr Dollond says, that the sine of incidence in crown glass is to that of its general refraction as 1 to 1.53, and in flint glass as 1 to 1.583.

To apply this knowledge to practice, Mr Dollond went to work upon the object-glasses of telescopes; not doubting but that, upon the same principles on which a refracted colourless ray was produced by prisms, it might be done by lenses also, made of similar materials. And he succeeded, by considering, that, in order to make two spherical glasses that should refract the light in contrary directions, the one must be concave and the other convex; and as the rays are to converge to a real focus, the excess of refraction must evidently be in the convex lens. Also, as the convex glass is to refract the most, it appeared from his experiments, that it must be made of crown glass, and the concave of white flint glass. Further, as the refractions of spherical glasses are in an inverse ratio of their focal distances, it follows, that the focal distances of the two glasses shall be inversely as the ratios of the refractions of the wedges; for being thus proportioned, every ray of light that passes through this combined glass, at whatever distance it may pass from its axis, will constantly be refracted, by the difference between two contrary refractions, in the proportion required; and therefore the different refrangibility of the light will be entirely removed.

Notwithstanding our author had these clear grounds in theory and experiment to go upon, he found that he had many difficulties to struggle with when he came to reduce them into actual practice; but with great patience and address, he at length got into a ready method of making telescopes upon these new principles.

His principal difficulties arose from the following circumstances. In the first place, the focal distances, as well as the particular surfaces, must be very nicely proportioned to the densities or refracting powers of the glasses, which are very apt to vary in the same kind of glass at different times. Secondly, The centres of the two glasses must be placed truly in the common axis of the telescope, otherwise the defined effect will be in a great measure destroyed. Add to these, that there are four surfaces to be wrought perfectly spherical; and any pernicious, he says, but moderately practised in optical operations, will allow, that there must be the greatest accuracy throughout the whole work. At length, however, after numerous trials, and a persevering perseverance, he was able to construct reflecting telescopes, with such apertures and magnifying powers, under limited lengths, as, in the opinion of the best judges, far exceeded any thing that had been produced,
It was objected to Mr. Dollond's discovery, that the small dispersion of the rays in crown glass is only apparent, owing to the opacity of that kind of glass which does not transmit the fainter coloured rays in a sufficient quantity; but this objection is particularly confidered, and answered by M. Beguelin.

As Mr. Dollond did not explain the methods which he took in the choice of different spheres proper to destroy the effect of the different refrangibility of the rays of light, and gave no hint that he himself had any rule to direct himself in it; and as the calculation of the dispersion of the rays, in so complicated an affair, is very delicate; M. Clairaut, who had given a good deal of attention to this subject, from the beginning of the controversy, endeavoured to make out a complete theory of it.

Without some affittance of this kind, it is impossible, says this author, to contruct telescopes of equal goodnes with those of Mr. Dollond, except by a ser­vile imitation of his; which, however, on many accounts, would be very unlikely to answer. Besides, Mr. Dollond only gave his proportions in general, and pretty near the truth; whereas the greatest possible precision is necessary. Alfo the bett of Mr. Dollond's tele­scopes were far short of the Newtonian ones (a); whereas it might be expected that they should exceed them, if the foci of all the coloured rays could be as perfectly united after refraction through glafs, as after reflection from a mirror; since there is more light left in the latter cafe than in the former.

With a view, therefore, to aftift the artift, he endeavoured to afeertain the refractive power of different kinds of glass, and alfo their property of separating the rays of light, by the following exact methods. He made ufe of two prifms placed close to one another, as Mr. Dollond had done; but, instead of looking through them, he placed them in a darkened room; and when the image of the fun, transmitted through them, was perfectly white, he concluded that the different ref­rangibility of the rays was corrected.

In order to afeertain with more eafe the true angles that prifms ought to have to destroy the effect of the difference of refrangibility, he contructed one which had one of its surfaces cylindrical, with feveral degrees of amplitude. By this means, without changing his prifms, he had the choice of an infinity of angles; among which, by examining the point of the curve surface, which, receiving the folar ray, gave a white image, he could eafily find the true one.

He alfo afeertained the proportion in which different kifs of glafs separated the rays of light, by measuring, with proper precautions, the oblong image of the fun, made by transmitting a beam of light through them. In making these experiments, he hit upon an eafy method of convincing any peron of the greater refractive power of English flint-glafs above the common French glafs, both with refpect to the mean refraction, and the different refrangibility of the co­lours; for having taken two prifms, of these two kinds of glafs, but equal in all other refpects, and placed them fo that they received, at the fame time, two rays of the fun, with the fame degree of incidence, he faw, that, of the two images, that which was pro­duced by the English flint-glafs was a little higher up on the wall than the other, and longer by more than one half.

M. Clairaut was affifted in these experiments by M. De Tournieres, and the refults agreed with Mr. Dollond's in general; but whereas Mr. Dollond had made the dispersion of the rays in glafs and in water to be as five to four (acknowledging, however that he did not pretend to do it with exactness), thefe gentlemen, who took more pains, and used more precautions, found it to be as three to two. For the theorems and problems deduced by M. Clairaut from these new principles of optics, with a view to the perfedion of telescopes, we muft refer the reader to Mem. Acad. Par. 1756, 1757.

The labours of M. Clairaut were fucceeded by thofe of M. D'Alembert, which feem to have given the makers of thofe achromatic telescopes all the aid that calculations can afford them. This excellent mathematician has likewise propofed a variety of new con­structions of thofe telescopes, the advantages and di­advantages of which he difcretly notes; at the fame time that he points out feveral methods of correcting the errors to which they are liable: as by placing the objed-glafs, in fome cafes, at a small distance from one another, and fometimes by using eye-glafs of different refractive powers; which is an expedient that seems not to have occurred to any peron before him. He even fhow, that telescopes may be made to advantage, confifing of only one objed-glafs, and an eye-glafs of a different refractive power. Some of his con­structions have two or more eye-glafs of different kinds of glafs. This subjeft he afeerted at large in one of the volumes of his Opuscula Mathemati­que. We have alfo three memoirs of M. D'Alembert upon this subjeft, among thofe of the French Academy; one in the year 1764, another in 1765, and a third in 1767.

At the conclusion of his second memoir he fays, that he does not doubt, but, by the different methods he propofes, achromatic telescopes may be made to far greater degrees of perfection than any that have been feen hitherto, and even fuch as is hardly credibly: And though the crown glafs, by its greenish colour, may absorb fome part of the red or violet rays, which, however, is not found to be the cafe in fact; that objection cannot be made to the common French glafs, which is white, and which on this account he thinks must be preferable to the English crown glafs.

Notwithstanding Mefiis Clairaut and D'Alembert seemed to have exhausted the business of calculation on the subjeft of Mr. Dollond's telescopes, no ufe could be made of their labours by foreign artifts. For all the telescopes made in England, according to no exact rule,

(a) This affirmation of M. Clairaut might be true at the time that it was made, but it is by no means fo at present.
rule, as foreigners supposed, were greatly superior to any that could be made elsewhere, though under the immediate direction of those able calculators. For this M. Beguelin aligned several reasons. Among others, he thought that their geometrical theories were too general, and their calculations too complicated, for the use of workmen. He also thought, that in consequence of neglecting small quantities, which their calculators professedly did, in order to make their algebraical expressions more commodious, their conclusions were not sufficiently exact. But what he thought to be of the most consequence, was the want of an exact method of measuring the refractive and dispersing powers of the different kinds of glafs; and for want of this, the greatest precision in calculation was altogether useless.

These considerations induced this gentleman to take another view of this subject; but still he could not reconcile the actual effect of Mr Dollond's telescopes with his own conclusions: so that he imagined, either that he had not the true refraction and dispersion of the two kinds of glafs given him; or else, that the aberration which still remained after his calculations, must have been destroyed by some irregularity in the surfaces of the lenfes. He finds several errors in the calculations both of M. D'Alembert and Clairaut, and concludes with expressing his design to pursue this subject much farther.

M. Euler, who first gave occasion to this inquiry, which terminated so happily for the advancement of science, being persuaded both by his reasoning and calculations, that Mr Dollond had discovered no new principle in optics, and yet not being able to controvert Mr Short's testimony in favour of the goodness of his telescopes, concluded that this extraordinary effect was owing, in part, to the crown glafs not transmitting all the red light, which would otherwise have come to a different focus, and have distorted the image; but principally to his happening to hit on a juft curvature of his glafs, which he did not doubt would have produced the same effect if his lenfes had all been made of the same kind of glafs. In another place he imagines that the goodness of Mr Dollond's telescope might be owing to the eye-glas. If my theory, says he, be true, this disagreeable consequence follows, that Mr Dollond's object-glafs cannot be exempt from the dispersion of colours: yet a regard to the respectable testimony of Mr Short embarras my extremity, it being as difficult to question such express authority, as to abandon a theory which appears to me perfectly well founded, and to embrace an opinion, which is as contrary to all the established laws of nature as it is strange and seemingly absurd. He even appeals to experiments made in a darkened room: in which, he says, he is confident that Mr Dollond's object-glafs would appear to have the fame defects that others are subject to.

Not doubting, however, that Mr Dollond, either by chance, or otherwise, had made forms; considerable improvement in the construction of telescopes, by the combination of glafs, he abandoned his former project, in which he had recourse to different mediums, and confined his attention to the correction of the errors which arise from the curvature of lenfes. But while he was proceeding, as he imagined, upon the true principles of optics, of which, however, he made but little use, he could not help expressing his surprize that Mr Dollond should have been led to so important a discovery by reasoning in a manner quite contrary to the nature of things. At length, however, M. Euler was convinced of the reality and importance of Mr Dollond's discoveries; and very frankly acknowledges, that he should perhaps never have been brought to assent to it, had not his friend M. Clairaut affirmed him that the experiments of the English optician might be depended upon. However, the experiments of M. Zeither of Peterburg gave him the most complete satisfaction with respect to this new law of refraction.

This gentleman demonstrated, that it is the lead in the composition of glafs that gives it this remarkable property, that while the refraction of the mean rays is nearly the fame, that of the extremes differs considerably. And, by increasing the quantity of lead in the mixture, he produced a kind of glafs, which occasioned a much greater separation of the extreme rays than the flint glafs which Mr Dollond had made use of. By this evidence M. Euler owns that he was compelled to renounce the principle which, before this time, has been considered as incontestible, viz. that the dispersion of the extreme rays depends upon the refraction of the mean: and that the former varies with the quality of the glafs, while the latter is not affected by it.

From these new principles M. Euler deduces theorems concerning the combination of the lenfes, and, in a manner similar to M. Clairaut and D'Alembert, points out methods of conftructing archromatic telescopes.

While he was employed upon this subject, he informs us, that he received a letter from M. Zeither, dated Peterburg 30th of January 1764, in which he gives him a particular account of the succéss of his experiments on the composition of glafs; and that, having mixed minium and sand in different proportions, he obtained the result of the mean refraction and the dispersion of the rays varied according to the following table.

<table>

By this table it is evident that a greater quantity of lead not only occasions a greater dispersion of the rays, but also considerably increases the mean refraction. The first of these kinds of glafs, which contains three times as much minium as flint, will appear very extraordinary; since, hitherto, no transparent substance has been known, whose refractive power exceeded the ratio of two to one, and that the dispersion occasioned by this glafs is almost five times as great as that of crown glafs, which could not be believed by those who enter-
entertained any doubt concerning the same property in flint glasses, the effect of which is three times as great as crown glasses. One may observe, however, in these kinds of glasses, something of a proportion between the mean refraction and the dispersion of rays, which may enable us to reconcile these surprising effects with other principles already known.

Here, however, M. Euler announces to us another discovery of the same M. Zehrer, no less surprising than the former, and which discoursed all his schemes for reconciling the above-mentioned phenomena. As the six kinds of glass mentioned in the above table were composed of nothing but minutum and flint, M. Zehrer happened to think of mixing all-aline salts with them, in order to give the glasses a confidence more proper for dioptric uses; when he was much surprised to find this mixture greatly diminished the mean refraction, almost without making any change in the dispersion. After many trials, he at length obtained a kind of glass greatly superior to the flint-glass of Mr Dollond, with respect to the construction of telescopes; since it occasioned three times as great a dispersion of the rays as the common glasses, at the same time that the mean refraction was only as 1.61 to 1.

M. Euler also gives particular instructions how to find both the mean and extreme refractive power of different kinds of glasses; and particularly advises to make use of prisms with very large refracting angles, not less than 70°.

Notwithstanding it evidently appeared, we may say, to almost all philosophers, that Mr Dollond had made a real discovery of something not comprehended in the optical principles of Sir Isaac Newton, it did not appal to Mr Murdoch. Upon this occasion, he interposed in the defence, as he imagined, of Sir Isaac Newton; maintaining, that Mr Dollond's positions, which, he says, he knows not by what mischief have been deemed paradoxes in Sir Isaac's theory of light, are really the necessary consequences of it. He also endeavours to shew that Sir Isaac might not be mistaken in his account of the experiment above-mentioned. But, admitting all that he advances in this part of his defence, Newton must have made use of a prism with a much smaller refracting angle than, from his own account of his experiments, we have any reason to believe that he ever did make use of.

The fact probably was, that Sir Isaac deceived himself in this case, by attending to what he imagined to be the clear consequence of his other experiments; and though the light he saw was certainly tinged with colours, and he must have seen it to be so, yet he might imagine that this circumstance arose from some imperfection in his prisms, or in the disposition of them, which he did not think it worth his while to examine. It is also observable, that Sir Isaac is not so particular in his description of his prisms, and other parts of his apparatus, in his account of this experiment, as he generally is in other cases; and therefore, probably, wrote his account of it from his memory only. In reality, it is no reflection upon Sir Isaac Newton, who did so much, to say that he was mistaken in this particular case, and that he did not make the discovery that Mr Dollond did; though it be great praise to Mr Dollond, and all those persons who contributed to this discovery, that they ventured to call in question the authority of so great a man.

Mr Dollond, however, was not the only optician who had the merit of making this discovery; it had been made and applied to the same purpose by a private gentleman—Mr Chelf of Chelf hill. He had observed that prisms of flint glasses gave larger spectrums than prisms of water when the mean refraction was the same in both, i.e. when the deviation of the refracted ray from the direction of the incident was the same. He tried prisms of other glasses, and found similar differences; and he employed the discovery in the same manner, and made achromatic experiments some time before Dollond. These facts came out in a process raised at the instance of Watkins optician at Charing-cross, as also in a publication by Mr Ramden optician. There is, however, no evidence that Dollond stole the idea from Mr Chelf, or that they had not both claims to the discovery.

Still the best refracting telescopes, constructed on the principles of Mr Dollond, are defective, on account of that colour which, by the aberration of the rays, they give to objects viewed through them, unless the object be of small diameter. This defect of men of genius and science have laboured to remove, some by one contrivance and some by another. Father Boiwick, to whom every branch of optics is much indebted, has, in his attempts for this purpose, displayed much ingenuity; but the philosopher whose exertions have of late been crowned with most success, and who has perhaps made the most important discovery in this branch of science since the era of Newton, is Dr Robert Blair, regius professor of astronomy in the college of Edinburgh. By a judicious set of experiments ably conducted, he has proved, that the quality of dispersing the rays in a greater degree than crown glasses, is not confined to a few mediums, but is possessed by a great variety of fluids, and by some of these in a most extraordinary degree. He has shown, that although the greater refrangibility of the violet rays than of the red rays, when light palls from any medium whatever into a vacuum, may be considered as a law of nature; yet in the passages of light from one medium into another, it depends entirely on the qualities of the mediums which of these rays shall be the most refrangible, or whether there shall be any difference in their refrangibility. In order to correct the aberration arising from difference of refrangibility among the rays of light, he instituted a set of experiments, in the conducting of which he detected a very singular and important quality in the muriatic acid. In all the dispersive mediums hitherto examined, the green rays, which are the mean refrangible in crown glasses, were found among the least refrangible; but in the muriatic acid, these same rays were by him found to make a part of the more refrangible. This discovery led to complete success in removing the great defect of optical instruments, viz. that diffraction or aberration of the rays which arise from their unequal refrangibility, and has hitherto rendered it impossible to converge all of them to one point either by single or opposite refractions. A fluid, in which the particles of muriatic acid and metallic particles hold a due proportion, at the same time that it separates the extreme rays of the

Hh spectrum.
OPTICS.

Mr Michell supposes that the arrival of fewer or more rays at one time, especially from the smaller or the more remote fixed stars, may make such an unequal impression upon the eye, as may, at least, have some share in producing this effect; since it may be supposed that even a single particle of light is sufficient to make a sensible impression upon the organs of sight; so that very few particles arriving at the eye in a second of time, perhaps no more than three or four, may be sufficient to make an object confusively visible. For though the impression may be considered as momentary, yet the perception occasioned by it is of some duration. Hence, he says, it is not improbable that the number of the particles of light which enter the eye in a second of time, even from Sirius himself (the light of which does not exceed that of the smallest visible fixed star, in a greater proportion than that of about 1000 to 1), may not exceed 3000 or 4000, and from stars of the second magnitude they may, therefore, probably not exceed 100. Now the apparent increase and diminution of the light which we observe in the twinkling of the stars, seems to be repeated at not very unequal intervals, perhaps about four or five times in a second. He therefore thought it reasonable to suppose, that the inequalities which will naturally arise from the chance of the rays coming sometimes a little denter, and sometimes a little rarer, in so small a number of them as must fall upon the eye in the fourth or fifth part of a second, may be sufficient to account for this appearance. An addition of two or three more or a single one, upon 20, especially if there should be an equal deficiency out of the next 20, would, he supposed, be very sensible, as he thought was probable from the very great difference in the appearance of stars, the light of which does not differ so much as is commonly imagined. The light of the middlesmall star in the tail of the Great Bear does not, he thinks, exceed the light of the very small star that is next to it in a greater proportion than that of about 1000 to 1; and M. Bouger found, that a difference in the light of objects of one part in 6 is sufficiently distinguishable. It will perhaps, he says, be objected, that the rays coming from Sirius are too numerous to admit of a sufficient inequality arising from the common effect of chance so frequently as would be necessary to produce this effect, whatever might happen with respect to the smaller stars; but he observes, that, till we know what inequality is necessary to produce this effect, we can only guess at it one way or the other.

Since these observations were published, Mr Michell has entertained some suspicion that the unequal density.
History.

OPTICS.

§ 3. Observations concerning the Reflection of Light.

However much the ancients might have been misled by the nature of light, we are told that the ancients were acquainted with two very important accidents of the light: viz., that light is propagated in a right line, and that the angle of incidence is equal to the angle of reflection. Who it was that first made these important observations is not known. But indeed, important as they are, and the foundation of a great part of the present system of optics, it is possible that, if they were known, we might not be allowed to have any thine of merit, at least for the former of them; the fact is too obvious, and too useful, to be disbelieved. As to the latter, that the angle of incidence is equal to the angle of reflection, it was probably first discovered by observing a ray of the sun reflected from the surface of water, or some other polished body; or from observing the images of objects reflected by such surfaces. If philosophers attended to this phenomenon, they could not but take notice of the fact, and it was reflected near the perpendicular; and if it fell obliquely, it was reflected obliquely: and if the sun was thought to be the source of the light, the equality of the angles, however coarse and imperfect, they could not but feel that there was a sufficient reason to assert their equality. At the same time they could not but know that the incident and reflected rays were both in the same plane.

Aristotle was sensible that it is the reflection of light from the atmosphere which prevents total darkness after the sun sets, and in places where he doth not shine in the daytime. He was also of opinion, that rainbows, halos, and mock suns, were all occasioned by the reflection of the sun-beams in different circumstances, by which an imperfect image of his body was produced, the colour only being exhibited, and not his proper figure. The image, he says, is not a glistening mirror; for each drop of rain is too small to reflect a visible image, but the conjunction of all the images is visible.

Without enquiring any farther into the nature of Euclid's light or vision, the ancient geométricians contested the propriety of two observations mentioned above, viz., the rectilinear progress of light, and the equality of the angles of incidence and reflection. The treatise of optics which has been ascribed to Euclid is employed about determining the apparent size and figure of objects, from the angle under which they appear, or from which the extremities of them subtend at the eye, and the apparent place of the image of an object reflected from a polished mirror; which he fixes at the place where the reflected ray meets a perpendicular to the mirror drawn through the object. But this work is so imperfect, and so inaccurately drawn up, that it is not generally thought to be the production of that great geometer.

It appears from a circumstance in the history of the ancients, that the effects of burning-glases had also been observed by the ancients; and it is probable that glades of the Romans had a method of lighting their fanned fire by means of a concave speculum. It seems indeed to have been known pretty early, that there is an in-
creased of heat in the place where the rays of light meet, when they are reflected from a concave mirror. The burning power of concave mirrors is taken notice of by Euclid in the second book of the treatise above-mentioned. If we give but a small degree of credit to what some ancient historians are said to have written concerning the exploits of Archimedes, we shall be induced to think that he made great use of this principle, in constructing some very powerful burning-mirrors; but nothing being said of other persons making use of his inventions, the whole account is very doubtful. It is allowed, however, that this eminent geometer did write a treatise on the subject of burning-mirrors, though it be not now extant.

B. Porta supposes that the burning-mirrors of the ancients were of metal, in the form of a parabola. It follows from the properties of this curve, that all the rays which fall upon it, parallel to its axis, will meet in the same point at the focus. Consequent-ly, if the vertex of the parabola be cut off, as in fig. 1, it will make a convenient burning-mirror. In some drawings of this instrument the fruitbume is so small, as to look like a ring. With an instrument of this kind, it is thought, that the Romans lighted their sacred fire. Some have also thought that this was the form of the mirror with which Archimedes burnt the Roman fleet; using either a lens, to throw the rays parallel, when they had been brought to a focus; or applying a smaller parabolic mirror for this purpose, as is represented fig 2. But Dechales shows, that it is impossible to convey any rays in a direction parallel to one another, except those that come from the same point in the fun’s disk.

All this time, however, the nature of reflection was very far from being understood. Even lord Bacon, who made much greater advances in natural philosophy than his predecessors, and who pointed out the true method of improving it, was so far deceived with regard to the nature of refraction and reflection, that he supposed it possible to see the image reflected from a looking-glass, without seeing the glass itself; and to this purpose he quotes a story of friar Bacon, who is reported to have apparently walked in the air between two sleepers, and which was thought to have been effected by reflection from glasses while he walked upon the ground.

The whole business of seeing images in the air may be traced up to Vitellio; and what he said upon the subject seems to have pabled from writer to writer, with considerable additions, to the time of lord Bacon. What Vitellio endeavours to show is, that it is possible, by means of a cylindrical convex speculum, to see the images of objects in the air, out of the speculum, when the objects themselves cannot be seen. But, if his description of the apparatus requisite for this experiment be attended to, it will be seen that the eye was to be directed towards the speculum, which was placed within a room, while both the object and the speculum were without it. But though he recommends this observation to the diligent study of his readers, he has not described it in such a manner as is very intelligible; and, indeed, it is certain, that no such effect can be produced by a convex mirror. If he himself did make any trial with the apparatus that he describes for this purpose, he must have been under some deception with respect to it.

B. Porta says, that this effect may be produced by a plane mirror only; and that an ingenious person may succeed in it: but his more particular description of a method to produce this extraordinary appearance is by a plane mirror and a concave one combined.

Kircher also speaks of the possibility of exhibiting these pendulous images, and supposes that they are re-

flected from the denser air; and the most perfect and pleasing deception depending upon the images in the air is one of which this writer gives a particular account in his Ars Magna Lucis et Umbrae, p. 78. In this case the image is placed at the bottom of a hollow polished cylinder, by which means it appears like a real solid substance, suspended within the mouth of the vessel. In this manner, he says, he once exhibited a representation of the attention of Christ; when the images were so perfect, that the spectators could not be persuaded, but by attempting to handle them, that they were not real substances.

Among other amusing things that were either invented or improved by Kircher, was the method of throwing the appearance of letters, and other forms of things, into a darkened room from without, by means of a lens and a plane mirror. The figures or letters were written upon the face of the mirror, and inverted; and the focus of the lens was contrived to fall upon the screen or wall that received their images. In this manner, he says, that with the light of the sun he could throw a plain and distinct image 500 feet.

It was Kepler who first discovered the true reason of the apparent places of objects seen by reflecting mirrors, as it depends upon the angle which the rays of light, issuing from the extreme part of an object, make with one another after such reflections. In plane mirrors these rays are reflected with the same degree of inclination to one another that they had before their incidence; but he shows that this inclination is changed in convex and concave mirrors.

Mr Boyle made some curious observations concerning the reflecting powers of differently coloured substances. Many learned men, he says, imagined that snow affects the eyes, not by a borrowed, but by a native light; but having placed a quantity of snow in a room from which all foreign light was excluded, neither he nor any body else was able to perceive it. To try whether white bodies reflect more light than others, he held a sheet of white paper in a sun-beam admitted into a darkened room; and observed that it reflected much more light than a paper of any other colour, a considerable part of the room being enlightened by it. Farther, to show that white bodies reflect the rays outwards, he adds, that common burning-glases will not of a long time burn or discoulour white paper. When he was a boy, he says, and took great pleasure in making experiments with these glases, he was much surprized at this remarkable circumstance; and it fel on him very early upon gauging at the nature of white-ness, especially as he observed that the image of the sun was not so well defined upon white paper as upon black; and as, when he put ink upon the paper, the moisture would be quickly dried up, and the paper, which he could not burn before, would presently take fire.
fire. He also found, that, by exposing his hand to the sun, with a thin black glove upon it, it would be suddenly and more considerably heated, than if he held his naked hand to the rays, or put on a glove of thin white leather.

To prove that black is the reverse of white, with respect to its property of reflecting the rays of the sun, he procured a large piece of black marble; and having got it ground into the form of a large spherical concave speculum, he found that the image of the sun reflected from it was far from offending or dazzling his eyes, as it would have done from another speculum; and though this was large, he could not in a long time let a piece of wood on fire with it; though a far less speculum, of the same form, and of a more reflecting substance, would presently have made it flame.

To satisfy himself still farther with respect to this subject, he took a broad and large tile; and having made one half of its surface white and the other black, he exposed it to the summer sun. And having let it lie there some time, he found, that while the whited part remained cool, the part that was black was grown very hot. For his farther satisfaction, he sometimes left part of the tile of its native red; and, after exposing the whole to the sun, observed that this part grew hotter than the white, but was not so hot as the black part. He also observes, that rooms hung with black are not only darker than they would otherwise be, but warmer too; and he knew several persons, who found great inconvenience from rooms hung with black. As another proof of his hypothesis, he informs us, that a virtuoso, of unsuspected credit, acquainted him, that, in a hot climate, he had seen eggs well roasted in a short time, by first blackening the shell, and then exposing them to the sun.

We have already taken notice of the remarkable property of lignum nehrriticum first observed by Kircher. (See Gulandina.) However, all his observations with regard to it fell very short of Mr Boyle. He describes this lignum nehrriticum to be a whitish kind of wood, that was brought from Mexico, which the natives call coatl or tlapanzatl, and which had been thought to tinge water of a green colour only; but he says that he found it to communicate all kinds of colours. If, says he, an infusion of this wood be put into a glass globe, and exposed to a strong light, it will be as colourless as pure water; but if it be carried into a place a little shaded, it will be a most beautiful green. In a place still more shaded, it will incline to red; and in a very shady place, or in an opaque vessel, it will be green again.

A cup of this remarkable wood was sent to Kircher by the procurator of his society at Mexico, and was presented by him to the emperor as a great curiosity. It is called lignum nehrriticum, because the infusion of it was imagined to be of service in diseases of the kidneys and bladder, and the natives of the country where it grows do make use of it for that purpose.

Mr Boyle corrected several of the hasty observations of Kircher concerning the colours that appear in the infusion of lignum nehrriticum, and he diversified the experiments with it in a very pleasing manner. He first distinctly noted the two very different colours which this remarkable tincture exhibits by transmitting and reflected light. If, says he, it be held directly between the light and the eye, it will appear tinged (excepting the very top of it, where a fly-coloured circle sometimes appears) almost of a golden colour, except the infusion be too strong; in which case it will be dark or reddish, and requires to be diluted with water. But if it be held from the light, so that the eye be between the light and the phial, it will appear of a deep lovely blue colour; as also the drops, if any, lie on the outside of the glass.

When a little of this tincture was poured upon a sheet of white paper, and placed in a window where the sun could shine upon it, he observed, that if he turned his back upon the sun, the shadow of his pen, or any such slender substance, projected upon the liquid, would not be all dark, like other shadows; but that part of it would be curiously coloured, the edge of it next the body being almost of a lively golden colour, and the more remote part blue. These, and other experiments of a similar nature, many of his friends, he says, beheld with wonder; and he remembered an excellent oculist, who accidentally meeting with a phial full of this liquor, and being unacquainted with this remarkable property of it, imagined, after he had viewed it a long time, that some new and strange diliemper had feized his eyes; and Mr Boyle himself acknowledges, that the oddness of the phenomenon made him very defirous to find out the cause of it; and his inquiries were not altogether unsuccessful.

Observing that this tincture, if it were too deep, was not tinged in so beautiful a manner, and that the impregnating virtue of the wood did, by being frequently infused in fresh water, gradually decay, he conjectured that the tincture contained much of the essential sial of the wood; and to try whether the subtle parts, on which the colour depended, were volatile enough to be distilled, without dissolving their texture, he applied some of it to the gentle heat of a lamp-furnace; but he found all that came over was as limpid and colourless as rock water, while that which remained behind was of so deep a blue, that it was only in a very strong light that it appeared of any colour.

Suspecting that the tinging particles abounded with salts, whole texture, and the colour thence arising, would probably be altered by acids, he poured into a small quantity of it a very little spirit of vinegar, and found that the blue colour immediately vanished, while the golden one remained, on which ever side it was viewed with respect to the light.

Upon this he imagined, that as the acid salts of the vinegar had been able to deprive the liquor of its blue colour, a sulphureous salt, which is of a contrary nature, would destroy their effects; and having placed himself between the window and the phial, and let fall into the same liquor a few drops of oil of tartar per di. liquum, he found that it was immediately restored to its former blue colour, and exhibited all the same phenomena which it had done at the first.

Having sometimes brought a round long-necked phial, filled with this tincture, into a darkened room, into which a beam of the sun was admitted by a small aperture, and holding the phial sometimes near the sun-beams, and sometimes partly in them and partly out
OPTICS.

History.

It was not only in this tincture of lignum naphthoricum that Mr Boyle observed the difference between reflected and transmitted light. He observed it even in gold, though no person explained the causes of these effects before Sir Isaac Newton. He took a piece of leaf-gold, and holding it between his eye and the light, observed that it did not appear of a golden colour, but of a greenish blue. He also observed the same change of colour by candle light; but the experiment did not succeed with a leaf of silver.

The constitution of the atmosphere and of the sea, we shall find, by observations made in later periods, to be similar to that of this mixture: for the blue rays, and others of a faint colour, do not penetrate so far into them as the red, and others of a stronger colour: but what this constitution is, which is common to them all, deserves to be inquired into. For all natural substances, as well as all other semi-transparent coloured substancess, as glafs, appear of the same hue in all positions of the eye. To increase or diminish the quantity makes no difference, but to make the colour deeper or more dilute.

The first distinct account of the colours exhibited by thin plates of various substancess, are met with among the observations of Mr Boyle. To show the chemists that colours may be made to appear or vanish, where there is no accession or change either of the sulphurous, the saline, or the mercurial principle of bodies he observes, that all chemical essential oils, as also good spirit of wine, being shaken till they rise in bubbles, appear of various colours; which immediately vanish when the bubbles burst, so that a colourless liquor may be immediately made to exhibit a variety of colours, and lose them in a moment, without any change in its essential principles. He then mentions this of lignum naphthoricum, the colours that appear in bubbles of soap and water, and also in turpentine. He sometimes got glafs blown so thin as to exhibit similar colours; and observes, that a feather, of a proper shape and size, and also a black ribbon, held at a proper distance, between his eye and the sun, shewed a variety of little rainbows, as he calls them, with very vivid colours, none of which were constantly to be seen in the same objects.

Much more pains were taken with this subject, and a much greater number of observations respecting it were made, by Dr Hooke. As he loved to give prius by his discoveries, he promised, at a meeting of the society on the 7th of March 1672, to exhibit, at their next meeting, something which had neither reflection nor refraction, and yet was diaphanous. Accordingly, at the time appointed, he produced the famous coloured bubble of soap and water, of which such admirable use was afterwards made by Sir Isaac Newton, but which Dr Hooke and his contemporaries seem to have overlooked in Mr Boyle's treatise on colours, though it was published nine years before. It is no wonder that so curious an appearance excited the attention of that inquisitive body, and that they should desire him to bring an account of it in writing at their next meeting.

By the help of a small glass-pipe, there were blown several small bubbles; out of a mixture of soup and water; where it was observable, that, at first, they appeared white and clear; but that, after some time, the film of water growing thinner, there appeared upon it all the colours of the rainbow: First a pale yellow; then orange, red, purple, blue, green, &c. with the same series of colours repeated; in which it was farther observable, that the first and last series were very faint, and that the middlemost order of series was very bright. After these colours had passed over the changes above-mentioned, the film of the bubble began to appear white again; and presently, in several parts of this second white film, there appeared several holes, which by degrees grew very big, several of them running into one another. After relating other observations, which are not of much consequence, he says it is strange, that though both the encompassing and encompassed air have surfaces, yet he could not observe that they afforded either reflection or refraction, which all the other parts of the encompassed air did. This experiment, he says, at first sight, may appear very trivial, yet, as the finding out the nature and causes of reflection, refraction, colours, congruity and incongruity, and several other properties of bodies, he looked upon it as one of the most instructive. And he promised to consider it more afterwards; but we do not find that ever he did; nor indeed is it to be much regretted, as we shall soon find this business in better hands. He adds, that that which gives one colour by reflection, gives another by refraction; not much unlike the tincture of lignum naphthoricum.

Dr Hooke was the first to observe, if not to describe, the beautiful colours that appear in thin plates of mufcovy glafs. These, he says, are very beautiful to the naked eye, but much more when they are viewed with a microscope. With this instrument he could perceive that these colours were ranged in rings surrounding the white specks or flaws in this thin substance, that the order of the colours was the same as in the rainbow, and that they were often repeated ten times. But the colours, he says, were disposed as in the outer bow, and not the inner. Some of them also were much brighter than others; and some of them very much broader. He also observed, that if there was a place where the colours were very broad, and conspicuous to the naked eye, they might be made, by pressing the place with the finger, to change places, and move from one part to another. Lastly, he observed, if great care be used, this substance may be split into plates of 1/4 or 1/5 of an inch in diameter, each of which will appear through a microscope to be uniformly adorned with some one vivid colour, and that those plates will be found upon examination to be of the same thickness throughout.

As a fact similar to this, but observed previous to it, we shall here mention that Lord Bereton, at a meeting of the Royal Society in 1666, produced some pieces
History.

**OPTICS.**

Pieces of glass taken out of a window of a church, both on the north and on the south side of it; observing, that they were all eaten in by the air, but that the piece taken from the south side had some colours like those of the rainbow upon it, while the others on the north side had not. This phenomenon has been frequently observed since, and in other circumstances. It is not to be doubted, but that in all these cases, the glass is divided into thin plates, which exhibit colours, upon the same principle with those which Dr. Hooke observed in the bubble of soap and water, and in the thin plate of air, which we shall find more fully explained by Sir Isaac Newton. With care the thin plates of the glass may be separated, and the theory verified.

An observation made by Otto Guericke, well explains why the flaws are visible by day at the bottom of a well.

But of all those who have given their attention to this subject of the reflection of the light, none seems to have given such satisfaction as M. Bouguer; and next to those of Sir Isaac Newton, his labours seem to have been the most successful. The object of his curious and elaborate experiments was to measure the directions of light, whether emitted, reflected, or refracted, by different bodies. They were originally occasioned by an article of M. Mairan's in the memoirs of the French academy for 1751, in which the proportion of the light of the sun at the two solstices was supposed to be known; and his laudable attempt to verify what had been before taken for granted, suggested a variety of new experiments, and opened to him and to the world a new field of optical knowledge. His first production upon this subject was a treatise intitled *Étude d'Ocultes*, which was received with great approbation. Afterwards, giving more attention to this subject, he formed an idea of a much larger work, to which many more experiments were necessary; but he was prevented, by a variety of interruptions, from executing his design in so far as he had proposed; and he had hardly completed it at the time of his death, in 1758; so that we are obliged to his friend, M. de la Caille for the care of the publication. At length, however, it was printed at Paris in 1760, under the title of *Traité d’Optique*.

At the entrance upon this treatise, we are induced to form the most pleasing expectations from our author's experiments, by his account of the variety, the singular accuracy, and circumstantiality, with which he made them; whereby he must, to all appearance, have guarded against every avenue to error, and particularly against those objections to which the few attempts that had been made of a similar nature, before him, had been liable. In order to compare different degrees of light, he always contrived to place the bodies from which it proceeded, or other bodies illuminated by them, in such a manner that he could view them distinctly at the same time; and he either varied the distances of these bodies, or modified their light in some other way, till he could perceive no difference between them. Then, considering their different distances of the other circumstances by which their light was affected, he calculated the proportion which they would have borne to each other at the same distance, or in the same circumstances.

To ascertain the quantity of light lost by reflection, he placed the mirror, or reflecting surface, B, on which the experiment was to be made, truly upright; and having taken two tablets, of precisely the same colour, or of an equal degree of whiteness, he placed them exactly parallel to one another at E and D, and threw light upon them by means of a lamp or candle, P, placed in a right line between them. He then placed himself so, that with his eye at A he could see the tablet E, and the image of the tablet D, reflected from the mirror B, at the same time; making them, as it were, to touch one another. He then moved the candle along the line ED, so as to throw more or less light upon either of them, till he could perceive no difference in the strength of the light that came to his eye from them. After this, he had nothing more to do than to measure the distances EP and DP; for the squares of these distances expressed the degree in which the reflection of the mirror diminished the quantity of light. It is evident, that if the mirror reflected all the rays it received, the candle P must have been placed at C, at an equal distance from each of the tablets, in order to make them appear equally illuminated; but because much of the light is lost in reflection, they can only be made to appear equally bright by placing the candle nearer the tablet D, which is seen by reflection only.

To find how much light is lost by oblique reflection, he took two equally polished plates, D and E, and caused them to be enlightened by the candle P; and while one of them, D, was seen at A, by reflection from B, placed in a position oblique to the eye, the other, E, was so placed, as to appear contiguous to it; and removing the plate E, till the light which it reflected was no stronger than that which came from the image D seen by reflection at B, he estimated the quantity of light that was lost by this oblique reflection, by the squares of the distances of the two objects from the candle.

It need scarcely be added, that in these experiments all foreign light was excluded, that his eye was shaded, and that every other precaution was observed in order to make his conclusions unquestionable.

In order to ascertain the quantity of light lost by reflection with the greatest exactness, M. Bouguer introduced two beams of light into a darkened room, as by the apertures P and Q; which he had so contrived, that he could place them higher or lower, and enlarge or diminish them at pleasure; and the reflecting surface (that of a fluid contained in a vessel) was placed horizontally at O, from whence the light coming through the hole P, was reflected to R, upon the eye in GI, where it was compared with another beam of light that fell upon S, through the hole Q, which he had made to much less than P, in such a manner that the spaces S and R were equally illuminated; and by the proportion that the apertures P and Q bore to each other, he calculated what quantity of light was lost by the reflection at O.

It was necessary, he observes, that the two beams of light
OPTICS.

Light PO and QS (which he usually made 7 or 8 feet long) should be exactly parallel, that they might come from two points of the sky equally elevated above the horizon, and having precisely the same intensity of light. It was also necessary that the hole Q should be a little higher than P, in order that the two images should be at the same height and near one another. It is no less necessary, he says, that the screen GH be exactly vertical, in order that the direct and reflected beams may fall upon it with the same inclination; since, otherwise, though the two lights were perfectly equal, they would not illuminate the screen equally.

This disposition he says, serves to answer another important condition in these experiments for the direct ray QS must be of the same length with the sum of the incident and reflected rays, PO and OR, in order that the quantity of light introduced into the room may be sensibly proportional to the sizes of the apertures.

We shall now proceed to recite the result of the experiments which he made to measure the quantity of light that is lost by reflection in a great variety of circumstances; but we shall introduce them by the recital of some which were made previous to them on the burning-glass. From these experiments it appeared, that more light was reflected than could be from the candle diverges,

and therefore falls more obliquely upon the mirror than the light of the sun, the rays of which are nearly parallel.

The quantity of light reflected by a mirror, he found, that when it was placed at an angle of 15° to the incident rays, it reflected 628 parts of the light which fell upon it; at the same time that a mirror, which he tried in the same circumstances, reflected only 561 of the light of the sun. And thus much more light was reflected; so that at an angle of three degrees the glafs reflected 700 parts, and the metal something less, as in the former case.

Proceeding to make farther observations on the subject of reflected light, he premises the two following theorems, which he demonstrates geometrically. 1. When the luminous body is at an infinite distance, and its light is received by a globe, the surface of which has a perfect polish, and aborbs no light, it reflects the light equally in all directions, provided it be reflected at a considerable distance. He only excepts the place where the shadow of the globe falls; but this, he says, is no more than a single point, with respect to the immensity of the spherical surface which receives its light.

2. The quantity of light reflected in one certain direction will always be exactly the same, whether it be reflected by a very great number of small polished hemispheres, by a little number of larger hemispheres, or by a single hemisphere, provided they occupy the same space, or cover the same ground-plan.

The use he proposes to make of these theorems is to assist him in distinguishing whether the light reflected from bodies be owing to the extintion of it within them, or whether the roughness or eminences which cover them have not the same effect with the small polished hemispheres abovementioned.
flames with different degrees of obliquity; but it is almost as great in some opaque substances, and it was always more or less so in every thing that he tried. He found the greatest inequality in black marble, in which he was at length to find, that, with an angle of 5° 35' of incidence, though not perfectly polished, yet it reflected almost as well as quicksilver. Of 1000 rays which it received, it returned 600; but when the angle of incidence was 14 degrees, it reflected only 156; when it was 30, it reflected 51; and when it was 80, it reflected only 23.

Similar experiments made with metallic mirrors always gave the differences much less considerable. The greatest was hardly ever an eighth or a ninth part of it, but they were always in the same way.

The great difference between the quantity of light reflected from the surface of water, at different angles of incidence, is truly surprising; but our author observes, that this difference was greater when the smallest inclinations were compared with those which were near to a right angle. He sometimes suspected, that, at very small angles of incidence, the reflection from water was even greater than from quicksilver. All things considered, he thought it was not quite so great, though it was very difficult to determine the precise difference between them. In very small angles, he says, that water reflects nearly 4/5 of the direct light.

There is no person, he says, but has sometimes felt the force of this strong reflection from water, when he has been walking in still weather on the brink of a lake opposite to the sun. In this case, the reflected light is 3/5, or sometimes a greater proportion of the light that comes directly from the sun, which is an addition to the direct rays of the sun that cannot fail to be very palpable. The direct light of the sun diminishes gradually as it approaches the horizon, while the reflected light at the same time grows stronger: so that there is a truly surprising fact, in which the united force of the direct and reflected light will be the greatest possible, and this he says is 12 or 13 degrees.

On the other hand, the light reflected from water at great angles of incidence is extremely small. Our author was assured, that, when the light was perpendicular, it reflected no more than the 35th part that quicksilver does in the same circumstances; for it did not appear, from all his observations, that water reflects more than the 60th, or rather the 55th, part of perpendicular light. When the angle of incidence was 90 degrees, the light reflected from the surface of water was about the 32d part of that which mercury reflected; and as the reflection from water increases with the diminution of the angle of incidence, it was twice as strong in proportion at 39 degrees for it was then the 16th part of the quantity that mercury reflected.

In order to procure a common standard by which to measure the proportion of light reflected from various fluid substances, he pitched upon water as the most commodious; and partly by observation, and partly by calculation, which he always found to agree with his observations, he drew up the following table of the quantity of light reflected from the surface of water, at different angles with the surface.

Pouring a quantity of water into a vessel containing quicksilver, it is evident that there will be two images of any objects seen by reflection from them, one at the surface of the water, and the other at that of the quicksilver. In the largest angles of incidence, the image at the surface of the water will disappear, which will happen when it is about a 60th or an 80th part less luminous than the image at the surface of the quicksilver. Depressing the eye, the image on the water will grow stronger, and that on the quicksilver weaker in proportion; till at last, the latter will be incomparably weaker than the former, and at an angle of about 10 degrees they will be equally luminous. According to the table, 1/10 of the incident rays are reflected from the water at this angle of 10 degrees. At the surface of the mercury they were reduced to 500; and of these, part being reflected back upon it from the under surface of the water, only 333 remained to make the image from the mercury.

It has been observed by several persons, particularly by Mr Edwards, (see Phil. Trans. vol. 53, p. 229.) that there is a remarkable strong reflection into water, with respect to rays issuing from the water; and persons under water have seen images of things in the air in a manner peculiarly distinct and beautiful: but this fact had not been observed with a sufficient degree of attention, till it came into M. Bouguer's way to do it, and he acknowledges it to be very remarkable. In this case, he says, that from the smallest angles of incidence, to a certain number of degrees, the greatest part of the rays are reflected, perhaps in as great a proportion as at the surface of metallic mirrors, or of quicksilver, while the other part, which does not.

Vol. XIII.
does not escape into the air, is extinguished or absorbed; so that the surface of the transparent body appears opaque on the inside. If the angle of incidence be increased only a few degrees, the strong reflection ceases altogether, a great number of rays escape into the air, and very few are absorbed or extinguished. In proportion as the angle of incidence is farther increased, the quantity of the light reflected becomes less and less; and when it is near 90 degrees, almost all the rays escape out of the transparent body, its surface losing almost all its power of reflection, and becoming almost as transparent as it is in other cases, or when the light falls upon it from without.

This property belonging to the surfaces of transparent bodies, of absorbing or extinguishing the rays of light, is truly remarkable, and, as there is reason to believe, had not been noticed by any person before M. Bouguer. It had been conjectured by Sir Isaac Newton, that rays of light become extinct only by impinging upon the solid parts of bodies; but these observations of M. Bouguer show that the fact is quite otherwise; and that this effect is to be attributed, not to the solid parts of bodies, which are certainly more numerous in a long tract of water than in the passage of water into air, but to some power lodged at the surface of bodies only, and therefore probably the same with that which reflects, refracts, and injects the light.

One of the abovementioned observations, viz. all the light being reflected at certain angles of incidence from air into denser substances, had frequently been made, especially in glass prisms; so that Newton made use of one of them, instead of a reflecting mirror, in the construction of his telescope. If a beam of light fall upon the air from within these prisms, at an angle of 10°, 20°, or 30° degrees, the effect will be nearly the same as at the surface of quicksilver, a fourth or a third of the rays being extinguished, and 1/4 or 1/3 reflected. This property retains its full force as far as an incidence of 49° (supposing the proportion to be 31 and 29 for the mean refrangible rays); but if the angle of incidence be increased but one degree, the quantity of light reflected inwards decreases suddenly, and a great part of the rays escape out of the glass, so that the surface becomes suddenly transparent.

All transparent bodies have the same property, with this difference, that the angle of incidence at which the strong reflection ceases, and at which the light which is not reflected is extinguished, is greater in some than in others. In water this angle is about 41° 32'; and in every medium it depends so much on the invariable proportion of the sine of the angle of refraction to the sine of the angle of incidence, that this law alone is sufficient to determine all the phenomena of this new circumstance, at least as to this accidental opacity of the surface.

When our author proceeded to measure the quantity of light reflected by these internal surfaces at great angles of incidence, he found many difficulties, especially on account of the many alterations which the light underwent before it came to his eye; but at length, using a plate of crystal, he found, that, at an angle of 75 degrees, this internal reflection diminished the light 27 or 28 times; and as the external reflection at the same angle diminished the light only 26 times, it follows that the internal reflection is a little stronger than the other.

Repeating these experiments with the fame and different pieces of crystal, he sometimes found the two reflections to be equally strong; but, in general, the internal was the stronger. Also, the image reflected internally was always a little redder than an object which was seen directly through the plate of crystal.

Refusing his observations on the diminution of light, occasioned by the reflection of opaque bodies obliquely situated, he compared it with the appearances of similar substances which reflected the light perpendicularly. Using pieces of silver made very white, he found, that, when one of them was placed at an angle of 75 degrees with respect to the light, it reflected only 64 parts out of 1000. He then varied the angle, and also used white plaster and fine Dutch paper, and drew up the following table of the proportion of the light reflected from each of those substances at certain angles.

### Quantity of Light reflected from

Supposing the asperities of opaque bodies to consist of very small planes, it appears from these observations, that there are fewer of them in those bodies which reflect the light at small angles of incidence than at greater; and our author says, that the cage was nearly the same with respect to all the opaque bodies that he tried. None of them had their roughness equivalent to small hemispheres, which would have dispersed the light equally in all directions; and, from the data in the preceding table, he deduces mathematically the number of the little planes that compose those surfaces, and that are inclined to the general surface at the angles abovementioned, supposing that the whole surface contains 1000 of them that are parallel to itself, so as to reflect the light perpendicularly, when the luminous body is situated at right angles with respect to it. His conclusions reduced to a table, corresponding to the preceding, are as follow:

### Inclinations of the small surfaces with respect to the large one.

These:
History.

Thee variations in the number of little planes, or surfaces, he expresses in the form of a curve; and afterwards he shows, geometricaly, what would be the effect if the bodies were enlightened in one direction, and viewed in another; upon which subject he has several curious theorems and problems; as, the position of the eye being given, to find the angle at which the luminous body must be placed, in order to its reflecting the most light; or, the situation of the luminous body being given, to find a proper situation for the eye, in order to see the most enlightened, &c. But it would carry us too far into geometry to follow him through all these disquisitions.

Since the planets, as this accurate observer takes notice, are more luminous at their edges than at their centres, he concludes, from the abovementioned principles, that the bodies which form them are constituted in a manner different from ours; particularly that their opaque surfaces consist of small planes, more of which are inclined to the general surface than they are in terrestrial substances; and that there are in them an infinity of points, which have exactly the same splendour.

Our philosopher and geometrical next proceeds to ascertain the quantity of surface occupied by the small planes of each particular inclination, from considering the quantity of light reflected by each, allowing those that have a greater inclination to the common surface to take up proportionally less space than those which are parallel to it. And comparing the quantity of light that would be reflected by small planes thus disposed, with the quantity of light that was actually reflected by the three substances abovementioned, he found, that pallafer, notwithstanding its extreme whiteness, absorbs much light; for that, of 1000 rays that fall upon it, of which 166 or 167 ought to be reflected at an angle of 77 degrees, only 67 are in fact returned; so that 100 out of 167 were extinguished, that is, about three fifths.

With respect to the planets, our author concludes, that 500,000 rays which the moon receives, 172,000 are absorbed, or perhaps 204,100.

Having considered the surfaces of bodies as consisting of planes only, he thus explains himself:—Each small surface, separately taken, is extremely irregular, and some of them are really concave, and others convex; but, in reducing them to a middle state, they are to be considered as planes. Nevertheless he considers them as planes only with respect to the reception of the rays; for as they are almost all curves, and as, besides this, many of those whose situation is different from others contribute to the same effect, the rays always inflect from an actual or imaginary focus, and after reflection always diverge from another.

If it be asked, what becomes of those rays that are reflected from one aperture to another? he shows that very few of the rays can be in those circumstances; since they must fall upon planes which have more than 45 degrees of obliquity to the surface, of which there are very few in natural bodies. These rays must also fall at the bottom of those planes, and must meet with other planes similarly situated to receive them; and considering the great irregularity of the surfaces of opaque bodies, it may be concluded that very few of the rays are thus reflected upon the body itself; and that the little that is so reflected is probably lost to the spectators, being extinguished in the body.

We are obliged to Mr. Melville for some ingenious observations on the manner in which bodies are heated by light. He observes, that, as each colorific particle of an opaque body must be somewhat moved by the reaction of the particles of light, when it is reflected backwards and forwards between the same particles, it is manifest that they must likewise be agitated with a vibratory motion, and the time of a vibration will be equal to that which light takes up in moving from one particle of a body to another adjoining. This distance, in the most solid opaque bodies, cannot be supposed greater than \( \frac{1}{10} \) th of an inch, which space a particle of light describes in the \( \frac{1}{10} \) th of a second. With so rapid a motion, therefore, may the internal parts of bodies be agitated by the influence of light, as to perform \( 125,000,000,000,000 \) vibrations, or more, in a second of time.

The arrival of different particles of light at the surface of the same colorific particle, in the same or different rays, may disturb the regularity of its vibrations, but will evidently increase their frequency, or raise full smaller vibrations among the parts which compose those particles; by which means the infinite motion will become more subtle, and more thoroughly diffused. If the quantity of light admitted into the body be increased, the vibrations of the particles must likewise increase in magnitude and velocity, till last they may be so violent, as to make all the component particles dash one another to pieces by their mutual collision; in which case, the colour and texture of the body must be destroyed.

Since there is no reflection of light but at the surface of a medium, the same person observes, that the greatest quantity of rays, though crowded into the smallest space, will not of themselves produce any heat.

From hence it follows, that the portion of air which lies in the focus of the most potent speculum, is not at all affected by the passage of light through it, but continues of the same temperature with the ambient air; though any opaque body, or even any transparent body denser than air, when put in the same place, would be intensely heated in an instant.

This consequence, evidently flowing from the plainest and most certain principles, not seeming to have been rightly understood by many philosophers, and even the silence of most physical writers concerning this paradoxical truth making it probable that they were unacquainted with it, he thought it worth while to say something in explanation of it. He observes, that the safest way to be satisfied of the matter experimentally is, to hold a hair, or a piece of down, immediately above the focus of a lens or speculum, or to blow a stream of smoke from a pipe horizontally over it; for if the air in the focus were hotter than the surrounding fluid, it would continually ascend upon account of its rarefaction, and thereby necessarily agitate those slender bodies. Or a lens may be so placed as to form its focus within a body of water, or some other transparent substance, the heat of which may be examined from time to time with a thermometer; but care must be taken, in this experiment, to hold the lens as near as possible to the transparent body, left the rays, by falling closer than ordinary on its surface,
surface, should warm it more than the common sun-beams (b).

To apply these observations to the explanation of natural phenomena, he observes, that the atmosphere is not much warmed by the passage of the sun’s light through it, but chiefly by its contact with the heated surface of the globe. This, he thought, furnished one very simple and plausible reason why it is coldest in all climates on the tops of very high mountains; namely, because they are removed to the greatest distance from the general surface of the earth. For it is well known, that a fluid heated by its contact with a solid body, decreases in heat in some inverse proportion to the distance from the body. He himself found, by repeated trials, that the heat of water in deep lakes decreases regularly from the surface downwards. But to have this question fully determined, the temperature of the air in the valley and on the mountain-top must be observed every hour, both night and day, and carefully compared together.

From this doctrine he thinks it reasonable to suppose, that the heat produced by a given number of rays, in an opaque body of a given magnitude, must be greater when the rays are more inclined to one another, than when they are less so; for the direction of the vibrations raised by the action of the light, whether in the colorific particle, or those of an inferior order, will more interfere with one another; from whence the intestine shocks and collisions must increase. Besides this, the colorific particles of opaque bodies being dispersed in various situations, perhaps, upon the whole, the rays will fall more directly on each, the more they are inclined to one another. Is not this, says he, the reason of what has been remarked by philosophers, that the heat of the sun’s light, collected into a cone, increases in approaching the focus in a much higher proportion than according to its density? That the difference of the angle in which the rays fall on any particle of a given magnitude, placed at different distances from the focus, is but small, is no proof that the phenomenon cannot be ascribed to it; since we know not what high proportion one or both of the circumstances now mentioned may operate. However, that it proceeds not from any unknown action of the rays upon one another, as has been inferred, is evident from this, that each particular ray, after passing through the focus, preserves its own colour and its own direction, in the same manner as if it were alone.

The attempts of the Abbé Nollet to fire inflammable substances by the power of the solar rays collected in the focus of burning mirrors, have a near relation to the present subject. Considering the great power of burning mirrors and lenses, especially those of late construction, it will appear surprising that this celebrated experimental philosopher should not be able to fire any liquid substance. But though he made the trial with all the care imaginable on the 19th of February 1757, he was not able to do it either with spirit of wine, olive-oil, or pitch; and though he could fire sulphur, yet he could not succeed with Spanish wax, rosin, black pitch or fume. He both threw the focus of these mirrors upon the substances themselves, and also upon the flames that rose from them; but all the effect was, that the liquid boiled, and was dispersed in vapour or very small drops, but would not take fire. When linseed-rags, and other solid substances, were moistened with any of these inflammable liquids, they would not take fire till the liquid was dispersed in a copious fume; so that rags thus prepared were longer in burning than those that were dry.

M. Beaume, who assisted M. Nollet in some of these experiments, observed farther, that the same effects which were easily fired by the flame of fumits burning bodies, could not be set on fire by the contact of the hottest bodies that did not actually flame. Neither ether nor spirit-of-wine could be fired with a hot coal, or even red-hot iron, unless they were of a white heat. From these experiments our author concludes, that, supposing the electric matter to be the same thing with fire or light, it must fire spirit-of-wine by means of fire, another principle. The members of the academy Del Cimento had attempted to fire several of these substances, though without success; but this was so early in the history of philosophy, that nobody seems to have concluded, that. because they failed in this attempt, the thing could not be done. However, the Abbé informs us, that he read an account of his experiments to the Royal Academy at Paris several years before he attended to what had been published by the Italian Philosophers.

By the help of optical principles, and especially by observations on the reflection of light, Mr Melville discovered that bodies which seem to touch one another are not always in actual contact. "It is common (says he) to admire the volatility and fulphure of drops of rain that lie on the leaves of celerworts, and some other vegetables;" but no philosopher, as far as he knew, had put himself to the trouble of explaining this curious phenomenon. Upon inspecting them narrowly, he found that the fulphure of the drop is produced by a copious reflection of light from the flattened part of its surface contiguous to the plant. He observed farther, that, when the drop rolls along a part which has been wetted, it immediately loses all its fulphure, the green plant being then seen clearly through it; whereas, in the other case it is hardly to be discerned.

From these two observations put together, he concluded, that the drop does not really touch the plant, when it has the mercurial appearance, but is suspended in the air at some distance from it by the force of a repulsive power. For there could not be any copious reflection of white light from its under-surface, unless there were a real interval between it and the surface of the plant.

If that surface were perfectly smooth, the under-surface of the drop would be fo likewise, and would therefore show an image of the illuminating body by reflection.
reflection, like a piece of polished silver; but as it is considerably rough and unequal, the under-surface becomes rough likewise, and so, by reflecting the light copiously in different directions, assumes the refulgent white colour of unpolished silver.

It being thus proved by an optical argument, that the drop is not really in contact with the plant which supports it, it may easily be conceived whence its volatility arises, and why it leaves no moisture where it rolls.

Before we conclude the history of the observations concerning the reflection of light, we must not omit to take notice of two curious miscellaneous ones. Baron Alexander Funk, visiting some silver mines in Sweden, observed, that, in a clear day, it was as dark as pitch underground in the eye of a pit, at 60 or 70 fathoms deep; whereas, in a cloudy or rainy day, he could even see to read at 106 fathoms deep. Inquiring of the miners, he was informed that this is always the case; and, reflecting upon it, he imagined that it arose from this circumstance, that when the atmosphere is full of clouds, light is reflected from the moons into the pit in all directions, and that thereby a considerable proportion of the rays are reflected perpendicularly upon the earth; whereas, when the atmosphere is clear, there are no opaque bodies to reflect the light in this manner, at least in a sufficient quantity; and rays from the sun itself can never fall perpendicularly in that country. The other was that of the ingenious Mr. Grey, who makes such a figure in the history of electricity. This gentleman took a piece of fluff brown paper, and pricking a small hole in it, he held it at a little distance before him; when, applying a needle to his eye, he was surprised to see the point of it inverted. The nearer the needle was to the hole, the more it was magnified, but the less divided; and if it was so held, as that its image was near the edge of the hole, its point seemed crooked. From these appearances he concluded, that these small holes, or something in them, produce the effects of concave speculums; and from this circumstance he took the liberty to call them aerial speculums.

§ 4. Discoveries concerning the Infection of Light.

This property of light was not discovered till about the middle of the last century. The person who first made the discovery was Father Grimaldi; at least he first published an account of it in his treatise De luminis, coloribus, et iride, printed in 1666. Dr. Hooke, however, laid claim to the same discovery, though he did not publish his observations till five years after Grimaldi; having probably never seen his performance.

Dr. Hooke having made his room completely dark, admitted into it a beam of the sun's light by a very small hole in a brass plate fixed in the window-shutter. This beam spreading itself, formed a cone, the apex of which was in the hole, and the base was on a paper, so placed as to receive it at some distance. In this image of the sun, thus painted on the paper, he observed that the middle was much brighter than the edges, and that there was a kind of dark penumbra about it, of about a 16th part of the diameter of the circle; which penumbra, he says, must be ascribed to a property of light, which he promised to explain—

Having observed this, at the distance of about two inches from the former he let in another cone of light; and receiving the basons of them at such a distance from the hole as that the circles intersected each other, he observed that there was not only a penumbra, or darker ring, encompassing the lighter circle, but a manifest dark line, or circle, which appeared even where the limb of one interfered with that of the other. This appearance is distinctly represented, fig. 6.

Comparing the diameter of this base with its distance from the hole, he found it to be by no means the same as it would have been if it had been formed by straight lines drawn from the extremities of the sun's disk, but varied with the size of the holes, and the distance of the paper.

Struck with this appearance, he proceeded to make farther experiments concerning the nature of light thus transmitted. To give a just idea of which, he held an opaque body BB, fig. 7, fo as to intercept the light that entered at a hole in the window shutter O, and was received on the screen AP. In these circumstances, he observed, that the shadow of the opaque body (which was a round piece of wood, not bright or polished) was all over somewhat enlightened, but more especially towards the edge. Some persons who were present, imagining that this light within the shadow might be produced by some kind of reflection from the side of this opaque body, on account of its roundness; and others supposing it might proceed from some reflection from the sides of the hole in the piece of brass through which the light was admitted into the room; to obviate both these objections, he admitted the light through a hole burnt in a piece of plateboard, and intercepted it with a razor which had a very sharp edge; but still the appearances were the same as before: so that, upon the whole, he concluded that they were occasioned by a new property of light, different from any that had been observed by preceding writers.

He farther diversified this experiment, by placing the razor so as to divide the cone of light into two parts, the hole in the shutter remaining as before, and placing the paper so as that none of the enlightened part of the circle fell upon it, but only the shadow of the razor; and, to his great surprise, he observed what he calls a very bright and visible radiation striking down upon the paper, of the same breadth with the diameter of the luminous circle, and this radiation always struck perpendicularly from the line of shadow, and, like the tail of a comet, extended more than 10 times, and probably more than 100 times the breadth of the remaining part of circle: nay, as far as he could find, by many trials, the light from the edge struck downwards into the shadow very near to a quadrant, though the greater were the deflections of this new light from the direct radiations of the cone, the more faint they were.

Observing this appearance with more attention, he found, wherever there was a part of the intercepted body higher than the rest, that, opposite to it, the radiation of light into the shadow was brighter, as in the figure; and wherever there was a notch or gap in it, there would be a dark stroke in the half-enlightened shadow. From all these appearances, he concluded, that they
were to be ascribed to a new property of light, whereby it is deflected from straight lines, contrary to what had been before ascertained by optical writers.

It does not appear, however, that our philosopher ever professed this experiment to any purpose; as all that we find of his on the subject of light, after this time, are some crude thoughts which he read at a meeting of the Royal Society, on the 18th of March 1675; which, however, as they are only short hints, we shall not consider here.

They consist of eight articles; and, as he thought, contained an account of several properties of light that had not been noticed before. There is a deflection of light, differing both from refraction and reflection, and seeming to depend on the unequal density of the constituent parts of the ray, whereby the light is deflected from the place of condensation, and rafied, or gradually defcredited into a quadrant. 2. This deflection is made towards the superfcies of the opaque body perpendicularly. 3. Those parts of the defcred radiations which are defcredited by the greatest angle from the straight or direct radiations are the fainteft, and those that are defcredited by the leafl angels are the fonkeft. 4. Rays cutting each other in one common foramen do not make the angles at the vertex equal. 5. Colours may be made without refraction. 6. The diameter of the fun cannot be truly taken with the naked eye. 7. The fame rays of light, falling upon the fame point of an opaque body, will turn into all sorts of colours, by the various inclinations of the object. 8. Colours begin to appear when two pulfes of light are blended fo well, and fo near together, that the fene takes them for one.

We fhall now proceed to the discoveries of Father Grimaldi. Having introduced a ray of light, through a very fmal hole, AB, fig. 8. into a darkened room, he obferved that the light was defcredited in the form of a cone, the bafe of which was CD; and that if any opaque body, FE, was placed in this cone of light, at a conliderable distance from the hole, and the shadow was received upon a piece of white paper, the boundaries of it were not conflined within GH, or the penumbra IL, occafioned by the light proceeding from different parts of the aperture, and of the dill of the fun, but extended to MN; at which he was very much surprifed, fuppecting, and finding by calculation, that it was conliderably broader than it could have been made by rays palling in right lines by the edges of the object.

But the moft remarkable circumstance in this appearance was, that upon the lucid part of the bafe, CM and ND, ftreaks of coloured light were plainly diftinguifhed, each being terminated by blue on the fide next to the shadow, and by red on the other; and though thefe coloured ftreaks depended, in some measure, on the fize of the aperture AB, because they could not be made to appear if it was large, yet he found that they were not limited either by it, or by the diameter of the fun’s dill.

He farther obferved, that fee coloured ftreaks were not all of the fame breadth, but grew narrower as they receded from the shadow, and were each of them broader the farther the shadow was received from the opaque body, and also the more obliquely the paper on which they were received was held with respect to it. He never obferved more than three of these ftreaks.

To give a clearer idea of thefe coloured ftreaks, he drew the representation of them, exhibited in fig. 9, in which NMO represents the breadth and moft luminous ftreak, next to the dark shadow X. In the space in which M is placed there was no deftruction of colour, but the space NN was blue, and the space OO, on the other fide of it, was red. The fcond ftreak, QPR, was narrower than the former; and of the three parts of which it confisted, the space P had no particular colour, but QQ was a faint blue, and RR a faint red. The third ftreak, TSV, was exactly similar to the two others, but narrower than either of them, and the colours ftil fainter.

These coloured ftreaks he obferved to lie parallel to the shadow of the opaque body; but when it was of an angular form they did not make the fame acute angles, but were bent into a curve, the outermost being rounder than thofe that were next the shadow, as is reprefented in fig. 10. If it was an inward angle, as DCH, the coloured ftreaks, parallel to each other of the two fides, crofled without obliterating one another; only the colours were thereby rendered either more intense or mixed.

The light that formed thefe coloured ftreaks, the reader will perceive, must have been bent from the body; but this attentive obferver has likewife given an account of other appearances, which must have been produced by the light bending towards the body. For within the shadow itself he sometimes perceived coloured ftreaks, fimilar to thofe abovementioned on the outfide of the shadow. Sometimes he faw more of them, and sometimes fewer; but for this purpofe a very frong light was re inflate, and the opaque body was obliged to be long, and of a moderate breadth; which, he fays, is eafily found by experience. A hair, for infance, or a fine needle, did not anfwer fo well as a thin and narrow plate; and the ftreaks were moft diftinguifhable when the shadow was taken at the greateft distance; but then the light grew fainter in the fame proportion.

The number of thefe ftreaks within the shadow was greater in proportion to the breadth of the plate. They were at leafl two, and sometimes four, if a thicker rod were made use of. But, with the fame plate or rod, more or fewer ftreaks appeared, in proportion to the distance at which the shadow was received; but they were broader when they were few, and narrower when there were more of them; and they were all much more defined when the paper was held obliquely.

These coloured ftreaks within the shadow, like thoee on the outfide of it, were bent in an arch, round the acute angles of the shadow, as they are reprefented in fig. 11. At this angle also, as at D, other shorter lucid ftreaks were visible, bent in the form of a plume, as they are drawn between D and C, each bending round and meeting again in D. These angular ftreaks appeared, though the plate or rod was not wholly immeled in the beam of light, but the angle of it only; and there were more or fewer in number in proportion to the breadth of the rod or plate. If the plate or
or rod was very thin, the coloured streaks within the shadow might be seen to bend round from the opposite sides, and meet one another, as at B. A only represents a section of the figure, and not a proper termination of the shadow, and the streaks within each side of it. The coloured streaks without the shadow, he also observes, bend round it in the same manner.

Our author acknowledges, that he omits several observations of less consequence, which cannot but occur to any person who shall make the experiment; and he says, that he was not able to give a perfectly clear idea of what he has attempted to describe, nor does he think it in the power of words to do it.

In order to obtain the more satisfactory proof that rays of light do not always proceed in straight lines, but really bend, in passing by the edges of bodies, he diversified the first of the abovementioned experiments in the following manner. He admitted a beam of light by a very small aperture, into a darkened room, as before; and, at a great distance from it, he fixed a plate EF, fig. 12, with a small aperture, GH, which admitted only a part of the beam of light, and found, that when the light transmitted through this plate was received at some distance upon a white paper, the base IK was considerably larger than it could possibly have been made by rays issuing in right lines through the two apertures, as the other straight lines drawn close to their edges plainly demonstrated.

That those who choose to repeat these experiments may not be disappointed in their expectations from them, our author gives the following more particular instructions. The fun's light must be very intense, and the apertures through which it is transmitted very narrow, particularly the first, CD, and the white paper, IK, on which it is received, must be at a considerable distance from the hole GH, otherwise it will not much exceed NO, which would be the breadth of the beam of light proceeding in straight lines. He generally made the aperture CD 1/2 or 1/3 part of an ancient Roman foot, and the second aperture, GH, 1/4 or 1/5; and the distances DG and GN were, at least, 14 such feet. The observation was made in the summer-time, when the atmosphere was free from all vapours, and about mid-day.

F. Grimaldi also made the same experiment that has been recited from Dr Hooke, in which two beams of light, entering a darkened room by two small apertures near to one another, projected cones of light, which, at a certain distance, in part coincided; and he particularly observed that the dark boundaries of each of them were visible within the lucid ground of the other.

To these discoveries of Grimaldi, we shall subjoin an additional observation of Dechales; who took notice, that if small scratches be made in any piece of polished metal, and it be exposed to the beams of the sun in a darkened room, it will reflect the rays streaked with colours in the direction of the scratches; as will appear if the reflected light be received upon a piece of white paper. That these colours are not produced by refraction, he says, is manifest; for that, if the scratches be made upon glass, the effect will be the same; and in this case, if the light had been refracted at the surface of the glass, it would have been transmitted through it. From these, and many other observations, he concludes that colour does not depend upon the refraction of light only, nor upon a variety of other circumstances, which he particularly enumerates, and the effects of which he discusses, but upon the intensity of the light only.

We shall here give an account of a phenomenon of vision observed by M. De la Hire, because the subject of this section, viz. the infection of light, seems to supply the true solution of it, though the author himself thought otherwise. It is observable, he says, that when we look at a candle, or any luminous body, with our eyes nearly shut, rays of light are extended from it, in several directions, to a considerable distance, like the tails of comets. This appearance exercised the sagacity of Descartes and Rohault, as well as of our author; but all three seem to have been mistaken with respect to it. Descartes ascribed this effect to certain wrinkles in the surface of the humours of the eye. Rohault says, that when the eye-lids are nearly closed, the edges of them act like convex lenses. But our author says, that the moisture on the surface of the eye, adhering partly to the eye itself, and partly to the edge of the eye-lid, makes a concave mirror, and so diffuses the rays at their entrance into the eye. But the true reason seems to be, that the light passing among the eye-lashes, in this situation of the eye, is reflected by its near approach to them, and therefore enters the eye in a great variety of directions. The two former of these opinions are particularly stated and objected to by our author.

The experiments of Father Grimaldi and Dr Hooke were not only repeated with the greatest care by Sir Isaac Newton, but carried much farther than they had thought of. So little use had been made of Grimaldi's observations, that all philosophers before Newton had ascribed the broad shadows, and even the fringes of light which he described, to the ordinary refraction of the air; but we shall see them placed in a very different point of view by our author.

He made in a piece of lead a small hole with a pin, the breadth of which was the 42nd part of an inch. Through this hole he let into his darkened chamber a beam of the sun's light; and found, that the shadows of hairs, and other slender substances placed in it, were considerably broader than they would have been if the rays of light had passed by those bodies in right lines. He therefore concluded, that they must have passed as they are represented in fig. 1, in which X represents a section of the hair, and AD, BE, &c. rays of light passing by at different distances, and then falling upon the wall GQ. Since, when the paper which receives the rays is at a great distance from the hair, the shadow is broad, it must follow, as he observes, that the hair acts upon the rays of light at some considerable distance from it, the action being strongest on those rays which are at the least distance, and growing weaker and weaker on those which are farther off, as is represented in this figure; and from hence it comes to pass that the shadow of the hair is much broader in proportion to the distance of the paper from the hair, when it is nearer than when it is at a great distance.

He found, that it was not material whether the hair was surrounded with air, or, with any other fluid;
shadows began to be invisible.

"the laid laying another polished plate of glass so that the water might fill up the space between the glasses, and holding them in the beam of light, he found the shadow at the same distances was as big as before. Also the shadows of scratches made in polished plates of glass, and the veins in the glass, cast the like broad shadows; so that this breadth of shadow must proceed from some other cause than the refraction of the air.

The shadows of all bodies, metals, stones, glass, wood, horn, ice, &c. in this light were bordered with three parallel fringes, or bands of coloured light, of which that which was contiguous to the shadow was the broadest and most luminous, while that which was the most remote was the narrowest, and so faint as not easily to be visible. It was difficult to distinguish these colours, unless when the light fell very obliquely upon a smooth paper, or some other smooth white body, so as to make them appear much broader than they would otherwise have done; but in these circumstances the colours were plainly visible, and in the following order. The first or innermost fringe was violet, and deep blue next the shadow, light blue, green, and yellow in the middle, and red without. The second fringe was almost contiguous to the first, and the third to the second; and both were blue within, and yellow and red without; but their colours were very faint, especially those of the third. The colours, therefore, proceeded in the following order from the shadow; violet, indigo, pale blue, green, yellow, red; blue, yellow, red; pale blue, pale yellow, and red. The shadows made by scratches and bubbles in polished plates of glass were bordered with the like fringes of coloured light.

He also observes, that by looking on the fun through a feather, or black ribbon, held close to the eye, several rainbows will appear, the shadows which the fibres or threads cast on the retina being bordered with the like fringes of colours.

Measuring these fringes and their intervals with the greatest accuracy, he found the former to be in the proportion of the numbers 1, √3, √3, and their intervals to be in the same proportion with them, that is, the fringes and their intervals together to be in continual proportion of the numbers 1, √3, √3, √3, √3, or thereabouts. And these proportions held the same nearly at all distances from the hair, the dark intervals of the fringes being as broad in proportion to the breadth of the fringes at their first appearance as afterwards, at great distances from the hair, though not so dark and defined.

In the next observation of our author, we find a very remarkable and curious appearance, which we should hardly have expected from the circumstances, though it is pretty similar to one that was noticed by Dr Ho ke. The fun shining into his darkened chamber, through a hole 3 of an inch broad, he placed, at the distance of two or three feet from the hole, a sheet of pasteboard, black on both sides; and in the middle of it he had made a hole about 1 of an inch square, through which the light passed through; and behind the hole he fastened to the pasteboard the blade of a sharp knife, to intercept some part of the light which passed through the hole. The planes of the pasteboard and blade of the knife were parallel to one another, and perpendicular to the rays; and when they were so placed that none of the light fell on the pasteboard, but all of it passed through the hole to the knife, and there part of it fell upon the blade of the knife, and part of it passed by its edge, he let that part of the light which passed by fall on a white paper, 2 or 3 feet beyond the knife, and there saw two streams of faint light shoot out both ways from the beam of light into the shadow, like the tails of comets. But because the fun's direct light, by its brightness upon the paper, obscured their faint streams, so that he could scarce see them, he made a little hole in the midst of the paper for that light to pass through and fall on a black cloth behind it; and then he saw the two streams plainly. They were like one another, and pretty nearly equal in length, breadth, and quantity of light. Their light, at that end which was next to the sun's direct light, was pretty strong for the space of about ½ of an inch, or 3 of an inch, and decreased gradually till it became insensible.

The whole length of either of these streams, measured upon the paper at the distances of 3 feet from the knife, was about 6 or 8 inches; so that it passed through an angle at the edge of the knife, of about 10 or 12, or at most 14, degrees. Yet sometimes he thought he saw it shoot 3 or 4 degrees farther; but with a light so very faint, that he could hardly perceive it. This light he suspected might, in part at least, arise from some other cause than the two streams. For, placing his eye in that light, beyond the end of that stream which was behind the knife, and looking towards the knife, he could see a line of light upon its edge; and that not only when his eye was in the line of the streams, but also when it was out of that line, either towards the point of the knife, or towards the handle. This line of light appeared contiguous to the edge of the knife, and was narrower than the light of the innermost fringe, and narrowest when his eye was farther from the direct light; and therefore seemed to pass between the light of that fringe and the edge of the knife: and that which passed near the edge seemed to be most bent, though not all of it.

He then placed another knife by the former, so that their edges might be parallel, and looked towards one another, and that the beam of light might fall upon both the knives, and some part of it pass between their edges. In this situation he observed, that when the distance of their edges was about the 40th part of an inch, the stream divided in the middle, and left a shadow between the two parts. This shadow was so black and dark, that all the light which passed between the knives seemed to be bent and turned aside to the one hand or the other; and as the knives still approached one another, the shadow grew broader and the streams thinner next to it, till, upon the contact of the knives, all light vanished.

From this experiment our author concludes, that the light which is least bent, and which goes to the inward ends of the streams, passes by the edges of the knives at the greatest distance; and this distance, when the shadow began to appear between the streams, was about the 80th part of an inch; and the light which passed by the edges of the knives at distances still less
and left, was more and more faint, and went to those parts of the streams which were farther from the direct light; because, when the knives approached one another till they touched, those parts of the streams vanished last which were farthest from the direct light.

In the experiment of one knife only, the coloured fringes did not appear; but, on account of the breadth of the hole in the window, became so broad as to run into one another, and, by joining, to make one continual light in the beginning of the streams; but in the last experiment, as the knives approached one another, a little before the shadow appeared between the two streams, the fringes began to appear on the inner ends of the streams, on either side of the direct light: three on one side, made by the edge of one knife, and three on the other side, made by the edge of the other knife. They were the most distinct when the knives were placed at the greatest distance from the hole in the window, and became still more distinct by making the hole less; so that he could sometimes see a faint trace of a fourth fringe beyond the third above-mentioned: and as the knives approached one another, the fringes grew more distinct and larger, till they vanished; the outermost vanishing first, and the innermost last. After they were all vanished, and the line of light which was in the middle between them was grown very broad, extending itself on both sides into the streams of light described before, the abovementioned shadow began to appear in the middle of this line, and to divide it along the middle into two lines of light, and increas’d till all the light vanished. This enlargement of the fringes was so great, that the rays which went to the innermost fringe seemed to be bent about 20 times more when the fringe was ready to vanish, than when one of the knives was taken away.

From both these experiments compared together, one may conclude, that the light of the first fringe passed by the edge of the knife at a distance greater than the 800th part of an inch; that the light of the second fringe passed by the edge of the knife, at a greater distance than the light of the first fringe, and that of the third at a greater distance than that of the second; and that the light of which the streams abovementioned consisted, passed by the edges of the knives at less distances than that of any of the fringes.

He then got the edges of two knives ground truly straight, and pricking their points into a board, so that their edges might look towards one another, and meeting near their points, contain a right line angle, he fastened their handles together, to make the angle invariable. The distance of the edges of the knives from one another, at the distance of 4 inches from the angular point, where the edges of the knives met, was the 8th part of an inch; so that the angle contained by their edges was about 1° 54'. The knives being thus fixed together, he placed them in a beam of the sun’s light let into his darkened chamber, through a hole the 42d part of an inch wide, at the distance of 10 or 13 feet from the hole; and he let the light which passed between their edges fall very obliquely on a smooth white ruler, at the distance of ½ inch, or an inch, from the knives; and there he saw the fringes made by the two edges of the knives run along the edges of the shadows of the knives, in lines parallel to those edges, without growing feebly broader, till they met in angles equal to the angle contained by the edges of the knives; and where they met and joined, they extended, without croffing one another. But if the ruler was held at a much greater distance from the knives, the fringes, where they were farther from the place of their meeting, were a little narrower, and they became something broader as they approached nearer to one another, and after they met they croffed one another, and then became much broader than before.

From these observations he concluded, that the distances at which the light composing the fringes passed by the knives were not increased or altered by the approach of the knives, but that the angles in which the falls were there bent were much increas’d by that approach; and that the knife which was nearest to any ray determined which way the ray should be bent, but that the other knife increas’d the bending.

When the rays fell very obliquely upon the ruler, at the distance of a third part of an inch from the knives, the dark line between the first and second fringe of the shadow of one knife, and the dark line between the first and second fringe of the shadow of the other knife, met one another, at the distance of the fifth part of an inch from the end of the light which passed between the knives, where their edges met one another; so that the distance of the edges of the knives, at the meeting of the dark lines, was the 160th part of an inch; and one half of that light passed by the edge of one knife, at a distance not greater than the 320th part of an inch, and, falling upon the paper, made the fringes of the shadow of that knife; while the other half passed by the edge of the other knife, at a distance not greater than the 340th part of an inch, and, falling upon the paper, made the fringes of the shadow of the other knife. But if the paper was held at a distance from the knives greater than the third part of an inch, the dark lines abovementioned met at a greater distance than the fifth part of an inch from the end of the light which passed between the knives, at the meeting of their edges; so that the light which fell upon the paper where those dark lines met passed between the knives, where their edges were farther distant than the 160th part of an inch. For at another time, when the two knives were 8 feet and 5 inches from the little hole in the window, the light which fell upon the paper where the abovementioned dark lines met passed between the knives, where the distance between their edges was, as in the following table, at the distances from the paper there noted.

From these observations he concluded, that the light...
O P T I C S.

That the light which makes the fringes upon the paper is not the fame light at all distances of the paper from the knives; but that, when the paper is held near the knives, the fringes are made by light which passes by the edges of the knives at a less distance, and is more bent than when the paper is held at a greater distance from the knives.

When the fringes of the shadows of the knives fell perpendicularly upon the paper, at a great distance from the knives, they were in the form of hyperbolas, their dimensions being as follows. Let CA, CB, represent lines drawn upon the paper, parallel to the edges of the knives; and between which all the light would fall if it suffered no inflection. DE is a right line drawn through C, making the angles ACD, BCE, equal to one another, and terminating all the light which falls upon the paper, from the point where the edges of the knives meet. Then e i s, f k t, and g l o, will be three hyperbolical lines, representing the boundaries of the shadow of one of the knives, the dark line between the first and second fringes of that shadow, and the dark line between the second and third fringes of the same shadow. Also s g, y k, and s t, will be three other hyperbolical lines, representing the boundaries of the shadow of the other knife, the dark line between the first and second fringes of that shadow, and the dark line between the second and third fringes of the same shadow. These three hyperbolas are similar, and equal to the former three, and cross them in the points i, k, and l; so that the shadows of the knives are terminated, and distinguished from the first luminous fringes, by the lines e i s and s g, till the meeting and crossing of the fringes; and then those lines cross the fringes in the form of dark lines terminating the first luminous fringes on the inside, and distinguishing them from another light, which begins to appear at i, and illuminates all the triangular space p DEs, comprehended by these dark lines and the right line DE. Of these hyperbolas one asymptote is the line DE, and the other asymptotes are parallel to the lines CA and CB.

The fun shining into his darkened room through the small hole mentioned above, he placed at the hole a prism to refract the light, and to form on the opposite wall the coloured image of the sun; and he found, that the shadows of all bodies held in the coloured light between the prism and the wall, were bordered with fringes of the colour of that light in which they were held; and comparing the fringes made in the several coloured lights, he found, that those made in the red light were the largest, those made in the violet were the least, and those made in the green were of a middle bigness. For the fringes with which the shadow of a man's hair were bordered, being measured across the shadow, at the distance of six inches from the hair, the distance between the middle and most luminous part of the first or innermost fringe on one side of the shadow, and that of the like fringe on the other side of the shadow, was, in the full red light \( \frac{1}{7} \) of an inch; and in the full violet \( \frac{1}{5} \). The like distance between the middle and most luminous parts of the second fringes, on either side of the shadow, was in the full red light \( \frac{1}{5} \) and the violet \( \frac{1}{4} \) of an inch; and these distances of the fringes held the same proportion at all distances from the hair, without any sensible variation.

From these observations it was evident, that the rays which made the fringes in the red light, passed by the hair at a greater distance than those which made the like fringes in the violet; so that the hair, in causing the fringes, acted alike upon the red light or least refrangible rays at a greater distance, and upon the violet or most refrangible rays at a less distance; and thereby occasioned fringes of different sizes, without any change in the colour of any part of light.

It may therefore be concluded, that when the hair in the first observation was held in the white beam of the sun's light, and cast a shadow which was bordered with three fringes of coloured light, those colours arose not from any new modifications impressed upon the rays of light by the hair, but only from the various inflections whereby the several sorts of rays were separated from one another, which before separation, by the mixture of all their colours, composed the white beam of the sun's light; but, when separated, composed lights of the several colours which they are originally disposed to exhibit.

The person whose name we find first upon the list of those who pursued any experiments similar to those discoveries of Newton on infected light is M. Miraldi; whose observations chiefly respected the infection of light towards other bodies, whereby their shadows are partially illuminated; and many of the circumstances which he noticed relating to it are well worthy of our attention, as the reader will be convinced from the following account of them.

He exposed in the light of the sun a cylinder of Experi­mented three feet long, and 6\(\frac{1}{2}\) lines in diameter; when means con­templating the shadows of cylinders.

As the cylinder was removed to a greater distance from the paper, the two black lines continued to be nearly of the same breadth, and the same degree of obscurity; but the penumbra in the middle grew lighter, and its breadth diminished, so that the two dark lines at the extremity of the shadow approached one another, till, at the distance of 60 inches, they coincided, and the penumbra in the middle entirely vanished. At a full greater distance a faint penumbra was visible; but it was ill defined, and grew broader as the cylinder was removed farther off, but was sensible at a very great distance.

Besides the black and dark shadow, which the cylin­der formed near the opaque body, a narrow and faint penumbra was seen on the outside of the dark shadow. And on the outside of this there was a track more strongly illuminated than the rest of the paper.
The breadth of the external penumbra increased with the distance of the shadow from the cylinder, and the breadth of the tract of light on the outside of it was also enlarged; but its splendor diminished with the distance.

He repeated these experiments with three other cylinders of different dimensions; and from them all he inferred, that every opaque cylindrical body, exposed to the light of the sun, makes a shadow which is black and dark to the distance of 30 to 45 diameters of the cylinder, which forms it; and that, at a greater distance, the middle part begins to be illuminated in the manner described above.

In explaining these appearances, our author supposes that the light which diluted the middle part of the shadow was occasioned by the inflection of the rays, which, bending inward on their near approach to the body, did at a certain distance enlighten all the shadow, except the edges, which was left undisturbed. At the same time other rays were deflected from the body, and formed a strong light on the outside of the shadow, and which might at the same time contribute to dilute the outer shadow, though he supposed that penumbra to be occasioned principally by that part of the sun's disk only, according to the known principles of optics.

The same experiments he made with globes of several diameters; but, he found, that, whereas the shadows of the cylinders did not disappear but at the distance of 45 of their diameters, those of the globes were not visible beyond 15 of their diameters; which he thought was owing to the light being inflected on every side of a globe, and consequently in such a quantity as to diffuse the shadows sooner than in the case of the cylinders.

In all these cases, the penumbra occasioned by the inflected light began to be visible at a less distance from the body in the stronger light of the sun than in a weaker, on account of the greater quantity of rays inflected in those circumstances.

Considering the analogy between these experiments and the phenomena of an eclipse of the moon, immersed in the shadow of the earth, he imagined, that part of the light by which the sun is then visible is inflected light, and not that which is reflected by the atmosphere; though this may be so copious as to efface several of the abovementioned appearances, occasioned by reflected light only. But this gentleman should have considered, that as no light is inflected but what passes exceedingly near to any body, perhaps so near as the distance of 15 parts of an inch, that cause must be altogether inadequate to the effect.

Being sensible that the abovementioned phenomena of the shadows were caused by inflected light, he was induced to give more particular attention to this remarkable property; and, in order to it, to repeat the experiments of Grimaldi and Sir Isaac Newton in a darkened room. In doing this, he presently observed, that, besides the enlarged shadow of a hair, a fine needle, &c., the bright gleam of light that bordered it, and the three coloured rings next to this enlightened part, when the shadow was at a considerable distance from the hair, the dark central shadow was divided in the middle by a mixture of light; and that it was not of the same density, except when it was very near the hair.

This new appearance will be seen to be exactly similar to what our philosopher had observed with respect to the shadows in the open daylight observations; but the following observations, which he made with some variation of his apparatus, are much more curious and striking, though they arise from the same cause.

Having placed a bristle, which is thicker than a common hair, in the rays of the sun, admitted into a dark chamber by a small hole, at the distance of nine feet from the hole, it made a shadow, which, being received at five or six feet from the object, he observed to consist of several streaks of light and shade. The middle part was a light shadow, or rather a kind of penumbra, bordered by a darker shadow, and after that by a narrower penumbra; next to which was a light streak broader than the dark part, and next to the streak of light, the red, violet, and blue colours were seen as in the shadow of the hair.

In the same manner he placed, in the same rays of the sun, several needles of different sizes; but the appearances were so exceedingly various, that he supposed that he does not receive them particularly, but chooses rather to give, at some length, the observations he made on the shadows of two plates, as by that means he could better explain the phenomena of the round bodies.

He exposed in the rays of the sun, admitted by a small hole into a dark chamber, a plate that was two inches long, and a little more than half a line broad, containing the plate being fixed perpendicularly to the rays, at the distance of nine feet from the hole, a thin light plate, was seen uniformly dispersed over the shadow, when it was received perpendicularly to it, and very near. The shadow of the same plate being received at the distance of two feet and a half, it was divided into four very narrow black streaks, separated by small lighter intervals equal to them. The boundaries of this shadow on each side had a penumbra, which was terminated by a very strong light, next to which were the coloured streaks of red, violet, and blue, as before. This is represented in Plate CCCLIII. fig. 4.

The shadow of the same plate, at 4½ feet distance from it, was divided into two black streaks only, the two outermost having disappeared, as in fig. 5; but these two black streaks which remained were broader than before, and separated by a lighter shade, twice as broad as one of the former black streaks, when the shadow was taken at 2 ½ feet. This penumbra in the middle had a tinge of red. After the two black streaks there appeared a pretty strong penumbra, terminated by the two streaks of light, which were now broad and splendid, after which followed the coloured streaks.

A second plate, two inches long and a line broad, being placed like the former, 14 feet from the hole by which the rays of the sun were admitted, its shadow being received perpendicularly very near the plate, was illuminated by a faint light, equally dispersed, as in the case of the preceding plate. But being received at the distance of 13 feet from the plate, six small black streaks...
Firebreaks began to be visible, as in fig. 6. At 17 feet from the plate, the black firebreaks were broader, more distint, and more separated from the firebreaks that were less dark. At 42 feet from the plate, only two black firebreaks were seen in the middle of the penumbra, as in fig. 7. This middle penumbra between the two black firebreaks was tinged with red. Next to these firebreaks there always appeared the firebreaks of light, which were broad, and the coloured firebreaks next to them.

Receiving the shadow of the same plate at the distance of 72 feet, the appearances were the same as in the former situation, except that the two black firebreaks were broader, and the interval between them, occupied by the penumbra, was broader also, and tinged with a deeper red.

In the same rays of the sun he placed different plates, and larger than the former, one of them a line and a half, another two lines, another three lines broad, &c. but receiving their shadows upon paper, he could not perceive in them those firebreaks of faint light which he had observed in the shadows of the small plates, though he received these shadows at the distance of 36 feet. Nothing was seen but a weak light, equally diffused, as in the shadows of the two smallest plates, received very near them. But had his dark chamber been large enough, he did not doubt, but that, at a proper distance, there would have been the same appearances in the shadows of the larger plates as in those of the smallest. For the same reason, he supposed, that, if the shadows of the small needles could have been distinctly viewed very near those bodies, the different firebreaks of light and shade would have been as visible in them as in those of the small plates; and indeed he did observe the same appearances in the shadows of needles of a middling size.

The firebreaks of light in these shadows our author ascribed to the rays of light which are inflected at different distances from the bodies; and he imagined that their crossing one another was sufficient to account for the variations observable in them at different distances.

The extraordinary size of the shadows of these small substances M. Maraldi thought to be occasioned by the shadow from the enlightened part of the sky, added to that which was made by the light of the sun, and also to a vortex occasioned by the circulation of the inflected light behind the object; but our readers will probably not think it necessary for us either to produce all his reasons for this hypothesis, or to enter into a refutation of them.

Our author having made the preceding experiments upon single long substances, had the curiosity to place two of them so as to cross one another in a beam of the sun's light. The shadows of two hairs placed in this manner, and received at some distance from them, appeared to be painted reciprocally one upon the other, so that the obscure part of one of them was visible upon the obscure part of the other. The firebreaks of light also crossed one another, and the coloured firebreaks did the same.

Having placed a needle and a hair crossing one another, their shadows, at the same distance, exhibited the same appearances as the shadows of the two hairs, though the shadow of the needle was the stronger.

He also placed in the rays of the sun a bristle and a plate of iron a line thick, so that they crossed one another obliquely; and when their shadows were received at the same distance, the light and dark firebreaks of the shadow of the bristle were visible so far as the middle of the shadow of the plate, on the side of the acute angle, but not on the side of the obtuse angle, whither the bristle or the plate were placed next to the rays. The plate made a shadow sufficiently dark, divided into six black firebreaks; and these were again divided by as many light ones equal to them; and yet all the firebreaks belonging to the shadow of the bristle were visible upon it, as in fig. 8. To explain this appearance, he supposed that the rays of the sun glided a little along the bristle, so as to enlighten part of that which was behind the plate. But this seems to be an arbitrary and improbable supposition.

Our philosopher did not fail to expose several small globes in the light of the sun in his dark chamber, and to compare their shadows with those of the long substances, as he had done in the day-light, and the appearances were still similar. It was particularly evident, that there was much more light in the shadows of the globes than in those of the cylinders, not only when they were both of an equal diameter, but when that of the globe was larger than that of the cylinder, and the shadows of both the bodies were received at the same distance. He also observed, that he could perceive no difference of light in the shadows of the plates which were a little more than one line broad, though they were received at the distance of 72 feet; but he could easily see a difference of shades in those of the globes, taken at the same distance, tho' they were 24 lines in diameter.

In order to explain the colours at the edges of these shadows, he contrived to throw some of the shadows upon others; and the following observations, though they did not enable him to accomplish what he intended, are curious and worth reciting.

Having thrown several of the similar colours upon Experience one another, and thereby produced a tinge more lively than before, he threw the gleam of light, which always intervened between the colours and the darker part of the shadow, upon different parts of other shadows; and observed, that, when it fell upon the exterior penumbra made by another needle, it produced a beautiful sky-blue colour, almost like that which was produced by two blue colours thrown together. When the same gleam of light fell upon the deeper shadow in the middle, it produced a red colour; which seemed to prove, that the reddish colour in the middle of several of the shadows might come from the little light inflected into that place. But here our author seems to have been misled by some false hypothesis concerning colours.

He placed two plates of iron, each three or four lines broad, very near one another, but with a very small interval between them; and having placed them in the rays of the sun, and received their shadows at the distance of 15 or 20 feet from them, he saw no light between them but a continued shadow, in the middle.
History.

OPTICS.

Middle of which were some frizzles of a lively purple, parallel to one another, and separated by other black frizzles; but between them there were other frizzles, both of a very faint green, and also of a pale yellow. He also informs us, that M. D'Adre had observed colours in the frizzles of light and shade, which are observable in shadows taken near the bodies.

Among those who followed Sir Isaac Newton in his observations on the reflection of light, we also find the ingenious M. Murin; but without attempting the discovery of new facts, he only endeavoured to explain the old ones, by the hypothesis of an atmosphere surrounding all bodies; and consequently making two reflections and refractions of the light that impinges upon them, one at the surface of the atmosphere, and the other at that of the body itself. This atmosphere he supposed to be of a variable density and refractive power, like the air.

M. Murin was succeeded by M. du Tour, who thought the variable atmosphere superfusious, and imagined that he could account for all the phenomena by the help of an atmosphere of an uniform density, and of a less refractive power than the air surrounding all bodies. But what we are most obliged to this gentleman for, is, not his ingenious hypothesis, but the beautiful variety with which he has exhibited the experiments, which will render it much easier for any person to investigate the true cause of them.

Before M. du Tour gave his attention to this subject, only three frizzles had been observed in the colours produced by the reflection of light; but he was accidentally led to observe a greater number of them, and adopted from Grimaldi the following ingenious method of making them all appear very distinct.

He took a circular board ABEF (Fig. 9.), 13 inches in diameter, the surface of which was black, except at the edge, where there was a ring of white paper about three lines broad, in order to trace the circumference of a circle, divided into 360 degrees, beginning at the point A, and reckoning 180 degrees on each hand to the point E; B and D being each of them placed at 90 degrees. A flip of parchment three inches broad, and disposed in the form of a hoop, was fastened round the board, and pierced at the point E with a square hole, each side being four or five lines, in order to introduce a ray of the sun's light. Lastly, to the centre of the board C, and perpendicular to it, he fixed a pin about $\frac{1}{2}$ of a line in diameter.

This hoop being so disposed, that a ray of light entering the dark chamber, through a vertical cleft of two lines and a half in length, and about as wide as the diameter of the pin, went through the hole at E, and passing parallel to the plane of the board, projected the image of the sun and the shadow of the pin at A.

In these circumstances he observed,

1. That quite round the concave surface of this hoop there were a multitude of coloured frizzles; but that the space $\frac{1}{2}$ the 18 degrees, the middle of which was occupied by the image of the sun, was covered with a faint light only.

2. The order of the colours in these frizzles was generally such that the most refrangible rays were the nearest to the incident ray $ECA$; so that, beginning from the point A, the violet was the first and the red the last colour in each of the frizzles. In some of them, however, the colours were disposed in a contrary order.

3. The image of the sun, projected on each side of the point A, was divided by the shadow of the pin, which was bordered by two luminous frizzles.

4. The coloured frizzles were narrower in some parts of the hoop than others, and generally decreased in breadth in receding from the point A.

5. Among these coloured frizzles, there were sometimes others which were white, a line or a line and a half in breadth, which were always bordered on both sides by a frizzle of orange colour, at least when the light of the sun was intense, and the chamber sufficiently dark.

From this experiment he thought it was evident, that the rays which passed beyond the pin were not the only ones that were decomposed, for those which were reflected back from the pin were decomposed also; from which he concluded, that they must have undergone some refraction. He also thought that those which went beyond the pin suffered a reflection, so that they were all affected in a similar manner.

In order to account for these facts, our author describes the progress of a ray of light through an uniform atmosphere, which he supposes to surround the pin; and shows, that the differently refrangible rays will be separated at their emergence from it; but he refers to some experiments and observations in a future memoir, to demonstrate that all the coloured frizzles are produced by rays that are both refracted and reflected.

To give some idea of his hypothesis, he shows that Account of the ray $a$, fig. 10, after being refracted at $t$, refracted at $t$, $s$, $r$ and $x$, and again refracted at $s$ and $t$, will be divided into its proper colours; the least refrangible or the red rays passing at $s$, and the most refrangible or violet at $t$; which agrees with his observations. Those frizzles in which the colours appear in a contrary order he thinks are to be ascribed to inequalities in the surface of the pin. This might easily have been ascertained by turning the pin round; in which case these differently-coloured frizzles would have changed their places.

If any person should choose to repeat these experiments, he observes that it requires that the sky be very clear and free from vapours, in order to exhibit the colours with the greatest distinctness; since even the vapours that are imperceptible will diminish the lustre of the colours on every part of the hoop, and even efface some of them, especially those which are on that part in which the beam of light enters, as at E, fig. 9, where the colours are always fainter than in any other place, and indeed can never be distinguished except when the hole E is confined by black sublimates, so as to intercept a part of the light that might reach the pin; and unlefs also those rays which go beyond the pin to form the image of the sun at A be stopped, so that no rays are visible except those that are reflected towards the hole, and which make the faint frizzles.

The coloured frizzles that are next the shadow of the pin, he shows, are formed by those rays which, entering the atmosphere, do not fall upon the pin; and, without any reflection, are only refracted at their entering;
OPTICS.

We may here make a general observation, applicable to all the attempts of philosophers to explain the phenomena by atmospheres. These attempts give no explanation whatever of what is attempted, i.e., the physical cause of the phenomena. A phenomenon is some individual fact or event in nature. We are said to explain it when we point out the general fact in which it is comprehended, and show the manner in which it is so comprehended, or the particular modification of the general fact. Philosophy resembles natural history, having for its subject the event's nature; and its investigations are nothing but the classification of these events, or the arrangement of them under the general facts of which they are individual instances. In the present instance there is no general fact referred to. The atmosphere is a mere gratuitous supposition; and all that is done is to show a resemblance between the phenomena of inflection of light to what would be the phenomena were bodies surrounded with such atmospheres; and even in this point of view, the discussions of Maïran and Du Tour are extremely deficient. They have been satisfied with very vague resemblances to a fact observed in one single instance, and not sufficiently examined or described in that instance, namely, the refraction of light through the atmosphere of this globe.

The attempt is to explain how light is turned out of its direction by passing near the surface of bodies. This indicates the action of forces in a direction transverse to that of the light. Newton took the right road of investigation, by taking the phenomenon in its original simplicity, and attending merely to this, that the rays are deflected from their former course; and the sole aim of his investigation was to discover the laws, i.e., the more general facts in this deflection.

He deduced from the phenomena, that some rays are more deflected than others, and endeavoured to determine in what rays the deflections are most remarkable; and no experiment of M. Du Tour has shown that he was mistaken in his modified assertion, that those rays are most inflected which pass nearest to the body. We lay modified assertion; for Newton points out with great sagacity many instances of alternate fits of refraction and deflection; and takes it for granted, that the law of continuity is observed in these phenomena, and that the change of inflection into deflection is gradual.

But these analytical discussions are eminently deficient in another respect: They are (prima facie) held out as mechanical explanations of the changes of motion observed in rays of light. When shall be shown, that these are precisely such as are observed in refracting atmospheres, nothing is done towards deciding the original question; for the action of refracting atmospheres presents it in all its difficulties, and we must still ask how do these atmospheres produce this effect? No advance whatever is gained in science by thrashing in this hypothetical atmosphere; and Newton did wisely in attaching himself to the simple fact: and he thus gives us another step in science, by showing us a refraction, fact unknown before, viz., that the action of bodies and inflection on light is not confined to transparent bodies. He added another general fact to our former flock, that light as well as other matter is acted on at a distance; and thus he made a very important deduction, that refraction is.
When therefore the glass ball mentioned above puts the other in motion by striking it, we are intitled to say, that unless the pressure during the stroke has been equal to 800 pounds for every square inch of contact, the motion has been produced without contact or real impulse, by the action of repulsive forces exerted between the balls, in the same manner as would happen between two magnets floating on cork with their north poles fronting each other; in which case (if the motion has been sufficiently slow) the striking magnet will be brought to rest, and the other move off, with its original velocity, in the same manner as happens to the glass balls. Many such communications of motion happen, where we cannot say that the impulse produced without real impulse, by repulsive forces acting at a distance. This evidently diminishes to a great degree the familiarity of the fact of impulse.

But we conclude too hastily, from the phenomena of the object glases, that a pressure exceeding 800 pounds on the square inch will produce contact.

Blow a soaps bubble, and let it fall on a piece of cloth, and cover it with a glass bell; after some time you will observe rings of colours upon its upper part, which will increase in number and breadth, and be in every respect similar to those between the object-glasses. These arise from the gradual thinning on the upper part of the soap bubble; a certain thickness of this, as well as of the interval between the glases, invariably reflecting a certain colour. At last a black spot appears a-top, which is sharply defined, and increases in diameter. Soon after this the bubble bursts. Thus then there is a certain thickness necessary for enabling the plate of soap to reflect light so as to be very sensible. Analogy obliges us to extend this to the object-glasses, and to say, not that the glases touch each other through the extent of the black spot, but that their distance is too small for the sensible reflection of light; and it remains undecided whether any pressure, however great, can annihilate all distance between them. So far, therefore, from impulse being a familiar fact, and its supposed laws being proper and it is doubtless the result of reasoning and explanation, it appears extremely doubtful whether the fact has ever been observed; and it must therefore be against the rules of logic to adduce the laws of impulse for the explanation of any insensible phenomenon.

Latter and other fluid atmospheres have often been referred to by philosophers puzzle for an explanation; and all this trouble has been taken to avoid the supposed difficulty of bodies acting at a distance. We now see that this is only putting the difficulty a step farther off. We may here add, that in all these attempts the very thing is supposed, which the philosophers wish to avoid. These authors have been fitted for their tasks by supposing them of variable densities. It is quite easy to show, that such a variation in density cannot be conceived without supposing the particles not in contact with them, and to a distance as great as that to which the change of the phenomenon extends. The very simple form of an elastic fluid supposes this, either with respect to its own particles, or with respect to the particles of a fluid more subtle.
subtle fluid, from the interpenetration of which it derives its efficacy. To get rid of one action at a distance, therefore, we introduce millions. Instead, therefore, of naturalists pluming themselves on such explanations, and having recourse, in all their difficulties, to the other of Sir Isaac Newton, which they make a drudge, a Mungo here, Mungo there, Mungo every where; let us rather wonder how that great man, not more eminent for penetration and invention than for accuracy of conception and justness of reasoning, should so far forget himself, and deviate, from that path of logical investigation in which he had most successfully advanced, and should, in his fabrication of other, and application of it to explain the more abstruse phenomena of nature, at once transgress all the rules of philosophizing which he had prescribed to himself and others. Let this flip, this mark of frail mortality, put us on our guard, lest we also be seduced by the specious offers of explanation which that vision, he found, that every time the wire was passed before his pupil, the fleas seemed to change its place, and some hills beyond the fleas seemed to have the same motion, just as if a lens had been drawn between his eye and them.

Examining this appearance more attentively, he found that there was a portion of the wire, but very difficult to keep, in which the fleas seemed not to have any motion, when the wire was passed before his eye; and in this case the fleas appeared less distinctly, and seemed to be magnified. These effects being similar to those of a lens, he attended to them more particularly; and placed his eye in such a manner with respect to the fleas, that the rays of light by which he saw it must come very close to the edge of a window, where he had placed himself to make his observations. Then pulling the wire once more before his eye, he observed, that, when it was in the visual axis, the fleas appeared nearer to the window, on whichever side the wire was made to approach. He repeated this experiment, and consistently with the same result, the object being always magnified, and nearly doubled, by this means.

This phenomenon is easily explained by fig. 14, in which A represents the eye, B the fleas, and C the diameter of the wire. The black lines express the cone of light by which the natural image of the fleas A is formed, and which is much narrower than the diameter of the wire C; but the dotted lines include not only that cone of light, but the rest of the wire in its course by the wire, but also more distant rays inflected by the wire, and thereby thrown more converging into the pupil; just as would have been the effect of the interposition of a lens between the eye and the object. The result of this experiment was the same, whatever substances he made use of in the place of the wire provided they were of the same diameter.

Maurolycus was the first who showed the true theory of vision, by demonstrating that the crystalline humour of the eye is a lens which collects the light diffusing from external objects, and throws them upon the retina, where is the focus of each pencil. He did not however, find out, that by means of this reflection of the rays, an image of every visible object is formed upon the retina, though this seems hardly to have been a step beyond the discovery he had already made. Maurolycus indeed conjectures, that he was prevented from mentioning this part of the discovery by the difficulty of accounting for the upright appearance of objects, as the image on the retina is always inverted. This discovery was made by Kepler; but he, too, was much confused with the inverted position of the image. The rectification of these images, he says, is the business of the mind; which, when it perceives an impression on the lower part of the retina, considers it as made by rays proceeding from the higher parts of objects; tracing the rays back to the pupil, where they cross one another. But this hypothesis can scarcely be deemed satisfactory.—Kepler did not pretend to account for the manner in which the mind perceives the images upon the retina, and very much blames Vitello for attempting prematurely to determine a question of this nature, and which indeed, he says, does not belong to optics. He accounts, however, though not in a satisfactory manner, for the power of seeing distinctly at different distances.

The discovery concerning vision was completed by Scheiner. For, in cutting away the coats of the back of the eye, he found that there was a portion of the wire, but very difficult to keep, in which the fleas seemed not to have any motion, when the wire was passed before his eye; and in this case the fleas appeared less distinctly, and seemed to be magnified. These effects being similar to those of a lens, he attended to them more particularly; and placed his eye in such a manner with respect to the fleas, that the rays of light by which he saw it must come very close to the edge of a window, where he had placed himself to make his observations. Then pulling the wire once more before his eye, he observed, that, when it was in the visual axis, the fleas appeared nearer to the window, on whichever side the wire was made to approach. He repeated this experiment, and consistently with the same result, the object being always magnified, and nearly doubled, by this means.

This phenomenon is easily explained by fig. 14, in which B represents the eye, A the fleas, and C the diameter of the wire. The black lines express the cone of light by which the natural image of the fleas A is formed, and which is much narrower than the diameter of the wire C; but the dotted lines include not only that cone of light, but the rest of the wire in its course by the wire, but also more distant rays inflected by the wire, and thereby thrown more converging into the pupil; just as would have been the effect of the interposition of a lens between the eye and the object. The result of this experiment was the same, whatever substances he made use of in the place of the wire provided they were of the same diameter.
OPTICS.

Descartes makes a good number of observations on the phenomena of vision. He explains satisfactorily the natural methods of judging of the magnitudes, situations, and distances, of objects by the direction of the optic axes: comparing it to a blind man's judging of the size and distance of an object, by feeling at it with two ficks of a known length, when the hands in which he holds them are at a known distance from each other. He also observes, that having been accustomed to judge of the situation of objects by their images falling on a particular part of the eye; if by any distortion of the eye they fall on a different place we are apt to mistake their situation or imagine one object to be two; as, till we become accustomed to it, we imagine one stick to be two, when it is placed between two contiguous fingers laid across one another. But he observes, that all the methods we have of judging of the distances of objects are very uncertain, and extend but to narrow limits. The direction of the optic axes, he says, will not serve us beyond 15 or 20 feet, and the change of form of the crystalline not more than three or four feet. For he imagined that the eye conforms itself to the view of near or distant objects by a change in the curvature of the crystalline, which he supposed to be a muscle, the tendons of it being the processus ciliares. In another place, he says, that the change in the conformation of the eye is of no use to us for the purpose of judging of distances beyond four or five feet, and the angle of the optic axes not more than 100 or 200 feet: for this reason he says, that the fun and moon are conceived to be much more nearly of the same size than they are in reality. White and luminous objects, he says, appear larger than others, and also the parts contiguous to those on which the rays actually impinge; and for the same reason, if the objects be small and placed at a great distance, they will always appear round, the figure of the angles disappearing.

The celebrated Berkeley bishop of Clonnie published, in 1709, An Essay towards a new Theory of Vision, which contains the solution of many difficulties. He does not admit that it is by means of those lines and angles, which are extremely useful in explaining the theory of optics, that different distances are judged of by the sense of sight: neither does he think that the mere direction of the optic axes, or the greater or lesser divergency of the rays of light, are sufficient, for this purpose. "I appeal (says he) to any one's experience, whether, upon sight of an object, he compute its divergency by the bigness of the angle made by the meeting of the two optic axes? or whether he ever thinks of the greater or lesser divergency of the rays which arrive from any point to his pupil? Nay, whether it be not perfectly impossible for him to perceive, by sense, the various angles wherein the rays according to their greater or lesser divergency fall upon his eye?" That there is a necessary connection between these various angles, &c. and different degrees of distance, and that this connection is known to every person skillful in optics, he readily acknowledges; but "in vain (says he) shall all the mathematicians in the world tell me that I perceive certain lines and angles, which introduce into my mind the various notions of distance so long as I am myself conscious of no such thing." Distance, magnitude, and even figure, he maintains to be the objects of immediate perception only by the sense of touch; and that when we judge of them by sight, it is from different sensations felt in the eye which experience has taught us to be the consequence of viewing objects of greater or less magnitude, of different figures, and at different distances. Those various sensations, with the respective distances, figures, and magnitudes by which they are occasioned, become so closely associated in the mind long before the period of distinct recollection, that the presence of the one instantly suggests the other; and we attribute to the sense of sight those notions which are acquired by the sense of touch, and of which certain usual sensations are merely the signs or symbols, just as words are the symbols of ideas. Upon these principles he accounts, in a manner worthy of the reader's attention, for single vision by both eyes, and for our perceiving objects erect by inverted images of them on the retina tunica. Subsequent writers have made great discoveries in the theory of vision; and among them there is hardly any one to whom this branch of science is so much indebted as to Dr Reid. Their reasonings, however, our limits will not permit us to detail, nor do they properly belong to this part of the article; they are connected with the description of the eye itself, the various modes of vision, and optical deceptions to which we are liable; and these will be considered in a succeeding part of this treatise.

§ 6. Of Optical Instruments, and Discoveries concerning them.

So little were the ancients acquainted with the invention of Spectacles, that they seem to have had no instrument of the optical kind, excepting the glass globes and spectacles formerly mentioned, which they used in some cases for magnifying and burning. Alhazen, as we have seen, gave the first hint of the invention of spectacles, and it is probable that they were found out soon after his time. From the writings of Alhazen, together with the observations and experiments of Roger Bacon, it is not improbable that some monks gradually hit upon the construction of spectacles; to which Bacon's lefser segment, notwithstanding his mistake concerning it, was a nearer approach than Alhazen's larger one. Whoever they were that pursued the discoveries of Bacon, they probably observed, that a very small convex glass, when held at a greater distance from the book, would magnify the letters more than when it was placed close to them, in which position only Bacon seems to have used it. In the next place, they might try whether two of these small segments of a sphere placed together, or a glass convex on both sides, would not magnify more than one of them. They would then find, that two of these glasses, one for each eye, would answer the purpose of reading better than one; and lastly, they might find, that different degrees of convexity suited different persons.

It is certain that spectacles were well known in the 13th century, and not long before. It is said that
Alexander Spina, a native of Pisa, who died in 1311, and who was very ingenious in executing whatever he saw or heard of as having been done by others, happened to see a pair of spectacles in the hands of a person who would not explain them to him; but that he succeeded in making a pair for himself, and immediately made the construction public, for the good of others. It is also inscribed on the tomb of Salvinus Armatus, a nobleman of Florence, who died 1317, that he was the inventor of spectacles.

The use of concave glasses, to help those persons who are short sighted, was probably a discovery that followed not long after that of convex ones, for the relief of those whose sight is defective in the contrary extreme, though we find no trace of this improvement. Whoever made this discovery, it was probably the result of nothing more than a random experiment. Perhaps a person who was short sighted, finding that convex glasses did him more harm than good, had the curiosity to make trial of a contrary curvature of the glass.

From this time, though both convex and concave lenses were sufficiently common, yet no attempt was made to form a telescope by a combination of them, till the end of the 16th century. Descartes considers James Metius, a person who was no mathematician, though his father and brother had applied to those sciences, as the first constructor of a telescope; and says, that as he was amusing himself with making mirrors and burning-glasses, he causally thought of looking through two of his lenses at a time; and that happening to take one that was convex and another that was concave, and happening also to hit upon a pretty good adjustment of them, he found, that, by looking through them, distant objects appeared very large and distinct. In fact, without knowing it, he had made a telescope.

Other persons say, that this great discovery was first made by John Lipperheim, a maker of spectacles at Middelburgh, or rather by his children; who, like Metius, were diverting themselves with looking through two glasses at a time, and placing them at different distances from one another. But Borellus, the author of a book intitled, De vero telescopii inventore, gives this honour to Zacharias Joannis, i.e. Janen, another maker of spectacles, at the same place, who made the first telescope in 1590; and it seems now to be the general opinion, that this account of Borellus is the most probable.

Indeed, Borellus's account of the discovery of telescopes is so circumstantial, and so well authenticated, that it does not seem possible to call it in question. It is not true, he says, that this great discovery was made by a person who was no philosopher; for Zacharias Jansen was a diligent inquirer into nature; and being engaged in these pursuits, he was trying what uses could be made of lenses for that purpose, when he fortunately hit upon the construction.

This ingenious mechanic, or rather philosopher, had no sooner found the arrangement of glasses that produced the effect he desired, than he included them in a tube, and ran with his instrument to prince Maurice; who, immediately conceiving that it might be of use to him in his wars, desired the author to keep it a secret. But this, though attempted for some time, was found to be impossible; and several persons in that city immediately applied themselves to the making and selling of telescopes. One of the most distinguished of these was Hans Laprey, called Lipperhein by Sirrus. By him some person in Holland being very early supplied with a telescope, he passed with many for the inventor; but both Metius above-mentioned, and Cornelius Drebbel of Alemain, in Holland, applied to the inventor himself in 1620; as also did the first Galileo, and many others. The first telescope made by Janen did not exceed 15 or 16 inches in length; but Sirrus, who says that he had seen it, and made use of it, thought it the best that he had ever examined.

Jansen, having a philosophical turn, particularly applied his instruments to such purposes as he had in view when he hit upon the construction. Directing it towards celestial objects, he distinctly viewed the spots on the surface of the moon; and discovered many new stars, particularly seven pretty confiderable ones in the Great Bear. His son Joannes Zacharias, noted the lunar circle near the limb of the moon, from whence several bright rays seem to dart in different directions; and he says, that the full moon, viewed through this instrument, did not appear flat, but was evidently spherical, the middle part being prominent. Jupiter also, he says, appeared round, and rather spherical; and sometimes he perceived two, sometimes three, and at the most four small stars, a little above or below him; and, as far as he could observe, they performed revolutions round him; but this, he says, he leaves to the consideration of astronomers. This, it is probable, was the first observation of the satellites of Jupiter, though the person who made it was not aware of the importance of his discovery.

The Francisc Fontana, an Italian, also claims the invention; but as he did not pretend to have made it before the year 1608, and as it is well known that the instruments were made and sold in Holland some time before, his pretensions to a second discovery are not much regarded.

There are some who say that Galileo, the inventor of telescopes; but he himself acknowledges, that he first heard of the instrument from a German; but he says, that being informed of nothing more than the effects of it, first by common report, and a few days after by a French nobleman, J. Badovere, at Paris, he himself discovered the construction, by confidering the nature of refraction: and thus he had much more real merit than the inventor himself.

The account of what Galileo actually did in this business is so circumstantially related by the author of his life, prefixed to the quarto edition of his works, printed at Venice in 1744, and it contains so many particulars, which cannot but be pleasing to every person who is interested in the history of telescopes, that we shall abridge a part of it, intermixing circumstances collected from other accounts.

About April or May, in 1609, it was reported at Venice, where Galileo (who was professor of mathemat-ics in the university of Padua; then happened to visitit), be, that a Dutchman had pretended to Count Maurice of Nassau, a certain optical instrument, by means of which, distant objects appeared as if they were near; but no further account of the discovery had reached
that place, though this was near 20 years after the first discovery. Struck, however, with this account, Galileo instantly returned to Padua, considering what kind of an instrument this must be. The night following, the construction occurred to him; and the day after, putting the parts of the instrument together, as he had previously conceived of it, and notwithstanding the imperfection of the glasse that he could then procure, the effect answered his expectations, as he presently acquainted his friends at Venice to which place he fix days afterwards carried another and a better instrument that he made, and where, from several eminences, he showed to some of the principal senators of that republic a variety of distant objects, to their very great astonishment. When he had made farther improvements in the instrument, he with his usual generosity and frankness in communicating his discoveries, made a present of one of them to the Doge, Leonardo Donati, and at the same time to all the senators of Venice; giving along with the instrument a written paper, in which he explained the structure and wonderful uses that might be made of it both by land and at sea. In return for so noble an entertainment, the republic, on the 25th of August, in the same year, more than tripled his salary as professor.

Our philosopher having amused himself for some time with the view of terrestrial objects, at length directed his tube towards the heavens; and, observing the moon, he found that the surface of it was diversified with hills and valleys, like the earth. He found that the fixed stars and planets consisted of a collection of fixed stars, which on account either of their vast distance, or extreme smallness, were invisible to the naked eye. He also discovered innumerable fixed stars dispersed over the face of the heavens, which had been unknown to all the ancients; and examining Jupiter, with a better instrument than any he had made before, he found that he was accompanied by four stars which, in certain fixed periods, performed revolutions around him, and which, in honour of the house of Medici, he called Medicean planets.

This discovery he made in January 1610, new style, and, continuing his observations the whole of February following, in the beginning of March next he published an account of all his discoveries, in his Nuncius Sidereus, printed at Venice, and dedicated to the great duke of Tuscany, who, by a letter which he wrote to him on the 8th of July 1610, invited him to quit Padua, and assigned him an ample stipend, as primate and extraordinary professor at Pisa, but without any obligation to read lectures, or to reside.

The extraordinary discoveries contained in the Nuncius Sidereus, which was immediately reprinted both in Germany and France, were the cause of much speculation and debate among the philosophers and astronomers of that time; many of whom could not be brought to give any credit to Galileo's account, while others endeavoured to decry his discoveries as being nothing more than fictions or illusions. Some could not be prevailed upon even to look through a telescope; so devoted were they to the system of Aristotle, and so averse to admit any other source of knowledge besides his writings. When it is found to be in vain to oppose the evidence of facts, some did not scruple to assert that the invention was taken from Aristotle, and producing a passage from his writings, in which he attempts to give a reason why stars are seen in the day time from the bottom of a deep well, said, that the well corresponded to the tube of the telescope, and that the vapours which arose from it gave the hint of putting glasses into it; and lastly, that in both cases the light is strengthened by the transmission of the rays through a thick and dark medium. Galileo himself tells this story with a great deal of humour; comparing such men to alchymists, who imagine that the art of making of gold was known to the ancients, but lay concealed under the fables of the poets.

In the beginning of July of the same year, 1610, Galileo being still at Padua, and getting an imperfect view of Saturn's ring, imagined that that planet consisted of three parts; and therefore, in the account which he gave of this discovery to his friends, he calls it planetam tergemann.

Whilst he was still at Padua, which must have been either in the same month of July, or the beginning of August following, he observed some spots on the face of the sun; but contrary to his usual custom, he did not choose, at that time, to publish his discovery; partly for fear of incurring more of the hatred of many obstinate peripatetics; and partly in order to make more exact observations on this remarkable phenomenon, and to form some conjecture concerning the probable cause of it. He therefore contented himself with communicating his observations to some of his friends at Padua and Venice, among whom we find the name of father Paul. This delay, however, was the cause of this discovery being contested with him by the famous Scheiner, who likewise made the same observation in Oct. 1611, and we suppose had anticipated Galileo in the publication of it.

About the end of August, Galileo left Padua and went to Florence; and in November following he was satisfied, that, from the September preceding, Venus had been continually increasing in bulk, and that she changed her phases like the moon. About the end of March 1611, Galileo went to Rome where he gratified the cardinals, and all the principal nobility, with a view of the new wonders he had discovered in the heavens, and among others the solar spots.

From these discoveries Galileo obtained the name of Lyncus, after one of the Argonauts, who famous in antiquity for the acuteness of his sight; and moreover, the marquis of Monticelli instituted an academy, with the title of Dè Lincei, and made him a member of it. Twenty-nine years Galileo enjoyed the use of his telescope, continually enriching astronomy with his observations; but by too close an application to that instrument, and the detriment he received from the nocturnal air, his eyes grew gradually weaker, till in 1639 he became totally blind: a calamity which, however, neither broke his spirits, nor interrupted the course of his studies.

The first telescope that Galileo constructed magnified only three times: but presently after, he made another which magnified 18 times: and afterwards, with great trouble and expense, he constructed one that magnified 33 times; and with this it was that he discovered the satellits of Jupiter and the spots of the sun.
Notwithstanding Galileo must be allowed to have considerable merit with respect to telescopes, it was neither that of the person who first hit upon the construction, nor that of him who thoroughly explained the rationale of the instrument. This important service to science was performed by John Kepler, whose name is famous on many accounts in the annals of philosophy, and especially by his discovery of the great law of motion respecting the heavenly bodies; which is, that the squares of their periodical times are as the cubes of their distances from the body about which they revolve; a proposition which, however, was not demonstrated before Sir Isaac Newton. Kepler was astro­nomer to several of the emperors of Germany; he was the associate of the celebrated astronomer Tycho Brahe, and the master of Descartes.

Kepler made several discoveries relating to the nature of vision; and not only explained the rationale of the telescope which he found in use, but also pointed out a number of contrivances others of superior powers and more commodious application.

It was Kepler who first gave a clear explication of the effects of lenses, in making the rays of a pencil of light converge or diverge. He showed, that a plano-convex lens makes rays that were parallel to its axis, to meet at the distance of the diameter of the sphere of convexity; but that if both sides of the lens be equally convex, the rays will have their focus at the distance of the radius of the circle, corresponding to that degree of convexity. But he did not investigate any rule for the foci of lenses unequally convex. He only says, in general, that they will fall somewhere in the medium, between the foci belonging to the two different degrees of convexity. It is to Cavalieri that we owe this investigation. He laid down this rule: As the sum of both the diameters is to one of them, so is the other to the distance of the focus. All these rules concerning convex lenses are applicable to those that are concave; with this difference that the focus is on the concave side of the glass, as will be particularly shown in the second part of this treatise.

The principal effects of telescopes depend upon these plain maxims, viz. That objects appear larger in proportion to the angles which they subtend at the eye; and the effects is the same whether the pencils of rays by which objects are visible to us, come directly from the objects themselves, or from any place nearer to the eye, where they may have been united so as to form an image of the object; because they issue again from those points where there is no real substanee, in certain directions, in the same manner as they did from the corresponding points in the objects themselves. In fact, therefore, all that is effected by a telescope is, first to make such an image of a distant object, by means of a lens or mirror: and then to give the eye some assistance for viewing that image as near as possible; so that the angle which it shall subtend at the eye, may be very large compared with the angle which the object itself would subtend in the same situation. This is done by means of an eye-glass, which reflects the pencils of rays, as they may afterwards be brought to their several foci by the natural humour of the eye. But if the eye was so formed as to be able to see the image with sufficient distinctness at the same distance without any eye-glass, it would appear to him as much magnified as it does to another person who makes use of a glass for that purpose, though he would not in all cases have so large a field of view.

If instead of an eye-glass, an object, or the image of an object, be looked at through a small hole in a thin plate or piece of paper held close to the eye, it may be viewed very near to the eye, and, at the same distance, the apparent magnitude of the object will be the same as it is in both cases. For if the hole be so small as to admit but a single ray from every distinct point of the object, these rays will fall upon the retina in as many other distinct points, and make a distinct image. They are only pencils or cones of rays, which have a sensible base, as the breadth of the pupil, that are capable, by their spreading on the retina, of producing an indistinct image. As very few rays, however, can be admitted through a small hole, there will seldom be light sufficient to view any object to advantage in this manner.

If no image be actually formed by the foci of the pencils without the eye, yet if by the help of any eye­glases, the pencils of rays shall enter the pupil, just as they would have done from any place without the eye, the visual angle will be the same as if an image had actually been formed in that place. Objects will not appear inverted through this telescope, because the pencils which form the images of them, only cross one another once, viz. at the object itself, as in natural vision they do in the pupil of the eye.

Such is the telescope that was first discovered and Galilean used by philosophers; and it is remarkable that it should be of a much more difficult construction than some other kinds that have been invented since. The great inconvenience attending it is, that the field of view is exceedingly small. For since the pencils of rays enter the eye very much diverging from one another but few of them can be intercepted by the pupil, this inconvenience increases with the magnifying power of the telescope; so that philosophers at this day cannot help wondering, that it was possible, with such an instrument, for Galileo and others to make the discoveries they did. It must have required incredible patience and address. No other telescope, however, than this, was so much as thought of for many years after the discovery. Descartes, who wrote 30 years after, mentions no others as actually constructed, though Kepler had suggested some.

It is to this great man that we are indebted for the construction of what we now call the astronomical telescope, being the best adapted for the purpose of viewing the heavenly bodies. The rationale of this instrument is explained, and the advantages of it are clearly pointed out by this philosopher, in his Catoptrics; but, what is very surprising, he never actually reduced his excellent theory into practice. Montucla conjectures, that the reason why he did not make trial of his new construction was, his not being aware of the great increase of the field of view; so that being engaged in other pursuits, he might not thik it of much consequence to take any pains about the construction of an instrument, which could do little more than answer the same purpose with those of which he was already possessed.

He must also have foreseen, that the length of this telescope must have been greater in proportion to its magnifying power: so that it might appear to him to be
be upon the whole not quite so good a construction as the former.

It was not long, however, before Kepler's new scheme of a telescope was executed: and the first person who actually made an instrument of this construction was Father Scheiner, who had given a description of it in his late 'De Optica', published in 1610. If, says he, you insert two similar lenses (that is, both convex) in a tube, and place your eye at a convenient distance, you will see all terrestrial objects inverted, indeed, but magnified and very distinctly, with a considerable extent of view. He afterwards subjoins an account of a telescope of a different construction, with two convex eye-glasses, which again reverses the images, and makes them appear in their natural position. This disposition of the lenses had also been pointed out by Kepler but had not been reduced to practice by him, any more than the former. This construction, however, unravelled the end but very imperfectly; and Father Rheita presently hit upon a better construction, using three eye-glasses instead of two. This got the name of the terrestrial telescope, being chiefly used for terrestrial objects.

The first and last of these constructions are those which are now in common use. The proportion in which the first telescope magnifies, is as the focal length of the object-glass to that of the eye-glass. The only difference between the Galilean telescope and the other is, that the pencils by which the extremities of any object are seen in this case, enter the eye diverging; whereas, in the other, they enter it converging; but if the sphere of concavity in the eye-glass of the Galilean telescope be equal to the sphere of convexity in the eye-glass of another telescope, the magnifying power will be the same. The concave eye-glasses, however, being placed between the object-glasses and its focus, the Galilean telescope will be shorter than the other, by twice the focal length of the eye-glasses. Consequently, if the length of the telescopes be the same, the Galilean will have the greater magnifying power.

The invention of the telescope and microscope having incited mathematicians to a more careful study of dioptrics, and this having soon become almost a perfect science, by means of the discovery of Snellius, many different constructions were offered to the public. Huygens was particularly eminent for his systematic knowledge of the subject, and is the author of the chief improvements which have been made on all the dioptrical instruments till the time of Mr Dollond's discovery. He was well acquainted with the theory of aberration arising from the spherical figure of the glasses, and had showed several ingenious methods of diminishing them by proper contructions of the eye-glasses. He first showed the advantages of two eye-glasses on the astronomical telescope and double microscope, and gave rules for this construction, which both enlarges the field and shortens the instrument.

Mr Dollond adapted his construction to the terrestrial telescope of De Rheita; and his five eye-glasses are nothing but the Huygenian eye-piece doubled. This construction has been too hastily given up by the artists of the present day for another, also of Mr Dollond's, of four glasses. Vicon is more distinct in the Galilean telescope than in the other, owing perhaps in part to there being no intermediate image between the eye and the object. Beside, the eye-glass being very thin in the centre, the rays will be less liable to be distorted by irregularities in the substance of the glasses whatever be the cause, we can sometimes see Jupiter's satellites very clearly in a Galilean telescope not more than twenty inches or two feet long; when one of four or five feet of the common fort, will hardly make them visible.

The same Father Rheita, to whom we are indebted for the useful construction of a telescope for land-objects, invented a binocular telescope, which Father Cherubino, of Orleans, endeavored to bring into use afterwards. It consists of two telescopes fastened together, and made to point to the same object. When this instrument is well fixed, the object appears larger and nearer to the eye, when it is seen through both the telescopes, than through one of them only, though they have the same magnifying power. But this is only an illusion, occasioned by the stronger impression that two equal images, equally illuminated, make upon the eye. This advantage, however, is counter-balanced by the inconvenience attending the use of it.

The first who distinguished themselves in grinding terrestrial telescopes were two Italians. Enfachio Divini of Rome, and Campani at Bologna, whose telescope was much superior to that of Divini, or that of any other person of his time; though Divini himself pretended, that, in all the trials that were made with their glasses, his, of a great focal distance, performed better than those of Campani, and that his rival was not willing to try them fairly, side by side, with equal eye-glasses. It is generally supposed, however, that Campani really excelled Divini, both in the goodness and the focal length of his object-glasses. It was with telescopes made by Campani that Capitini discovered the nearest satellites of Saturn. They were made by the express order of Louis XIV, and were of 86, 100, and 156 Parilian feet focal length.

Campani held his lenses for a great price, and took every possible method to keep his art of making them, a secret. His laboratory was inaccessible to all the world, till after his death; when it was purchased by Pope Benedict XIV, who made a present of it to the academy called the Infriltute, established in that city; and by the account which M. Foucheroux has given of what he could discover from it, we learn that (except a machine, which M. Campani constructed, to work the basons on which he ground his glasses) the goodness of his lenses depended upon the clearance of his glasses, his Venetian tripods, the paper with which he polished his glasses, and his great skill and address as a workman. It was also the general opinion at Bologna, that he owed a great part of his reputation, to the secrecy and air of mystery which he affected; and that he made a great number of object-glasses which he rejected, showing only those that were good. He made few lenses of a very great focal distance; and having the misfortune to break one of 141 feet in two pieces, he took incredible pains to join the two parts together, which he did at length, effectually, so that it was used as it had been entire; but it is not probable that he would have taken so much pains about it, if, as he pretended, he could very easily have made another as good.
Sir Paul Neile, Dr Hooke says, made telescopes of 36 feet, pretty good, and one of 50, but not of proportional goodness. Afterwards Mr Reive first, and then Mr Cox, who were the most celebrated in England as grinders of optic glases, made some good ones of 50 and 60 feet focal distance, and Mr Cox made one of 100; but how good, Dr Hooke could not assert.

Borelli also, in France, made object-glases of a great focal length, one of which he presented to the Royal society; but we do not find any particular account of their goodness.

With respect to the focal length of telescopes, these and others were far exceeded by M. Auzout, who made one object-glase of 600 feet focus; but he was never able to manage it, so as to make any use of it. Hartsocker is even said to have made some of a still greater focal length; but this ingenious mechanic, finding it impossible to make use of object-glases the focal distance of which was much less than this, when they were inclosed in a tube, contrived a method of using them without a tube, by fixing them at the top of a tree, a high wall, or the roof of a house.

Mr Huygens, who was also an excellent mechanic, made considerable improvements in the method of using an object-glase without a tube. He placed it at the top of a very long pole, having previously inclosed it in a short tube, which was made to turn in all directions, by means of a ball and socket. The axis of this tube he could command with a fine silken string; so as to bring it into a line with the axis of another short tube, which he held in his hand, and which contained the eye-glases. In this method he could make use of object-glases of the greatest magnifying power, at whatever altitude his object was, and even in the zenith, provided his pole was as long as his telescope; and to adapt it to the view of objects of different altitudes, he had a contrivance by which he could raise or depresse a stage that supported his object-glases at pleasure.

M. De la Hire made some improvement in this method of managing the object-glases, fixing it in the centre of a board, and not in a tube; but as it is not probable that this method will ever be made use of, since the discovery of both reflecting and achromatic telescopes, which are now brought to great perfection, and have even micrometers adapted to them, we shall not describe this apparatus minutely; but shall only give a drawing of M. Huygen's pole, which with a very short explanation, will be sufficient for the purpose. In fig. 1. a represents the pully by the help of which a flage of a, b, c, d (that supports the object glasse a, and the apparatus belonging to it), may be raised higher or lower at pleasure; the whole being counterpoised by the weight d, fastened to a string g. n is a weight, by means of which the centre of gravity of the apparatus belonging to the object glasse is kept in the ball and socket, so that it may be easily managed by the string l, n, and its axis brought into a line with the eye-glases at o. When it was very dark, M. Huygens was obliged to make his object-glases visible by a lantern, so constructed as to throw the rays of light in a parallel direction up to it.

The recollection of the incredible pains which philosophers of the last age took in making observations, and the great expences they were obliged to be at for that purpose, should make us sensible of the obligations we are under to such men as Gregory, Newton, and Dollond, who have enabled us to get clearer and more satisfactory views of the remote parts of our system, with much less labour and expence; and should likewise make us more diligent and solicitous to derive all the advantages we possibly can from such capital improvements.

The reason why it is necessary to make the common dioptric telescope so very long, is, that the length of them must be increased in no less a proportion than the duplicate of the increase of their magnifying power; so that, in order to magnify twice as much as before, with the same light and distinctness, the telescope must be lengthened four times; and to magnify thrice as much, nine times; and so on.

Before we mention the reflecting telescope, it must be observed, that M. Auzout, in a paper delivered to the Royal society, observed, that the apertures which the object-glases of refracting telescopes can bear with distinctness, are in about a sub-duplicate proportion to their lengths; and upon this supposition he drew up a table of the apertures proper for object-glases of a great variety of focal lengths, from 4 inches to 400 feet. Upon this occasion, however, Dr Hooke observed, that, the same glases will bear a greater or less aperture, according to the less or greater light of the object. If, for instance, he was viewing the sun, or Venus, or any of the fixed stars, he used smaller apertures: but if he wanted to view the moon by daylight; or Saturn, Jupiter, or Mars, by night, he used a larger aperture.

But the merit of all these improvements was in a manner cancelled by the discovery of the much more commodious reflecting telescope. For a refracting telescope, even of 1000 feet focus, supposing it possible to be made use of, could not be made to magnify with distinctness more than 1000 times; whereas a reflecting telescope, not exceeding 9 or 10 feet, will magnify 1200 times.

"It must be acknowledged (says Dr Smith in his History of Complete System of Optics), that Mr James Gregory of the refection telescope was the first inventor of the reflecting telescope; but his contrivance is quite different from Sir Isaac Newton's, and not nearly so advantageous."

But according to Dr Pringle, Merlemius was the man who entertained the first thought of a reflector. A telescope with specula he certainly proposed to the celebrated Descartes many years before Gregory's invention, though indeed in a manner so very unsatisfactory that Descartes, who had given particular attention to the improvement of the telescope, was so far from approving the project, that he endeavoured to convince Merlemius of its fallacy (a). Dr Smith, it
O P T I C S.

History.

It appears, had never perused the two letters of Descartes to Merianus which briefly touch on that subject.

Again, as to his assertion, that Gregory's construction was not nearly so advantageous as Newton's, it may be accounted for from having left it down early in the composition of his work, and forgetting to qualify it afterwards, when, more the publication, he had received pretty sure information to the contrary. Or perhaps he was influenced by the example of doctor Bradley, who had been a most successful observer, and yet had always preferred the Newtonian telescope to the other. But we must certainly judge the superiority to the latter, as that is now, and has been for several years past, the only instrument of the kind in request.

Gregory, a young man of an uncommon genius, was led to the invention, in seeking to correct two imperfections of the common telescope: the first was its too great length, which made it less manageable; the second the incorrectness of the image. Mathematicians had demonstrated, that a pencil of rays could not be collected in a single point by a spherical lens; and also, that the image transmitted by such a lens would be in some degree incurved. These inconveniences he believed would be obviated by substituting for the object-glass a metallic speculum, of a parabolic figure, to receive the image, and to reflect it towards a small speculum of the same metal: this again was to return the image to an eye-glass placed behind the great speculum, for that purpose was to be perforated in its centre. This construction he published in 1663, in his Optica Promot. But as Gregory, by his own account, was endowed with no mechanical dexterity, nor could find any workmen capable of realizing his invention, after some fruitless attempts in that way he was obliged to give up the pursuit; and probably, had not some new discoveries been made in light and colours, a refracting telescope would never have been thought of, considering the difficulty of the execution, and the small advantages that could accrue from it, deducible from the principles of optics that were then known.

But Newton, whose genius for experimental knowledge was equal to that for geometry, happily interposed, and favored this noble invention from well-nigh perishing in its infant state. He likewise at an early period of life had applied himself to the improvement of the telescope; but imagining that Gregory's specula were neither very necessary, nor likely to be executed, he began with prosecuting the views of Descartes, who aimed at making a more perfect image of an object, by grinding lenses, not to the figure of a sphere, but to that of one of the conic sections. Now, whilst he was thus employed, three years after Gregory's publication, he happened to take to the examination of the colours formed by a prism, and having by the means of that simple instrument discovered the different refrangibility of the rays of light, he then perceived that the errors of telescopes, arising from that cause alone, were some hundred times greater than such as were occasioned by the spherical figure of lenses. This circumstance forced, as it were, Newton to fall into Gregory's track, and to turn his thoughts to reflectors. "The different refrangibility of the rays of light (says he, in a letter to Mr Oldenburg, secretary to the Royal Society, dated in Feb. 1672) made me take reflections into consideration: and finding them regular, so that the angle of reflection of all sorts of rays was equal to the angle of incidence, I understood that by their mediation optical instruments might be brought to any degree of perfection imaginable, providing a reflecting substance could be found which would polish as finely as glass, and reflect as much light as glass transmits and the art of communicating to it a parabolic figure be also obtained. Amidst these thoughts I was forced from Cambridge by the intervening plague, and it was more than two years before I proceeded further."

It appears, then, that if Newton was not the first inventor of the reflecting telescope, he was the main and effectual inventor. By the force of his admirable genius, he fell upon this new property of light; and thereby found, that all lenses of whatever figure, would be affected more or less with such prismatic aberrations of the rays as would be an insuperable obstacle to the perfection of a dioptric telescope.

It was towards the end of 1668, or in the beginning of the following year, when Newton, being thus obliged to have recourse to reflectors, and not relying on any artificer for making his specula, set about the work himself, and early in the year 1672 completed two small reflecting telescopes. In these he ground the great speculum into a spherical concave; not but that he approved of the parabolic form proposed by Gregory, though he found himself unable to accomplish it. In the letter that accompanied one of these instruments which he presented to the Society he writes, "that though he then despaired of performing that work (to wit, the parabolic figure of the great speculum) by geometrical rules, yet he doubted not but that the thing might in some measure be accomplished by mechanical devices."

Not less did the difficulty appear to find a metallic substance that would be of a proper hardness, have the fewest pores, and receive the smoothest polish: a difficulty in truth which he deemed almost insurmountable, when he considered, that every irregularity in a reflecting surface would make the rays of light stray five or six times more out of their due course, than the like irregularities in a refracting one. In another letter, written soon after, he tells the secretary, "that he was very sensible that metal reflects less light than glass transmits; but as he had found some metallic substances to be more strongly reflective than others, to polish better, and to be freer from tarnishing than others, so he hoped that there might in time be found out some substances much freer from these inconveniences than any yet known." Newton therefore laboured till he found a composition that answered in some degree, and left it to those who should come after him to find a better, and presented a reflecting telescope to the Royal Society from whom he received such thanks as were due to so curious and valuable a present. And Huygens, one of the greatest geniuses of the age, and himself a distinguished improver of the refractor, no sooner was informed by Mr Oldenburg of the discovery, than he wrote in answer, "that it was an admirable telescope; and that Mr Newton had well considered the advantage which a
...concave speculum had above convex glasses in collecting the parallel rays, which according to his own calculation was very great. Hence that Mr. Newton could give a far greater aperture to that speculum than to an object-glass of the same distance of focus, and consequently magnify much more in this way than by an ordinary telescope: besides, that by the reflector he avoided an inconvenience inseparable from object-glasses, which were the obliquity of both their surfaces, which vitiated the refraction of the rays that pass towards the sides of the glases, and did more hurt than men were aware of: Again, that by the mere reflection of the metallic speculum there were not so many rays lost as in glasses, which reflected a considerable quantity by each of their surfaces, and besides intercepted many of them by the obscurity of their matter: That the main business would be, to find a manner for the speculum that would bear as good and even a polish as glasses. Lastly, he believed that Mr. Newton had not been without considering the advantage which a parabolic speculum would have over a spherical one in this construction; but had despair'd, as he himselfe had done, of working other surfaces than sferical ones with due exactness." Huygens was not satisfied with thus expressing to the society his high approbation of the late invention; but drew up a favourable account of the new telescope, which he caused to be published in the Journal des Savans for the year 1672; and by that channel it was soon known over Europe.

But how excellent forever the contrivance was; how well forever supported and announced to the public: yet whether it was that the artifices were deterred by the difficulty and labour of the work, or that the discoveries even of a Newton were not to be exempted from the general fatality attending great and useful inventions, the making a flow and venation progress to the authors; the fact is, that excepting an unsuccessful attempt which the society made by employing an atificer to imitate the Newtonian construction, but upon a larger scale, and a difguised Gregorian telescope set up by Caffegrain abroad as a rival to Newton's and that in theory only (for it never was put in execution by the author), no reflector was heard of for nearly half a century after. But when that period was elaps'd, a reflecting telescope was at last produced to the world of the Newtonian construction by Dr. Hadley, which the author had the satisfaction to find executed in such a manner as left no room to fear that the invention would any longer continue in obscurity.

This memorable event was owing to the genius, dexterity, and application, of Mr. Hadley the inventor of the reflecting quadrant, another most valuable instrument. The two telescopes which Newton had made were but six inches long, were held in the hand for viewing objects, and in power were compared to a six-feet refractor: whereas Hadley's was above five feet long, was provided with a well-contrived apparatus for managing it and equalled in performance the famous aerial telescope of Huygens of 123 feet in length. Excepting as to the manner of making the specula, we have, in the transations of 1723, a complete description, with a figure, of this telescope, together with that of the machine for moving it; but by a strange omission, Newton's name is not once mentioned in that paper, so that any person not acquainted with the history of the invention, and reading that account only, might be apt to conclude that Hadley had been the sole contriver of it.

The same celebrated artific, after finishing the two telescopes of the Newtonian construction, accomplished a third in the Gregorian way; but, it would seem, less successfully, by Dr. Smith's declaring so fluently in favour of the other. Mr. Hadley spared no pains to instruct Mr. Molynex and the reverend Dr. Bradley; and when those gentlemen had made a sufficient proficiency in the art, being desirous that these telescopes should become more public, they liberally communicated to some of the principal instrument-makers of London the knowledge they had acquired from him. Now such scholars, as it is easy to imagine, soon advanced beyond their masters, and completed reflectors by other and better methods than what had been taught them.

Certain it is, at least, that Mr. James Short, as early as the year 1734, had signal'd himself at Edinburgh by his work of this kind. Mr. Maclaurin wrote that year to Dr. Jurin, "that Mr. Short, who had begun with making glasses specula, was then applying himself to improve the metallic; and that by taking care of the figure, he was enabled to give them larger apertures than others had done; and that upon the whole they surpassed in perfection all that he had seen of other worksmen." He added, "that Mr. Short's telescopes were all of the Gregorian construction; and that he had much improved that excellent invention." This character of excellence Mr. Short maintained to the last; and with more facility, as he had been well ground'd both in the geometrical and philosophical principles of optics, and upon the whole was a most intelligent person in whatever related to his profession. It was supposed he had fallen, upon a method of giving the parabolic figure to his great speculum: a point of perfection that Gregory and Newton had wished for, but despair'd of attaining; and that Hadley had never, as far as we know, attempted either in his Newtonian or Gregorian telescope. Mr. Short indeed said he had acquired that faculty, but never would tell by what peculiar means he effected it; so that the secret of working that configuration, whatever it was, as far as it then appeared died with that ingenious artific. Mr. Mudge, however, hath lately realized the expedition of Sir Isaac Newton, who, above 100 years ago, prefaged that the public would one day possess a parabolic speculum, not accomplished by mathematical rules, but by mechanical devices.

This was a defideratum, but it was not the only want supplied by this gentleman; he has taught us likewise a better composition of metals for the specula, how to grind them better, and how to give them a finer polish; and this last part, (namely, the polish), he remarks, was the most difficult and essential of the whole operation. "In a word (says Sir John Pringle), I am of opinion, there is no opician in this great city (which hath been so long and so justly renowned for ingenious and dexterous makers of every kind of mathematical instruments) so partial to his own abilities as
as not to acknowledge, that, however some parts of
the mechanical procels now discovered might have been
known before by individuals of the profession, yet
that Mr Mudge has opened to them all some new
and important lights, and upon the whole has
greatly improved the art of making reflecting tele-
scopes." The late reverend and ingenious John Edwards de-
voted much of his time to the improvement of re-
flecting telescopes, and brought them to such per-
feciion, that Dr Maskelyne, the astronomer royal,
found telescopes constructed by him for spurs in bright
ness, and other essentials, those of the same size
made by the best artificers in London. The chief ex-
cellence of his telescopes arises from the composition,
which, from various trials on metals and semimetals,
he discovered for the specula, and from the true pa-
ruhelic figure, which, by long practice, he had found
a method of giving them, preferable to any that was
known before him. His directions for the composition
of specula, and for casting, grinding, and polishing
them, were published, by order of the commissioners
of longitude, at the end of the Nautical Almanack
for the year 1787. To the same almanack is also
annexed his account of the cause and cure of the
tremors which particularly affect reflecting telescopes more
than refracting ones, together with remarks on the
field tremors by Dr Maskelyne. See Telescope.

But in constructing reflecting telescopes of extra-
ordinary magnifying powers, Dr Herchel has dis-
played skill and ingenuity surpassing all his predecessors
in this department of mechanics. He has made them
from 7, 10, 20, to even 40 feet in length; and with
the instrument of these latter dimensions he is now emplo-
yed in making discoveries in astronomy. Of its
construction, magnifying powers, and the curious col-
clection of machinery by which it is supported and
moved from one part of the heavens to another, ac-
counts will be given under the word Telescope.

The greatest improvement in reflecting telescopes hitherto made public (c) is that of Mr Dollond, of
which an account has already been given in a preced-
ing section, wherein his discoveries in the science of
Optics were explained. But, besides the obligation
we are under to him for correcting the aberration of
the rays of light in the focus of object-glasses, arising
from their different refrangibility, he made another
considerable improvement in telescopes, viz. by cor-
recting, in a great measure, both this kind of aber-
racion, and also that which arises from the spheri-
cal form of lenses, by an expedient of a very different
nature; viz. increasing the number of eye-glasses.

If any person, says he, would have the visual angle
of a telescope to contain 20 degrees, the extreme pen-
cils of the field must be bent or refracted in an angle
of 10 degrees; which, if it be performed by one eye-
glass, will cause an aberration from the figure, in pro-
portion to the cube of that angle; but if two glasses
are fo proportioned and situated, as that the refraction
may be equally divided between them, they will each
of them produce a refraction equal to half the required
angle; and therefore, the aberration being in propor-
tion to the square of half the angle taken twice ever,
will be but a fourth part of that which is in propor-
tion to the cube of the whole angle; because twice
the cube of 1 is but 4 of the cube of 2; so the aber-
ration from the figure, where two eye-glasses are
rightly proportioned, is but a fourth of what is most
unavoidably be, where the whole is performed by a
single eye-glass. By the same way of reasoning, when
the refraction is divided between three glases, the
aberration will be found to be but the ninth part
of what would be produced from a single glass; because
three times the cube of 1 is but one ninth of the cube
of 3. Whence it appears, that by increasing the num-
ber of eye-glasses, the indistinctness which is ob-
erved near the borders of the field of a telescope may
be very much diminished, though not entirely taken
away.

The method of correcting the errors arising from
the different refrangibility of light is of a different con-
sideration from the former. For, whereas the errors
from the figure can only be diminished in a certain
proportion according to the number of glases, in this
they may be entirely corrected by the addition of only
one glass; as we find in the astronomical telescope, that
two eye-glasses, rightly proportioned, will cause the
edges of objects to appear free from colours, quite to
the borders of the field. And in the day-telescope,
where no more than two eye-glasses are absolutely ne-
necessary for erecting the object, we find, that by the
addition of a third, rightly situated, the colours, which
would otherwise make the image confused, are entirely
removed. This, however, is to be understood with
some limitation: for though the different colours into
which the extreme pencils must necessarily be divided
by the edges of the eye-glasses, may in this manner
be brought to the eye in a direction parallel to each
other, so as, by the humours of the eye, to be made
to converge to a point on the retina; yet, if the glases
exceed a certain length, the colours may be spread to
wide to be capable of being admitted through the
pupil or aperture of the eye; which is the real fact, that
in long telescopes, constructed in the common manner,
with three eye-glasses, the field is always very much
contracted.

These considerations first set Mr Dollond on con-
triving how to enlarge the field, by increasing the num-
ber of eye-glasses without any hinderance to the distin-
ctions or brightness of the image; and though others
had been about the same work before, yet, observing
that some five-glass telescopes which were then made
would admit of further improvement, he endeavoured
to construct one with the same number of glases in a
better

(c) Dr Blair's discovery, mentioned n° 19, will undoubtedly lead to improvements superior to those of
Dollond; but as his memoir on the subject is not yet published, we feel not ourselves at liberty to make longer
extracts from it. The reader will see the whole in the Philosophical Transactions of the Royal Society of
Edinburgh, whenever that body shall be pleased to favour the public with a third volume of its learned
labours.
better manner; which so far answered his expectations, as to be allowed by the best judges to be a considerable improvement on the former.

Encouraged by this success, he resolved to try if he could not make some farther enlargement of the field, by the addition of another glass, and by placing and proportioning the glasses in such a manner as to correct the aberrations as much as possible, without any detriment to the diurnality; and at last he obtained as large a field as is convenient or necessary, and that even in the longest telescopes that can be made.

These telescopes with fix glasses having been well received, and some of them being gone into foreign parts, it seemed a proper time to the author to settle the date of his invention; on which occasion he drew up a letter, which he addressed to Mr. Short, and which was read at the Royal Society, March 1, 1758.*

Various other attempts were made about this time to shorten and otherwise improve telescopes. Among these we must just mention that of Mr. Caleb Smith, who, after giving much attention to the subject, thought that he had found it possible to rectify the errors which arise from the different degrees of refrangibility, on the principle that the fines of refraction, or rays differently refrangible, are to one another in a given proportion, when their fines of incidence are equal; and the method by which he proffed for this purpose was to make the spectulums of glass instead of metal, the two surfaces having different degrees of concavity. But we do not find that his scheme was ever executed; nor is it probable, for reasons which have been mentioned, that any advantage could be made of it.

To Mr. Short we are indebted for the excellent contrivance of an equatorial telescope, or, as he likewise called it, a portable observatory; for with it very precise observations may be made with very little trouble, by those who have no building adapted to the purpose. The instrument consists of an ingenious piece of machinery, by the help of which a telescope mounted upon it may be directed to any degree of right ascension or declination, so that the place of any of the heavenly bodies being known, they may be found without any trouble, even in the day-time. Also, being made to turn parallel to the equator, any object is easily kept in view, or recovered, without moving the eye from its situation. By this instrument, Mr. Short informs us, that most of the stars of the first and second magnitude have been seen even at midday, and the sun shining bright; as also Mercury, Venus, and Jupiter. Saturn and Mars are not so easy to be seen, on account of the faintness of their light, except when the sun is but a few hours above the horizon. This particular effect depends upon the telescope excluding almost all the light, except what comes from the object itself, and which might otherwise efface the impression made by its weaker light upon the eye. Any telescope of the same magnifying power would have the same effect, could we be sure of pointing it right. For the same reason, also, it is that stars are visible in the day-time from the bottom of a deep pit. Mr. Ramsden has lately invented a portable observatory or equatorial telescope, which may perhaps supercede the use of Mr. Short's. See Astronomy, n° 504.

In order to enable us to see the fixed stars in the day-time, it is necessary to exclude the extraneous light as much as possible. For this reason the greater magnifying power of any telescope is used, the more easily a fixed star will be distinguished in the day-time; the light of the star remaining the same in all magnifying powers of the same telescope, but the ground upon which it is seen being darker by increasing the magnifying power; and the visibility of a star depends very much upon the difference between its own light and that of the ground upon which it is seen. A fixed star will be very nearly equally visible with telescopes of very different apertures, provided the magnifying power remains the same.

If a comet, or any other heavenly body, be viewed through this equatorial telescope, properly rectified, it is seen immediately by the help of the same machinery what is its true place in the heavens. Other astronomical problems may also be solved by it, with great ease and certainty.

Mr. Epinus proposes to bend the tubes of long tele- scopes at right angles, fixing a plane mirror in the angle, in order to make them more commodious for viewing objects near the zenith of the observer; and he gives particular instructions how to make them in this form, especially when they are furnished with micrometers. We are also informed that a little plane speculum is sometimes placed between the last eye-glasses and the eye in the reflecting telescopes, at an angle of 45°, for the same purpose.

The invention of Microscopes was not much later than that of telescopes; and, according to Borellus, whose account we do not find to have been called in question by any person, we are indebted for them to the same author, at least to Z. Janfens, in conjunction with his son; and for this latter favour we may, perhaps, be considered as under more obligation to them than for the former, the microscope having more various and extensive uses, with respect to philosophy, than the telescope. In our ideas, however, it appears something greater, and more extraordinary, to be able to see objects too distant to be perceived by the naked eye, than those that are too near to be seen by us; and therefore there is more of the sublime in the telescope than the microscope. These two instruments, though different in their application, are notwithstanding very similar; as both of them allow us in the discovery of objects that we must otherwise have remained unacquainted with, by enlarging the angle which they subtend at the eye.

The Janfens, however, have not always enjoyed undisturbed, that share of reputation to which they seem to be entitled, with respect either to the telescope or the microscope. The discovery of the latter, in particular, has generally been considered as more uncertain than that of the former. All that many writers say we can depend upon is, that microscopes were first used in Germany about the year 1621. Others say positively, that this instrument was the contrivance of Cor-

* This paragraph is extracted from this paper in the Transactions; but Dollond's improvement there described, is not accompanied by any diagram. For a minute account of it, and of eye pieces in general, see Ludlam's Essays.
History.

Cornelius Drebell, no philosopher, but a man of curiosity and ingenuity, who also invented the thermometer.

According to Borellus, Zacharias Janfen and his son presented the first microscopes they had constructed to prince Maurice, and Albert archduke of Austria. William Borell, who gives this account in a letter to his brother Peter, says, that when he was ambassadoor in England, in 1619, Cornelius Drebell, with whom he was intimately acquainted, showed him a microscope, which he said was the same archduke had given him, and had been made by Janfen himself. This instrument was not so short as they are generally made at present, but was six feet long, consisting of a tube of gilt copper, an inch in diameter, supported by three brass pillars in the shape of dolphins, on a base of ebony, on which the small objects were placed.

This microscope was evidently a compound one, or rather something between a telescope and a microscope, what we should now, perhaps, choose to call a megascope; so that it is possible that single microscopes might have been known, and in use, some time before: but perhaps nobody thought of giving that name to single lenses; though, from the first use of lenses, they could not but have been used for the purpose of magnifying small objects. In this sense we have seen, that even the ancients were in possession of microscopes; and it appears from Jamblicus and Plutarch, whom Dr. Rogers, that they gave such instruments as they used for this purpose the name of dioptia. As spectacles were certainly in use long before the invention of telescopes, one can hardly help concluding, that lenses must have been made smaller, and more convex, for the purpose of magnifying minute objects; especially as the application of this kind of microscope was nearly the same with that of a spectacles, both of them being held close to the eye. At what time lenses were made so small as we now generally use them for magnifying in single microscopes, we have not found. But as this must necessarily have been done gradually, the only proper object of inquiry is the invention of the double or compound microscope; and this is clearly given, by the evidence of Borellus abovementioned, to Zacharias Janfen, the inventor of the telescope, or his son.

The invention of compound microscopes is claimed by the same Fontana who claimed the discovery of this invention till the year 1646 (notwithstanding he pretended to have made the discovery in 1618), Montucla, not having attended perhaps to the testimony of Borellus, is willing to allow his claim, as he thought there was no other person who seemed to have any better right to it.

Eutachio Divini made microscopes with two common object-glasses, and two plano-convex eye-glasses joined together on their convex sides so as to meet in a point. The tube in which they were inclosed was as big as a man's leg, and the eye-glasses almost as broad as the palm of a man's hand. Mr. Oldenburg, secretary to the royal society, received an account of this instrument from Rome, and read it at one of their meetings, August 6. 1668.

It was in this period that Hartsocker improved single microscopes, by using small globules of glass, made by melting them in the flame of a candle, instead of the lenses which had before been made use of for that purpose. By this means he first discovered the animalcula in femine maludio, which gave rise to a new system of generation. A microscope of this kind, consisting of a globule of $\frac{1}{16}$ of an inch in diameter, M. Huygens demonstrated to magnify 100 times; and since it is easy to make them of less than half a line in diameter, they may be made to magnify 500 times.

Were it not for the difficulty of applying objects to these magnifiers, the want of light, and the small field of diffined vision, they would certainly have been the most perfect of all microscopes.

But no man distinguished himself so much by microscopical discoveries as the famous M. Leeuwenhoek, though he used only single lenses with short focus, preferring diffuseness of vision to a large magnifying power.

M. Leeuwenhoek's microscopes were all single ones, each of them consisting of a small double convex-glass, set in a socket between two silver plates riveted together, and pierced with a small hole; and the object was placed on the point of a needle, so contrived as to be placed at any distance from the lens. If the objects were solid, he hardened them with glue; and if they were fluid, or on other accounts required to be spread upon glafs, he placed them on a small piece of Mufcovy tale, or glafs blown very thin; which he afterwards glued to his needle. He had, however, a different apparatus for viewing the circulation of the blood, which he could fix to the fame microscopes.

The greatest part of his microscopes M. Leeuwenhoek bequeathed to the Royal Society. They were contained in a small Indian cabinet, in the drawers of which were 13 little boxes, or cases, in each of which were two microscopes, neatly fitted up in silver; and both the glafs and the apparatus were made with his own hands.

The glafs of these lenses is exceedingly clear, but none of them magnifies so much as those globules which are frequently used in other microscopes; but Mr. Folkes, who examined them, thought that they showed objects with much greater diffuseness, which M. Leeuwenhoek principally valued. His discoveries, however, are not to be ascribed so much to the goodness of his glases, as to his great judgment, acquired by long experience, in using them. He also particularly excelled in his manner of preparing objects for being viewed to the most advantage.

Mr. Baker, who also examined M. Leeuwenhoek's microscopes, and made a report concerning them to the Royal Society, found that the greatest magnifier among them enlarged the diameter of an object about 160 times, but that all the rest fell much short of that power; so he concluded that M. Leeuwenhoek must have had other microscopes of a much greater magnifying power for many of his discoveries. And it appears, he says, by many circumstances, that he had such microscopes.

It appears from M. Leeuwenhoek's writings, that he was not acquainted with the method of viewing opaque objects by means of a small convex or reflecting mirror, which was afterwards improved by M. Lieberkun.

For, after describing his apparatus for viewing eels in glafs tubes, he adds, that he had an instrument to which he screwed a microscope set in brass, upon
upon which microscope he fastened a little dish of 
brafs, probably that his eye might be thereby allith 
to fee objects better; for he says he had fixed the brafs 
which was round his microscope as bright as he could, 
that the light, while he was viewing objects, might be 
reflected from it as much as possible. This micro-
scope, with its dish, is contrived upon principles fo 
similar to those which are the foundation of our single 
microscope by reflection (see Microscopes), that it 
might well be supposed to have given the hint to the 
ingenuous inventor of it, provided he ever attended 
to it.

In 1702, Mr Wilton made several ingenious im-
provements in the method of using single magnifiers, 
for the purpose of viewing transparent objects; and 
his microscope, which is also a necessary part of the 
dual microscope, is in very general use at this day. 
(See Microscopes, sect. 1.)

In 1710, Mr Adams gave to the Royal Society the 
following account of his method of making small glo-
bules for large magnifiers. He took a piece of fine 
window-glass, and cut it with a diamond into as many 
lengths as he thought proper, not exceeding ¼ of an 
inch in breadth; then, holding one of them between 
the fore-finger and thumb of each hand over a very 
fine flame, till the glass began to soften, he drew it 
out till it was as fine as a hair, and broke; then 
putting each of the ends into the purest part of the flame, 
he had two globules presently, which he could make 
larger or less at pleasure. If they were held a long 
time in the flame, they would have spots in them, so 
that he drew them out presently after they became 
round. The stem he broke off as near to the globe 
as he could, and lodging the remainder between the 
plates, in which holes were drilled exactly round, the 
microscope, he says, performed to admiration. Thro' 
these magnifiers, he says, that the same thread of very 
fine muslin appeared three or four times bigger than it 
did in the largest of Mr Wilton's magnifiers.

The ingenious Mr Grey hit upon a very easy expre-
dent to make very good temporary microscopes, at a 
very little expense. They consist of nothing but very 
small drops of water, taken up with a point of a pin, 
and put into a small hole made in a piece of metal. 
These globules of water do not, indeed, magnify so 
much as those which are made of glass of the same 
size, because the refractive power of water is not so 
great; but the same purpose will be answer'd nearly 
as well by making them somewhat smaller.

The same ingenious person, observing that small he-
terogeneous particles inclosed in the glass of which mi-
croscopes are made, were much magnified when those 
glass were looked through, thought of making his 
microscopes of water that contained living animalcula, 
to see how they would look in this new situation; and 
he found his scheme to answer even beyond his utmost 
expectation, so that he could not even account for 
their being magnified so much as they were: for it 
was much more than they would have been if they had 
been placed beyond the globe, in the proper 
place for viewing objects. But Montucla observes, 
that, when any object is inclosed within this small 
transparent globule, the hinder-part of it acts like a 
concave mirror, provided they be situated between that 
globe and the focus; and that, by this means, they 
are magnified above 3½ times more than they 
would have been in the usual way.

After the happy execution of the reflecting tele-
scope, it was natural to expect that attempts would 
also be made to render a similar service to microscopes. 
Accordingly we find two plans of this kind. The 
first was that of Dr Robert Barker. His instrument 
differs in nothing from the reflecting telescope, 
excepting the distance of the two speculums, in order to 
prevent it to those pencils of rays which enter the 
microscope diverging; whereas they come to the tele-
scope from very distant objects nearly parallel to each 
other.

This microscope is not so easily to manage as the 
common fort. For vision by reflection, as it is much 
more perfect, so it is far more difficult than that by 
refraction. Nor is this microscope so useful for any 
but very small or transparent objects. For the object, 
being between the speculum and image, would, if it 
were large and opaque, prevent a due reflection.

Dr Smith invented a double reflecting microscope, 
the conducting of a work so multifarious as ours is, 
always liable, this instrument was omitted under the 
article Microscopes. As it is constructed on 
principles essentially different from all others, and, in 
the opinion of the ablest judges whom we have consulted, 
comparably inferior to them all, the reader will not 
be ill pleased with the following practical description, 
though it appears not perhaps in its most proper place.

Fig. 2. is a section of this microscope, where ABC 
circuit, and abe are two specula, the former concave, and 
the latter convex, inclosed within the tube DEFG. The 
speculum ABC, is perforated like the speculum of a 
Gregorian telescope; and the object to be magnified is 
placed between the centre and principal focus of that 
speculum, that the rays flowing from it to ABC are 
reflected towards an image pq. But before they are 
united in that image they are received by the convex 
speculum abe, and thence reflected through the hole 
bc in the vertex of the concave abe a second image 
ps, to be viewed through an eye-glass f. The object 
may either be situated between the two specula, or, 
which is perhaps better, between the principal focus 
and vertex c of the convex speculum abe, a small hole 
being made in its vertex for the incident rays to pass 
through. When the microscope is used, the object 
bc is included between two little round plates of 
Mucoavy glases, fixed in a hole of an oblong brass plate 
mn, intended to slide close to the back side of the convex 
speculum; which must therefore be ground flat on 
that side, and so thin that the object may come pre-
 cisely to its computed distance from the vertex of the 
speculum. The slider must be kept taut to the back 
of the metal by a gentle spring. The distance of the 
object being thus determined once for all, distinct vi-
sion to different eyes, and through different eye-glasses, 
must be procured by a gentle motion of the little 
tubes that contain these glases. These tubes must be 
made in the usual form of those that belong to Sir 
Isaac Newton's reflecting telescope, (see Telescope), 
having a small hole in the middle of each plate, at the 
ends of the tubes, situated exactly in each focus of the 
glases;
the microscope, particularly in adapting it to the view of opaque objects; but in what manner this end was effected, M. Aepinus, who was highly entertained with the performances, and who mentions the fact, was not able to recollect; and the death of the ingenious inventor prevented his publishing any account of it himself. M. Aepinus invites those persons who came into the possession of M. Lieberkühn's apparatus to publish an account of this instrument; but it did not appear that his method was ever published.

This improvement of M. Lieberkühn's induced M. Aepinus himself to attend to the subject; and by this means he produced a very valuable improvement in this instrument. For by throwing the light upon the fore-side of any object by means of a mirror, before it is transmitted through the object-lens, all kinds of objects are equally well represented by it.

M. Euler proposed a scheme to introduce vision by reflected light into the magic lantern and solar microscope, by which many inconveniences to which those instruments are subject might be avoided. For this purpose, he says, that nothing is necessary but a large concave mirror, perforated as for a telescope; and that the light be so situated, that none of it may pass directly through the perforation, so as to fall on the images of the objects upon the screen. He proposes to have four different machines, for objects of different sizes; the first for those of six feet long, the second for those of one foot, the third for those of two inches, and the fourth for those of two lines; but it is needless to be particular in the description of these, as more perfect instruments are described under the article Microscope.

Several improvements were made in the apparatus to the solar microscope, as adapted to view opaque objects, by M. Zeiler, who made one construction for the larger kind of objects, and another for the smaller ones.

Mr. Martin having constructed a solar microscope of a larger size than common, for his own use, the illuminating lens being 4½ inches in diameter, and all the other parts of the instrument in proportion, found, that by the help of an additional part, which he does not describe, he could see even opaque objects very well. If he had made the lens any larger, he was aware that the heat produced at the focus would have been too great for the generality of objects to bear. The expense of this instrument, he says, does not much exceed the price of the common solar microscope.

The smallest globules, and consequently the greatest in durability, for microscopes, that have yet been executed, were made by T. Di Torre of Naples, who, in 1765, first took them to the Royal Society. The largest of them was only two Paris points in diameter, and it was said to magnify the diameter of an object 640 times. The second was the size of one Paris point, and...
and the third was no more than half of a Faris point, or the 14th part of an inch in diameter, and was said to magnify the diameter of an object 2560 times. One of these globules was wanting when they came into the hands of Mr Baker to whose examination they were referred by the Royal Society. This gentleman, so famous for his skill in microscopes, and his extraordinary expertness in managing them, was not able to make any use of them. With that which magnifies the leaf, he was not able to see any object with satisfaction; and he concludes his account with expressing his hopes only, that, as his eyes had been much used to microscopes, they were not injured by the attention he had given to them, though he believed there were few persons who would not have been blinded by it.

The construction of a telescope with six eye-glasses led Mr Euler to a similar construction of microscopes, by introducing into them six lenses, one of which admits of so small an aperture, as to serve, instead of a diaphragm to exclude all foreign light, though, as he says, it neither lessens the field of view, nor the brightness of objects.

The improvement of all dioptric instruments is greatly impeded by inequalities in the substance of the glasses of which they are made; but though many attempts have been made to make glasses without that imperfection, none of them have been hitherto quite effectual. M. A. D. Merklain, having found some glasses which had been melted when a building was on fire, and which proved to make excellent object glasses, for telescopes, concluded that its peculiar goodness arose from its not having been disturbed when it was in a fluid state; and therefore he proposed to take the metal out of the furnace in iron vessels, of the same form that was wanted for the glasses; and after it had been perfectly fluid in those vessels, to let it cool without any disturbance. But this is not always found to answer.

**PART I. THEOREY OF OPTICS.**

This part of the science contains all that hath been discovered concerning the various motions of the rays of light, either through different mediums, or when reflected from different substances in the same medium. It contains also the rationale of every thing which hath been discovered with regard to vision; the optical d. eceptions to which we are liable; and, in short, ought to give the reason of all the known optical phenomena.—The science is commonly divided into three parts, viz. dioptries, which contains the laws of refraction, and the phenomena depending upon them; catoptries, which contains the laws of reflection, and the phenomena which depend on them; and, lastly, chromatics, which treat of the phenomena of colour. But this definition is of no use in a treatise of Optics, as most of the phenomena depend both on refraction and reflection, colour itself not excepted. For this reason though we have given detached articles under the words Dioptries, Catoptries, and Chromatics; we have referred to this place the explanation of the laws of reflection and refraction, by which all optical phenomena may be accounted for.

**Sect. I. Of the properties of Light in general.**

Under the article Light we have given some account of the controversies concerning its nature. The opinions of philosophers may, in general, be arranged under these two: 1. That the phenomena of vision and illumination are produced by the undulations of an elastic fluid, much in the same manner as found is produced by the undulations of air. This opinion was first offered to the public by Des Cartes, and afterwards by Mr Hogkens, and has lately been revived by Mr Euler, who has endeavoured to explain the phenomena upon mechanical principles.—2d. That the phenomena of vision are produced by the motion and action of matter emitted from the living body with immense velocity, moving uniformly in straight lines, and acted on by other bodies; so as to be reflected, refracted, or inflected, in various ways, by means of forces which act on it in the same manner as on other inert matter. Sir Isaac Newton has shown, in the most incontrovertible manner, the total dissimilarity between the phenomena of vision and the legitimate consequences of the undulations of an elastic fluid. All Mr Euler's ingenious and laborious discussions have not removed Newton's objections in the smallest degree. Sir Isaac adopts the vulgar opinion, therefore, making light of the difficulties objected to it, because none of them are inconsistent with the established principles of mechanics, and are merely difficulties of conception to limited faculties like ours. We need not despair of being able to decide, by experiment, which of these opinions is nearest to the truth; because there are phenomena where the result should be sensibly different in the two hypotheses. At present, we shall content ourselves with giving some account of the legitimate consequences of the vulgar opinion as modified by Sir Isaac Newton, viz. that light consists of small particles emitted with very great velocity, and attracted or repelled by other bodies at very small distances.

Every visible body emits or reflects inconceivably small particles of matter from each point of its surface, in straight lines from each point in a luminous space.

That the particles which constitute light are exceedingly small, appears from hence, viz. that if a helix be made through a piece of paper with a needle, rays of light from every object on the farther side of it are capable of passing through it at once without the least confusion; for any one of those objects may as clearly be seen through it, as if no rays passed through it from any of the rest. Further, if a candle is lighted, and there be no obstacle in the way to obstruct the pro-
of light to make any number of angles in their course, it
is impossible for us to make them describe a curve, ex-
cept in one single case, namely, where they pass through
a medium, the density of which uniformly either in-
creases or decreases. This is the case with the light of
the celestial bodies, which passes downwards through
our atmosphere, and likewise with that which is re-
lected upwards through it by terrestrial objects. In
both these cases, it describes a curve of the hyperbolic
kind; but at all other times it proceeds in straight
lines, or in what may be taken for straight lines witho-
out any sensible error.

§ 1. The cause of Refraction, and the law by which
it is performed.

The phenomena of refraction are explained by an
attractive power in the medium through which light
passes, in the following manner: All bodies being en-
dowed with an attractive force, which is extended to
some distance beyond their surfaces; when a ray of
light passes out of a rarer into a denser medium (if this
latter has a greater attractive force than the former, as
is commonly the case), the ray, just before its entrance,
will begin to be attracted towards the denser medium;
and this attraction will continue to act upon it, till
some time after it has entered the medium; and there-
fore, if a ray approaches a denser medium in a direc-
tion perpendicular to its surface, its velocity will be
continually accelerated during its passage through the
space in which that attraction exerts itself; and there-
fore, after it has passed that space, it will move on,
till it arrives at the opposite side of the medium, with
a greater degree of velocity than it had before it en-
tered. So that in this case its velocity only will be al-
tered. Whereas, if a ray enters a denser medium obli-
quely, it will not only have its velocity augmented
thereby, but its direction will become less oblique
to the surface. Just as when a stone is thrown down-
wards obliquely from a precipice, it falls to the surface
of the ground in a direction nearer to a perpendicular
one, than that with which it was thrown from the
hand. From hence we see a ray of light, in passing
out of a rarer into a denser medium, is refracted to-
wards the perpendicular; that is, supposing a line
drawn perpendicularly to the surface of the medium,
through the point where the ray enters, and extended
both ways, the ray in passing through the surface is
refracted or bent towards the perpendicular line; or,
which is the same thing, the line which it describes by
its motion after it has passed through the surface,
makes a less angle with the perpendicular, than the
line it described before. All which may be illustrated
in the following manner.

Let us suppose first, that the ray passes out of va-
cuum into the denser medium ABCD (fig. 3.), and

Plate CCCLIV. that the attractive force of each particle in the medium
is extended from its respective centre to a distance
equal to that which is between the lines AB and EF,
or AB and GH; and let KL be the path described
by a ray of light in its passage towards the denser
medium. This ray, when it arrives at L, will enter the
attractive forces of those particles which lie in AB the
surface of the denser medium, and will therefore cease
to proceed any longer in the right line KL, but will be
deviated from its course by being attracted towards

Plate
Now the line which a ray describes before it enters a denser or a rarer medium, is called the incident ray; that which it describes after it has entered, is the refracted ray.

The angle comprehended between the incident ray and the perpendicular, is the angle of incidence; and that between the refracted ray and the perpendicular, is the angle of refraction.

There is a certain and immutable law or rule, by which refraction is always performed; and that is this: Whatever inclination a ray of light has to the surface of any medium before it enters it, the degree of refraction will always be such, that the proportion between the sine of the angle of its incidence, and that of the angle of its refraction, will always be the same in that medium.

To illustrate this: Let us suppose $ABCD$ (fig. 4) to represent a denser, and $ABEF$ a rarer medium; let $GH$ be a ray of light passing through the first and entering the second at $H$, and let $HI$ be the refracted ray; then suppose the perpendicular $PK$ drawn through the point $H$, on the centre $H$, and with any radius, describe the circle $APBR$; and from $G$ and $I$, where the incident and refracted rays cut the circle, let fall the lines $GK$ and $IL$ perpendicularly upon the line $PR$; the former of these will be the sine of the angle of incidence, the latter of refraction. Now if in this case the ray $GH$ is so refracted at $H$, that $GK$ is double or triple, &c. of $IL$, then, whatever other inclination the ray $GH$ might have had, the sine of its angle of incidence would have been double or triple, &c. to that of its angle of refraction. For instance, had the ray passed in the line $GH$ before refraction, it would have passed in some line as $HN$ afterwards, so situated that $MO$ should have been double or triple, &c. of $NO$.

When a ray passes out of a vacuum into air, the sine of the angle of incidence is found to be to that of refraction as 100036 to 100000.

When it passes out of air into water, as about 4 to 3.

When out of air into glass, as about 17 to 11.

When out of air into a diamond, as about 5 to 2.

This relation of the sine of the angle of incidence to that of refraction, which is a proposition of the most extensive use in explaining the optical phenomena on physical or mechanical principles, may be demonstrated in the following easy and familiar manner.

Lem. I. The augmentations or diminutions of the squares of the velocities produced by the uniform action of accelerating or retarding forces, are proportional to the forces, and to the spaces along which they act, jointly, or are proportional to the products of the forces multiplied by the spaces.

Let two bodies be uniformly accelerated from a state of rest in the points $A$, along the spaces $AB$, $a b$, fig. 5, by the accelerating forces $F$, and let $AC$, $a c$, be spaces described in equal times; it is evident from what has been said under the articles Gravity and Acceleration, that because these spaces are described with motions uniformly accelerated, $AC$ and $ac$ are respectively the halves of the spaces which would be uniformly described during the same time with the velocities acquired at $C$ and $c$, and are therefore

Part I.

therefore measures of these velocities. And as these velocities are uniformly acquired in equal times, they are measures of the accelerating forces. Therefore AC : ac = F : f. Also, from the nature of uniformly accelerated motion, the spaces are proportional to the squares of the acquired velocities. Therefore, (using the symbols \(v, v', x, a, c\), &c. to express the squares of the velocities at C, &c.) we have

\[
\begin{align*}
\sqrt{v} & = \sqrt{v} = AB : AC \\
\sqrt{v} & = \sqrt{v} = CA : ac \\
\sqrt{v} & = \sqrt{v} = \frac{1}{b} = \frac{1}{c} : ab \\
\end{align*}
\]

Therefore, by equality of compound ratios

\[
\sqrt{v} = \sqrt{v} = AB \cdot AC : AB = AB : AB = ab : af,
\]

And in like manner \(\sqrt{v} = \sqrt{v} = AD : ab \cdot ac = AF = AB \cdot x = af = ab \cdot x\); and \(\sqrt{v} = \sqrt{v} = AD : \sqrt{v} = BD \cdot DF = ab \cdot x = af = ab \cdot x\).

Q. E. D.

Corol. If the forces are as the squares inversely, the augmentations or diminutions of the squares of the velocities are equal.

Remark. If DB, ab, be taken extremely small, the products BD \(\cdot\) DF and ab \(\cdot\) x may be called the momentary actions of the forces, or the momentary increments of the squares of the velocities. It is usually expressed, by the writers on the higher mechanics, by the symbol \(\int f = x\), where \(f\) means the accelerating force, and \(x\) or \(d\) means the indefinitely small space along which it is uniformly exerted. And the proposition is expressed by the fluxional equation \(f \cdot s = v\), because \(v = \frac{1}{x}\) the half of the increment of \(v\), as is well known.

Lemma 2. (being the 30th proposition of the first book of Newton's Principia.) If a particle of matter, moving with any velocity along the line AC, be impelled by an accelerating or retarding force, acting in the same or in the opposite direction, and if the intensity of the force in the different points B, H, C, &c. be represented by the ordinates BD, FG, &c. to the line DGE, the areas BFGD, BHKD, &c. will be as the changes made on the square of the velocity at B, when the particle arrives at the points F, H, &c.

For let BC be divided into innumerable small portions, of which let BF be one, and let the force be supposed to act uniformly, or to be of variable intensity during the motion along BH; draw GI perpendicular to HK: It is evident that the rectangle \(\text{FHIG}\) will be as the product of the accelerating force by the space along which it acts, and will therefore express the momentary increment of the square of the velocity. (Lemma 1.) The same may be said of every such rectangle. And if the number of the portions, such as FH, be in reality, and their magnitude diminished without end, the rectangles will ultimately occupy the whole curvilinear area, and the force will be continually varying in its intensity. The curvilinear areas will therefore be as the finite changes made on the square of the velocity, and the proposition is demonstrated.

Corol. The whole change made on the square of the velocity, is equal to the square of that velocity which the accelerating force would communicate to the particle by impelling it along BC from a state of rest in B. For the area TCFD will still express the square of this velocity, and it equally expresses the change made on the square of any velocity whereby the particle may pass through the point B, and is independent of the magnitude of that velocity.

Remark. The figure is adapted to the case where the forces all conpire with the initial motion of the particle, or all oppose it, and the area expresses an augmentation or a diminution of the square of the initial velocity. But the reasoning would have been the same, although, in some parts of the line BC, the forces had been contrary to the initial motion, and in other parts had opposed it. In such a case, the ordinates which express the intensity of the forces must lie on different sides of the abscissa BC, and that part of the area which lies on one side must be considered as negative with respect to the other, and be subtracted from it. Thus, if the forces are represented by the ordinates of the dotted curve line DH, which crosses the abscissa in H, the figure will correspond to the motion of a particle, which, after moving uniformly along AB, is subjected to the action of a variable accelerating force during its motion along BH, and the square of its initial velocity is increased by the quantity BHD; after which it is retarded during its motion along HC, and the square of its velocity in H is diminished by a quantity HCD. Therefore the square of the initial velocity is changed by a quantity BHD—HCD, or HCD—BHD.

This proposition is perhaps the most important in the whole science of mechanics, being the foundation of every application of mechanical theory to the explanation of natural phenomena. No traces of it are to be found in the writings of philosophers before the publication of Newton's Principia, although it is ascribed by John Bernoulli and other detractors from Newton's greatness as an elementary truth, without any acknowledgment of their obligations to its author. It is usually expressed by the equation \(\int f = x\), and \(\int f = x\), \(\int f = x\), i.e. the sum of the momentary actions is equal to the sum of the infinite increment of the square of the velocity.

Plate

PROPOSITION 76

When light passes obliquely into or out of a transparent medium, it is refracted so that the sine of the angle of incidence is to the sine of the angle of incidence as the sine of the angle of refraction is to the sine of the angle of refraction in the constant ratio of the velocity of the refracting light to that of the incident light.

Let ST, KR (fig. 7.), represent two planes (parallel to, and equidistant from, the refracting surface XY) which bound the space in which the light, during its passage, is acted on by the refracting forces, as explained in \(\text{t} 3\). The intensity of the refracting forces being supposed equal at equal distances from the bounding planes, although any number of different distances from them, may be represented by the ordinates \(\text{T} \alpha, \text{n} \beta, \text{p} \xi, \text{r} R\), &c. of the curve \(\alpha b \beta \xi\), of which the form must be determined from observation, and may remain for ever unknown. The phenomena of refracted light show us that it is attracted by the refracting substances at some distances, and repelled at others.

Let the light, moving uniformly in the direction AB, enter the refracting stratum at B. It will not proceed in that direction, but its path will be incurved upwards, while acted on by a repulsive force, Na,
and downwards, while impelled by an attractive force. It will describe some curvilinear path $BdO$ CDE, which $AB$ touches in $B$, and will finally emerge from the refracting stratum at $E$, and move uniformly in a straight line $EF$, which touches the curve in $E$. If, through $b$, the interference of the curve of forces with its abscissa, we draw $b\phi$, cutting the path of the light in $\phi$, it is evident that this path will be concave upwards between $B$ and $\phi$, and concave downwards between $\phi$ and $E$. Also, if the initial velocity of the light has been sufficiently small, its path may be so much bent upwards, that in some point $d$ its direction may be parallel to the bounding planes. In this case it is reflected, making the angle of reflection equal to that of incidence. By which it appears how reflection, refraction, and inflexion, are produced by the same forces and performed by the same laws.

But let the velocity be supposed sufficiently great to enable the light to penetrate through the refracting stratum, and emerge from it in the direction $EF$; let $AB$ and $EF$ be supposed to be described in equal times: They will be proportional to the initial and final velocities of the light. Now, because the refracting forces must act in a direction perpendicular to the refracting surface (since they arise from the joint action of all the particles of a homogenious substance which are within the sphere of mutual action), they cannot affect the motion of the light estimated in the direction of the refracting surface. If, therefore, $AG$ be drawn perpendicular to $ST$, and $FK$ to $KR$, the lines $GB$, $EK$, must be equal, because they are the motions $AB$, $EF$, estimated in the direction of the planes. Draw now $EL$ parallel to $AB$. It is also equal to it. Therefore $EL$, $EF$, are as the initial and final velocities of the light. But $EF$ is to $EL$ as the sine of the angle $ELK$ to the sine of the angle $EFK$; that is, as the sine of the angle $ABH$ to the sine of the angle $FEI$; that is, as the sine of the angle of incidence to the sine of the angle of refraction.

By the same reasoning it will appear that light, moving in the direction and with the velocity $EF$, will describe the path $EDB$, and will emerge in the direction and with the velocity $EB$.

Let another ray enter the refracting stratum perpendicularly at $B$, and emerge at $Q$. Take two points $N$, $P$, in the line $BQ$, extremely near to each other, so that the refracting forces may be supposed to act uniformly along the space $NP$. Draw $NC$, $PD$, parallel to $ST$, $CM$ perpendicular to $DP$, and $MO$ perpendicular to $CD$, which may be taken for a straight line. Then, because the forces at $C$ and $N$ are equal, by supposition they may be represented by the equal lines $CM$ and $NP$. The force $NP$ is wholly employed in accelerating the light along $NP$; but the force $CM$ being transferred to the motion $BD$, is partly so employed, and may be conceived as arising from the joint action of the forces $CO$, $O\phi$, of which $CO$ only is employed in accelerating the motion of the light, while $OM$ is employed in curvating its path. Now it is evident, from the similarity of the triangles $DCM$, $MCO$, that $DC \cdot CM = \text{CM} = \text{NP} \cdot \text{NP}$. But $\text{DC} \cdot \text{CO} \cdot \text{NP} \cdot \text{NP}$ are the products of the spaces by the accelerating forces, and express the momentary increments of the squares of the velocities at $C$ and $N$. (Lemma 1.) These increments, therefore, are equal. And as this must be said of every portion of the paths $BCE$ and $BNQ$, it follows that the whole increment of the square of the initial velocity produced in the motion along $BCE$, is equal to the increment produced in the motion along $BNQ$. And, because the initial velocities were equal in both paths, their squares are equal. Therefore the squares of the final velocities are also equal in both paths, and the final velocities themselves are equal. The initial and final velocities are therefore in a constant ratio, whatever are the directions; and the ratio of the squares of the angles of incidence and refraction being the ratio of the velocities of the refracted and incident light, by the former case of prop. 1. it is also constant.

Remark. The augmentation of the square of the initial velocity is equal to the square of the velocity which a particle of light would have acquired, if impelled from a state of rest at $B$ along the line $BQ$, (Corol. of the Lemma 2.), and is therefore independent on the initial velocity. As this augmentation is expressed by the curvilineal area $a T b n p c R$, it depends both on the intensity of the refracting forces, expressed by the ordinates, and on the space through which they act, viz. $TR$. These circumstances arise from the nature of the transparent substance, and are characteristic of that substance. Therefore, to abbreviate language, we shall call this specific velocity.

This specific velocity is easily determined for any substance in which the refraction is observed, by drawing $Li$ perpendicular to $EL$, meeting in $i$ the circle described with the radius $EF$. For $iE$ being equal to $EF$, will represent the velocity of the refracted light, and $EL$ represents the velocity of the incident light, and $EL^2 = EL^2 + Li^2$, and therefore $Li$ is the augmentation of the square of the initial velocity, and $Li$ is the specific velocity.

It will now be proper to deduce some corollaries from these propositions, tending to explain the chief phenomena of refraction.

1. When light is refracted towards the perpendicular to the refracting surface, it is accelerated; and it is retarded when it is refracted from the perpendicular.

In the first case, therefore, it must be considered as having been acted on by forces conspiring (in part at least) with its motion, and vice versa. Therefore, because we see that it is always refracted towards the perpendicular, when passing from a void into any transparent substance, we must conclude that it is, on the whole attracted by that substance. We must draw the same conclusion from observing, that it is refracted from the perpendicular in its passage out of any transparent substance whatever into a void. It has been attracted backwards by that substance.

This acceleration of light in refraction is contrary to the opinion of those philosophers who maintain, that illumination is produced by the undulation of an elastic medium. Euler attempts to prove, by mechanical laws, that the velocities of the incident and refracted light are proportional to the lines of incidence and refraction, while our principles make them in this ratio.
Part I

case of refraction.

Boscovich proposed a fine experiment
for deciding this question. The aberration of the fixed
flars arises from the combination of the motion of
light with the motion of the telescope by which it is
observed. Therefore this aberration should be greater
or less when observed by means of a telescope filled
with water, according as light moves slower in water
than through air. He was mistaken in the manner in which the conclusion should be drawn
from the observation made in the form prescribed by
him; and the experiment has not yet been made in a
convincing manner; because no fluid has been found
of sufficient transparency to admit of the necessary
magnifying power. It is an experiment of the great-
estic importance to optical science.

2. If the light be moving within the transparent
substance, and if its velocity (estimated in a direction
perpendicular to the surface) do not exceed the specific
velocity of that substance, it will not emerge from
it, but will be reflected backwards in an angle equal
to that of its incidence. For it must be observed, that
in the figure of last proposition, the excess of the
square of $EF$ above the square of $EL$, is the same
with the excess of the square of $KF$ above the square of
$KL$. Therefore the square of the specific velocity
is equal to the augmentation or diminution of the
square of the perpendicular velocity. If therefore the
initial perpendicular velocity $FK$ (fig. 8.) be precisely
equal to the specific velocity, the light will just reach
the farther side of the attracting stratum, as at $B$,
where its perpendicular velocity will be completely
diminished, and its motion will be in the direction $BT$.
But it is here under the influence of forces tending
towards the plane $KR$, and its motion will therefore
be still inerated towards it; and it will describe a
curve $BD$ equal and similar to $EB$, and finally emerge
back from the refracting stratum into the transparent
substance in an angle $RDA$ equal to $KEF$.

If the direction of the light be still more oblique, so
that its perpendicular velocity is less than the specific
velocity, it will not reach the plane $ST$, but be re-
lected as soon as it has penetrated so far that the
specific velocity of the part penetrated (estimated by
the compounding part of the area of forces) is equal
to its perpendicular velocity. Thus the ray $fE$ will
describe the path $EFD$ penetrating to $bd$, so that the
corresponding area of forces $abc$ is equal to the square
of $fE$, its perpendicular velocity.

The extreme brilliancy of dew drops and of jewels
had often excited the attention of philosophers, and
they always appeared a difficulty how light was reflected
at all from the posterior surface of transparent bodies. It
afforded Sir Isaac Newton his strongest argument
against the usual theory of reflection, viz. that it was
produced by impact on solid elastic matter. He was
the first who took notice of the total reflection in great
obliquities; and very properly asked how it can be said
that there is any impact in this case, or that the re-
fleting impact should cease at a particular obli-
quity?

It must be acknowledged that it is a very curious
circumstance, that a body which is perfectly trans-
parent should cease to be so at a certain obliquity; that
a great obliquity should not hinder light from passing
from a void into a piece of glass; but that the same
obliquity should prevent it from passing from the glafs
into a void. The finest experiment for illustrating the
fact is, to take two pieces of mirror-glafts, not filtered,
and put them together with a piece of paper between
them, forming a narrow margin all round to keep
them apart. Plunge this apparatus into water. When
it is held nearly parallel to the surface of the water,
every thing at the bottom of the vessel will be seen
clearly through the glafts; but when they are turned
do as to be inclined about 50 degrees, they will in-
tercept the light as much as if they were plates of iron.
It will be proper to soak the paper in varnish, to pre-
vent water from getting between the glafts.

What is called the brilliant cut in diamonds, is such
dispersion of the posterior facets of the diamond,
that the light is made to fall upon them so obliquely
that none of it can go through, but all is reflected.

To produce this effect in the greatest possible degree,
is a matter of calculation, and merits the attention of
the lapidary. When diamonds are too thin to admit
of this form, they are cut in what is called the rofe-
fashion. This has a plain back, and the facets are all
on the front, and so disposed as to reflect the rays in-
to sufficient obliquities, to be strongly reflected from
the posterior plane. Doublets are made by cutting
one thin diamond rose-fashion, and another similar one
is put behind it, with their plane surfaces joined. Or,
more frequently, the outside diamond has the anterior
facets of the brilliant, and the inner has the form of
the inner part of a brilliant. If they be joined with
very pure and strongly refracting varnish, little light
is reflected from the separating plane, and their brilli-
ancy is very considerable, though still inferior to a
true and deep brilliant. If no varnish be used, much
of the light is reflected from the flat side, and the ef-
fect of the posterior facets is much diminished. But
doublets might be constructed, by making the touch-
ing surfaces of a spherical form (of which the curvature
should have a due proportion to the size of the stone),
that would produce an effect nearly equal to that of
the most perfect brilliant.

3. Since the change made on the square of the velo-
cy of the incident light is a constant quantity, it
follows, that the refraction will diminish as the velo-
cy of the incident light increases. For if $Li$ in
fig. 7 be a constant quantity, and $EL$ be increased, it
is evident that the ratio of $EL$, or its equal $EF$, to
$EL$ will be diminished, and the angle LEF, which
constitutes the refraction, will be diminished. The
physical cause of this is easily seen: When the velocity
of the incident light is increased, it employs less time in
passing through the refracting stratum or space be-
tween the planes ST and KR, and is therefore less in-
fluenced by the refracting forces. A similar effect
would follow if the transparent body were moving
with great velocity towards the luminous body.

Some naturalists have accounted for the different
refrangibility of the differently coloured rays, by sup-
posing that the red rays move with the greatest rapid-
ity, and they have determined the difference of ori-
ignal velocity which would produce the observed dif-
ference of refraction. But this difference would be
observed in the eclipses of Jupiter's satellites. They
should be ruddy at their emersions, and be some sec-
onds before they attain their pure whiteness; and
129
they should become bluish immediately before they vanish in immersions. This is not observed. Besides, the difference in refrangibility is much greater in flint-glass than in crown-glass, and this would require a proportionally greater difference in the original velocities. This explanation therefore must be given up.

It should follow, that the refraction of a star which is in our meridian at six o'clock in the evening should be greater than that of a star which comes on the meridian at six in the morning; because we are moving away from the first, and approaching to the last. But the difference is but 1/36 of the whole, and cannot be observed with sufficient accuracy in any way yet practiced. A form of observation has been proposed by Dr. Blair professor of practical astronomy in the university of Edinburgh, which promises a very sensible difference of observation with sufficient accuracy in any way yet practiced. It should be expected, that a difference will be observed in the refraction of the light from the eastern and western ends of Saturn's ring. Its diameter is about 26 times that of the earth, and it revolves in 10h. 23' 10 so that the velocity of its edge is about 100,000 of the velocity of the sun's light. If therefore the light be reflected from it according to the laws of perfect elasticity, or in the manner here explained, that which comes to us from the western extremity will move more slowly than that which comes from the eastern extremity in the proportion of 2500 to 2401. And if Saturn can be seen distinctly after a refraction of 30° through a prism, the diameter of the ring will be increased one half in one position of the telescope, and will be as much diminished by turning the telescope half round its axis; and an intermediate position will exhibit the ring of a distorted shape. This experiment is one of the most interesting to optical science, as its result will be a severe touchstone of the theories which have been attempted for explaining the phenomena on mechanical principles.

If the tail of a comet be impelled by the rays of the sun, as is with great probability supposed by Euler and others, the light by which its extreme parts are seen by us must have its velocity greatly diminished, being reflected by particles which are moving away from the sun with immense velocity. This may perhaps be discovered by its greater aberration and refrangibility.

As common daylight is nothing but the sun's light reflected from terrestrial bodies, it is reasonable to expect that it will suffer the same refraction. But nothing but observation could assure us that this would be the case with the light of the stars; and it is rather surprising that the velocity of their light is the same with that of the sun's light. It is a circumstance of connection between the solar system and the rest of the universe. It was as little to be looked for on the light of terrestrial luminaries. If light be conceived as small particles of matter emitted from bodies by the action of accelerating forces of any kind, the vast diversity which we observe in the constitution of sublunary bodies should make us expect differences in this particular. Yet it is found, that the light of a candle, of a low-worm, &c. suffers the same refraction, and consists of the same colours. This circumstance is adduced as an argument against the theory of emulsion. It is thought more probable that this sameness of velocity is owing to the nature of the medium, which determines the frequency of its undulations and the velocity of their propagation.

4. When two transparent bodies are contiguous, the light in its passage out of the one into the other will be refracted towards or from the perpendicular, according as the refracting forces of the second are greater or less than those of the first, or rather according as the area expressing the square of the specific velocity is greater or less. And as the difference of these areas is a determined quantity, the difference between the velocity in the medium of incidence and the velocity in the medium of refraction, will also be a determined quantity. Therefore the sine of the angle of incidence will be in a constant ratio to the sine of the angle of refraction; and this ratio will be compounded of the ratio of the sine of incidence in the first medium to the sine of refraction in a void; and the ratio of the sine of incidence in a void to the sine of refraction in the second medium. If therefore a ray of light, moving through a void in any direction, shall pass through any number of media bounded by parallel planes, its direction in the last medium will be the same as if it had come into it from a void.

5. It also follows from these propositions, that if the obliquity of incidence on the posterior surface of a transparent body be such, that the light should be reflected back again, the placing a mass of the same or another medium in contact with this surface, will change its refraction, and this the more completely, as the added medium is more dense or more refractive; and the reflection from the separating surface will be the more vivid in proportion as the posterior substance is less dense or of a smaller refractive power. It is not even necessary that the other body be in contact; it is enough if it be so near that those parts of the refracting frusta which are beyond the bodies interfere with or coincide with each other.

All these conceptions are agreeable to experience. The brilliant reflection from a dew drop seems when it touches the leaf on which it rests: The brilliancy of a diamond is greatly damaged by fibre getting behind it; The opacity of the combined mirror plates mentioned in the second corollary, is removed by letting water pass between them: A piece of glass is distinctly or clearly seen in air, more faintly when immersed in water, still more faintly amidst oil of olives, and it is hardly perceived in spirits of turpentine. These phenomena are incompatible with the notion that reflection is occasioned by impact on solid matter, whether of the transparent body, or of any other or other fancied fluid behind it; and their perfect coincidence with the legitimate consequences of the affumed principles is a strong argument in favour of the truth of those principles.

It is worth while to mention here a fact taken notice of by Dr. Beguelin, and proposed as a great difficulty in the Newtonian theory of refraction. In order to get the greatest possible refraction, and the dimplest measure of the refracting power at the anterior surface of any transparent substance, Sir Isaac Newton enjoins us to employ a ray of light falling on the surface quam obliquius. But Mr Beguelin found, that when the obliquity of incidence in glass was about
OPTICS

Part I.

89° 30' no light was refracted, but that it was wholly reflected. He also observed, that when he gradually increased the obliquity of incidence on the posterior surface of the plate, the light which emerged last of all did not skim along the surface, making an angle of 90° with the perpendicular, as it should do by the Newtonian theory, but made an angle of more than ten minutes with the posterior surface. Also, when he began with very great obliquities, so that all the light was reflected back into the glass, and gradually diminished the obliquity of incidence, the first ray of light which emerged did not skim along the surface, but was refracted about 10 or 15 minutes.

But all these phenomena are necessary consequences of our principles, combined with what observation teaches us concerning the forces which bodies exert on the rays of light. It is evident, from the experiments of Grimaldi and Newton, that light is both attracted and repelled by solid bodies. Newton's sagacious analysis of these experiments discovered several alterations of actual infection and deflection; and he gives us the precise distance from the body when some of these attractions end and repulsion commences; and the most remote action to be observed in his experiments is repulsion. Let us suppose this to be the case, although it be not absolutely necessary. Let us suppose that the forces are represented by the ordinates of a curve **abnpe** (see fig. 7.) which crosses the abscissa in b. Draw be parallel to the refracting surface. When the obliquity of incidence of the ray AB has become so great, that its path in the glass, or in the refracting stratum, does not cut, but only touches the line ob, it can penetrate no further, but is totally reflected; and this will happen in all greater obliquities. On the other hand, when the ray LE, moving within the glass, has but a very small perpendicular velocity, it will penetrate the refracting stratum no further than till this perpendicular velocity is extinguished, and its path becomes parallel to the surface, and it will be reflected back. As the perpendicular velocity increases by diminishing the obliquity of incidence, it will penetrate farther; and the last reflection will happen when it penetrates so far that its path touches the line ob. Now diminish the obliquity by a single second; the light will get over the line ob, will describe an arch of B concave upwards, and will emerge in a direction BA, which does not skim the surface, but is feebly raised above it. And thus the facts observed by M. Beguelin, instead of being an objection against this theory, afford an argument in its favour.

7. Those philosophers who maintain the theory of undulation, are under the necessity of connecting the divergent powers of bodies with their mean refractive powers. Mr Euler has attempted to deduce a necessary difference in the velocity of the rays of different colours from the different frequency of the undulations, which he aligns as the cause of their different colorific powers. His reasoning on this subject is of the most delicate nature, and unintelligible to such as are not completely master of the infinitesimal calculus of partial differences, and is unsatisfactory to such as are able to go through its intricacies. It is contradicted by fact. He says, and indeed to be confident he must say it, that musical sounds which differ greatly in acuteness are propagated through the air with different velocities: but one of the smallest bells in the chimneys of St. Giles church in Edinburgh was struck against the rim of the very deep-tuned bell on which the hours are struck. When the sound was listened to by a wise observer at the distance of more than two miles, no interval whatever could be observed. A similar experiment was exhibited to Mr Euler himself, by means of a curious musical instrument (if it can be so called) fixed at St. Peterburg, and which may be heard at three or four miles distance. But the experiment with the bells is unquestionable, as the two sounds were produced in the very same instant. This connection between the refrangibility in general and the velocity must be admitted, in its full extent, in every attempt to explain refraction by undulation; and Euler was forced by it to adopt a certain consequence which made a necessary connection between the mean refraction and the dispersion of heterogeneous rays. Confident of his analysis, he gave a deaf ear to all that was told him of Mr Dollond's improvements on telescopes, and asserted, that they could not be such as were related; for an increase of mean refraction must always be accompanied with a determined increase of dispersion. Newton had said the same thing, being misled by a limited view of his own principles; but the dispersion assigned by him was different from that assigned by Euler. The dispute between Euler and Dollond was confined to the decision of this question only; and when some glasses made by a German chemist at St. Peterburg convinced Euler that his determination was erroneous, he had not the candour to give up the principle which had forced him to this determination of the dispersion, but immediately introduced a new theory of the achromatic telescopes of Dollond; a theory which took the artists out of the track marked out by mathematicians, and in which they had made considerable advances, and led them into another path, proposing maxima of constitution hitherto untried, and inconsistent with real improvements which they had already made. The leading principle in this theory is to arrange the different ultimate images of a point leads which arise either from the errors of a spherical figure or different refrangibility, in a straight line passing through the centre of the eye. The theory itself is new, and it being evident, that it requires great mathematical skill to accomplish this point, and hardly less to decide on the propriety of the constitution which it recommends. It is therefore but little known. But that it is a false theory, is evident, from one simple consideration. In the most indistinct vision arising from the worst constitution, this reducible arrangement of the images obtains completely in that pencil which is situated in the axis, and yet the vision is indistinct. But, what is to our present purpose, this new theory is purely mathematical, suiting any observed dispersive power, and has no connection with the physical theory of undulations, or indeed with any mechanical principles whatever. But, by admitting any dispersive power, whatever may be the mean refraction, all the physical doctrines in his *Novo Theoria Lucis et Colorum* are overlooked, and therefore never once mentioned, although the effects of Mr Zeuner's glasses are taken notice of as inconsistent with that mechanical propo-
They are indeed inconsistent with the universality of
that proposition. Newton advances it in his optics
merely as a mathematical proposition highly pro-
bable, but says that it will be corrected if it shall
fail. The ground on which he seems (for he does
not expressly say so) to refer it is probability is a
limited view of his own principle, the action of bodies
on light. He (not knowing any cause to the contrary)
supposed that the action of all bodies was similar on
the different kinds of light, that is, the specific
velocities of the differently coloured rays had a de-
determined proportion to each other. This was gratui-
tious; and it might have been doubted by him who
had observed the analogy between the chemical ac-
tions of bodies by elective attractions and repulsions,
and the similar actions on light. Not only have dif-
ferent menstrua unequal actions on their solids, but
the order of their affinities is also different. In like
manner, we might expect not only that some bodies
would attract light in general more than others, but
also might differ in the proportion of their actions on
the different kinds of light, and this so much, that
some might even attract the red more than the violet.
The late discoveries in chemistry show us some very
difficult proofs, that light is not exempted from the
laws of chemical action, and that it is susceptible of
chemical combination. The changes produced by
the sun's light on vegetable colours, show the necessity
of illumination to produce the green fucula; and
the aromatic oils of plants, the irritability of their leaves
by the action of light, the curious effects of it on the
mineral acids, on manganese, and the caleys of bit-
muth and lead, and the imbibing and subseque-
taneous emulsion of it by phosphorecent bodies, are strong
proofs of its chemical affinities, and are quite inex-
plicable on the theory of undulations.
All these considerations taken together, had they
been known to Sir Isaac Newton, would have made
him expect differences quite anomalous in the dife-
ferent powers of different transparent bodies; at the same
time that they would have afforded to his sagacious
mind the strongest arguments for the actual emission
of light from the luminous body.

Having in this manner established the observed law
of refraction on mechanical principles, showing it to be
a necessary consequence of the known action of bo-
dies on light, we proceed to trace its mathematical con-
sequences through the various cases in which it may be
exhibited to our observation. These constitute that
part of the mathematical branch of optical science which
is called spectrums.

We are quite unacquainted with the law of action
of bodies on light, that is, with the variation of the
intensity of the attractions and repulsions exerted at
different distances. All that we can say is, that from
the experiments and observations of Grimaldi, New-
ton, and others, light is decreed towards a body or
is attracted by it, at some distances, and repelled at
others, and this with a variable intensity. The action
may be extremely different, both in extent and
force, in different bodies, and change by a very dif-
ferent law by the same change of distance. But,

amidst all this variety, there is a certain similarity ar-
ing from the joint action of many particles, which
should be noticed, because it tends both to explain
the similarity observed in the refractions of light, and also
its connection with the phenomena of reflection.

The law of variation in the joint action of many par-
ticles adjoining to the surface of a refracting medium,
is extremely different from that of a single particle;
but when this last is known, the other may be found out.
We shall illustrate this matter by a very simple cafe. Let
DE (fig. 9.) be the surface of a medium, and let us
suppose that the action of a particle of the medium
on a particle of the light extends to the distance EA,
and that it is proportional to the ordinate ED, Ff, Gg,
Hh, &c. of the line AB CG D; that is, that the action
of the particle E of the medium on a particle of light
in F, is to its action on a particle in H as Ff to Hh,
and that it is attracted at F but repelled at H, as ex-
spected by the situation of the ordinates with respect to
the abscissae. In the line AE produced to B, make
EB, Bx, Ex, Ey, E%, &c. respectively equal to EA,
EH, EC, EG, EF, &c.

It is evident that a particle of the medium at B will
exert no action on the particle of light in E, and that
the particles of the medium in E9, E9, will exert on
its actions proportional to Hh, Gg, Ff, ED. There-
fore, supposing the matter of the medium continuous,
the whole action exerted by the row of particles EB
will be represented by the area AECDE; and the ac-
tion of the particles between B and E will be repre-
sented by the area AECF, and that of the particles be-
 tween E and E will be represented by the area EFD.

Now let the particle of light be in F, and take
Fo = AE. It is no les evident that the particle of
light in F, will be acted on by the particles in E alone,
and that it will be acted on in the same manner as a
particle in E is acted on by the particle in St. There-
fore the action of the whole row of particles EB on a
particle in F will be represented by the area AEC/F.
And thus the action on a particle of light in any point
of AE will be represented by the same area which lies
beneath it.

But let us suppose the particles of light to be with-
in the medium, as at E, and make go = AE. It is
again evident that it is acted on by the particles of
the medium between E and D with a force repre-
sented by the area AECDE, and in the opposite direc-
tion by the particles in E, with a force repre-
sented by the area EFD. This balances an
equal quantity of action, and there remains an action
experienced by the area AEC/F. Therefore, if an equal
and similar line to AECDE be described on the abscissa
EB, the action of a medium on the particle of light
in E will be represented by the area EAC/F, lying be-

If we now draw a line AKLMNPC whole ordinates
CK, Fig. 9. &c. are as the areas of the other
curve, diminished from A and B; these ordinates will
represent the whole forces which are exerted by the
particles in EB, on a particle of light moving from A
to B. This curve will cut the axis in points L, N,
fich, that the ordinates drawn through them inter-
cept areas of the first curve, which are equal each of
the other, and in these points the particle of light
fulfills no action from the medium. These points are
very

OPTICS.

Plate CCCLV.

Law of refraction in plane surfaces.

Lemma. The indefinitely small variation of the angle of incidence is to the simultaneous variation of the angle of refraction as the tangent of the angle of incidence is to the tangent of the angle of refraction; and as the cotemporaneous variations of the angles of incidence and refraction are proportional to the tangents of the angles of incidence.

Let RVF, rVF (fig. 10) be the progress of the rays refracted at V (the angle rVR being considered in its nacent or evanent plane), and VF perpendicular to the refracting surface VA. From C draw CD, CB perpendicular to the incident and refracted rays RV, VF, cutting rV, rVF in & and b, and let CD, CB be perpendicular to rV, rVF.

Because the lines of incidence and refraction are in a constant ratio, their simultaneous variations are in the same constant ratio. Now the angle RVR is the angle FVF in the ratio of B to D; that is, of BC to BV, or the tangent of the angle of incidence.

tan. incid. : tan. refr. ; that is, of
fin. incid. : fin. refr. ; that is, of
cot. incid. : cot. refr.

Corollary. The difference of these variations is to the greatest of them as the difference of the tangents to the greatest or least tangent.

PROBLEM.

Let two rays RV, RP diverge from, or converge to, a point R (figs. 1, 2, 3, 4), and pass through the plane surface PV separating two refracting mediums AB, of which let B be the most refracting, and let RV be perpendicular to the surface. It is required to determine the point of divergence or convergence, F, of the refracted rays VP, PD.

Make VR to VG as the sine of refraction to the sine of incidence, and draw GIK parallel to the surface, cutting the incident ray in I. About the centre P, with the radius PI, describe an arch of a circle IF, cutting VR in F; draw PE tending from or towards F. We say PE is the refracted ray, and F the point of divergence or convergence of the rays RV, RP, or the conjugate focus to R.

For since GI and PV are parallel and PF equal to PI, we have PF : PR = PI : PR, = fin. incid. : sin. refr. But PF : PR = sin. PRV : sin. PFV, and RRV is equal to the angle of incidence at P; therefore PFV is the corresponding angle of refraction, FPE is the refracted ray, and F the conjugate focus to R.

Corol. 1. If diverging or converging rays fall on the surface of a more refracting medium, they will diverge or converge less after refraction, F being farther from the surface than R. The contrary must happen when the diverging or converging rays fall on the surface of a less refracting medium, because, in this case, F is nearer to the surface than R.

Corol. 2. Let RP be another ray, more oblique than RP, the refracting point R being farther from V, and let PR be the refracted ray determined by the same construction. Because the arches PI, PII, are perpendicular to their radii, it is evident that they will converge to some point within the angle RIIK, and therefore will not cross each other between F and I; therefore Rf will be greater than RF, as RF is greater than RG, for similar reasons.

Hence it follows that all the rays which tended from or towards R, and were incident on the whole of VP, will not diverge from or converge to F, but will be diffused over the line GF. This diffusion is called aberration from the focus, and is so much greater as the rays are more oblique. No rays flowing from or towards R will have point of concourse with RV nearer to R than F is; but if the obliquity be inconsiderable, so that the ratio of RP to RF does not differ sensibly from that of RV to VF, the point of concourse will not be sensibly removed from G. G is therefore usually called the conjugate focus to R. It is the conjugate focus of an infinitely slender pencil of rays falling perpendicularly on the surface. The conjugate focus of an oblique pencil, or even of two oblique rays, whole division on the surface is considerable, is of more difficult investigation. See Gravefand's Natural Philosophy for a very neat and elementary determination (s).

In a work of this kind, it is enough to have pointed out in an easy and familiar manner, the nature of optical aberration. But as this is the chief cause of the imperfection of optical instruments, and as the only method of removing this imperfection is to diminish this aberration, or correct it, by a subsequent inclination in the opposite direction, we shall here give a fundamental and very simple proposition, which will (with obvious alterations) apply to all important cases. This is the determination of the focus of an infinitely slender pencil of oblique rays RP, R.

"Retaining the former construction for the ray PF, (fig. 1.) suppose the other ray RP infinitely near to RP. Draw PS perpendicular to PV, and R perpendicular to RP, and make PR : PS = RV : VF. On PR describe the semicircle RRP, and on PS the semicircle SP, cutting the refracted ray PF in q, draw pr, ps, pq."

It follows

(s) We refer to Gravefande, because we consider it as of importance to make such a work as ours serve as a general index to science and literature. At the same time we take the liberty to observe, that the focus in question is virtually determined by the construction which we have given for the points P, F of the line PF are determined, and therefore its position is also determined. The same is true of the position of PF, and therefore the intersection of the two lines is likewise determined.
follows from the lemma, that if \( \phi \) be the focus of refracted rays, the variation \( P\phi \) of the angle of refraction is to the corresponding variation \( P\alpha \) of the angle of incidence as the tangent of the angle of refraction \( VFP \) to the tangent of the angle of incidence \( VRP \). Now \( P\phi \) may be considered as coinciding with the arch of the semicircle. Therefore the angles \( P\phi, P\alpha, \) are equal, as also the angles \( P\phi, P\phi, \) \( P\phi, \) But \( P\phi \) is to \( P\alpha \) as \( P \) to \( PS \); that is, as \( VR \) to \( VF \); that is, as the cotangent of the angle of incidence to the cotangent of the angle of refraction; that is, as the tangent of the angle of refraction to the tangent of the angle of incidence. Therefore the point \( \phi \) is the focus.

**Of Refraction by Spherical Surfaces.**

**General Problem.**

To find the focus of refracted rays, the focus of incident rays being given.

Let \( PV \) (figs. 5, 6, 7, 8, 9, 10, 11, 12, 13, 14,) be a spherical surface whose centre is \( C \), and let the incident light diverge from or converge to \( R \).

**Solution.** Draw the ray \( RC \) through the centre, cutting the surface in the point \( V \), which we shall denominate the *vertex*, while \( RC \) is called the *axis*. This ray passes on without refraction, because it coincides with the perpendicular to the surface. Let \( RP \) be another incident ray, which is refracted at \( P \), draw the radius \( PC \). In \( RP \) make \( RE \) to \( RP \) as the line of incidence \( m \) to the line of refraction \( n \); and about the centre \( R \), with the distance \( RE \), describe the circle \( EK \), cutting \( PC \) in \( R \); draw \( RK \) and \( PF \) parallel to it, cutting the axis in \( F \). \( PE \) is the refracted ray, and \( F \) is the focus.

For the triangles \( RFC \), \( KCR \), \( CPF \) are similar, and the angles at \( P \) and \( K \) are equal. Also \( PK \) is equal to \( PE \), and \( RPD \) is the angle of incidence. Now \( m : n = PK : PE = \sin DPR : \sin RKP = \sin DPR : \sin CPF \). Therefore \( CPF \) is the angle of refraction corresponding to the angle of incidence \( RPD \), and \( PF \) is the refracted ray and \( F \) the focus. Q.E.D.

**Cor. 1.** \( CK : CP = CR : CF \), and \( CF = \frac{CP \times CR}{CK} \)

Now \( CP \times CR \) is a constant quantity; and therefore \( CF \) is reciprocally as \( CK \), which evidently varies with a variation of the arch \( VP \). Hence it follows, that all the rays flowing from \( R \) are not collected at the conjugate focus \( F \). The ultimate situation of the point \( F \), at the point \( P \) gradually approaches to, and at last coincides with, \( V \), is called the *conjugate focus of central rays*, and the distance between this focus and the focus of a lateral ray is called the *aberration* of that ray, arising from the spherical figure.

There are, however, two situations of the point \( R \) such, that all the rays which flow from it are made to diverge from one point. One of those is \( C \) (fig. 5), because they all pass thro' without refraction, and therefore still diverge from \( C \); the other is when rays in the rare medium with a convex surface flow from a point \( R \), situated beyond the centre that \( CV \) is to \( CR \) as the sine of incidence in a rare medium is to the sine of refraction in the denser, or when rays in the rare medium fall on the convex surface of the denser, converging to \( F \), so situated that \( CV : CR = m : n \). In this case they will all be dispersed from refraction.

**N.B.** When \( m \) is less than \( n \), \( m-n \) is a negative quantity.—Also observe, that in applying symbols to this computation of the focal distances, those lines are to be accounted positive which lie from their beginnings, that is, from the vertex or the centre, or the radiant point, in the direction of the incident rays. Thus when rays diverge from \( R \) on the convex surface of a medium, \( V \) is accounted negative and \( VC \) positive. If the light passes out of air into glasses, \( m \) is greater than \( n \); but if it passes out of glasses into air, \( m \) is less than \( n \). If, therefore, parallel rays fall on the convex surface of glasses out of air, in which case \( m : n = 2 \) very nearly, we have for the principal focal distance \( \frac{3}{2} VC \), or \( +3 VC \). But if it passes out of glasses into a convex surface of air, we have \( VO = -2 VC \), or \( -2 VC \); that is, the focus \( O \) will be in the same side of the surface with the incident light. In like manner, we shall have for these two cases \( CO = +2 VC \) and \( -3 VC \).
The refraction point, being expressed by the symbol $r$, the distance of the focus of refracted rays by the symbol $f$, and the radius of the spherical surface by $a$; we have

$$mr - nr - a = m petition of parallel rays coming from the opposite side, we shall have $Q = a$.

If $Q = a$, the focus of the parallel rays lying in the same plane as $Q = a$, we have $Q = a = m$. And when the point $P$ coincides with the point $V$, $q$ must coincide with $Q$, and we have $Q = a = m$. This is the most general optical theorem, and is applied equally to lenses, or even to a combination of them, as to simple surfaces. It is also applicable to reflections, with this difference, that $Q$ is to be supposed the focus of parallel rays coming with the plane of the incident rays. It affords us the most comprehensive methods of computing symbolically and arithmetically the focal distances in all cases.

6. We have also $Q = a$.

7. There are four points $Q$, $C$, $F$, and $R$, either of them all one way from $Q$, or two of them coming from two backward.

8. Also, adding $Q$, $C$, $F$, and $R$, either of them all one way from $Q$, or two of them coming from two backward.

9. From this construction we may also derive a very easy and expeditious method of drawing many refracted rays. Draw through the centre $C$ (fig. 15, 16.) a line to the point of incidence $P$, and a line $C A$ parallel to the incident ray $RP$. Draw $QV$ parallel to $VC$ as the line of incidence to the plane of illumination, and about $A$ with the radius $QV$, describe an arc of a circle cutting $PC$ produced in $B$. Join $AB$; and $PF$ parallel to $AB$ is the refracted ray. When the incident light is parallel to $RC$, the point $A$ coincides with $V$, and a circle described round $V$ with the distance $QV$ will cut the lines $PC$, $QV$. $QV$. The demonstration is evident.

Having thus determined the focal distance of refracted rays, it will be proper to point out a little more particularly its relation to its conjugate focus of incident rays. We shall consider the four cases of this theorem.

1. Let light moving in air fall on the convex surface of a glass (fig. 4, to fig. 14.). Let $Q$, suppose it tending to a point beyond the glass infinitely distant. It will be collected to its principal focus $O$ beyond the vertex $V$. Now let the incident light converge a little, so that $R$ is at a great distance beyond the surface. The focus of refracted rays $F$ will be a little within $O$ or nearer to $V$. As the incident rays are made to converge more and more, the point $R$ comes nearer to $V$, and the point also approaches $R$, but with a much slower motion, being always situated between $O$ and $C$ till it is overtaken by $R$ at the centre $C$, when the incident light is perpendicular to the surface in every point, and therefore suffers no refraction. As $R$ has overtaken $O$, it now passes it, and is again overtaken by it at $V$. Now the point $R$ is on the side from which the light comes, so is, the rays diverge from $R$. After refraction they will diverge from $F$ a little without $R$; and as $R$ recedes farther from $V$, $F$ recedes still farther, and with an accelerated motion, till, when $R$ comes to $Q$, $F$ has gone to an infinite distance, or the refracted rays are parallel. When $R$ is recedes, $F$ now appears on the other side, or beyond $V$; and as $R$ recedes back to an infinite distance, $F$ has come to $O$, and this completes the series of variations, the motion of $F$ during the whole changes of situation being in the same direction with the motion of $R$.

2. Let the light moving in air fall on the convex surface of a glass; and let us begin with parallel incident rays, conceiving, as before, $Q$ to lie beyond the glass at an infinite distance. The refracted rays will move as if they came from the principal focus $O$, lying on that side of the glass from which the light comes. As the incident rays are made gradually more diverging, and the point of convergence $R$ comes toward the glass, the conjugate focus $F$ moves backward from $O$; the refracted rays growing less diverging, till the point $R$ comes to $Q$, the principal focus on the other side. The refracted rays are now parallel, or $F$ has retrograded to an infinite distance. The incident light converging still more, or $R$ coming between $Q$ and $V$, $F$ will appear on the other side, or beyond the surface; and the gaufs, and will approach it with a retarded motion, and finally overtake $R$ at the surface of the glass. Let $R$ continue its motion backwards (for it has all the while been moving backwards, or in a direction contrary to that of the light); that is, let $R$ now be a radiant point, moving backwards from the surface of the glass. $F$ will at first be without it, but will be overtaken by it at the centre $C$, when the rays will suffer no refraction. $R$ still receding, will get without $F$; and while $R$ recedes to an infinite distance, $F$ will recede to $O$, and the series will be completed.

3. Let the light moving in air fall on the convex surface of the air; that is, let it come out of the concave surface of the glass, and let the incident rays be parallel, or tending to $R$, infinitely distant; they will be diffracted by refraction from the principal focus $O$ within the glass. As they are made more converging, the ray $R$ comes nearer, and $F$ retreats backward, till $R$ comes to $O$. This will complete the series of variations.
To find the focus of parallel rays falling almost perpendicularly upon any given lens.

Let E be the centre of the lens, R and r the centres of its surfaces, Re its axis, gEG a line parallel to the principal focus of parallel incident rays upon the surface B, whose centre is R. Parallel to gE draw a semidiameter BR, in which produced let V be the focus of the rays after their first refraction at the surface B, and joining VR, let it cut gE upon any produced in G, and G will be the focus of the rays that emerge from the lens.

For since V is also the focus of the rays incident upon the second surface A, the emergent rays must have their focus in some point of that ray which passes straight through this surface; that is, in the line Vr drawn through its centre r; and since the whole course of another ray is reckoned a straight line gEG, its focus determined by the intersections G with Vr, and G & Vr determines the focus of them from Lem. iii. Q. E. D.

Corol. 1. When the incident rays are parallel to the axis rR, the focal distance EF is equal to EG. For let the incident rays which were parallel to gE be gradually more inclined to the axis till they become parallel to it; and their first and second focuses V and G will describe circular arches VS and GF whose centres are R and E. For the line RV is invariable; being in proportion to RB in a given ratio of the deference of the lines of incidence and refraction to their deference; consequently the line EG is also invariable, being in proportion to the given line RV in the given ratio of ER to RV, because the triangles ERG and VRF are equiangular.

Corol. 2. The last proportion gives the following rule for finding the focal distance of any thin lens. As RV, the interval between the centres of the surfaces, is to rE, the semidiameter of the second surface, so is RV or RT, the continuation of the first semidiameter to the first focus, to EG or EF, the focal distance of the lens; which, according as the lens is thicker or thinner in the middle than at its edges, must lie on the
Part I.

Of Glases, the same side as the emergent rays, or on the opposite side.

Corol. 1. Hence when rays fall parallel on both sides of any lens, the focal distances EF, Ef are equal. For let rt be the continuation of the semidiameter Er to the first focus t of rays falling parallel upon the surface A; and the same rule that gave rR to E as RT to EF, gives also rR to RE as rt to Ef. Whence EF and Ef are equal, because the rectangles under rE, RT and also under RE, rt are equal. For rE is to rt and also RE to rt in the same given ratio.

Corol. 4. Hence in particular in a double convex or double-concave lens made of glass, it is as the sum of their semidiameters (or in a meniscus as their difference) to either of them, so is double the other, to the focal distance of the glass. For the continuations RT, rt are severally double their semidiameters; because in glass Et is to TR and also Et to tr as 3 to 2.

Corol. 5. Hence if the semidiameters of the surfaces of the glass be equal, its focal distance is equal to one of them; and is equal to the focal distance of a plano-convex or plano-concave glass whose semidiameter is as short again. For considering the plane surface as having an infinite semidiameter, the ratio of the last mentioned proportion may be reckoned a ratio of equality.

PROPOSITION II.

The focus of incident rays upon a single surface, spheric, or lens being given, it is required to find the focus of the emergent rays.

Let any point Q be the focus of incident rays upon a spherical surface, lens, or sphere, whose centre is E; and let other rays come parallel to the line EQ in the contrary way to the given rays, and after refraction let them belong to a focus F; then taking EF equal to EF in the lens or sphere, but equal to FC in the single figure, say as QF to FE fo Ef to fj; and placing fj the contrary way from f to that of FQ from F, the point q will be the focus of the refracted rays, without sensible error; provided the point Q be not too remote from the axis, nor the surfaces too broad, as to cause any of the rays to fall too obliquely upon them.

For from the centre E and semidiameters EF and EF describe two arcs EF, Ej cutting any ray QAQ in G and g, and draw EG and Eg. Then supposing G to be a focus of incident rays (as GA), the emergent rays (as agq) will be parallel to GE; and on the other hand supposing G another focus of incident rays (as ga), the emergent rays (as AGQ) will be parallel to gE. Therefore the triangles QGE, Egg are equiangular, and consequently QG is to GE as Eg to gj that is, when the ray QAQ is the nearest to QEG, QG is to FE as Ef to fj. Now when Q ascends to F and coincides with it, the emergent rays become parallel, that is qcedes to an infinite distance; and consequently when Q passes to the other side of F, the focus q will also pass through an infinite space from one side of f to the other side of it. Q. E. D.

Corol. 1. In a sphere or lens the focus q may be found by this rule: As QF to EQ fo EQ to Qg, to be placed the same way from Q as QF lies from Q. Let the incident and emergent ray QA, qa be produced till they meet in e; and the triangles QGE, Of GfE, Qeq being equiangular, we have QG to EQ as Qr to Qg; and when the angles of their triangles are vanishing, the point r will coincide with E; because in the sphere the triangle Aac is equiangular at the base Ace, and consequently Aec and ar will at last become semidiameters of the sphere. In a lens the thickness Ac is inconsiderable.

The focus may also be found by this rule: — QF : FE : : QE : Eq, for QG : GE : QA : Ag. And then the rule formerly demonstrated for single surfaces holds good for the lenses.

Corol. 2. In all cases when the distance fj varies reciprocally as FQ does; and they lie contrarywise from f and F; because the rectangle or the square under EF and Ef, the middle terms in the foregoing proportions, is invariable.

The principal focal distance of a lens may not only be found by collecting the rays coming from the sun, considered as parallel, but also (by means of this proposition) it may be found by the light of a candle or window. For, because Qg : QA : : QE : Eq, we have (when A coincides with E) Qg : : QE : Eq; that is, the distance observed between the radiant object and its picture in the focus is to the distance of the lens from the focus as the distance of the lens from the radiant is to its principal focal distance. Multiply therefore the distances of the lens from the radiant and focus, and divide the product by their sum.

Corol. 3. Convex lenses of different shapes that have equal focal distances, when put into each other's places, have equal powers upon any pencil of rays to refract them to the same focus. Because the rules abovementioned depend only upon the focal distance of the lens, and not upon the proportion of the semidiameters of its surfaces.

Corol. 4. The rule that was given for a sphere of an uniform density, will serve also for finding the focus of a pencil of rays refracted through any number of concentric surfaces, which intersect uniform mediums of any different densities. For when rays come parallel to any line drawn through the common centre of those mediums, and are refracted through them all, the distance of their focus from that centre is invariable, as in a uniform sphere.

Corol. 5. When the focuses Q, q lie on the same side of the refracting surfaces, if the incident rays flow from Q, the refracted rays will also flow from q; and if the incident rays flow towards Q, the refracted will also flow towards q: and the contrary will happen when Q and q are on contrary sides of the refracting surfaces. Because the rays are continually going forwards.

From this proposition we also derive an easy method of drawing the progress of rays through any number of lenses ranged on a common axis.

Let A, B, C, (fig. 7) be the lenses, and RA a ray incident on the first of them. Let a, b, c be their foci for parallel rays coming in the opposite direction; draw the perpendicular ad, cd, cutting the incident ray in d, and draw da through the centre of the lens: AB parallel to da will be the ray refracted by the first lens. Through b the focus of the second lens draw the perpendicular be, cutting AB in o o 2.
OPTICS.

Part I.

§ 3. Of Vision.

Having described how the rays of light, flowing from objects, and passing through convex glasses, are collected into points, and form the images of the objects; it will be easy to understand how the rays are affected by passing through the humours of the eye, and are thereby collected into innumerable points on the bottom of the eye, and thereon form the images of the objects which they flow from. For, the different humours of the eye, and particularly the crystalline humour, are to be considered as a convex glass; and the rays in passing through them to be affected in the same manner as in passing through a convex glass. A description of the coats and humours, &c. has been given at large in Anatomy; but for the reader's convenience in this place, we shall repeat in a few words as much of the description as will be sufficient for our present purpose.

The eye is nearly globular. It consists of three coats and three humours. The part D H H G of the outer coat, is called the sclerotic; the rest, D E F P G, the cornea. Next within this coat is that called the choroides, which serves as it were for a lining to the other, and joins with the iris, m n m n. The iris is composed of two sets of muscular fibres; the one of a circular form, which contracts the hole in the middle called the pupil, when the light would otherwise be too strong for the eye; and the other of radical fibres, tending everywhere from the circumference of the iris, towards the middle of the pupil; which fibres, by their contraction, dilate and enlarge the pupil when the light is weak, in order to let in the more of its rays. The third coat is only a fine expansion of the optic nerve L, which spreads like net-work all over the inside of the choroides, and is therefore called the retina; upon which are painted (as it were) the images of all visible objects, by the rays of light which either flow or are reflected from them.

Under the cornea is a fine transparent fluid like water, which is therefore called the aqueous humour. It gives a protruberant figure to the cornea, fills the two cavities m m and n n, which communicate by the pupil P; and has the same limpidity, specific gravity, and refractive power, as water. At the back of this lies the crystalline humour II, which is shaped like a double convex-glass; and is a little more convex on the back than the fore-part. It converges the rays, which pass through it from every visible object to its focus at the bottom of the eye. This humour is transparent like crystal, is much of the consistence of hard jelly, and exceeds the specific gravity of water in the proportion of 11 to 10. It is interposed in a fine transparent membrane, from which proceed radial fibres oo, called the ligamentum ciliare, all around its edge; and join to the circumference of the iris.

At the back of the crystalline, lies the vitreous humour KK, which is transparent like glass, and is largest of all in quantity, filling the whole orb of the eye, and giving it a globular shape. It is much of O f Vision a confluence with the white of an egg, and very little exceeds the specific gravity and refractive power of water.

As every point of an object ABC, (ill.) sends forth rays in all directions, some rays, from every point on the retina, on the side next the eye, will fall upon the cornea between E and F; and by passing on through the humour and pupil of the eye, they will be converged to as many points on the retina or bottom of the eye, and will thereon form a distinct inverted picture c b a of the object. Thus, the pencil of rays g r s that flows from the point A of the object, will be converged to the point a on the retina; those from the point B will be converged to the point b; those from the point C will be converged to the point c; and of all the intermediate points; by which means the whole image a b c is formed, and the object made visible. Although it must be owned, that the method by which this sensation is carried from the eye by the optic nerve to the common fenitory in the brain, and there discerned, as above the reach of our comprehension.

But that vision is effected in this manner, may be demonstrated experimentally. Take a bullock's eye whilst it is fresh; and having cut off the three coats from the back-part, quite to the vitreous humour, put a piece of white paper over that part, and hold the eye towards any bright object, and you will see an inverted picture of the object upon the paper.

Since the image is inverted, many have wondered why the object appears upright. But we are told that the retina is only a relative term: and, right.

2. That there is a very great difference between the real object and the means or image by which we perceive it. When all the parts of a distant prospect are painted upon the retina, they are all right with respect to one another, as well as the parts of the prospect itself; and we can only judge of an object's being inverted, when it is turned round to its natural position with respect to other objects which we see and compare it with.—If we lay hold of an upright brick in the dark, we can tell which is the upper or lower part of it, by moving our hand downward or upward; and know very well that we cannot feel the upper end by moving our hand downward. Just so we find by experience, that upon directing our eyes towards a tall object, we cannot see its top by turning our eyes downward, nor its foot by turning our eyes upward; but must trace the object the same way by the eye to see it from head to foot, as we do by the hand to feel it; and as the judgment is informed by the motion of the hand in one case, so it is also by the motion of the eye in the other.

In fig. 9 is exhibited the manner of seeing the same object ABC, by both the eyes D and E at once.

When any part of the image c b a falls upon the optic nerve L, the corresponding part of the object becomes invisible. On which account, nature has wisely placed the optic nerve of each eye, not in the middle of the bottom of the eye, but towards the side next the nose; so that whatever part of the image falls upon the optic nerve of one eye, may not fall upon the optic nerve of the other. Thus the point a of the image...
PART I.

OPTICS.

Of Vision.

The image of a fall upon the optic nerve of the eye D, but not of the eye E; and the point of the optic nerve of the eye E, but not of the eye D; and therefore, to both eyes taken together, the whole object is visible.

The nearer that any object is to the eye, the larger is the angle under which it is seen, and the magnitude under which it appears. Thus to the eye D (Fig. 1.) the object ABC is seen under the angle APB; and its image CBA is very large upon the retina; but to the eye E, at a double distance, the same object is seen under the angle APC, which is equal only to half the angle APB, as is evident by the figure. The image CBA is likewise twice as large in the eye D, as the other image CBA is in the eye E. In both these representations, a part of the image falls upon the optic nerve, and the object in the corresponding part is invisible.

As the sense of feeling is allowed to be occasioned by the impulse of the rays from the visible object upon the retina of the eye, and forming the image of the object thereon, and that the retina is only the part of the optic nerve that is visible, and especially at that nerve is allowed to be the instrument by which the impulse and image are conveyed to the common sensibility in the brain.

That the part of the image which falls upon the middle of the optic nerve is lost, and consequently the corresponding part of the object is rendered invisible, is plain by experiment. For if a person fixes three patches, A, B, C, (Fig. 2.) upon a white wall, at the height of the eye, and at the distance of about a foot from each other, and places himself before them, shutting the right eye, and directing the left towards the patch C, he will see the patches A and C, but the middle patch B will disappear. Or, if he shuts his left eye, and directs the right towards A, he will see both A and C, but B will disappear; and if he directs his eye towards B, he will see both B and A, but not C. For whatever patch is directly opposite to the optic nerve N, vanishes. This requires a little practice; after which he will find it easy to direct his eye so as to lose the sight of whichever patch he wishes.

This experiment, first tried by M. Mariotte, occasioned a new hypothesis concerning the feat of vision; which he supposed not to be in the retina, but in the choroides. An improvement was afterwards made upon it by M. Picard, who contrived that an object should disappear when both the eyes were kept open. He fastened upon a wall a round white paper, an inch or two in diameter; and by the side of it he fixed two marks, one on the right hand, and the other on the left, each at about 2 feet distance from the paper, and somewhat higher. He then placed himself directly before the paper, at the distance of 9 or 10 feet, and putting the end of his finger over against both his eyes, so that the left-hand mark might be hid from the right eye, and the right-hand mark from the left eye. Remaining in this posture, and looking steadily, with both eyes, on the end of his finger, the paper which was not at all covered by it would totally disappear. This, he says, is the more surprising because, without this particular encounter of the optic nerves, where no vision is made, the paper will appear double, as is the case when the finger is not rightly placed.

M. Mariotte observes, that this improvement on his experiment, by M. Picard, is ingenious, but difficult to execute, since the eyes must be considerably strained in looking at any object so near to them as four inches; and proposes another not less surprising, and more easy. Place, says he, on a dark ground, two round pieces of white paper, at the same height, and three feet from one another; then place yourself opposite to them, at the distance of 12 or 13 feet, and hold your thumb before your eyes, at the distance of about eight inches, so that it may conceal from the right eye the paper that is to the left hand, and from the left eye the paper to the right hand. Then, if you look at your thumb steadily with both eyes, you will lose sight of both the papers; the eyes being so disposed, that each of them receives the image of one of the papers upon the base of the optic nerve, while the other is intercepted by the thumb.

M. Le Cat pursued this curious experiment a little farther than M. Mariotte had done. In the place of the second paper, he fixed a large white board, and observed, that at a proper distance he lost sight of a circular space in the centre of it. He also observed the size of the paper which is thus concealed from the fight, corresponding to several distances, which enabled him to ascertain several circumstances relating to this part of the structure of the eye more exactly than had been done before.

The manner in which this curious experiment is now generally made, and which is both the easiest with respect to the eye, and the most indispensible with respect to the fact, is the following. Let three pieces of paper be fastened upon the side of a room, about two feet asunder; and let a person place himself opposite to the middle paper, and beginning near it, retire gradually backwards, all the while keeping one of his eyes shut, and the other turned obliquely towards that outside paper which is towards the covered eye, and he will find a situation (which is generally at about five times the distance at which the papers are placed from one another), where the middle paper will entirely disappear, while the two outermost continue plainly visible; because the rays which come from the middle paper will fall upon the retina where the optic nerve is inferred.

It will not surprise any person, even those who are the strongest advocates for the retina being the place at which the pencils of rays are terminated, and consequently the proper feat of vision, that M. Mariotte was led by this remarkable observation, to suspect the contrary. He not only did so; but, in consequence of attentively considering the subject, a variety of other arguments in favour of the choroides occurred to him, particularly his observation, that the retina is transparent, as well as the crystalline and other humours of the eye, which he thought could only enable it to transmit the rays farther, and he could not persuade himself that any substance could be considered as being the termination of the pencils, and the proper feat of vision, at which the rays are not stopped in their progress.

He was further confirmed in his opinion of the small degree
OF VISION.  

Optics.  

Part I.  

We must add, that M. Pecquet also observed, that of vision, notwithstanding the insensibility of the retina at that insertion of the optic nerve when the light is only moderate; yet that luminous objects, such as a bright candle placed at the distance of four or five paces, do not absolutely disappear, in the same circumstances in which a white paper would; for that this strong light may be perceived through the picture fall on the back of the nerve. "I cannot help supposing, however, (says Dr Prieffley,); that M. Pecquet did not make this observation with sufficient care. A large candle makes no impression on that part of my eye, though it is by no means able to bear a strong light."

The common opinion was also favoured by the anatomical description of several animals by the members of the French academy, and particularly their account of the sea-calf and porcupine; in both of which the optic nerve is inserted in the very axis of the eye, exactly opposite to the pupil, which was thought to leave no room to doubt, that in these animals the retina is perfectly insensible to the impression of light at the insertion of the nerve. But this observation may defer be reconsidered.

M. De la Hire took part with M. Pecquet, arguing in favour of the retina from the analogy of the senses, in all of which the nerves are the proper seat of sensation. This philosopher, however, supposed that the choroides receives the impression of images, in order to transmit them to the retina.

M. Perrault also took the part of M. Pecquet against M. Marriot, and in M. Perrault's works we have several letters that passed between these two gentlemen upon this subject.

This dispute about the immediate instrument of vision was revived upon the occasion of an odd experiment of M. Mery, recorded in the memoirs of the French academy for 1704. He plunged a cat in water, and exposing her eyes to the strongest light of the sun, observed that the pupil was not at all contracted by it; from which he concluded, that the contraction of the iris is not produced by the action of the light, but by some other circumstance. For he contended that the eye receives more light in this situation than in the open air. At the same time he thought he observed that the retina of the cat's eye was transparent, and that he could see the opaque choroides beyond it; from which he concludes, that the choroides is the substance intended to receive the rays of light, and to be the chief instrument of vision. But M. De la Hire replies to this argument of M. Mery, in a memoir for the year 1709, p. 119; in which he endeavours to show that fewer rays enter the eye under water, and that in those circumstances it is not so liable to be affected by them. Besides, it is obvious to be remarked, that the cat must be in great terror in this situation; and being an animal that has a very great voluntary power over the muscles of the iris, and being now extremely attentive to every thing about her, she might keep her eye open notwithstanding.

(1) M. Musschebroeck says, that in many animals, as the lion, camel, bear, ox, flag, sheep, dog, cat, and many birds, the choroides is not black, but blue, green, yellow, or some other colour. *Introductio,* Vol. II. p. 748.
standing the action of the light upon it, and though it might be very painful to her. We are informed, that when a cat is placed in a window through which the sun is shining, and consequently her iris nearly closed, if she hear a ruffling, like that which is made by a mouse, on the outside of the window, she will immediately open her eyes to their greatest extent, without in the least turning her face from the light.

M. Le Cat took part with M. Mariotte in this controversy, it being peculiarly agreeable to his general hypothesis, viz. that the pia mater, of which the choroid is a production, and not the nerves themselves, is the proper instrument of sensation. He thought that the change which takes place in the eyes of old people (the choroides growing less black with age) favoured his hypothesis, as they do not see with that distinctness with which young persons do. M. Le Cat supposed that the retina answers a purpose similar to that of the scar-fish, covering the papilla pyramidales, which are the immediate organ of feeling, or that of the porous membrane which covers the glandulous papilla of the tongue. The retina, he says, receives the impression of light, moderates it, and prepares it for its reception. If we suppose the seat of vision to be at the nearer from the light, and is therefore, peculiarly adapted to see by the fainter coloured lights, alld and yet such animals see even more distinctly than others. And we cannot but suppose that, in whatever manner vision is effected, it is the same in the eyes of all animals. If the seat of vision be at the farther surface of the retina, and it be performed by direct rays, a white choroides could be of no use, and if it were by reflected rays, a black one could not answer the purpose.

It is likewise an argument in favour of the choroides being the organ of vision, that it is a substance which receives a more distinct impression from the rays of light than any other membrane in any part of the animal system, excepting (and perhaps not excepting) that white cuticular which lies under the scales of fishes; whereas the retina is a substance on which the light makes an exceedingly faint impression, and perhaps no impression at all; since light, in passing out of one transparent medium into another immediately contiguous to it, suffers no refraction or reflection, nor are any of the rays absorbed, unless there is some difference in the refracting power of the two media, which probably is not the case between the retina and the vitreous humour, which is in contact with it. And wherever the light is not affected by the medium it falls upon, we can hardly suppose the medium to receive any impression from the light, the action being probably always mutual and reciprocal.

Besides, the retina is so situated, as to be exposed to many rays besides those which terminate in it, and which, therefore, cannot be favourable to vision, if it be performed there. Now this is not the case with the choroides, which is in no shape transparent, and has no reflecting substance beyond it.

It is, moreover, peculiarly favourable to the hypothesis of the seat of vision being in the choroides, that we can then see a sufficient reason for the diversity of its colour in different animals, according as they are circumstanced with respect to vision. In all terrestrial animals, which have occasion to make use of their eyes by night, the choroides is either of a bright white, or of some very vivid colour, which reflects the light very strongly. On this account vision may be performed with less light, but it cannot be with great distinctness, the reflection of the rays doubling their effect, since it must extend over some space, all reflection being made at a distance from the reflecting body. Besides, the choroides in brutes is not in general perfectly white, but a little inclined to blue; and is therefore, probably, better adapted to see by the fainter coloured light, which chiefly prevails in the night; and we would add, is on the same account more liable to be strongly impressed by the colours to which they are chiefly exposed.

On the other hand, the choroides of birds in general, especially eagles, hawks, and other birds of prey, is black; by which means they are able to see with the greatest distinctness, but only in bright day-light. The owl, however, seeking her food by night, has the choroides white, like that of a cat. Lastly, in the eyes of man, which are adapted to various uses, the choroides is neither so black as that of birds, nor so white as that of those animals which make the greatest use of their eyes in the night.

As to a third hypothesis, which is in effect that of M. De la Hire, which makes both the retina and the choroides equally necessary to vision, and supposes it to be performed by the impression of light on the choroides.
 communicated to the retina; Mr Michell observes, that the perceptions can hardly be supposed to be so acute, when the nervous, which are the chief instruments of sensation, do not receive the impressions immediately, but only after they have been communicated to another substance. Besides, it must be more natural to suppose, that, when the principal impression is made upon the choroides, it is communicated to the brain by its own proper nerves, which are abundantly sufficient for the purpose.

The dimensions and precise form of the spot in the eye in which there is no vision, were more accurately calculated by Daniel Bernouilli, in the following manner. He placed a piece of mould C (fig. 3) upon the floor; and then turning one of his eyes, and making a pendulum to swing, so that the extremity of it might be nearly in the line AO, he observed at what place C it began to be invisible, and where it again emerged into view at A. Raising the pendulum higher and lower, he found other points, as H, N, P, C, B, at which it began to be invisible; and others, as M, L, E, A, at which it began to be visible again; and drawing a curve through them, he found that it was elliptical; and, with respect to his own eye, the dimensions of it were as follow; OC was 23, AC 10, BD 3, DH 13, and EG 14. So that the centre being at P, the greater axis was to the less as 8 to 7.

From these data, the plane on which the figure was drawn being obliquely situated with respect to the eye, he found, that the place in the eye that corresponded to it was a circle, the diameter of which was a seventh part of the diameter of the eye, the centre of it being 27 parts of the diameter from the point opposite to the pupil, a little above the middle. He concludes with observing, that, in order that this space in which there is no vision may be as small as possible, it is necessary that the nerve should enter the eye perpendicularly, and that both this end, and also its entering the eye at a distance from its axis, are gained by the particular manner in which the two optic nerves unite and become separate again, by crossing one another.

In favour of one of the observations of Mr Michell, concerning the use of the choroides in vision, Dr Priestley observes, that Aquapendente mentions the case of a person at Piña, who, as it was very well in the night, but very little or none at all in the daytime. This is also said to be the case with those white people among the blacks of Africa, and the inhabitants of the islands of America, who, from this circumstance, are called moon-eyed. Our author thinks it probable that their choroides is not of a dark colour, as it is in others of the human species; but white or light-coloured, as in those animals which have most occasion for their eyes in the night. See ALBINOs.

The following considerations in favour of the retina being the proper seat of vision, are worthy of remark.

Dr Porterfield observes, that the reason why there is no vision at the entrance of the optic nerve into the eye, may be, that it wants that softness and delicacy which it has when it is expanded upon the choroides; and that, in those animals in which that nerve is inserted in the axis of the eye, it is observed to be equally delicate, and therefore probably equally sensitive, in that place as in any other part of the retina.

In general, the nerves, when confined by their coats, have but little sensibility in comparison of what they are ended with when they are divested of them, and unfolded in a soft and pulpy substance.

Haller observes, that the choroides cannot be the universal instrument of vision, because that sometimes in men and birds, but especially in fish, it is covered internally with a black mucus, through which the rays cannot penetrate. This writer speaks of a fibrous membrane in the retina distinct from its pulpy substance. On these fibres, he conjectures, that the images of objects are painted.

M. De la Hire's argument in favour of the retina, from the analogy of the senses, is much strengthened by considering that the retina is a large nervous apparatus, immediately exposed to the impression of light; whereas the choroides receives but a slender supply of nerves, in common with the fleshy parts, conjunctiva, and the eyelids, and that its nerves are much less exposed to the light than the naked fibres of the optic nerve. Indeed, from anatomical considerations, one might imagine that any other part of the body was as sensible of the impression of light as the choroides.

That the optic nerve is of principal use in vision, is farther probable from several phenomena attending some of the diseases in which the sight is affected.

When an amaurosis has affected one eye only, the optic nerve of that eye has been found manifestly altered from its sound state. Dr Priestley was present when Mr Hey examined the brain of a young girl, who had been blind of one eye, and saw that the optic nerve belonging to it was considerably smaller than the other; and he informed him, that upon cutting into it, he found it to be much harder, and ciceritious. Morgagni, indeed, mentions two cases, in which he found the optic nerves smaller than usual, and of a ciceritious colour, when, upon inquiry, he was informed that the person had not been blind, though there might have been some defect in the sight of one of the eyes. In the other case, only one of the optic nerves was affected in that manner, and the eye itself was in other respects very perfect. Here, also, he was expressly told, that the person was not blind of that eye: but it appears that he himself had not been acquainted with the persons whom he dissected; and there have been many cases of persons being blind of one eye, without knowing it themselves, for a considerable time.

Moreover, as the optic nerve is solely intent in forming the retina, so no function of the eye, not immediately subservient to vision, is affected by an amaurosis.

On the contrary, those nerves which go to the choroides are found to retain, in this disease, their natural influence. The iris will contract in a recent guttation of one eye, if the other remains found, and is suddenly exposed to a strong light. The sclerotic, conjunctiva, and eyelids, which receive their nerves from the same branches as the choroides, retain their sensibility in this disorder.

The manner in which persons recover from an amaurosis, favours the supposition of the seat of vision being in the retina; since those parts which are the most distantly from the inception of the nerve recover their sensibility the sooner, being in those places the
Of Vision, most pulpy and soft; whereas there is no reason to think that there is any difference in this respect in the different parts of the choroides. Mr Hey has been repeatedly informed, by persons labouring under an imperfť amaurosis, or gutta serena, that they could not, when looking at any object with one eye, see it so distinctly when it was placed directly opposite to the pupil, as when it was situated somewhat obliquely. And those persons whom he had known to recover from a perfect amaurosis, first discovered the objects whose images fell upon that part of the retina which is at the greatest distance from the optic nerve.

We shall conclude these remarks with observing, that if the retina be as transparent as it is generally represented to be, so that the termination of the pencils must necessarily be either upon the choroides, or some other opaque substance interposed between it and the retina, the action and reaction occasioned by the rays of light being at the common surface of this body and the retina, both these mediums (supposing them to be equally sensitive to the impression of light) may be equally affected; but the retina, being naturally much more sensitive to this kind of impression, may be the only instrument by which the sensation is conveyed to the brain, though the choroides, or the black substance with which it is sometimes lined, may also be absolutely necessary for the purpose of vision. Indeed, when the reflection of the light is made at the common boundary of any two mediums, it is with no propriety that this effect is ascribed to one of them rather than the other; and the strongest reflections are often made back into the denser mediums, when they have been contiguous to the rarer, or even to a vacuum. This is not far from the hypothesis of M. de la Hire, and will completely account for the entire defect of vision at the intension of the optic nerve.

Vision is distinguished into bright and obscure, distinct and indistinct. It is said to be bright, when a sufficient number of rays enter the pupil at the same time; obscure, when too few. It is distinct when each pencil of rays is collected into a focus exactly upon the retina; indistinct, when they meet before they come at it, or when they would pass it before they meet; for, in either of these last cases, the rays flowing from different parts of the object will fall upon the same part of the retina, which must necessarily render the image confused and indistinct. Now, that objects may appear with a due brightness, whether more or fewer rays proceed from them, we have a power of contracting or dilating the pupil, by means of the muscular fibres of the iris, in order to take in more or fewer rays as occasion requires. But this power has its limits. In some animals it is much greater than in others; particularly in such as are obliged to seek their food by night as well as by day, as in cats, &c.

That the rays may be collected into points exactly upon the retina, that is, that objects may appear distinct, whether they be nearer or farther off, &c. whether the rays proceeding from them diverge more or less, we have a power of contracting or relaxing the ligamenta ciliaria, and thereby altering the form of the crystalline humour, and with it the focal distance of the rays. Thus, when the object we view is far off, and the rays fall upon the pupil with a very small degree of divergence, we contract the ligamenta ciliaria, which, being concave towards the vitreous humour, do thereby compress it more than otherwise they would do: by this means it is made to press harder upon the backside of the crystalline humour, which is thereby rendered flatter; and thus the rays proceed farther before they meet in a focus, than otherwise they would have done. Add to this, that we dilate the pupils of our eyes (unless in cases where the light is too strong that it offends the eye), and thereby admit rays into them that are more diverging than those which would otherwise enter. And, when the rays come from an object that is very near, and therefore diverge too much to be collected into their respective foci upon the retina, by relaxing the ligamenta ciliaria, we give the crystalline a more convex form, by which means the rays are made to fall upon a proportionally greater degree of refraction in passing through it. Some philosophers are of opinion that we do this by a power of altering the form of the eye; and others, by removing the crystalline forwards or backwards as occasion requires: but neither of these opinions is probable; for the coats of the eye are too hard, in some animals, for the first; and, as to moving the crystalline out of its place, the cavities of the eye seem to be too well filled with the humourous to admit of such removal.

Besides this, in the case abovementioned, by contracting the pupils of our eyes, we exclude the more diverging rays, and admit only such as are more easily refracted into their respective foci. But vision is not distinct at all distances, for our power of contracting and relaxing the ligamenta ciliaria, is also circumscribed within certain limits.

In those eyes where the tunica cornea is very protruberant and convex, the rays of light suffer a very considerable refraction at their entrance into the aqueous humour, and are therefore collected into a focus before they fall upon the retina, unless the object be placed very near, so that the rays which enter the eye may have a considerable degree of divergence. People that have such eyes are said to be purblind. Now, the nearer an object is to the eye, the greater is the image of it therein, as explained above: these people, therefore can see much smaller objects than others, as seeing much nearer ones with the same c ſ ci - l i a r i a ; and their sight continues good longer than that of other people, because the tunica cornea of their eyes, as they grow old, becomes plainer, for want of that redundance of humours with which they were filled before. On the contrary, old men having the cornea of their eyes too flat for want of a sufficient quantity of the aqueous humour to fill them out, if the rays diverge too
Of Vision.

too much before they enter the eye, they cannot be brought to a focus before they reach the retina; on which account those people cannot see distinctly, unless the object be situated at a greater distance from the eye than it is requested for those who only have an eye of a due form. The latter require the assistance of convex glasses to make them see objects distinctly; the former of concave ones. For if either the cornea $a$ $b$ (fig. 4.), or crystalline humour $s$, or both of them, be too flat, as in the eye $A$, their focus will not be on the retina as at $A$, where it ought to be, in order to render vision distinct; but beyond the eye, as at $f$. This is remedied by placing a convex glass $g$ $b$ before the eye, which makes the rays converge sooner, and imprint the image duly on the retina at $d$. Again, if either the cornea, or crystalline humour, or both of them, be too convex, as in the eye $B$, the rays that enter it from the object $C$ will be converged to a focus in the vitreous humour, as at $f$; and by diverging from thence to the retina, will form a very confused image thereon; and so, of course, the observer will have as confused a view of the object as if his eye had been too flat. This inconvenience is remedied by placing a concave glass $g$ $b$ before the eye; which glass, by causing the rays to diverge between it and the eye, lengthens the focal distance $f_0$, that if the glass be properly chosen, the rays will unite at the retina, and form a distinct image of the object upon it.

Such eyes as are of a due convexity, cannot see any object distinctly at less distance than six inches; and there are numberless objects too small to be seen at that distance, because they cannot appear under any sensible angle. Concerning the least angle under which any object is visible, there was a debate between Dr Hooke and Hevelius. The former asserted, that no object could well be seen if it subtended an angle less than one minute; and, if the object be round, as a black circular spot upon a white ground, or a white circle upon a black ground, it follows, from an experiment made by Dr Smith, that this is the truth; and from thence he calculates, that the diameter of the picture of such least visible point upon the retina is the Seventieth part of an inch; which he therefore calls a "visible point of the retina." On the other hand, Dr Courtrivon concluded from his experiments, that the smallest angle of vision was 40 seconds. According to Dr Jurin, there are cases in which a much smaller angle than one minute can be discerned by the eye; and in order to throw light upon the subject, he observes, that in order to our perceiving the impression made by any object upon our sense, it must either be of a certain degree of force, or of a certain degree of magnitude. For this reason, a thread, which appears only as a lucid point through a telescope, subtending not so much an angle as one second, is visible to the eye; though a white or black spot, of 25 or 30 seconds, is not to be perceived. Also a line of the same breadth with the circular spot will be visible, at such a distance as the spot is not to be perceived at, because the quantity of impression from the line is much greater than from the spot; and a longer line is visible at a greater distance than a shorter one of the same breadth. He found by experience, that a silver wire could be seen when it subtended an angle of three seconds and a half; and that a silk thread could be seen when it subtended an angle of two seconds and a half.

This greater visibility of a line than of a spot seems to arise only from the greater quantity of the impression; but without the limits of perfect vision, our author observes, that another cause concurs, whereby the difference of visibility between the spot and the line is rendered much more considerable. For the impression upon the retina made by the line is then not only much greater, but also much stronger, than that of the spot; because the faint image, or penumbra, of any one point of the line, when the whole is placed beyond the limits of distinct vision, will fall within the faint image of the next point, and thereby much increase the light that comes from it.

In some cases our author found the cause of indistinct vision to be the unsteadiness of the eye; as our being able to see a single black line upon a white ground, or a single white line upon a black ground, and not a white line between two black ones on a white ground. In viewing either of the former objects, if the eye be imperceptibly moved, all the effect will be, that the object will be painted upon a different part of the retina; but, wherever it is painted, there will be but one picture, single and uncompounded with any other. But in viewing the other, if the eye fluctuate ever so little, the image of one or other of the black lines will be shifted to that part of the retina which was before filled by the white line; and this must occasion such a dazzle in the eye, that the white line cannot be distinctly perceived, and distinguished from the black lines; which, by a continual fluctuation, will alternately occupy the space of the white line, whence must arise an appearance of one broad dark line, without any manifest separation.

By trying this experiment with two pins of known diameters, let in a window against the sky light, with a space between them equal in breadth to one of the pins, he found that the distance between the pins could hardly be distinguished when it subtended an angle of less than 40 seconds, though one of the pins alone could be distinguished when it subtended a much less angle. But though a space between two pins cannot be distinguished by the eye when it subtends an angle less than 40 seconds, it would be a mistake to think that the eye must necessarily commit an error of 40 seconds in estimating the distance between two pins, when they are much farther from one another. For if the space between them subtend an angle of one minute, and each of the pins subtend an angle of four seconds, which is greater than the least angle of the eye can distinguish, it is manifest that the eye may judge of the place of each pin within two seconds at the most; and consequently the error committed in taking the angle between them cannot at the most exceed four seconds, provided the instrument be sufficiently exact. And yet, says he, upon the like mistake was founded the principal objection of Dr Hooke against the accuracy of the celestial observations of Hevelius.

A black spot upon a white ground, or a white spot upon a black ground, he says, can hardly be perceptible by the generality of eyes when it subtends a less angle than one minute. And if two black spots be made upon
Ihi,

black fpot was

light feerns to

thereby

penumbra, and the penumbra

be very faint. Upon the fame principles he likewife

placed at the

five feet, the mind cann0t diftinguifh it into fmall

fspace, the mind cann0t diftinguifh it into fmall

fspace between them equal in

breath to one of their diameters, that space is not to

be diftinguifhed, even within the limits of perfect vifion; under fo small an angle as a fingle fpot of the

fame fize can be diftinguifhed. To fee the two fpots
diftinely, therefore, the breadth of the space between

them muft fubftend an angle of more than a minute. It

would be very difficult, he fays, to make this exper­

iment accurately, within the limits of perfect vifion;

because the objects muft be extremely fmall; but by a

rude trial made with square bits of white paper, placed

upon a black ground, he judged, that the leaft

angle under which the interval of two objects could

be perceived, was at lead at a fourth part greater than

the leaft angle and r which a fingle object can be per­
ceded. So that an eye which cannot perceive a fingle

object under a smaller angle than one minute, will not

perceive the interval between two fuch objects under a

leaft angle than 75 feconds.

Without the limits of perfect vifion, the diftance at

which a fingle object ceafs to be perceivable will be

much greater in proportion than the diftance at which

the space of equal breadth between two fuch objects

caefts to be perceivable. For, without these limits,

the image of each of the objects will be attended with

a penumbra, and the penumbra of the two near ob­

jects will take up part of the space between them, and

thereby render it lefs perceivable; but the penumbra

will add to the breadth of the fingle object, and will

thereby make it more perceivable, unlefs its image

be very faint. Upon the fame principles he likewise

accounts for the radiation of the flares, whereby the

light feme to project from them different ways at the

fame time.

Mr Mayer made many experiments in order to af­
certain the fmal1efl angle of vifion in a variety of ref­
pects. He began with obferving at what diftance a

black fpot was visible on white paper; and found, that

when it could barely be diftinguifhed, it fubf tended an

angle of about 34 feconds. When black lines were

diffused with intervals broader than themselves, they

were diftinguifhed at a greater diftance than they could

be when the objects and the intervals were of an equal

breadth. In all thefe cafes it made no difference

whether the objects were placed in the shade or in the

strong light of the fun; but when the degrees of light

were fmall, their differences had a confiderable ef­

fect, though by no means in proportion to the dif­

ferences of the light. For if an object was illuminated to fuch

degree as to be juft visible at the diftance of nine

feet, it would be visible at the diftance of four feet,

though the light was diminished above 160 times. It

appeared in the course of thofe experiments, that com­
mon day-light is, at a medium, equal to that of

25 candles placed at the diftance of one foot from the

object.

As an image of every visible object is painted on the

retina of each of our eyes, it thence becomes a nat­

ural queftion, Why do we not fee every thing double?

It was the opinion of Sir Isaac Newton and others,

that objects appear double becaufe the two optic nerves

unite before they reach the brain. But Dr Portefield

shows, from the obfervation of feveral anatomifts, that

the optic nerves do not mix, or confound their fub­

stances, being only united by a close cohesion; and ob­
jets have appeared fingle where the optic nerves were

found to be difjoined.

Dr Briggs fuppofed that fingle vifion was owing to the

equal tension of the correffponding parts of the optic dif­
	
nic nerves, whereby they vibrated in a fynchronouf manner.

But, beside several improbable circumstances in this ac­

count, Dr Portefield shows that fails do by no means ferve it.

To account for this phenomenon, this ingenious

writer fuppofes, that by an original law in our natures,

we imagine objects to be fituated somewhere in a right

line drawn from the picture of it upon the retina,

through the centre of the papil. Confequently, the

fame object appearing to both eyes to be in the fame

place, the mind cannot diftinguifh it into two.

In an­

swer to an objection to this hypothesis, from objects

appearing double when one eye is diftorfed, he lays

the mind mistakes the position of the eyes, imagining

that it had moved in a manner correffponding to the

other, in which cafe the conclufion would have been

juft. In this cafe he seems to have recoue to the

power of habit, though in words he DISCLAIMS that hy­

pothefis.

This principle, however, has gene­ally been thought

to be fufficient to account for this appearance. Ori­

ginal­ly, every object making two pictures, one in each

eye, is imagined to be double; but by degrees, we

find that when two correffponding parts of the retina

are impressed, the object is but one; but if thofe corre­

fponding parts be changed, by the diftorfion of one

of the eyes, the object muft again appear double at

the firft. This seems to be verified by Mr Ches­

felden; who informs us, that a gentleman, who from

a blow on his head had one eye diftorfed, found

found a certain object to appear double; but by degrees the

third familiar ones came to appear fingle again, and in

time all objects did fo, without any amendment of the

diftorfion. A cafe similar to this is mentioned by

Dr Smith.

On the other hand, Dr Reid is of opinion, that the

corréffpondence of the centres of the two eyes, on which

fingle vifion depends, does not arife from custom, but

from some natural constitution of the eye and of the

mind. He makes feveral juft objections to the cafe of

Mr Porterfield, rectified by Dr Smith and others; and

thinks that the cafe of the young man touched by Ches­
	
felden, who faw fingly with both eyes immediately upon

receiving his fight, is nearly defitive in proof of his fup­

position. He alfo found that three young gentlemen,

whom he endeavoured to cure of fquinting, faw ob­
jects fingly, as fon as ever they were broug­ht to di­

tect the centres of both their eyes to the fame

eye, though they had never been used to do fo from

their infancy; and he obferves, that there are cafes,

in which, notwithstanding the fullest conviction of an

object being fingle, no practice of looking at it will

ever make it appear fo, as when it is feen through a

multiplying glafs.

To all these solutions of the difficulty respecting

fingle vifion by both eyes, objections have been lately

made which seem infurmoutable. By experiment

judiciously conceived and accurately conducted, Dr

Wells has fhewn, that it is neither by custom alone,

nor by an original property of the eyes alone, that ob­
jects appear fingle; and having demolished the theories
OPTICS.

"Hitherto I have supposed the holes almost touching the face. But they have the same unity of appearance, in whatever part of the optic axes they are placed; whether both be at the same distance from the eyes, or one be close to the eye in the axis of which it is, and the other almost contiguous to the object seen through them. If a line, therefore, be drawn from the object to one of the eyes, it will represent all the real or tangible positions of the hole, which allow the object to be seen by that eye, and the whole of it will coincide with the optic axis. Let a similar line be drawn to the other eye, and the two must appear as one line; for if they do not, the two holes in the optic axes will not, at every distance, appear one, whereas experiments prove that they do. This united line will therefore represent the visible direction of every object situated in either of the optic axes. But the end of it, which is toward the face, is seen by the right eye to the left, and by the left eye as much to the right. It must be seen then in the middle between the two, and consequently in the common axis. And as its other extremity coincides with the point where the optic axes intersect each other, the whole of it must lie in the common axis. Hence the truth of the proposition is evident, that objects situated in the optic axis, do not appear to be in that line, but in the common axis.

He then proves by experiments, for which we must refer to his work, that objects situated in the common axis, do not appear to be in that line, but in the axis of the eye by which they are not seen: that is, an object situated in the common axis appears to the right eye in the axis of the left, and vice versa. His next proposition, proved likewise by experiments, is, that "objects, situated in any line drawn through the mutual intersection of the optic axes to the visual base, do not appear to be in that line, but in another, drawn through the same intersection, to a point in the visual base distant half this base from the similar extremity of the former line: towards the left, if the object be seen by the right eye, but towards the right if seen by the left eye."

From these propositions he thus satisfactorily accounts for single vision by both eyes. "If the question be concerning an object at the concourse of the optic axes, it is seen fingle, because its two similar appearances, in regard to size, shape, and colour, are seen by both eyes in one and the same direction, or, if you will, in two directions, which coincide with each other through the whole of their extent. It therefore matters not whether the distance be truly or falsely estimated; whether the object be thought to touch our eyes, or to be infinitely remote. And hence we have a reason, which no other theory of visible direction affords, why objects appeared fingle to the young gentleman mentioned by Mr. Chefelden, immediately after his being couched, and before he could have learned to judge of distance by sight."

"When two similar objects are placed in the optic axes, one in each, at equal distances from the eyes, they will appear in the same place, and therefore one, for the same reason that a truly fingle object, in the concourse of the optic axes, is seen fingle."

"To finish this part of my subject, it seems only necessary to determine, whether the dependence of visible direction upon the actions of the muscles of the eyes.

Of Vision, he thus accounts for the phenomena himself.

"The visible place of an object being composed of its visible distance and visible direction, to show how it may appear the same to both eyes, it will be necessary (thus he) to explain in what manner the distances and direction, which are perceived by one eye, may coincide with those which are perceived by the other."

With respect to visible distance, the author's opinion seems not to differ from that which we have stated elsewhere (see Metaphysics, no. 49, 59); and therefore we have to attend only to what he says of visible direction.

When a small object is so placed with respect to either eye, as to be seen more distinctly than in any other situation, our author says that it is then in the optic axis, or the axis of that eye. When the two optic axes are directed to a small object not very distant, they may be conceived to form two sides of a triangle, of which the base is the interval between the points of the corners where the axes enter the eyes. This base he called the visual base; and a line drawn from the middle of it to the point of intersection of the optic axes he calls the common axis. He then proceeds to show, that objects really situated in the optic axis do not appear to be in that line, but in the common axis.

"Every perfim (says he) knows, that if an object be viewed through two small holes, one applied to each eye, the two holes appear but as one. The theories hitherto invented afford two explanations of this fact. According to Aguilonius, Dechals, Dr. Porterfield, and Dr. Smith, the two holes, or rather their borders, will be seen in the same place as the object viewed through them, and will consequently appear united, for the same reason that the object itself is seen single. But whoever makes the experiment will distinctly perceive, that the united hole is much nearer to him than the object; not to mention that any fallacy on this head might be corrected by the information from the fame of touch, that the card or other substance in which the holes have been made is within an inch or less of our face. The other explanation is that furnished by the theory of Dr. Reid. According to it, the centres of the retinas, which in this experiment receive the picture of the holes, will, by an original property, represent but one. This theory, however, though it makes the two holes to appear one, does not determine where this one is to be seen. It cannot be seen in only one of the perpendiculars to the images upon the retinas, for no reason can be given why this law of visible direction, which Dr. Reid thinks established beyond dispute, if it operates at all, should not operate upon both eyes at the same time; and if it be seen by both eyes in such lines, it must appear where those lines cross each other, that is, in the same place with the object viewed through the holes, which, as I have already mentioned, is contrary to experience. Nor is it seen in any direction, the consequence of a law affecting both eyes considered as one organ, but suspended when each eye is used separately. For when the two holes appear one, if we pay attention to its situation, and then close one eye, the truly single hole will be seen by the eye remaining open in exactly the same direction as the apparently single hole was by both eyes."
Part I.

OPTICS.

eyes be established by nature, or by custom. But facts are here wanting. As far as they go, however, they have to prove that it arises from an original principle of our constitution. For Mr Cheielden's patient few objects single, and consequently in the same directions with both eyes, immediately after he was cured; and persons affected with squinting from their earliest infancy fee objects in the same directions with the eye they have never been accustomed to employ, as they do with the other they have contantly used.

The author removes many difficulties, and obviates the objections to which his theory may seem most liable. The whole work deserves to be attentively studied by every oculist; and we therefore recommend it to the perusal of our readers.

We are indebted to Dr Jurin for the following curious experiments, to determine whether an object seen by both eyes appears brighter than when seen with one only.

He laid a slip of clean white paper directly before him on the table, and applying the side of a book close to his right temple, so that the book was advanced considerably more forward than his face, he held it in such a manner, as to hide from his right eye that half of the paper which lay to his left hand, while the left half of the paper was seen by both eyes, without any impediment.

Then looking at the paper with both eyes, he observed it to be divided, from the top to the bottom, by a dark line, and the part which was seen with one eye only was manifestly darker than that which was seen with both eyes; and applying the book to his left temple, he found, by the result of the experiment, that both his eyes were of equal goodness.

He then endeavoured to find to what degree this excess of brightness amounted; and comparing it with the appearance of an object illuminated partly by one candle and partly by two, he was surprised to find that an object seen with two eyes is by no means twice as luminous as when it is seen with one only; and after a number of trials, by which he made the proportion less and less continually, he found, that when one paper was illuminated by a candle placed at the distance of three feet, and another paper by the same candle at the same distance, and by another candle at the distance of 11 feet, the former seen with both eyes and the latter with one eye only, appeared to be of equal whiteness; so that an object seen by both eyes appears brighter than when it is seen with ony one by about a 13th part. But he acknowledges, that it is difficult to make this experiment exactly.

He then proceeded to enquire, whether an object seen with both eyes appears any thing larger than when seen with one only; but he concluded that it did not, except on account of some particular circumstances, as in the case of the binocular telescope and the concave speculum.

M. du Tour maintains, that the mind attends to more than the image made in one eye at a time; and produces several curious experiments in favour of this hypothesis, which had also been maintained by Kepler and almost all the first oculists. But, as M. Buffon observes, it is a sufficient answer to this hypothesis, how ingeniously it ever it may be supported, that we see more distinctly with two eyes than with one; and that when a round object is near us, we plainly see more of the surface in one case than in the other. There are also other facts which clearly prove the contrary of what is maintained by M. du Tour.

With respect to single vision with two eyes, Dr Hartley observes, that it deserves particular attention, that the optic nerves of men, and such other animals as look the same way with both eyes, unite in the cella turcica in a ganglion, or little brain, as one may call it, peculiar to themselves: and that the sensations between synchronous impressions on the two retinae must be made sooner and cemented stronger on this account, also that they ought to have a much greater power over one another's images, than in any other part of the body. And thus an impression made on the right eye alone, by a single object, may propagate itself into the left, and there raise up an image almost equal in vividness to itself; and consequently when we see with one eye only, we may, however, have pictures in both eyes.

A curious deception in vision, arising from the use of both eyes, was observed and accounted for by Dr Smith. It is a common observation, he says, that objects seen with both eyes appear more vivid and stronger than they do to a single eye; especially when both of them are equally good. A person not short-sighted may soon be convinced of this fact, by looking attentively at objects that are pretty remote, first with one eye and then with both. This observation gave occasion to the construction of the biocular telescope, in the use of which the phenomenon is still more striking.

Besides this, our author observes, that there is another phenomenon observable with this instrument, which is very remarkable. In the focus of the two telescopes there are two equal rings, as usual, which terminate the pictures of the objects there formed, and consequentl'y the visible area of the objects themselves. These equal rings, by reason of the equal eye-glasses, appear equal, and equally distant when seen separately by each eye: but when they are seen with both eyes, they appear much larger, and more distant also; and the objects seen through them do also appear much larger, though circumscribed by their united rings, in the same places as when they were seen separately.

He observes, that the phenomenon of the enlarged circle of the visible area in the binocular telescope, may be seen very plainly in looking at distant objects through a pair of spectacles, removed from the eyes about four or five inches, and held steady at that distance. The two innermost of the four apparent rings, which hold the glasses will then appear united in one larger and more distant ring than the two outermost, which will hardly be visible unless the spectacles be farther removed.

A curious circumstance relating to the effect of one eye upon the other, was noticed by M. Epinus, who observed, that, when he was looking through a hole made in a plate of metal, about the 1oth part of a line in diameter, with his left eye, both the hole itself appeared larger, and also the field of view seen through it was more extended, whenever he shut his right eye; and both these effects were more remarkable when that eye was covered with his hand. He found considerable difficulty in measuring this augmentation of the apparent.
OPTICS.

Part I. Appearance of Objects through Media of different Forms.

1. That as each point of an object, when viewed by the naked eye, appears in its proper place, and as that place is always to be found in the line in which the axis of a pencil of rays flowing from it enters the eye, or else in the line which Dr Wells calls the common axis; we from hence acquire an habit of judging the point to be situated in that line: and, because the mind is unacquainted with what fractions the rays suffer before they enter the eye, therefore, in cases where they are diverted from their natural course, by passing through any medium, it judges the point to be, in that line produced back in which the axis of a pencil of rays flowing from it is situated the instant they enter the eye, and not in that it was in before refraction. We shall therefore, in what follows, suppose the apparent place of an object, when seen through a refracting medium, to be somewhere in that line produced back in which the axis of a pencil of rays flowing from it proceeds after they have passed through the medium.

2. That we are able to judge, though imperfectly, of the distance of an object by the degree of divergency, wherein the rays flowing from the same point of the object enter the pupil of the eye, in cases where that divergency is considerable; but because in what follows it will be necessary to suppose an object, when seen through a medium whereby its apparent distance is altered, to appear in some determinate situation, in those cases where the divergency of the rays at their entrance into the eye is considerable, we will suppose the object to appear where those lines which they describe in entering, if produced back, would cross each other; though it must not be affirmed, that this is the precise distance; because the brightness, diffuseness, and apparent magnitude of the object, on which its apparent distance in some measure depends, will also suffer an alteration by the refraction of the rays in passing through that medium.

3. That we estimate the magnitude of an object by that of the optic angle.

4. That vision is the brighter, the greater the number of rays which enter the pupil. And,

5. That, in some cases, the apparent brightness, diffuseness, and magnitude of an object, are the only means whereby our judgment is determined in estimating the distance of it.

Prop. I. An object placed within a medium terminated by a plane surface on that side which is next the eye, if the medium be such that in which the eye is (as we shall always suppose it to be, unless where the contrary is expressed), appears nearer to the surface of the medium than it is.

Thus, if A be a point of an object placed within the medium BCDE (fig. 5), and AB AC be two rays proceeding from thence, these rays passing out of a denser into a rarer medium, will be refracted from their respective perpendiculars b d, c e, and will enter the eye at H, suppose in the directions h f, e g; let then these lines be produced back till they meet in F; this will be the apparent place of the point A; and because the refracted rays h f, e g will diverge more than the incident ones A b, A c, it will be nearer to the points b and c than the point A; and as the same is true of each point in the object, the whole will appear to an eye at H, nearer to the surface BC than it is.

From hence it is, that when one end of a straight stick is put under water, and the stick is held in an oblique position, it appears bent at the surface of the water; viz. because each point that is under water appears nearer the surface, and consequentially higher then it is.

From hence likewise it is, that an object at the bottom of a vessel may be seen when the vessel is filled with water, though it be so placed with respect to the eye, that it cannot be seen when the vessel is empty. To explain this, let ABCD (fig. 6.) represent a vessel, and let E be an object lying at the bottom of it. This object, when the vessel is empty, will not be seen by an eye at F, because HB, the upper part of the vessel, will obstruct the ray EH; but when it is filled with water to the height GH, the ray EK being refracted at the surface of the water into the line KE, the eye at F shall see the object by means of that.

In like manner, an object situated in the horizon appears above its true place, upon account of the refraction of the rays which proceed from it in their passage through the atmosphere of the earth. For, firstly, if the object be situated beyond the limits of the atmosphere, its rays in entering it will be refracted towards the

Plate CCCLVIII

The various appearances of objects seen through media of different forms rated and approved by the Royal Society.
Part I.

**Appearance of Object through Media of different Forms.**

The perpendicular; that is, towards a line drawn from the point where they enter, to the centre of the earth, which is the centre of the atmosphere: and as they pass on, they will be continually refracted the same way, because they are all along entering a denser part, the centre of whose convexity is still the same point; upon which account the line they describe will be a curve bending downwards: and therefore none of the rays that come from that object can enter an eye upon the surface of the earth, except what enter the atmosphere higher than they need to do if they could come in a right line from the object: consequently the object must appear above its proper place. Secondly, if the object be placed within the atmosphere, the eye is still the same; for the rays which flow from it must continually enter a denser medium whose centre is below the eye: and therefore being refracted towards the centre, that is, downwards as before, those which enter the eye must necessarily proceed as from some point above the object; wherefore the object will appear above its proper place.

From hence it is, that the sun, moon, and stars, appear above the horizon, when they are just below it; and higher than they ought to do, when they are above it: Likewise distant hills, trees, &c. seem to be higher than they are.

Further, the lower these object are in the horizon, the greater is the obliquity with which the rays which flow from them enter the atmosphere, or pass from the rarer into the denser parts of it; and therefore they appear to be the more elevated by refraction: upon which account the lower parts of them are apparently more elevated than the other. This makes their upper and under parts seem nearer than they are; as is evident from the sun and moon, which appear of an oval form when they are in the horizon, their horizontal diameters appearing of the same length they would do if the rays suffered no refraction, while their vertical ones are shortened thereby.

**Prop. II.** An object seen through a medium terminated by plane and parallel surfaces, appears nearer, brighter, and larger, than with the naked eye.

For instance, let AB (fig. 7.) be the object, CDEF the medium, and GH the pupil of an eye, which is here drawn large to prevent confusion in the figure. And, as, let RK, RL, be two rays proceeding from the point R, and enter the denser medium at K and L; these rays will here be refracted by refraction be made to diverge less, and to proceed afterwards, suppose in the lines Ka, Lb; at a and b where they pass out of the denser medium, they will be as much refracted the contrary way, proceeding in the lines ac, bd, parallel to their first direction. Produce these lines back till they meet in r: this will be the apparent place of the point R; and it is evident from the figure, that it must be nearer the eye than that point; and because the same is true of all other pencils flowing from the object AB, the whole will be seen in the situation f, nearer to the eye than the line AB. 2d. As the rays RK, RL, would not have entered the eye, but have passed by it in the directions Kr, Ln, had they not been refracted in passing through the medium, the object appears brighter. 3d. The rays AB, Bi, will be refracted at b into the less converging lines b'k, b'il, and at the other surface into b'k, b'il, M, parallel to Ab and Bi produced; so that the extremities of the object will appear in the lines Mj, Ml produced, viz. in A and G, and under as large an angle MjA, as the angle ABG under which an eye at q would have seen it had there been no medium intercepting the rays; and therefore it appears larger to the eye at GH, being seen through the interposed medium, than otherwise it would have done. But it is here to be observed, that the nearer the point e appears to the eye on account of the refraction of the rays RK, RL, the shorter is the image /, because it is terminated by the lines Mj and Ml, upon which account the object is made to appear less; and therefore the apparent magnitude of an object is not much augmented by being seen through a medium of this form.

Further, it is apparent from the figure, that the effect of a medium of this form depends wholly upon its thickness; for the distance between the lines Rr and e, and consequently the distance between the points R and r, depends upon the length of the line Ka. Again, the distance between the lines AM and fM depends on the length of the line bk; but both Ka and bk depend on the distance between the surfaces CE and DF, and therefore the effect of this medium depends upon its thickness.

**Prop. III.** An object seen through a convex lens, appears larger, brighter, and more pellitant, than with the naked eye.

To illustrate this, let AB (fig. 8.) be the object, CD the lens, and EF the eye. 1. From A and B, the extremities of the object, draw the lines AR, BX, crossing each other in the pupil of the eye; the angle ARB comprehended between these lines, is the angle under which the object would be seen with the naked eye. But by the interposition of a lens of this form, whose property is to render converging rays more so, the rays AY and BX will be made to cross each other before they reach the pupil. There the eye at E will not perceive the extremities of the object by means of these rays (for they will pass with it, ut entering), but by some others which must fall without the points Y and X, or between them; but if they fall between them, they will be made to concur nearer than they themselves would have done; and therefore, if the extremities of the object could not be seen by them, it will much less be seen by the eye. It remains therefore, that the rays which will enter the eye from the points A and B after refraction, must fall upon the lens without the points Y and X; let then the rays AO and BP be thus. These after refraction entering the eye at r, the extremities of the object will be seen in the line QR, or QT, produced, and under the angle QRT, which is larger than ARB, and therefore the apparent magnitude of the object will be increased.

2. Let GHI be a pencil of rays flowing from the point G; as it is the property of this lens to render diverging rays less diverging, parallel, or converging, it is evident that some of those rays, which would proceed on to F and E, and miss the eye, were they to suffer no refraction in passing through the lens, will now enter it; by which means the object will appear brighter. 3. As to the apparent distance of the object, that will vary according to the situation of it with respect to the focus of parallel rays of the lens.
Then, let us suppose the object placed so much nearer the lens than its focus of parallel rays, that the refracted rays KE and LF, though rendered less diverging by passing through it, may yet have a considerable degree of divergency, so that we may be able to form a judgment of the distance of the object thereby. In this case, the object ought to appear where £K, FL, produced back concour; which, because they diverge less than the rays GH, GI, will be beyond G; that is, at a greater distance from the lens than the object is. But because both the brightness and magnitude of the object will at the same time be augmented, prejudice will not permit us to judge it quite so far off as the point where those lines meet, but somewhere between that point and its proper place.

Let the object be placed in the focus of parallel rays, then will the rays KE and LF be parallel; and though in this case the object would appear at an immense distance, if that distance were to be judged of by the direction of the rays KE and LF, yet upon account of the brightness and magnitude of it, we shall not think it much farther from us than if it were seen by the naked eye. But if the object be situated beyond the focus of parallel rays, as in BA (fig. 9.), the rays flowing from thence and falling upon the lens CD, will be collected into their respective foci at a and b, and the intermediate points, m, n, &c. and will there form an image of the object AB; and after crossing each other in the several points of it, as expressed in the figure, will pass on diverging as from a real object. Now if an eye be situated at r, where Ac, Be, rays proceeding from the extreme point of the object, make not a much larger angle AcB, than they would do if there were no lens interposed, and the rays belonging to the same pencil do not converge so much as those which the eye would receive if it were placed nearer to a or b, the object upon these accounts appearing very little larger or brighter than with the naked eye, is seen nearly in its proper place; but if the eye recedes a little way towards ab, the object then appearing both brighter and larger, seems to approach the lens; which is an evident proof of what has been so often asserted, viz. that we judge of the distance of an object in some measure by its brightness and magnitude; for the rays converge the more the farther the eye recedes from the lens; and therefore if we judged of the distance of the object by the direction of the rays which flow from it, we ought in this case to conceive it at a greater distance, than when the rays were parallel, or diverged at their entrance into the eye.

That the object should seem to approach the lens in this case, was a difficulty that exceedingly puzzled the learned Barrow, and which he pronounces imperceptible, and not to be accounted for by any theory we have of vision. Moreover also leaves it to the solution of others, as that which will be inexplicable, till a more intimate knowledge of the vitreous faculty, as he expresses it, be obtained by mortals.

They imagined, that seeing an object appears farther off, the less the rays diverge which fall upon the eye, if they should proceed parallel to each other, it ought to appear exceeding remote; and if they should converge, it should then appear more distant still; the reason of this, was because the looked upon the apparent place of an object, as owing only to the direction of the rays whatever it was, and not at all to its apparent magnitude or splendor.

Perhaps it may proceed from our judging of the distance of an object in some measure by its magnitude, that that deception of sight commonly observed by travellers may arise; viz. that upon the first appearance of a building larger than usual, as a cathedral church, or the like, it generally seems nearer to them, than they afterwards find it to be.

Prop. IV. If an object be placed farther from a convex lens than its focus of parallel rays, and the eye be situated farther from it on the other side than the place where the rays of the several pencils are collected into their respective foci, the object appears inverted, and pendulous in the air, between the eye and the lens.

To explain this, let AB (fig. 9.) represent the object, CD the lens, and let the rays of the pencil ACB be collected in a, and those of BCD in b, forming there an inverted image of the object AB, and let the eye be situated at e. It is apparent from the figure, that some of the refracted rays which pass through each point of the image will enter the eye as from a real object in that place; and therefore the object AB will appear there, as the proposition asserts. But we are so little accustomed to see objects in this manner, that it is very difficult to perceive the image with one eye; but if both eyes are situated in such a manner, that rays flowing from each point of the image may enter both, as at G and H, and we direct our optic axes to the image, its is easy to be perceived.

If the eye be situated in a or b, or very near them on either side, the object appears exceedingly confused, viz. if at a, the rays which proceed from the same point of the object converge very much, and if at e, they diverge so much, that they cannot be collected together upon the retina, but fall upon it as if they were the axes of so many distinct pencils coming from every point of the lens; whereas more little more than one single point of the object is seen at a time, and that appears all over the lens; from whence nothing but confusion arises.

If the lens be so large that both eyes may be applied to it, as in b and f, the object will appear double; for it is evident from the figure, that the rays which enter the eye at b from either extremity of the object A or B, do not proceed as from the same point with that from whence those which enter the other at f seem to flow; the mind therefore is here deceived, and looks upon the object as situated in two different places, and therefore judges it to be double.

Prop. V. An object seen through a concave lens appears nearer, smaller, and less bright, that with the naked eye.

Thus, let AB (fig. 10.) be the object, CD the pupil of an eye, and EF, the lens. Now, as it is the property of a lens of this form to render diverging rays more fo, and converging ones less so, the diverging rays rays GH, GI, proceeding from the point C, will be made to diverge more, and to enter the eye as from some nearer point g; and the rays AH, BI, which converge, will be made to converge less, and to enter the eye as from the points a and b; wherefore the objects will appear in the situation a g b, less and
and nearer than without the lens. Further, as the rays which proceed from $G$ are rendered more diverging, some of them will be made to pass by the pupil of the eye, which otherwise would have entered it, and therefore each point of the object will appear less bright.

**Prop. VI.** An object seen through a polygonal glafs, that is, such as is terminated by several plain surfaces, is multiplied thereby.

For instance, let $A$ (fig. 11.) be an object, and $BC$ a polygonal glafs terminated by the plain surfaces $BD$, $DE$, &c. and let the situation of the eye $F$ be such, that the rays $AB$ being refracted in passing through the glafs, may enter it in the direction $BF$, and the rays $AC$ in the direction $CF$. Then will the eye, by means of the former, see the object in $G$, and by the latter in $H$; and by means of the rays $AI$, the object will appear also in its proper situation $A$.

**Sect. III. Of the Reflection of Light.**

When a ray of light falls upon any body, however transparent, the whole of it never passes through the body, but some part is always driven back or reflected from it; and it is by this reflected light that all bodies which have no light of their own become visible to us. Of that part of the ray which enters, another part is also reflected from the second surface, or that which is farthest from the luminous body. When this part arrives again at the first surface, part of it is reflected back from that surface; and thus it continues to be reflected between the two surfaces, and to pass backwards and forwards within the substance of the medium, till some part is totally extinguished and lost. Besides this inconsiderable quantity, however, which is lost in this manner, the second surface often reflects much more than the first; inasmuch that, in certain positions, scarce any rays will pass through both sides of the medium. A very considerable quantity is also unaccountably lost or extinguished at each reflecting surface; insomuch that no body, however transparent, can transmit all the rays which fall upon it; neither, tho' it be ever so well fitted for reflection, will it reflect them all.

§ 1. Of the Cause of Reflection.

The reflection of light is by no means so easily accounted for as the refraction of the same fluid. This property, as we have seen in the last section, may be accounted for in a satisfactory manner by the supposition of an attractive power diffused throughout the medium, and extending a very little way beyond it; but with regard to the reflection of light, there seems to be no satisfactory hypothesis hitherto invented. Of the principal opinions on this subject Mr. Rowning hath given us the following account.

1. It was the opinion of philosophers, before Sir Isaac Newton discovered the contrary, that light is reflected by impinging upon the solid parts of bodies.

But that it is not so, is clear for the following reasons:

And first, it is not reflected at the first surface of a body by impinging against it.

For it is evident, that, in order to the due and regular reflection of light, that is, that the reflected rays should not be dispersed and scattered one from another, there ought to be no refractions or unevenness in the reflecting surface large enough to bear a visible proportion to the magnitude of a ray of light; because if the surface abounds with such, the reflected rays will rather be scattered like a parcel of pebbles thrown upon a rough pavement, than reflected with that regularity with which light is observed to be from a polished metal. Now those surfaces, which to our senses appear perfectly smooth and well polished, are far from being so; for to polish, is no other than to grind off the larger eminences and protuberances of the metal with the rough and sharp particles of sand, emery, or putty, which must of necessity leave behind them an infinity of refractions and scuffings, which, though inconsiderable with regard to the former roughnesses, and too minute to be discerned by us, must nevertheless bear a large proportion to, if not val'ly exceed, the magnitude of the particles of light.

Secondly, it is not reflected at the second surface by nor at the impinging against any solid particles.

That it is not reflected by impinging upon the solid particles which constitute the second surface, is sufficiently clear from the foregoing argument; the second surfaces of bodies being as incapable of a perfect polish as the first; and it is further confirmed from hence, viz., that the quantity of light reflected differs according to the different density of the medium behind the body. And that it is not reflected by impinging upon the particles which constitute the surface of the medium behind it, is evident, because the strongest reflection of all at the second surface of a body, is when there is a vacuum behind it. This therefore wants no further proof.

II. It has been thought by some, that it is reflected by supposing the Attractive force at the first surface of a body, by a repulsive or attractive force; equally diffused over it; and at the second, by an attractive force.

1. If there be a repulsive force diffused over the surface of bodies that repels rays of light at all times, then, fine by increasing the obliquity of a ray we diminish its perpendicular force (which is that whereby it must make its way through this repulsive force), however weakly that force may be supposed to act; rays of light may be made to fall with so great a degree of obliquity on the reflecting surface, that there shall be a total reflection of them there; and not one particle of light be able to make its way through; which is contrary to observation; the reflection of light at the first surface of a transparent body being never total in any obliquity whatever. The hypothesis therefore in this particular must be false.

2. As to the reflection at the second surface by the attractive attractive force of the body; this may be considered force in two respects: first, when the reflection is total; secondly, when it is partial.

And first, in cases where the reflection is total, the cause of it is undoubtedly that same attractive force by which light would be refracted in passing out of the same body. This is manifest from that analogy which is observable between the reflection of light at this second surface, and its refraction there. For otherwise, what can be the reason that the total reflection should begin just when the obliquity of the incident light is
OPTICS.

Part I.

Causes of Reflection.

When a ray of light strikes a surface, it is reflected at an angle equal to the angle of incidence. This is known as the law of reflection. The angle of incidence is the angle between the incident ray and the normal to the surface, while the angle of reflection is the angle between the reflected ray and the normal. This principle is fundamental in understanding how light interacts with surfaces.

Suppose a parcel of cork-balls all hanging as pendulum vibrations in a symmetrical order, and that an electrified ball passes through the midst of them; it is very easy to show that it may proceed through this assemblage in various directions with a confined motion, and without touching any of them, and that its ultimate direction will have a certain inclination to its primary direction, depending on the outline of the assemblage, just as is observed in the motion of light; and, in the mean time, the cork-balls will be variolously agitated. Just so must it happen to the particles of a transparent body, if we suppose that they act on the particles of light by mutual attractions and repulsions.

An attentive consideration of what happens here will show us that the superficial particles will be much more agitated than the rest; and thus a stratum be produced, which, in any infant, will act on those particles of light which are then approaching them in a manner different from that in which they will act on similarly situated particles of light, which come into the place of the first in the following moment, when these acting particles of the body have (by their motion of vibration) changed their own situation. Now it is clearly understood, that in all motions of vibration, such as the motions of pendulums, there is a moment when the body is in its natural situation, as when the pendulum is in the vertical line. This may happen in the same infant in each atom of the transparent body. The particles of light which then come to the sphere of action may be wholly reflected in the next moment, particle of light in the very situation of the first may be refracted.

Then will arise a separation of light; and as this will depend on the manner in which the particles of bodies are agitated by it during its passage, and as this again will depend on the nature of the body, that is on the law of action of those forces which connect the particles with each other, and with the particles of light, it will be different in different bodies. But in all bodies there will be this general resemblance, that the separation will be more copious in great obliquities of incidence, which gives the repulsive forces more time for action, while it diminishes the perpendicular force of the light. Such a resemblance between the phenomena and the legitimate consequences of the assumption (the agitation of the parts of the body), gives us some authority for attributing this as the cause; nor can the assumption...
Part I.

OPTICS.

Causes of Reflection.

Another Hypothesis.

III. Some being apprehensive of the insufficiency of a reflexive and attractive force diffused over the surfaces of bodies and acting uniformly, have supposed, that, by the action of light upon the surface of bodies, the matter of these bodies is put into an undulatory motion; and that where the surface of it is subsiding, light is transmitted, and in those places where it is rising light is reflected. But to overlook the objections which we have just made to this theory of undulation, we have only to observe, that, were it admitted, it seems not to advance us one jot further; for in those cases, suppose where red is reflected and violet transmitted, how comes it to pass that the red impinges only on those parts when the waves are rising, and the violet when they are subsiding?

IV. The next hypothesis that we shall take notice of, is that remarkable one of Sir Isaac Newton's fits of easy reflection and transmission, which we shall now explain and examine.

That author, as far as we can apprehend his meaning in this particular, is of opinion, that light in its passage from the luminous body, is diffused to be alternately reflected by and transmitted through any refracting surface it may meet with; that these diffusions (which he calls fits of easy reflection and easy transmission) return successively at equal intervals; and that they are communicated to it at its first emission out of the luminous body it proceeds from, probably by some very subtle and elastic substance diffused through the universe, and that in the following manner. As bodies falling into water, or passing through the air, cause undulations in each, so the rays of light may excite vibrations in this elastic substance. The quickness of which vibrations depending on the elasticity of the medium (as the quickness of the vibrations in the air, which propagate sound, depend solely on the elasticity of the air, and not upon the quickness of those in the founding body) the motion of the particles of it may be quicker than that of the rays; and therefore, when a ray at the instant it impinges upon any surface, is in that part of a vibration of this elastic substance which conspires with its motion, it may be easily transmitted; and when it is in that part of a vibration which is contrary to its motion, it may be reflected. He further supposes, that when light falls upon the surface of a body, if it be not in a fit of easy transmission, every ray is there put into one, so that when these rays come to the other body, (for the elastic substance, easily pervading the pores of bodies, is capable of the same vibrations within the body as without it), the rays of one colour shall be in a fit of easy transmission, and those of another in a fit of easy reflection, according to the quickness of the body, the intervals of the fits being different in rays of different kind. This seems to account for the different colours of the bubble and thin plate of air and water, as is obvious enough; and likewise for the reflection of light at the second surface of a thicker body; for the light reflected from thence is thicker, and to form rings according to the different thicknesses of the body, when not intermixed and confounded with other light, as will appear from the following experiment. If a piece of glass be ground concave on one side and convex on the other, both its concavity and convexity having one common centre; and if a ray of light be made to pass through a small hole in a piece of paper held at that common centre, and permitted to fall on the glass; besides those rays which are regularly reflected back to the hole again, there will be others reflected to the paper, and form coloured rings surrounding the hole, not unlike those occasioned by the reflection of light from thin plates.

It is ever with extreme reluctance, that we venture to call in question the doctrines of Newton; but to his theory of reflection there is this insuperable objection, that it explains nothing, unless the fits of more easy reflection and transmission be held as legitimate, namely, that they are produced by the undulations of another elastic fluid, incomparably more elastic than light, acting upon it in the way of impulse. The fits themselves are matters of fact, and no way different from what we have endeavoured to account for: but to admit this theory of them would be to transgress every rule of philosophising, as we have shown them to be susceptible of explanation from acknowledged optical laws.

§ 2. Of the Laws of Reflection.

The fundamental law of the reflection of light, is, that in all cases the angle of reflection is equal to the angle of incidence. This is found by experiment to be the case, and may be demonstrated mathematically from the laws of percussion in bodies perfectly elastic. The axiom therefore holds good in every case of reflection, whether it be from plane surfaces or spherical ones, and that whether they are convex or concave; and hence the seven following propositions relating to the reflection of light from plane and spherical surfaces may be deduced.

I. Rays of light reflected from a plane surface have the same degree of inclination to one another that their respective incident ones have. For the angle of reflection of each ray being equal to that of its respective incident one, it is evident, that each reflected ray will have the same degree of inclination to that portion of the surface from whence it is reflected that its incident one has; but it is here supposed, that all those portions of surface from whence the rays are reflected, are situated in the same plane; consequently the reflected rays will have the same degree of inclination to each other that their incident ones have, from whatever part of the surface they are reflected.

II. Parallel rays reflected from a concave surface are rendered converging. To illustrate this, let AF CD, EB (fig. 1.) represent three parallel rays falling upon the concave surface FB, whose centre is C. To the points F and B draw the lines CF, CB; the reflected there being drawn from the centre will be perpendicular to the surface at those points. The incident ray CD also falling through the centre, will be perpendicular to the surface, and therefore will return after refraction in the same line, but the oblique rays AF

Plate CCCLXIX.
and EB will be reflected into the lines FM and BM, situated on the contrary side of their respective perpendicular CF and CB. They will therefore proceed converging after reflection towards some point, as M, in the line CD.

III. Converging rays falling on the like surface, are made to converge more.—For, every thing remaining as above, let GF, HF, be the incident rays. Now, because these rays have larger angles of incidence than the parallel ones AF and EB in the foregoing case, their angles of reflection will also be larger than those of the others; they will therefore converge after reflection, suppose in the lines FN and BN, having their point of convergence N farther from the point C than M, that to which the parallel rays AF and EB converged in the foregoing case; and their precise degree of convergency will be greater than that wherein they converged before reflection.

IV. Diverging rays falling upon the like surface, are, after reflection, parallel, diverging, or converging. If they diverge from the focus of parallel rays, they then become parallel; if from a point nearer to the surface than that, they will diverge, but in a less degree than before reflection; if from a point between that and the centre, they will converge after reflection, and that to some point on the contrary side of the centre, but situated farther from it than the point from which they diverged. If the incident rays diverge from a point beyond the centre, the reflected ones will converge to one on the other side of it, but nearer to it than the point they diverged from; and if they diverge from the centre, they will be reflected thither again.

1. Let them diverge in the lines MF, MB, proceeding from E, the focus of parallel rays; then, as the parallel rays AF and EB were reflected into the lines FM and BM (by Prop. II.), these rays will now on the contrary be reflected into them.

2. Let them diverge from N, a point nearer to the surface than the focus of parallel rays, they will then be reflected into the diverging lines FG and BI, which the incident rays GF and HB described that were shown to be reflected into them in the foregoing proposition; but the degree wherein they diverge will be less than that wherein they diverged before reflection.

3. Let them proceed diverging from X, a point between the focus of parallel rays and the centre; they then make less angles of incidence than the rays MF and MB, which became parallel by reflection: they will consequently have less angles of reflection, and proceed therefore converging towards some point, as Y; which point will always fall on the contrary side of the centre, because a reflected ray always falls on the contrary side of the perpendicular with respect to that on which its incident one falls; and of consequence it will be farther distant from the centre than X.

4. If the incident ones diverge from Y, they will, after reflection, converge to X; those which were the incident rays in the former case being the reflected ones in this. And lastly,

5. If the incident rays proceed from the centre, they fall in with their respective perpendiculars; and for that reason are reflected thither again.

V. Parallel rays reflected from a convex surface are rendered diverging.—For, let AB, GD, EF (fig. 2,) be three parallel rays falling upon the convex surface BF, whose centre of convexity is C, and CCCLXIX. let one of them, viz. GD, be perpendicular to the surface. Through B, D, and F, the points of reflection, draw the lines CV, CG, and CT; which, because they pass through the centre, will be perpendicular to the surface, at these points. The incident ray GD being perpendicular to the surface, will return after reflection in the same line, but the oblique ones AB and EF in the lines BK and FL, arising on the contrary side of their respective perpendiculars BV and FT. They will therefore diverge, after reflection, as from some point M in the line GD produced; and this point will be in the middle between D and C.

VI. Diverging rays reflected from the like surface are rendered more diverging.—For, every thing remaining as above, let GB, GF, be the incident rays. These having larger angles of incidence than the parallel ones AB and EF in the preceding case, their angles of reflection will also be larger than theirs: they will therefore diverge after reflection, suppose in the lines BP and FQ, as from some point N, farther from C than the point M; and the degree wherein they will diverge will be greater than that wherein they diverged before reflection.

VII. Converging rays reflected from the like surface, are parallel, converging, or diverging. If they tend towards the focus of parallel rays, they then become parallel: if to a point nearer the surface than that, they converge, but in a less degree than before reflection; if to a point between that and the centre, they will diverge after reflection, as from some point on the contrary side of the centre, but situated farther from it than the point they converged to: if the incident rays converge to a point beyond the centre, the reflected ones will diverge as from one on the contrary side of it, but nearer to it than the point to which the incident ones converged; and if the incident rays converge towards the centre, the reflected ones will proceed as from thence.

1. Let them converge in the lines KB and LF, tending towards M, the focus of parallel rays; then, as the parallel rays AB, EF were reflected into the lines BK and FL (by Prop. V.), those rays will now on the contrary be reflected into them.

2. Let them converge in the lines PB, QF, tending towards N a point nearer the surface than the focus of parallel rays, they will then be reflected into the converging lines BG and FG, in which the rays GB, GF proceeded that were shown to be reflected into them by the last proposition: but the degree wherein they will converge will be less than that wherein they converged before reflection.

3. Let them converge in the lines RB and SF proceeding towards X, a point between the focus of parallel rays and the centre: their angles of incidence will then be less than those of the rays KB and LF, which became parallel after reflection: their angles of reflection will therefore be less; on which account they must necessarily diverge, suppose in the lines BH and FI, for some point, as Y; which point (by Prop. IV.) will fall on the contrary side of the centre.
4. If the incident rays tend towards \( Y \), the reflected ones will diverge as from \( X \); those which were the incident ones in one case being the reflected ones in the other.

5. Lastly, if the incident rays converge towards the centre, they fall in with their respective perpendiculars; on which account they proceed after reflection as from the centre.

We have already observed, that in some cases there is a very great reflection from the second surface of a transparent body. The degree of inclination necessary to cause a total reflection of a ray at the second surface of a medium, is that which requires that the refracted angle (supposing the ray to pass out there) should be equal to or greater than a right one; and consequently it depends on the refractive power of the medium through which the ray passes, and is therefore different in different media. When a ray passes through glass surrounded with air, and is inclined to its second surface under an angle of \( 42 \) degrees or more, it will be wholly reflected there. For, as \( \frac{1}{1} \) is to \( 17 \) (the ratio of refraction out of glass into air), \( 0 \) is the sine of an angle of \( 42 \) degrees to a fourth number that will exceed the sine of a right angle. From hence it follows, that when a ray of light arrives at the second surface of a transparent substance with as great or a greater degree of obliquity than that which is necessary to make a total reflection, it will there be all returned back to the first: and if it proceeds towards that with as great an obliquity as it did towards the other (which it will do if the surfaces of the medium be parallel to each other), it will there be all reflected again, &c. and will therefore never get out, but pass from side to side, till it be wholly refracted and lost within the body.—From hence may arise an obvious inquiry, how it comes to pass, that light falling very obliquely upon a glass window from without, should be transmitted into the room. In answer to this it must be considered, that however obliquely a ray falls upon the surface of any medium whose sides are parallel (as those of the glass in a window are), it will suffer such a degree of refraction in entering there, that it shall fall upon the second with a less obliquity than that which is necessary to cause a total reflection.

For instance, let the medium be glass, as supposed in the present case: then, as \( 17 \) is to \( 11 \) (the ratio of refraction out of air into glass), \( 0 \) is the sine of the largest angle of incidence with which a ray can fall upon any surface to the sine of a less angle than that of total reflection. And therefore, if the sides of the glass be parallel, the obliquity with which a ray falls upon the first surface, cannot be so great, but that it shall pass the second without suffering a total reflection there.

When light passes out of a denser into a rarer medium, the nearer the second medium approaches the first in density (or more properly in its refractive power), the less of it will be refracted in passing from one to the other; and when their refracting powers are equal, all of it will pass into the second medium.

The above propositions may be all mathematically demonstrated in the following manner.

Prop. 1. Of the reflection of rays from a plane surface.

"When rays fall upon a plane surface, if they diverge, the focus of the reflected rays will be at the same distance behind the surface, that the radiant point was before it: if they converge, it will be at the same distance before the surface that the imaginary focus of the incident rays is behind it."

This proposition admits of two cases.

Case I. Of diverging rays.

Dem. Let \( AB, AC \), (fig. 3.) be two diverging rays incident on the parallel surface \( DE \), the one perpendicularly, the other obliquely: the perpendicular one \( AB \) will be refracted to \( A \), proceeding as from some point in the line \( AB \) produced, the oblique one \( AC \) will be refracted into some line as \( CF \), such that the point \( C \), where the line \( FG \) produced intersects the line \( AB \) produced also, shall be at an equal distance from the surface \( DE \) with the radiant \( A \). For the perpendicular \( CH \), being drawn, \( AC \) and \( FC \) will be the angles of incidence and reflection; which being equal, their complements \( ACB \) and \( FCE \) are also equal: but the angle \( BCG \) is equal to \( FCE \), as being vertical to it; therefore in the triangles \( ABC \) and \( GBC \) the angles at \( C \) are equal, the side \( BC \) is common, and the angles at \( B \) are also equal to each other, as being right ones; therefore the lines \( AB \) and \( BC \), which respect the equal angles at \( C \), are also equal; and consequently the point \( G \), the focus of the incident rays \( AB, AC \), is at the same distance behind the surface, that the point \( A \) is before it. Q. E. D.

Case 2. Of converging rays.

This is the converse of the former case. For supposing \( FC \) and \( AB \) to be two converging incident rays, \( CA \) and \( BA \) will be the reflected ones (the angles of incidence in the former case being now the angles of reflection, and vice versa), having the point \( A \) for their focus; but this, from what was demonstrated above, is at an equal distance from the reflecting surface with the point \( G \), which in this case is the imaginary focus of the incident rays \( FC \) and \( AB \).

Obs. It is not here, as in the refraction of rays in passing through a plane surface, where some of the refracted rays proceed as from one point, and some as from another; but they all proceed after reflection as from one and the same point, however obliquely they may fall upon the surface; for what is here demonstrated of the ray \( AC \) holds equally of any other, as \( AI \), \( AK \), &c.

The case of parallel rays incident on a plane surface is included in this proposition: for in that case we are to suppose the radiant to be at an infinite distance from the surface, and then by the proposition the focus of the reflected rays will be \( F \); that is, the rays will be parallel after reflection, as they were before.

Prop. II. Of the reflection of parallel rays from a spherical surface.

"When parallel rays are incident upon a spherical surface, the focus of the reflected rays will be the middle point between the centre of convexity and the surface."

This proposition admits of two cases.

Case 1. Of parallel rays falling upon a convex surface.

Dem. Let \( AB, DH \), (fig. 4.) represent two parallel rays incident on the convex surface \( BH \), the one perpendicularly, the other obliquely; and let \( C \) be the centre of convexity; suppose \( H \) to be the reflected ray of the oblique incident one \( DH \) proceeding as from \( F \), a
OPTICS.

Laws of Reflection.

A point in the line AB produced. Through the point H draw the line CI, which will be perpendicular to the surface at that point; and the angles DHI and IHE, being the angles of incidence and reflection, will be equal. To the former of these, the angle HCF is equal, the lines AC and HI being parallel; and to the latter the angle CHF, being vertical; wherefore the triangle CHF is isosceles, and consequently the sides CF and FH are equal; but supposing BH to vanish, FH is equal to FB; and therefore upon this supposition FC and FB are equal, that is, the focus of the reflected rays is the middle point between the centre of convexity and the surface. Q.E.D.

Case 2. Of parallel rays falling upon a concave surface.

Dem. Let AB, DH, (fig. 5.) be two parallel rays incident, the one perpendicularly, the other obliquely, on the concave surface BH, whose centre of concavity is C. Let BF and HC be the reflected rays meeting each other in F; this will be the middle point between B and C. For drawing through C the perpendicular CI, which will be perpendicular to the surface at that point; and the angles DHI and IHE, being the angles of incidence and reflection, will be equal, to the former of which the angle HCF is equal, as alternate; and therefore the triangle CHF is isosceles. Wherefore CF and FH are equal: but if we suppose BH to vanish, FB and FH are also equal, and therefore CF is equal to FB; that is, the focal distance of the radius, is everywhere of the same length, the equal sides of the triangle CHF are equal, that is, the focus in the point F, all the rays incident from the point R, as from the point C, will proceed from the concave surface would have proceeded as from the point F; and those reflected from the concave would have fallen upon it, however distant their incident ones from one point, and convex surface would have proceeded as from the point F, and those reflected from the concave would have fallen upon it, however distant their incident ones from one point. For in a spherical surface the rays reflected from the concave (that is, with the surface of the parabola) equal to those which are made with the same tangents by lines drawn from thence to the focus; therefore, if the incident rays describe those parallel lines, the reflected ones will necessarily describe these other, and so will all proceed as from, or meet in, the same point.

Prop. III. Of the reflection of diverging and converging rays from a spherical surface.

When rays fall upon any spherical surface, if they Properly diverge, the distance of the focus of the reflected rays is less than the distance of the incident rays from the same (or, if they converge, to that of the imaginary focus of the incident rays), as the distance of the focus of the reflected rays from the centre is to the distance of the radiant point (or imaginary focus of the surface) and the incident rays) from the same.

This proposition admits of ten cases.

Case 1. Of diverging rays falling upon a convex surface.

Dem. Let RB, RD (fig. 7.) represent two diverging rays flowing from the point R as from a radiant, and falling the one perpendicularly, the other obliquely, on the convex surface BD, whose centre is C. Let DE be the reflected ray of the incident ones AB, CD, proceed as from the point F, those of the incident ones AB, CD, viz. DK, GL, will proceed as from N, those of the incident ones EG, HI, as from O. because the farther the incident ones CD, EG, &c. are from AB, the nearer to the surface are the points F, f, f, in the line BF, from which they proceed after reflection; so that properly the foci of the reflected rays BA, DK, GL, &c. are not in the line AB produced, but in a curve line passing through the points F, N, O, &c.

The surface is applicable to the case of parallel rays reflected from a concave surface, as expressed by the pricked lines on the other half of the figure, where IQ, RS, TV, are the incident rays; QF, Sf, Vf, the reflected ones, interfering each other in the points X, Y, and F; so that the foci of these rays are not in the line FB, but in a curve passing through those points.

Had the surface EH in fig. 4. or 5. been formed by Rays proceeding the revolution of a parabola about its axis having its ceeding focus in the point F, all the rays reflected from the point F, and those reflected from the concave would have fallen upon it, however distant their incident ones from one point, and convex surface would have proceeded as from the point F, and those reflected from the concave would have fallen upon it, however distant their incident ones from one point.
was there demonstrated, that FB is to RB as CF to CR; that is, the distance of the focus from the surface is to the distance (in this Case) of the imaginary focus of the incident rays, as the distance of the focus from the centre is to the distance of the imaginary focus of the incident rays from the same.

\[Q.E.D.\]

**Case 3.** Of converging rays falling upon a convex surface, and tending to a point between the focus of parallel rays and the centre.

**Dem.** Let BD (fig. 8.) represent a convex surface whose centre is C, and whose focus of parallel rays is P; and let AB, KD, be two converging rays incident upon it, and having their imaginary focus at R, a point between P and C. Now because KD tends to a point between the focus of parallel rays and the centre, the reflected ray DE will diverge from some point on the other side the centre, suppose F; as explained above (p. 308.) under Prop. 7. Through D draw the perpendicular CD, and produce it to H; then will KDH and HDE be the angles of incidence and reflection, which being equal, their vertical ones RDC and CDF will be so too, and therefore the vertex of the triangle RDF is bisected by the line DC: wherefore (3 El. 6.) FD and DR, or BD vanishing, FB and BR are to reach each other as FC to CR; that is, the distance of the focus of the reflected rays is to that of the imaginary focus of the incident ones, as the distance of the former from the centre is to the distance of the latter from the same.

\[Q.E.D.\]

**Case 4.** Of converging rays falling upon a concave surface, and proceeding from a point between the focus of parallel rays and the centre.

**Dem.** Let RB, RD, (fig. 8.) be the diverging rays incident upon the concave surface BD, having their radiant point in the point R, the imaginary focus of the incident rays in the foregoing case. Then as RD was in that case reflected into DE, R will now be reflected into DF. But it was there demonstrated, that FB and RB are to each other as CF to CR; that is, the distance of the focus is to that of the radiant as the distance of the former from the centre is to the distance of the latter from the same.

\[Q.E.D.\]

The angles of incidence and reflection being equal, it is evident, that if in any case, the reflected ray be made the incident one, the incident will become the reflected one; and therefore the four following cases may be considered respensively as the converse of the four foregoing; for in each of them the incident rays are supposed to coincide with the reflected ones in the other. Or they may be demonstrated independently of them as follows.

**Case 5.** Of converging rays falling upon a convex surface, and tending to a point nearer the surface than the focus of parallel rays.

**Dem.** Let ED, RB (fig. 7.) be the converging rays incident upon the convex surface BD whose centre is C, and focus of parallel rays is P; and let the imaginary focus of the incident rays be at F, a point between B and P; and let DR be the reflected ray. From C and R draw the lines CH, RH, the one passing through D, the other parallel to FE. Then will the angle EHD be equal to HDE the angle of incidence, as alternate to it; and therefore equal to HDR, the angle of reflection; wherefore the triangle HDR is isosceles, and consequently DR is equal to RH. Now the lines FD and RH being parallel, the triangles FDC and HRC are similar; and therefore RH, or RD is to FD as CR to CF; but BD vanishing, RD and FD coincide with RB and FB, wherefore RB is to FB as CR to CF; that is, the distance of the focus from the surface is to the distance of the imaginary focus of the incident rays, as the distance of the focus from the centre is to the distance of the imaginary focus of the incident rays from the same.

\[Q.E.D.\]

**Case 6.** Of converging rays falling upon a concave surface, and proceeding from a point between the focus of parallel rays and the surface.

**Dem.** Let RD and FB represent two diverging rays flowing from the point F as a radiant, which was the imaginary focus of the incident rays in the foregoing case. Then as ED was in that case reflected into DR, FD will be reflected into DK (for the reason mentioned in Case 2.), so that the reflected ray will proceed as from the point R: but it was demonstrated in the case immediately foregoing, that RB is to FB as CR to CF; that is, the distance of the focus from the surface is to that of the radiant from the same, as the distance of the former from the centre is to that of the latter from the same.

\[Q.E.D.\]

**Case 7.** Of converging rays falling upon a convex surface, and tending towards a point beyond the centre.

**Dem.** Let AB, ED (fig. 8.) be the incident rays tending to P, a point beyond the centre C, and let DK be the reflected ray of the incident one ED. Then because the incident ray ED tends to a point beyond the centre, the reflected ray DK will proceed as from one on the contrary side, suppose R; as explained above under Prop. VII. Through D draw the perpendicular CD, and produce it to H. Then will EDH and HDK be the angles of incidence and reflection; which being equal, their vertical ones CDF and CDR will be so too; consequently the vertex of the triangle HDF is bisected by the line CD: wherefore, RD is to DF, or (3 Elem. 6.) BD vanishing, RB is to BF as RC to CF; that is, the distance of the focus of the reflected rays is to that of the imaginary focus of the incident rays, as the distance of the former from the centre is to the distance of the latter from the same.

\[Q.E.D.\]

**Case 8.** Of converging rays falling upon a concave surface, and proceeding from a point beyond the centre.

**Dem.** Let FB, FD, be the incident rays having their radiant in F, the imaginary focus of the incident rays in the foregoing case. Then as ED was in that case reflected into DK, FD will now be reflected into DR; so that R will be the focus of the reflected rays. But it was demonstrated in the foregoing case, that RB is to FB as RC to CF; that is, the distance of the focus of the reflected rays from the surface is to the distance of the radiant from the same, as the distance of the focus of the reflected rays from the centre is to the distance of the radiant from thence.

\[Q.E.D.\]

The two remaining cases may be considered as the converse of those under Prop. II. (p. 309, 310.) beyond the
the foregoing, as follows.

Case 9. Converging rays falling upon a convex surface, and tending to the focus of parallel rays, become parallel after reflection.

Demonstration. Let ED, RB (fig. 7.) represent two converging rays incident on the convex surface BD, and tending towards F, which we will suppose to be the focus of parallel rays; and let DR be the reflected ray, and C the centre of convexity of the reflecting surface. Through C draw the line CD, and produce it to H, drawing RH parallel to ED produced to F. Now it has been demonstrated (Case 5. where the incident rays are supposed to tend to the point F), that RB is to RF as RC to CF; but F in this case being supposed to be the focus of parallel rays, it is the middle point between C and B (by Prop. II.), and therefore FB and FC are equal; and consequently the two other terms in the proportion, viz. RB and RC, must be so too; which can only be upon the supposition that R is at an infinite distance from B; that is, that the reflected rays BR and DR are parallel. \( \therefore E.D. \)

Case 10. Diverging rays falling upon a concave surface, and proceeding from the focus of parallel rays, become parallel after reflection.

Demonstration. Let RD, RB (fig. 8.) be two diverging rays incident upon the concave surface BD, as supposed in Case 4, where it was demonstrated that FB is to RB as RC to CF; but F in the present case RB and CR are equal, because R is supposed to be the focus of parallel rays; therefore FB and FC are so too; and which cannot be unless F be taken at an infinite distance from B; that is, unless the reflected rays BF and DF are parallel. \( \therefore E.D. \)

OBS. It is here observable, that in the case of diverging rays falling upon a convex surface (see fig. 7.), the farther the point D is taken from B, the nearer the point F, the focus of the reflected rays, approaches to B, while the radiant R remains the same. For it is evident from the curvature of a circle, that the point D (fig. 9.) may be taken so far from B, that the reflected ray DE shall proceed as from F, G, H, or even from B, or from any point between B and R; and the farther it is taken from B, the fatter the point from which it proceeds approaches towards R; as will easily appear if we draw several incident rays with their respective reflected ones, in such manner that the angles of reflection may be all equal to their respective angles of incidence, as is done in the figure. The like is applicable to any of the other cases of diverging or converging rays incident upon a spherical surface. This is the reason, that when rays are considered as reflected from a spherical surface, the distance of the oblique rays from the perpendicular one is taken so small, that it may be supposed to vanish.

From hence it follows, that if a number of diverging rays are incident upon the convex surface BD at the several points B, D, D, &c. they shall not proceed after reflection as from any point in the line RB produced, but as from a curve line paffing through the several points F, f, f, &c. The same is applicable to all the other cases.

Had the curvature BD (fig. 7.) been hyperbolical, having its foci in R and F; then R would be the radiant (or the imaginary focus of incident rays), F would have been the focus of the reflected ones, and vice versa; however distant the points B and D might be taken from each other. In like manner, had the curve BD (fig. 8.) been elliptical, having its foci in F and R, the one of these being made the radiant (or imaginary focus of incident rays), the other would have been the focus of reflected ones, and vice versa. For both in the hyperbola and ellipsis, lines drawn from each of their foci through any point make equal angles with the tangent to that point. Therefore, if the incident rays proceed to or from one of their foci, the reflected ones will all proceed as from or to the other. So that, in order that diverging or converging rays may be accurately reflected to or from a point, the reflecting surface must be formed by the revolution of an hyperbola about its longer axis, when the incident rays are such, that their radiant or imaginary focus of incident rays shall fall on one side of the surface, and the focus of the reflected ones on the other; when they are both to fall on the same side, it must be formed by the revolution of an ellipse about its longer axis.

However, upon account of the great facility with which spherical surfaces are formed in comparison of that with which surfaces formed by the revolution of any of the conic sections about their axes are made, the latter are very rarely used. Add to this another inconvenience, viz. that the foci of these curves being mathematical points, it is but one point of the surface of an object that can be placed in any one of them at a time; so that it is only in theory that surfaces formed by the revolution of these curves about their axes render reflection perfect.

Now, because the focal distance of rays reflected from a spherical surface cannot be found by the analogy of the focal distance of rays reflected from a convex surface, we shall here give an incidental reflection whereby the method of doing it in all others will readily appear.

Problem. Let it be required to find the focal distance to which diverging rays incident upon a convex surface, whose radius of convexity is 5 parts, and the distance of the radiant from the surface is 20.

Solution. Call the focal distance sought \( x \); then will the distance of the focus from the centre be \( 5 - x \), and that of the radiant from the same 25, therefore by prop. 3. we have the following proportion, viz. \( x : 20 = 5 : x \); and multiplying extremes together and means together, we have \( 25x = 100 - 20x \), which, after due reduction, gives \( x = 4 \frac{2}{3} \).

If in any case it should happen that the value of \( x \) should be a negative quantity, the focal point must then be taken on the contrary side of the surface to that on which it was supposed that it would fall in reflecting the problem.

If letters instead of figures had been made use of in the foregoing solution, a general theorem might have been ratted, to have determined the focal distance of reflected rays in all cases whatever. See this done in Suppl. to Gregory's Optics, 2d edit. p. 112.
Part I.

OPTICS.

To explain this, let AB (fig. 12.) represent an ob.

§ 3. Of the Appearance of Bodies seen by Light reflected from plane and spherical Surfaces.

Whatever has been said concerning the appearance of bodies seen by refracted light through lenses, respects also the appearance of bodies seen by reflection. But besides this, the object of the present Section is to determine the point to or from which any given incident ray proceeds after reflection, is much more simple. It is only necessary to draw a perpendicular from the point of reflection to the reflecting surface, and is perpendicular to the reflecting surface.

The truth of this appears sufficiently from the propositions formerly laid down: in each of which, rays flowing from any radiant point, are shown to proceed after reflection to or from some point in a line that passes through the said point and is perpendicular to the reflecting surface.

This observation, however, except where an object is presented to the view from a plane surface, relates only to those cases where the representation is made by means of such rays as fall upon the reflecting surface with a very small degree of obliquity; because such rays may fall at a considerable distance from the perpendicular, proceed not after reflection as from any point in that perpendicular, but as from other points situated in a certain curve, as hath already been explained; upon which account these rays are neglected, as making a confused and deformed representation. And therefore it is to be remembered, that however the situation of the eye with respect to the object and reflecting surface may be represented in the following figures, it is to be supposed as situated in such a manner with respect to the object, that rays flowing from thence and entering it after reflection, may be such only as fall with a very small degree of obliquity upon the reflecting surface; that is, the eye must be supposed to be placed almost directly behind the object, or between it and the reflecting surface. The reason why it is never always so placed, is only to avoid confusion in the figures.

I. When an object is seen by reflection from a plane surface, the image of it appears at the same distance behind the surface that the object is placed before it, of the same magnitude therewith, and directly opposite to it.

Vol. XIII.
OPTICS.

Part I.

The Appearance of objects seen by Reflection from different Surfaces.

1. The image therefore will be on the opposite side of the surface with respect to the object: it will be more distant than it; and consequently being terminated by the perpendicular CI and CM, it will also be larger.

2. When the object is placed in the focus of parallel rays, the reflected rays enter the eye parallel; in which case the image ought to appear at an infinite distance behind the reflecting surface: but the representation of it, for the like reasons that were given in the foregoing case, being large and difficult, we judge it not much farther from the surface than the image.

3. When the object is placed between the focus of parallel rays and the centre, the image falls on the opposite side of the centre, is larger than the object, and in an inverted position.

Thus let AB (fig. 14.) represent the object, SV the reflecting surface, P its focus of parallel rays, and C its centre. Through A and B, the extremities of the object, draw the lines CE and CN, which will be perpendicular to the surface; and let AR, AG, be a pencil of rays flowing from A. These rays proceeding from a point beyond the focus of parallel rays, will after reflection converge towards some point on the opposite side of the centre, which will fall upon the perpendicular EC produced, but at a greater distance from C than the radiant A from which they diverged. For the same reason, rays flowing from B will converge to a point in the perpendicular NC produced, which shall be farther from C than the point B; from whence it is evident, that the image IM is larger than the object AB, that it falls on the contrary side of the centre, and that their positions are inverted with respect to each other.

4. If the object be placed beyond the centre of convexity, the image is then formed between the centre and the focus of parallel rays, is less than the object, and its position is inverted.

It is proposed to consider the converse of the foregoing: for as in that case rays proceeding from A were reflected to I, and from B to M; so rays flowing from I and M will be reflected to A and B; if therefore an object be supposed to be situated beyond the centre in IM, the image of it will be formed in AB between that and the focus of parallel rays, will be less than the object, and inverted.

5. If the middle of the object be placed in the centre of convexity of the reflecting surface, the object and its image will be coincident; but the image will be inverted with respect to the object.

That the place of the image and the object should be the same in this case needs little explanation; for the middle of the object being in the centre, rays flowing from thence will fall perpendicularly upon the surface, and therefore necessarily return thither again; so that the middle of the image will be coincident with the middle of the object. But that the image should be inverted is perhaps not so clear. To explain this, let AB (fig. 15.) be the object, having its middle point C in the centre of the reflecting surface SV; through the centre and the point R draw the Apothem OR, which will be perpendicular to the reflecting surface; join the points AR and BR, and let AR represent a ray flowing from A; this will be reflected into RB; for C being the middle point between A and B, the angles ARC and CRB are equal; and a ray from B will likewise be reflected to A, and therefore the position of the image will be inverted with respect to that of the object.

In this proposition it is to be supposed, that the object AB is so situated with respect to the reflecting surface, that the angle ACR may be right; for otherwise the angles ARC and BRC will not be equal, and part of the image will therefore fall upon the object and part off.

6. If in any of the three last cases, in each of which the image is formed on the same side of the reflecting surface with the object, the eye be situated farther from the surface than the place where the image falls, the rays of each pencil, crossing each other in the several points of the image, will enter the eye as from a real object situated there; so that the image will appear pendulous in the air between the eye and the reflecting surface, and in the position wherein it is formed, viz., inverted with respect to the object, in the same manner that an image formed by refracted light appears to an eye placed beyond it; which was fully explained under Prop. IV. (p. 304.), and therefore needs not be repeated.

But as what relates to the appearance of the object, when the eye is placed nearer to the surface than the image, was not there fully inquired into, that point shall now be more briefly examined under the following case, which equally relates to refracted and reflected light.

7. If the eye be situated between the reflecting surface and the plane of the image, the object is then seen beyond the surface; and the farther the eye recedes from the surface towards the place of the image, the more confused, larger, and nearer, the object appears.

To explain this, let AB (fig. 16.) represent the object AC; IM its image, one of whose points M is formed by the concurrence of the reflected rays DM, EM, &c., which before reflection came from B; the other, I, by the concurrence of DI, EI, &c., which came from A; and let a b be the pupil of an eye, situated between the surface DP and the image. This pupil will admit the rays H a, K b; which, because they are tending towards I, are such as came from A, and therefore the point A will appear diffused over the space RS. In like manner the pupil will also receive into it the reflected rays K a and L b, which, because they are tending towards M, by interception came from C; and therefore the point A will be seen spread as it were over the space TV, and the object will seem to fill the space RV; but the representation of it will be confused, because the intermediate points of the object being equally enlarged in appearance, there will not be room for them between the points S and T, but they will coincide in part one with another: for instance, the appearance of that point in the object C, whose representation falls upon c in the image, will fill the space mn; and so of the rest. Now, if the same pupil

Plate CCCLIX.
pupil be removed into the situation $e$, the reflected rays $Ex$ and $Gf$ will then enter the eye, and therefore every ray of the object will appear to cover the space $XY$; and because the rays $Og$ and $Le$ will also enter it in their progress towards $M$, the point $B$, from whence they came, will appear to cover $OZ$; the object therefore will appear larger and more confused than before. And when the eye recedes quite to the image, it sees but one single point of the object, and that appears diffuse all over the reflecting surface: for instance, if the eye recedes to the point $M$, then rays flowing from the point $B$ enter it upon whatever part of the surface they fall; and so for the rest. The object also appears nearer to the surface the farther the eye recedes from it towards the place of the image; probably because, as the appearance of the object becomes more and more confused, its place is not so easily distinguished from that of the reflecting surface itself, till at last when it is quite confused (as it is when the eye is arrived at $M$) they both appear as one, the surface affuming the colour of the object.

As to the precise apparent magnitude of an object seen after this manner, it is such that the angle it appears under shall be equal to that which the image of the same object would appear under were we to suppose it seen from the same place: that is, the apparent object (for such we must call it) will be equal to the angle $EF$ from the point $E$ to the image of the same object and the image subtend equal angles at the eye.

**Dem.** Here we must suppose the pupil of the eye to be a point only, because the magnitude of that causes small alteration in the apparent magnitude of the object; as we shall see by and by. Let then the point $a$ represent the pupil, then will the extreme rays that can enter it be $Ha$ and $Ka$: the object therefore will appear under the angle $HaK$, which is equal to its vertical one $MaI$, under which the image $I$ would appear were it to be seen from $a$. Again, if the eye be placed in $f$, the object appears under the angle $GfO$ equal to $Iff$, which the image subtends at the same place, and therefore the apparent object and image of it subtend equal angles at the eye.

**L. E. D.**

Now if we suppose the pupil to have any sensible magnitude, such as, suppose, that its diameter may be $ab$; then the object seen by the eye in that situation will appear under the angle $Haf$, which is larger than the angle $HaK$, under which it appeared before; because the angle at $K$ is nearer than the angle at $a$, to the line $IM$, which is a sufficient common to them both.

From this proposition it follows, that, were the eye close to the surface at $K$, the real and apparent object would be seen under equal angles (for the real object appears from that place under the same angle that the image does, as will be shown at the end of this section): therefore, when the eye is nearer to the image than that point, the image will subtend a larger angle at it than the object does; and consequently, since the image and apparent object subtend equal angles at the eye, the apparent object must necessarily be seen under a larger angle than the object itself, whenever the eye is placed between the surface and the image.
IV. As objects are multiplied by being seen through transparent media, whose surfaces are properly disposed, so they may also by reflecting surfaces. Thus,

1. If two reflecting surfaces be disposed at right angles, as the surfaces AB, BC, (fig. 21.), an object at D may be seen by an eye at E, after one reflection at F, in the line EF produced; after two reflections, the first at G, the second at H, in the line EH produced, and so after one reflection made at A, in the line EA produced.

2. If the surfaces be parallel, as AB, CD, (fig. 22.), and the object be placed at E and the eye at F, the object will appear multiplied an infinite number of times: thus, it may be seen in the line FG produced, after one reflection at G; in the line FH produced, after two reflections, the first at I, the second at H; and also in FP produced, after several successive reflections of the ray EL, at the points L, M, N, and P: and so on in infinitum. But the greater the number of reflections are, the weaker their representation will be.

Sect. IV. Of the different Refrangibility of Light.

As this property of light solves a great number of the phenomena which could not be understood by former opticians, we shall give an account of it in the words of Sir Isaac Newton, who first discovered it; especially as his account is much more full, clear, and perspicuous, than those of succeeding writers.

In a very dark chamber, at a round hole F (fig. 1.), about one third of an inch broad made in the shutter of a window, I placed a glass prism ABC, whereby the beam of the sun's light SF, which came in at that hole, might be refracted upwards, toward the opposite wall of the chamber, and there form a coloured image of the sun, represented at TP. The axis of the prism (that is the line passing through the middle of the prism, from one end of it to the other end, parallel to the edge of the refracting angle) was in this and the following experiments perpendicular to the incident rays. About this axis I turned the prism slowly, and saw the refracted light on the wall, or coloured image of the sun, first to ascend, and then to descend. Between the ascent and descent, when the image seemed stationary, I stopped the prism, and fixed it in that posture.

Then I let the refracted light fall perpendicularly upon a sheet of white paper, MN, placed at the opposite wall of the chamber, and observed the figure and dimensions of the solar image, PT, formed on the paper by that light. This image was oblong, and not oval, but terminated by two reftilinear and parallel sides and two semicircular ends. On its sides it was bounded pretty distinctly; but on its ends very confusedly and indifferently, the light there decaying and vanishing by degrees. At the distance of 18½ feet from the prism the breadth of the image was about 2½ inches, but its length was about 10½ inches, and the length of its reftilinear sides about eight inches, and ABC, the refracting angle of the prism, whereby so great a length was made, was 64 degrees. With a less angle the length of the image was less, the breadth remaining the same. It is farther to be observed, that the rays went on in straight lines from the prism to the image, and therefore at their going out of the prism had all that inclination to one another from which the length of the image proceeded. This image PT was coloured, and the more eminent colours lay in this order from the bottom at T to the top at P; red, orange, yellow, green, blue, indigo, violet; together with all their intermediate degrees in a continual succession perpetually varying.

Our author concludes from this experiment, and many more to be mentioned hereafter, that the light consists of a mixture of several sorts of coloured rays, some of which at equal incidences are more refracted than others, and therefore are called more refrangible. The red at T, being nearest to the place Y, where the rays of the sun would go directly if the prism was taken away, is the least refracted of all the rays; and the orange, yellow, green, blue, indigo, and violet, are continually more and more refracted, as they are more and more diverted from the course of the direct light. For by mathematical reasoning he has proved, that when the prism is fixed in the posture abovementioned, so that the place of the image shall be the lowest possible, or at the limit between its descent and ascent, the figure of the image ought then to be round like the spot at Y, if all the rays that tended to it were equally refracted. Therefore, seeing by experience it is found that this image is not round, but about five times longer than broad, it follows that all the rays are not equally refracted. And this conclusion is farther confirmed by the following experiments.

In the sun's beam SF (fig. 2.), which was propagated into the room thro' the hole in the window-shutter EG, at the distance of some feet from the hole, I held the prism ABC in such a posture, that its axis might be perpendicular to that beam: then I looked through the prism upon the hole F, and turning the prism to and fro about its axis to make the image PT of the hole ascend and descend, when between its two contrary motions it seemed stationary, I stopped the prism; in this situation of the prism, viewing through it the said hole F, I observed the length of its refracted image PT to be many times greater than its breadth; and that the most refracted part thereof appeared violet at P; the least refracted red, at T; and the middle parts indigo, blue, green, yellow, and orange, in order. The same thing happened when I removed the prism out of the sun's light, and looked through it upon the hole shining by the light of the clouds beyond it. And yet if the refraction of all the rays were equal according to one certain proportion of the lines of incidence and refraction, as is vulgarly supposed the refracted image ought to have appeared round, by the mathematical demonstration abovementioned. So then by these two experiments it appears, that in equal incidences there is a considerable inequality of refractions.
Light differently refrangible.

In the middle of two thin boards, DE, (fig. 3.), I made a round hole in each, at G, and g, a third part of an inch in diameter; and in the window shut a much larger hole being made, at F, to let into my darkened chamber a large beam of the sun's light, I placed a prism, ABC, behind the shut in that beam, to refract it towards the opposite wall; and close behind this prism I fixed one of the boards DE, in such a manner that the middle of the refracted light might pass through the hole made in it at G, and the rest be intercepted by the board. Then at the distance of about 12 feet from the first board, I fixed the other board, d b, in such manner that the middle of the refracted light, which came through the hole in the first board, and fell upon the opposite wall, might pass thro' the hole g in this other board d b, and the rest being intercepted by the board, might pass upon it the coloured spectrum of the sun. And close behind this board I fixed another prism a b c, to refract the light which came through the hole g. Then I returned speedily to the first prism ABC, and by turning it slowly to and fro about its axis, I caused the image which fell upon the second board d b, to move up and down upon that board, that all its parts might pass successively through the hole in that board, and fall upon the prism behind it. And in the mean time I noted the places, M, N, on the opposite wall, to which that light after its refraction in the second prism did pass; and by the difference of the places at M and N, I found that the light, which being more refracted in the first prism ABC, did go to the blue end of the image, was again more refracted by the second prism a b c than the light which went to the red end of that image. For when the lower part of the light which fell upon the second board d b, was cast through the hole g, it went to a lower place M on the wall; and when the higher part of the light was cast through the same hole g, it went to a higher place N on the same wall; and when any intermediate part of the light was cast through that hole, it went to some place in the wall between M and N. The unaltered position of the holes in the boards made the incidence of the rays upon the second prism to be the same in all cases. And yet in that common incidence some of the rays were more refracted and others less; and those were more refracted in this prism, which by a greater refraction in the first prism were more turned out of their way; and therefore, for their confluence of being more refracted, are deservedly called more refrangible.

Our author shows also, by experiments made with convex glasses, that lights (reflected from natural bodies) which differ in colour, differ also in degrees of refrangibility; and that they differ in the same manner as the rays of the sun do.

The sun's light consists of rays differing in refrangibility, and those rays are more refrangible than others which are more refrangible. A prism, ABC (fig. 4.), whose two angles, at its base BC, were equal to one another and half right ones, and the third at A a right one, I placed in a beam FM of the sun's light, let into a dark chamber through a hole F one third part of an inch broad. And turning the prism slowly about its axis until the light which went through one of its angles ABC, and was refracted by it to G and H, began to be reflected into the line MN by its base BC, at which till then it went out of the glass; I observed that those rays, as MH, which had suffered the greatest refraction, were sooner reflected than the rest. To make it evident that the rays which vanished at H were reflected into the beam MN, I made this beam pass through another prism XYZ, and being refracted by it to N, afterwards upon a sheet of white paper p t placed at some distance behind it, and there by that refraction to paint the usual colours at p t. Then causing the first prism to be turned about its axis according to the order of the letters ABC, I observed that when those rays MH, which in this prism had suffered the greatest refraction, and appeared blue and violet, began to be totally reflected, the blue and violet light on the paper which was most refracted in the second prism received a sensible increase at p, above that of the red and yellow; and afterwards, when the rest of the light, which was green, yellow, and red, began to be totally reflected and vanished at G, the light of those colours at p, on the paper p t, received as great an increase as the violet and blue had received before. Which puts it past dispute, that those rays became first of all totally reflected at the base BC, which before at equal incidences with the rest upon the base BC had suffered the greatest refraction. I do not here take notice of any refractions made in the sides AC, AB, of the first prism, because the light enters almost perpendicularly at the first side, and goes out almost perpendicularly at the second; and therefore suffers none, or so little, that the angles of incidence at the base BC are not sensibly altered by it; especially if the angles of the prism at the base BC be each about 40 degrees. For the rays FM begin to be totally reflected when the angle CMF is about 50 degrees, and therefore they will then make a right angle of 90 degrees with AC.

It appears also from experiments, that the beam of light MN, reflected by the base of the prism, being augmented first by the more refrangible rays and afterwards by the less refrangible, is composed of rays differently refrangible.

The light whose rays are all alike refrangible, I call simple, homogeneal, and similar; and that whose rays are some more refrangible than others, I call compound, heterogeneal, and dissimilar. The former light I call homogeneal, not because I would affirm it so in all respects; but because the rays which agree in refrangibility agree at least in all their other properties which I consider in the following discourse.

The colours of homogeneal lights I call primary, homogeneal, and simple; and those of heterogeneal lights, simple or compound. For these are always compoundes of homogeneal lights, as will appear in the following discourse.

The homogeneal light and rays which appear red, or rather make objects appear so, I call rubric, or red-making; those which make objects appear yellow, green, blue, and violet, I call yellow-making, green-making, blue-making, violet-making. And so of the rest. And if at any time I speak of light and rays as coloured or endowed with colours, I would be understood to speak not philosophically and properly, but grossly, and according to such conceptions as vulgar people...
people in fecting all these experiments would be apt to frame. For the rays, to speak properly, are not coloured. In them there is nothing else than a certain power and disposition to fill up a fenation of this or that colour. For as found, in a bell or musical string or other sounding body, is nothing but a trembling motion, and in the air nothing but that motion propagated from the object, and in the fenatorium it is a fenfe of that motion under the form of found; so colours in the object are nothing but a disposition to reflect this or that fort of rays more copiously than the rest; in rays they are nothing but their dispositions to propagate this or that motion into the fenatorium; and in the fenatorium they are fenations of those motions under the forms of colours. See Chromatics.

By the mathematical proposition abovementioned, it is certain that the rays which are equally refrangible do fall upon a circle anfwering to the fun's apparent difk, which will also be proved by experiment by and by. Now let AG (fig. 5.) repreffen the circle which all the moft refrangible rays, propagated from the whole difk of the fun, would illuminate and paint upon the opposite wall if they were alone; EL the circle, which all the least refrangible rays would illuminate if they were alone; BH, CI, DK, the circles which fo many intermediate forts would paint upon the wall, if they were fingly propagated from the fun in fuccedent order, the refi being intercepted; and conceive that there are other circles without number, which innumerable other intermediate forts of rays would fuccedently paint upon the wall, if the fun should fuccedently emit every fort apart. And seeing the fun emits all these forts at once, they mall all together illuminate and paint innumerable equal circles; of all which, being according to their degrees of refrangibility placed in order in a continual feries, that oblong fpéctrum PT is compofed, which was defcribed in the firt experiment.

Now if these circles, whilft their centres keep their diftanccs and poftitions, could be made les in diameter, their interfemng one with another, and confquently the mixture of the heterogeneous rays, would be proportionally diminifhcd. Let the circles AG, BH, CI, &c. remain as before; and let ag, bh, ci, &c. be fo many lefs circles lying in a like continual feries, between two parallel right lines ae and gl, with the fame diftanccs between their centres, and illuminated with the fame forts of rays; that is, the circle ag with the fame fort by which the corre fpoding circle AG was illuminated; and the ref of the circles bh, ci, dk, &c. reffpectively with the fame forts of rays by which the corre fpoding circles BH, CI, DK, EL, were illuminated. In the figure PT, compofed of the great circles, three of thofe, AG, BH, CI, are fo expanded into each other, that three forts of rays, by which thofe circles are illuminated, together with innumerable other forts of intermediate rays, are mixed at QR in the middle of the circle BH. And the like mixture happens throughout almoft the whole length of the figure PT. But in the figure PT, compofed of the lefs circles the three lefs circles ag, bh, ci, which anfwer to thofe three greater, do not extend into one another; nor are there anywhere mingled fo much as any two of the three forts of rays by which thofe circles are illuminated, and which in the figure PT are all of them in terminated at QR. So then, if we would diminifh the Light-diff. mixture of the rays, we are to diminifh the diameters of the circles. Now thofe would be diminifhcd if the fun's diameter, to which they anfwer, could be made les than it is, or (which comes to the fame purpofe) if without doors, at a great diftance from the prim towards the fun, fome opaque body were placed with a round hole in the middle of it to intercept all the fun's light, except so much as coming from the middle of his body could pass through that hole to the prim. For fo the circles AG, BH, and the ref, would not any longer anfwer to the whole difk of the fun, but only to that part of it which could be feen from the prim through that hole; that is, to the apparent magnitude of that hole viewed from the prim. But that thofe circles may anfwer more diftinftly to that hole, a lens is to be placed by the prim to call the image of the hole (that is, every one of the circles AG, BH, &c.) diftinftly upon the paper at PT; after fuch a manner, as by a lens placed at a window the pictures of objects abroad are call'd diftinftly upon a paper within the room. If this be done, it will not be neceffary to place that hole very far off, no not beyond the window. And therefore, instead of that hole, I used the hole in the window-flut as follows.

In the fun's light let into my darkened chamber through a small round hole in my window-flut, at about 10 or 12 feet from the window, I placed a lens MN (fig. 6.), by which the image of the hole F might be diftinftly call'd upon a fheet of white paper placed at I. Then immediately after the lens I placed a prim ABC, by which the trajected light might be refractioned either upwards or sideways, and thereby the round image which the lens alone did call upon the paper at I, might be drawn out into a long one with parallel fides, as reprefented at pt. This oblong image I let fall upon another paper at about the fame diftance from the prim as the image at I, moving the paper either towards the prim or from it, until I found the just diftance where the refilinear fides of the image pt become most diftinft. For in this cafe the circular images of the hole, which compofe that image, after the manner that the circles ag, bh, ci, &c. do the figure pt, were terminated most diftinftly, and therefore extended into one another the leaff that they could, and by conftquence the mixture of the heterogeneous rays was now the leaff of all. The circles ag, bh, ci, &c. which compofe the image pt, are each equal to the circle at I; and therefore, by diminishing the hole F, or by removing the lens farther from it, may be diminished at pleafure, whilft their centres keep the fame diftanccs from each other. Thus, by diminifhing the breadth of the image pt, the circles of heterogeneous rays that compofe it may be separated from each other as much as you please. Yet instead of the circular hole F, it is better to dif tribute an oblong hole shaped like a parallelogram, with its length parallel to the length of the prim. For if this hole be an inch or twentv feet long, and but a 1/20th part of an inch bred, or narrower, the light of the image pt will be as fimple as before, or fimpler: and the image being much broader, is therefore fitter to have experiments tried in its light than before.

Homogeneous light is refractioned regularly without any dilatation, splitting, or fattering of the rays; and the
PART I.

OPTICS.

Light differently refrangible.

The image of a black paper I made a round hole about a fifth or a sixth part of an inch in diameter. Upon this paper I caused the spectrum of homogeneal light, described in the former article, so that some part of the light might pass through the hole in the paper. This transmitted part of the light I refracted with a prism placed behind the paper; and letting this refracted light fall perpendicularly upon a white paper, two or three feet distant from the prism, I found that the spectrum formed on the paper by this light was not oblong, as when it is made in the first experiment, by refracting the sun's compound light, but was, so far as I could judge by my eye, perfectly circular, the length being nowhere greater than the breadth; which shows that this light is refracted regularly without any dilatation of the rays, and is an ocular demonstration of the mathematical proposition mentioned above.

In the homogeneal light I placed a paper circle of a quarter of an inch in diameter; and in the sun's unreftacted, homogeneal, white light, I placed another paper circle of the same bigness; and going from these papers to the distance of some feet, I viewed both circles through a prism. The circle illuminated by the sun's heterogeneal light appeared very oblong, as in the second experiment, the length being many times greater than the breadth. But the other circle illuminated with homogeneal light appeared circular, and distinctly defined, as when it is viewed by the naked eye; which proves the whole proposition mentioned in the beginning of this article.

In the homogeneal light I placed flies and fish like minute objects, and viewing them through a prism I saw their parts as distinctly defined as if I had viewed them with the naked eye. The same objects placed in the sun's unreftacted heterogeneal light, which was white, I viewed also through a prism, and saw them most confusedly defined, so that I could not distinguish their smaller parts from one another. I placed also the letters of a small print one while in the homogeneal light and then in the heterogeneal; and viewing them through a prism, they appeared in the latter case so confused and indistinct that I could not read them; but in the former, they appeared so distinct that I could read readily, and thought I saw them as distinctly as when I viewed them with my naked eye: in both cases, I viewed the same objects through the prism, at the same distance from me, and in the same situation. There was no difference but in the lights by which the objects were illuminated, and which in one case was sun's, in the other compound; and therefore the distinct vision in the former case, and confused in the latter, could arise from nothing else than from that difference in the lights. Which proves the whole proposition.

In these three experiments, it is farther very re-

remarkable, that the colour of homogeneal light, was never changed by the refraction. And as these colours were not changed by refractions, so neither were they by refractions. For all white, grey, red, yellow, green, blue, violet bodies, as paper, ather, red lead, orpiment, indigo, bice, gold, silver, copper, grafs, blue flowers, violet, bubbles of water tinged with various colours, peacocks feathers, the tincture of lignum naphriticum, and such like, in red homogeneal light appeared totally red, in blue light totally blue, in green light totally green, and so of other colours. In the homogeneal light of any colour they all appeared totally of that same colour; with this only difference that, some of them reflected that light more brightly, others more faintly. I never yet found any body which by reflecting homogeneal light could sensibly change its colour.

From all which it is manifest, that if the sun's light consisted of but one fort of rays, there would be but one colour in the world, nor would it be possible to produce any new colour by refractions and reflections; and by consequence, that the variety of colours depends upon the composition of light.

The solar image, formed by the refracted rays in the fifth experiment, did in the progress from its end by which the most refrangible rays fell, unto its end by which the least refrangible rays fell, appear tinged with this fars of colours; violet, indigo, blue, green, yellow, orange, red, together with all their intermediate degrees in a continued succession perpetually varying; so that there appeared as many degrees of colours as there were sorts of rays differing in reftra-\footnote{The common} frangibility. And since these colours could not be changed by refractions nor by refractions, it follows, that all homogeneal light has its proper colour answering to its degree of reftrangibility.

Every homogeneal light considered apart is refra-\footnote{Every} gated, according to one and the same rule: so that its homogeneal light is to its fine of refraction in a given ratio: that is, every different coloured ray has a different ratio belonging to it. This our author has determined by experiment, and by other experiments has the same determined by what numbers those given ratios are expressed. For instance, if an heterogeneal white ray of the sun emerges out of glafs into air; or, which is that same thing, if rays of all colours be supposed to succeed one another in the same line AC, and AD (fig. 15): their common fine of incidence in glafs be divided into 50 equal parts, then EF and GH, the fines of refraction into air, of the least and most refrangible rays, will be 77 and 78 such parts respectively. And since every colour has several degrees, the fines of refraction of all the degrees of red will have all intermediate degrees of magnitude from 77 to 77, of all the degrees of orange from 77 to 77, of all the degrees of yellow from 77 to 77, of all the degrees of green from 77 to 77, of blue from 77 to 77, of indigo from 77 to 77, and of violet from 77 to 78.
Sect. I. The Application of the foregoing Theory to several natural Phenomena.

§ 1. Of the Rainbow.

This beautiful phenomenon hath engaged the attention of all ages. By some nations it hath been deified; though the more sensible part always looked upon it as a natural appearance, and endeavoured, however imperfectly, to account for it. The observations of the ancients and philosophers of the middle ages concerning the rainbow were such as could not have escaped the notice of the bandmen who gazed at the even after the dawn of true philosophy in this world, before we find any discovery of importance on this subject. Maurolycus was the first who pretended to have measured the diameters of the two rainbows with much exactness; and he reports, that he found that of the inner bow to be 44 degrees, and that of the outer bow 56; from which Descartes takes occasion to observe, how little we can depend upon the observations of those who were not acquainted with the cause of the appearances.

One Clicheoures (the same, it is probable, who distinguished himself by his opposition to Luther, and who died in 1543) had maintained, that the second bow is the image of the first, as he thought was evident from the inverted order of the colours. For, said he, when we look into the water, all the images that we see reflected by it are inverted with respect to the objects themselves; the tops of the trees, for instance, that stand near the brink, appearing lower than the roots.

That the rainbow is opposite to the sun, had always been observed. It was, therefore, natural to imagine, that the colours of it were produced by some kind of reflection of the rays of light from drops of rain, or vapour. The regular order of the colours was another circumstance that could not have escaped the notice of any person. But, notwithstanding mere reflection had in no other case been observed to produce colours, and it could not but have been observed that refraction is frequently attended with that phenomenon, yet no person seems to have thought of having recourse to a proper refraction in this case, before one Fletcher of Breciau, who in a treatise which he published in 1577, endeavoured to account for the colours of the rainbow by means of a double refraction and one reflection. But he imagined that a ray of light, after entering a drop of rain, and suffering a refraction both at its entrance and exit, was afterwards reflected from another drop, before it reached the eye of the spectator. He seems to have overlooked the reflection at the farther side of the drop, or to have imagined that all the bendings of the light within the drop would not make a sufficient curvature to bring the ray of the sun to the eye of the spectator. That he should think of two refractions, was the necessary consequence of his supposing that the ray entered the drop at all. This supposition, therefore, was all the light that he threw upon the subject. B. Porta supposed that the rainbow is produced by the refraction of light in the whole body of rain or vapour, but not in the separate drops.

After all, it was a man whom no writers allow to have had any pretensions to philosophy, that hit upon this curious discovery. This was Antonio De Dominis, bishop of Spalatro, who published De Radiis Vitrif et Lucis, was published by J. Bartolus in 1611. He first advanced, that the double reflection of Fletcher, with an intervening refraction, was sufficient to produce the colours of the bow, and also to bring the rays that formed them to the eye of the spectator, without any subsequent refractions. He distinctly describes the progress of a ray of light entering the upper part of the drop, where it suffers one refraction, and after being thereby thrown upon the back part of the inner surface, is from thence reflected to the lower part of the drop; at which place undergoing a second refraction, it is thereby bent, so as to come directly to the eye. To verify this hypothesis, this person (no philosopher as he was) proceeded in a very sensible and philosophical manner. For he procured a small globe of solid glass, and viewing it when it was exposed to the rays of the sun, in the same manner in which he had supposed that the drops of rain were situated with respect to them, he actually observed the same colours which he had seen in the true rainbow, and in the same order.

Thus the circumstances in which the colours of the rainbow were formed, and the progress of a ray of light through a drop of water were clearly understood; but philosophers were a long time at a loss when they endeavoured to assign reasons for all the particular colours, and for the order of them. Indeed nothing but the doctrine of the different refrangibility of the rays of light, which was a discovery reserved for the great Sir Isaac Newton, could furnish a complete solution of this difficulty. De Dominis supposed that the red rays were those which had traversed the least space in the inside of a drop of water, and therefore retained more of their native force, and consequentlly striking the eye more briskly, gave it a stronger sensation; that the green and blue colours were produced by those rays, the force of which had been, in some measure, abated by passing through a greater body of water; and that all the intermediate colours were composed (according to the hypothesis which generally prevailed at that time) of a mixture of these three primary ones. That the different colours were caused by some difference in the impulsion of light upon the eye, and the greater or less impression that was thereby made upon it, was an opinion which had been adopted by many persons, who had ventured to depart from the authority of Aristotle.

Afterwards the same De Dominis observed, that all the rays of the same colour must leave the drop of water in a part similarly situated with respect to the eye, in
in order that each of the colours may appear in a circle, the centre of which is a point of the heavens, in a line drawn from the sun through the eye of the spectator. The red rays, he observed, must issue from the drop nearest to the bottom of it, in order that the circle of red may be the outermost, and therefore the most elevated in the bow.

Notwithstanding De Dominis conceived so justly of the manner in which the inner rainbow is formed, he was far from having as just an idea of the cause of the exterior bow. This he endeavoured to explain in the very same manner in which he had done the interior, viz. by one reflection of the light within the drop, preceded and followed by a refraction; supposing only that the rays which formed the exterior bow were returned to the eye by a part of the drop lower than that which transmitted the red of the interior bow. He also supposed that the rays which formed one of the bows came from the superior part of the sun’s disk, and those which formed the other from the inferior part of it. He did not consider, that upon those principles, the two bows ought to have been contiguous; or rather, that an infinite number of bows would have had their colours all intermixed; which would have been no bow at all.

When Sir Isaac Newton discovered the different refrangibility of the rays of light, he immediately applied his new theory of lights and colours to the phenomena of the rainbow, taking this remarkable object of philosophical inquiry where De Dominis and Descartes, for want of this knowledge, were obliged to leave their investigations imperfect. For they could give no good reason why the bow should be coloured, and much less could they give any satisfactory account of the orders in which the colours appear.

If different particles of light had not different degrees of refrangibility, on which the colours depend, the rainbow, besides being much narrower than it is, would be colourless; but the different refrangibility of differently coloured rays being admitted, the reason is obvious, both why the bow should be coloured, and also why the colours should appear in the order in which they are observed. Let a (fig. 8.) be a drop of water, and S a pencil of light; which, on its leaving the drop of water, reaches the eye of the spectator. This ray, at its entrance into the drop, begins to be decomposed into its proper colours; and upon leaving the drop, after one refraction and a second reflection, it is further decomposed into as many small differently-coloured pencils as there are primitive colours in the light. Three of them only are drawn in this figure, of which the blue is the most, and the red the least refracted.

The doctrine of the different refrangibility of light enables us to give a reason for the size of a bow of each particular colour. Newton, having found that the lines of refraction of the most refrangible and least refrangible rays, in passing from rain-water into air, are in the proportion of 183 to 182, when the angle of incidence is 15°, calculated the size of the bow; and he found, that if the sun was only a physical point, without sensible magnitude, the breadth of the inner bow would be 2 degrees; and if to this 30′ was added for the apparent diameter of the sun, the whole breadth would be 2½ degrees. But as the outermost colours, especially the violet, are extremely faint, the breadth of the bow will now in reality appear to exceed two degrees. He finds, by the same principles, that the breadth of the exterior bow, if it were everywhere equally vivid, would be 4° 20′. But in this case there is a greater deduction to be made. In account of the faintness of the light of the exterior bow; so that, in fact, it will not appear to be more than 3 degrees broad.

The principal phenomena of the rainbow are all explained on Sir Isaac Newton’s principles in the following propositions.

When the rays of the sun fall upon a drop of rain and enter into it, some of them, after one refraction and two reflections, may come to the eye of a spectator who has his back towards the sun, and his face towards the drop.

Ir XY (fig. 9.) is a drop of rain, and the sun explains itself upon it in any lines s f, s d, s a, &c. most of the rays will enter into the drop; some few of them only will be reflected from the first surface; those rays which are reflected from thence do not come under our present consideration, because they are never refracted at all. The greatest part of the rays then enter the drop, and those passing on to the second surface, will most of them be transmitted through the drop; but neither do those rays which are thus transmitted fall under our present consideration, since they are not reflected. For the rays, which are described in the proposition, are such as are twice refracted and once reflected. However, at the second surface, or hinder part of the drop, at p g, some few rays will be reflected, whilst the rest are transmitted; those rays proceed in some such lines as a r, a q; and coming out of the drop in the lines r o, q t, may fall upon the eye of a spectator, who is placed anywhere in those lines, with his face towards the drop, and consequently with his back towards the sun, which is supposed to shine upon the drop in the lines s f, s d, s a, &c. These rays are twice refracted and once reflected; they are refracted when they pass out of the air into the drop; they are reflected from the second surface, and are refracted again when they pass out of the drop into the air.

When rays of light reflected from a drop of rain come to the eye, those are called effective which are able to excite a sensation.

When rays of light come out of a drop of rain, they will not be effective, unless they are parallel and contiguous.

There are but few rays that can come to the eye at all; for since the greatest part of those rays which enter the drop XY (fig. 9.) between X and a, pass out of the drop through the hinder surface p g; only few are reflected from thence, and come out through the nearer surface between a and y. Now, such rays as emerge, or come out of the drop, between a and y, will be ineffective, unless they are parallel to one another, as r o and q t are; because such rays as come out diverging from one another will be so far asunder when they come to the eye, that all of them cannot enter the pupil; and the very few that can enter it will not be sufficient
sufficient to excite any sensation. But even rays, which are parallel, as $r v$, $q t$, will not be effectual, unless there are several of them contiguous or very near to one another. The two rays $r v$ and $q t$ alone will not be perceived, though both of them enter the eye; for so very few rays are not sufficient to excite a sensation.

When rays of light come out of a drop of rain after one reflection, these will be effectual which are parallel, or from the same point, and which entered the drop near to one another.

Any rays, as $s b$ and $c d$, (fig. 10,) when they have passed out of the air into a drop of water, will be refracted towards the perpendiculars $b l, d l$; and as the ray $s b$ falls farther from the axis $a v$ than the ray $c d$, $s b$ will be more refracted than $c d$; so that these rays, though parallel to one another at their incidence, may describe the lines $b e$ and $d e$ after refraction, and be both of them reflected from one and the same point $v$. Now all rays which are thus reflected from one and the same point, when they have described the lines $e f$, $e g$, and after refraction emerge at $f$ and $g$, will be so refracted, when they pass out of the drop into the air, as to describe the lines $f h, g i$, parallel to one another. If these rays were to return from $e$ in the lines $e b, e d$, and were to emerge at $b$ and $d$, they would be refracted into the lines of their incidence $b t, d e$. But if these rays, instead of being returned in the lines $e b, e d$, are reflected from the same point $e$ in the lines $e g, e f$, the lines of refraction $e g$ and $e f$ will be inclined both to one another, and to the surface of the drop; just as much as the lines $e b$ and $e d$ are. First $e b$ and $e g$ make just the same angle with the surface of the drop: for the angle $b e x$, which $e b$ makes with the surface of the drop, is the complement of incidence, and the angle $g e v$, which $e g$ makes with the surface, is the complement of reflection; and these two are equal to one another. In the same manner we might prove, that $e d$ and $e f$ make equal angles with the surface of the drop. Secondly, The angle $b e d$ is equal to the angle $f e g$; or the reflected rays $e g$, $e f$, and the incident rays $e b$, $e d$, are equally inclined to each other. For the angle of incidence $b e l$ is equal to the angle of refraction $g e l$, and the angle of incidence $d e l$ is equal to the angle of refraction $f e l$; consequently the difference between the angles of incidence is equal to the difference between the angles of refraction, or $b e l - d e l = e f l - f e l$, or $b e d = e f s$. Since therefore either the lines $e g$, $e f$, or the lines $b e$, $d e$, are equally inclined both to one another and to the surface of the drop; the rays will be refracted in the same manner, whether they were to return in the lines $e b, e d$, or are reflected in the lines $e g, e f$. But if they were to return in the lines $e b, e d$, the refraction, when they emerge at $b$ and $d$, would make them parallel. Therefore, if they are reflected from one and the same point $e$ in the lines $e g, e f$, the refraction, when they emerge at $g$ and $f$, will likewise make them parallel.

But though such rays as are reflected from the same point in the hinder part of a drop of rain, are parallel to one another when they emerge, and so have one condition that is requisite towards making them effectual; yet there is another condition necessary; for rays, that are effectual, must be contiguous as well as parallel. And though rays, which enter the drop in different places, may be parallel when they emerge, those only will be contiguous which enter it nearly at the same place.

Let $X Y$ (fig. 9,) be a drop of rain, $a g$ the axis or diameter of the drop, and $a s$ a ray of light that comes from the sun and enters the drop at the point $a$. This ray $a s$, because it is perpendicular to both the surfaces, will pass straight through the drop in the line $a b$, without being refracted; but any collateral rays, such as those that fall about $s h$, as they pass through the drop, will be made to converge to their axis, and passing out at $n$ will meet the axis at $b$: rays which fall farther from the axis than $s b$, such as those which fall about $s c$, will likewise be made to converge; but then their focus will be nearer to the drop than $b$. Suppose therefore $i$ to be the focus to which the rays that fall about $s c$ will converge, any ray $s e$, when it has descried the line $e o$ within the drop, and is tending to the focus $i$, will pass out of the drop at the point $o$. The rays that fall upon the drop about $s d$, more remote still from the axis, will converge to a focus still nearer than $i$, as suppose at $k$. These rays therefore go out of the drop at $p$. The rays, that fall still more remote from the axis, as $s r$, will converge to a focus nearer than $k$, as suppose at $l$; and the ray $s s$, when it has descried the line $e o$ within the drop, and is tending to the focus $l$, will pass out at the point $o$. The rays that fall still more remote from the axis will converge to a focus still nearer. Thus the ray $s f$ will after refraction converge to a focus at $m$, which is nearer than $k$; and having descried the line $e o$ within the drop, it will pass out to the point $n$. Now here we may observe, that as any rays $s e$ or $s c$, fall farther above the axis $a s$, the points $o$, or $n$, where they pass out behind the drop, will be farther above $g$; or that, as the incident ray rises from the axis $a s$, the arc $g n o$ increases, till we come to some ray $s d$, which passes out of the drop at $p$, and this is the highest point where any ray that falls upon the quadrant or quarter arc can pass out: for any rays $s e$, or $s f$, that fall higher than $s d$, will not pass out in any point above $p$, but at the points $o$ or $n$, which are below it. Consequently, the arc $g n o$ increases, whilst the distance of the incident ray from the axis $a s$ increases, till we come to the ray $s d$; yet afterwards, the higher the ray falls above the axis $a s$, this arc $p o n g$ will decrease.

We have hitherto spoken of the points on the hinder part of the drop, where the rays pass out of it; but this was for the sake of determining the points from whence those rays are reflected, which do not pass out behind the drop. For, in explaining the rainbow, we have no further reason to consider those rays which go through the drop; since they can never come to the eye of a spectator placed anywhere in the lines $r v$ or $q t$ with his face towards the drop. Now, as there are many rays which pass out of the drop between $g$ and $p$, if we few rays will be reflected from thence; and consequently the several points between $g$ and $p$, which are the points where some of the rays pass out of the drop, are likewise the points of reflection for the rest which do not pass out. Therefore, in respect of those rays which are reflected, we may call $g p$ the arc of refraction; and may say, that this arc,
Part II.

Of the Rainbow.

Of the Rainbow.

... of reflection increases, as the distance of the incident ray from the axis $a$ increases, till we come to the ray $sd$; the arc of reflection is $gn$ for the ray $sb$, it is $go$ for the ray $se$, and $ps$ for the ray $sd$. But after this, as the distance of the incident ray from the axis $a$ increases, the arc of reflection decreases; for $gq$ less than $ps$ is the arc of reflection for the ray $se$, and $ng$ is the arc of reflection for the ray $sf$.

From hence it is obvious, that some one ray, which falls above $sd$, may be reflected from the same point with some other ray which falls below $sd$. Thus, for instance, the ray $sb$ will be reflected from the point $n$, and the ray $sf$ will be reflected from the same point: and consequently, when the reflected rays $nr, nq$, are refracted as they pass out of the drop at $r$ and $q$, they will be parallel, by what has been shown in the former part of this proposition. But since the intermediate rays, which enter the drop between $s$ and $b$, are not reflected from the same point $n$, these two rays alone will be the parallel to one another when they come out of the drop, and the intermediate rays will not be parallel to them. And consequently these rays $rv, qv$, though they are parallel after they emerge at $r$ and $q$, will not be contiguous, and for that reason will not be effective; the ray $sd$ is reflected from $p$, which has been shown to be the limit of the arc of reflection; such rays as fall just above $sd$, and just below $sd$, will be reflected from nearly the same point $p$, as appears from what has been already shown. These rays therefore will be parallel, because they are reflected from the same point $p$; and they will likewise be contiguous, because they all of them enter the drop at one and the same place very near to $d$. Consequently, such rays as enter the drop at $d$, and are reflected from $p$ the limit of the arc of reflection, will be effective; since, when they emerge at the fore part of the drop between $a$ and $y$, they will be both parallel and contiguous.

If we can make it out hereafter that the rainbow is produced by the rays of the sun which are thus reflected from drops of rain as they fall whilst the sun shines upon them, this proposition may serve to show us, that this appearance is not produced by any rays that fall upon any part, and are reflected from any part of those drops; since this appearance cannot be produced by any rays but those which are effective; and effective rays must always enter each drop at one certain place in the fore part of it, and must likewise be reflected from one certain place in the hinder surface.

When rays that are effective emerge from a drop of rain after one reflection and two refractions, those which are most refrangible will, at their emergence, make a less angle with the incident rays than those do which are least refrangible; and by this means the rays of different colours will be separated from one another.

Let $fh$ and $gi$ (fig. 10.) be effecntial violet rays emerging from the drop at $fgj$; and $fn$, $gp$, effecntial red rays emerging from the same drop at the same place. Now, though all the violet rays are parallel to one another, because they are supposed effecntial, and though all the red rays are likewise parallel to one another for the same reason; yet the violet rays will not be parallel to the red rays. These rays, as they have different colours, and different degrees of refrangibility, will diverge from one another; any violet ray $gi$, which emerges at $g$, will diverge from any red ray $gp$, which emerges at the same place. Now, both the violet ray $gi$, and the red ray $gp$, as they pass out of the drop of water into the air, will be refracted from the perpendicular $lo$. But the violet ray is more refrangible than the red one; and for that reason $gi$, or the refracted violet ray, will make a greater angle with the perpendicular than $gp$ the refracted red ray; or the angle $igp$ will be greater than the angle $pgi$. Suppose the incident ray $lo$ to be continued in the direction $lk$, and the violet ray $gi$ to be continued backward in the direction $ik$, till it meets the incident ray at $k$. Suppose likewise the red ray $pg$ to be continued backwards in the same manner, till it meets the incident ray at $w$. The angle $ikl$ is that which the violet ray, or most refrangible ray at its emergence, makes with the incident ray; and the angle $pwi$ is that which the red ray, or least refrangible ray at its emergence, makes with the incident ray.

From hence it is evident, that either of thefe lines might be turned in the opposite manner, so that the ray $gi$ might coincide with the ray $wp$, and the ray $pg$ with the ray $lw$. But if in the triangle, $gwr$, $gow$, or $pwi$, the angle $pgi$ is left greater than the angle $pwi$, or the angle $gwr$ is left less than the angle $gow$; then the violet rays will have a greater angle with the incident rays than the red ones. Therefore, the violet rays at their emergence make a less angle with the incident rays than the red ones.

And for the same reason, in all the other parts of rays, those which are most refrangible, at their emergence from a drop of rain after one reflection, will make a less angle with the incident rays, than those do which are least refrangible.

Or otherwise: When the rays $gi$ and $gp$ emerge at the same point $g$, as they both come out of water into air, and consequently are refracted from the perpendicular, instead of going straight forwards in the line $eg$ continued, they will both be turned round upon the point $g$ from the perpendicular $ge$. Now it is easy to conceive, that either of these lines might be turned in this manner upon the point $g$ as upon a centre; till they became parallel to $sb$ the incident ray. But if either of these lines or rays were refracted so much from $eg$ as to become parallel to $sb$, the ray so much refracted, would, after emergence, make no angle with $sb$, because it would be parallel to it. And consequently that ray which is most turned round upon the point $g$, or that ray which is most refrangible, will after emergence be nearest parallel to the incident ray, or will make the least angle with it. The same may be proved of all other rays emerging parallel to $gi$ and $gp$ respectively or of all effecntial rays; those which are least refrangible will after emergence make a less angle with the incident rays, than those do which are least refrangible.

But since the effecntial rays of different colours make different angles with $sb$ at their emergence, they will be separated from one another; so that if the eye was placed in the beam $fgbi$, it would receive only rays of one colour from the drop $xagv$; and if it was placed
OPTICS.

In the beam $f g h p$, it would receive only rays of some other colour.

The angular space $s o t$, which the least refrangible or red rays make with the incident ones when they emerge as to be effectual, is found by calculation to be $42^\circ$ 2 minutes. And the angle $t k l$, which the most refrangible rays make with the incident ones when they emerge as to be effectual, is found to be $40^\circ$ 17 minutes. The rays which have the intermediate degrees of refrangibility, make with the incident ones intermediate angles between $42^\circ$ 2 minutes, and $40^\circ$ 17 minutes.

If a line is supposed to be drawn from the centre of the sun through the eye of the spectator, the angle which any effectual rays, after two refractions and one reflection, make with the incident ray, will be equal to the angle which it makes with that line.

Let the eye of the spectator be at $i$, (fig. 10.) and let $g i$ be the line supposed to be drawn from the centre of the sun through the eye of the spectator; the angle $g i t$, which any effectual ray makes with this line, will be equal to the angle $t k l$, which the same ray makes with the incident ray $s k i$. If $t k$ is a ray coming from the centre of the sun, then since $g i$ is supposed to be drawn from the same point, these two lines, upon account of the remoteness of the point from whence they are drawn, may be looked upon as parallel to one another. But the right line $t k i$ crossing these two parallel lines will make the alternate angles equal. (Euc. b. i. prop. 29.) Therefore $t k i$ or $g i t$ is equal to $s k i$.

When the sun shines upon the drops of rain as they are falling, the rays that come from those drops to the eye of a spectator, after one reflection and two refractions, produce the primary rainbow.

If the sun shines upon the rain as it falls, there are commonly seen two bows, as $A F B$, $C H D$, (fig. 11.) or if the cloud and rain does not reach over that whole side of the sky where the bows appear, then only a part or one of the bows is seen. In the same manner, it is found that the bows are seen at different places where the rain falls. Of these two bows, the inner one is $A F B$, the outer is $C H D$. The outer part of the bow VEX is violet; the intermediate parts, reckoning from the red to the violet, are orange, yellow, green, blue, and indigo. Suppose the spectator's eye to be at $O$, and let $L O P$ be an imaginary line drawn from the centre of the sun through the eye of the spectator; if a beam of light $S$ coming from the sun falls upon any drop $F$; and the rays that emerge at $F$ in the line $F O$, so as to be effectual, make an angle $F O P$ of $42^\circ$ 2' with the line $L P$; then these effectual rays make an angle of $42^\circ$ 2' with the incident rays, by the preceding proposition, and consequently these rays will be red, so that the drop $F$ will appear red. All the other rays, which emerge at $F$, and would be effectual if they fell upon the eye are, refracted more than the red ones, and consequently will pass above the eye. If a beam of light $S$ make upon the drop $E$, and the rays that emerge at $E$ in the line $E O$, so as to be effectual, make an angle $E O P$ of $40^\circ$ 17' with the line $L P$; then these effectual rays make likewise an angle of $40^\circ$ 17' with the incident rays, and the drop $E$ will appear of a violet colour. All the other rays, which emerge at $E$, and would be effectual if they came to the eye, are refracted less than the violet ones, and therefore pass below the eye. The intermediate drops between $F$ and $E$ will for the same reasons be of the intermediate colours.

Thus we have shown why a set of drops from $F$ to $E$, as they are falling, should appear of the primary colours, red, orange, yellow, green, blue, indigo, and violet. It is not necessary that the several drops, which produce these colours, should all of them fall at exactly the same distance from the eye. The angle $F O P$, for instance, is the same whether the distance of the drop from the eye is $O F$, or whether it is in any other part of the line $O F$ something nearer to the eye. And whilst the angle $F O P$ is the same, the angle made by the emerging and incident rays, and consequently the colour of the drop, will be the same. This is equally true of any other drop. So that although in the figure the drops $F$ and $E$ are represented as falling perpendicularly one under the other, yet this is not necessary in order to produce the bow.

But the coloured line $F E$, which we have already accounted for, is only the breadth of the bow. It still remains to be shown, why not only the drop $F$ should appear red, but why all the other drops quite from $A$ to $B$ in the arc $A T F Y B$ should appear of the same colour. Now it is evident, that wherever a drop of rain is placed, if the angle which the effectual rays make with the line $L P$ is equal to the angle $F O P$, that is, if the angle which the effectual rays make with the incident rays is $42^\circ$ 2', any of those drops will be red, for the same reason that the drop $F$ is of this colour.

If $F O P$ was to turn round upon the line $O P$, so that one end of this line should always be at the eye, and the other be at $P$ opposite to the sun; such a motion of this figure would be like that of a pair of compasses turning round upon one of the legs $O P$ with the opening $F O P$. In this revolution the drop $F$ would describe a circle, $F$ would be at the centre, and $A T F Y B$ would be an arc in this circle. Now finally, in the motion of the line and drop $O F$, the angle made by $F O$ with $O P$, that is, the angle $F O P$, continues the same; if the sun to shine upon this drop as it revolves, the effectual rays would make the same angle with the incident rays, in whatever part of the arc $A T F Y B$ the drop was to be. Therefore, whether the drop is at $A$, or at $T$, or at $Y$, or at $B$, or wherever else it is in this whole arc, it would appear red, as it does at $F$.

The drops of rain, as they fall, are not indeed turned round in this manner; but then, as innumerable of them are falling at once in right lines from the cloud, whilst one drop is at $F$, there will be others at $Y$, at $T$, at $B$, at $A$, and in every other part of the arc $A T F Y B$; and all these drops will be red for the same reason that the drop $F$ would have been red, if it had been in the same place. Therefore, when the sun shines upon the rain as it falls, there will be a red arc $A T F Y B$ opposite to the sun. In the same manner, because the drop $E$ is violet, we might prove that any other drop, which, whilst it is falling, is in any part of the arc $A V E X B$, will be violet; and consequently, at the same time that the red arc $A T F Y B$ appears, there will like-
The primary rainbow is never a greater arc than a semicircle.

Since the line LOP is drawn from the sun through the eye of the spectator, and since P (fig. 9) is the centre of the rainbow: it follows, that the centre of the rainbow is always opposite to the sun. The angle FOP is an angle of $42^\circ 2'$, as was observed, or F the highest part of the bow is $42^\circ 2'$ from P the centre of it. If the fun is more than $42^\circ 2'$ high, P the centre of the rainbow, which is opposite to the fun, will be more than $42^\circ 2'$ below the horizon; and consequently F the top of the bow, which is only $42^\circ 2'$ from P, will be above the horizon; that is, when the fun is more than $42^\circ 2'$ high, no primary rainbow will be seen. If the fun is something less than $42^\circ 2'$ high, then P will be something less than $42^\circ 2'$ below the horizon; and consequently F, which is only $42^\circ 2'$ from P, will be just above the horizon; that is, a small part of the bow at this height of the fun will appear close to the ground opposite to the fun. If the fun is $20^\circ$ high, then P will be $20^\circ$ below the horizon; and F the top of the bow, being $42^\circ 2'$ from P, will be $22^\circ 2'$ above the horizon; therefore, at this height of the fun, the bow will be an arc of a circle whose centre is below the horizon; and consequently that arc of the circle which is above the horizon, or the bow, will be left as a semicircle. If the fun is in the horizon, then P, the centre of the bow, will be in the opposite part of the horizon; F, the top of the bow, will be $42^\circ 2'$ above the horizon; and the bow itself, because the horizon paffes through the centre of it, will be a semicircle. More than a semicircle can never appear; because if the fun was more than a semicircle, P the centre of it must be above the horizon; but P is always opposite to the fun, therefore P cannot be above the horizon, unless the fun is below it; and when the fun is set or is below the horizon, it cannot shine upon the drops of rain as they fall; and consequently, when the fun is below the horizon, no bow at all can be seen.

When the rays of the fun fall upon a drop of rain, some of them, after two refractions and two refractions, may come to the eye of a spectator, who has his back towards the fun and his face towards the drop.

If HGW (fig. 12) is a drop of rain, and parallel rays coming from the fun, as $\alpha, \gamma, \omega$, fall upon the lower part of it, they will be refracted towards the perpendiculars $\nu \ell$, $\omega \nu$, as they enter into it, and will describe some such lines as $\omega \nu, \omega \nu$. At $b$ and $i$ great part of these rays will pass out of the drop; but some of them will be reflected from thence in the lines $h \ell, \ell g$. At $f$ and $g$ again, great part of the rays that were reflected thither will pass out of the drop. But these rays will not come to the eye of a spectator at $e$. However, here again all the rays will not pass out; but some few will be reflected from $f$ and $g$, in some such lines as $f l, g b$; and these, when they emerge out of the drop of water into the air at $b$ and $d$ will be refracted from the perpendiculars, and, describing the lines $d b, b o$, may come to the eye of the spectator who has his back towards the fun and his face towards the drop.

These rays, which are parallel to one another after they have been once refraeted and once reflected in a drop of rain, could be effeected when they emerge after two refractions and two refractions.

No rays can be effectual, unless they are contiguous and parallel. From what was said, it appears, that when rays come out of a drop of rain contiguous to one another, either after one or after two refractions, they must enter the drop nearly at one and the fame place. And if such rays as are contiguous are parallel after the first reflection, they will emerge parallel, and therefore will be effectual. Let $\omega \nu, \omega \nu$ be contiguous rays which come from the fun, and are parallel to one another when they fall upon the lower part of the drop, suppose these rays to be refracted at $\omega$ and $\nu$, and to be reflected at $b$ and $i$; if they are parallel to one another, as $b \ell, \ell g$, after this first reflection, then, after they are reflected a second time from $f$ and $g$, and refracted a second time as they emerge at $d$ and $b$, they will go out of the drop parallel to one another in the lines $d b, b o$, and will therefore be effectual.

The rays $\omega \nu, \omega \nu$ are refracted towards the perpendiculars $\nu \ell, \ell \omega$, when they enter the drop, and will be made to converge. As these rays are very oblique, their focus will not be far from the surface $\omega \omega$. If this focus is at $k$, the rays, after they have passed the focus, will diverge from thence in the directions $k b, k i$; and if $k i$ is the principal focal distance of the concave reflecting surface $b i$, the reflected rays $b i, i g$, will be parallel. These rays $i f, i g$, are reflected again from the concave surface $f g$, and will meet in a focus at $\epsilon$, so that $g e$ will be the principal focal distance of this reflecting surface $f g$. And because $b i, f g$ are parts of the same sphere, the principal focal distances $g e$ and $k i$ will be equal to one another. When the rays have passed the focus $e$, they will diverge from thence in the lines $e \ell, \ell b$; and we are to show, that when they emerge at $d$ and $b$, and are refracted there, they will become parallel.

Now if the rays $\omega \nu, \omega \nu$, when they have met at $k$, were to be turned back again in the directions $k \omega, k \omega$, and were to emerge at $\nu$ and $\nu$, they would be refracted into the lines of their incidence, $\nu \omega, \omega \omega$, and therefore would be parallel. But since $g e$ is equal to $k b$, as has already been shown, the rays $e b, e b$, that diverge from $e$ fall in the same manner upon the drop at $d$ and $b$, as the rays $k \omega, k \omega$, would fall upon it at $\nu$ and $\nu$; and $e \ell, e \ell$, are just as much inclined to the refracting surface $e \ell$, as $k \omega, k \omega$, would be to the surface $\omega \omega$. From hence it follows, that the rays $e \ell, e \ell$, emerging at $d$ and $b$, will be refracted in the same manner, and will have the same direction in respect to one another, as $k \omega, k \omega$, would have. But $k \omega$ and $k \omega$ would be parallel after refraction. Therefore $e \ell$ and $e \ell$ will emerge in lines $e \ell, e \ell$, so as to be parallel to one another, and consequently so as to be effectual.
Plate CCCLX.

If rays of different colours, which are differently refrangible, emerge at any point b (fig. 12), these rays will not be all of them equally refracted from the perpendicular. Thus, if bo is a red ray, which is of all the other the least refrangible, and bm is a violet ray, which is of all others the most refrangible; when these two rays emerge at b, the violet ray will be refracted more from the perpendicular bm than the red ray, and the refracted angle zbo will be greater than the refracted angle zdo. From hence it follows, that these two rays, after emersion, will diverge from one another. In like manner, the rays that emerge at d will diverge from one another; a red ray will emerge in the line dp, a violet ray in the line dt. So that though all the effectual red rays of the beam bdmt are parallel to one another, and all the effectual red rays of the beam bdo are likewise parallel to one another, yet the violet rays will not be parallel to the red ones, but the violet beam will diverge from the red beam. Thus the rays of different colours will be separated from one another.

This will appear farther, if we consider what the proposition affirms, That any violet or most refrangible ray will make a greater angle with the incident rays, than any red or least refrangible ray makes with the same incident rays. Thus if yw is an incident ray, by a violet ray emerging from the point b, and bo a red ray emerging from the same point; the angle which the violet ray makes with the incident one is yrm, and that which the red ray makes with it is yro. Now yrm is a greater angle than yro. For in the triangle brs the internal angle brs is less than byz the external angle at the base. (Eucl. B. I. prop. 16.) But yro is the complement of brz or byz to two right ones, and yrm is the complement of brz to two right ones. Therefore, since byz is less than brz, the complement of byz to two right angles will be greater than the complement of brz to two right angles; or yrm will be greater than yro.

Or otherwise: Both the rays bo and bm, when they are refracted in passing out of the drop at b, are turned round upon the point b from the perpendicular bm. Now either of these lines bo or bm might be turned round in this manner, till it made a right angle with yro. Consequently, that ray which is most turned round upon bo, or which is most refracted, will make an angle with ywo that will be nearer to a right one than that ray makes with it which is least turned round upon bo, or which is least refracted. Therefore that ray which is most refracted will make a greater angle with the incident ray than that which is refracted.

But since the emerging rays, as they are differently refrangible, make different angles with the same incident ray ywo, the refraction which they suffer at emersion will separate them from one another.

The angle yrm, which the most refrangible or violet rays make with the incident ones, is found by calculation to be 54° 7'; and the angle ywo, which the least refrangible or red rays make with the incident ones, is found to be 50° 57'; the angles which the rays of the intermediate colours, indigo, blue, green, yellow, and orange, make with the incident rays, are intermediate angles between 54° 7' and 50° 57'.

If a line is supposed to be drawn from the centre of the sun through the eye of the spectator; the angle which, after two refractions and two reflections, any effectual ray makes with the incident ray, will be equal to the angle which it makes that line.

If ywo (fig. 12.) is an incident ray, by an effectual ray, and gw a line drawn from the centre of the sun through the eye of the spectator; the angle ywo, which the effectual ray makes with the incident ray, is equal to son the angle which the same effectual ray makes with the line gn. For ywo and gn, considered as drawn from the centre of the sun, are parallel; bo crosses them, and consequently makes the alternate angles ywo, son, equal to one another. Eucl. B. I. Prop. 29.

When the sun shines upon the drops of rain, as they are falling, the rays that come from these drops to the eye of a spectator, after two refractions and two reflections, produce the secondary rainbow.

The secondary rainbow is the outermost CHD...
Part II.

Of the Rainbow

~ ~ ~

will be the same to an eye placed at \( O \), whether the drop is at \( N \), or at \( H \), or at \( R \), or anywhere else in that arc. Now, though the drop does not thus turn round as it falls, and does not pass through the several parts of this arc, yet, since there are drops of rain falling everywhere at the same time, when one drop is at \( H \), there will be another at \( R \), another at \( N \), and others in all parts of the arc; and these drops will all of them be violet-coloured, for the same reason that the drop \( H \) would have been of this colour if it had been in any of those places. In like manner, as the drop is red when it is at \( G \), it would likewise be red in any part of the arc \( CGQD \); and so will any other drop, when, as it is falling, it comes to any part of that arc. Thus as the sun shines upon the water, whilst it falls, there will be two arcs produced, a violet coloured one \( CNHRD \), and a red one \( CGQD \); and for the same reason the intermediate space between these two arcs will be filled up with arcs of the intermediate colours. All these arcs together make up the secondary rainbow.

The colours of the secondary rainbow are fainter than those of the primary rainbow; and are ranged in the contrary order.

The primary rainbow is produced by such rays as have been only once reflected; the secondary rainbow is produced by such rays as have been twice reflected. But at every reflection some rays pass out of the drop of rain without being reflected; so that the number of the rays are reflected, the fewer of them are left. Therefore the colours of the secondary bow are produced by fewer rays, and consequently will be fainter, than the colours of the primary bow.

In the primary bow, reckoning from the outside of it, the colours are ranged in this order; red, orange, yellow, green, blue, indigo, violet. In the secondary bow, reckoning from the outside, the colours are violet, indigo, blue, green, yellow, red. So that the red, which is the outermost or highest colour in the primary bow, is the innermost or lowest colour in the secondary one.

Now the violet rays, when they emerge, as to be effectual after one reflection, make a less angle with the incident rays than the red ones; consequently the violet rays make a less angle with the line \( OP \) (fig. 111.) than the red ones. But, in the primary rainbow, the rays are only once reflected, and the angle which the effective rays make with \( OP \) is the distance of the coloured drop from \( P \) the centre of the bow. Therefore the violet drops or violet arc in the secondary bow will be farther from the centre of the bow than the red drops or red arc; that is, the outermost colour in the secondary bow will be violet, and the innermost colour will be red. And, for the same reason, through the whole secondary bow, every colour will be further from the centre, \( P \), as the rays of that colour are more refrangible.

§ 2. Of Coronas, Parhelia, &c.

Under the articles Corona and Parhelia a pretty full account is given of the different hypotheses concerning these phenomena, and likewise of the method by which these hypotheses are supported, from the known laws of refraction and reflection; to which therefore, in order to avoid repetition, we must refer.

§ 3. Of the apparent Place, Distance, Magnitude, and Motion of Objects.

Philosophers in general had taken for granted, that the place to which the eye refers any visible object seen by reflection or refraction, is that in which the visual ray meets a perpendicular from the object upon the reflecting or refracting plane. But this method of judging of the place of objects was called in question by Dr. Barrow, who contended that the arguments brought in favour of the opinion were not conclusive. These arguments are, that the images of theory reflect objects appear straight in a plane mirror, but curved in passing a convex or concave one; that a straight thread, when partly immersed perpendicularly in water, does not appear crooked as when it is obliquely plunged into the fluid; but that which is within the water seems to be a continuation of that which is without. With respect to the reflected image, however, of a perpendicular right line from a convex or concave mirror, he says, that it is not easy for the eye to distinguish the curve that it really makes; and that, if the appearance of a perpendicular thread, part of which is plunged in water, be closely attended to, it will not favour the common hypothesis. If the thread is of any shining metal, as silver, and viewed obliquely, the image of the part immersed will appear to detach itself sensibly from that part which is without the water, so that it cannot be true that every object appears to be in the same place where the refracted ray meets the perpendicular; and the same observation, he thinks, may be extended to the case of reflection. According to this writer, we refer every point of an object to the place from which the pencils of light, that give us the image of it, issue, or from which they would have issued if no reflecting or refracting substance intervened. Pursuing this principle, he proceeds to investigate the place in which the rays issuing from each of the points of an object, and which reach the eye after one reflection or refraction, meet; and he found, that if the refracting surface was plane, and the refraction was made from a denser medium into a rarer, those rays would always meet in a place between the eye and a perpendicular to the point of incidence. If a convex mirror be used, the case will be the same; but if the mirror be plane, the rays will meet in the perpendicular, and beyond it if it be con-
Probable as Dr Barlow thought the maxim which
he endeavoured to establish, concerning the suppos'd
place of visible objects, he has the candour to mention
an objection to it, and to acknowledge that he was
not able to give a satisfactory solution of it. It is this.
Let an object be placed beyond the focus of a convex
lens; and if the eye be close to the lens, it will appear
confuded, but very near to its true place. If the eye
be a little withdrawn, the confusion will increase, and
the object will seem to come nearer, and when the
eye is very near the focus, the confusion will be ex-
ceedingly great, and the object will seem to be close
to the eye. But in this experiment the eye receives
no rays but those that are converging; and the point
from which they issue is so far from being nearer than
the object, that it is beyond it; notwithstanding
which, the object is conceived to be much nearer
than it is, though no very distinct idea can be formed of its
precise distance. It may be observed, that in reality,
the rays falling upon the eye in this case in a manner
quite different from that in which they fall upon in other
circumstances, we can form no judgment about the
place from which they issue. This subject was afterwards
taken up by Berkeley, Smith, Montucla, and others.

M. de la Hire made several valuable observations
concerning the distance of visible objects, and various
other phenomena of vision, which are well worth our
notice. He also took particular pains to ascertain the
manner in which the eye forms itself to the view
of the objects placed at different distances. He enumerates
five circumstances, which affit us in judging of the
distance of objects, namely, their apparent magnitude,
the strength of the colouring, the direction of the two
eyes, the parallax of the objects, and the diffin Kendrick
of their small parts. Painters, he says, can only take
advantage of the two first mentioned circumstances,
and therefore pictures can never perfectly deceive the
eye; but in the decorations of theatres, they, in some
measure, make use of them all. The size of objects,
and the strength of their colouring, are diminished in
proportion to the distance at which they are intended
to appear. Parts of the same object which are to ap-
pear at different distances, as columns in an order of
architecture, are drawn upon different planes, a little
removed from one another, that the two eyes may be
obliged to change their direction, in order to distin-
guish the parts of the nearer plane from those of the more
remote. The small distance of the planes serves to
make a small parallax, by changing the position of the
eye; and do not preserve a distinct idea of the
quantity of parallax, corresponding to the different
distances of objects, it is sufficient that we perceive
there is a parallax, to be convinced that these planes
are distant from one another: without determining
what that distance is; and as to the last circumstance,
viz. the diffin Kendrick of the small parts of objects, it is
of no use in discovering the deception, on account of the
false light that is thrown upon these decorations.

To these observations concerning deceptions of
light, we shall add a similar one of M. le Cat, who
took notice that the reason why we imagine objects to
be larger when they are seen through a mill, is the
dimness or obscurity with which they are then seen;
this circumstance being associated with the idea of
great distance. This he says is confirmed by our be-
ing surprised to find, upon approaching such objects,
that they are so much nearer to us, as well as so much
smaller than we had imagined.

Among other cases concerning illusion, which fell
under the consideration of M. de la Hire, he men-
ments one which is of difficult solution. It is when a
nail, in a dark place, and situated beyond the
limits of distant vision, is viewed through a very nar-
row chink in a card; in which case a considerable
number of candles, sometimes so many as fifty, will be
seen along the chink. This appearance he attributes
to small irregularities in the surface of the humours of
the eye, the effect of which is not sensible when rays
are admitted into the eye through the whole extent of
the pupil, and consequently one principal image effaces
a number of small ones; whereas, in this case, each
of them is formed separately, and no one of them is
so considerable as to prevent the others from being
perceived at the same time.

There are few persons, M. de la Hire observes,
who have both their eyes perfectly equal, not only
with respect to the limits of distant vision, but also
with respect to the colour with which objects appear
when they are viewed by them, especially if one of
the eyes has been exposed to the impression of a
strong light. To compare them together in this re-
spect, he directs us to take two thin cards, and to
make in each of them a round hole of a third or
fourth of a line in diameter, and, applying one of them
to each of the eyes, to look through the holes on a
white paper, equally illuminated; when a circle of
the paper will appear to each of the eyes, and, placing
the cards properly, these two circles may be made to
touch one another, and thereby the appearance of the
same object to each of the eyes may be compared to
the greatest advantage. To make this experiment
with the greatest exactness, it is necessary, he says,
that the eyes be kept shut some time before the cards be
applied to them.

M. de la Hire first endeavoured to explain the cause
of those dark spots which seem to float before the eyes,
especially those of old people. They are most visible
when the eyes are turned towards an uniform white
object, as the snow in the open field. If they be
fixed when the eye is so, this philosopher supposed
that they were occasioned by extravaated blood upon
the retina. But he thought that the moveable spots
were occasioned by opaque matter floating in the
aqueous humour of the eye. He thought the vitreous
humour was not sufficiently limiter for this purpose.

By the following calculation, M. de la Hire gives
us an idea of the extreme sensibility of the optic
nerves. One may see very easily, at the distance of 4000
feet, the tail of a wind-mill, 6 feet in diameter; and
the eye being suppos'd to be an inch in diameter, the picture
of this fail, at the bottom of the eye, will be \( \frac{6}{4000} \) of
an inch, which is less than the 666th part of a line, and
is about the 600rd part of a common hair, or the 8th
part of a single thread of silk. So small, therefore,
mult one of the fibres of the optic nerve be, which he
says.
Part II.

O P T I C S.

fays is almost inconceivable, since each of these fibres is a tube that contains spirits. If birds perceive distant objects as well as men, which he thinks very probable, he observes that the fibres of their optic nerves must be much finer than ours.

The person who first took much notice of Dr Barrow's hypothesis was the ingenious Dr Berkeley, bishop of Cloyne, who distinguished himself so much by the objections which he started to the reality of a material world, and by his opposition to the Newtonian doctrine of fluxions. In his Essay towards a New Theory of Vision, he observes, that the circle formed upon the retina, by the rays which do not come to a focus, produce the same confusion in the eye, whether they cross one another before they reach the retina, or tend to do it afterwards; and therefore that the judgment concerning distance will be the same in both the cases, without any regard to the place from which the rays originally issued; so that in this case, as, by receding from the lens, the confusion, which always accompanies the nearness of an object, increases, the mind will judge that the object comes nearer.

But, fays Dr Smith, if this be true, the object ought always to appear at a lesser distance from the eye than at which the object is seen distinctly, which is not the case; and, to explain this appearance, as well as every other in which a judgment is formed concerning distance, he maintains, that we judge of it by the apparent magnitude of objects only, or chiefly; so that, since the image grows larger as we recede from the lens through which it is viewed, we conceive the object to come nearer. He also endeavours to show, that, in all cases in which glasses are used, we judge of distance by the same simple rule; from which he concludes universally, that the apparent distance of an object seen in a glafs is to its apparent distance seen by the naked eye as the apparent magnitude to the naked eye is to its apparent magnitude in the glafs.

But that we do not judge of distance merely by the angle under which objects are seen, is an observation as old as Alhazen, who mentions several instances, in which, though the angles under which objects appear to be different, the magnitudes are universally and instantaneously deemed not to be so. And Mr Robins, clearly shews the hypotheses of Dr Smith to be contrary to fact in the most common and simple cases. In microscopes, he fays, it is impossible that the eye should judge the object to be nearer than the distance at which it has viewed the object itself, in proportion to the degree of magnifying. For when the microscope magnifies much, this rule would place the image at a distance, of which the sight cannot possibly form any opinion, as being an interval from the eye at which no object can be seen. In general, he fays, he believes, that whoever looks at an object through a convex glafs, and then at the object itself without the glafs, will find it to appear nearer in the latter case, though it be magnified in the glafs; and in the same trial with the concave glafs, though by the glafs the object be diminished, it will appear nearer through the glafs than without it.

But the most convincing proof that the apparent distance of the image is not determined by its apparent magnitude, is the following experiment. If a double convex glafs be held upright before some luminous object, as a candle, there will be seen two images, one erect, and the other inverted. The first is made simply by reflection from the nearest surface, the second by reflection from the farther surface, the rays undergoing a refraction from the first surface both before and after the reflection. If this glafs has not too short a focal distance, when it is held near the object, the inverted image will appear larger than the other, and also nearer, but if the glafs be carried off from the object, though the eye remain as near to it as before, the inverted image will diminish so much faster than the other, that, at length, it will appear very much less than it, but still nearer. Here, fays Mr Robins, two images of the same object are seen under one view, and their apparent distances immediately compared; and it is evident, that those distances have no necessary connection with the apparent magnitude. He also shows how this experiment may be made still more convincing, by taking a piece of paper on the middle of the lens, and viewing it through a short tube.

M. Bouguer adopts the general maxim of Dr Barrow, in supposing that we refer objects to the place from which the pencils of rays seemingly converge at their entrance into the pupil. But when rays issue from below the surface of a vessel of water, or any other refracting medium, he finds that there are always two different places of this seeming convergence; one of them of the rays that issue from it in the same vertical circle, and therefore fall with different degrees of obliquity upon the surface of the refracting medium; and another, of those that fall upon the surface with the same degree of obliquity, entering the eye laterally with respect to one another. Sometimes, he fays, one of these images is attended to by the mind, and sometimes the other, and different images may be observed by different persons. An object plunged in water affords an example, he fays, of this duplicity of images.

If BA (fig. 1.) be part of the surface of water, and the object be at O, there will be two images of it in two different places; one at G, on the caustic by refraction, and the other at E, in the perpendicular AO, which is as much a caustic as the other line. The former image is visible by the rays ODM, O'd'm', which are one higher than the other, in their progress to the eye; whereas the image at E is made by the rays ODM, O'd'm', which enter the eye laterally. This, fays he, may serve to explain the difficulty of Father Tacquet, Barrow, Smith, and many other authors, and which Newton himself considered as a very difficult problem, though it might not be absolutely insoluble.

G. W. Kraft has ably supported the opinion of Dr Barrow, that the place of any point, seen by reflection from the surface of any medium, is that in which rays issuing from it, infinitely near to one another, would meet; and considering the caule of a distant object, viewed in a concave mirror, by an eye very near to it, when the image, according to Euclid and other writers, would be between the eye and the object, and the rule of Dr Barrow cannot be applied; he fays that in this case the speculum may be considered as a plane, the effect being the same, only the image is more obscure.

Dr
Dr. Porterfield gives a distinct and comprehensive view of the natural methods of judging concerning the distance of objects.

The conformation of the eye, he observes, can be of no use to us with respect to objects that are placed without the limits of distinct vision. As the object, however, does then appear more or less confused, according as it is more or less removed from those limits, this confusion afflicts the mind in judging of the distance of the object; it being always esteemed so much the nearer, or the farther off, by how much the confusion is greater. But this confusion hath its limits, also, beyond which it can never extend; for when an object is placed at a certain distance from the eye, to which the breadth of the pupil bears no sensible proportion, the rays of light that come from a point in the object, and pass the pupil, are so little diverging that they may be considered as parallel. For a picture on the retina will not be feebly more confused, though the object be removed to a much greater distance.

The most universal, and frequently the most sure means of judging of the distance of objects is, he says, the angle made by the optic axis. For our two eyes are like two different flations, by the assemblance of which distances are taken; and this is the reason why those persons who are blind of one eye, so frequently mis their mark in pouring liquor into a glass, or when they do not appear at all, we judge that the brighter object is the nearer of the two.

The fifth method consists in the different appearance of the small parts of objects. When these parts appear distinct, we judge that the object is near; but when they appear confused, or when they do not appear at all, we judge that it is at a greater distance.

The sixth and last method by which we judge the distance of objects is, that the eye does not represent to our mind one object alone, but at the same time all those that are placed betwixt us and the principal object, whose distance we are considering; and the more this distance is divided into separate and distinct parts, the greater it appears to be. For this reason, distances upon uneven surfaces appear les than upon a plane: for the inequalities of the surfaces, such as hills, and holes, and rivers, that lie low and out of sight either do not appear, or hinder the parts that lie behind them from appearing; and so the whole apparent distance is diminished by the parts that do not
Part II.

OPTICS.

Apparent place, &c., of objects.

Several fallacies of vision explained.

Dr. Porterfield very well explains several fallacies in vision depending upon our mistaking the distances of objects. Of this kind, he says, is the appearance of parallel lines, and long vistas consisting of parallel rows of trees; for they seem to converge more and more as they are farther extended from the eye. The reason of this, he says, is because the apparent magnitudes of their perpendicular intervals are perpetually diminishing, while, at the same time, we mistake their distance. Hence we may see why, when two parallel rows of trees stand upon an ascent, whereby the more remote parts appear farther off than they really are, because the line that measures the length of the vistas now appears under a greater angle than when it was horizontal, the trees, in such a case, will seem to converge less, and sometimes, instead of converging, they will be thought to diverge.

For the same reason that a long vista appears to converge more and more the farther it is extended from the eye, the eye, the more remote they are the higher they will appear, till the last be seen on a level with the eye; whereas the ceiling of a long gallery appears to descend towards a horizontal line, drawn from the eye of the spectator. For this reason, also, the surface of the sea, seen from an eminence, seems to rise higher and higher the farther we look; and the upper parts of high buildings seem to stoop, or incline forwards over the eye below, because they seem to approach towards a vertical line proceeding from the spectator's eye; so that flatness on the top of such buildings, in order to appear upright, must recline, or bend backwards.

Our author also shows the reason why a windmill, seen from a great distance, is sometimes imagined to move the contrary way from what it really does, by our taking the nearer end of the sail for the more remote. The uncertainty we sometimes find in the course of the motion of a branch of lighted candles, turned round at a distance, is owing, he says, to the same cause; as also our sometimes mistaking a convex for a concave surface, more especially in viewing seals and impreffions with a convex glass or a double microscope; and lastly, that, upon coming in a dark night into a street, in which there is but one row of lamps, we often mistake the side of the street they are on.

Far more light was thrown upon this curious subject by M. Bouguer.

The proper method of drawing the appearance of two rows of trees that shall appear parallel to the eye, is a problem which has exercised the ingenuity of several philosophers and mathematicians. That the apparent magnitude of objects decreases with the angle under which they are seen, has always been acknowledged. It is also acknowledged, that it is only by custom and experience that we learn to form a judgment both of magnitudes and distances. But in the application of these maxims to the abovementioned problem, all persons, before M. Bouguer, made use of the real distance instead of the apparent one; by which only the mind can form its judgment. And it is manifest, that, if any circumstances contribute to make the distance appear otherwise than it is in reality, the apparent magnitude of the object will be affected by it; for the same reason, that, if the magnitude be misapprehended, the idea of the distance will vary.

For want of attending to this distinction, Tacquet pretended to demonstrate, that nothing can give the idea of two parallel lines (rows of trees for instance) to an eye situated at one of their extremities, but two hyperbolic curves, turned the contrary way; and M. Varignon maintained, that in order to make a vista appear of the same width, it must be made narrower, instead of wider, as it recedes from the eye.

M. Bouguer observes, that very great distances, and those that are considerably less than they, make nearly the same impression upon the eye. We, therefore, always image great distances to be less than they are, and for this reason the ground plan of a long vista always appears to rise. The visual object is in a determinate direction but as we imagine that they terminate sooner than they do, we necessarily conceive that the place from which they issue is elevated. Every large plane, therefore, as AB (fig. 2.) viewed by an eye at O, will seem to lie in such a direction as C.C.LXI., to AB, and consequently, in order to appear truly parallel on the plane AB, must be drawn so as that they would appear parallel on the plane AB, and be from thence projected to the plane AB.

To determine the inclination of the apparent ground plan AB to the true ground-plan AB, our ingenious author directs us to draw upon a piece of level ground two straight lines of a sufficient length (for which purpose lines lighten to small ficks are very convenient), making an angle of 3 or 4 degrees with one another. Then a person, placing himself within the angle, and his back towards the angular point, more walk backwards and forwards till he can fancy the lines to be parallel. In this situation, a line drawn from the point of the angle through the place of his eye, will contain the same angle with the true ground-plan which this does with the apparent one.

M. Bouguer then shows other more geometrical methods of determining this inclination; and says, that by these means he has often found it to be 4 or 5 degrees, though sometimes only 2 or 2°. The determination of this angle, he observes, is variable, depending upon the manner in which the ground is illuminated and the intensity of the light. The colour of the foil is also not without its influence, as well as the particular conformation of the eye, by which it is more or less affected by the same degree of light, and also the part of the eye on which the object is painted. When, by a flight motion of his head, he contrived, that certain parts of the foil, the image of which fell towards the bottom of his eye, should fall towards the top of the retina, he always thought that this apparent inclination became a little greater.

But what is very remarkable, and what he says he can assure his reader may be depended upon, is, that if he look towards a rising ground, the difference between the apparent ground-plan and the true one will be much more considerable, so that they will sometimes make an angle of 25 or 30 degrees. Of this he had
had made frequent observations. Mountains, he says, begin to be inaccessible when their sides make an angle from 35 to 37 degrees with the horizon, as then it is not possible to climb them but by means of flumes or shrubs, to serve as steps to fix the feet on. In these cases, both he and his companions always agreed that the apparent inclination of the side of the mountain was 60 or 70 degrees.

These deceptions are represented in fig. 3, in which, when the apparent plan AM, or AN, are much inclined, the apparent ground-plan AM, or AM, makes a very large angle with it. On the contrary, if the ground dips below the level, the inclination of the apparent to the true ground-plan diminishes, till, at a certain degree of the slope, it becomes nothing at all; the two plans AP and Ap being the same, so that parallel lines drawn upon them would always appear fo.

If the inclination below the horizon is carried beyond the situation AP, the error will encrease; and what is very remarkable, it will be on the contrary side; the apparent plan AR being always below the true plan AR, so that if a person would draw upon the plan AR lines that shall appear parallel to the eye, they must be drawn converging, and not diverging, as is usual on the level ground; because they must be the projections of two lines imagined to be parallel, on the plan AR, which is more inclined to the horizon than AR.

These remarks, he observes, are applicable to different planes exposed to the eye at the same time. For if BH, fig. 4, be the front of a building, at the distance of AB from the eye, it will be reduced in appearance to the distance A b; and the front of the building will be hb, rather inclined towards the spectator, unless the distance be inconsiderable.

After making a great number of observations upon this subject, our author concludes, that when a man stands upon a level plane, it does not seem to rise sensibly but at some distance from him. The apparent plane, therefore, has a curvature in it, at that distance, the form of which is not very easy to determine; so that a man standing upon a level plane, of infinite extent, will imagine that he stands in the centre of a basin. This is also, in some measure, the case with a person standing upon the level of the sea.

He concludes with observing, that there is no difficulty in drawing lines according to these rules, so as to have any given effect upon the eye, except when some parts of the prospect are very near the spectator, and others very distant from him; because, in this case, regard must be had to the conical or conical idea of a surface. A right line passing at a small distance from the observer, and below the level of his eye, in that case almost always appears sensibly curved at a certain distance from the eye; and almost all figures in this case are subject to some complicated optical alteration to which the rules of perspective have not as yet been extended. If a circle be drawn near our feet, and within that part of the ground which appears level to us, it will always appear to be a circle, and at a very considerable distance it will appear an ellipse; but between these two situations, it will not appear to be either the one or the other, but will be like one of those ovals of Descartes, which is more curved on one of its sides than the other.

On these principles a parterre, which appears distorted when it is seen in a low situation, appears perfectly regular when it is viewed from a balcony or any other eminence. Still, however, the apparent irregularity takes place at a greater distance, while the part that is near the spectator is exempt from it. If AB, fig. 5, be the ground plane, and As be a perpendicular, under the eye, the higher it is situated, at Q, to the greater distance will T, the place at which the plane begins to have an apparent ascent along TS, be removed.

All the varieties that can occur with respect to the visible motion of objects, are thus fancifully summed up by Dr Porterfield under eleven heads.

1. An object moving very swiftly is not seen, unless it be very luminous. Thus a cannon-ball is not seen if it is viewed tranversely: but if it be viewed according to the line it describes, it may be seen, because its picture continues long on the same place of the retina; which, therefore, receives a more sensible impression from the object.

2. A live coal swung briskly round in a circle appears a continued circle of fire, because the impressions made on the retina by light, being of a vibrating and consequently of a lasting nature, do not presently perish, but continue till the coal performs its whole circuit, and returns again to its former place.

3. If two objects, unequally distant from the eye, move with equal velocity, the more remote one will appear the flower; or, if their velocities be proportional to their distances, they will appear equally swift.

4. If two objects, unequally distant from the eye, move with unequal velocities in the same direction, their apparent velocities are in a ratio compounded of the direct ratio of their true velocities, and the reciprocal one of their distances from the eye.

5. A visible object moving with any velocity appears to be at rest, if the space described in the interval of one second is imperceptible at the distance of the eye. Hence it is that a near object moving very slowly, as the index of a clock, or a remote one very swiftly, as a planet, seems to be at rest.

6. An object moving with any degree of velocity will appear at rest, if the space it runs over in a second of time be to its distance from the eye as 1 to 1400.

7. The eye proceeding straight from one place to another, a lateral object, not too far off, whether on the right or left, will seem to move the contrary way.

8. The eye proceeding straight from one place to another, and being sensible of its motion, distant objects will seem to move the same way, and with the same velocity. Thus, to a person running eastwards, the moon on his right hand appears to move the same way, and with equal swiftness; for, by reason of its distance, its image continues fixed upon the same place of the retina, from whence we imagine that the object moves along with the eye.

9. If the eye and the object move both the same way, only the eye much swifter than the object, the latter will appear to go backwards.

10. If two or more objects move with the same velocity, and a third remain at rest, the moveable ones will appear fixed, and the quiescent in motion the contrary way.
At the conclusion of these observations, our author endeavours to explain another phenomenon of motion, which, though very common and well known, had not, as far as he knew, been explained in a satisfactory manner. It is this: If a person turns swiftly round, without changing his position, all objects about will seem to move round in a circle contrary to way; and this deception continues not only while the person himself moves round, but, which is more surprising, the image changes its place on the retina, and thence the eye is in motion, though difficult to explain: for though, we conclude that either the object, contrary way, Thus clouds moving very swiftly, their parts seem to acquire their situation, and the moon to move the contrary way.

11. If the eye be moved with great velocity, lateral objects at rest appear to move the contrary way. Thus to a person sitting in a coach, and riding briskly along a road, the trees seem to retire to the contrary way; and to people in a ship, &c. the shores seem to recede.

At the conclusion of these observations, our author endeavours to explain another phenomenon of motion, which, though very common and well known, had not, as far as he knew, been explained in a satisfactory manner. It is this: If a person turns swiftly round, without changing his position, all objects about will seem to move round in a circle contrary to way; and this deception continues not only while the person himself moves round, but, which is more surprising, the image changes its place on the retina, and thence the eye is in motion, though difficult to explain: for though, we conclude that either the object, contrary way, Thus clouds moving very swiftly, their parts seem to acquire their situation, and the moon to move the contrary way.

This is ingenius, but perhaps not just. An account of this matter, which seems to us more satisfactory, has been lately given to the public by Dr Wells. "Some of the older writers upon optics (says this able philosopher) imagined the vivfe spirits to be contained in the head, as water is in a vessel; which, therefore, when once put in motion by the rotation of our body, must continue in it for some time after this has ceased; and to this real circular movement of the vivfe spirits, while the body is at rest, they attributed the apparent motions of objects in giddiness. Dechalesa saw the weakness of this hypothesis; and conjectured, that the phenomenon might be owing to a real movement of the eyes; but produced no fact in proof of his opinion. Dr Porte-rfield, on the contrary, supposed the difficulty of explaining it to consist in showing, why objects at rest appear in motion to an eye which is also at rest. The solution he offered of this representation of the phenomenon, is not only extremely ingenious, but is I believe the only probable one which can be given. It does not apply, however, to the fact which truly exists; for I shall immediately show, that the eye is not at rest, as he imagined. The late author I know of who has touched upon this subject is Dr Darwin. His words are, 'When any one turns round rapidly on one foot till he becomes dizzy, and falls upon the ground, the spectre of the ambient objects continue to present themselves in rotation, or appear circular, and he seems to behold them for some time in motion.' I do not indeed pretend to understand his opinion fully; but this much seems clear, that if such an apparent motion of the surrounding objects depends in any way upon their spectre, or the illusive representations of those objects, occasioned by their former impressions upon the retinas, no similar motion would be observed, were we to turn ourselves round with our eyes shut, and not to open them till we became giddy; for in this case, as the surrounding objects could not send their pictures to the retinas, there would consequently be no spectre to present themselves afterward in rotation. But whoever will make the experiment, will find, that objects about him appear to be equally in motion when he has become giddy by turning himself round, whether this has been done with his eyes open or shut. I shall now venture to propose my own opinion upon this subject. If the eye be at rest, we judge an object to be in motion when its picture falls in succeeding times upon different parts of the retina; and if the eye be in motion, we judge an object to be at rest, as long as the change of the place of its picture upon the retina holds a certain correspondence with the change of the eye's position. Let us now suppose the eye to be in motion, while, from some disorder in the flxen of sensation, we are either without those feelings which indicate the various positions of the eye, or are not able to attend to them. It is evident, that in such a state of things an object at rest must appear to be in motion, since it sends in succeeding times its picture to different parts of the retina. And this seems to be what happens in giddiness. I was first led to think so from observing, that, during a flight fit of giddiness, I was accidentally involved with a coloured light, occasioned by looking hastily at a luminous body, and upon which I happened at that moment to be making an experiment, was moved in a manner altogether independent of the positions I conceived my eyes to be in. To determine this point, I again produced the spot, by looking some time at the flame of a candle, then turning myself round till I became giddy, I suddenly discontinued this motion, and directed my eyes to..."
to the middle of a sheet of paper, fixed upon the wall of my chamber. The spot now appeared upon the paper; but only for a moment; for it immediately after seemed to move to the side, and the paper to the other, notwithstanding I conceived the position of my eyes to be in the mean while unchanged. To go on with the experiment, when the paper and spot had proceeded to a certain distance from each other, they suddenly came together again; and this separation and conjunction were alternately repeated a number of times, the limits of the separation gradually becoming less, till at length the paper and spot both appeared to be at rest, and the latter to be projected upon the middle of the former. I found also, upon repeating and varying the experiment a little, that when I had turned myself from left to right, the paper moved from right to left, and the spot consequentially the contrary way; but that when I had turned from right to left, the paper would then move from left to right. These were the appearances observed while I stood erect. When I inclined, however, my head in such a manner as to bring the side of my face parallel to the horizon, the spot and paper would then move from each other, one upward and the other downward. But all these phenomena demonstrate, that there was a real motion in my eyes at the time I imagined them to be at rest; for the apparent situation of the spot, with respect to the paper, could not possibly have been altered, without a real change of the position of those organs. To have the same thing proved in another way, I defined a perfon to turn quickly round, till he became very giddy; then to flop himself, and look intently at me. He did so, and I could plainly see, that although he thought his eyes were fixed, they were in reality moving in their sockets, first toward one side and then toward the other."

M. Le Cat well explains a remarkable deception, by which a person shall imagine an object to be on the opposite side of a board, when it is not so, and also inverted and magnified. It is illustrated by fig. 6, in which D represents the eye, and CB a large black board, pierced with a small hole. E is a large white board, placed beyond it, and strongly illuminated; and a pin, or other small object, held between the eye and the first board. In these circumstances, the pin shall be imagined to be at F, on the other side of the board, where it will appear inverted and magnified; because what is in fact perceived, is the shadow of the pin upon the retina; and the light that is stopped by the upper part of the pin coming from the lower part of the enlightened board, and that which is stopped by the lower part coming from the upper part of the board, the shadow must necessarily be inverted with respect to the object.

There is a curious phenomenon relating to vision, which some persons have ascribed to the infection of light, but which Mr Melville explains in a very different and very simple manner.

"When any opaque body is held at the distance of three or four inches from the eye, so that a part of some more distant luminous object, such as the window, or the flame of a candle, may be seen by rays passing near its edge, if another opaque body, nearer to the eye, be brought assez from the opposite side, the edge of the firft body will seem to swell outward, and meet the latter; and in doing so will intercept a portion of the luminous object that was seen before."

This appearance he explains in the following manner: Let AB (fig. 7) represent the luminous object to which the light is directed, CD the more distant opaque body, GH the nearer, and EF the diameter of the pupil. Join ED, FD, EG, FG, and produce them till they meet AB in K, N, M, and L. It is plain that the parts AN, MB, of the luminous object cannot be seen. But taking any point a between N and K, and drawing a D a, since the portion a F of the pupil is filled with light flowing from that point, it must be visible. Any point b, between a and K, mustfill / F, a great proportion of the pupil, and therefore must appear brighter. Again, any point c, between b and K, must appear brighter than b, because it fills a greater portion of the light. The point K itself, and every other point in the space K, must appear very luminous, since they send entire pencils of rays EF, EL, EA, to the eye, and the visible brightness of every point from L towards M, must decrease gradually, as from K to N; that is, the spaces KN, LM, will appear as dim shadowy borders, or fringes, adjacent to the edges of the opaque bodies.

When the edge G is brought to touch the right line KF, the penumbra unites; and as soon as it reaches NDF, the above phenomenon begins; for it cannot pass that right line without meeting some line a D a', drawn from a point between N and K, and, by intercepting all the rays that fall upon the pupil, render it invisible. In advancing gradually to the line KDE, it will meet other lines b D b', c D c', and therefore render the points b, c, &c. from N to K, successively invisible; and therefore the edge of the fixed opaque body CD must seem to swell outwards, and cover the whole space NK; while GH, by its motion, covers MK. When GH is placed at a greater distance from the eye, CD continuing fixed, the space OP to be passed over in order to intercept NK is left; and therefore, with an equal motion of GH, the apparent swelling of CD must be quicker; which is found true by experience.

If ML represent a luminous object, and REFQ any plane exposed to its light, the space FQ will be entirely waded from the rays, and the space FE will be occupied by a penumbra, gradually darker, from E to F. Let now GH continue fixed, and CD move parallel to the plane EF; and as soon as it passes the line LF, it is evident that the shadow QF will seem to swell outwards; and when CD reaches ME, so as to cover with its shadow the space RE, QF, by its extension, will cover FE. This is found to hold true likewise by experiment.

§ 4. Of the Concave Figure of the Sky.

This apparent concavity is only an optical deception founded on the incapacity of our organs of vision to take in very large distances. —Dr Smith, in his Complete System of Optics, hath demonstrated, that if the surface of the earth were perfectly plane, the distance of the visible horizon from the eye would exceed the distance of 5000 times the height of the eye above the ground, supposing the height of the eye between five and five feet; beyond this distance, all
The concavity of the heavens appears to the eye, which is the only judge of an apparent figure, to be a less portion of a spherical surface than a hemisphere. Dr Smith says, that the centre of the concavity is much below the eye; and by taking a medium among several observations, he found the apparent distance of the sky, its parts at the horizon to be generally between three and four times greater than the apparent distance of its parts overhead. For let the arch ABCD represent the apparent concavity of the sky, O the place of the eye, OA and OC the horizontal and vertical apparent distances, whose proportion is required. First observe when the sun or the moon, or any cloud or star, is in such a position at B, that the apparent arches BA, BC, extended on each side of this object towards the horizon and zenith, seem equal to the eye; then taking the altitude of the object B with a quadrant, or a cross-staff, or finding it by astronomy from the given time of observation, the angle AOB is known. Drawing therefore the line OB in the position thus determined, and taking in it any point B at pleasure, in the vertical line CO produced downwards, seek the centre E of the circle ABC, whose arches BA, BC, intercepted between B and the legs of the right angle AOC, shall be equal to each other; then will this arch ABCD represent the apparent figure of the sky.

For by the eye we estimate the distance between any two objects in the heavens by the quantity of sky that appears to lie between them; as upon earth we estimate it by the quantity of ground that lies between them. The centre E may be found geometrically by constructing a cubic equation, or as quickly and sufficiently exact by trying whether the chords BA, BC, of the arch ABC drawn by conjecture are equal, and by altering its radius BE till they are so.

Now in making several observations upon the sun, and some others upon the moon and stars, they seemed to our author to bisect the vertical arch ABC at B, when their apparent altitudes or the angle AOB was about 23 degrees; which gives the proportion of OB to OA as 3 to 10 or 1 to 3½ nearly. When the sun was but 30 degrees high, the upper arch seemed always less than the under one; and, in our author's opinion, always greater when the sun was about 16 or 20 degrees high.

§ 5. Of the Blue Colour of the Sky, and of Blue and Green Shadows.

The opinions of ancient writers concerning the colour of the sky merit no notice. The first who gave any rational explanation was Fromondus. By him it was suppos'd, that the blue ness of the sky proceeded from a mixture of the white light of the sun with the black space beyond the atmosphere, where there is neither refraction nor reflection. This opinion prevailed very generally even in modern times, and was maintained by Otto Guerick and all his contemporaries, who asserted that white and black may be mixed in such a manner as to make a blue. M. Bouguer had recourse to the vapours diffused through the atmosphere, to account for the reflection of the blue rays rather than any other. He seems however to suppose, that it arises from the confusion of the air itself, whereby the fainter coloured rays are intercepted in making their way through any considerable part of it. Hence he is of opinion, that the colour of the air is properly blue; to which opinion Dr Smith seems also to have inclined.

To this blue colour of the sky is owing the appearance of blue and green shadows in the mornings and evenings.
Blue colour of the Sky.

Buffon in the month of July 1742, when he observed that the shadows of trees which fell upon a white wall were green. He was at that time standing upon an eminence, and the sun was setting in the cleft of a mountain, so that he appeared considerably lower than the horizon. The sky was clear, excepting in the west, which, though free from clouds, was lightly shaded with vapours, of a yellow colour, inclining to red. Then the sun itself was exceedingly red, and was seemingly at least four times as large as he appears to be at mid-day. In these circumstances, he saw very distinctly the shadows of the trees, which were 30 or 40 feet from the white wall, coloured with a light green, inclining to blue. The shadow of an arbour, which was three feet from the wall, was exactly drawn upon it, and looked as if it had been newly painted with verdigris. This appearance lasted near five minutes; after which it grew fainter, and vanished at the same time with the light of the sun.

The next morning, at sunrise, he went to observe other shadows, upon another white wall; but instead of finding them green, as he expected, he observed that they were blue, or rather of the colour of lively indigo. The sky was serene, except a flight covering of yellow vapours in the east; and the sun arose behind a hill, so that it was elevated above his horizon. In these circumstances, the blue shadows were only visible three minutes; after which they appeared black, and in the evening of the same day he observed the green shadows exactly as before. Six days passed without his being able to repeat his observations, on account of the clouds; but the 7th day, at sunset, the shadows were not green, but of a beautiful sky-blue. He also observed, that the sky was in a great measure free from vapours at that time; and that the sun set behind a rock, so that it disappeared before it came to his horizon. Afterwards he often observed the shadows both at sunrise and sunset; but always observed them to be blue, though with a great variety of shades of that colour. He showed this phenomenon to many of his friends, who were as much surprised at it as he himself had been; but he says that any person may see a blue shadow, if he will only hold his finger before a piece of white paper at sunrise or sunset.

The first person who attempted to explain this phenomenon was the Abbé Mazeras, in a memoir of the Society in Berlin for the year 1752. He observed, that when an opaque body was illuminated by the moon and a candle at the same time, and the two shadows were cast upon the same white wall, that which was enlightened by the candle was reddish, and that which was enlightened by the moon was blue. But, without attending to any other circumstances, he supposed the change of colour to be occasioned by the diminution of the light; but M. Melville, and M. Bouguer, both independent of one another, seem to have hit upon the true cause of this curious appearance, and which had been already hinted at. The former of these gentlemen, in his attempts to explain the blue colour of the sky, observes, that since it is certain that no body assumes any particular colour, but because it reflects one sort of rays more abundantly than the rest; and since it cannot be supposed that the blue colour is only the constituent parts of pure air are gross enough to separate the blue from any colours of themselves; we must conclude with Sir Isaac Newton, that the violet and blue making rays are reflected more copiously than the rest, by the finer vapours diffused through the atmosphere, whose parts are not big enough to give them the appearance of visible opaque clouds. And he shows, that in proper circumstances, the bluish colour of the sky-light may be actually seen on bodies illuminated by it, as, he says, it is objected should always happen upon this hypothesis. For that if, on a clear cloudless day, a sheet of white paper be exposed to the sun's beams, when any opaque body is placed upon it, the shadow which is illuminated by the sky only will appear remarkably bluish, compared with the rest of the paper, which receives the sun's direct rays.

M. Bouguer, who has taken the most pains with this subject, observes, that as M. Buffon mentions the shadows appearing green only twice, and that at all other times they were blue, this is the colour which they regularly have, and that the blue was changed into green by some accidental circumstance. Green, he says, is only a composition of blue and yellow, so that this accidental change may have arisen from the mixture of some yellow rays in the blue shadow; and that perhaps the wall might have had that tinge, so that the blue is the only colour for which a general reason is required. And this, he says, must be derived from the colour of pure air, which always appears blue, and which always reflects that colour upon all objects without distinction; but which is too faint to be perceived when our eyes are strongly affected by the light of the sun, reflected from other objects around us.

To confirm this hypothesis, he adds some curious observations of his own, in which this appearance is agreeably diversified. Being at the village of Boucholz in July 1764, he observed the shadows projected on the white paper of his pocket-book, when the sky was clear. At half an hour past 6 in the evening, when the sun was about four degrees high, he observed that the shadow of his finger was of a dark grey, while he held the paper opposite to the Sun; but when he inclined it almost horizontally, the paper had a bluish cast, and the shadow upon it was of a beautiful bright blue.

When his eye was placed between the fun and the paper laid horizontally, it always appeared of a bluish cast; but when he held the paper thus inclined between his eye and the sun, he could distinguish upon every little eminence occasioned by the inequality of the surface of the paper, the principal of the prismatic colours. He also perceived them upon his nails, and upon the skin of his hand. This multitude of coloured points, red, yellow, green, and blue, almost faced the natural colour of the objects.

At three quarters past 6, the shadows began to be blue, even when the rays of the sun fell perpendicularly. The colour was the most lively when the rays fell upon it at an angle of 45 degrees; but with a left inclination of the paper, he could distinctly perceive, that the blue shadow had a border of a stronger blue on that side which looked towards the sky, and a red border on that side which was turned towards the earth. To see these borders, the body that made the shadow

2

235 Curiosities of the phenomena attempted by Abbé Mazeras.

234 Melville's and Bouguer's explanations.
shadow was illuminated either by the red rays reflected from the clouds, when the sun is near the horizon, or from some terrestrial bodies in the neighbourhood. This conjecture is favoured by the necessity he was under of placing any body near the paper, in order to produce this bordered shadow, as he says it is easily demonstrated, that the interception of the sky-light can only take place when the breadth of the opaque body is to its distance from the white ground on which the shadow falls, as twice the sine of half the amplitude of the sky to its own.

At the conclusion of his observations on these blue shadows, he gives a short account of another kind of them, which, he does not doubt, have the same origin. These he often saw early in the morning when he was reading by the light of a candle in the morning, and consequently the twilight mixed with that of his candle. In these circumstances, the shadow that was made by intercepting the light of his candle, at the distance of about six feet, was of a beautiful clear blue, which became deeper as the opaque body which made the shadow was brought nearer to the wall, and was exceedingly deep at the distance of a few inches only. But wherever the day-light did not come, the shadows were all black without the least mixture of blue.

§ 6. Of the Irradiations of the Sun's Light appearing through the interstices of the Clouds.

This is an appearance which every one must have observed when the sky was pretty much overcast with clouds at some distance from each other. At that time several large beams of light, something like the appearance of the light of the sun admitted into a smoky room, will be seen generally with a very considerable degree of divergence, as if the radiant point was situated at no great distance above the clouds. Dr Smith observes that this appearance is one of those which serve to demonstrate that very high and remote objects in the heavens do not appear to us in their real figures and positions, but according to their perspective projections on the apparent concavity of the sky. He acquaints us, that though these beams are generally seen diverging, as represented in fig. 11, it is not always the case. He himself, in particular, often saw them converging towards a point diametrically opposite to the fun: for, as near as he could conjecture, the point to which they converged was situated as much below the horizon as the sun was then elevated above served by the opposite part of it. This part is represented by the line $DB$, and the point below it in opposition to fig. 12, the fun is $E'$; towards which all the beams $v, u, &c.$ appeared to converge.

Observing (says our author) that the point of the phenomenon was opposite to the sun, I began to suspect the menon ex that this unusual phenomenon was but a case of the usual apparent divergence of the beams of the sun from his apparent place among the clouds, as represented in fig. 11. I say an apparent divergence, for though nothing is more common than for rays to diverge from a luminous body, yet the divergence of these beams in such large angles is not real, but apparent. Because it is impossible for the direct rays of the sun to crofs one another at any point of the apparent concavity of the sky, in a greater angle than about half a degree. For
OPTICS.

Irradiations of the Sun's Light, &c.

338

The diameter of the earth being so extremely small, in comparison to the distance of the sun, as to subtend an angle at any point of his body of but 20 or 22 seconds at most, and the diameter of our visible horizon being extremely smaller than that of the earth; it is plain, that all the rays which fall upon the horizon from any given point of the sun, must be inclined to each other in the smallest angles imaginable: the greatest of them being as much smaller than that angle of 22 seconds, as the diameter of the visible horizon is smaller than that of the earth. All the rays that come to us from any given point of the sun may therefore be considered as parallel to each other; as the rays $aB$ from the point $a$, or $fB$ from the opposite point $f$; and consequently the rays of these two pencils that come from opposite points of the sun's real diameter, and cross each other in the sun's apparent place $B$ among the clouds, can constitute no greater an angle with each other than about half a degree; this angle of their intersection $eBf$ being the same as the fun would appear under to an eye placed among the clouds at $B$, or (which is much the same) to an eye at $O$ upon the ground. Because the sun's real distance $OS$ is inconceivably greater than his apparent distance $OB$. Therefore the rays of the sun, as $Bg$, $Bb$, do really diverge from his apparent place $B$ in no greater angles $gBb$ than about half a degree. Nevertheless they appear to diverge from the place $B$ in all possible angles, and even in opposite directions. Let us proceed then to an explanation of this apparent divergence, which is not only evident by any means; though at first light we are apt to think it is, by not distinguishing the vast difference between the true and apparent distances of the sun.

"What I am going to demonstrate is this. Supposing all the rays of the sun to fall accurately parallel to each other upon the visible horizon, as they do very nearly, yet in both cases they must appear to diverge in all possible angles. Let us imagine the heavens to be partly overcast with a species of bed of broken clouds, $v$, $v$, $v$, &c. lying parallel to the plane of the visible horizon, here represented by the line $AOD$; and when the sun's rays fall upon these clouds in the parallel lines $v$, $v$, $v$, &c. let some of them pass through their intervals in the lines $v$, $v$, $v$, &c. and fall upon the plane of the horizon at the places $t$, $t$, &c. and since the rest of the incident rays $v$, $v$, $v$, are supposed to be intercepted from the place of the spectator at $O$ by the cloud $x$, and from the intervals between the transmitted rays $v$, $v$, $v$, &c. by the clouds $v$, $v$, &c. a small part of these latter rays $v$, $v$, $v$, when reflected every way from some certain kind of thin vapours floating in the air, may undoubtedly be sufficient to affect the eye with an appearance of lights and shades, in the form of bright beams in the places $v$, $v$, $v$, and of dark ones in the intervals between them; just as the like lights of beam and shade appear in a room by refractions of the sun's rays from a smoky or dusty air within it; the lights and shades being here occasioned by the transmittal of the rays through some parts of the window; and by their interruption at other parts.

"Now, if the apparent concavity of this bed of clouds $v$, $v$, to the eye at $O$, be represented by the arch $ABCD$, and be cut in the point $B$ by the line $OB$, drawn parallel to the beams $v$, $v$; it will be evident by the rules of perspective, that these long beams will not appear in their real places, but upon the concave $AB$ $CD$ diverging every way from the place $B$, where the sun himself appears, or the cloud $x$ that covers his body, as represented separately in full view in fig. 11.

"And for the same reason, if the line $BO$ be produced towards $E$, below the plane of the horizon $AOD$, the eye be directed towards the region of the sky directly above $E$, the lower ends of the same real beams $v$, $v$, will now appear upon the part $DF$ of this concave; and will seem to converge towards the point $E$, situated just as much below the horizon as the opposite point $B$ is above it: which is separately represented in full view in fig. 12.

"For if the beams $v$, $v$, be supposed to be visible throughout their whole lengths, and the eye be directed in a plane perpendicular to them, here represented by the line $OF$; they and their intervals will appear broadest in and about this plane, because these parts of them are the nearest to the eye; and therefore their remoter parts and intervals will appear gradually narrower towards the opposite ends of the line $BE$. As a farther illustration of this matter, we may conceive the spectator at $O$ to be situated upon the top of a large a defcent $OH$ towards a remote valley $IK$, and the sun to be so very low, that the point $E$, opposite to him, may be seen above the horizon of this shady valley. In this case it is manifest, that the spectators at $O$ would now see these beams converging so far as to meet each other at the point $E$ in the sky itself.

"I do not remember to have ever seen any phenomenon of this kind by moon-light; not so much as of vapours diverging from her apparent place. Probably moon-light is too weak after refractions from any kind of vapours, to cause a sensible appearance of lights and shades so as to form these beams. And in the unusual phenomenon I well remember, that the converging sun-beams towards the point below the horizon were not quite so bright and strong as those usually that diverge from him; and that the sky beyond them appeared very black (several showers having passed that way), which certainly contributed to the evidence of this appearance. Hence it is probable that the thiness and weakness of the reflected rays from the vapours opposite to the sun, is the chief cause that this appearance is so very uncommon in comparison to that of other of diverging beams. For as the region of the sky round about the sun is always brighter than the opposite one, the light of the diverging beams ought also to be brighter than that of the converging ones. For, though rays are reflected from rough unpolished bodies in all possible directions, yet it is a general observation, that more of them are reflected forwards obliquely, than are reflected more directly backwards. Besides, in the present case, the incident rays upon the opposite region to the sun, are more diminished by continual refractions from a longer tract of the atmosphere, that the incident rays upon the region next the sun.

"The common phenomenon of diverging beams, I think, is more frequent in summer than in winter, and also when the sun is lower than when higher up; probably because the lower vapours are denser, and therefore more strongly reflective than the higher; because the lower sky-light is not so bright as the upper;
per; because the air is generally quieter in the mornings and evenings than about noon-day; and lastly, because many sorts of vapors are exhaled in greater plenty in summer than in winter, from many kinds of volatile vegetables; which vapors, when the air is cooled and condensed in the mornings and evenings, may become dense enough to reflect a sensible light."

§ 7. Of the Illumination of the Shadow of the Earth by the Refraction of the Atmosphere.

Two ancient philosophers, who knew something of the refractive power of the atmosphere, were very much perplexed to account for the body of the moon being visible when totally eclipsed. At such times the generally appears of a dull red colour, like tarnished copper, or of iron almost red-hot. This, they thought, was the moon's native light, by which it became visible when hid from the brighter light of the sun. Plutarch indeed, in his discourse upon the face of the moon, attributes this appearance to the light of the fixed stars reflected to us by the moon; but this must by far too weak to produce that effect. The true cause of it is the scattered beams of the sun bent into the earth's shadow by refractions through the atmosphere in the following manner.

"Let the body of the sun, rays Dr Smith, be represented a circumscribed circle ab, and that of the earth by the letter c ; and let the lines ade and bde touch them both on their opposite sides, and meet in e beyond the earth; then the angular space cde will represent the figure of the earth's shadow, which would be totally deprived of the sun's rays, were none of them bent into it by the refractive power of the atmosphere. Let this power first vanish at the circle b'i, concentric to the earth, so that the rays a b and b i, which touch its opposite sides, may proceed unrefracted, and meet each other at k. Then the two nearest rays to these which flow within, from the same points a and b, being refracted towards through the margin of the atmosphere, will cross each other at a point /, somewhat nearer to the earth than k; and in like manner, two opposite rays next within the two last will cross each other at a point m, somewhat nearer to the earth than l, having suffered greater refractions, by falling through longer and denser tracts of air lying somewhat nearer to the earth. The like approach of the successive interferences k, l, m, is to be understood of innumerable couples of rays, till you come to the interference n of the two innermost; which we may suppose just to touch the earth at the points o and p. It is plain then, that the space bounded by these rays on, op will be the only part of the earth's shadow which is deprived of the sun's rays. Let Vm represent part of the moon's orbit when it is nearest to the earth, at a time when the earth's dark shadow vp is the longest: in this case I will show that the ratio of tv to tm is about 4 to 3; and consequently that the moon, though centrally eclipsed at m, may yet be visible by means of those scattered rays above-mentioned, first transmitted to the moon by refraction through the atmosphere, and from thence reflected to the earth.

"For let the incident and emergent parts a q, r n, Fig. 2, of the ray agorn, that just touches the earth at a, be produced till they meet at n, and let a q produced meet the axis i t produced in s, and joining s and r m, since the refractions of an horizontal ray falling from a to r, or from a to q, would be alike and equal, the external angle ans is the double quantity of the usual refraction of an horizontal ray; and the angle ans is the apparent measure of the sun's semidiameter seen from the earth; and the angle at s is that of the earth's semidiameter tv seen from the sun (called his horizontal parallax); and lastly, the angle ans is that of the earth's semidiameter seen from the moon (called her horizontal parallax), because the elevation of the point n above the earth is too small to make a sensible error in the quantity of these angles; whose measures by astronomical tables are as follow:

The sun's least apparent semidiameter
The sun's horizontal parallax
Their difference* is
Double the horizontal refraction
The sun's full =
Their semidiameter is
The moon's greatest horizontal parallax
Therefore (by a preceding prop.) we have tm : tn ::
(ang. tnu : ang. tmu :: 83° - 10' : 62° - 10' :: 4 : 3 in round numbers; which was to be proved. It is easy to collect from the moon's greatest horizontal parallax of 62° - 10', that her least distance tm is about 55½ semidiameters of the earth; and therefore the greatest length tn of the dark shadow, being three quarters of tm, is about 41½ semidiameters.

"The difference of the last mentioned angles tnu, tmu, is nu = 21°, that is, about two thirds of 31° - 40', the angle which the whole diameter of the sun subtends at u. Whence it follows, that the middle point m of the moon centrally eclipsed, is illuminated by rays which come from two thirds of every diameter of the sun's disk, and pass by one side of the earth; and also by rays that come from the opposite two thirds of every one of the said diameters, and pass by the other side of the earth. This will appear by conceiving the ray agorn to be inflexible, and its middle point o to slide upon the earth, while the part r n is approaching to touch the point m; for then the opposite part qa will trace over two thirds of the sun's diameter. The true proportion of the angles num, aus, could not be preferred in the scheme, by reason of the sun's immense distance and magnitude with respect to the earth.

"Having drawn the line at n, it is observable, that all the incident rays, as a q, au, flowing from any one point of the sun to the circumference of the earth, will be collected to a focus a, whose distance ta is less than tm in the ratio of 62 to 67 nearly; and thus an image of the sun will be formed at A, whose rays

Of Optics.

Measure of Light.

Why the moon appears duller when eclipsed in her perigee than in her apogee.

§ 8. Of the Measures of Light.

That some luminous bodies give a stronger, and others a weaker light, and that some reflect more light than others, was always obvious to mankind; but no person, before M. Bouguer, hit upon a tolerable method of ascertaining the proportion that two or more lights bear to one another. The methods he most commonly used were the following. He took two pieces of wood or pasteboard EC and CD (fig. 4.), in which he made two equal holes P and Q, over which he drew pieces of oiled or white paper. Upon these holes he contrived that the light of the different bodies he was comparing should fall; while he placed a third piece of pasteboard PC, so as to prevent the two lights from mixing with one another. Then placing himself sometimes on one side, and sometimes on the other, but generally on the opposite side of this instrument, with respect to the light, he altered their position till the papers in the two holes appeared to be equally enlightened. This being done, he computed the proportion of their light by the squares of the distances at which the luminous bodies were placed from the objects. If, for instance, the distances were as three and nine, he concluded that the light they gave were as nine and eighty-one. Where any light was very faint, he sometimes made use of lenses, in order to condense it; and he inclosed them in tubes or not as his particular application of them required.

To measure the intensity of light proceeding from the heavenly bodies, or reflected from any part of the sky, he contrived an instrument which resembs a kind of portable camera obscura. He had two tubes, of which the inner was black, fastened at their lower extremities by a hinge C, (fig. 5.) At the bottom of these tubes were two holes, R and S, three or four lines in diameter, covered with two pieces of fine white paper. The two other extremities had each of them a circular aperture, an inch in diameter; and one of the tubes contained of two, one of them sliding into the other, which produced the same effect as varying the aperture at the end. When this instrument is used, the observer has his head, and the end of the instrument C, if covered, that no light can fall upon his eye, besides that which comes through the two holes S and R, while an assistant manages the instrument, and draws out or shortens the tube DE, as the observer directs. When the two holes appear equally illuminated, the intensity of the lights is judged to be inversely as the squares of the tubes.

In using this instrument, it is necessary that the object should subtend an angle larger than the aperture A or D, seen from the other end of the tube; for otherwise, the lengthening of the tube has no effect. To avoid, in this case, making the instrument of an inconvenient length, or making the aperture D too narrow, he has recourse to another expedient. He constructs an instrument, repersented (fig. 6.), consisting of two object-glasses, AE and DF, exactly equal, fixed in the ends of two tubes six or seven feet, or, in some cases, 10 or 12 feet long, and having their focus at the other ends. At the bottom of these tubes B, are two holes, three or four lines in diameter, covered with a piece of white paper; and this instrument is used exactly like the former.

If the two objects to be observed by this instrument be not equally luminous, the light that issues from them must be reduced to an equality, by diminishing the aperture of one of the object-glasses; and then the remaining aperture of the two glaas will give the proportion of their lights. But for this purpose, the central parts of the glaas must be covered in the same proportion with the parts near the circumference, leaving the aperture such as is represented (fig. 7.), because the middle part of the glass is thicker and less transparent than the reft.

If all the objects to be observed lie nearly in the same direction, our author observes, that these two long tubes may be reduced into one, the two object-glasses being placed close together, and one eye-glass sufficient for them both. The instrument will then be the same with that of which he published an account in 1748, and which he called a heliometer, or of the intensity of light.

Our author observes, that it is not the absolute quantity, but only the intensity of the light, that is measured by these two instruments, or the number of rays, in proportion to the surface of the luminous body; and it is of great importance that these two things be
OPTICS.

Measure of Light.

The intensity of light may be very great, when the quantity, and its power of illumination, other bodies, may be very small, on account of the smallness of its surface; or the contrary may be the case, when the surface is large.

Having explained these methods which M. Bouguer took to measure the different proportions of light, we shall subjoin in this place a few miscellaneous examples of his application of them.

It is observable, that when a person stands in a place where there is a strong light, he cannot distinguish objects that are placed in the shade; nor can he see any thing upon going immediately into a place where there is very little light. It is plain, therefore, that the action of a strong light upon the eye, and also the impression which it leaves upon it, makes it insensible to the effect of a weaker light. M. Bouguer had the curiosity to endeavour to ascertain the proportion between the intensities of the two lights in this case; and by throwing the light of two equal candles upon a board, he found that the shadow made by intercepting the light of one of them, could not be perceived by his eye, upon the place enlightened by the other, at little more than eight times the distance; from whence he concluded, that when one light is eight times eight, or 64 times less than another, its presence or absence will not be perceived. He allows, however, that the effect may be different on different eyes; and supposes that the boundaries in this case, with respect to different persons, may lie between 60 and 80.

Applying the two tubes of his instrument, mentioned above, to measure the intensity of the light reflected from different parts of the sky; he found, that when the sun was 25 degrees high, the light was four times stronger at the distance of eight or nine degrees from his body, than it was at 32 or 32 degrees. But what struck him the most was to find, that when the sun is 15 or 20 degrees high, the light decreases on the same parallel to the horizon to 110 or 120 degrees, and then increases again to the place exactly opposite to the sun.

The light of the sun, our author observes, is too strong, and that of the stars too weak, to determine the variation of their light at different altitudes; but as, in both cases, it must be in the same proportion with the diminution of the light of the moon in the same circumstances, he made his observations on that luminary, and found, that its light at 10° 16' is to its light at 66° 11', as 1681 to 2500; that is, the one is nearly two thirds of the other. He chose those particular altitudes, because they are thofe of the sun at the two solstices at Crofle, where he then resided.

When one limb of the moon touched the horizon of the sea, its light was 2000 times less than at the altitude of 66° 11'. But this proportion he acknowledges must be subject to many variations, the atmosphere near the earth varying so much in its density. From this observation he concludes, that at a medium light it is diminished in the proportion of about 2500 to 1681, in travelling about 460 toises of dense air.

Lastly, our accurate philosopher applied his instrument to the different parts of the sun's disk, and found parts of the that the centre is considerably more luminous than the disks of the sun and planets.

As near as he could make the observation, it was more luminous than a part of the disk of the sun of the semidiameter from it, in the proportion of 35 to 28; which, as he observes, is more than in the proportion of the fides of the angles of obliquity.

On the other hand, he observes, that both the primary and secondary planets are more luminous at their edges than near their centres.

The comparison of the light of the fun and moon is a subject that has frequently exercised the thoughts of philosophers; but we find nothing but random conjectures, before our author applied his accurate measurements in this cafe. In general, the light of the moon is imagined to bear a much greater proportion to that of the sun than it really does; and not only are the imaginations of the vulgar, but those of philosophers also, imposed upon with respect to it. It was a great surprise to M. de la Hille to find that he could not, by the help of any burning mirror, collect the beams of the moon in a sufficient quantity to produce the least sensible heat. Other philosophers have since made like attempts with mirrors of greater power, though without any greater success; but this will not surprise us, when we see the result of M. Bouguer's observations on this subject.

In order to solve this curious problem concerning the comparison of the light of the sun and moon, he compared each of them to that of a candle in a dark room, one in the day-time, and the other in the night following, when the moon was at her mean distance from the earth; and, after many trials, he concluded that the light of the sun is about 300,000 times greater than that of the moon; which is such a disproportion, that, as he observes, it can be no wonder that philosophers have had so little success in their attempts to collect the light of the moon with burning glasses. For the largest of them will not encrease the light 1000 times; which will still leave the light of the moon, in the focus of the mirror, 300 times less than the intensity of the common light of the sun.

To this account of the proportion of light which we actually receive from the moon, it cannot be displeasing to the reader, if we compare it with the quantity which would have been transmitted to us from that opaque body, if it reflected all the light it receives. Dr Smith thought that he had proved, from two different considerations, that the light of the full moon would be to our day-light as 1 to about 90,000, if no rays were lost at the moon.

In the first place, he supposes that the moon, en-Dr Smith's lightened by the sun, is as luminous as the clouds are at calculation. He therefore supposed the light of the sun to be equal to that of a whole hemisphere of clouds, or as many moons as would cover the surface of the heavens. But on this Dr Priestley observes, that it is true, the light of the sun shining perpendicularly upon any surface would be equal to the light reflected from the whole hemisphere, if every part reflected all the light that fell upon it; but the light that would in fact be received from the whole hemisphere (part of it being received obliquely) would be only one-half as much as would be received from the whole hemisphere, if every part of it shone directly upon the surface to be illuminated.

In his Remarks, par. 97, Dr Smith demonstrates his method of calculation in the following manner.
“Let the little circle $fdg$ represent the moon’s body half enlightened by the sun, and the great circle $ab$, a spherical shell concentric to the moon, and touching the earth; $ab$, any diameter of that shell perpendicular to a great circle of the moon’s body, represented by its diameter $cd$; $e$, the place of the shell receiving full moon-light from the bright hemisphere $fdg$. Now, because the surface of the moon is rough like that of the earth, we may allow that the sun’s rays, incident upon any small part of it, with any obliquity, are reflected from it every way alike, as if they were emitted. And therefore if the segment $df$ alone, the points $a, s$, would be equally illuminated by it; and likewise if the remaining bright segment $dg$ alone, the points $be$ would be equally illuminated by it. Consequently, if the light at the point $a$ was increased by the light at $b$, it would become equal to the full moon-light at $e$. And conceiving the same transfer to be made from every point of the hemispherical surface $bbk$ to their opposite points in the hemisphere $kaeb$, the former hemisphere would be left quite dark, and the latter would be uniformly illuminated with full moon-light; arising from a quantity of the sun’s light, which, immediately before its incidence on the moon, would uniformly illuminate a circular plane equal to a great circle of her body, called her clyk. Therefore the quantities of light being the same upon both surfaces, the density of the sun’s incident light is to the density of full moon-light, as that hemispherical surface $bbk$ is to the said disk; that is, as any other hemispherical surface whose centre is at the eye, to that part of it which the moon’s disk appears to occupy nearly, because it subtends but a small angle at the eye: that is, as radius of the hemisphere to the verified fine of the moon’s apparent semidiameter, or as 10,000,000 to 1106—OR AS 90,400 TO 1: TAKING THE MOON’S MEAN

horizontal diameter to be 16° 7’.

“Strictly speaking, this rule compares moon-light at the earth with day-light at the moon; the medium of which, at her quadratures, is the same as our day-light; but is less at her full in the duplicate ratio of 365 to 366, or therewithal, that is of the sun’s distances from the earth and full moon; and therefore full-moon light would be to our day-light at least 90,000, if not rays were lost at the moon.

“Secondly, I say that full-moon light is to any other moon light as the whole disk of the moon to the part that appears enlightened, considered upon a plane surface. For now let the earth be at $b$, and let $dl$ be perpendicular to $fg$, and $gm$ to $cd$; then it is plain, that $gl$ is equal to $dm$, and that $g$ is equal to a perpendicular section of the sun’s rays incident upon the arch $dg$, which at $b$ appears equal to $dm$; the eye being unable to distinguish the unequal distances of its parts. In like manner, conceiving the moon’s surface to consist of innumerable physical circles parallel to $cdg$, as represented at $A$, the same reason holds for every one of these circles as for $cdg$. It follows then, that the bright part of the surface visible at $b$, when reduced to a flat as represented at $B$, by the crescent $pdgmp$, will be equal and similar to a perpendicular section of all the rays incident on that part, represented at $C$ by the crescent $pglp$. Now of aberration, the whole disk being in proportion to this crescent, as the quantities of light incident upon them; and the light falling upon every rough particle, being equally rarified in diverging to the eye at $b$, considered as equidistant from them all; it follows, that full moon-light is to this moon-light as the whole disk $pdgmp$ to the crescent $pglp$.

“Therefore, by compounding this ratio with that in the former remark, day-light is to moon-light as the surface of an hemisphere whose centre is at the eye, to the part of that surface which appears to be possessed by the enlightened part of the moon.

Mr Michell made his computation in a much more simple and easy manner, and in which there is much less danger of falling into any mistake. Considering the distance of the moon from the sun, and that the density of the light must decrease in the proportion of the square of that distance, he calculated the density of the sun’s light, as that distance, in proportion to its density at the surface of the sun; and in this manner he found, that if the moon reflected all the light it receives from the sun, it would only be the 45,000th part of the light we receive from the greater luminary. Admitting, therefore, that moon-light is only a 500,000th part of the light of the sun, Mr Michell concludes, that it reflects no more than between the 6th and 7th part of what falls upon it.

\[\text{OPTICS.}\]

Part II. Of Aberration.

\[\text{Sect. IV. Of Aberration.}\]

The great practical use of the science of optics is Theory of to aid human sight; but it has been repeatedly ob- served during the progress of this article, that in constraining optical instruments for this proper, great difficulties, arise from the aberration of light. It has been shown, page 288, &c. how to determine the concourse of any refracted ray $PF$, with the ray $RVCF$ (figs. 5, 6, &c. Plate CCLV.) which passes through the centre $C$, and therefore falls perpendicularly on the spherical surface at the vertex $V$, and suffers no refraction. This is the conjugate focus for the two rays $RP$, $RV$, and for another ray flowing from $R$ and falling on the surface at an equal distance on the opposite side to $P$. In short, it is the conjugate focus for all the rays flowing from $R$ and falling on the spherical surface in the circumference of a circle described by the revolution of the point $P$ round the axis $RVC$; that is, of all the rays which occupy the conical surface described by the revolution of $RP$, and the refracted rays occupy the conical surface produced by the revolution of $PF$.

But no other rays flowing from $R$ are collected at $F$; for it appeared in the demonstration of that proposition, that rays incident at a greater distance from the axis $RC$ were collected at a point between $C$ and $P$; and then the rays which are incident on the whole arch $PC$, or the spherical surface generated by its revolution round $RC$, although they all cross the axis $RC$, are diffused over a certain portion of it, by what has been called the aberration of figure. It is called also (but improperly) the aberration from the geometrical focus, by which is meant the focus of an infinitely slender pencil of rays, of which the middle ray (or axis of the pencil) occupies the lens $RC$, and suffers
Of Aberration. — But there is no such focus. But if we make \( \overline{mR} = \overline{mC} ; \overline{mR} = \overline{mC} ; \overline{VF} \), the point \( F \) is called the geometrical focus, and is the remotest limit from \( C \) of all the foculi (equally geometrical) of rays flowing from \( R \). The other limit is easily determined by considering the problem for the extreme point of the given arch.

It is evident from the construction, that while the point of incidence \( P \) is near to \( V \), the line \( CR \) increases but very little, and therefore \( CF \) diminishes little, and the refracted rays are but little diffused from \( F \); and therefore they are much denser in its vicinity than any other point of the axis. It will soon be evident that they are incomparably denser. It is on this account that the point \( F \) has been called the conjugate focus \( = \frac{\overline{F}}{\overline{P}} \), to \( R \), and the geometrical focus and the diffuseness has been called aberration. A geometrical point \( R \) is thus represented by a very small circle (or physical point as it is improperly called) at \( F \), and \( F \) has drawn the chief attention. And as, in the performance of optical instruments, it is necessary that this extended representation of a mathematical point \( R \) be very small, that may not feebly interfere with the representations of the points adjacent to \( R \), and thus cause indistinct vision, a limit is thus set to the extent of the refracting surface which must be employed to produce this representation. But this evidently diminishes the quantity of light, and renders the vision obscure, though distinct. Artists have therefore endeavored to execute refracting surfaces of forms not spherical, which collect accurately to one point the light issuing from another, and the mathematicians have furnished them with forms having this property; but their attempts have been fruitless. Spherical surfaces are the only ones which can be executed with accuracy. All are done by grinding the refracting substance into a mould of proper materials. When this is spherical, the two work themselves, with moderate attention, into an exact sphere; because if any part is more prominent than another, it is ground away, and the whole gets of necessity one curvature. And it is astonishing to what degree of accuracy this is done. An error of the millioneth part of an inch would totally destroy the figure of a mirror of an inch focal distance, so as to make it useless for the lowest instrument. Therefore all attempts to make other figures are given up. Indeed other forms make them worse than spherical, even when accurately executed. They would not collect to accurate focus the rays of oblique pencils.

It is evident from their observations, that the theory of aberrations is absolutely necessary for the successful composition of optical instruments; and it must be acceptable to the reader to have a short account of it in this place. Enough shall be said here to show the general nature and effects of it in optical instruments, and in some of the more curious phenomena of nature. Under the article Telescope the subject will be resum'd, in such a manner as to enable the reader who possesses a very moderate share of mathematical knowledge, not only to understand how aberrations are increased and diminished, but also how, by a proper employment of contrary aberrations, their hurtful effects may be almost entirely removed in all important cases. And the manner in which the subjea shall be treated in the present general sketch, will be of Aberration.
OPTICS.

In this manner, \( BF = BC \times \text{fin.} \), \( BCE = CE \times \text{fin.} \), \( CB = CE \times \text{fin.} \), \( BDC \); and also \( BF = BC \times \text{fin.} \), \( BCE = CE \times \text{fin.} \), \( CB = CE \times \text{fin.} \). This manner of considering the phenomenon which occur in geometrical constructions is of immense use in all parts of mixed mathematics; and no more remarkably than in optics, the most beautiful example of them. Of this an important instance shall now be given.

Corol. 1. The distance \( fG \) of this lateral focus from the axis \( CV \) (that is, from the line drawn through the centre parallel to the incident light) is proportional to the cube of the semi-aperture \( PH \) of the spherical surface.

For \( fG = BE \).

Now \( BE = CB \times \text{fin.} \), \( BCE = CB \times \text{fin.} \), \( CPA \); and \( CB = RC \times \text{cof. RC} \), \( RC = CP \times \text{fin.} \), \( CPR \); therefore \( fG = PC \times \text{fin.} \), \( CP \times \text{fin.} \), \( PC \times \text{fin.} \), \( CP \times \text{fin.} \), \( \text{refr.} \times \text{fin.} \), \( \text{incid.} \).

But \( \text{sin.} \), \( \text{refr.} = \frac{m}{n} \), \( \text{sin.} \), \( \text{incid.} \).

Therefore, finally, \( BE \), or \( fG = PC \times \frac{m}{n} \times \text{fin.} \), \( \text{incid.} \); but \( PC \), \( \text{fin.} \), \( \text{incid.} \), evidently \( PH \) the semi-aperture; therefore the proposition is manifest.

Corol. 2. Now let this slender pencil of rays be incident at the vertex \( V \). The focus will now be a point \( F \) in the axis, determined by making \( CV : CF = m = n : m \). Let the incident pencil gradually recede from the axis \( CB \), till, however, keeping parallel to it. The focus \( F \) will always be found in a curve line \( DC \), so constituted that the ordinate \( G \) will be as the curve of the line \( PH \), perpendicular to the axis intercepted between the axis and that point of the surface which is cut by a tangent to the curve in \( F \).

All the refracted rays will be tangents to this curve, and the adjacent rays will cross each other in these lateral foci \( F \); and will therefore be incomparably more dense along the curve than any where within its area. This is finely illustrated by receiving on white paper the light of the sun refracted through a globe or cylinder of glass filled with water. If the paper is held parallel to the axis of the cylinder, and close to it, the illuminated part will be bounded by two very bright parallel lines, where it is cut by the curve; and these lines will gradually approach each other as the paper is withdrawn from the vessel, till they coalesce into one very bright line at \( F \), or near it. If the paper be held with its end touching the vessel, and its plane nearly perpendicular to the axis, the whole progress of the curve will be distinctly seen.

As such globes were used for burning-glafls, the point of greatest concentration (which is very near but not exactly in \( F \)) was called the focus. When these curves were observed by Sir Tchirnhaus, he called them caustics; and those formed by refraction he called diacaustics, to distinguish them from the ordinary caustics formed by reflection.

It is somewhat surprising, that these curves have been so little studied since the time of Tchirnhaus. The doctrine of aberrations has indeed been considered in a manner independent of their properties. But whoever considers the progress of rays in the eye piece of optical instruments, will find that the knowledge of the properties of diacaustic curves determines directly, and almost accurately, the focus and images that are formed there. For, let the object-glafls of a telescope or microscope be of any dimensions, the pencils incli-
Part II.

OPTICS.

Of aberration of the foci of all the intermediate rays, and CO the diameter of the circle of smallest diffusion.

It is plain, that from the centre O there can be drawn two rays OV, Ov, touching the caustic in V, v. Therefore the point O will receive the ray EO, which passes through the vertex of the refracting surface, and all the rays which are incident on the circumference of a circle described on the refracting surface by the extremity of the ray OV, or Ov. The density of the light at O will therefore be indefinitely great.

From the point C there can be drawn two rays; one of them CT touching the caustic in C, and the other C, touching it at d on the opposite side. The rays which touch the caustic in the immediate vicinity of CD, both in the arch CV and the arch CI will cut OC in points indefinitely near to each other; because their distance from each other in the line OC will be to their uniform distance on the refracting surface as the distance between their points of contact with the caustic to the distance of those points from the refracting surface. Here therefore at C the density of the light will also be indefinitely great.

From any point H, lying between O and C, may be drawn three rays. One of them, LHT, P, touching the arch CD of the caustic in T, cutting the refracting surface in P, and the axis in L: another, HP, touching the arch CI of the caustic in r. The third is Hr, touching the arch ed of the opposite branch of the caustic in e.

It will greatly assist our conceptions of this subject, if we consider a ray of light from the refracting surface as a thread attached at I of this figure, or at F of fig. 1, and gradually unrolled from the caustic DVCI on one side, and then lapped on the opposite branch I e cd; and attend to the point of its interference with the diameter eOC of the circle of smallest diffusion.

Therefore, 1. let the ray be first supposed to pass through the refracting surface at F, the right hand extremity of the aperture. The thread is then folded up on the whole right hand branch ICVD of the caustic; and if the straight part of it ED be produced, it will cut the diameter of the circle of smallest diffusion in the opposite extremity e. Or suppose a ruler in place of the thread, applied to the caustic at D and to the refracting surface at F, the part of it DQ, which is detached from the caustic, cuts CO; in the point e. 2. Now suppose the ruler to revolve gradually, its extremity moving across the arch FA of the refracting surface while the edge is applied to the caustic; the point of contact with the caustic will shift gradually down the branch DV of the caustic, while its edge passes across the line eC; and when the point of contact arrives at V, the extremity will be at Y on the refracting surface, and the interference of the edge will be at O. 3. Continuing the motion, the point of contact shifts from V to Z, the extremity from Y to Q, and the interference from O to Q, to OC; that OC'= \( \frac{1}{2} \) as will presently appear. 4. After this, the point of contact will shift from Z to C, the extremity from Q' to X, halfway from F to A, as will soon be shown, and the interference from Q to C. 5. The point of contact will now shift from C down to I, the extremity will pass from X to A, and the interference will go back from C to O. 6. The ruler must now be applied to the other branch of the caustic ICOD, and the point of contact will advance from I to C, the extremity will pass from A to X, halfway to F from A, and the interference from O to C. 7. The point of contact will advance from C to Z, the extremity passes from X to Q', and the interference from C to Q, Oq' being \( \frac{1}{2} \).

While the contact of the ruler and caustic shifts from Z to C, the extremity shifts from Q' to Q, and the interference from C to Q, Oq being \( \frac{1}{2} \).

We may form a notion of the density of the light: Density of any point H, by supposing the incident light of unit intensity from density at the refracting surface, and attending to the composition of the rays in the circle of smallest diffusion. Their vicinity may be estimated both in the direction of the radii OH, and in the direction of the circumference described by its extremity H, during its revolution round the axis; and the density must be conceived as proportional to the number of originally equidistant rays, which are collected into a spot of given area. These have been collected from a corresponding spot or area of the refracting surface; and as the number of rays is the same in both, the density at H will be to the density of the refracting surface, as the area occupied by the refracting surface to the corresponding area at H. The vicinity of the rays in the direction of the radius depends on the proportion between PT and TH. For the ray adjacent to PTH may be supposed to cross it at the point of contact T, and therefore the uniform diffuseness between them at the surface of that medium is to the distance between the same rays at H as the distance of T from the refracting surface to its distance from H. Therefore the number of rays which occupy a tenth of an inch, for example, of the radius AP, is to the number which would occupy a tenth of an inch at H as TH to TP; and the radial density at P is to the radial density at H as TH to TP. In the next place, the circumferential density at P is to that at H as the radius AP to the radius OH. For supposing the figure to turn round its axis AL, the point P of the refracting surface will describe a circumference whose radius is AP, and H will describe a circumference whose radius is OH; and the whole rays which pass through the first circumference pass also thro' the last; and therefore their circumferential densities will be in the inverse proportion of the spaces into which they are collected. Now the radius AP is to the radius OH as AL to OL; and circumferences have the same proportion with their radii. Therefore the circumferential density at P is to that in H as AL to OL inversely; and it was found that the radial density was as AN to ON inversely, being as TH to TP, which are very nearly in this ratio. Therefore the absolute density (or number of rays collected in a given space) at P will be to that at H, in the ratio compounded of the three ratios; that is, in the ratio of ON x OL to AN x AL. But as NL bears but a very small ratio to AN or AL, x AN x AL.
OPTICS.

Part II.

The multiplying-gla

The multiplying-gla is made by grinding down the round side of a plano-convex gla AB, into several flat surfaces, as bb, bd, dk. An object C will not appear magnified when seen through this gla by the eye at H; but it will appear multiplied into as may different objects as the gla contains plane surfaces. For, since rays will flow from the object C to all parts of the gla, and each plane surface will refract these rays to the eye, the same object will appear to the eye in the direction of the rays which enter it through each surface. Thus, a ray gH, falling perpendicularly on the middle surface, will go through the gla to the eye without suffering any refraction; and will therefore show the object in its true place at C; whilst a ray a H flowing from the same object, and falling obliquely on the plane surface bb, will be refracted in the direction aH, by passing through the gla; and, upon leaving it, will go on to the eye in the direction eH; which will cause

that a ray Ap, parallel to the axis CV, and incident on the point P, as far from its vertex V as P in the other lens is from its vertex, is deflected from r, the distance dV being equal to rV, while the central rays are deflected from P, as far from V as R is from V.

It is evident, that if these lences be joined as in fig. 4. a ray An, parallel to the common axis CV, will be collected at the distance VF equal to VF in the fig. 4, and that rays passing through both lences in the neighborhood of the axis will be collected at the same point F.

This compound lense is said to be without spherical aberration; and it is true that the central and the extreme rays are collected in the same point F; but the rays which fall on the lense between the centre and margin are a little diffused from F, and it is not possible to collect them all to one point. For in the rules for computing the aberration, quantities are neglected which do not preserve (in different apertures) the same ratio to the quantities retained. The diffusion is least when the aberration is corrected, not for the very extremity, but for a certain intermediate point (varying with the aperture, and having no known ratio to it); and when this is done the compound lense is in its state of greatest perfection, and the remaining aberration is quite insensible.

This subjeft will be refumed under the article Telescope, and proceeded as far as the construction of optical instruments requires.

Sacr. IV. Of Optical Instruments.

Or the mechanism of optical instruments particular accounts are given in this work under their respective denominations. These it would be improper to repeat; but as it belongs to the science of optics to explain, by the laws of refraction and reflection, the several phenomena which thofe instruments exhibit, we must in this place enumerate the instruments themselves, omitting entirely, or stating very briefly, fuch facts as are stated at large in other places. In this enumeration we fhall begin with the multiplying-gla,

not because it is first in importance, but that it may not intervene between instruments more ufeful, and which have a mutual relation to one another.

§ 1. The Multiplying-gla.

Plate CCLXXIV.

236. Phenomena of the multiplying-gla.

The multiplying-gla is made by grinding down the round side of a plano-convex gla AB, into several flat surfaces, as bb, bd, dk. An object C will not appear magnified when seen through this gla by the eye at H; but it will appear multiplied into as may different objects as the gla contains plane surfaces. For, since rays will flow from the object C to all parts of the gla, and each plane surface will refract these rays to the eye, the same object will appear to the eye in the direction of the rays which enter it through each surface. Thus, a ray gH, falling perpendicularly on the middle surface, will go through the gla to the eye without suffering any refraction; and will therefore show the object in its true place at C; whilst a ray a H flowing from the same object, and falling obliquely on the plane surface bb, will be refracted in the direction aH, by passing through the gla; and, upon leaving it, will go on to the eye in the direction eH; which will cause

that a ray Ap, parallel to the axis CV, and incident on the point P, as far from its vertex V as P in the other lens is from its vertex, is deflected from r, the distance dV being equal to rV, while the central rays are deflected from P, as far from V as R is from V.

It is evident, that if these lences be joined as in fig. 4. a ray An, parallel to the common axis CV, will be collected at the distance VF equal to VF in the fig. 4, and that rays passing through both lences in the neighborhood of the axis will be collected at the same point F.

This compound lense is said to be without spherical aberration; and it is true that the central and the extreme rays are collected in the same point F; but the rays which fall on the lense between the centre and margin are a little diffused from F, and it is not possible to collect them all to one point. For in the rules for computing the aberration, quantities are neglected which do not preserve (in different apertures) the same ratio to the quantities retained. The diffusion is least when the aberration is corrected, not for the very extremity, but for a certain intermediate point (varying with the aperture, and having no known ratio to it); and when this is done the compound lense is in its state of greatest perfection, and the remaining aberration is quite insensible.

This subjeft will be refumed under the article Telescope, and proceeded as far as the construction of optical instruments requires.

Sacr. IV. Of Optical Instruments.

Or the mechanism of optical instruments particular accounts are given in this work under their respective denominations. These it would be improper to repeat; but as it belongs to the science of optics to explain, by the laws of refraction and reflection, the several phenomena which thofe instruments exhibit, we must in this place enumerate the instruments themselves, omitting entirely, or stating very briefly, fuch facts as are stated at large in other places. In this enumeration we fhall begin with the multiplying-gla,

not because it is first in importance, but that it may not intervene between instruments more ufeful, and which have a mutual relation to one another.

§ 1. The Multiplying-gla.

The multiplying-gla is made by grinding down the round side of a plano-convex gla AB, into several flat surfaces, as bb, bd, dk. An object C will not appear magnified when seen through this gla by the eye at H; but it will appear multiplied into as may different objects as the gla contains plane surfaces. For, since rays will flow from the object C to all parts of the gla, and each plane surface will refract these rays to the eye, the same object will appear to the eye in the direction of the rays which enter it through each surface. Thus, a ray gH, falling perpendicularly on the middle surface, will go through the gla to the eye without suffering any refraction; and will therefore show the object in its true place at C; whilst a ray a H flowing from the same object, and falling obliquely on the plane surface bb, will be refracted in the direction aH, by passing through the gla; and, upon leaving it, will go on to the eye in the direction eH; which will cause

that a ray Ap, parallel to the axis CV, and incident on the point P, as far from its vertex V as P in the other lens is from its vertex, is deflected from r, the distance dV being equal to rV, while the central rays are deflected from P, as far from V as R is from V.

It is evident, that if these lences be joined as in fig. 4. a ray An, parallel to the common axis CV, will be collected at the distance VF equal to VF in the fig. 4, and that rays passing through both lences in the neighborhood of the axis will be collected at the same point F.

This compound lense is said to be without spherical aberration; and it is true that the central and the extreme rays are collected in the same point F; but the rays which fall on the lense between the centre and margin are a little diffused from F, and it is not possible to collect them all to one point. For in the rules for computing the aberration, quantities are neglected which do not preserve (in different apertures) the same ratio to the quantities retained. The diffusion is least when the aberration is corrected, not for the very extremity, but for a certain intermediate point (varying with the aperture, and having no known ratio to it); and when this is done the compound lense is in its state of greatest perfection, and the remaining aberration is quite insensible.

This subjeft will be refumed under the article Telescope, and proceeded as far as the construction of optical instruments requires.

Part II.

Plane Mirrors.

cause the same object C to appear also at E, in the direction of the ray H, produced in the right line HDE. And the ray cd, flowing from the object C, and falling obliquely on the plane surface dd, will be refracted, (by passing through the glass, and leaving it at f) to the eye at H; which will cause the same object to appear at D, in the direction HDE. If the glass be turned round the line gH, as an axis, the object C will keep its place, because the surface bid is not removed; but all the other objects will seem to go round C, because the oblique planes, on which the rays ab & cd fall, will go round by the turning of the glass.

§ 2. Mirrors.

It has been elsewhere observed, that of mirrors there are three principally used in optical experiments (See Catoptrics, Sec. I.); the plane mirror, the spherical convex mirror, and the spherical concave mirror. Of these the plane mirror first claims our attention, as it is more common, and undoubtedly more ancient, than the other two. It has been said (ubi supra), that the image reflected by this mirror appears as far behind the surface as the object is before it; that the image will appear of the same size, and, in the same position with the object; that every such mirror will reflect an image of twice its own length and breadth; and that in certain circumstances it will reflect several images of the same object. For these phenomena it is our business in this place to account by the laws of reflection.

Let AB (fig. 2) be an object placed before the reflecting surface gh of the plane mirror CD; and let the eye be at O. Let AB be a ray of light flowing from the top A of the object, and falling upon the mirror at a, and km be a perpendicular to the surface of the mirror at a; the ray AB will be reflected from the mirror to the eye at o, making an angle mbo equal to the angle Akm; then will the top of the image E appear to the eye in the direction of the reflected ray eO produced to E, where the right line APE, from the top of the object, cuts the right line oE, at E. Let Bt be a ray of light proceeding from the foot of the object at B to the mirror at t; and n is a perpendicular to the mirror from the point t, where the ray Bt falls upon it; this ray will be reflected in the line tO, making an angle nio equal to the angle Bin, with that perpendicular, and entering the eye at o; then will the foot F of the image appear in the direction of the reflected ray eO produced to F, where the right line BF cuts the reflected ray produced to F. All the other rays that flow from the intermediate points of the object AB, and fall upon the mirror between b and i, will be reflected to the eye at o; and all the intermediate points of the image EF will appear to the eye in the direction of their reflected rays produced. But all the rays that flow from the object, and fall upon the mirror above b, will be reflected back above the eye at o; and all the rays that flow from the object, and fall upon the mirror below i, will be reflected back below the eye at o; so that none of the rays that fall above b, or below i, can be reflected to the eye at o; and the distance between b and i is equal to half the length of the object AB.

Hence it appears, that if a man sees his whole image in a plane looking-glass, the part of the glass that reflects his image must be just half as long and half as broad as himself, let him stand at any distance from it whatever; and that his image must appear just as far behind the glass as he is before it. Thus, the man AB (fig. 3) viewing himself in the plane mirror CD, in which a is just half as long as himself, sees his whole image as at EF, behind the glass, exactly equal to his own size. For a ray AC proceeding from his eye whole at A, and falling perpendicularly upon the surface of the glass at C, is reflected back to his eye, in the same line CA; and the eye of his image will appear at E, in the same line produced to E, beyond the glass, and a ray BD, flowing from his foot, and falling obliquely on the glass at D, will be reflected as obliquely on the other side of the perpendicular ab D, in the direction DA; and the foot of his image will appear at F, in the direction of the reflected ray AD, produced to F, where it is cut by the right line BGF, drawn parallel to the right line ACE. Just as if the glass were taken away, and a real man stood at F, equal in size to the man standing at B: for to his eye at A, the eye of the other man at E would be seen in the direction of the line ACE; and the foot of the man at F would be seen by the eye A, in the direction of the line ADF.

If the glass be brought nearer the man AB, as suppose to c, he will see his image as at CDG: for the reflected ray CA (being perpendicular to the glass) will flow the eye of the image as at C; and the incident ray Bg, being reflected in the line ab, will flow the foot of his image as at G; the angle of reflection aB being always equal to the angle of incidence Bca; and so of all the intermediate rays from A to B. Hence, if the man AB advances towards the glass CD, his image will approach towards it; and if he recedes from the glass, his image will all recede from it.

If the object be placed before a common looking-glass, and viewed obliquely, three, four, or more images of it will appear behind the glass.

To explain this, let ABCD (fig. 11) represent the plane glass; and let EF be the axis of a pencil of rays of rays flowing from E, a point in an object situated there. The rays of this pencil will in part be reflected at F, impinging into the line FG. What remains will (after reflection at F, which we do not consider here) pass on to H; from whence (on account of the quicksilver which is spread over the internal surface of the glass of this kind to prevent any of the rays from being transmitted there) they will be strongly reflected to X, where part of them will emerge and enter an eye at L. By this means one representation of the solid point will be formed in the line EL produced, impinging in M; and a second in the line FM produced, impinging in J; and, thirdly, another pencil, whose axis is ER, after reflection at the several points R, S, H, T, V, successively, will exhibit a third representation of the same point at Q; and so on in infinite. The image being true of each point in the object, the whole will be represented in the line manner; but the representations will be faint, in proportion to the number of reflections the rays suffer, and the length of their pursuits within the
OPTICS.

2. Of Concave and Convex Mirrors.  The effects of these in magnifying and diminishing objects have been already in general explained; but for the better understanding the nature of reflecting telescopes, it will still be proper to subjoin the following particular description of the effects of concave ones.

When parallel rays (fig. 4.), as \( dfc, Cmb, etc. \), fall upon a concave mirror \( AB \) (which is not transparent, but has only the surface \( A\hat{B}B \) of a clear polish), they will be reflected back from that mirror, and meet in a point \( m \), at half the distance of the surface of the mirror from \( C \) the centre of its concavity; for they will be reflected at as great an angle from a perpendicular to the surface of the mirror, as they fell upon it with regard to that perpendicular, but on the other side thereof. Thus, let \( C \) be the centre of concavity of the mirror \( A\hat{B} \); and let the parallel rays \( dfc, Cmb, \) and \( ecl \), fall upon it at the points \( a, b, \) and \( c \). Draw the lines \( C\hat{a}, C\hat{b}, \) and \( C\hat{c} \), from the centre \( C \) to these points; and all these lines will be perpendicular to the surface of the mirror, because they proceed thereto like so many radii or spokes from its centre. Make the angle \( C\hat{a}b \) equal to the angle \( d\hat{A}C \), and draw the line \( a\hat{m}b \), which will be the direction of the ray \( dfc \), after it is reflected from the point \( a \) of the mirror; so that the angle of incidence \( d\hat{a}C \) is equal to the angle of reflection \( C\hat{a}b \); the rays making equal angles with the perpendicular \( C\hat{a} \) on its opposite sides.

Draw also the perpendicular \( C\hat{e}b \) to the point \( c \), where the ray \( ecl \) touches the mirror; and having made the angle \( C\hat{c}e \) equal to the angle \( C\hat{c}e, \) draw the line \( cm\), which will be the course of the ray \( ecl \), after it is reflected from the mirror.

The ray \( Cmb \) falling through the centre of concavity of the mirror, and falling upon it at \( b \), is perpendicular to it; and is therefore reflected back from it in the same line \( b\hat{m}c \).

All these reflected rays meet in the point \( m \); and in that point the image of the body which emits the parallel rays \( d\hat{a}, C\hat{b}, \) and \( ecl \), will be formed; which point is distant from the mirror equal to half the radius \( b\hat{m}C \) of its concavity.

The rays which proceed from any celestial object may be esteemed parallel at the earth; and therefore the image of that object will be formed at \( m \), when the reflecting surface of the concave mirror is turned directly towards the object. Hence, the focus of all parallel rays is not in the centre of the mirror's concavity, but half way between the mirror and that centre.

The rays which proceed from any remote terrestrial object are nearly parallel at the mirror; not strictly so, but come diverging to it, in separate pencils, or as it were bundles of rays, from each point of the side of the object next the mirror; and therefore they will not be converged to a point at the distance of half the radius of the mirror's concavity from its reflecting surface, but into separate points at a little greater distance from the mirror. And the nearer the object is to the mirror, the farther these points will be from it; and an inverted image of the object will be formed in them, which will seem to hang pendant in the air; and will be seen by an eye placed beyond it (with regard to the mirror) in all respects like the object, and as distant as the object itself.

Let \( A\hat{B} \) (fig. 5.) be the reflecting surface of a mirror, whose centre of concavity is at \( C \); and let the upright object \( DE \) be placed beyond the centre \( C \), and form a conical pencil of diverging rays; from its upper extremity \( D \), to every point of the concave surface of the mirror \( A\hat{B} \). But to avoid confusion, we only draw three rays of that pencil, as \( DA, Dc, DB \).
