ENCYCLOPÆDIA;
OR, A
DICTIONARY
OF
ARTS, SCIENCES,
AND
MISCELLANEOUS LITERATURE;
Constructed on a Plan,
BY WHICH
THE DIFFERENT SCIENCES AND ARTS
Are digested into the Form of Distinct
TREATISES OR SYSTEMS,
COMPREHENDING
THE HISTORY, THEORY, and PRACTICE, of each,
According to the Latest Discoveries and Improvements;
AND FULL EXPLANATIONS GIVEN OF THE
VARIOUS DETACHED PARTS OF KNOWLEDGE,
WHETHER RELATING TO
NATURAL and ARTIFICIAL Objects, or to Matters ECCLESIASTICAL,
CIVIL, MILITARY, COMMERCIAL, &c.
Including ELUCIDATIONS of the most important Topics relative to RELIGION, MORALS, MANNERS,
and the OECOMONY OF LIFE:
TOGETHER WITH
A DESCRIPTION of all the Countries, Cities, principal Mountains, Seas, Rivers, &c.
throughout the WORLD;
A General History, Ancient and Modern, of the different Empires, Kingdoms, and States;
AND
An Account of the Lives of the most Eminent Persons in every Nation,
from the earliest ages down to the present times.

Compiled from the writings of the best Authors, in several languages; the most approved Dictionaries, as well of general science as of its particular branches; the Transactions, Journals, and Memoirs, of various Learned Societies, the MS. Lectures of Eminent Professors on different sciences; and a variety of Original Materials, furnished by an Extensive Correspondence.

THE FIRST AMERICAN EDITION, IN EIGHTEEN VOLUMES, GREATLY IMPROVED.

ILLUSTRATED WITH FIVE HUNDRED AND FORTY-TWO COPPERPLATES.

VOL. XIV.

PHILADELPHIA:
PRINTED BY THOMAS DOBSON, AT THE STONE HOUSE, NO. 41, SOUTH SECOND STREET.
M.DCC.XCVIII.
[Copy-Right secured according to law.]
PASSIFLORA, or Passion-flower; a genus of the pentandria order belonging to the gynandria class of plants; and in the natural method ranking under the 34th order, Cucurbitaceae. The calyx is pentaphyllosous: there are five petals; the stamens a crown; the berry is pedicellate. There are near 30 different species; all of them natives of warm foreign countries, only one of which is sufficiently hardy to succeed well in the open ground in England; all the others requiring the shelter of a green-house or floor, but chiefly the latter. The most remarkable are,

1. The cardinum, or blue-rayed crown; palmated passion-flower, hath long, slender, shrubby, purplish-green stalks, branchy, and ascending upon support by their claspers 30 to 40 feet high; with one large palmated leaf at each joint, and at the axillae large spreading flowers, with white-green petals, and a blue radiated stamens; succeeded by a large, oval, yellowish fruit. It flowers from July until October; the flowers are very large, conspicuous, and their composition is exceedingly curious and beautiful. The general structure of the ingress flowers of this plant is, they come out at the axillae on pedunculi about three inches long, which they terminate, each flower having just close under the calyx, a three-lobed involucrum-like appendage; a five-leaved calyx, and a five-petalous corolla, the face, figure, and colour of the calyx, &c. the petals arranging alternately with the calical lobes; the whole, including the involucrum, calyx, and corolla, make just 13 lobes and petals, all expanded flat: and within the corolla is the nektarium, composed of a multitude of thread-like fibres, of a blue and purple colour, disposed in circular rays round the column of the fructification; the outer ray is the longest, flat, and spreading on the pedals; the inner is short, erect, and narrows towards the centre: in the middle is an eel-shaped column or pillar, crowned with the someth germ, having at its base five horizontal spreading filaments, crowned with incumbent yellow anthers, that move about every way; and from the side of the germ arises three slender spreading styles, terminated by headed stigmas; the germs afterwards gradually becomes a large oval fleshy fruit, ripening to a yellowish color. These wonderful flowers are only of one day's duration, generally, opening about 11 or 12 o'clock, and frequently in hot sunny weather burst open with effusion, and continue fully expanded all that day: and the next they gradually close, assuming a decayed-like up, carcass, and never open any more; the treeing put a period to their existence; but they are succeeded by new ones daily on the same plant.—This plant and flowers are held in great veneration in some foreign Catholic countries, where the religious make the leaves, tendrils, and different parts of the flower, to represent the instruments of our blessed Saviour's passion; hence the name passiflora.

2. The incarnata, incarnated, or flesh coloured Italian passion-flower, hath a strong perennial root; slender, herbaceous stalks, rising upon support four or five feet high; leaves composed of three fleshy lobes, each leaf attended by a twining tendril; and at the axillae long slender pedunculi, terminated each by one whitish flower, having a greenish calyx, and a reddish or purple radiated stamens, surrounding the column of the fructification, which succeed to a large, round, fleshy fruit, ripening to a beautiful orange colour. The flowers of this species are also very beautiful though of short duration, opening in the morning, and night puts a period to their beauty; but they are succeeded by a daily supply of new ones. The fruit of this sort is also very ornamental, as ripening to a fine reddish orange colour; but these rarely attain perfection here, unless the plants are placed in the floor; therefore when there is such accommodation, it highly merits that indulgence, where it will exhibit both flowers and green and ripe fruit, all at the same time, in a beautiful manner.

3. The vespertilio, or bat's wing passion-flower, hath slender, striated, branchy stalks; large, bilobate, or two-lobed leaves, the base roundish and glandular, the lobes acute, widely divaricated like a bat's wing, and dotted underneath; and axillary flowers, having white petals and rays. The leaves of these species have a singular appearance, the two lobes being expanded fix or seven inches wide, resembling the wings of a bat upon flight: hence the name vespertilio.

As all the species are natives of warm climates, in this country they are mostly of a tender quality, except the first sort, which succeeds very well in the full ground, in a warm situation; only their young branches are sometimes killed in very severe winters; but plenty of new ones generally rise again in spring following: the other, denominated flower kinds, must always be retained in that repository.

PASSION, is a word of which, as Dr Reid observes, the meaning is not precisely ascertained either in common discourse or in the writings of philosophers. In its original import, it denotes every fasting of the mind occasioned by an extrinsic cause; but it is generally used to signify some antithetical of mind, opposed to that state of tranquillity in which a man is most

\[ \text{A} \]
The Greeks and Romans, is evident from Cicero’s rendering of the word by which the philosophers of Greece expressed it; by perturbatio in Latin. In this sense of the word, passion cannot be itself a definition and independent principle of action; but only an occasional degree of vehemence given to those dispositions, desires, and affections, which are at all times present to the mind of man; and that this is its proper sense, we need no other proof than that passion has always been conceived to bear analogy to a storm at sea or to a tempest in the air.

With respect to the number of passions of which the mind is susceptible, different opinions have been held by different authors. Le Brun, a French writer on painting, justly considering the expression of the passions as a very important as well as difficult branch of his art, has enumerated no fewer than thirty, of which the signs may be expressed by the pencil on canvas. That there are so many different states of mind producing different effects which are visible on the features and the gestures, and that those features and gestures ought to be diligently studied by the artist, are truths which cannot be denied; but it is absurd to consider all these different states of mind as passions, since tranquillity is one of them, which is the reverse of passion.

The common division of the passions into desire and affection, hope and fear, joy and grief, love and hatred, has been mentioned by every author who has treated of them, and needs no explication; but it is a question of some importance in the philosophy of the human mind, whether these different passions be each a degree of an original and innate disposition, distinct from the dispositions, which are respectively the foundations of the other passions, or only different modifications of one or two general dispositions common to the whole race.

The former opinion is held by all who build their system of metaphysics upon a number of distinct internal fancies; and the latter is the opinion of those who, with Locke and Hartley, resolve what is commonly called instinct into an early association of ideas. (See Instinct.) That without deliberation mankind instinctively feel the passion of fear up the apprehension of danger, and the passion of anger or resentment upon the reception of an injury, are truths which cannot be denied: and hence it is inferred, that the seeds of these passions are innate in the mind, and that they are not generated, but only woven to magnitude on the prospect of their respective objects. In support of this argument, it has been observed that children, without any knowledge of their danger, are instinctively afraid of being placed on the brink of a precipice; and that this passion contributes to their safety long before they acquire, in any degree equal to their necessities, the exercise of their rational powers. Deliberate anger, caused by a voluntary injury, is acknowledged to be part founded on reason and reflection; but where anger impels one suddenly to return a blow, even without thinking of doing mischief, the passion is instinctive. In proof of this, it is observed that instinctive anger is frequently roused by bodily pain, occasioned even by a tick or a stone, which infamity becomes an object of resentment, that we are violently incited to crush to atoms. Such conduct is certainly not rational, and therefore it is supposed to be necessarily instinctive.

With respect to other passions, such as the lust of power, of fame, or of knowledge, innumerable instances, says Dr Reid, occur in life, of men who sacrifice to them their ease, their pleasures, and their health. But it is absurd to suppose that men should sacrifice the end to what they desire only as means of promoting that end; and therefore he seems to think that these passions must be innate. To add strength to this reasoning, he observes, that we may perceive some degree of these principles even in brute animals of the more fagacious kind, who are not thought to desire means for the sake of ends which they have in view.

But it is in accounting for the passions which are disinterested that the advocates for innate principles seem most completely to triumph. As it is impossible not to feel the passion of pity upon the prospect of a fellow-creature in distress, they argue, that the basis of that passion must be innate; because pity, being at all times more or less painful to the person by whom it is felt, and frequently of no use to the person who is its object, it cannot in such instances be the result of deliberation, but merely the exertion of an original instinct. The same kind of reasoning is employed to prove that gratitude is the exercise of an innate principle. That good offices are, by the very constitution of our nature, apt to produce good will towards the benefactor, in good and bad men, in the savage and in the civilized, cannot surely be denied by any one in the least acquainted with human nature. We are grateful not only to the benefactors of ourselves as individuals, but also to the benefactors of our country; and that, too, when we are conscious that from our gratitude neither they nor we can reap any advantage. Nay, we are impelled to be grateful even when we have reason to believe that the objects of our gratitude know not our existence. This passion cannot be the effect of reasoning, or of association founded on reasoning; for, in such cases as those mentioned, there are no principles from which reason can infer the propriety or usefulness of the feeling. That public spirit, or the affection which we bear to our country, or to any subordinate community of which we are members, is founded on instinct, is deemed so certain, that the man destitute of this affection, if there be any such, has been pronounced as great a monster as he who has but two heads.

All the disinterested passions are founded on what philosophers have termed benevolent affection. Instead therefore of enquiring into the origin of each passion separately, which would swell this article to no purpose, let us listen to one of the finest writers as well as ablest reasoners of the age, treating of the origin of benevolent affection, "We may lay it down as a principle (says Dr Reid), that all benevolent affections are in their nature agreeable: that it is essential to them to desire the good and happiness of their objects; and that their objects must therefore be being capable of happiness. A thing may be desired either on its own account, or as the means in order to something else. That only can properly be called an object of desire which is desired upon its own account, and
and therefore I consider as benevolent those affections only which define the good of their objects, ultimately, and not as means in order to something else. To say that we define the good of others, only to procure some pleasure or good to ourselves, is to say that there is no benevolent affection in human nature. This indeed has been the opinion of some philosophers both in ancient and in later times. But it appears as unreasonable to resolve all benevolent affections into self-love, as it would be to resolve hunger and thirst into self-love. These appetites are necessary for the preservation of the individual. Benevolent affections are no less necessary for the preservation of society among men; without which men would become an easy prey to the beasts of the field. The benevolent affections planted in human nature, appear therefore no less necessary for the preservation of the human species than the appetites of hunger and thirst. In a word, pity, gratitude, friendship, love, and patriotism, are founded on different benevolent affections; which our learned author holds to be original parts of the human constitution.

This reasoning has certainly great force; and if authority could have any weight in settling a question of this nature, we know not that name to which greater deference is due than the name of him from whom it is taken. Yet it must be confessed that the philosophers, who consider the affections and passions as early and deep-rooted associations, support the opinion with very plausible arguments. On their principles we have endeavoured elsewhere to account for the passions of fear and love, (see Instinct and Love); and we may here safely deny the truth of what has been flattered respecting fear, which seems to militate against that account. We have attended with much solicitude to the actions of children; and have no reason to think that they feel terror on the brink of a precipice till they have been repeatedly warned of their danger in such situations by their parent or their keepers. Every parent knows not only that they have no original or instinctive dread of fire, which is as dangerous to them as any precipice; but that it is extremely difficult to keep them from that destructive element till they are either capable of weighing the force of arguments, or have repeatedly experienced the pain of being burnt by it. With respect to sudden repentment, we cannot help considering the argument, which is brought in proof of its being instinctive, as proving the contrary in a very foreseeable manner. Instinct is some mysterious influence of God upon the mind exciting to actions of beneficial tendency: but can any benefit arise from wrecking our infant vengeance in a flock or a fowl? or is it palpable that a being of infinite wisdom would excite us to act in extravagantly foolish? We learn from experience to defend ourselves against rational or insensible enemies by retaliating the injuries which they inflict upon us; and if we have been often injured in any particular manner, the idea of that injury becomes in time a force associated with the means by which it has been constantly repelled, so that never receive such a injury—a blow for instance—with being prompted to make the usual retaliation, without reflecting whether the object be sensible or insensible. So far from being instinctive does repentment appear to us, that we think an attentive observer may easily perceive how the seeds of it are gradually infused into the youthful mind; when the child, from being at first a timid creature trembling from every pain, learns by degrees to return blow for blow and threat for threat.

But instead of urging what appears to ourselves of most weight against the intuitive system, we shall lay before our readers a few extracts from a dissertation on the Origin of the Passions by a writer whose elegance of language and ingenuity of investigation do honour to the school of Hartley.

"When an infant is born (says Dr Sayers), there is every reason to suppose that he is born without ideas. These are rapidly communicated through the medium of the senses. The same senses are also the means of conveying to him pleasure and pain. These are the hinges on which the passions turn; and till the child is acquainted with these sensations, it would appear that no passion is formed in his mind; for till he has felt pleasure and pain, how can he direct any object, or wish for its removal? How can he either love or hate? Let us observe then the manner in which Love and hatred are formed; for the passions depend all the rest. When a child endures pain, and is able to detect the cause of it, the idea of pain is connected in his mind with that of the thing which produced it; and the object which occasioned pain be again presented to the child, the idea of pain associated with it arises also. This idea consequently urges the child to avoid or to remove the object; and thus arises the passion of dislike or hatred. In the same manner, the passion of liking or love is readily formed in the mind of a child from the association of pleasant ideas with certain objects which produced them.

"The passions of hope and fear are states of the mind depending upon the good or bad prospects of gratifying love or hatred; and joy or sorrow arising from the final success or disappointment which attends the exertions produced by love or hatred. Out of these passions, which have all a precise relation to our own good, and are universally acknowledged to be selfish, all our other passions are formed."

To account for the passions called disinterested, he observes, that in the history of the human mind we find many instances of our dropping an intermediate idea, which has been the means of our connecting two other ideas together; and that the association of these two remains after the link which originally united them has vanished. Of this truth the reader will find sufficient evidence in different articles of this work (See Instinct, n. 19, and Metaphysics, n. 101): and, to apply it to the disinterested passions, let us suppose with Dr Sayers, that any individual has done to us many offices of kindness, and has consequently much contributed to our happiness; it is natural for us to feel some anxiety for the continuance of these pleasures which he is able to communicate. But we find a different, that the surest way of obtaining the continuance of his friendly offices is to make them, as much as possible, a source of pleasure to himself. We therefore do everything he is power to promote his happiness in return for the good he has conferred upon us, that thus we may attach him to us as much as we are able. Hobbes, it is plain, selfish. We have been with reluctance, for the sake of our own future grati-
P A S  [4]  PAS

Pain. gratification, to promote the happiness of this person: but observe the consequence. We have thus, by contemplating the advantage to be derived to ourselves from promoting the prosperity of our friend, learned to associate a lot of pleasant ideas with his happiness; but the link which has united them gradually escapes us, while the union itself remains. Continuing to associate pleasure with the well-being of our friend, we endeavour to promote it for the sake of his instantaneous gratification, without looking farther; and in this way his happiness, which was first attended to only as a means of future enjoyment, finally becomes an end. Thus then the passion which was originally selfish, is at length disinterested; its gratification being completed merely by its success in promoting the happiness of another.

In this way does our author account for the origin of gratitude; which at last becomes a habit, and flows spontaneously towards every man who has either been or intended to be our benefactor. According to him, it is easy to observe also, that from associating pleasure with the happiness of an individual when we procure ourselves, it must of course soon follow, that when the happiness is pleasure from a view of his happiness any way produced; such happiness raising at all times pleasant ideas when it is presented to our minds. This is another feature of a disinterested affection, to feel delight from the mere increase of happiness in the object whom we love.

It may be objected, perhaps, that parents seem to have an infinite disinterested love of their offspring: but surely the love of a parent (a) for a new-born infant is not usually equal to that for a child of four or five years old. When a child is first born, the prospect and hopes of future pleasure from it are sufficient to make a parent anxious for its preservation. As the child grows up, the hope of future enjoyment from it must increase; hence would pleasure be associated with the well-being of the child, the love of which would of course become in due time disinterested.

Our author does not analyze pity, and trace it to its source in selfishness; but he might easily have done it, and it has been ably done by his master. Pity or compassion is the scene of which a man feels at the misery of another. It is generated in every mind during the years of childhood; and there are many circumstances in the constitution of children, and in the mode of their education, which make them particularly susceptible of this passion. The very appearance of any kind of misery which they have experienced, or of any signs of distress which they understand, excite in their minds painful feelings from the remembrance of what they have suffered, and the apprehension of their suffering it again. We have seen a child a year old highly entertained with the noise and struggles made by its elder brother when plunged naked into a vessel filled with cold water. This continued to be the case for many days, till it was thought proper to plunge the younger as well as the elder; after which the daily entertainment was soon at an end. The little creature had not been itself plunged above twice till it ceased to find diversion in its brother's sufferings.

On the third day it cried with all the symptoms of the bitters worst anguish upon seeing its brother plunged, though no preparation was then made for plunging itself: but surely this was not disinterested sympathy, but a feeling wholly selfish, excited by the remembrance of what it had suffered itself, and was apprehensive of suffering again. In a short time, however, the painful feelings accompanying the sight of its brother's struggles, and the found of his cries, were doubtless so associated with that sight and that sound, that the appearance of the latter would have brought the former along with them, even though the child might have brooked or been under apprehension of plunging itself. This association, too, would soon be transmitted to every boy in the same circumstances, and to similar sounds and struggles, from whatever cause they might proceed.

Thus, as Dr. Hartley observes, "when several observations on Man.

(a) That this is true of the father is certain; but it may be questioned whether it be equally true of the mother. A woman is no sooner delivered of her infant, than she cares for it with the utmost possible fondness. We believe, that if she were under the necessity of making a choice between her child of four years, and her infant an hour old, she would rather be deprived of the latter than of the former; but we are not convinced that this would proceed from a less degree of affection to the infant than to the child. She knows that the child has before its fourth year escaped many dangers which the infant must encounter, and may not escape; and it is therefore probable that her choice would be the result of prudent reflection. Though we are not admirers of that philosophy which supposes the human mind a bundle of infinites, we can as little approve of the opposite scheme, which allows it no infinites at all. The affection of a mother to her new born infant is undoubtedly irrelative, as the only thing which at that moment can be associated with it in her mind is the pain she has suffered in bringing it to the world.
compassion, by coincidence with the rest. Agreeably to this method of reasoning, it may be observed, that persons whose nerves are easily irritable, and those who have experienced great trials and afflictions, are in general more disposed to compasse than others; and that we are most apt to pity others in those diseases and calamities which we either have felt or of which we apprehend ourselves to be in danger.

The origin of patriotism and public spirit is thus traced by Dr. Sayers: "The pleasures which our country affords are numerous and great. The wish to perpetuate the enjoyment of those pleasures includes, the wish to promote the safety and welfare of our country, without which many of them would be lost. All this is evidently selfish; but, as in the progress of gratitude, it finally becomes disinterested. Pleasent ideas are thus strongly connected with the welfare of our country, after the tie which first bound them together has escaped our notice. The prosperity which was at first definable as the means of future enjoyment, becomes itself an end: we feel delight in such prosperity, however produced; and we look not beyond this immediate delight. It is thus not difficult to observe in what manner a general and disinterested benevolence take place in a mind which has already received pleasure from the happiness of a few; the transition is easy towards associating it with happiness in general, with the happiness of any being, whether produced by ourselves or by any other cause whatever."

From this reasoning, our author concludes, that all our passions may be traced up to original feelings of regard for ourselves. "Thus (in the forcible language of a learned writer of the same school) does self-love, under the varying appearance of natural affection, domestic relation, and the connections of social habitues, at first work blindly on, obscure and deep, in dirt: But as it makes its way, it continues rising till it emerges into light; and then suddenly expiring, leaves behind it the fairest flower,"—benevolent affection.

Self-love forsook the path it first pursu'd, And found the private in the public good.

Thus have we stated the two opposite theories respecting the origin of passions in the mind, and given our readers a short specimen of the reasonings by which they are supported by their respective patrons. Were we called upon to decide between them, we should be tempted to say, that they have both been carried to extremes by some of their advocates, and that the truth lies in the middle between them. "It is impossible* but that creatures capable of pleasant and painful sensations, should love and choose the one, and dislike and avoid the other. No being who knows what happiness and misery are, can be supposed indifferent to them, without a plain contradiction. Pain is not a positive object of desire, nor happiness of aversion." To prefer a greater good though distant, to a less good that is present; or to choose a present evil, in order to avoid a greater future evil—is indeed wise and rational conduct; but to choose evil ultimately, is absolutely impossible. Thus far then must be admitted that every being possessed of sense and intelligence, necessarily desires his own good as soon as he knows what it is; but if this knowledge be not innate, neither can the desire. Every human being comes into the world with a capability of knowledge, and of course with a capability of affections, desires, and passions; but it seems not to be conceivable how he can actually love, or hate, or dread any thing, till he know whether it be good, or ill, or dangerous. If, therefore, we have no innate ideas, we cannot possibly have innate desires or aversions. Those who contend that we have, seem to think, that without them reason would be insufficiant, either for the preservation of the individual or the continuation of the species; and some writers have alleged, that if our affections and passions were the mere result of early associations, they would necessarily be more capricious than we ever find them. But this objection seems to arise from their not rightly understanding the theory of their antecedents. The disciples of Locke and Hartley do not suppose it possible for any man in society to prevent such associations from being formed in his mind as shall necessarily produce desires and aversions; and let us do they think it possible to form associations of ideas utterly repugnant, so as to dispose that as good which his senses and intellect have experienced to be evil. Associations are formed by the same means, and at the same time, the ideas and notions are impressed upon the mind; but as pain is never mistaken for pleasure by the senses, so an object which has given us only pain is never associated with any thing that makes it defirable. We say an object that has given us only pain because it is possible to form such an association between life and the loss of a limb, as to make us grateful to the surgeon by whom it was amputated. Associations being formed according to the same laws by which knowledge is acquired, it by no means follows that passions resulting from them should be more capricious than they are found to be; and they certainly are sufficiently capricious to make us suspect that the greater part of them has this origin, rather than that they are all infused into the mind by the immediate agency of the Creator. If man be a being formed with no innate ideas, and with no other instinctive principles of action than what are absolutely necessary to preserve his existence and perpetuate the species, it is easy to perceive why he is placed in this world as in a state of probation, where he may acquire habits of virtue to fit him for a better. It is likewise easy to perceive why some men are better than others, and why some are the slaves of the most criminal passions. But all this is unintelligible, upon the supposition that the seeds of every passion are innate, and that man is a compound of reason and of instincts so numerous and various as to suit every circumstance in which he can be placed.

*Dr. Price's Review. &c.

If passions, whatever be their origin, operate instantaneously, and if they be formed according to fixed laws, it may be thought a question of very little importance whether they be instinctive or acquired. This was long our own opinion; but we think, that upon mature reflection, we have reason to change it. If passions be the result of early associations, it is of the utmost consequence that no improper associations be formed in the minds of children, and that none of their unreasonable desires be gratified. Upon this theory it seems indeed to depend almost wholly upon education, whether a child shall become a calm, benevolent, ready, and upright man; or a passionate, capricious,

precious, foolish, illogical. By teaching him to resent every petty injury, the seeds of irritability are sown in his mind, and taken root, that before the age of manhood he becomes intolerable to all with whom he must converse. By exciting numberless defects in his youthful mind, and instantly gratifying them, you make him capricious, and impatient of disappointment; and by representing other children as in any degree inferior to him, you inspire him with the hateful passion of pride. According to the instinctive theory, education can only augment or diminish the strength of passions; according to the other theory, it is the source of by far the greater part of them. On either supposition, parents should watch with solicitude over the actions of their children; but they will freely think themselves obliged to be doubly watchful, if they believe, that through their neglect their children may acquire hateful passions, to which, if properly educated, they might have remained strangers through their whole lives. And let it be remembered, that this solicitude should begin at an early period: because the mind is susceptible of deep impressions much sooner than is sometimes imagined. Without this susceptibility no language could be learned; and therefore a child by the time he learns to speak, may have planted in his mind the seeds of passions, on the just regulation and subordination of which depends in a great measure the happiness of mankind. See Max. & Phil. Philosophy, Part 1, Chap. 1 & 2, Part III, n° 216.

P. 1034 and Emotions, difference between them. See 

e and P. 1034 and Emotions, difference between them. External Signs of Emotions and Passion. So intimately connected are the soul and body, that every agitation in the former produces a visible effect on the latter. There is, at the same time, a wonderful uniformity in that operation; each clus of emotions and passions being invariably attended with an external appearance peculiar to itself. These external appearance, or signs, may not improperly be considered as a natural language, expressing to all beholders emotions and passions as they arise in the heart. Hope, fear, joy, grief, are displayed externally: the character of a man can be read in his face; and beauty, which makes so deep an impression, is known to reflect, not so much from regular features and a fine complexion, as from good nature, good-nature, sweetness, sweetness, or other mental quality, expressed on the countenance. Though perfect skill in that language be rare, yet what is generally known is sufficient for the ordinary purposes of life. But by what means we come to understand the language, is a point of some intricacy. It cannot be by light merely; for upon the most attentive inspection of the human visage, all that can be discerned are, figure, colour, and motion, which, singly or combined, never can represent a passion nor a sentiment: the external sign is indeed visible; but to understand its meaning, we must be able to connect it with the passion that causes it; an operation far beyond the reach of eye sight. Where then is the instructor to " find that can unveil this secret connection? If we apply to experience, it is yielded, that from long and diligent observation, we may gather, in some measure, in what manner these we are acquainted with express their passions externally; but with respect to strangers, we are left in the dark; and yet are not puzzled about the meaning of these external expessions in a stranger, more than in a bosom companion. Further, had we no other means but experience for understanding the external signs of passion, we could not expect any uniformity, nor any degree of skill, in the bulk of individuals; yet matters are so much better ordered, that the external expression of passion form a language understood by all, by the young as well as the old, by the ignorant as well as the learned. We talk of the plain and legible characters of that language; for undoubtedly we are much indebted to experience, in deciphering the dark and more delicate expressions. Where then shall we apply for a solution of this intricate problem, which seems to penetrate deep into human nature? Undoubtedly if the meaning of external signs be not derived to us from sight, nor from experience, there is no remaining source whereto it can be derived but from nature.

We may then venture to pronounce, with some degree of confidence, that man is provided by nature with a sense or faculty that lays open to him every passion by means of its external expressions. And we cannot entertain any reasonable doubt of this, when we reflect, that the meaning of external signs, is not hid even from infants: an infant is remarkably affected with the passions of its nurse expressed on her countenance; a smile causes it; a frown makes it afraid; but fear cannot be without apprehending danger; and what danger can the infant apprehend, unless it be sensible that its nurse is angry? We must therefore admit, that a child can read anger in its nurse's face, of which it must be sensible intuitively, for it has no other mean of knowledge. We do not affirm, that these particulars are clearly apprehended by the child; for to produce clear and distinct perceptions, reflection and experience are requisite; but that even an infant, when afraid, must have some notion of its being in danger, is evident.

That we should be conscious intuitively of a passion from its external expressions, is conformable to the analogy of nature; the knowledge of that language is of too great importance to be left upon experience; because a foundation so uncertain and precarious, would prove a great obstacle to the formation of societies. Wisely therefore is it ordered, and agreeably to the fictions of providence, that we should have nature for our instructor.

Such is the philosophy of Lord Kames, to which objections unanswerable may be made. It is part of the intuitive system of metaphysics, which his Lordship has carried farther than all who wrote before him, and perhaps farther than all who have succeeded him in this department of science. That a child intuitively reads anger in its nurse's face, is so far from being true, that for some short time after birth it is not perceived by the most menacing gestures. It is in deed absolutely incapable of fear till it has suffered pain, (see Inst.); and could we constantly care it with that is called an angry look, it would be cheere by that look, and frightened as a lamb. It feels, however, the effects of anger, and is more capable of obeying the peculiarities of feature with which that passion is usually accompanied; and these two become in a short time so linked together in its tender mind, that
that the appearance of the one necessarily suggests to
it the reality of the other.

Should it be said that a loud and sudden noise
stirres a child immediately after birth, and that, there­fore
the infant must be instinctively afraid, the fact
may be admitted, without any necessity of admitting
the inference. The nerves of an infant are commonly
very irritable, and the strong impulse on the auditory
nerves may agitate its whole frame, without inspiring
it with the passion of fear. The loud noise is, in all
probability not the sign of approaching danger, but
the immediate cause of real pain, from which the in­fant
shrinks, as it would from the prick of a pin, or
the tearing of a candle. But we have said enough in
the article immediately preceding, and in others
which are there quoted, to show how the passions may
be formed by associations even in early infancy, and
yet operate as if they were instinctive. This being
the case, we shall through the remainder of this article
suffer his Lordship to speak his own language, with­out
making any further remarks upon it. We are
induced to do this for two reasons; of which the first
is that many of our readers will probably prefer his
theory to ours; and the second is, that his conclusions
receding the signs and language of passion hold
equally good from either theory.

We perfectly agree with him, that manifold and
admirable are the purposes to which the external signs
of passion are made subservient by the Author of our
nature.

1. The signs of internal agitation displayed exter­nally to every spectator, tend to fix the signification
of many words. The only effectual means to ascertain
the meaning of any doubtful word, is an appeal to the
thing it represents; and hence the ambiguity of words
expressive of things that are not objects of external
sense; for in that case an appeal is denied. Passion,
strictly speaking, is not an object of external sense;
but its external signs are: and by means of these signs,
passions may be appealed to with tolerable accuracy:
thus the words that denote our passions, next to those
that denote external objects, have the most distinct
meaning. Words signifying internal action and the
more delicate feelings, are least distinct. This defect,
with regard to internal action, is what chiefly occa­sions
the intricacy of logic; the terms of that science are
far from being sufficiently ascertained, even after
much care and labour bestowed by an eminent writer
* to whom, however, the world is greatly indebted, for
removing a mountain of rubbish, and moulding the
subject into a rational and correct form. The same de­fect is remarkable in criticism, which has for its ob­ject the more delicate feelings; the terms that denote
these feelings being not more distinct than those of
logic.

2. Society among individuals is greatly promoted
by that universal language. Looks and gestures give
direct access to the heart, and lead us to feel, with
tolerable accuracy, the persons who are worthy of our
confidence. It is surprising how quickly, and for the
most part how correctly, we judge of character from
external appearance.

3. After social intercourse is commenced these ex­ternal signs, which diffuse through a whole assemblage
the feelings of each individual, contribute above all
other means to improve the social affections. Lan­guage,
o doubt, is the most comprehensive vehicle for
communicating emotions; but in expedieney as well
as in power of conviction, it falls short of the signs
under consideration; the involuntary signs especi­ally,
which are incapable of deceit. Where the counte­nance,
the tones, the gestures, the actions join with
the words in communicating emotions, these united
have a force irresistible. Thus all the plentiful emo­tions of the human heart, with all the social and virtu­ous affections, are by means of these external signs,
ot only perceived but felt. By this admirable con­vivence, conversation becomes the lively and anim­ating amusement, without which life would at best
be insipid; one joyful countenance spreads cheerfulness
instantaneously through a multitude of spectators.

4. Domestic passions, being hurtful by prompting
violence and mischief, are noted by the most conspicuous
external signs, in order to put us upon our guard; thus anger and revenge, especi­ally when sudden,
display themselves on the countenance in legible char­acters. The external signs, again, of every passion
that threatens danger, raise in us the passion of
fear; which frequently operating without reason or reflection,
moves us by a sudden impulse to avoid the impending
danger.

Those external signs are remarkably subservient to
morality. A painful passion, being accompanied with disagreeable external signs, must produce in every
spectator a painful emotion; but then if the passion be
social, the emotion he produces is attractive, and con­nects the spectator with the person who suffers. Dis­fociat passions only are productive of repulsive emo­tions, involving the spectator's aversion, and frequently
his indignation. This artful contrivance makes us
cling to the virtuous, and abhor the wicked.

6. Of all the external signs of passions, those of aff­liction or distress are the most illustrious with respect
to a final cause, and deservedly merit a place of dif­inction. They are illustrious by the singularity of
their contrivance; and also by inspiring sympathy, a
passion to which human society is indebted for its
greatest blessings, that of providing relief for the dis­tressed. A subject so interesting deserves a leisur­ely and attentive examination. The conformity of the na­ture
of man to his external circumstances is in every
particular wonderful: his nature makes him prone to
society; and society is necessary to his well-being, be­cause in a solitary state he is a helpless being, de­stitute of support, and in his distresses destitute of re­lief; but mental support, the soothing attribute of
society, is of too great moment to be left depend­ent upon cool reason; it is ordered more wisely, and
with greater conformity to the analogy of nature, that
it should be enforced even intuitively by the pas­sion of sympathy. Here sympathy makes a capital
figure; and contributes more than any other means,
to make life easy and comfortable. But however es­sential the sympathy of others may be to our well­being, one beforehand would not readily conceive how
it could be raised by external signs of distress: for con­sidering the analogy of nature, if these signs be agree­able they must give birth to a pleasant emotion lead­ing every beholder to be pleased with human woes; if
disagreeable, as they undoubtedly are, ought they not naturaly

* Lock.
naturally to repel the spectator from them, in order to be relieved from pain? Such would be the reasoning beforehand; and such would be the effect were man purely a selfish being. But the benevolence of our nature gives a very different direction to the painful passion of sympathy, and to the degree involved in it; instead of avoiding diftrust, we fly to it in order to afford relief; and our sympathy cannot be otherwise gratified but by giving all the succour in our power. Thus external signs of diftrust, though disagreeable, are attractive; and the sympathy they inspire is a powerful cause, impelling us to afford relief even to a stranger, as if he were our friend or relation.

It is a noted observation, that the deepest tragedies are the most crowded: which in an overly view will be thought an accountable bias in human nature. Love of novelty, desire of occupation, beauty of action, make us fond of theatrical representations; and when once engaged, we must follow the story to the conclusion, whatever diftrust it may create. But we generally become wise by experience: and when we foresee what pain we shall suffer during the course of the representation, is it not surprizing that persons of reflection do not avoid such spectacles altogether? And yet one who has fcarcely recovered from the diftrust of a deep tragedy, resolves coolly and deliberately to go to the very next, without the slightest obstruction from felo-love. The whole mystery is explained by a single observation: That sympathy, though painful, is attractive; and attaches us to an object in diftrust, instead of prompting us to fly from it. And by this curious mechanism it is, that persons of any degree of sensibility are attracted by affliction still more than by joy.

To conclude: the external signs of passion are a strong indication, that man, by his very constitution, is framed to be open and sincere. A child, in all things obedient to the impulses of nature, hides none of its emotions: the savage and clown, who have no guide but pure nature, expose their hearts to view, by giving way to all the natural signs. And even when men learn to disguise their sentiments, and when behavious are generates into art, there still remain checks, that keep dissimulation within bounds, and prevent a great part of its mischievous effects: the total suppression of the voluntary signs during any vivid passion, begets the utmost uneasiness, which cannot be endured for any considerable time: this operation becomes indeed less painful by habit; but luckily the involuntary signs cannot, by any effort be suppressed nor even dissembled. An absolute hypocrisy, by which the character is concealed and a fictitious one assumed, is made impracticable; and nature has thereby prevented much harm to society. We may pronounce, therefore, that Nature herself, sincere and candid, intends that mankind should preserve the same character, by cultivating simplicity and truth, and banishing every sort of dissimulation that tends to mischief.

Influence of Passion with respect to our Perceptions, Opinions, and Belief. So intimately are our perceptions, passions, and actions, connected, it would be wonderful if they should have no mutual influence. That our actions are too much influenced by passion, is a well known, that passion hath also an influence upon our perceptions, opinions, and belief. For example, the opinions we form of men and things are generally directed by affection: an advice given by a man of figure hath great weight; the same advice from one in a low condition is despised or neglected; a man of courage under-rates danger; and to the indolent the slightest obstacle appears insurmountable. All this may be accounted for by the simple principle of affection.

There is no truth more universally known, than that tranquillity and sedateness are the proper state of mind for accurate perception and cool deliberation; and for that reason we never regard the opinion even of the wise man, when we discover prejudice or passion behind the curtain. Passion hath such influence over us, as to give a false light to all its objects. Agreeable passions prepare the mind in favour of their objects; and disagreeable passions, not leaves against their objects; A woman is all perfection in her lover's opinion, while in the eye of a rival beauty she is awkward and disagreeable: when the passion of love is gone, beauty vanishes with it—nothing is left of that genteel motion, that sprightly conversation, those numberless graces, which formerly, in the lover's opinion, charmed all hearts. To a zealot every one of his own sect is a saint, while the most upright of a different sect are to him children of perdition: the talent of speaking is a friend, is more regarded than prudent conduct in any other. Nor will this surprise any one acquainted with the world; our opinions, the result frequently of various and complicated views, are commonly for flight and wavering, as readily to be susceptible of a bias from passion.

With that natural bias another circumstance consurs, to give passion an undue influence on our opinions and belief: and that is a fixing tendency in our nature to justify our passions as well as our actions, not to others only, but even to ourselves. That tendency is peculiarly remarkable with respect to disagreeable passions: by its influence, objects are magnified, or softened, circumstances supplied or suppressed, every thing coloured and disguised to answer the end of justification. Hence the foundation of self-deceit, where a man imposes upon himself innocently, and even without suspicion of a bias.

We proceed to illustrate the foregoing observations by proper examples.

Gratitude, when warm, is often exerted upon the children of the benefactor; especially where he is removed out of reach by death or absence. The passion in this case being exerted for the sake of the benefactor requires no peculiar excellence in his children; but the practice of doing good to these children produces affection for them, which never fails to advance them in our esteem. By such means strong connections of affection are often formed among individuals, upon the flint foundation now mentioned.

Envy is a passion, which, being altogether unjustifiable, cannot be excused by disguising it under some plausible name. At the first sight, no passion is more eager than envy to give its object a disagreeable appearance: it magnifies every bad quality, and fixes on the most humblest circumstances.
Plaudit men was a god among many of
And entertain a cheerful disposition.

The troubled Tyber chafing with his thores,
Cæsar says to me, Dar't thou, Cæsar, now
Leap in with me into this angry flood,
And swim to yonder point.—Upon the word,
Accosted as I was, I plunged in,
And bid him follow; so indeed he did.
The torrent roar'd, and we did buffet it
With lusty finews; throwing it aside,
And fleming it with hearts of controversly.
But ere we could arrive the point propos'd,
Cæsar cry'd, Help me, Cælius, or I sink:
As Æneas, our great ancestor,
Died from the flames of Troy upon his shoulder
The old Anchises bear; so from the waves of Tyber
Did I the tired Cæsar: and this man
Is now become a god; and Cælius is
A wretched creature, and must bend his body
If Cæsar carelessly but nod on him.
He had a fever when he was in Spain;
And when the fit was on him, I did mark
How he did shake. 'Tis true, this god did shake;
His coward lips did from their colour fly;
And that fame eye whose bend did awe the world
Did lose its luster: I did hear him groan;
Ay, and that tongue of his, that bade the Romans
Mark him, and write his speeches in their books,
Alas! I it cry'd—Give me some drink, Titinius,—
As a sick girl. Ye gods, it doth amaze me,
A man of such a feeble temper should
So get the start of the majestick world,
And bear the palm alone. Julius Cæsar, &c. 1. 3.

Glo'tier, inflamed with resentment against his son
Edgar, could even force himself into a momentary
conviction that they were not related:

O strange fathers' villain!
Would he deny his letter?—I never got him.

King Lear, &c. 2. 3.

When by great sensibility of heart, or other means,
grief becomes immoderate, the mind, in order to ju-
lify itself, is prone to magnify the cause; and if the
real cause admit not of being magnified, the mind seeks
a cause for its grief in imagined future events:

Busy, Madam, your majesty is much too sad:
You promis'd, when you parted with the king,
To lay aside self-harming heaviness,
And entertain a cheerful disposition.

Queen. To please the king I did; to please myself,

Vol. XIV.

(1) We have already shown how a man may be instigated to wreck his vengeance on a flock or a fone, without ever considering, whether it be sensible or insensible; (See Passi. 

If the story of Xerxes be true, he may have considered the sea as sensible and animated without dreaming that a flock or a fone is so. The sea was a god among many of the pagans, and was considered as such by Xerxes; or he could not have ap-
plauded men not sacrificing to it.
King Richard, full of indignation against his favourite horfe for carrying Bolingbroke, is led into the conviction of his being rational:

Groom. O, how it yearn'd my heart, when I beheld
In London streets, that coronation-day,
When Bolingbroke rode on Roan Barbary,
That horfe that thou so often halft beltrid,
That horfe that I fo carefully have dressed.

K. Rich. Rode he on Barbary? tell me, gentle friend,
How went he under him?

Groom. So proudly as he had disdain'd the ground.
K. Rich. So proud that Bolingbroke was on his back!
That jade had eat bread from my royal hand.
This hand hath made him proud with clapping him.
Would he not stumble? would he not fall down,
(Since pride must have a fall), and break the neck
Of that proud man that did usurp his back!

Richard II. ad 5. fe. 11.

Hamlet, swelled with indignation at his mother's second marriage, was strongly inclined to lessen the time of her widowhood, the shortness of the time being a violent circumstance against her; and he deludes himself by degrees into the opinion of an interval shorter than the real one:

Hamlet.——That it should come to this!

But two months dead! nay, not so much; not two——
So excellent a king, that was to this,
Hyperion to a fincer: so loving to my mother,
That he permitted not the wind of heav'n
Vifit her face too roughly. Heav'n and earth!
Muft I remember—why, she would hang on him,
As if increafe of appetite had grown
By what it fed on: yet, within a month——
Let me not think—Frailty! thy name is Woman!
A little month! or ere those shoes were old,
With which she followed my poor father's body,
Like Niobe, all tears—why she, ev'n she—
(O heav'n! a beak, that wants discourse of reason,
Wou'd have mourn'd longer) married with mine uncle,
My father's brother; but no more like my father
Than I to Hercules. Within a month!——
Ere yet the fall of most unrighteous tears
Had left the fuffing in her galled eyes,
She married—Oh, most wicked speed! to poft
With such dexterity to inculcous fheets
It is not, nor is not, come to good,
But break my heart, for I muft hold my tongue.

Ad. 1. fe. 3.

The power of passion to falsify the computation of time is remarkable in this instance; because time, which hath an accurate measure, is left obsequious to our desires and wishes, than objects which have no precise standard of less or more.

Good news are greedily swallowed upon very slender evidence; our wishes magnify the probability of the event, as well as the veracity of the relater; and we believe as certain, what at first is doubtful:

Quel, che l'huom vede, amor li fa invibile
E' l'invivibile fa veder amore.

Quelto creduto fu, che 'l mifer fuole
Dar facile credenza a quel, che vuole.

Orland. Partho. cont. 1. fl. 56.

For the same reason, bad news gain also credit upon the flightest evidence; fear, if once alarmed, has the same effect with hope, to magnify every circumstance that tends to conviction. Shakespeare, who shows more knowledge of human nature than any of our philosophers, hath in his Cymbeline represented this bias of the mind; for he makes the person who alone was affected with the bad news, yield to evidence that did not convince any of his companions. And Othello is convinced of his wife's infidelity from circumstances too slight to move any person less interested.

If the news interest us in fo low a degree as to give place to reason, the effect will not be altogether the fame: judging of the probability or improbability of the story, the mind settles in a rational conviction either that it is true or not. But even in that case, the mind is not allowed to rest in that degree of conviction which is produced by rational evidence; if the news be in any degree favourable, our belief is raised by hope to an improper height; and if unfavourable, by fear.

This observation holds equally with respect to future events; if a future event be either much wished or dreaded, the mind never fails to augment the probability beyond truth.

That eafines of belief, with respect to wonders and prodigies, even the most abfur'd and ridiculous, is a strange phenomenon; because nothing can be more evident than the following proposition, That the more singular any event is, the more evidence is required to produce belief; a familiar event daily occurring, being in itself extremely probable, finds ready credit, and therefore is vouch'd by the lightest evidence; but to overcome the improbability of a strange and rare event, contrary to the course of nature, the very strongest evidence is required. It is certain, however, that wonders and prodigies are swallowed by the vulgar, upon evidence that would not be sufficient to ascertain the most familiar occurrence. It has been reckoned difficult to explain that irregular bias of mind; but we are now made acquainted with the influence of passion upon opinion and belief; a story of ghosts or fairies, told with an air of gravity and truth, rafeth an emotion of wonder, and perhaps of dread; and these emotions imposing on a weak mind, impress upon it a thorough conviction contrary to reason.

Opinion and belief are influenced by propensity as well as by passion. An innate propensity is all we have to convince us that the operations of nature are uniform; influenced by that propensity, we often rashly think that good or bad weather will never have an end; and in natural philosophy, writers, influenced by the same propensity, stretch commonly their analogical

reason.
Wisdom is the highest of all the faculties; and among great to leave me the power of weeping; but the Son be so highly concerned for a poor man, now or related to thee. Piammeticus returned the following answer: "Son of Cyrus, the calamities of my family are too great to leave me the power of weeping; but the misfortunes of a companion, reduced in his old age to want of bread, is a fit subject for lamentation."

Surprise and terror are silent passions, for a different reason: they agitate the mind so violently, as for a time to suspend the exercise of its faculties, and among others the faculty of speech. Love and revenge, when immediate, are not more loquacious than immediate grief. But when those passions become moderate, they set the tongue free, and, like moderate grief, become loquacious. Moderate love, when unsuccessful, is vented in complaints; when successful, is full of joy expressed by words and gestures.

As no passion hath any long uninterrupted existence, nor boats always with an equal pulse, the language suggested by passion is not only unequal but frequently interrupted; and even during an uninterrupted fit of passion, we only express in words the more capital sentiments. In familiar conversation, one who vents every single thought, is justly branded with the character of loquacity; because sensible people express no thoughts but what make some figure; in the same manner, we are only disposed to express the strongest impulses of passion, especially when it returns with impetuosity after interruption.

It is elsewhere observed * that the sentiments ought to be turned to the passion, and the Language to both article Sen-Elevated sentiments require elevated language; tender sentiments ought to be clothed in words that are soft and flowing; when the mind is depressed with any passion, the sentiments must be expressed in words that are humble, not low. Words being intimately connected with the ideas they represent, the greatest harmony is required between them; to express, for example, an humble sentiment in high sounding words, is disagreeable by a discordant mixture of feelings; and the discord is not less when elevated sentiments are dressed in low words:

Verfibus exponi tragicis res comici non vult.
Indignatur item privatis ac prope focco
	Dignus carminibus narrari cona Thyseste.

Horat. Ars poet. l. 89.

This, however, excludes not figurative expression, which, within moderate bounds, communicates to the sentiment an agreeable elevation. We are sensible of an effect directly opposite, where figurative expression is indulged beyond a just measure: the opposition between the expression and the sentiment makes the discord appear greater than it is in reality.

At the same time, figures are not equally the language of every passion; pleasant emotions, which elevate or swell the mind, vent themselves in strong epithets and figurative expression; but humbling and de-spiriting passions affect to speak plain:

Et tragicus plerumque dolet fermono pedestri.
Telephus et Paeus, cum pauper et exul uterque,
Proiect ampullus et fequipedialia verba,
Sic curat cor spectans tetigisse querela.

Horat. Ars poet. 95.

Figurative expression, being the work of an enlivened imagination, cannot be the language of anguish or distress. Orway, sensible of this, has painted a scene of distress in colours finely adapted to the subject: there is scarce a figure in it, except a short and natural mimic with which the speech is introduce.1 Belvidera, talking to her father of her husband:

Think you saw what past our last parting,
Think you beheld him like a raging lion,
That as he pressed the earth, and tearing up his rep,

Fix'd on my throat, while the extended other
Grasp'd a keen threatening dagger: oh, 'twas this
We last embac'd, when, trembling with revenge.
To preserve the foregoing resemblance between words and their meaning, the sentiments of active and hurry ing passions ought to be drest in words where syllables prevail that are pronounced short or faint: for these make an impression of hurry and precipitation. Emotions, on the other hand, that rest upon their objects, are best expressed by words where syllables prevail that are pronounced long or flow. A person affected with melancholy has a languid and slow train of perceptions. The expression best suited to that state of mind, is where words, not only of long but of many syllables, abound in the composition; and for that reason, nothing can be finer than the following passage:

In those deep solitudes, and awful cells,
Where heavenly-pensive Contemplation dwells,
And ever-musing Melancholy reigns.

To preserve the same resemblance, another circumstance is requisite, that the language, like the emotion, be rough or smooth, broken or uniform. Calm and sweet emotions are best expressed by words that glide softly: surprize, fear, and other turbulent passions, require an expression both rough and broken.

It cannot have escaped any diligent inquirer into nature, that, in the hurry of passion, one generally expresses that thing first which is most at heart; which is beautifully done in the following passage:

Me, me; adsum qui feci: in me converse facrum,
O Rutuli, mea frans omnis Parnass. ix. 427.

Passion has often the effect of redoubling words, the better to make them express the strong conception of the mind. This is finely imitated in the following examples:

Thou fun, said I, fair light!
And thou enlight'ned earth, so freth and gay!
Ye hills and dales, ye rivers, woods, and plains!
And ye that live, and move, fair creatures! tell,
Tell, if ye saw, how came I thus, how here. —
Paradise Lost, b. viii. 273.

Both have finned! but thou
Against God only; I, gaining God and thee:
And to the place of judgment will return;
There with my cries importune Heaven, that all
The sentence, from thy head remov'd, may light
On me, sole caufe to thee of all this wo;
Me! me! only just object of his ire.
Paradise Lost, b. x. 930.

In general, the language of violent passion ought to be broken and interrupted. Soliloquies ought to be so in a peculiar manner: language is intended by nature for society; and a man when alone, though he always clothes his thoughts in words, seldom gives his words utterance, unless when prompted by some strong emotion: and even then by starts and intervals only. Shakespeare's soliloquies may be justly esteemed as a model; for it is not easy to conceive any model more perfect. Of his many incomparable soliloquies, the following two only shall be quoted, being different in their manner.

Hamlet, Oh, that this too, too solid flesh, would
Thaw, and resolve itself into a dew! [melts.
Or that the Everlasting had not fixed
His canon 'gainst self-slaughter! O God! O God!
How weary, stale, flat, and unprofitable,
Seem to me all the uses of this world!
Fie on't! O fie! 'tis an unweeded garden,
That grows to seed; things rank and gross in nature
Posse it merely. — Thus it should come to this!
But two months dead! nay, not so much; not two—
So excellent a king, that was, to this,
Hyperion to a satyr: so loving to my mother,
That he permitted not the winds of heav'n
Visit her face too roughly. Heav'n and earth!
Muf't I remember—why, the world hung on him,
As if increafe of appetite had grown
By what it fed on; yet, within a month—
Let me not think. —Frailty, thy name is Woman!
A little month: or ere these shoes were old,
With which the follow'd my poor father's body,
Like Niobe, all tears— why, even the
(O heav'n! a beast, that wants discourse of reason,
Would have murr'd longer)— married with mine
uncle,
My father's brother; but no more like my father
Than to Hercules. Within a month—
Ere the last of most unrighteous tears
Hadj left the flushing in her gall'd eyes.
She married—Oh, most wicked speed, to post
With such dexterity to incestuous sheets!
It is not, nor it cannot come to good,
But break, my heart, for I must hold my tongue.

Hamlet, ad 1: fc. 3.

"Ford. Hum! ha! is this a vision? is this a dream?
"do I sleep? Mr Ford; awake; awake, Mr Ford;
"there's a hole made in your belt cock, Mr Ford;
"this 'tis to be married! this 'tis to have linen and
"buck-baskets? Well, I will proclaim myself what
"I am; I will now take the leacher; he is at my
"house; he cannot escape me; 'tis impossible he
"should; he cannot creep into a halfpenny purse,
"nor into a pepper-box. But let the devil that
"guides him should aid him, I will search impossible
"places; tho' what I am I cannot avoid, yet to be
"what I would not, shall not make me tame."

Merry Wives of Windsor, ad. 3. sc. left.

These soliloquies are accurate and bold copies of nature; in a passionate soliloquy one begins with thinking aloud, and the strongest feelings only are expressed; as the speaker warms, he begins to imagine one listening; and gradually slides into a connected discourse.

How far distant are soliloquies generally from these models? So far indeed as to give disgust instead of
Language ought not to be elevated above the tone of the sentiment.

Paffeon.

Paffeon.

Light and airy language is unsuitable to a severe passion.

Imagery and figurative expression are discordant in the highest degree, with the agony of a mother, who is deprived of two hopeful sons by a brutal murder. Therefore the following passage is undoubtedly in a bad taste;

Queen. Ah, my poor princes! ah, my tender babes! My unblown flowers, now appearing sweets! If yet your gentle souls fly in the air, And be not fixt in doom perpetual, Hover about me with your airy wings, And hear your mother's lamentation.

Richard III. act 4. sc. 4.

Again,

K. Philip. You are as fond of grief as of your child.

Coniurers. Grief fills the room up of my absent child, Lies in his bed, walks up and down with me, Puts on his pretty looks, repeats his words, Remembers me of all his gracious parts, Stuffs out his vacant garment with his form; Then have I reason to be fond of grief.

King John, act 3. sc. 9.

Thoughts that turn upon the expression instead of the subject, commonly called a play of words, being low and childlish, are unworthy of any commendation, whether gay or serious, that pretends to any degree of elevation.

In the Aminta of Tasso, the lover falls into a mere play of words, demanding how he who had himself, could find a mistress. And for the same reason, the
The following passage in Corneille has been generally condemned:

Chimene. Mon père est mort, Elvire, et la première épée
Dont s'est armée Rodrigue à la trame coupée.
Pleurez, pleurez, mes yeux, et fondez-vous en eaux,
La moitié de ma vie a mis l'autre au tombeau.
Et m'oblige à venger, après ce coup furelfe,
Celle que je n'ai plus, fur celle que me relè.

Cid, aii 3. fc. 3.

To die is to be banish'd from myself; And Sylvia is myself; banish'd from her, Is felt from self; a deadly banishment!

Two Gentlemen of Verona, aii 3. fc. 3.

Countess. I pray thee, Lady, have a better cheer: If thou engrodst all the griefs as thine, Thou robb'st me of a moiety.

All's well that ends well, aii 3. fc. 3.

K. Henry. O my poor kingdom sick with civil blows!

When that my care could not with-hold thy riots,
What wilt thou do when riot is thy care?
O, thou wilt be a wilderness again,
Peopled with wolves, thy old inhabitants.

Second Part of Henry IV. aii 4. fc. 11.

Cruda Amarilli, che col nome ancora
D'amai, ah laffo, amaramente insegno.

Paflor Fido, aii 1. fc. 2.

Antony, speaking of Julius Cæsar:

O world! thou wait the forest of this hart;
And this indeed, O world, the heart of thee.
How like a deer, fricken by many princes,
Doft thou here lie? "Julius Cæsar, aii 3. fc. 3.

Playing thus with the found of words, which is still worse than a pun, is the meanest of all conceits. But Shakespeare, when he descends to a play of words, is not always in the wrong; for it is done sometimes to denote a peculiar character, as in the following passage:

Lewis. I do, my Lord, and in her eye I find
A wonder, or a wondrous miracle:
The shadow of myself form'd in her eye;
Which being but the shadow of your son,
Becomes a son, and makes your son a shadow.
I do protest, I never lov'd myself
Till now infid'd I beheld myself
Drawn in the flattering table of her eye.

Fauconbridge. Drawn in the flattering table of her eye!

Hang'd in the frowning wrinkle of her brow! And quarter'd in her heart! he doth efpy
Himself Love's traitor; this is pity now,
'That hang'd, and drawn, and quarter'd should be
In such a love to vile a lout as he.

King John, aii 2. fc. 5.

A jingle of words is the lowest species of that low wit, which is scarce sufferable in any case, and least of all in an heroic poem; and yet Milton in some instances has descended to that puerility:

And brought into the world a world of woe.

Begirt th' Almighty throne
Begirt th' Almighty throne
Begirt th' Almighty throne
Begirt th' Almighty throne
Begirt th' Almighty throne
Begirt th' Almighty throne

At one flight bound high overlap'd all bound.

With a thront
Loud as from numbers without number.

One should think it unnecessary to enter a caveat against an expression that has no meaning, or no distinct meaning; and yet somewhat of that kind may be found even among good writers.

Scipio. I beg no pity for this mould'ring clay.

For if you give it burial, there it takes Possession of your earth:

If burnt and scatter'd in the air; the winds
That blow thy dust, diffuse thy royalty,
And spread me o'er your clime; for where one atom
Of mine shall light, know there Scipio reigns.

Dryden, Don Sebastian King of Portugal, aii 1.

Cleopatra. Now, what news, my Charmion?

Will he be kind? and will he not forake me?

Am I to live or die? nay, do I live?

Or am I dead? for when he gave his answer,

Fate took the word, and then I liv'd or dy'd.

Dryden, All for love, aii 2.

If she be coy, and scorn my noble fire.

If her chill heart I cannot move;

Why, I'll enjoy the very love,

And make a mistress of my own desire.

Cowley, poem inscribed "The Requête."

His whole poem inscribed My Picture is a jargon of the same kind.

"Tis he they cry, by whom

Not men, but war itself is overcome.

Indian Queen.

Such empty expressions are finely ridiculed in the Rehearsal.

Was't not unjust to ravish hence her breath,

And in lie's stead to leave us nought but death?

All 1. fc. 1.

Passions, in medicine make one of the non-naturals, and produce very sensible effects. Joy, anger, and fear, are the principal. In the two first, the spirits are hurried with too great vivacity; whereas, in fear or dread, they are as it were curbed and concentrated: whence we may conclude, that they have a very bad effect upon health: and therefore it will be best to keep them within bounds as much as possible, and to prefer an inward serenity, calmness, and tranquility.

Passions, in painting, are the external expressions of the different dispositions and affections of the mind; but particularly their different effects upon the several features of the face: for though the arms, and indeed every part of the body, serve likewise, by their quick, languid, and various motions, to express the passions of the soul; yet, in painting, this difference is 37.
P A S

is most conspicuous in the face. See Painting, p. 620.

and Drawing, § 8.

As we have given engravings of Le Brun’s drawings of the passions, we shall here subjoin the account which he has given of each of these heads. See Plates CCLXXXVIII. and CCLXXXIX.

1. The effects of attention are, to make the eye brows sink and approach the fides of the nose; to turn the eye-balls toward the object that causes it; open the mouth, and especially the upper part; to decline the head a little; and fix it without any other remarkable alteration.

2. Admiration causes but little agitation in the mind, and therefore alters but very little the parts of the face; nevertheless the eye brow rises; the eye opens a little more than ordinary; the eye-ball placed equally between the eye-lids appears fixed on the object; the mouth half opens, and makes no sensible alteration in the cheeks.

3. The motions that accompany admiration with astonishment are hardly different from those of simple admiration, only they are more lively and stronger marked; the eye-brow more lively and stronger opens the eye-ball further from the lower eye-lid, and more readily fixed: The mouth is more open, and all the parts in a much stronger emotion.

4. Admiration begets esteem, and this produces veneration, which, when it has for its object something divine or beyond our comprehension, makes the face decline, and the eye-brows bend down; the eye-balls and eye-brows rise directly up; the mouth half opens, and the two corners are also a little turned up; the other parts remain in their natural state.

5. Although rapture has the same object as veneration, only considered in a different manner, its motions are not the same; the head inclines to the left side; the eye balls and eye-brows rise directly up; the mouth half opens, and the two corners are also a little turned up; the other parts remain in their natural state.

6. The passion of desire brings the eye-brows close together and forwards toward the eyes, which are more open than ordinary; the eye-ball is inflamed, and places itself in the middle of the eye; the nostrils rise up, and are contracted towards the eyes; the mouth half opens, and the spirits being in motion give a lively glowing colour.

7. Very little alteration is remarked in the face of those that feel within themselves the sweetness of joy, or joy with tranquility. The forehead is serene; the eye-brow without motion, elevated in the middle; the eye pretty open and with a laughing air; the eye-ball lively and shining; the corners of the mouth turn up a little; the complexion is lively; the cheeks and lips are red.

8. Laughter, which is produced by joy mixed with surprise, makes the eye-brows rise towards the middle of the eye, and bend towards the sides of the nose; the eyes are almost shut, and sometimes appear wet, or shed tears, which make no alteration in the face; the mouth half open, shows the teeth; the corners of the mouth drawn back, cause a wrinkle in the cheeks, which appear so swelled as to hide the eyes in some measure; the nostrils are open, and all the face is of a red colour.

9. Acute pain makes the eye-brows approach one another and rise towards the middle; the eye-ball is hid under the eye-brows; the nostrils rise and make a wrinkle in the cheeks; the mouth half opens and draws back; all the parts of the face are agitated in proportion to the violence of the pain.

10. Simple bodily pain produces proportionally the same motions as the last, but not so strong: The eye-brows do not approach and rise so much; the eye-ball appears fixed on some object; the nostrils rise, but the wrinkles in the cheeks are less perceivable; the lips are further afunder towards the middle, and the mouth is half open.

11. The dejection that is produced by sadness makes the eye brows rise towards the middle of the forehead more than towards the cheeks; the eye-ball appears full of perturbation; the white of the eye is yellow; the eye-lids are drawn down, and a little swelled; all about the eyes is livid; the nostrils are drawn downward; the mouth is half open, and the corners are drawn down; the head carelessly leaning on one of the shoulders; the face is of a lead colour; the lips pale.

12. The alterations that weeping occasions are strongly marked: The eye brows sink down towards the middle of the forehead; the eyes are almost closed, wet, and drawn down towards the cheeks; the nostrils swelled; the muscles and veins of the forehead appear; the mouth is shut, and the sides of it are drawn down, making wrinkles on the cheeks; the under lip pushed out, presses the upper one; all the face is wrinkled and contracted; its colour is red, especially about the eye brows, the eyes, the nose, and the cheeks.

13. The lively attention to the misfortunes of another, which is called compassion, causes the eye-brows to sink towards the middle of the forehead; the eye-ball to be fixed upon the object; the sides of the nostrils next the nose to be a little elevated, making wrinkles in the cheeks; the mouth to be open; the upper lip to be lifted up and thrust forwards; the muscles and all the parts of the face sinking down and turning towards the object which excites the passion.

14. The motions of fear are lively and strong: The forehead is wrinkled; the eye-brow is knit; the eye of it next the nose sinks down, and the other side rises very much; the eye is open, and the eye-ball is in the middle; the nostrils rise, and draw towards the eyes, and make wrinkles in the cheeks; the mouth shuts, its sides finking down, and the under lip is pulled out beyond the upper one.

15. An object despised sometimes causes horror, and then the eye-brow knits, and finks a great deal more. The eye-ball, placed at the bottom of the eye, is half covered by the lower eye lid; the mouth is half open, but closer in the middle than the sides, which being drawn back, makes wrinkles in the cheeks; the face grows pale, and the eyes become livid; the muscles and the veins are marked.

16. The violence of terror or fright alters all the parts of the face; the eye-brow rises in the middle;
its muscles are marked, swelled, preffed one against the other, and sunk towards the nose, which draws up as well as the noftrils; the eyes are very open; the upper eye-lid is hid under the eye brow; the white of the eye is encompassed with red; the eye ball fixes to¬ward the lower part of the eye; the lower part of the eye lid swells and becomes livid; the muscles of the nose and cheeks swell, and these last terminate in a point toward the sides of the noftrils; the mouth is very open, and its corners very apparent; the muscles and veins of the neck stretched; the hair stands on end; the colour of the face, that is, the end of the nose, the lips, the ears, and round the eyes, is pale and livid: and all ought to be strongly marked.

17. The effects of anger show fhow its nature. The eyes become red and Infamed; the eye-ball is daring and sparkling; the eye-brows are sometimes elevated and sometimes fink down equally; the forehead is very much wrinkled, with wrinkles between the eyes; the noftrils are open and enlarged; the lips prefling against one another, the under one riding over the upper one leaves the corners of the mouth a little open, making a cruel and difdainful grin.

18. Hatred or jealousy wrinkles the forehead; the eye-brows are funk down and knit; the eye-ball is half hid under the eye-brows, which turn towards the object; it fhould appear full of fire, as well as the white of the eye and the eye-lid; the noftrils are pale, open, more marked than ordinary, and drawn backward fo as to make wrinkles in the cheeks; the mouth is fo shut as to fhew the teeth are closed: the corners of the mouth are drawn back and very much funk; the muscles of the jaw appear funk; the colour of the face is partly inflamed and partly yellowish; the lips pale or livid.

19. As defpair in extreme, its motions are fo likewife; the forehead wrinkles from the top to the bottom; the eye-brows bend down over the eyes, and pref£ one another on the fides of the nose; the eye seems to be on fire, and full of blood; the eye ball is disturbed, hid under the eye-brow, sparkling and unfixed; the eye-lid is swelled and livid; the noftrils are large, open, and lifted up; the end of the nose finks down; the muscles, tendons, and veins are swelled and fretched; the upper part of the cheeks is large, marked, and narrow towards the jaw; the mouth drawn backwards is more open at the fides than in the middle; the lower lip is large and turned out; they gnath their teeth; they foam; they bite their lips, which are pale; as is the reft of the face; the hair is ftrait and stands on end.

PASSIVE. See PASSIFLORA.

Passion-Week, the week immediately preceding the fefivial of Easter; fo called, because in that week our Saviour's passion and death happened. The Thursday of this week is called Maunday Thursday; the Friday, Good Friday; and the Saturday, the Great Saturday.

PASSIVE, in general, denotes some thing that suffers the action of another, called an agent or active power. In grammar, the verb or word that expresses this passion is termed a passive verb: which in the learned languages, has a peculiar termination; as amor doceor, &c. in Latin: that is an r is added to the actives amo doceo; and, in the Greek, the inflection is made by changing w into xwpi;

Seymour Jr.
PASSOVER, a solemn festival of the Jews, instituted in commemoration of their coming out of Egypt, because the night before their departure, the destroying angel, who put to death the first-born of the Egyptians, passed over the houses of the Hebrews without entering therein, because they were marked with the blood of the lamb which was killed the evening before, and which for this reason was called the paschal lamb. This feast was called pesach by the old Greeks and Romans: not we pronounce from ψαχνω, "I suffer," as Chrysolom, Ireneus, and Tertullian, suppose, but from the Hebrew word pesach, pesag, hep.

The following is what God ordained concerning the passover of the Jews, (Exod. xii.) The month of the coming forth from Egypt was looked upon from this time to be the first month of the sacred or ecclesiastical year, and the fourteenth day of this month, between the two vespers, that is, between the sun's decline and his setting: or rather, according to our manner of reckoning, between two o'clock in the afternoon and six o'clock in the evening, at the equinox, they were to kill the paschal lamb, and to abstain from leavened bread. The day following being the fifteenth, counting from six o'clock of the foregoing evening, which concluded the fourteenth, was the grand feast of the passover, which continued seven days. But it was only the first and the seventh day that were solemn. The lamb that was killed ought to be without any defect, a male, and yeased that year. If no lamb could be found, they might take a kid. They killed a lamb or a kid in every family: and if the number of those that lived in the house was not sufficient to eat a lamb, they might join two houses together. With the blood of the paschal lamb they sprinkled the door-posts and lintel of every house, that the destroying angel, at the flight of the blood, might pass over them, and save the Hebrew children. They were to eat the lamb the same night that followed the sacrifice; they eat it roasted, with unleavened bread, and a collation of wild lettuce. The Hebrew says literally, with bitter things, as suppofoe mustard, or any thing of this nature to give a relish. It was forbid to eat any part of it raw, or boiled in water, nor were they to break a bone, (Exod. xii. 46. Numb. ix. 12. John xix. 36.;) and if any thing remained in the house, the following day, it was thrown into the fire. They that eat it were to be in the posture of travellers, having their reins girt, their shoes on their feet, their feet in their hands, and eating in a hurry. But this last part of the ceremony was but little observed, at least it was of no obligation, but only upon that night they came forth out of Egypt. For the whole eight days of the passover no leavened bread was to be used: and whoever should eat any, was threatened to be cut off from his people. With regard to the ceremonies which are observed in relation to the bread, see the article Passover, p. 351. col. 2.

They kept the first and last day of the feast, ye to us, that it was allowed to dress victuals, which was forbidden on the Sabbath-day. The obligation of keeping the passover was so strict, that whoever should neglect to do it, was punished to death, (Numb. ix. 13.) But those who had any lawful impediment, as a journey, sickness, or any uncleanness, voluntary or involuntary; for example, those that had been present at a funeral, or by any other accident had been defiled, were to defer the celebration of the passover till the second month of the ecclesiastical year, or to the fourteenth day of the month Iyar, which answers to April and May. It was thus the Lord ordered Moses, upon the occasion of the invention of unleavened bread, who had been obliged to pay their last offices to their relations, and who being thus polluted, were not capable of partaking of the paschal sacrifice, (2 Chr. xxx. 1, 2, &c.) The modern Jews observe in general the same ceremonies that were practised by their ancestors, in the celebration of the passover. On the fourteenth of Nisan, the first-born fell in memory of God's息ting the first-born of the Egyptians. The morning prayers are the same as those paid on other festivals. They take the roll of the pentateuch out of the chancels, and read it as far as the end of the twelfth chapter of Exodus, and what is contained in the eighteenth chapter of Numbers, relating to the passover. The matrion of the family then spreads a table, and sets on it two unleavened cakes, and two pieces of the lamb, a shoulder boiled and another stewed, to put them in mind that God delivered them with a stretched out arm. To this they add some small fishes, because of the leviathan; a hard egg, because of the viz.; some meal, because of the festa of John (these three animals being appointed for the feast of the children in the other life); and peas and nuts for the children to provoke their curiosity to ask the reason of this ceremony. They likewise use a kind of mustard, which has the appearance of mortar, to represent their making bricks in Egypt. The father of the family sits down with his children and slaves, because on this day all are free. Being set down, he takes bitter herbs, and dips them in the mustard, then eats them, and distributes to the rest. Then they eat of the lamb, the history and institution of which is at that time recited by the master of the family. The whole repast is attended with hymns and prayers. They pray for the prince under whose dominion they live, according to the advice of Jeremiah (xxix. 7.), "Seek the peace of the city whither I have caused you to be carried away captives, and pray unto the Lord for it: for in the peace thereof shall ye have peace." See the article Pray., &c. The same things are put in practice the two following days; and the festival is concluded by the ceremony hadala or disfinition. This ceremony is performed at the closing of the Sabbath-day, at which time the master of the house pronounces certain benedictions, accompanied with certain formalities, requesting that every thing may succeed well the week following. After going out of the synagogue, they then eat leavened bread for the last time. (Leo of Vol. XIV. Modena,
PAS [18]

PASSOVER, PASSPORT

Modena, p. iii. c. 3, and the Rabbins.) While the temple was standing, they brought their lambs thither, and sacrificed them, offering the blood to the priest, who poured it out at the foot of the altar. The passover was typically predictive of Christ our christian passover, (1 Cor. v. 7.) As the destroying angel passed over the houses marked with the blood of the passchal lamb, so the wrath of God passes over them whose souls are sprinkled with the blood of Christ. The passchal lamb was killed before Israel was delivered, so it was necessary Christ should suffer before we could be redeemed. It was killed before Moses's law or Aaron's sacrifices were enjoined, to show that deliverance comes to mankind by none of them; but only the true passover, that lamb of God slain from the foundation of the world, (Rom. iii. 25, Heb. ix. 14.) It was killed the first month of the year, which prefigured that Christ should suffer death in this month, (John xviii. 28.) It was killed in the evening, (Exod. xix. 6.) So Christ suffered in the last days, and at this time of the year, (Matt. xxvii. 46, Heb. i. 2.) At even also the fun feits, which shows that it was the Sun of Righteousness who was to suffer and die, and that in his passion universal darkness should be upon the whole earth, (Luke xxvii. 44.) 'The passover was reclined with fire, to denote the sharp and dreadful pains which Christ should suffer, not only from men, but from God also. It was to be eaten with bitter herbs, not only to put them in remembrance of their bitter bondage in Egypt, but also to typify our mortification to sin, and readiness to undergo afflictions for Christ, (Col. i. 24.) Many erroneously imagine, that the passover was instituted in memory of the Israelites passing the Red Sea; though it is certain the feast was held, and had its name, before the Israelites took a leaf of their way out of Egypt, and consequently several days before their passing the Red Sea. Besides the passover celebrated on the fourteenth of the first month, there was a second passover held on the fourteenth of the second month after the exodus, instituted by God in favour of travellers and sick persons who could not attend at the first, nor be at Jerusalem on that day. The Greeks, and even some of the catholic doctors, from the thirteenth, eighteenth, and nineteenth chapters, of St John, take occasion to conclude, that Jesus anticipated the day marked for the passover in the law; but the authority of three evangelists seems to evince the contrary. See Whitby's Dissertation on this subject, in an appendix to the fourteenth chapter of St Mark. F. Lamy supposes, that our Lord did not attend at the passover the last year of his life; which sentiment has drawn upon him abundance of opposers. F. Hardouin afferts, that the Galileans celebrated the passover on one day, and the Jews on another.

PASSPORT, or PASS, a licence or writing obtained from a prince or governor, granting permission and a safe conduct to pass through his territories without molestation: Also a permission granted by any state to navigate in some particular sea, without hindrance or molestation from it. It contains the name of the vessel, and that of the master, together with her tonnage and the number of her crew, certifying that she belongs to the subjects of a particular state, and requiring all persons at peace with that state to suffer her to proceed on her voyage without interruption.

The violation of safe-conducts or passports expressly granted by the state or by its ambassadors to the subjects of a foreign power in time of mutual war, or committing acts of hostility against such as are in amity, league or truce with us, who are here under a general implied safe conduct, are breaches of the public faith, without which there can be no intercourse or commerce between one nation and another; and such offences may according to the writers upon the law of nations, be a proper ground of a national war. And it is enacted by the statute 51 Hen. VI. cap. 4. fill in force, that if any of the king's subjects attempt or offend upon the sea, or in any port within the king's obedience, or against any stranger in amity, league, or truce, or under safe-conduct, and especially by attacking his person, or spoiling him, or robbing him of his goods; the lord chancellor, with any of the justices of either the king's-bench or common-pleas, may cause full restitution and amendments to be made to the party injured. Paquier says, that passport was introduced for passe partout. Balzac mentions a very honourable passport given by an emperor to a philosopher in these terms: "If there be any one on land or sea hardy enough to molest Potamon, let him consider whether he be strong enough to wage war with Caesar."

PASSPORT is used likewise for a licence granted by a prince for the importing or exporting merchandizes, moveables, &c. without paying the duties. Merchants procure such passports for certain kinds of commodities; and they are always given to ambassadors and ministers for their baggage, equipage, &c.

PASSPORT is also a licence obtained for the importing or exporting of merchandizes deemed contraband, and declared such by tariffs, &c. as gold, silver, precious stones, ammunition of war, horses, horn, wool, &c. upon paying duties.

PASSUS, among the Romans, a measure of length, being about four feet ten inches, or the thousandth part of a Roman foot. The word properly signifies, the space between the feet of a man walking at an ordinary rate. See MEASURE.

PASTE, in cookery, a soft composition of flour, wrought up with proper fluids, as water, milk, or the like, to serve for puddings or pastries, therein to bake meats, fruits, &c. It is the ball or foundation of pies, tarts, patties, pâtés, and other works of pastry. It is also used in confectionary, &c. for a preparation of some fruit made by beating the pulp thereof with some fluid or other admixture, into a soft pappy consistence, spreading it into a dish, and drying it with sugar, till it becomes as pliable as an ordinary paste. It is used occasionally also for making the crusts and bottoms of pies, &c. Thus, with proper admixtures, are made almond pastes, apple pastes, apricot pastes, cherry, currant, lemon, plum, peach, and pear pastes.

Paste is likewise used for a preparation of wheat flour, boiled up and incorporated with water; used by various artificers, as upholsterers, saddlers, bookbinders, &c. instead of glue or size, to fasten or cement their cloths, leathers, papers, &c. When paste is used by bookbinders, or for paper hangings to rooms, they mix a fourth, fifth, or sixth, of the weight of the flour of powdered rye; and where it is wanted still more tenacious,
PASTEBOARD, a kind of thick paper, formed of several single sheets pasted upon one another. The chief use of pasteboard is for binding books, making letter-cases, &c. See Paper.

PASTERN, or PASTER, among painters, a kind of palete made of different colours ground up with gum-water, in order to make Crayons.

PASTIL, in pharmacy, is a dry composition of sweet-smelling resin, aromatic woods, &c. sometimes burnt to clear and scent the air of a chamber.

PASTIME, a sport, amusement, or diversion. Pastimes of some kind seem to be absolutely necessary, and to none more than to the man of study; for the most vigorous mind cannot bear to be always bent. Constant application to one pursuit, if it deeply engage the mind, and to generate madness: of which the Don Quixote of Cervantes, and the almoner of Johnson, are two admirably conceived instances. But though pastime is necessary to relieve the mind, it indicates great frivolity when made the business of life; and yet the rich and the great, who are not obliged to labour for the means of subsistence, too often rove from pastime to pastime with as constant avidity as the mechanic toils for his family, or as the philosopher devotes himself to the cultivation of science. When those pastimes tend to give relish to the mind or strength to the body, such conduct is not only allowable, but praiseworthy; but when they produce effects the reverse of these, it is both hurtful and criminal. The gaming-table, the masquerade, the midnight assembly of any fort, must of necessity enfeeble both the body and the mind; and yet such are the fashionable amusements of the present day, to which many a belle and many a beau sacrifice their beauty, their health, their quiet, and their virtue.

Far different were the pastimes of our wiser ancestors. Remote from vice and effeminacy, they were innocent, manly, and generous exercises. From the ancient records of this country, it appears that the sports, amusements, pleasures, and recreations, of our ancestors, as described by Fitz Stephen (a), added strength and agility to the wheels of state mechanism, while they had a direct tendency towards utility. For most of those ancient recreations are resolvable into the public defence of the state against the attacks of a foreign enemy. The play at ball derived from the Romans, is first introduced by this author as the common exercise of every school boy. The performance was in a field, where the refolt of the most martial and considerate citizens, to give encouragement and countenance to this sort of agility, was splendid and numerous. The intention of this amusemenit at this period of time was to make the juvenile race active, nimble, and vigorous; which qualities were requisite whenever their assistance should be wanted in the protection of their country. The next species of pastime indeed does not seem to have this tendency; but it was only, as it seems, an annual eulogium: This was cock fighting. The author tells us, that in the afternoon of Shrove-Tuesday, on which day this custom prevailed, they concluded the day in throwing the ball: which seems to intimate, that the cock fighting was merely in conformity to ancient usage, and limited only to part of the day, to make way for a more laudable performance. We may reasonably suppose, although this author is entirely silent upon this head, that while cock-fighting was going on, cock throwing was the sport of the lowest class of people, who could not afford the expense of the former (a). Another species of manly exercise was truly martial, and intended to qualify the adventures for martial discipline. It is related by Fitz-Stephen thus: "Every Friday in Lent, a company of young men comes into the field on horseback, attended and conducted by the best horsemen: then march forth the sons of the citizens, and other young men, with disarmed lances and shields; and there practise feats of war. Many courtiers likewise, when the king is near the spot, and attendants upon noblemen, do repair to these exercises; and while the hope of victory does inflame their minds, they show by good proof how serviceable they would be in martial affairs."

C 2

This

(a) Otherwise called William Stephanides, a monk of Canterbury, who lived in the reign of King Stephen, to the time of Richard I. He wrote a Latin treatise, in which he gives an account of the several pastimes which were countenanced in his time. Bale in his writings draws a pleasing portrait of him. He is likewise sketched in strong and forcible outlines of praise and commendation by Leland. Bale says thus of him: "The time which other people usually misemployed in an idle and frivolous manner, he consecrated to inquiries which tended to increase the fame and dignity of his country: in doing which he was not unworthy of being compared to Plato; for, like him, he made the study of men and heaven his constant exercise."

(b) There were places set apart for the battles of these animals, as at this day, where no one was admitted without money. These places, commonly called pits, were schools, as at this day, in which people were instructed in the doctrines of chance, lots and gains, betting and wagers, and particularly in the liberal art of laying two to one. Cock-throwing has been laudably abolished: for it was a species of cruelty towards an innocent and useful animal; and such cruelty as would have kindled compassion in the heart of the most barbarian.
This evidently is of Roman descent, and immediately brings to our recollection the *Ludus Trojus*, supposed to be the invention, as it was the common exercise, of Aulus Gallus. The common people, in this age of masculine manners, made every amusement where strength was exerted the subject matter of instruction and improvement: instructed to exert their bodily strength in the maintenance of their country's rights; and their minds improved, by such exertion, into every manly and generous principle.

In the vacant intervals of industry and labour, commonly called the holy-days, indolence and inactivity, which at this day mark this portion of time, were found only in those whose lives were distempered with age or infirmity.

The view which Fitz-Stephen gives of the Easter-holydays is animated, "In Easter-holydays they fight battles upon the water: A shield is hanged upon a pole, fixed in the middle of the stream. A boat is prepared without oars, to be borne along by the violence of the water; and in the forepart thereof standeth a young man, ready to give charge upon the shield with his lance. If so be that he break his lance against the shield, and doth not fall, he is thought to have performed a worthy deed. If without breaking his lance he runs strongly against the shield, down he falleth into the water; for the boat is violently forced with the tide; but on each side of the shield ride two boats, furnished with young men, who recover him who falleth as soon as they may. In the holydays all the summer youths are exercised in leaping, dancing, wrestling, calling the stone, and prafiding their shields; and the maidens trip with their timbrels, and dance as long as they can well fare. In winter, every holy-day before dinner, the boors prepared for brawn are set to fight, or else bulls or bears are baited."

These were the laudable pursuits to which leisure was devoted by our forefathers, so far back as the year 1150. Their immediate successors breathed the same generous spirit. In the year 1222, the 6th year of Henry III., we find, that certain masters in exercises of this kind made a public profession of their instructions and discipline, which they imparted to those who were desirous of attaining excellence and victory in these honourable achievements. At this period, the persons of better rank and family introduced the play of *Tennis* (c); and erected courts or oblong edifices for the performance of the exercise.

About the year 1253, in the 38th year of Henry III., the *Quintana* was a sport much in fashion in almost every part of the kingdom. This contrivance consisted of an upright post firmly fixed in the ground, upon the top of which was a cross piece of wood, moveable upon a spindle; one end of which was broad like the flat part of an halberd, while at the other end was hung a bag of sand. The exercitum was performed on horseback. The more lively performance was, when, upon the broad part being struck with a lance, which sometimes broke it, the assailant rode swiftly on, so as to avoid being struck on the back by the bag of sand, which turned round instantly upon the stroke given with a very swift motion. He who executed this feat in the most dexterous manner was declared victor, and the prize to which he became intitled was a peacock. But if upon the aim taken, the contender miscarried in striking at the broadside, his impotency of skill became the ridicule and contempt of the spectators.

Dr Plot, in his Natural History of Oxfordshire, tells us, that this pastime was in practice in his time at Deddington in this county. "They first (says this author) fixed a post perpendicularly in the ground, and then placed a small piece of timber upon the top of it, fastened on a spindle, with a board nailed to it on one end, and a bag of sand hanging at the other. Against this board they anciently rode with spears: now as I saw it at Deddington only with strong shaves, which violently bringing about the bag of sand, if they make not good speed away, it strikes them in the neck or shoulders, and sometimes perhaps strikes them down from their horses; the great design of the sport being to try the agility both of man and horse, and to break the board; which, whoever did, was accounted conqueror: for whom heretofore there was some reward always appointed." (d)

Matthew Paris, speaking of this manly diversion, says

(c) The word *Tennis* seems to owe its original to the French language: if so, the game is of French production. Yet the word *tennis* will hardly be found to afford incontrovertible evidence upon this subject. For the holding or keeping possession of the ball is not part of the game, but rather a circumstance casually attending it: since, during the performance of it, the ball is in continual motion, so there can be no *tennis* at this juncture. Perhaps a place in France called *Tennis* (as there is a town which differs only in a letter, called *Sennais*, in the district of Champagne) was the place where the balls were first made, and the game first introduced.

(d) This was certainly an exercise derived from a military institution of the Romans, though not instrumentally the same. Whoever considers the form and disposition of the Roman camps, which were formed into a square figure, will find there were four principal gates or passages. Near the *Quadriorium*, or *Quadror's* apartment, was the *Forum*, or what is now called a futting-house, and from being near the *Quadrior's* station called *Quadriorium forum*. At this part was a fifth gate *Quintana*, where the soldiers were instructed in the discipline of the *Paliares*, which was to aim at and strike their javelins against an upright post fixed in the ground, as a kind of *profulio* to a real engagement with an enemy. By the frequent practice of this exercise, sometimes called *exercitium ad palum* by Roman writers, the soldiers at length acquired not only a dexterity and address in the management of their arms, but a constant and regular exactness in the direction of them. *Titus Livius Patrickus*, cap. 2. *Pancratus Rumor Memoralis*. lib. ii. tit. 21. *Vitruvius in Augustian Monumentis*, lib. ii. p. 237.

Upon the irruption of the *Ifri* into the Roman camps, which they plundered, says Livius, *ad Quadriorium forum*, *quintanamque pervenerunt*. 

There are many places at this day, formerly report-ed to, for the practice of this noble art, distinguished by appellations which indicate their ancient usage: such as Brentford Butts, Newington Butts, and many others of the like denomination. It appears from 33 Hen. VIII. that by the intrusion of other pernicious games, archery had been for a long time diluted; to revive which this statute was made. It seems that the bows or the belt kind were made of yew; and that this wood might be readily obtained for this purpose, yew-trees were planted in churchyards. The sons of those only who were perfons of fortune and fashion, if under 17 years of age, were permitted to use such bows. The words of the statute are singular, and run thus: "No person under fourteen years, except he, or his father or mother, have lands or tenements to the yearly value of ten pounds, or be worth in value or movables the sum of forty marks sterling, shall shoot with any bow of yew, which shall be bought for him, after the seal of our Lady next coming, under the pain to lose and forfeit six shillings and eight-pence." Two observations arise here upon these words. One, that the yew-wood, not being so common as other wood, might probably be soon found deficient, as it was the best wood for making bows, if not restrained in the use of it to particular ages and persons, as young people wantonly destroy what is put into their hands for useful purposes. The other observation is, that the age of 17 is by this statute distinguished as the age of discretion, when young people are more attentive and con-fident in things of private concern; an age in these times which few ever arrive at, and some never. This statute makes provision of other kinds of wood for the common people in the following manner: "To the intent that every person may have bows of mean price, be it known, that every bowyer shall, for every bow that he makes of yew, make four other bows, meet to shoot with, of elm, hick, beaf, or other wood apt for the same, under pain to lose and forfeit for every such bow so lacking the sum of three shillings and fourpence." It seems there was a species of yew at this time called 6k, which wood was stronger and more plant than the common yew mentioned in this statute, and the price of it fixed. "Moreover, no bowyer shall fell or put to sale to any of the king's subjects, any bow of yew of the tax called 6k, above the price of three shillings and fourpence, under the pain to forfeit twenty shillings for every bow sold above the same price." From these several considerations which occur in this statute, we can trace three repellant qualities, courage, strength, and agility; which three united, inspired two more, generosity and magnanimity. Upon the decline of this and other polished (e) refinements, a savage deformity of manners sprung up, but.shanged.

(e) How widely different the conceptions of politeness at this day from what they were in the most refined ages of Greece and Rome! These two states agreed in fixing the standard of this accomplishment upon the fitness and propriety of things. Modern nations bend to an arbitrary imposture of language and manners which erewate the mind. To define politeness in its ancient and true sense, it is a manly exertion of conduct, founded upon every noble and virtuous principle. Much of the politeness of modern times is an effeminate impotence of demeanour, founded upon fallacy, evasion, and every insidious artifice. There can be no security, no...
Towards the beginning of James I.'s reign, military provosts seem to have founded a retreat (r). He, to gratify the importunity of the common people, and at the same time to obviate his own fears upon a refusal, published a book of sports, in which the people had been some time before usually indulged on Sunday evenings, but which had been lately prohibited. These sports consisted of dancing, fissing, wrestling, church plays, and other profane ins of that day.

Charles, his successor, wisely, in the very entrance of his reign, abolished these sports. The act of Charles states the several amusements in part; by which we may conjecture what was the remainder as stated in the book of sports by James. It is necessary to transfer that part of the act relating to this subject. "Forasmuch as there is nothing more acceptable to God, than the true and sincere worship of Him, and service according to His holy will, and that the holy keeping of the Lord's day is a principal part of the service of God, which in many places of this realm hath been, and now is, profaned and neglected by a disorderly sort of people, in exercising and frequenting bear-baiting, bull-baiting, interludes, common plays, and unlawful exercises and pastimes, neglecting divine service both in their own parishes and elsewhere: Be it enacted, that from and after forty days next after the end of this session of parliament, there shall be no meetings, assemblies, or concourse of people, out of their own parishes, on the Lord's day, within this realm of England, or any of the dominions thereof, for any sports or pastimes whatsoever: nor any bear-baiting, bull-baiting, interludes, common plays, or other unlawful exercises or pastimes, used by any person or persons within their own parishes: and that every person and persons offending in any of the said premises, shall forfeit for every offence the sum of three shillings and fourpence; the same to be employed and converted to the use of the poor of the parish where such offence shall be committed." All this was perhaps proper, and showed the distinguishing piety of this unfortunate monarch. But in this age likewise ended the manly sports of Britons, and nothing was introduced that could compensate for the loss.

All these licentious arts, considered as vehicles of pleasure, from the variety of their inventions, represent pleasure as a fleeting phantom; evincing at the same time the liability of happiness as springing from internal order. Even reflex acts, pregnant with future hopes of solace and social recreation, have more true feelings in expectancy than those which arise from the object in question. Nay, pleasure is found frequently in the imagination only: for Ixion's disappointment frequently awakens us when we advance to embrace this Juno of our desires.

Upon the whole, happiness, the only thing of intrinsic value, must aribe in the heart, and be something more solid than what mere amusements can possibly supply. Amusements or pastimes ought to be considered only as necessary relaxations from wearier and more useful employment; and in this point of view they may be safely pursued; but they become criminal when they occupy the place of the business of life.

PASTINACA, the Parner, a genus of the digynous order, belonging to the pennstata class of plants; and in the natural method ranking under the 45th order, Umbellifer. The fruit is an elliptical compressed plane; the petals are rustlated and entire. There are only two species of this genus; the principal of which is the *Pastinaca sativa*, or garden parner, which is an exhausting mealyulent root. It is to be propagated by sowing the seeds in February or March, in a rich mellow soil, which must be deep dug, that the roots may be able to run deep without hinderance.

It is a common practice to sow carrots at the same time, upon the same ground with the parners; and if the carrots are designed to be drawn young, there is no harm in it. The parners, when they are grown up a little, must be thinned to a foot distance, and carefully kept clear of weeds. They are finest tailed just at the fusion when the leaves are decayed: and such as are diiferous to eat in spring should have them taken up in autumn and preserved in kind. When the seeds are to be saved, some very strong and fine plants should be left four feet distance: and towards the end of August, or in the beginning of September, the seeds will be ripe: they must then be carefully gathered, and dried on a coarse cloth. They should always be sown the spring following, for they do not keep well.

Hints have been given and experiments made by agricultural societies respecting parners, in order to raise them for winter food to cattle. It has long been a custom in the parts of Brittany, to sow parners in the open field for the food of cattle; as we are informed by the first volume of the Transactions of a Society instituted in that province, for the encouragement of the economical and commercial interests of their country. "It is of great importance (say they) that parners should be universally cultivated; because they afford an excellent and wholesome food for all kinds of cattle during the winter, and may be used to great advantage to fatten them. Our hogs have no other food in all that season, and our bullocks and oxen thrive well upon it. Our cows fed with parners give more milk than with any other winter fodder, and that milk yields better butter than the milk of cows nourished with any other substance. Our horses fatten with this food; though some pretend that it renders them less mettle, and hurts their legs and eyes. Cattle eat these roots raw at first sliced lengthwise;

pinefs, no prosperity, awaiting those who fawn to fathions that disgrace humanity, and so manners which confit more of artificial afection than of manly freedom.

(r) It hath been confidently asserted by some historians, that James was, during his whole life, struck with terror upon the sight of a drawn sword; which was the reason of his great unwillingness in bellowing the honour of knighthood. For at this juncture, he had such a tremor upon him, that instead of laying the sword upon the shoulder of the person to be knighted, he frequently would be observed almost to thrust the point of it into the face of the party; which occasioned thes about him to assist him in the direction of his hand.
PASTORAL

In general, something that relates to shepherds: hence we lay, pastoral life, manners, poetry, &c.

Pastoral life may be considered in three different views; either such as it now actually is; when the state of shepherds is reduced to a mean, servile, and laborious state; when their employments are become disagreeable and their ideas grofs and low; or such as we may fancy it once to have been, in the more early and simple ages, when it was a life of ease and abundance; when the wealth of men consisted chiefly in flocks and herds, and the shepherd, though unreined in his manners, was respectable in his state; or, lastly, such as it never was, and never can in reality be, when, to the ease, innocence, and simplicity of the early ages, we attempt to add the polished taste, and cultivated manners, of modern times. Of these three states, the first is too grofs and mean, the last too refined and unnatural, to be made the ground-work of pastoral poetry. Either of these extremes is a rock upon which the poet will split if he approach too near it. We shall be difgusted if he give us too much of the servile employments and low ideas of actual peasants, as Theocritus is cenfured for having sometimes done; and if, like some of the French and Italian writers of pastoral, he makes his shepherds diffuse as if they were courtiers and philosophers, he then retains the name only, but wants the spirit of pastoral poetry.

PASTORAL POETRY. See POETRY, Part IV. Sect. IV.

PASTRY, that branch of cookery which is chiefly taken up in making pies, pasties, cakes, &c. See PASTRY.

Dr Cullen observes, that paife is very hard and indigestible without butter; and even with it, is apt to produce heart-burn and acidness. Perhaps this is increased by the burned butter, from a certain fehnibility in the stomach, which occasions all empyreumatic oils to be long retained, and so turn rancid and acid.

PASTURE, or PASTURE LAND, is that reffered for feeding cattle.

Pasture land is of such advantage to husbandry, that many prefer it even to corn-land, because of the small hazard and labour that attends it; and as it lays the foundation for most of the profit that is expected from the arable land, because of the manure afforded by the cattle which are fed upon it. Pasture ground is of two sorts; the one is meadow land, which is often overflowed; and the other is upland, which lies high and dry. The first of these will produce a much greater quantity of hay than the latter, and will not require manuring or dressing so often; but then the hay produced on the upland is much preferable to the other; as is also the meat which is fed in the upland more valued than that which is fattened in rich meadows; though the latter will make the fatter and larger cattle, as is seen by those which are brought from the low rich lands in Lincolnshire. But where people are nice in their meat, they will give a much larger price for such as hath been fed on the downs, or in short upland pasture, than for the other which is much larger. Besides this, dry pastures have an advantage over the meadows, that they may be fed all the winter, and are not so subject to poach in wet weather; nor will there be so many bad weeds produced; which are great advantages, and do in a great measure recom pense for the smallness of the crop.

We have already mentioned the advanges of meadow land, or such as is capable of being overflowed with water, and given directions for draining and improving low pasturage land, under the article MEADOWS; therefore shall not repeat that here, but just mention some methods for improving of upland pasture.

The first improvement of upland pasture is, by fencing it, and dividing it into small fields of four, five, six, eight, or ten, acres each, planting timber trees in the hedge-rows, which will screen the grass from the dry pinching winds of March, which will prevent the grass from growing in large open lands; so that if April proves a dry month, the land produces very little hay; whereas in the sheltered fields, the grass will begin to grow early in march, and will cover the ground, and prevent the sun from parching the roots of the grass, whereby it will keep growing, so as to afford a tolerable crop if the spring should prove dry. But in fencing of land the inclosure must not be made too small, especially when the hedge-rows are planted with trees; because, when the trees are advanced to a considerable height, they will spread over the land; and where they are close, will render the grass sour; so that instead of being of an advantage, it will greatly injure the pasture.

The next improvement of upland pasture is, to make the turf good, where, either from the badness of the soil, or for want of proper care, the grass hath been destroyed by ruthes, bushes, or mole hills. Where the surface of the land is clayey and cold, it may be improved by parching it off, and burning it; but if it is an hot sandy land, then chalk, lime, marle or clay, are very proper manures to lay upon it; but this should be laid in pretty good quantities, otherwise it will be of little service to the land.

If the ground is over run with bushes or ruthes, it will be of great advantage to the land to grub them up towards the latter part of summer, and after they are dried to burn them and spread the ashes over the ground just before the autumnal rains; at which time the surface of the land should be levelled, and tawn with grase feed, which will come up in a short time, and make good gras the following spring. See also, when the land is full of mole hills, these should be pulled off, and either burnt for the ashes, or spread immediately.
Failure of turf to thicken, where it has been thus managed, will be of great service to roll the turf in the months of February and March with an heavy wood roller; always observing to do it in moist weather, that the roller may make an impression; this will render the surface level, and make it much easier to mow the grass than when the ground lies in hills; and will also cause the turf to thicken, so as to have what the people usually term a good bottom. The grass likewise will be the sweetest for this lastardy, and it will be a great help to destroy bad weeds.

Another improvement of upland pastures is, the feeding of them; for where this is not practised, the land must be manured at least every third year; and where a farmer hath much arable land in his possession, he will not care to part with his manure to the pasture. Therefore every farmer should endeavour to proportion his manure to his arable land, especially where manure is scarce, otherwise he will soon find his error; for the pasture is the foundation of all the profit which may arise from the arable land.

Whenever the upland pastures are mended by manure, there should be a regard had to the nature of the soil, and a proper sort of manure applied: as for instance, all hot sandy land should have a cool manure; neat's dung and swine's dung are very proper for such lands; but for cold lands, horse dung, ashes, and other warm manures, are proper. And when these are applied, it should be done in autumn, before the rains have fouked the ground, and rendered it too soft to cart on; and it should be carefully spread, breaking all the clods as small as possible, and then harrowed with bushels, to let it down to the roots of the grass. When the manure is laid on at this season, the rains in winter will wash down the salts, so that the following spring the grasses will receive the advantage of it.

There should also be great care taken to destroy the weeds in the pasture every spring and autumn: for, where this is not practised, the weeds will ripen their seeds, which will spread over the ground, and thereby fill it with such a crop of weeds as will soon overbear the grass and destroy it; and it will be very difficult to root them out after they have gotten such possession, especially ragwort, and such other weeds as have down adhering to their feeds.

The grass which is sown in these upland pastures seldom degenerates, if the land is tolerably good: whereas as the low meadows, which are overflowed in winter, in a few years turn to an harsh rufhy grass, though the upland will continue a fine sweet grass for many years without renewing.

There is no part of husbandry of which the farmers are in general more ignorant than that of the pasture; most of them suppose, that when old pasture is plowed up, it can never be brought to have a good sward again; so their common method of managing their land after ploughing, is to sow with their crop of barley some grass seeds as they call them; that is, either the red clover, which they intend to stand two years after the corn is taken off the ground, or rye-grass mixed with rye; but as all these are at most but biennial plants, whole roots decay soon after their seeds are perfected, so the ground, having no crop upon it, is again ploughed for corn; and this is the constant round which the lands are employed in by the better sort of farmers.

But whatever may have been the practice of these people, it is certainly possible to lay down lands which have been in tillage with grouts, in such a manner that the sward shall be as good, if not better, than any natural sward, and of as long duration. But this is never to be expected in the common method of sowing a crop of corn with the grass seeds; for, wherever this has been practised, if the corn has succeeded well, the grass has been very poor and weak; so that if the land has not been very good, the grass has rarely been worth saving; for the following year it has produced but little hay, and the year after the crop is worth little, either to mow or feed. Nor can it be expected to be otherwise, for the ground cannot nourish two crops; and if there were no deficiency in the land, yet the corn, being the first and most vigorous of growth, will keep the grasses from making any considerable progress: so that the plants will be extremely weak, and but very thin, many of them which come up in the spring being destroyed by the corn; for whenever there are roots of corn, it cannot be expected there should be any grass. Therefore the grasses must be thin; and if the land is not in good heart to supply the grasses with nourishment, that the roots may branch out after the corn is gone, there cannot be any considerable crop of clover; and as their roots are biennial, many of the strongest plants will perish soon after they are cut; and the weak plants, which had made but little progress before, will be the principal part of the crop for the succeeding year; which is many times not worth standing.

Therefore, when ground is laid down for grass, there should be no crop of any kind sown with the feeds; or at least the crop should be sown very thin, and the land should be well ploughed and cleaned from weeds, otherwise the weeds will come up the first, and grow so strong as to overbear the grasses, and if they are not pulled up, will entirely spoil it. The best season to sow the grass seeds upon dry land, when no other crop is sown with them, is about the middle of September or sooner, if there is an appearance of rain: for the soil of the ground being then filled with frosts, there happen some good flowers of rain after the seed is sown, the grasses will soon make its appearance, and get sufficient rooting in the ground before winter; so will not be in danger of having the roots turned out of the ground by frost, especially if the ground is well rolled before the frost comes on, which will press it down and fix the earth close to the roots. Where this hath not been practised, the frost has often loosen the ground so much, as to let in the air to the roots of the grasses, and done it great damage; and this has been brought as an objection to the annual sowing of grasses; but it will be found to have no weight if the above direction is practised: nor is there any hazard of fowing the grasses at this season, but that of dry weather after the feeds are sown; for if the grasses come up well, and the ground is well rolled in the end of October, or the beginning of November, and repeated again the beginning of March, the sward will be closely joined at bottom, and a good crop of hay may be expected the
the same summer. But where the ground cannot be prepared for sowing at that season, it may be performed the middle or latter end of March, according to the season's being early or late; for, in backward springs, and in cold land, we have often sowed the grass in the middle of April with success; but there is danger, in sowing late, of dry weather, and especially if the land is light and dry; for we have seen many times the whole surface of the ground removed by brooky winds at that season; 1. so that the seeds have been driven in heaps to one side of the field. Therefore, whenever the seeds are sown late in the spring, it will be proper to roll the ground well soon after the seeds are sown, to settle the surface, and prevent its being removed.

The forts of seeds which are the best for this purpose, are, the best fort of upland hay-seeds, taken from the cleanest pastures, where there are no bad weeds; if this seed is fitted to clean it from rubbish, three bushels will be sufficient to sow an acre of land.

The other fort is the trifolium pratense album, which is commonly known by the names white Dutch clover, or white biennial grass. Eight pounds of this seed will be enough for one acre of land. The grass seed should be sown first, and then the Dutch clover-seed may be afterwards sown; but they should not be mixed together, because the clover-seeds being the heaviest will fall to the bottom, and consequently the ground will be unevenly sown.

When the seeds are come up, if the land should produce many weeds, these should be drawn out before they grow so tall as to overbear the grass; for where this has been neglected, the weeds have taken such possession of the ground as to keep down the grass, and starve it; and when these weeds have been suffered to remain until they have filled their seeds, the land has been so plentifully flocked with them as entirely to destroy the grass; therefore it is one of the principal parts of husbandry never to suffer weeds to grow on the land.

If the ground is rolled two or three times at proper distances after the grass is up, it will prefs down the grass, and cause it to make a thicker bottom: for, as the Dutch clover will put out roots from every joint of the branches which are near the ground, so, by pressing down of the flanks, the roots will mat so closely together, as to form a sward so thick as to cover the whole surface of the ground, and form a green carpet, and will better resist the drought. For if we do not examine the common pastures in summer, in most of which there are patches of this white huy-fuckel grass growing naturally, we shall find these patches to be the only verdure remaining in the fields. And this, the farmers in general acknowledge, is the sweetest feed for all sorts of cattle; yet never had any notion of propagating it by seed, nor has this been long practiced in England.

As the white clover is an abiding plant, so it is certainly the very best fort to sow, where pastures are laid down to remain; for as the hay-seeds which are taken from the best pastures will be composed of various sorts of grass, some of which may be but annual, and others biennial; so, if they go off, there will be many and large patches of ground left bare and naked, if there is not a sufficient quantity of the white clover to spread over and cover the land. Therefore a good sward can never be expected, where this is not found; for in most of the natural pastures, we find this plant makes no small share of the feed; and it is equally good for wet and dry land, growing naturally upon gravel and clay in most parts of England; which is a plain indication how easily this plant may be cultivated to great advantage in most sorts of land throughout Great Britain.

Therefore the true cause why the land which has been in tillage is not brought to a good turf again, in the usual method of husbandry, is, from the farmers not distinguishing which grasses are annual from those which are perennial: for if annual or biennial grasses are worn, these will only suffer decay; so that, unless some of their seeds may have ripened and fallen, nothing can be expected on the land but what will naturally come up. Therefore this, with the covetous method of laying down the ground with a crop of corn, has occasioned the general failure of increasing the pasture in many parts of Britain, where it is now much more valuable than any arable land.

After the ground has been sown in this manner before directed, and brought to a good sward, the way to preserve it good is, by constantly rolling the ground with a heavy roller, every spring and autumn, as hath been before directed. This piece of husbandry is rarely practiced by farmers; but those who do, find their account in it, for it is of great benefit to the grass. Another thing should also carefully be performed, which is, to cut up docks, dandelion, knapweed, and all such bad weeds, by their roots every spring and autumn, that so the quantity of good grasses may be preserved in the pastures. Dressing of these pastures every third year is also a good piece of husbandry; for otherwise it cannot be expected the ground should continue to produce good crops. Besides this, it will be necessary to change the feasons of mowing, and not to mow the same ground every year, but to mow one feasion and feed the next; for where the ground is every year mown, it must be constantly dressed, as are most of the grass grounds near London, otherwise the ground will be soon exhausted.

Patæci, in mythology, images of gods which the Phœnicians carried on the prows of their galleys. Herodotus, lib. iv. calls them πατακά. The word is Phœnician, and derived from patak, i. e. πατάκα. See Bochart's Channa,i, lib. ii. cap. 3. But Scaliger does not agree. Morin derives it from πατακας, pastoris, this animal having been an object of worship among the Egyptians, and hence might have been honoured by their neighbours. Mr Elrner has observed, that Herodotus does not call the pataci gods; but that they obtained this dignity from the liberalitd of Hsyichis and Suidas, and other ancient lexicographers, who place them at the stern of ships; whereas Herodotus placed them at the prow. Scaliger, Bochart, and Selden have taken some pains about this subject. Mr Morin has also given us a learned dissertation on this head in the Memoires de l'Acad. des Inscription & Belles Lettres, tom. i.; but Mr Elrner thinks it defective in point of evidence.

Patagonia, a country of South America, comprehending all that country extending from Chili...
Patagonia, and Paraguay to the utmost extremity of South America; that is, from 35° almost to 54° of latitude; being surrounded by the countries just mentioned, the South and North Seas, and the Straits of Magellan, which separate it from the island called Terra del Fuego, and extend about 156 leagues in length from sea to sea, but only from half a league to three or four in breadth.

This country had the name of Terra Magellan, from Ferdinand Magellan, a Portuguese officer in the service of the Catholic king, who is reported to have sailed through the straits also bear his name, from the North to the South Sea, in the year 1519.

The lofty mountains of the Andes, which are covered with snow a great part of the year, traversing the country from north to south, the air is said to be much colder than in the north under the same parallels of latitude. Towards the north, it is said to be covered with wood, and floored with an inexhaustible fund of large timber; whereas, to the southward, not so much as a single tree fit for any mechanical purpose is to be seen; yet there is good pasture, and incredible numbers of wild horned cattle and horsies, which were first brought thither by the Spaniards, and have increased amazingly. Freth water, we are told by some writers, is very scarce: but if that were really the case, it is difficult to conceive how the present inhabitants and such multitude of cattle could subsist. The east coast is monily low land, with few or no good harbours: one of the best is Port St Julian.

Patagonia is inhabited by a variety of Indian tribes; as the Patagons, from which the country takes its name; the Pampas, the Coiffars, &c. of whom we knew very little. Only it appears, from the accounts of former voyagers, lately confirmed by Commodore Byron and his crew, and the testimonies of other navigators, that some of them are of a gigantic stature, and clothed with skins; but it would seem that there are others who go almost quite naked, notwithstanding the inclemency of the climate. Some of them also, that live along the Straits, if we may credit the navigators who have passed that way into the South Sea, are perfect savages; but those with whom Commodore Byron and his people conversed, are represented as of a more gentle, humane disposition; only, like other savages, they live on fish and game, and what the earth produces spontaneously.

The Spaniards once built a fort on the Straits, and left a garrison in it, to prevent any European nation passing that way into the South Sea: but most of the men perished by famine, whence the place obtained the name of Port Famine; and no people have attempted to plant colonies here ever since.

About the middle of the Strait is a promontory called Cape Froward, which is the most foutherly on the continent of South America.

On the coasts of Patagonia lie a great number of islands, or clusters of islands. On the west coast are the islands Maider de Dios, Santa Trinidad, Santa Cruz, and the islands of Chubains and Huillas, the Sarmentos, and many others to the number of 80 in all, as some fay. Of those on the south coast, the most confiderable are Terra del Fuego, and Staten Land. See the articles.

A vallt deal has been said respecting the stature of the Patagonians, by people of different nations, and Patagonians on various occasions. We shall insert the following letter from Mr Charles Clarke, who was on board Byron's ship in 1764, and gave this account to Dr Mitty.

"We had not got above 10 or 12 leagues into the straits of Magellan, from the Atlantic Ocean, before we saw several people, some on horseback, some on foot, upon the north shore (continent), and with the help of our glasses could perceive them beckoning to us to come on shore, and at the same time observing to each other, that they seemed to be of an extraordinary size: However, we continued to stand on, and should have passed without taking the least further notice of them, could we have proceeded; but our breeze dying away, and the tide making against us, we were obliged to anchor; when the Commodore ordered his boat of 12 oars, and another of six, to be hoisted out, manned and armed. In the first went the Commodore, in the other Mr Cummins, our first lieutenant, and myself. At our first leaving the ship, their number did not exceed 40; but as we approached the shore, we perceived them pouring down from all quarters, some galloping, others running, all making use of their utmost expedition. They collected themselves into a body just at the place we steered off for. When we had got within 12 or 14 yards of the beach, we found it a disagreeable flat shore, with very large stones, which we apprehended would injure the boats; so we looked at two or three different places to find the most convenient for landing. They suppos'd we deferred coming on shore through apprehensions of danger from them; upon which they all threw open the skins which were over their shoulders, which was the only clothing they had, and consequently the only thing they could secret any kind of arms with, and many of them lay down close to the water's edge.—

The Commodore made a motion for them to go a little way from the water, that we might have room to land, which they immediately complied with, and withdrew 30 or 40 yards; we then landed, and formed each man with his musket, in case any violence should be offered. As soon as we were formed, the Commodore went from us to them, then at about 20 yards distance; they seemed vailly happy at his going among them, immediately gathered round him, and made a rude kind of动ing, as their countenances bespoke it a species of jollity. The Commodore then made a motion to them to sit down, which they did in a circle, with him in the middle, when Mr Byron took some beads and ribbons, which he had brought for that purpose, and tied about the women's necks, with which they seemed infinitely pleased. We were struck with the greatest astonishment at the sight of people of such a gigantic stature, notwithstanding our previous notice with glasses from the ship. Their body was increased, by the time we got in there, to the number of 500 men, women, and children. The men and women both rid in the same manner; the women had a kind of belt to close their skins round the waist, which the men had not, as theirs were only thrown over their shoulders, and tied with two little slips, cut from the skin, round the neck. At the time of the Commodore's motion for them to retire farther up the beach, they
Patagonia, all dismounted, and turned their horses loose, which were gentle, and herd very quiet. The Commodore having disposed of all his presents, and satisfied his curiosity, thought proper to retire; but they were vastly anxious to have him go up into the country to eat with them. That they wanted him to go with them to eat, we could very well understand by their motion, but their language was wholly unintelligible to us.—There was a very great smoke to which they pointed about a mile from us, where there must have been several fires; but some intervening hills prevented our seeing anything but the smoke. The Commodore returned the compliment, by inviting them on board the ship; but they would not favour him with their company; so we embarked, and returned to the ship. We were with them near two hours at noon-day, within a very few yards, tho' none had the honour of shaking hands but Mr Byran and Mr Cummins; however, we were near enough, and long enough with them, to convince our senses, so far as not to be cavilled out of the very existence of those fires at that time, which some of our countrymen and friends would absolutely attempt to do. They are of a copper colour, with long black hair, and some of them are certainly nine feet, if they do not exceed it. The Commodore, who is very near fix feet, could but just reach the top of one of their heads, which he attempted on tip-toes, and there were several taller than him, on whom the experiment was tried. They are prodigiously stout, and as well and as proportionably made as ever I saw people in my life. That they have some kind of arms among them, is, I think, indubitable, from their taking methods to convince us they had none as I saw people in my life. That they have some producing nothing but a coarse harsh grafs, and a few small shrubs, of which Sir John Naborough remarked, he could not find one of size enough to make the helve of an hatchet; which observation we found very just. It was some time in the winter we made this visit to our gigantic friends. I am debarr'd being so particular as I could wish, from the loss of my journals, which were demanded by their Lordships of the Admiralty immediately upon our return.

That the whole of this account is true, we cannot pretend to assert; but that the writer has been misled in some respects, and misinformed with regard to some of his facts, is at least probable; for Captain Wallis, who went out to the Straits of Magellan after Byron's return, gives a different turn to many of the observations; and with respect to the stature of the people, he differs very materially. We shall give the following epitome of his remarks on what occurred to him.—He had three ships with him, which entered the Straits on the 16th December 1766, and came to an anchor in a bay south of Cape Virjan Mary, where they were immediately accosted by a whole troop of Patagonians, who made signs for them to come on shore. The Captain, having made previous dispositions for the security of his men in case of an attack, manned all the boats belonging to the three ships, and with a party of marines landed on the beach where those giants had assembled. The commanders of the three ships, and most of their officers, were of this party. On their leaping ashore, the Indians seemed to welcome them; and being by signs desired to retreat, they all fell back, and made room for the marines to form. When they were drawn up, Captain Wallis advanced, and by signs directed the Indians to seat themselves in a semicircle, which they readily understood and obeyed. He then distributed among them knives, scissors, buttons, brasses, combs, and particularly ribbons, with which he complimented the women, who received them with a mixture of pleasure and respect. He then gave them to understand that he had filled more valuable articles to bellow, and showed them axes and bill-hooks; but, at the same time, pointed to four of those in the circle, intimating that he expected some of those in return; but they either did not, or would not, understand him; so that no traffic took place.

The whole company that were assembled on this occasion, had each a horse, with a saddle and bridle. The saddle had a foot of stirrups, and the bridle was made of thongs of leather very well put together, for the purpose of guiding the horses. The women, as well as the men, rode astride. The men, in general, wore each a wooden spur; but one of them had a large pair of Spanich spurs, brass stirrups, and a Spanish bridle. Their horses were nimble and spirited, but small in proportion to their riders, seemingly not above 14 hands high. Their dogs were of the Spanich breed. The Captain having purposely provided himself with measuring rods, found that the tallest man among them measured only fix feet seven inches high; several were within an inch or two as tall; but the ordinary size was from five feet ten inches to fix feet. It is a pity that none of our voyagers thought of measuring the whole size of one of those gigantic men. They tell us, indeed, that they are well made, that they are proportionally large, and that they are robust and bony; but they give us no criterion to judge of their bulk, nor one instance of their extraordinary strength. As they are represented not only peaceable, but remarkably tractable, some trials might have been made of the weight they could have lifted, and how much they could exceed in that respect the strongest men in the ships. This in a great measure would have determined the point, which is yet left doubtful by the different relations that are given by the different voyagers who
Patagonia, who have been these people, no two of them agreeing in the same description. All agree, however, that their hair is black, and harsh like bristles; that they are of a dark copper colour, and that their features are rather handsome than ugly; that they clothe themselves decently with the skins of guanacoos; that they paint themselves variously; and there is reason to fluff up, that by that variety they distinguish their tribes. Those seen by Commodore Byron were painted round both eyes, no two of them alike; those seen by Captain Wallis had only a red circle round the left eye; and those seen by Bougainville had no circle round the eyes, but had their cheeks painted red. This may account for the different reports of voyagers concerning their stature: it is not impossible, nay, it is very probable, that they may vary in this particular, according to their tribes; as is seen in the Highlands of Scotland, where one clan of the Campbells is remarkably tall, and another of the Frairs remarkably short. Were it not for some such natural discrimination, there could not be so wide a difference in the descriptions of gentlemen, who, having no ends to serve either in falsifying one another's reports, or in imposing upon the public, cannot be supposed to mistake willfully.

One remarkable observation made by our voyagers must not be omitted; and that is, that though our people could distinguish but one word of their language, which the English pronounce chawacu, yet the Patagonians could repeat whole sentences after our men more distinctly than almost any European foreigner of what nation soever. This appears the more singular, as among the Indians between the Tropics, it was hardly possible to make them articulate any of our words. Sydney Parkinson, in a specimen he has given us, says, that though the English remained at Oahicite three months, the nearest natives could approach the sound of Cook was fatoa; Banks, Opacu; Solander, Talano; Gore, Towara; Monkey, Mata; and so of the rest: whereas the Patagonians presently got by heart this sentence of invitation, Come offere, Englishmen! which they showed they well understood, by repeating it afterwards whenever the ships came so near the shore as to be within call.

Another very remarkable particular is, that they had none of the characters of a ferocious people; there was no offensive weapon among them, except the club already mentioned. The men, indeed, had a kind of fling, which they use in hunting, consisting of two round flints of about a pound weight each, connected together by a thong. These flints were fastened to the extremities of the thong; and, when they threw them, they held one flint in the hand, and swung the other about the head. "They are so expert in the management of this double-headed fling (says the writer of the voyage), that they will hit a mark not bigger than a flilling with both these flints at the distance of fifteen yards; but their method of availing themselves of their dexterity against the guanaco or ollinco is, to string the flints so as to entangle their legs, by which means they are retarded in their flight, and easily overtaken. Bougainville speaks of these flings as common among other Indian nations in South America; but we do not remember to have seen this allertion confirmed by any other voyager.

These people certainly dress differently as well as paint differently; for the dress described by Bougainville is very unlike the dress of those seen by the English voyagers. Captain Wallis invited some of them on board his ship; but, among all the wonders that were shown them, none seemed to attract their notice so much as the looking-glasses; they looked in the glasses and at each other; they laughed and gazed, and gazed again and laughed; in short, there was no end to their merriment when in possession of this article of curiosity. They eat whatever was given them, but would drink nothing but water. In this they differ from all the tribes of Indians in North America, who are immoderately fond of spirituous liquors. They admired the European sheep, hogs, and poultry; but did not seem over-deferous of anything they saw except clothes. When the marines were exercised to entertain them, they appeared disconcerted; an old man among them made signs, by striking his breast, and tumbling down and lying as if he had been dead upon the deck, that he knew the effective of their guns; and one of them seemed easy till the firing was over. When the Captain had satisfied his own curiosity, and, as he imagined, theirs, he gave them to understand, that he was going to sail, and that they must depart; which they were very unwilling to do. However, having given each of them a canvas bag, with some needles ready threaded, a knife, a pair of scissors, a few beads, a comb, and a looking-glass, he dismissed them, with great reluctance on their part, particularly on that of the old man's, who by very significant signs expressed his desire to stay till funet.

Patagonula, in botany; a genus of the monogynia order, and of the pentandria class of plants. The characters are these: the cup is an extremely small perianthium, divided into five segments, and remains after the flower is fallen; the flower consists of a single petal, with almost no tube, the margin of which is divided into five acute oval segments; the stamens are five filaments of the length of the flower; the anthers are entire; the stigmatic part is oval and pointed; the style is slender and slightly bifid, its ramifications are also bifid; this is of the same length with the filaments, and remains when the flower is fallen, the stigmata are simple; the fruit is an oval and pointed capsule, standing on a large cup, made up of five long segments emarginated or rimmed round their edges; the seeds of this plant are yet unknown; but the conformation of the cup, in which the capsule stands, is alone a sufficient distinction for this genus. There is but a single species.

Patan, a kingdom of Asia, in the East Indies, and in the peninsula of Malacca, and on the eastern coast between the kingdoms of Siam and Paha. The inhabitants are partly Mahometans and partly Gentoo; but they are all very volupmtious. The air is wholesome, though very hot; and they have no seasons but the winter and summer. The former is more properly the rainy season; and contains the months of November, December, and January. The woods are full of elephants and many wild animals. Some voyagers pretend that this country is governed by a queen, who never marries, but may have as many gallants as the pleases. They have some trade with the Chinese; and the principal town is of the name, which is one
of the strongest in their parts, having a well defended harbour.

Patan, a town of Asia, and capital of a province of the same name, in the dominions of the Great Mogul; it is very little known. E. Long. 109. o. N. Lat. 27. 30. 

Pataavin, among critics, denotes a peculiarity of Livy's diction, derived from Patavium or Padua, the place of his nativity; but where in this patavinity confines, they are by no means agreed.

Aelius Pollio, according to Quintilius, taxed Livy with patavinity. But what he meant by this centre we believe no man can say. Morhof believes it to be a singular turn of expression, and some phrasal peculiar to the Paduans. All we certainly know about it is, that it was a fault in the language of Livy, not in the sentiments or manners. In all probability it is one of those delicacies that are lost in a dead language. Dan. Georg. Morhof published a treatise De Patavinitate Liviana, at Kiel, 1635, where he explains, very learnedly, the urbity and peregrinity of the Latin tongue.

Pataara (Livy, Mel.) the capital of Lycia, to the east of the mouth of the river Cydnus; famous for a temple and oracle of Apollo; hence called Patarurus, three syllables only; but Patarusae (Horace). For the fix winter months, Apollo gave answers at Patara; and for the fix summer at Delos, (Virgil, S. rivus): there are the Ly iae Sortes of Virgil. The town was situated in a peninsula, called Lixnum Charionus, (Stephanus.)

Adexi. 1. St Paul in his passage from Philippi to Jerusalem, came to Miletus, hence to Coos, then to Rhodes, and from Rhodes, to Patara; where having found a ship that was bound for Phenicia, he went on board and arrived at Jerusalem, to be at the feast of Pentecost.

Pataeium (Tacitus, Strabo), a town of the Trampadar, situated on the left or north bank of the Medoacus Minor; founded by Antenor the Trojan, (Melis, Virgil, Oeneus); Patarusae, the people, (Livy); who himself was a na ve, and by Aelius Pollio charged with patavinity. Now Padua, in the territory and to the west of Venice. W. Long. 12. 15. N. Lat. 45. 30.

Patay, a town of France, in the province of Orléannois, remarkable for the defeat of the English in 1429, and where Joan of Arc did wonders. E. Long. 1. 43. N. Lat. 48. 5.

Pate, in fortification, a kind of plattform, resembling what is called an horfis fonce.

Patee, or Pattee, in heraldry, a crest, small in the centre, and widening to the extremities, which are very broad.

Pattella, or Kneefan, in anatomy. See there, no 59.

Pattell, or Limpet, a genus of invertebrate animals. The kind of the shell kind. The shells are of that clafs which is called unidens; they have no concave and are in the form of little pointed cones. They are always attached to some hard body. Their summit is sometimes acute, sometimes obtuse, flatted, turned back, or perforated. The rock or other hard body to which they are always attached adheres, serve, as a kind of second or under shell to preserve them from injury; and for this reason Alcorvandus and Rondelet have clasped them among the bivalves; but in this error they have not been followed by any other writer. Fabius Columna distinguishes four sorts of the lepas or limpets: lepas vulgaris, a sort very common at Naples, of an oval figure and ash colour. Lejas major castra, which comes from Spain, the shell is hard, thick, and ribbed in angles, and the rim is dentilate. The lepas angea, or Cyphora, is such a small shell, irregularly oval, of an ash colour, marked with radii and zones crossing each other, and perforated at the top by an aperture which serves the fish for a vent. And the patella regula, qua regi magna digerat, this is of a mother-of-pearl colour within, and is ribbed and perforated in many places: these shells have been found on the back of the sea-tortoise, or turtle, and on a large pine marina. The differing mark or characteristic of the lepas is to have but one convex shell, which abides by its rim to a rock, or some other hard substance. There are 36 species of this genus, which are principally distinguished by peculiarities in their shells. Of some of these shells we have given engravings in Plate CCLXXXI. of which we add the following description:

The limpet marked 1. has large yellow furrows and ridges from the centre to the circumference, which is indented; the eye is perfectly white, and shaped like a nipple.

That marked 2. is perfectly smooth, but radiated with brown stipples, and perforated in the summit.

Fig. 3. is ribbed, and indented at the circumference; its coat is spotted with brown, in a zig-zag form, and its eye is of a ruby colour.

Fig. 4. is a small brown shell, the ribs or frize of which are armed with small white points.

Fig. 5. is striated with radii, reaching from the eye to the circumference, which are crested by other stipples nearly parallel to the circumference; it is of the usual colour, and its eye is perforated.

Fig. 6. is white, shaped something like an hour shell, and has within a protuberance somewhat resembling a clapper.

Fig. 7. is a seven-sided limpet, divided at each angle by ridges from the summit, which form a star on a white ground, variegated with black spots.

Fig. 8. is a small ribbed shell, of a brown colour, and rough; it has a chamber, and a beak fashioned eye placed at one of its extremities.

Fig. 9. is the finest shell of this species; its size, the fine mother of pearl colour on the inside, and the beauty of its red spots without, which have the appearance of tortoise shell, give it the pre-eminence over all others. It is called the Tortoise shell buckler.

The wild limpet, or patella ferre, is a name very improperly applied by Rondllitis and Aldrovand to the aures marine, or clunca veneris, which certainly is not of the patella kind.

Patella, in the History of Insects, a name given by Linnaeus and other authors to a little huick or shell, found on the back of the cherry, plum, rose, and other trees, containing an animal within, and useful in colouring. These patellas are of the form of globes, except when they adhere to the tree, and are for the most part of a shining crimson colour. The huick itself strikes a very fine crimson colour on paper, and within it is found a white maggot which is of no value: this, in time hatches into a very small but beautiful bee. The size of this bee is about half that of an
PAT

PAT [39] PAT

They have a fissing like bees; and three spots placed in a triangle on the forehead, which are supposed to be eyes. They are of a black colour, and have a large round whitish or pale yellow spot on the back. The upper pair of wings are shaded and spotted, but the under pair are clear. It may be worth while to try the shells or husks in order to discover whether the colour they yield might not be useful. It is to be remarked, that the deepcoloured husks afford the finest and deepest purple; they must be used while the animal in them is in the maggot-form; for when it is changed into the bee state the shell is dry and colourless. Lifer, who first observed these patelle, went so far on comparing them with the common kermes, as to assert that they were of the same nature with that production; but his account of their being the workmanship of a bee, to prefer her young maggot in, is not agreeable to the true history of the kermes; for that is an insect of a very peculiar kind. He has in other instances been too fully confounded for his precipitancy of judging of things, and perhaps has fallen into an error by means of it. It is very possible that these paterae may be the same for it is to some animals with the kermes, but then it produces its young within the shell or hulk, which is no other than the skin of the body of the mother animal; but as there are many flies whose worms or maggots are lodged in the bodies of other animals, it may be that this little bee may love to lay its egg in the body of the proper insect, and the maggot hatched from that egg may eat up the proper progeny; and, undergoing its own natural changes there, issue at length in form of the bee. This may have been the case in some few which Dr Lister examined; and he may have been misled by this to sup­pose it the natural change of the insect.

PATENT, in general, denotes something that stands open or expanded: thus a leaf is said to be a patent, when it stands almost at right angles with the stalk.

PATENT, or LETTER Patent. See LETTER.

PATER NOSTER, the Lord's Prayer, so called from the two first words thereof in Latin.

PATER NOBILIS, islands of Asia, in the East Indian sea, so called because of the great number of rocks, which sailors have likened to the beads with which the Papists tell their pater wotter. They abound in corn and fruits, and are very populous.

PATER PATRATUS, was the name of the first and principal person of the college of heralds called Pictia. Some say the Pater Patratus was a confant officer and per­sonal chief of that body; and others suppose him to have been a temporary minister, elected upon account of making peace or denouncing war, which were both done by him. See PICTI.

PATERA, among antiquaries, a goblet or vessel used by the Romans in their sacrifices; wherein they offered their consecrated meats to the gods, and where­with they made libations. See SACRIFICE and LIBA­TION.

The word is Latin, formed from pater, "I am open," quod pat. a, because it has a great aperture; in contradistinction to bottles, &c. which have only narrow necks, or whose aperture is less than the body of the vessel.

On medals the patera is seen in the hands of several deities; and frequently in the hands of princes, to Paterculus mark the facerdotal authority joined with the imperial, &c.

Hence F. Joubert observes, that beside the patera, there is frequently an altar upon which the patera seems to be pouring its contents.

The patera was of gold, silver, balsam, brass, glass, or earth; and they used to inclose it in urns with the ashes of the deceased, after it had served for the libations of the wine and liquors at the funeral.

The patera is an ornament in architecture, frequently seen in the Doric freeze, and the tympanums of arches; and they are sometimes used by themselves, to ornament a spandrel; and in this case it is common to hang a string of husks or drapery over them; sometimes they are much enriched with foliage, and have a mask or head in the centre.

PATERCULUS (Caius Velleius), an ancient Roman historian, who flourished in the reign of Tiberius Cesar, was born in the year of Rome 735. His ances­tors were illustrious for their merit and their offices. His grandfather espoused the party of Tiberius Nero, the emperor's father; but being old and infirm, and not able to accompany Nero when he retired from Naples, he ran himself through with his sword. His father was a officer of rank, and so was Paterculus himself. He was a military tribune when Caius Cesar, a grand son of Augustus, had an interview with the king of the Partians, in an island of the river Euphrates, in the year 753. He commanded the cavalry in Germany under Tiberius, and accompanied that prince for nine years successively in all his expeditions. He re­ceived honourable rewards from him; but we do not find that he was preferred to any higher dignity than the praetorship. The praises he bestowed upon Sejanus give some probability to the conjecture, that he was looked upon as a friend of this favourite, and conse­quently that he was involved in his ruin. His death is placed by Mr Dodwell in the year of Rome 784, when he was in his 50th year.

He wrote an Abridgement of the Roman History in two books, which is very curious. His purpose was only to deduce things from the foundation of Rome to the time wherein he lived; but he began his work with things previous to that memorable era: for, though the beginning of his first book is wanting, we yet find in what remains of it, an account of many cities more ancient than Rome. He promised a larger history, and no doubt would have executed it well; for during his military expeditions he had seen, as he tells us, the provinces of Thrace, Macedonia, Asia, Asia Minor, and other more easterly regions; especially upon the shores of the Euxine sea, which had furnished his mind with much entertaining and useful knowledge. In the Abridgement which we have, many particulars are related that are no where else to be found; and this makes it the more valuable. The style of Paterculus, though mitterably disguised through the careless­ness of transcribers, and imposible to be restored to purity for want of manuscripts, is yet manifestly worthy of his age, which was the time of pure Latinity. The greatest excellence of this historian lies in his manner of com­mending and blaming those he speaks of; which he does in the finet terms and most delicate expressions. He is, however, condemned, and indeed with the greatest
The chromatic genus, with its greater and less raisins, either ascending or descending, is very proper for the pathetic; as is also an artful management of discord, with a variety of motions, now brisk, now languishing, now swift, now slow.

Nieuwenhuyse speaks of a musician at Venice who so excelled in the pathetic, that he was able to play any of his auditors into distraction: he says also, that the great means he made use of was the variety of motions, &c.

PATHOGENOMONIC, among physicians, an appellation for a symptom, or concourse of symptoms, that are inseparable from a derangement, and are found in that only, and in no other.

PATHOLOGY, that part of medicine which explains the nature of diseases, their causes and symptoms. See Medicine.

PATHOS, a Greek term, literally signifying passion.

PATHROS, a city and capital of Egypt, of which the prophets Jeremiah and Ezekiel make mention; Jerem. xlv. 15. Ezek. xix. 14. xxx. 14. We do not very well know its situation, though Pliny and Ptolemy the geographer speak of it by the name of Pharaonis; and it appears to have been in Upper Egypt. Ifaiah (xii. 2.) calls it Pathros; and it is the country of the Pathruim, the povertv of Mizraim, of whom Moses speaks, Gen. x. 14. Ezekiel threatens them with an entire ruin. The Jews retired thither not withstanding the remonstrances of Jeremiah; and the Lord says by Isaiah, that he will bring them back from thence.

PATIENCE, that calm and unoffended temper with which a good man bears the evils of life, from a conviction that they are at least permitted, if not sent, by the hand of Being, who makes all things work together for good to those who love and fear him.

The evils by which life is embittered may be reduced to these four: 1. Natural evils, or those to which we are subject as men, and as perishing animals. The greatest of these, are the death of those whom we love, and of ourselves. 2. Those from which we might be exempted by a virtuous and prudent conduct, but which are the inevitable consequences of imprudence or vice, which we shall call punishments; as infamy proceeding from fraud, poverty from prodigality, debility and disease from intemperance. 3. Those by which the fortune of the good are exercised; such as the perfections raised against them by the wicked. To these may be added, 4. The opposition against which we must perpetually struggle, arisii from the diversity of sentiments, manners, and characters of the persons among whom we live.

Under all these evils patience is not only necessary but useful: it is necessary, because the laws of nature have made it a duty, and to murmur against natural events is to affront providence; it is useful, because it renders our sufferings lighter, shorter, and less dangerous.

Is your reputation fulfilled by invincible calumnies? rejoice that your character cannot suffer but by false imputations. You are arraigned in a court of judicature; and are unjustly condemned: passion has influenced both your prosecutor and your judge, and you cannot forbear repining that you suffer although in-
maintain the dignity of their nature. To feel for patience others, dipoese us to exercise the amiable virtue of
tunity, which our religion indisputably requires.
It constitutes that enlarged benevolence which phi-
osophy inculcates, and which is indeed com-
prehended in Christian charity. It is the privilege
and the ornament of man; and the pain which it
causes is abundantly recompensed by that sweet sen-
tion which ever accompanies the exercise of ben-
eficence.
To feel our own misery with full force is not to be
decimated. Affliction fortifies and improves the heart.
Tears, to speak in the style of figure, fertilize the soil
in which the virtue grow. And it is the remark of
one who understood human nature, that the faculties
of the mind, as well as the feelings of the heart, are
meliornated by adversity.

But in order to promote these ends, our sufferings
must not be permitted to overwhelm us. We must
oppose them with the arms of reason and religion; and
to express the idea in the language of the philosopher
as well as the poet, of Nature, every one, while he is
compelled to feel his misfortunes like a man, should
resolve also to bear them like a man.

PATIGUMO (a corruption of the words patele-
guimauve); the name of a sort of patele or cakes much
used on the continent as an agreeable and useful
remedy for catarrhal outflows, and supposed by
Dr Percival to consist of gum-arabic combined with
sugar and the whites of eggs (See the article Hunger,
p. 715, col. 1.) But we have been informed that the
powdered substance of the marjoram is the chief
ingredient of the composition.
PATTIN (Guy), professor of physic in the royal col-
lege of Paris, was born in 1602. He made his way
into the world merely by the force of his genius, being
at first corrodor of a printing-house. He was a man
of great wit and erudition: he spoke with the gravity
of a Stoic, but his expressions were very satirical.
He hated bigotry, superstition, and knavery: had an
upright soul, and a well-disposed heart. He was a mol-
tender father, courteous to every body, and polite in
the highest degree. He died in 1673, and did not
owe his reputation to any writings published in his life-
time upon physic; but his letters which appeared after
his death have rendered his name very famous. He
left a son mentioned in the ensuing article.

PATIN (Charles), who made a great figure in the
world, and excelled in the knowledge of medals. He
was born in Paris in 1633; and made so surprizing a
progres, that he maintained thieves in Greek and La-
in, on all parts of philosophy, in 1647. He studied
the law in compliance to an uncle, and was admitted
an advocate in the parliament of Paris; but could not
lay aside that of physic, for which he always had an
inclination. He therefore quitted the law, and devoted
himself to physic: in which, after taking the doctor's
degree, he applied himself to practice with great suc-
cess. He afterwards travelled into Germany, Holland,
England, Switzerland, and Italy. In 1676 he was
appointed
Augustus was soon after reduced to beg a piece of Charles at any rate; and Charles granted it upon certain conditions, one of which was, that he should deliver up Patkul. This condition reduced Augustus to a very distressful dilemma: the Czar, at this very time, exclaimed Patkul as his ambassador; and Charles demurred, with threats, that he should be put into his hands. Augustus therefore contrived an expedient by which he hoped to satisfy both: he sent some guards to deliver Patkul, who was prisoner in the castle of Konigstein, to the Swedh troops; but by secret orders, privately dispatched, he commanded the governor to let him escape. The governor, though he received this order in time, yet disappointment its intention by his villainy and his avarice. He knew Patkul to be very rich; and having it now in his power to suffer him to escape with impunity, he demanded of Patkul a large sum for the favour: Patkul refused to buy that liberty which he made no doubt would be gratuitously restored, in consequence of the Czar's requisitions and remonstrances; and, in the mean time, the Swedh guards arrived with the order for his being delivered up to them. By this party he was first carried to Charles's head quarters at Albeinfried, where he continued three months, bound to a stake with a heavy chain of iron. He was then conducted to Cufmir, where Charles ordered him to be tried; and he was by his judge found guilty. His sentence depended upon the king; and after having been kept a prisoner some months, under a guard of Mayerfield's regiment, uncertain of his fate, he was, on the 8th of September 1707, towards the evening, delivered into the custody of a regiment of dragoons, commanded by Colonel Nicholas Helm. On the next day, the 29th, the colonel took the chaplain of his regiment aside, and telling him that Patkul was to die the next day, ordered him to acquaint him with his fate, and prepare him for it. About this very time he was to have been married to a Saxon lady of great quality, virtue, and beauty; a circumstance which renders his fate the more affecting. What followed in consequence of the colonel's order to the minister (a) will be related in his own words.

"Immediately after evening service I went to his prison, where I found him lying on his bed. The first compliments over, I entered upon the melancholy duty of my profession, and turning to the officer who had him in charge, told him the colonel's orders were, that I should be alone with his prisoner. The officer having withdrawn, Patkul grabbing both my hands in his, he cried out with most affecting anxiety and distress, My dear pastor! what are you to declare? what am I to hear? I bring you, replied I, the same tidings that the prophet brought to king Hezekiah, Set time both in order, for thou must die. To morrow by this time thou shalt be no longer in the number of the living! At this terrible warning he bowed himself upon his bed, and burst into tears. I attempted to comfort him, by saying that he must, without all doubt, have often meditated on this subject: Yes, cried he, I know, this! too well, that we must all die; but the death prepared for me will be cruel and inupportable. I assured him that the manner of his death..."
death was to me totally unknown; but, believing that he would be prepared for it, I was fore his foul would be received into the number of happy spirits. Here he rose up, and folding his hands together, "Merciful Jefus! let me then die the death of the righteous! A little after, with his face inclined to the wall, where flood his bed, he broke out into this foliloquy: Augustus! O Augustus, what must be thy lot one day! Must thou not answer for all the crimes thou hast committed? He then observed that he was driven out from his country, by a sentence against his life, pronounced for doing what the king himself encouraged him to do, saying to him one day in terms of much kindness, "Patrik, maintain the rights of your country like a man of honour, and with all the spirit you are capable of." That flying into an enemy's country was also unavoidable, as the country of an ally would not have afforded him protection; but that he was in Saxony a wretched exile, not a counsellor or adviser; that before his arrival every thing was already planned, the alliance with Mufovy signed, and the measures with Denmark agreed upon. 'My inclinations (said he, after a pause) were always to serve Sweden, though the contrary opinion has prevailed. The elector of Brandenburg owed his title of king of Prussia to the services I did him; and when, in recompence, he would have given me a considerable sum of money, I thanked him, and rejected the offer; adding, that the reward I most wished for was to regain the king of Sweden's favour by his intercession. This he promised, and tried every possible method to succeed, but without success. After this I laboured so much for the interest of the late emperor in his Spanish affairs, that I brought about what scarce any other man could have effected. The emperor as an acknowledgment gave me an allowance for 50,000 crowns, which I humbly laid at his feet, and only implored his imperial majesty's recommendation of me to my king's favour: this request he immediately granted, and gave his orders accordingly, but in vain. Yet, not to lose any opportunity, I went to Moscow while he owes me; which, being liquidated, will amount to 50,000 crowns; and as my relations are here in the service of Sweden, that monarch will probably obtain it for them.'

"At this he said, let us stop here a little; I will quickly return to finish this will; but now let us address ourselves to God by prayer. Prayers being ended, 'Now (cried he) I find myself yet better, yet in a quieter frame of mind: Oh! I were my death less dreadful, with what pleasure would I expiate my guilt by embracing it!—Yes (cried he, after a pause), I have friends in different places, who will weep over my deplorable fate. What will the mother of the king of Prussia say? What will be the grief of the Countes Lévalde who attends on her? But what thoughts must arise in the bosom of her to whom my grief is plighted? Unhappy woman! the news of my death will be fatal to her peace of mind. My dear pastor, may I venture to beg one favour of you? I assured him he might command every service in my power. 'Have the goodness then (said he, pressing my hand), the moment I am no more, to write—Alas! how will you feel about it! a letter to Madam Enfeidler, the lady I am promised to.—Let her know that I die her's; inform her fully of my unhappy fate! Send her my
farther, him my hand in promise that I would faithfully grace;

live long and able; and blessed.

would not fail; but at the last moment, as he was about to

then kneeled down, and went through his confession, before the din of the people without could rise to applaud him, to the coach. He wrapped his cloak, to get his name to what was already written? 'This is my wedding-day. I looked, alas! for another, but this is the happiest; for to-day shall my foul be introduced by her heavenly bridgroom into the assembly of the blest?' He then asked me, whether I yet knew in what way he was to die? I answered, that I did not. He conjured me, by the sacred name of Jesus, not to forfike him; for that he should find in my company some consolation even in the midst of tortures. Causing his eyes on the paper that lay on the table, 'This will (said he) can never be finished.' I asked him, whether he would put his name to what was already written? 'No, (replied he, with a deep sigh), I will write that hated confession.' 

it more honour than to have been the place of the punishment of Charles XI. He incited foreign powers to attack his country when under the government of a boy, hoping, as he said himself, that it would in such circumstances become an easy conquest. He was therefore a rebel of the worst kind; and where is the absolute monarch that is ready to pardon such unnatural rebellion? Let it be remembered, too, that Charles, among whose faults no other infraction of cruelty has been numbered, certainly thought that, in ordering the execution of Patkul, he was discharging his duty. That monarch, it is known, believed in the possibility of discovering the philosopher's stone. Patkul, when under sentence of death, contrived to impose so far upon the senate at Stockholm, as to perfuade them that he had, in their presence, converted into gold a quantity of bafer metal. An account of this experiment was tramitted to the king, accompanied with a petition to his majesty for the life of so valuable a subject; but Charles, blending magnanimity with his severity, replied with indignation, that he would not grant to intercede what he had refused to the calls of humanity and the intrigues of friendship.

PATMOS (anc. geog.), one of the Sporades (Dionysius); 30 miles in compass (Pliny); concerning which we read very little in authors. It was rendered famous by the exile of St John and the Revelation showed him there. The greatest part of interpreters think that St John wrote them in the same place during the two years of his exile; but others think that he did not commit them to writing till after his return to Ephesus. The island of Patmos is between the island of Icaria and the promontory of Miletus. Nothing has done it more honour than to have been the place of the banishment of St John. It is now called Patina, or Patina, or Patnol, or Pataou. Its circuit is five and twenty or thirty miles. It has a city called Patmos, with a harbour, and some monasteries of Greek monks. It is at present in the hands of the Turks. It is considerable for its harbours; but the inhabitants derive little benefit from them, because the corsairs have obliged them to quit the town and retire to a hill on which St John's convent stands. This convent is a citadel consisting of several irregular towers, and is a

join with me in prayer for this unhappy man. 'Yes (cried he), afflict me all of you with your supplications to heaven.' Here the executioner gave him the first stroke. His eyes were terrible: 'O Jesus! Jesu! have mercy upon me.' This cruel scene was much lengthened out, and of the utmost horror; for as the headman had no skill in his business, the unhappy victim received upwards of 15 several blows, with each of which were intermixed the most piteous groans and invocations of the name of God. At length, after two strokes given on the breast, his strength and voice failed him. In a faltering dying tone, he was just heard to say, 'Cut off my head!' and the executioner still lingering, he himself placed his head on the scaffold: After four strokes with an hatchet, the head was separated from the body, and the body quartered. Such was the end of the renowned Patkul!'

Charles XII. has been very generally and severely cenured for not pardoning him, and we are not inclined to vindicate the sovereign. Yet it must be remembered, that Patkul was guilty of a much greater crime than that which drew upon him the displeasure of Charles XI. He incited foreign powers to attack his country when under the government of a boy, hoping, as he said himself, that it would in such circumstances become an easy conquest. He was therefore a rebel of the worst kind; and where is the absolute monarch that is ready to pardon such unnatural rebellion? Let it be remembered, too, that Charles, among whose faults no other infraction of cruelty has been numbered, certainly thought that, in ordering the execution of Patkul, he was discharging his duty. That monarch, it is known, believed in the possibility of discovering the philosopher's stone. Patkul, when under sentence of death, contrived to impose so far upon the senate at Stockholm, as to persuade them that he had, in their presence, converted into gold a quantity of base metal. An account of this experiment was transmitted to the king, accompanied with a petition to his majesty for the life of so valuable a subject; but Charles, blending magnanimity with his severity, replied with indignation, that he would not grant to intercede what he had refused to the calls of humanity and the intrigues of friendship.

fab-
PATNA, a town of Asia, in the dominions of the Great Mogul, to the north of the kingdom of Bengal, where the English have factories for f. Ipetre, borax, and raw silk. It is the capital of the province of Bahar, a dependency of Bengal, in the empire of Indostan, situated in a pleasant country, 400 miles east of Agra. It extends seven miles in length on the banks of the Gandes, and is about half a mile in breadth. — Mr Ren nel gives strong reasons for supposing it to be the ancient Pallotra. The town is large and populous, but the houses are built at a distance from each other. E. Long. 85° 40'. N. Lat. 24° 25'.

PATOMACK, a large river in Virginia, which divides that state from Maryland, rises in the mountains within a small distance of the western waters, and receives in its course several considerable rivers, and empties itself into Chesapeake Bay. It is 74 miles wide at the mouth, 42 at Nomony Bay, 1½ at Halloing point, 1½ at Alexandria; its foundations are 7 fathoms at the mouth, 5 at George's Island, 4½ at lower Machodic, 3 from Swan's point to Alexandria, and thence 10 feet water to the falls. The distance from the Capes of Virginia to the termination of the tide water in this river is above 300 miles and it is navigable for ships of large burden nearly to that distance; from thence its navigation was obstructed by several falls; but the spirited exertions of the company incorporated for opening and improving the navigation of this noble river, have surmounted many of the difficulties which obstructed its navigation; their operations still continue, intending to open the navigation to within a short portage of the Monaghela. The city of Washington, intended for the future residence of Congress, is now building on its banks nearly 300 miles from the sea. Alexandria and George Town in its vicinity, are places of considerable and increasing trade, and about nine miles below is situated Mount Vernon, the beautiful seat of General Washington. Many elegant seats, and delightful situations are on both sides of the river; and it is likely soon to become a channel of very extensive trade, the land on both sides rapidly increasing in value.

PATONCE, in heraldry, is a cross, florid at the ends; from which it differs only in this, that the ends, instead of turning down like a fleur-de-lis, are extended somewhat in the pattée form. See FLORE.

PATRÉ, a city of Achaia. This place was visited by Dr Chandler, who gives the following account of it. "It has been often attacked by enemies, taken, and pillaged. It is a considerable town, at a distance from the sea, situated on the side of a hill, which has its summit crowned with a ruinous castle. This made a brave defence in 1447 against Sultan Morat, and held out until the peace was concluded, which first rendered the Morea tributary to the Turks. A dry flat before it was once the port, which has been choked with mud. It has now, as in the time of Strabo, only an indifferent road for vessels. The house of Nicholas Paul, Esq; the English consul, stood on a part of the wall either of the theatre or the odeum. By a fountain was a fragment of a Latin inscription. We saw also a large marble birth much defaced; and the French consul showed us a collection of medals. We found nothing remarkable in the citadel. It is a palace of some trade, and inhabited by Jews as well as by Turks and Greeks. The latter have several churches. One is dedicated to St Andrew the apostle, who suffered martyrdom there, and is of great sanctity. It had been recently repaired. The site by the sea is supposed that of the temple of Ceres. By it is a fountain. The air is bad, and the country round about over-run, with the low shrub called glycyrrhiza or licorice."

Of its ancient state, the same author speaks thus: "Patra afflicted the Atheiots when invaded by the Gauls under Brennus; but afterwards was unfortunate, reduced to extreme poverty, and almost abandoned. Augustus Cæsar united the scattered citizens, and made it a Roman colony, settling a portion of the troops which obtained the victory of Actium, with other inhabitants from the adjacent places. Patra refounded and enjoyed dominion over Naupactus, Cænetha, and several cities of Achaia. In the time of Pausanias, Patra was adorned with temples and porticoes, a theatre, and an odeum which was superior to any in Greece but that of Atticus Herodes at Athens. In the lower part of the city was a temple of Bacchus Ἁίσυμμετερος, in which was an image preferred in a cist, and conveyed, it was said, from Troy by Eurypylus; who, on opening it, became disorderly in his senses. By the port were temples; and by the sea, one of Ceres, with a pleasant grove and a prophet fountain of unerring veracity in determining the event of any illness."

PATRANA, or Patrana, a town of New Castile in Spain, with the title of a duchy. It is situated between the rivers Pajo and Tajama, in W. Long. 2° 45'. N. Lat. 40° 26'.

PATRAS, an ancient and flourishing town of European Turkey, in the Morea, capital of a duchy, with a Greek archbishop's see. It is pretty large and populous; and the Jews, who are one-third part of the inhabitants, have four synagogues. There are several handsome mosques and Greek churches. The Jews carry on a great trade in silk, leather, honey, wax, and cheese. There are cypress trees of a prodigious height, and excellent pomegranates, citrons, and oranges. It has been several times taken and retaken, and is now in the hands of the Turks. It is seated in E. Long. 21° 43'. N. Lat. 38° 17'.

PATRICA, a town of Italy in the territory of the church, and in the Campagna of Rome, towards the sea coast, and eight miles east of Olbia. About a mile from this place is a hill called Monte de Liviana, which some have thought to be the ancient Lavinium founded by Æneas.
Patriarch, one of the first fathers who lived towards the beginning of the world, and who became famous by their long lines of descendants. Abraham, Isaac, and Jacob, and his twelve sons, are the patriarchs of the Old Testament; Seth, Enoch, &c. are antediluvian patriarchs.

The authority of patriarchal government existed in the fathers of families, and their first-born after them, exercising all kinds of ecclesiastical and civil authority in their respective households; and to this government, which lasted till the time of the Israelites dwelling in Egypt, some have ascribed an absolute and despotic power, extending even to the punishment by death. In proof of this, is produced the curse pronounced by Noah upon Canaan (Gen. ix. 25.); but it must be observed, that in this affair Noah seems to have acted rather as a prophet than a patriarch. Another instance of supposed despotic power is Abraham's turning Hagar and Ishmael out of his family (Gen. xxi. 9, &c.); but this can hardly be thought to be of any singular authority vested in the patriarchs, as such, and peculiar to those ages. The third instance brought forward to the same purpose is that of Jacob's denouncing a curse upon Simeon and Levi (Gen. xxxviii. 7.), which is maintained by others to be an instance of prophetic inspiration more than of patriarchal power. The fourth instance is that of Judah with regard to Tamar (Gen. xxxvii. 24.); with regard to which it is remarked, that Jacob, the father of Judah, was still living; that Tamar was not one of his own family; and that she had been guilty of adultery, the punishment of which was death by burning; and that Judah on this occasion might speak only as a prosecutor.

On the whole, however, it is difficult to say, which of these opinions are most agreeable to truth. Men who believe the origin of civil government, and the obligation to obedience, to arise from a supposed original compact, either real or implied, will be naturally led to weaken the authority of the patriarchs; and those who esteem government to be a divine institution, will be apt to raise that authority to the highest pitch that either reason or scripture will permit them. It cannot be denied, that authority existed in fathers, and descended to their first-born, in the first ages of the world; and it is neither unnatural nor improbable to imagine, that the idea of hereditary power and hereditary honours was first taken from this circumstance. But whether authority has descended through father and son in this way to our times, is a circumstance that cannot in one instance be asserted, and cannot be denied in a thousand. The real source of the dignity and of the authority of modern times seems to have been, skill in the art of war, and success in the conduct of conquests.

Jewish Patriarch, a dignity; respecting the origin of which there are a variety of opinions. The learned authors of the Universal History think, that the first appearance and institution of these patriarchs happened under Nerva the successor of Domitian. It seems probable that the patriarchs were of the Aaronic or Le-Se-Dar-Patriarch, the tribe of Judah being at that time too much depressed, and too obnoxious to the Romans to be able to assume any external power. But of whatever tribe they were, their authority came to be very considerable. Their principal business was to instruct the people; and for this purpose they instituted schools in several cities. And having gained great reputation for their extraordinary learning, zeal, and piety, they might, in time, not only bring a great concourse of other Jews from other parts, as from Egypt and other western provinces of their dispersion, but likewise prove the means of their patriarchal authority's being acknowledged there. From them they ventured at length to levy a kind of tribute, in order to defray the charges of their dignity, and of the officers (A) under them, whose business it was to carry their orders and decisions through the other provinces of their dispersion, and to see them punctually executed by all, that some shadow of union at least might be kept up among the western Jews. They likewise nominated the doctors who were to preside over their schools and academies; and these were in process of time styled chief and princes, in order to raise the credit of that dignity, or to imply the great regard which their disciples were to pay to them. These chiefs became at length rivals of the patriarchs; and some of them possest both dignities at once; an usurpation which caused not only great confusion amongst them, but oftentimes very violent and bloody contentions. However, as the Jewish Rabbis have trumped up a much older era for this patriarchal dignity, and have given us a succession of them down to the fifth century, in which it was abolished, it will not be amiss to give our readers the substance of what they have written of this and those of this order of men; and at the same time to show them the absurdity and falsehood of that pretended succession to this imaginary dignity.

According to them, the first patriarch was Hillel, surnamed the Babylonian, because he was sent for from thence to Jerusalem about 145 years before the ruin of their capital, or 30 years before the birth of Christ, to decide a dispute about the keeping of Easter, which on that year fell out on the Sabbath-day; and it was on account of his wife's decision that he was raised to that dignity, which continued in his family till the said fifth century. He was likewise looked upon as a second Moses, because he lived like him 40 years in obscurity, and more in great reputation for learning and sanctity, and 40 more in possession of this patriarchal dignity. They make him little inferior to that lawgiver in other of his excellences, as well as in the great authority he gained over the whole Jewish nation. The wonder will be, how Herod the Great, who was so jealous of his own power, could suffer a stranger to be raised to such a height of it, barely for having decided a dispute which must in all likelihood have been adjudged by others long before that time.

However, Hillel was succeeded by his son Simeon, whom many Christians pretend to have been the venerable old person of that name, who received the divine infant in his arms. The Jews give him but a very
people so regretted his death, that an order was given, Patriarch, instead of 10 bumpers of wine, which were usually drank at the funeral of a faint, to drink 15 at his, on account of his martyrdom. These bumpers were in time multiplied, they tell us, to such shameful huge, that the fanhedrim was forced to make some new regulations to prevent that abuse.

Those are the patriarchs which, the Rabbies tell us, preceded the destruction of the temple; and we need no farther confusion of this pretended dignity, than the silence of the faced historians, who not only make not the least mention of it, but affurse us all along that they were the high-priests who professed in the fanhedrim; and before whom all cases relating to the Jewish religion were brought and decided. It was the high-priest who examined and condemned our Saviour; that condemned St Stephen; that forgave the apostles to preach in Christ's name; and who far as judge on the great apostle at the head of that supreme court. The fame may be urged from Josephus, who must needs have known and mentioned this pretended dignity, if any such there had been; and yet is it far from taking the least notice of it, that, like the evang-lists, he places the point ill among at the head of all the Jewish affairs; and names the high-priest Ananas as having the care and direction of the war against the Romans, which is an evident proof that there were then no such patriarchs in being. To all this let us add, that if there had been any such remarkable succession, the Talmudists would have preferred it to future ages, whereas, neither they, nor any of the ancient authors of the Jewish church, make any mention of it; but only some of their doctors, who have written a considerable time after them, a set of writers to whom little credit can be given in points of this nature, especially as there are such unfurnishable contradictions between them, as no authors either Jewish or Christian have, with all their pains, been hitherto able to reconcile.

Their succession, according to the generality of those rabbies, stands as follows:

According to Gants Tzemach David, who hath reduced them to 10, they are,

On the whole, it cannot be doubted but that their first rise was in Nerva's time, however much Jewish pride may have prompted them to falsify, and to assert their origin to have been more ancient than it really was. Nor have the Jews been faithful in giving an account of the authority of these men. They have exaggerated their power beyond all bounds, for the purpose of repelling...
Patriarchs among Christians, are ecclesiastical dignitaries, or bishops, called from their paternal authority in the church. The power of patriarchs was not the same in all, but differed according to the different customs of countries or the pleasures of kings and councils. Thus the patriarch of Constantinople grew to be a patriarch over the patriarchs of Ephesus and Cæsarea, and was called the ecumenical and universal patriarch; and the patriarch of Alexandria had some prerogatives which no other patriarch but himself enjoyed, such as the right of consecrating and approving every single bishop under his jurisdiction.

The patriarchate has been ever esteemed the supreme church: the bishop had only under him the territory of the city of which he was bishop; the metropolitan superintended a province; and had for suffragans the bishops of his province; the primate was the chief of what was then called a diocese (a), and had several metropolitans under him; and the patriarch had under him several dioceses, composing one exarchate, and the primates themselves were under him.

Ulter, Pagi, De Marca, and Morinus, attribute the establishment of the grand patriarchates to the apostles themselves; who, in their opinion, according to the description of the world then given by geometers, pitched on the three principal cities in the three parts of the known world; viz. Rome in Europe, Constantinople in Asia, and Alexandria in Africa; and thus formed a trinity of patriarchs. Others maintain that the name patriarch was unknown at the time of the council of Nice; and that for a long time afterwards patriarchs and primates were confounded together, as being all equally chiefs of dioceses, and equally superior to metropolitans, who were only chiefs of provinces. Hence Socrates gives the title patriarch to all the chiefs of dioceses, and reckons ten of them. Indeed, it does not appear that the dignity of patriarch was appropriated to the five grand sees of Rome, Constantinople, Alexandria, Antioch, and Jerusalem, till after the council of Chalcedon in 451: for when the council of Nice regulated the limits and prerogatives of the three patriarchs of Rome, Antioch, and Alexandria, it did not give them the title of patriarchs, though it allowed them the pre-eminence and privileges thereof; thus when the council of Constantinople adjudged the second place to the bishop of Constantinople, who till then was only suffragan of Heraclea, it laid nothing of the patriarchate. Nor is the term patriarch found in the decree of the council of Chalcedon, whereby the fifth place is assigned to the bishop of Jerusalem; nor did the five patriarchs govern all the churches.

There were besides many independent chiefs of dioceses, who, from owing the jurisdiction of the grand patriarchs, called themselves patriarchs; such as that of Aquileia; nor was Carthage ever subject to the patriarch of Alexandria. Molonem * imagines that the bishops, who enjoyed a certain degree of pre-eminence over the rest of their order, were distinguished by the Jewish title of patriarchs in the fourth century. The authority of the patriarchs gradually increased, till, about the close of the fifth century, all affairs of moment within the compass of their patriarchate came before them, either at first hand or by appeals from the metropolitans. They consecrated bishops; assembled yearly in council the clergy of their respective districts; pronounced a decisive judgment in those cases where accumulations were brought against bishops; and appointed vicars or deputies, clothed with their authority, for the preservation of order and tranquillity in the remotest provinces. In short, nothing was done without consulting them; and their decrees were executed with the same regularity and respect as those of the princes.

It deserves to be remarked, however, that the authority of the patriarchs was not acknowledged through all the provinces without exception. Several dioceses, both in the eastern and western empires, were exempted from their jurisdiction. The Latin Church had no patriarchs till the sixth century; and the churches of Gaul, Britain, &c. were never subject to the authority of the patriarch of Rome, whose authority only extended to the suburban provinces. There was no primacy, no exarchate...

(a) The word diocese was then of a very different import from what it bears now. Under the article Episcopacy, it was observed, that the first founders of churches regulated their extent and the jurisdiction of their bishops by the divisions of the Roman empire into civil jurisdictions. One of these divisions was into provinces and dioceses. A province comprised the cities of a whole region subjected to the authority of one chief magistrate, who reigned in the metropolis or chief city of the province. A diocese was a still larger district, comprehending within it several provinces, subject to the control of a chief magistrate, whose residence was in the metropolis of the diocese. The jurisdiction of the bishops of the Christian church was established upon this model: the authority of a private bishop included only over the city in which he resided, together with the adjacent villages and surrounding tract of country. The diocese was called eparchia, through it comprehended many parishes in the modern sense of that word. Under Arcadius and Honorius the empire was divided into thirteen dioceses: 1. The Oriental diocese, containing fifteen provinces; 2. The diocese of Egypt, six provinces; 3. The Asiatic diocese, ten provinces; 4. The Pontic diocese, ten provinces; 5. The diocese of Thrace, six provinces; 6. The diocese of Macedonia, six provinces; 7. The diocese of Dacia, five provinces; 8. The Italian diocese, seventeen provinces; 9. The diocese of Illyricum, six provinces; 10. The diocese of Italy, six provinces; 11. The Spanish diocese, seven provinces; 12. The Gallican diocese, seventeen provinces; 13. The Britannic diocese, five provinces. Each of these provinces comprehended many parishes, and each eparchia many modern parishes. See Bingham's Origins Saec., Book ix.
PATRICK (St), the apostle of Ireland, and first bishop of that country. He was born April 9th A.D. 373, of a good family, at Kirk Patric near Dumbarton, in what is now called Scotland, but then comprehended under the general name of Britain.---His baptismal name Succatus, signifies, in the British language, "valiant in war." On some account of certain exiles from Italy he was taken prisoner, and carried into that kingdom, where he continued five years in the service of Milcho, who had bought him of three others, when Patrick acquired the new name of Cathairg, or Cathar Tige, i.e. four families. In this time he made himself master of the Irish language, and at last made his escape, and returned home on board a ship. About two years after, he formed a design of converting the Irish, either in consequence of a dream, or of reflection on what he had observed during his acquaintance with them. The better to qualify himself for this undertaking, he travelled to the continent, where he continued 35 years, pursuing his studies under the direction of his mother's uncle St Martin, bishop of Tours, who had ordained him deacon; and after his death with St German, bishop of Auxerre, who ordained him priest, and gave him his third name Mauros or Magnim.

An ancient author, Hectoricus Antifodorenfs, who wrote a book concerning the miracles of St German, considers it as the highest honour of that prelate to have been the inductor of St Patrick: "As the glory of a father shines in the government of his sons, out of the many disciples in religion who are reported to have been his sons in Christ, suffice it briefly to mention one by far the most famous, as the feries of his actions shows, Patrick the particular apostle of Ireland, who being under his holy discipline 18 years, derived no little knowledge in the inspired writings from such a source. The most godly divine pontiff, considering him alike distinguished in religion, eminent for virtue, and steadfast in doctrine; and thinking it absurd to let one of the best labourers remain inactive in the Lord's vineyard, recommended him to Celeline, Pope of Rome, by his prebyster Segetius, who was to carry to the apostolic see a testimonial of ecclesiastical merit of this excellent man. Approved by his judgment, supported by his authority, and confirmed by his blessing, he sent out for Ireland; and being peculiarly defined to that people as their apostle, instructed them at that time by his doctrine and miracles, and now does and will for ever display the wonderful power of his apostleship." Lastly, Pope Celeline consecrated him bishop, and gave him his most familiar name Patrick, expressive of his honourable defect; and to give luire and weight to the communion which he now charged him with to convert the Irish. Palladius had been here a year before him on the same design, but with little success: the saints Kieran, Alba, Declan, and Ibar, were predecessors both to Palladius and Patrick. But the great office of apostle of Ireland was conferred for our peace, who landed in the country of the Eboe, or at Wicklow, A.D. 441. His first event was S nell, eighth in descent from Cormac king of Leinster; but not meeting with encouragement, he proceeded to Dublin, and thence to Ulter, where he founded a church (afterwards the famous abbey of Saul, in the county of Down), remarkable for its position, being made out of a barn, and its greatest length reaching from north to south. After labouring seven years indefatigably in his great work, he return-
the church at Battersea in Surrey, he was preferred to the rectory of St Paul's, Covent-garden, in London, where he continued all the time of the plague in 1665 among his parishes, to their great comfort. In 1668 he published his Family debate between a Conformist and a Nonconformist. This was answered by the Dilettanti, whom he had much exasperated by it; but by his moderation and conciliatory manners towards them afterwards, they were perfectly reconciled to him, and he brough over many of them to the communion of the established church. In 1678 he was made dean of Peterborough, where he was much beloved. In 1682, Dr Lewis de Moulin, who had been a history professor at Oxford, and written many better books against the church of England, sent for Dr Patrick upon his sick-bed, and made a solemn declaration of his regret on that account, which he signed, and was published after his death. During the reign of King James, the dean's behaviour showed that he had nothing more at heart than the protestant religion; for which he ventured all that was dear to him, by preaching and writing against the errors of the church of Rome. In 1687 he published a prayer composed for that difficult time, when persecution was expected by all who stood firm to their religion. The year after the Revolution, the dean was appointed bishop of Chichester, and was employed with others of the new bishops to settle the affairs of the church in Ireland. In 1691 he was translated to the see of Ely, in the room of the deprived Bishop Turner. He died in 1709, after having published various works; among which the most distinguished are his Paraphrases and Commentaries on the Holy Scriptures, three volumes folio. These, with Louth on the Proverbs, Arnold on the Apocrypha, and Whitby on the New Testament, make a regular continued commentary in English on all the sacred books.

PATRIMONY, a right or estate inherited by a person from his ancestors.

The term patrimony has been also given to church-estates or revenues; in which some authors still lay, the patrimony of the church of Rimini, Milan, &c. The church of Rome hath patrimonies in France, Africa, Sicily, and many other countries. To create the greater respect to the estates belonging to the church, it was usual to give their patrimonies the names of the saints they held in the highest veneration; thus the estate of the church of Ravenna was called the patrimony of St Apollinaris, that of Milan, the patrimony of...

(a) At Armagh St Patrick founded, A. D. 445 or 447, a priory of Augustine canons, dedicated to St Peter and St Paul, much enriched by the archbishops; restored by Imar O Hedegun in the 12th century. It was granted, A. D. 1611, to Sir Toby Caulfield, knight. St Patrick also founded there a house of canonesses of the same order, under his abbot Lupita, called Templina ferta, or the house of miracles.

We are told, that Armagh was made a metropolitan see in honour of St Patrick; in consequence of which it was held in the highest veneration not only by bishops and priests, but also by kings and bishops, as the venerable Bede informs us.

(a) There is a cave in the county of Donegal or Tirconnel, near the source of the Liffey, which, it is pretended was dug by Ulysses, in order to hold conversations with infernals. The present inhabitants call it Elan n’ Fadatory, or the “Island of Purgatory, and Patrick’s Purgatory.” They affirm, with a pious credulity, that St Patrick the apostle of Ireland, or some abbot of that name, obtained of God by his earnest prayers, that the pains and torments which await the wicked after this life might be here set forth to view, in order the more easily to recover the Irish from their sinful state and heathenish errors.
PA T R I O T I S M 

of St. Abboy; and the eftates of the Roman church were called the patriam of St Peter in Abruzzi, the patriam of St Peter in Sicily, and the like.

What is now called St Peter's patriam is only the duchy of Castro, and the territory of Orvieto. See CASTRO, &c.

P A T R I O T I S M, a love of one's country, which is one of the noblest passions that can warm and animate the human breast. It includes all the limited and particular affections to our parents, children, friends, neighbours, fellow-citizens, and countrymen. It ought to direct and limit their more confined and partial actions within their proper and natural bounds, and never let them encroach on those sacred and first regards we owe to the great public to which we belong.

Were we solitary creatures, detached from the rest of mankind, and without any capacity of comprehending a public interest, or without affections leading us to desire and pursue it, it would not be our duty to mind it, nor criminal to neglect it. But as we are parts of the public system, and are not only capable of taking in large views of its interests, but by the strongest affections connected with it, and prompted to take a share of its concerns, we are under the most sacred ties to prosecute its security and welfare with the utmost ardour, especially in times of public trial.

"Zeal for the public good (says Mr. Addison) is the characteristic of a man of honour and a gentleman, and must take place of pleasures, profits, and all other private gratifications: that whosoever wants this motive, is an open enemy, or an inglorious nurtor to mankind, in proportion to the misapplied advantages with which nature and fortune have blessed him." This love of our country does not import an attachment to any particular soil, climate, or spot of earth, where perhaps we first drew our breath, though those natural ideas are often associated with the moral ones; and, like external signs or symbols, help to ascertain and bind them; but it imports an affection to that moral system or community, which is governed by the same laws and magistrates, and whose several parts are variably connected one with the other, and all united upon the bottom of a common interest. Wherever this love of our country prevails in its genuine vigour and extent, it swallows up all forlorn and selfish regards; it conquers the love of ease, power, pleasure, and wealth; nay, when the amiable partialities of friendship, gratitude, private affection, or regards to a family, come in competition with it, it will teach us to sacrifice all, in order to maintain the rights, and promote and defend the honour and happiness of our country. To pursue therefore our private interests in subordination to the good of our country; to be examples in it of virtue, and obedient to the laws; to choose such representatives as we apprehend to be the best friends to its constitution and liberties; and if we have the power, to promote such laws as may improve and perfect it; ready to embrace every opportunity for advancing its prosperity; cheerfully to contribute to its defence and support; and, if need be, to die for it—these are among the duties which every man, who has the happiness to be a member of our free and Protestant constitution, owes to his country.

The constitution of man is such, that the most selfish passions, if kept within their proper bounds, have a tendency to promote the public good. There is no passion of more general utility than patriotism; but its origin may unquestionably be termed selfish. The love of one's relations and friends is the most natural expansion of self-love; this affection connects itself too with local circumstances, and sometimes cannot easily be separated from them: It often varies, as relationship or place varies; but acquires new power when the whole community becomes its object. It was therefore with singular propriety that the poet said, "Self love and social are the same." Under the article CALAIRI we have already given the outlines of the transactions of its siege by Edward III. during which the inhabitants displayed a degree of patriam in a truly wonderful manner. History scarcely contains a more distinguished instance of true patriotic virtue than on this occasion. We shall therefore give a fuller account of this remarkable affair, as one of the best examples that can possibly be selected of the virtue we have been explaining. The inhabitants, under Count Vienne their gallant governor, made an admirable defence against a well disciplined and powerful army. Day after day the English effected many a breach, which they repeatedly expected to storm by morning; but, when morning appeared, they wondered to behold new ramparts raised nightly, erected out of the ruins which the day had made. France had now put her sickle into her second harvest since Edward with his victorious army had driven the town. The eyes of all Europe were intent on the issue. The English made their approaches and attacks without remission; but the citizens were as obstinate in repelling all their efforts. As lengthened families did more for Edward than arms. After the citizens had devoured the lean carcasses of their half-starved cattle, they tore up old foundations and rubbish in search of vermin; they fed on boiled leather, and the weeds of exhausted gardens; and a morse of damaged corn was accounted matter of luxury. In this extremity they resolved to attempt the enemy's camp. They boldly fell upon the English joined battle; and, after a long and desperate engagement, Count Vienne was taken prisoner; and the citizens, who survived the slaughter, retired within their gates. On the captivity of their governor, the command devolved upon Euface Saint Pierre, the mayor of the town, a man of mean birth, but of exalted virtue. Euface soon found himself under the necessity of capitulating, and offered to deliver to Edward the city, with all the possessions and wealth of the inhabitants, provided he permitted them to depart with life and liberty. As Edward had long since expected to ascend the throne of France, he was exasperated to the last degree against these people, whose sole valor had defeated his warmest hopes; he therefore determined to take an exemplary revenge, though he wished to avoid the imputation of cruelty. He answered by Sir Walter Mauny, that they all deserved capital punishment, as obstinate traitors to him, their true and notable sovereign; that, however, in his wonted clemency, he contented to pardon the bulk of the plebeians, provided they would deliver up to him fix of their principal citizens with halters about their necks, as victims of due atonement for that spirit of rebellion with which they had insulted the common people. All the remains of this deplorable city were conveyed in the great square; and like men arraigned at a tribunal from whence there was no appeal, expected...
P A T       [  43  ]       P A T

ed with throbbing hearts the sentence of their conquer. When Sir Walter had declared his meagre, consolation and pale disfay was impressed on every face: each looked upon death as his own inevitable lot; for how should they desire to be saved at the price proposed? Whom had they to deliver up, save parents, brothers, kindred, or valiant neighbours, who had so often exposed their lives in their defence? To a long and dead silence, deep sighs and groans succeeded, till Eulalie Saint Pierre a ceding a little eminence, thus addressed the assembly: "My friends and fellow-citizens, you see the condition to which we are reduced; we must either submit to the terms of our cruel and enflaving conqueror, or yield up our tender infants, our wives, and chaste daughters, to the bloody and brutal lufts of the violating sordidly. We well know what that tyrant intends by his sanguine offers of mercy. It does not abate his vengeance to make us merely miserable, he would also make us criminal; he would make us contemptible; he will grant us life on no condition, save that of our being unworthy of it. Look about you, my friends, and fix your eyes on the person whom you will to deliver up as the victims of your own safety. Which of these would you appoint to the rack, the ax, or the halter? Is there any here who has not watched for you, who has not fought for you, who has not bled for you? Who, through the length of this invertebrate siege, has not suffered fatigues and miseries a thousand times worse than death, that you and your might survive to days of peace and prosperity? Is it your prefers, then, whom you would define to destruction? You will not, you cannot, do it. Justice, honour, humanity, make such a treason impossible. Where then is our resource? Is there any expedient left, whereby we may avoid guilt and infamy on one hand, or the defolation and horrors of a sacked city on the other? There is, my friends, there is one expedient left; a gracious, an excellent, a god-like expedient! Is there any here to whom virtue is dearer than life? Let him offer himself an obligation for the safety of his people! he shall not fail of a blessed approbation from that power, who offered up his only Son for the salvation of mankind." He spoke—but an universal silence ensued. Each man looked round for the example of that virtue and magnanimity in others, which all wished to approve in themselves, though they wanted the resolution. At length Saint Pierre resumed: "It had been base in me, my fellow-citizens, to propose any matter of damage to others, which I myself had not been willing to undergo in my own person. But I held it ungenerous to deprive any man of that preference and elevation, which might attend a first offer on so signal an occasion: for I doubt not but there are many here as ready, nay, more zealous for this martyrdom than I can be, however modestly and the fear of imputed offense may withhold them from being foremost in exhibiting their merits. Indeed the fixation to which the captivity of Count Vienne has unhappily raised me, imports a right to be the first in giving my life for your sakes. I give it freely, I give it cheerfully. Who comes next? Your son! exclaimed a youth, not yet come to maturity. — Ah, my child! cried St Pierre; I am then twice sacrificed. — But no—I have rather begun thee a second time. — Thy years are few, but full my son; the vicissitude of virtue has reached. Patience is the utmost purpose and goal of humanity. Who next, my friends? This is the hour of heroes. — Your kinman, cried John de Aire! Your kinman, cried James Villiant! Your kinman, cried Peter Villiant! "Ah! (exclaimed Sir Walter Mauny, bursting into tears), why was I not a citizen of Calais?"

The sixth victim was still wanting, but was quickly supplied by lot, from numbers who were now envious of so ennobling an example. The lots of the city were then delivered to Sir Walter. He took the prisoners into his custody. He ordered the gates to be opened, and gave charge to his attendants to conduct the remaining citizens with their families through the camp of the English. Before they departed, however, they defined permission to take their last adieu of their deliverers.—What a parting? what a scene? they crowded with their wives and children about St Pierre and his fellow-prisoners. They embraced, they clung around, they fell prostrate before them. They groaned; they wept aloud; and the joint clamour of their mourning passed the gates of the city, and was heard throughout the camp. At length Saint Pierre and his fellow victims appeared under the conduct of Sir Walter and his guard. All the tents of the English were instantly emptied. The soldiers pored from all parts, and arranged themselves on each side to behold, to contemplate, to admire this little band of patriots as they passed. They murmured their applause of that virtue which they could not but revere even in enemies; and they regarded those ropes which they had voluntarily affixed about their necks as enigmas of greater dignity than that of Briton Mauny. As soon as they had reached the royal presence, "Many (says the king), are these the principal inhabitants of Calais?" "They are (says Mauny); they are not only the principal men of Calais, they are the principal men of France, my lord, if virtue has any share in the act of ennobling."

"Were they delivered peaceably, (says Edward)? Was there no resistance, no commotion among the people?" "Not in the least, my lord. They are self-delivered, self-devoted, and come to offer up their inestimable heads as an ample equivalent for the ransom of thousands."

The king, who was highly incensed at the length and difficulty of the siege, ordered them to be carried away to immediate execution; nor could all the remonstrances and intreaties of his couriers divert him from his cruel purpose. But what neither a regard to his own interest and honour, what neither the dictates of justice, nor the feelings of humanity, could effect, was happily accomplished by the more powerful influence of conjugal affection. The queen, who was then big with child, being informed of the particulars respecting the six victims, flew into her husband's presence, threw herself on her knees before him, and, with tears in her eyes, besought him not to stain his character with an indelible mark of infamy, by committing such a horrid and barbarous deed. Edward could refuse nothing to a wife whom he so tenderly loved, and especially in her condition; and the queen, not satisfied with having saved the lives of the sixburghers, conducted them to her tent, where she applauded their virtue, regaled them with a plentiful
PAT

ful report, and having made them a present of money and clothes, sent them back to their fellow-citizen.

The love of their country, and of the public good, seems to have been the predominant passion of the Spartans. Pedaratus having milled the honour of being chosen one of the three hundred who had a certain rank in distinction in the city, went home extremely pleased and satisfied; saying, "He was overjoyed there were three hundred in Sparta more honourable than himself."

The patriotism of the Romans is well known, and has been justly admired. We shall content ourselves at present with the following example; a zeal and patriotic devotion similar to which is perhaps scarcely equalled, and certainly is not exceeded, in history.

Rome, under the consuls Cæsio Fabius and T. Virginius, had several wars to fulfill repast, and seem to have been the admiration of all ages.

To put a stop to the incursions of the last, it would have been necessary to have established a good garrison upon their frontiers to keep them in awe. But the commonwealth, exhausted of money, and menaced by abundance of other enemies, was not in a condition to provide for so many different cares and expences. The family of the Fabii showed a generosity and love of their country that has been the admiration of all ages. They applied to the senate, and by the mouth of the consuls demanded as a favour that they would be pleased to transfer the care and expences of the garrison necessary to oppose the enterprizes of the Viets to their house, which required an industrious rather than a numerous body, promising to support with dignity the honour of the Roman name in that post. Every body was charmed with so noble and unheard-of an offer; and it was accepted with great acknowledgment. The news spread over the whole city and no hint was talked of but the Fabii. Every body praised, and extolled them to the skies. "If there were two more such families in Rome," said they, "the one might take upon them the war against the Volsci, and the other against the Équi, whilst the commonwealth remained quiet, and the forces of particulars subdivided the neighbouring states."

Early the next day the Fabii set out, with the confult at their head, robed and with his insignia. Never was there so small, and at the same time so illustrious, an army seen; for which we have the authority of Livy. Three hundred and fix foldiers, all patriots, and of the same family, of whom not one but might be judged worthy of commanding an army, marched against the Veii full of courage and alacrity, under a captain of their own name, Fabius. They were followed by a body of their friends and clients, animated by the same spirit and zeal, and actuated only by great and noble views. The whole city flocked to see the fine sight; praised those generous foldiers in the highest terms; and promised them confulsips, triumphs, and the most glorious rewards. As they passed before the capitol and the other temples, every body implored the gods to take them into their protection; to favour their departure and undertaking, and to afford them a speedy and happy return. But their prayers were not heard. When they arrived near the river Crimera, which is not far from Veii,
to prevent disorders, or any number of people from assembling together; they are to see the lights in the soldiers' barracks put out, and to take up all the soldiers they find out of their quarters. Sometimes patrols consist of an officer and 30 or 40 men, as well infantry as cavalry; but when the enemy is generally near at hand, and consequently the danger greater.

PATRON, among the Romans, was an appellation given to a master who had freed his slave. As soon as the relation of master expired, that of patron began: for the Romans, in giving their slaves their freedom, did not depose themselves of all rights and privileges in them; the law still subjected them to considerate services and duties towards their patrons, the neglect of which was very severely punished.

Patron was also a name which the people of Rome gave to some great man, under whose protection they usually put themselves; paying him all kinds of honour and respect, and denominating themselves his clients; while the patron, on his side, granted them his credit and protection. They were therefore mutually and mutually obliged to each other; and by this means, in consequence of reciprocal ties, all those petitions, jealousies, and animosities, which are sometimes the effect of a difference of rank, were prudently avoided: for it was the duty of the patron to advise his clients in points of law, to manage their suits, to take care of them as of his own children, and secure their peace and happiness. The clients were to affist their patrons with money on several occasions; to ransom them or their children when taken in war; to contribute to the portions of their daughters; and to defray, in part, the charges of their public employments. They were never to accuse each other, or take contrary sides; and if either of them was convicted of having violated this law, the crime was equal to that of treason, and any one was allowed to kill the offender with impunity. This patronage was a tie as effectual as any confanguinity or alliance, and had a wonderful effect towards maintaining union and concord among the people for the space of 600 years; during which time we find no dissensions nor jealousies between the patrons and their clients, even in the times of the republic when the populace frequently mutinied against those who were most powerful in the city.

Patron, in the church of Rome, a faint whose name a person bears, or under whose protection he is put, and whom he takes particular care to invoke; or a faint in whose name a church or order is founded.

Patron, in the canon or common law, is a person who, having the advowson of a parsonage, vicarage, or the like spiritual promotion, belonging to his manor, hath on that account the gift and disposition of the benefice, and may present to it whenever it becomes vacant. The patron's right of disposing of a benefice originally arises either from the patron or his ancestors, &c. being the founders or builders of the church; from their having given lands for the maintenance thereof; or from the church being built on their ground; and frequently from all three together.

PATRONAGE, or ADVOWSON, a sort of incorporeal hereditament, confiding in the right of presentation to a church or ecclesiastical benefice. Advowson, abbrevio, signifies in clientela recipere, the taking...
Patronage, taking into protection; and therefore is synonymous with patronage, patronatus: and he who has the right of advowson is called the patron of the church. For when lords of manors first built churches on their own demesnes, and appointed the tithe of those manors to be paid to the officiating ministers, which before were given to the clergy in common (from whence arose the division of parishes), the lord who thus built a church, and endowed it with glebe or land, had of common right a power annexed of nominating such minister as he pleased (provided he were canonically qualified) to officiate in that church, of which he was the founder, endower, maintainer, or, in one word, the patron.

Advowsons are either advowsons appendant, or advowsons in gros. Lords of manors being originally the only founders, and of course the only patrons, of churches, the right of patronage or pretension, so long as it continues annexed to the possession of the manor, as some have done from the foundation of the church, is called an advowson appendant: and it will pass, or be conveyed, together with the manor, as incident and appendant thereto, by a grant of the manor, as some have done from the foundation of the church, is called an advowson in gros; or, at large, and never can be appendant any more; but it is for the future annexed to the person of its owner, and not to his manor or lands.

Advowsons are also either pretentiae, collative, or donative. An advowson pretentiae, is where the patron hath a right of pretension to the bishop or ordinary, and moreover to demand of him to inSTITUTE, or to take the pretension of and to officiate in the church. An advowson collative, is where the bishop and patron are one and the same person: in which case the bishop cannot pretend to himself; but he does, by the act of collation, or consecrating the benefice, the whole that is done in common cases, by both pretension and institution. An advowson donative, is where the king, or any subject by his licence, doth found a church or chapel, and ordains that it shall be merely in the gift of, and to the person of, the patron; subject to his visitation only, and not to that of the ordinary; and vested absolutely in the clerk by the patron's deed of donation, without pretension, institution, or induction. This is said to have been anciently the only way of conferring ecclesiastical benefices in England; the method of institution by the bishop not being established more early than the time of Archbishops Becket in the reign of Henry II. and therefore, though pope Alexander III. in a letter to Becket, severely inveighs against the præstum confuetudo, as he calls it, of investiture conferred by the patron only, this however shews what was then the common usage. Others contend that the claim of the bishops to institution is as old as the first planting of Christianity in this island; and in proof of it they allege a letter from the English nobility to the pope in the reign of Henry the third recorded by Matthew Paris, which speaks of presentation to the bishop as a thing immemorial. The truth seems to be, that, where the benefice was to be conferred on a mere layman, he was first presented to the bishop in order to receive ordination, who was at liberty to examine and refuse him: but where the clerk was already in orders, the living was usually vested in him by the sole donation of the patron; till about the middle of the 12th century, when the pope and his bishops endeavoured to introduce a kind of feudal dominium over ecclesiastical benefices, and, in consequence of that, began to claim and exercise the right of institution universally, as a species of spiritual investiture.

However this may be, if, as the law now stands, the true patron once waxes this privilege of donation, and pretends to the bishop, and his clerk is admitted and instituted, the advowson is now become for ever pretensive, and shall never be donative any more. For these exceptions to general rules and common right are ever looked upon by the law in an unfavourable view, and continued as strictly as possible. If therefore the patron, in whom such peculiar right resides, does once give up that right, the law, which loves uniformity, will interpret it to be done with an intention of giving it up for ever; and will therefore reduce it to the standard of other ecclesiastical livings. See further, Law, Part III. Sect. i. No. cit. 9—10.

Arms of Patronage, in heraldry, are those on the top of which are some marks of subjection and dependence: thus the city of Paris lately bore the fleurs-de-lis in chief, to shew her subjection to the king; and the cardinals, on the top of their arms, bear those of the pope, who gave them the hat, to shew that they are his creatures.

Patronymic, among grammarians, is applied to such names of men or women as are derived from those of parents or ancestors.

Patronymics are derived, 1. From the father; as Pelides, i. e. Achilles the son of Peleus. 2. From the mother; as Philides, i. e. Chiron the son of Philyra. 3. From the grandfather on the father's side; as Aëacides, i. e. Achilles the grandson of Aëacus. 4. From the grandfather by the mother's side; as Atlidaides, i. e. Mercury the grandson of Atlas, And, &; From the kings and founders of nations; as Romulides, i. e. the Romans, from their founder Romulus.

The termination of Greek and Latin patronymics are chiefly four, viz. des, of which we have examples above; et, as Thaumantias, i. e. Iris the daughter of Thamus; et, as Atlantias, i. e. Electra the daughter of Atlas; and as, as Nerine, the daughter of Nereus. Of these terminations des is masculine; and et, et, and as, feminine; des and ses are of the first declension, et and is of the third.

The Russians, in their usual mode of addressing, never prefix any title or appellation of respect to their names; but periphrases of all ranks, even those of the first distinction, call each other by their Christian names, to which they add a patronymic. These patronymics are formed in some cases by adding Vitch (the same as our Fitz, as Fitzhebert, or the son of Herbert) to the Christian name of the father; in others by Of or Of; the former is applied only to periphrases of condition, the latter to those of inferior rank. Thus, Ivan Ivanovitch, Ivan Ivanof, is Ivan the son of Ivan; Peter Alexievitch, Peter Alexof, Peter the son of Alexy.

The female patronymic is Ofna or Ofma, as Sophia Alex-
PAT

Alexeufna, or Sophia the daughter of Alexey; Maria Ivanofna, or Maria the daughter of Ivan.

Great families are also in general distinguished by a surname, as those of Romanoff, Galatzin, Sieremetof, &c.

PATTROS, mentioned by Jeremiah and Ezekiel, appears from the context to be a part of Egypt. Bochart thinks he denotes the higher Egypt: the Septuagint translates it the country of Patrobas; in Pliny we have the Noma Plautores; in the Thesaurus, in Ptolemy, Patrois, probably the metropolis. From the Hbrew appellation Patro comes the gentile name Patrobas, Mosis.

PATRO (Oliver), a counsellor in Parliament, and dean of the French academy, was born at Paris in 1604. He had an excellent faculty both of speaking and writing. Upon his admission into the French academy in 1640, he made an oration of thanks, that gave rise to the custom of admittance speeches, which are still in use in that society. M. de Vaugelas owned himself much indebted to him for his assistance in composing his remarks on the French tongue, of which he was by far the greatest master in France; so that he was consulted as an oracle by all the best writers of that nation.

Pattans, or Patans, of Afganistan, a very warlike race of men, who had been subjects of the vast empire of Bochara. They revolted under their governor Abtai Tag, in the 16th century, and laid the foundation of the empire of Ghizni or Gzana. In the Differtation prefixed to Vol. III. of Dow's History, we have this account of the Pattans.

They are divided into distinct communities, each of which is governed by a prince, who is considered by his subjects as the chief of their blood, as well as their sovereign. They obey him without reluctance, as they derive credit to their family by his greatness. They attend him in his wars with the attachment which children have to a parent; and his government, though severe, partakes more of the rigid discipline of a general than the caprice of a despot. Rude, like the face of their country, and fierce and wild as the forms which cover their mountains, they are addicted to incursions and depredations, and delight in battle and plunder. United firmly to their friends in war, to their enemies faithful and cruel, they place justice in force, and conceal treachery under the name of address.

The empire, which took its rise from the revolt of the Pattans, under a succession of warlike princes rose to surprising magnitude. In the beginning of the 18th century, it extended from Iphath to Bengal, and from the mouths of the Indus to the banks of the Jaxartes, which comprehends at least half of the continent of Asia. They had fled to the mountains on the borders of Persia, that they might escape the sword, or avoid submitting to the conquerors of India; and there they formed their state, which the Moguls were never able thoroughly to subdue. Indeed they sometimes exercised depredations on the adjacent countries; nor was it possible for the Moguls either to prevent it or to extirpate them. They were sensible that the climate and soil of the delicious plains would only serve to rob them of that hardiness which they had contracted in the hills to which they were confined; they, therefore, for a long time gave no indications of a desire to exchange them for more pleasing abodes, or a more accessible situation. This enabled them to brave the victorious army of Nadir Shah, whose troops they quietly penetrated into Hindostan, and visited his return with the spoils of that country.

They then harried his army in the braits and defiles of the mountains, and proved themselves such absolute masters of the valleys, that they forced him to purchase from them his passage into Persia.

In the beginning of the present century, they had spread themselves over the adjoining province of Kandahar; and such was the imbecility of the Persian empire at that time, that many other provinces and tributary states were also induced to revolt. When the king or sultan of that time, whose name was Husein, opposed the growing power of this warlike people, he was totally defeated, and Iphath was besieged and obliged to surrender, after having suffered dreadful calamities, to an army consisting of only 30,000 men. In consequence of this, they brought about a revolution in Persia, and subjected it to themselves. This sovereignty, however, they only held for seven years and 21 days, having fallen a sacrifice to the enterprising spirit of Kouli Khan, or Nadir Shah. See Persia, and in the Appendix As換え

PAU, a town of France, in the province of Gascogne and territory of Bearn, with a parliament, a mint, and a cattle. The city of Pau (says Whateley*) is Tournay, for ever memorable in history, since it was the birthplace of Henry IV. That immortal prince was born in the castle, then the usual residence of the kings of Navarre. It stands on one of the most romantic and singular spots I have ever seen, at the west end of the town, upon the brow of a rock which terminates perpendicularly. Below runs the Gave, a river or rather a torrent which rises in the Pyrenees, and empties itself into the Adour. On the other side, about two, miles
Pau

PAV

miles off, is a ridge of hills covered with vineyards, which produce the famous Vin de Joroncon, so much admired; and beyond all, at the distance of nine leagues appear the Pyrenees themselves, covering the horizon from east to west, and bounding the prospect. The castle, though now in a state of decay, is still habitable; and the apartments are hung with tapestry, said to be the work of Jane queen of Navarre, and mother of Henry IV. Gafnon IV. Count de Foix, who married Leonora heiress of the crown of Navarre, began the edifice in 1464; but his successor Henry d'Albret completed and enlarged it about the year 1519, when he made choice of the city of Pau for his residence, and where, during the remainder of his reign, he held his little court. In a chamber, which by its size was formerly a room of state, is a fine whole length portrait of that Jane queen of Navarre whom I have just mentioned. Her dress is very splendid, and resembles those in which Queen Elizabeth is usually painted. Her head dress is adorned with pearls; round her neck she wears a ruff; and her arms, which are likewise covered with pearls, are concealed by her habit quite down to the wrist. At her waist hangs by a chain a miniature portrait. The fingers of her right hand play on the strings of a guitar; and in her left she holds an embroidered handkerchief. The painter has drawn her as young, yet not in the first bloom of youth. Her features are regular, her countenance thin, but rather inclining to long; the eyes hazel, and the eyebrows finely arched. Her nose is well formed though large, and her mouth pretty. She was a great princess, of high spirit, and undaunted magnanimity. Her memory is not revered by the French historians, because she was the protetress of the Huguenots and the friend of Cologni; but the actions of her life evince her distinguished merit.

In one of the adjoining chambers, is another portrait of Henry IV, himself when a boy; and on the second floor is the apartment in which he was born. The particulars of his birth are in themselves so curious, and as relating to so great and good a prince are so peculiarly interesting, that I doubt not you will forgive me enumerating them, even though you should have seen them elsewhere.—His mother Jane had already lost two sons, the duke of Beaumont and the count de Marie. Henry d'Albret, her father, anxious to see an heir to his dominions, enquired her (when she accompanied her husband Antony of Bourbon to the wars of Picardy against the Spaniards), if she proved with child, to return to Pau, and to lie-in there, as he would himself superintend the education of the infant from the moment of its birth. He threatened to disinherit her if she failed to comply with this injunction. The princes, in obedience to the king's command, being in the ninth month of her pregnancy, quitted Compiègne in the end of November, traversed all France in 15 days, and arrived at Pau, where she was delivered of a son on the 15th December 1533. She had always been devout, and he her father's will, which he kept in a golden box; and he promised to show it to her, provided she admitted of his being present at her delivery, and would during the pains of her labour sing a song in the Bearnois language. Jane had courage enough to perform this unusual request; and the king being called on the first news of her illness, she immediately sung a Bearnois song, beginning, 'Notre Dame du bout du pont, aidez moi en cette heure.'—As she finished it, Henry was born. The king instantly performed his promise, by giving her the box, together with a golden chain, which he tied about her neck; and taking the infant into his own apartment, began by making him swallow some drops of wine, and rubbing his lips with a root of garlic. They still show a tortoise-shell which served him for a cradle, and is preserved on that account. Several of the ancient sovereigns of Navarre resided and died in the castle of Pau. François Thebus, who ascended the throne in 1479, died here in 1483. Pau is a handsome city, well built, and contains near 6000 inhabitants. It is a modern place, having owed its excellence entirely to the castle, and to the residence of the kings of Navarre. W. Long. o. 4. N. Lat. 43. 15.

PAVAN, or Pavé, a grave dance used among the Spaniards, and borrowed from them; wherein the performers make a kind of wheel or tail before each other, like that of pauro, "a peacock's" from whence the name is derived. The paavan was formerly in great repute; and was danced by gentlemen with cup and sword; by those of the long robe in their gowns, by princes with their mantles, and by the ladies with their gown tails trailing on the ground. It was called the grand bol, from the solemnity with which it was performed. To moderate its gravity, it was usual to introduce several flourishes, passes, and capers, &c. by way of episodes. Its tablature or score is given at large by Thoinot Arbeau in his Orchesographia.

PAVETTA, in botany; A genus of the monogynia order, belonging to the tetrandra class of plants; and in the natural method ranking under the 47th order, Stellatae. The corolla is monopetalous and funnel-shaped above; the stigma carved; the berry disperses.

Pavia, an ancient and celebrated town of Italy, in the duchy of Milan, and capital of the Pavian, with an university and bishop's see. It was formerly called Ticinum, from its situation on that river, and lies 50 miles to the southward of Milan. It was formerly the capital of the Longobardic kingdom, and is still remarkable for the breadth of its streets, the beauty and richness of some of its churches, and for its university, founded by Charlemagne, and for several other literary institutions. Here is a bishop's see, which was once the richest in Italy, but is now dependent on the pope; and upon the whole the city is gone to decay, its trade being ruined through the exactions of the government. The few objects within it worth the public attention belong to the clergy or monks; and the church and convent of the Carthusians are inexpressibly noble, the court of the convent being one of the finest in the world, and surrounded by a portico supported by pillars, the whole a mile in circumference. It is defended by strong walls, large ditches, good ramparts, excellent battlements, and a bridge over the river Tan. In the centre of the town is a strong castle, where the duke of Milan was wont to reside. There are a great number of magnificent cattles, and some colleges. It was taken by the duke of Savoy in 1706; by the French
PAVILION, in architecture, signifies a kind of turret or building, usually infilled, and contained under a single roof; sometimes square and sometimes in form of a dome: thus called from the resemblance of its roof to a tent.

Pavilions are sometimes also projecting pieces, in the front of a building, marking the middle thereof; sometimes the pavilion flanks a corner, in which case it is called an angular pavilion. The Lvivre is flanked with four pavilions; the pavilions are usually higher than the rest of the building. There are pavilions built in gardens, commonly called summer-houses, pleasure-houses, &c. Some castles or forts consist only of a single pavilion.

PAVILION, in military affairs, signifies a tent raised on poles, to lodge under in the summer-time.

PAVILION, is also sometimes applied to flags, colours, ensigns, standards, banners, &c.

PAVILION, in heraldry, denote a covering in form of a tent, which invests or wraps up the armorial devices of divers kings, and sovereigns, depending only on God and their subjects.

The pavilion consists of two parts: the top, which is the chaplain, or cornet; and the curtain, which makes the middle.

None but sovereign monarchs, according to the French heralds, may bear the pavilion entire, and in all its parts. Those who are elective, or have any dependence, may take the heralds off the head, and retain nothing but the curtains.

PAVILIONS, among jewellers, the underfides and corners of the brilliants, lying between the girdle and the corder.

PAVING, the construction of ground-flours, streets, or highways, in such a manner that they may be conveniently walked upon. In Britain, the pavement of the grand streets, &c. are usually of flint, or rubble-stone; courts, flables, kitchens, halls, churches, &c. are paved with tiles, bricks, flags, or firestone; sometimes with a kind of free-stone and rag-stone.

In some streets, &c. of Venice, the pavement is of brick: churches sometimes are paved with marble, and sometimes with mosaic work, as the church of St Mark at Venice. In France, the public roads, streets, courts, &c. are all paved with gres or grit, a kind of freestone.

In Amsterdam, and the chief cities of Holland, they call their brick pavement the burghe-masters pavement, to distinguish it from the stone or flint pavement, which usually takes up the middle of the street, and which serves for carriages; the brick which borders it being defined for the piazza of the people on foot.

Pavements of free-stone, flint, and flags, in streets, &c. are laid dry, i. e. in a bed of sand: those of courts, flables, ground-rooms, &c. are laid in a mortar of lime and sand; or in lime and cement, especially if there be vaults or cellars underneath. Some masons, after laying a floor dry, especially of brick, spread a thin mortar over it; sweeping it backwards and forwards to fill up the joints. The several kinds of pavement are as various as the materials of which they are composed and whence they derive the name by which they are distinguished; as,

1. Pebble-paving, which is done with stones collected from the sea-beach, mostly brought from the islands of Guernsey and Jersey: they are very durable, indeed the most so of any stone used for this purpose. They are used of various sizes, but those which are from six to nine inches deep, are esteemed the most serviceable. When they are about three inches deep, they are denominated builders or bowers; these are used for paving court yards, and other places not accustomed to receive carriages with heavy weights; when laid in geometrical figure, they have a very pleasing appearance.

2. Rag-paving was much used in London, but is very inferior to pebbles; it is dug in the vicinity of Maidstone in Kent, from which it has the name of Kentish rag-stone; there are squared stones of this material for paving coach-tracks and foot-ways.

3. Purbeck pitches, square stones used in foot-ways; they are brought from the island of Purbeck, and also frequently used in court yards; they are in general from six to ten inches square, and about five inches deep.

4. Squared paving, for decoration by some called Scotch paving, because the flat of this kind paved in the manner that has been and continues to be paved, came from Scotland; the first was a close close stone, called blue whinny, which is now disused, because it has been found inferior to others since introduced in the order they are hereafter placed.

5. Granite, a hard material, brought also from Scotland, of a reddish colour, very superior to the blue whinny quarry, and at present very commonly used in London.

6. Guernsey, which is the best, and very much in use; it is the same stone with the pebble before spoken of, but broken with iron hammers, and squared to any dimensions required of a prismatical figure, set with its smallest base downwards. The whole of the foregoing paving should be bedded and paved in small gravel.

7. Purbeck paving, for foot-ways, is in general got in large surfaces about 2; inches thick; the blue is the hardest and the best of this kind of paving.

8. York-stone paving, is an exceeding good material for the same purpules, and is not of almost any dimensions of the same thickness as the Purbeck. This stone will not admit the wet to pass through it, nor is it affected by the frost.

9. Ryegate, or fire-stone paving, is used for hearths, floors, ovens, and such places as are liable to great heat, which does not affect the stone if kept dry.

10. Newcastle flags, are stones about two feet square, and 1½ or two inches thick; they answer very well for paving out-offices: they are somewhat like the Yorkshire.

11. Portland paving, with stone from the island of Portland; this is sometimes ornamented with black marble dots.

12. Swadling paving, is a black slate dug in Leicestershire, and looks well for paving halls, or in party-coloured paving.

13. Marble paving, is mostly variegated with different marbles, sometimes inlaid in mosaic.

14. Flat brick paving, done with brick laid in sand, mortar

Vol. XIV.
PAUL [ 50 ]

Paving, or grotte, as when liquid lime is poured into the joints.

15. Bricks on edge paving, done with brick laid edge-wise in the same manner.
16. Bricks are also laid flat or edgewise in herring-bone.
17. Bricks are also sometimes laid endwise in sand, mortar, or grotte.
18. Paving is also performed with paving bricks.
19. With ten inch tiles.
20. With foot tiles.
21. With clinker for flables and outer offices.
22. With the bones of animals, for gardens, &c.

And, 23. We have knob-paving, with large gravel-flones, for porticoes, garden-peats, &c.

Pavements of churches, &c. frequently consist of flones of several colours; chiefly black and white, and of several forms, but chiefly squares and lozenges, artfully disposed, there being a great variety of colours to make a surprising diversity of figures and arrangements. M. Truchet, in the Memoirs of the French Academy, has shown by the rules of combination, that two square-flones, divided diagonally into two colours, may be joined together checkerwise in different ways: which appears surprising enough: since two letters or figures can only be combined in two ways.

The reason is, that letters only change their situation with regard to the first and second, the top and bottom remaining the same, but in the arrangement of these flones, each admits of four several situations, in which the order of the square may be changed six times, which gives 64 combinations.

Indeed, from a farther examination of these 64 combinations, he found there were only 32 different figures, each figure being repeated twice in the same situation, though in a different combination; so that the two only differed from each other by the transposition of the dark and light parts.

PAUL, formerly named Saul, was of the tribe of Benjamin, a native of Tarsus in Cilicia, a Pharisee by profession; first a persecutor of the church, and afterwards a disciple of Jesus Christ, and apostle of the Gentiles. It is thought he was born about two years before our Saviour, supposing that he lived 68 years, as we read in a homily which is in the fifth volume of St Chrysofom's works. He was a Roman citizen (Acts xxii. 27, 28.), because Augustus had given the freedom of the city to all the freemen of Tarsus, in consideration of their firm adherence to his interests. His parents sent him early to Jerusalem, where he studied the law at the feet of Gamaliel a famous doctor (id. xxii. 3.) He made very great progress in his studies, and his life was always blameless before men; being very zealous for the whole observance of the law of Moses (id. xxvi. 4, 5.) But his zeal carried him too far; he perverted the church, and insulted Jesus Christ in his members (1 Tim. i. 13.); and when the

protomartyr St Stephen was foned, Saul was not only confenting to his death, but he even stood by and took care of the clothes of those that foned him (Acts vii. 58, 59.) This happened in the 33d year of the common era, some time after our Saviour's death.

At the time of the perfecution that was raised against the church, after the death of St Stephen, Saul was one of those that allowed most violence in diffreting the believers (Gal. i. 13. and Acts xxvi. 11.) He entered into their houses, and drew out by force both men and women, loaded them with chains, and sent them to prison (Acts viii. 3. and xii. 4.) He even entered into the synagogues, where he caused those to be beaten with rods that believed in Jesus Christ, compelling them to blaspheme the name of the Lord.

And having got credentials from the high-priest Caiaphas, and the chief Jews of Damascus, with power to bring to Jerusalem all the Christians he should find there, he went away full of threats, and breathing nothing but blood (Acts ix. 1, 2, 3, &c.) But as he was upon the road, and now drawing near to Damascus, all on a sudden about noon, he perceived a great light to come from heaven, which encompassed him and all those that were with him. This splendor threw them on the ground; and Saul heard a voice that said to him, "Saul, Saul, why persectest thou me?" It was Jesus Christ that spoke to him. To whom Saul answered, "Who art thou, Lord?" And the Lord replied to him, "I am Jesus of Nazareth whom thou percutest; it is hard for thee to kick against the pricks." Saul, all in confusion, asked, "Lord, what is it that thou wouldst have me do?" Jesus bid him arise and go to Damascus, where the will of the Lord would be revealed to him.

Saul then rose from the ground, and felt that he was deprived of sight; but his companions led him by the hand, and brought him to Damascus, where he continued three days blind, and without taking any nourishment. He lodged at the house of a Jew named Judas. On the third day, the Lord commanded a disciple of his, named Ananias, to go to find out Saul, to lay his hands upon him, and to cure his blindness. And as Ananias made excuses, saying, that this man was one of the most violent persecutors of the church, the Lord said to him, Go and find him, because this man is an instrument that I have chosen, to carry my name before the Gentiles, before kings, and before the children of Israel; for I will shew him how many things he must suffer for my name. Ananias went therefore, and found Saul, laid his hand upon him, and restored him to his sight; then rising, he was baptized, and filled with the Holy Ghost. After this he continued some days with the disciples that were at Damascus, preaching in the synagogues, and proving that Jesus was the Messiah (a).

From Damascus he went to Arabia (Gal. i. 17.), probably

(a) The conversion of such a man, at such a time, and by such means, furnishes one of the most complete proofs that have ever been given of the divine origin of our holy religion. That Saul, from being a zealous persecutor of the disciples of Christ, became all at once a disciple himself, is a fact which cannot be controverted without overturning the credit of all history. He must therefore have been converted in the miraculou...
Paul, probably into the neighbourhood of Damascus, being then under the government of Aretas king of Arabi; and having remained there for a little while, he returned to Damascus, where he began again to preach the gospel. He could not hear to see the progress that the gospel made there; and so resolved to put him to death; and they gained to their side the governor of Damascus, who was to apprehend him, and to deliver him to them. Of this Saul had early notice; and knowing that the gates of the city were guarded night and day to prevent him from making his escape, he was let down over the wall in a basket. And coming to Jerusalem to see Peter (Gal. 1:38.), the disciples were afraid to have any correspondence with him, not believing him to be a convert. But Barnabas having brought him to the apostles, Saul related to them the manner of his conversion, and all that had followed in consequence of it. Then he began to preach both to the Jews and Gentiles; and spoke to them with such strength of argument, that not being able to withstand him in reasoning, they resolved to kill him. For this reason, the brethren brought him to Caesarea of Palestine, from whence he came, probably by sea, into his own country Tarfus in Cilicia.

There he continued about five or six years, from the year of Christ 37 to the year 43; when Barnabas coming to Antioch by the order of the apostles, and there having found many Christians, went to Tar­fus to see Saul, and brought him with him to Antioch (Acts xi. 20, 25, 26), where they continued together a whole year, preaching to and instructing the faithful. During this time, there happened a great famine in Judea (Id. ch. 27, 28, &c.), and the Christians of Antioch having made some collections to assist their brethren at Jerusalem, they made choice of Paul and Barnabas to go thither with their offering. They arrived there in the year of Christ 44; and having acquitted themselves of their commission, they returned again to Antioch. They had not been there long before God warned them by the prophets he had in this church, that he had appointed them to carry his word into other places. Then the church betook themselves to fasting and praying, and the prophets Simeon, Lucius, and Manaen, laid their hands on them,

culous manner in which he himself said he was, and of course the Christian religion be a divine revelation; or he must have been either an impostor, an enthusiast, or a dupe to the fraud of others. There is not another alternative possible.

If he was an impostor, who declared what he knew to be false, he must have been induced to act that part by some motive: (See Miracle.) But the only conceivable motives for religious imposture are, the hopes of advancing one's temporal interest, credit, or power; or the prospect of gratifying some passion or appetite under the authority of the new religion. That none of these could be St Paul's motive for professing the faith of Christ crucified, is plain from the state of Judaism and Christianity at the period of his forsaking the former and embracing the latter faith. Those whom he left were the possessors of wealth, of dignity, of power, in Judea: those to whom he went were indigent men, oppressed, and kept from all means of improving their fortunes. The certain consequence therefore of his taking the part of Christianity was the loss not only of all that he possessed, but all hopes of acquiring more; whereas, by continuing to persecute the Christians, he had hopes rising almo to a certainty of making his fortune by the favour of those who were at the head of the Jewish state, to whom nothing could so much recommend him as the zeal which he had shown in that persecution. As to credit or reputation, the scholar of Gamaliel hope to gain either by becoming a teacher in a college of fishermen? Could he flatter himself, that the doctrines which he taught would, either in or out of Judea, do him honour, when he knew that "they were to the Jews a stumbling block, and to the Greeks foolishness?" Was it then the love of power that induced him to make this great change? Power! over whom? over a flock of sheep whom he himself had afflicted to destroy, and whose very Shepherd had lately been murdered? Perhaps it was with the view of gratifying some licentious passion, under the authority of the new religion, that he commenced a teacher of that religion! This cannot be alleged; for his writings breathe nothing but the freest morality, obedience to magistrates, order, and government, with the utmost abhorrence of all licentiousness, idleness, or loose Behaviour, under the cloak of religion. We nowhere read in his works, that faults are above moral ordinances; that dominion is founded in grace; that monarchy is despotic in which ought to be abolished; that the fortunes of the rich ought to be divided among the poor; that there is no difference in moral actions; that any impulses of the mind are to direct us against the light of our reason and the laws of nature; or any of those wicked tenets by which the peace of society has been often disturbed and the rules of morality often broken, by men pretending to act under the sanction of divine revelation. He makes no distinction, like the impostor of Arabia, in favour of himself; nor does any part of his life, either before or after his conversion to Christianity, bear any mark of a licentious disposition. As among the Jews, so among the Christians, his conversations and manners were blameless. It has been sometimes objected to the other apostles, by those who were resolved not to credit their testimony, that, having been deeply engaged with Jesus during his life, they were obliged, for the support of their own credit, and from having gone too far to return, to continue the same professions after his death; but this can by no means be said of St Paul. On the contrary, whatever force there may be in that way of reasoning, it all tends to convince us, that St Paul must naturally have continued a Jew, and an enemy to Christ Jesus. If they were engaged on one side, he was as strongly engaged on the other. If shame withheld them from changing sides, much more ought it to have stopped him: who, from his superior education, must have been vastly more sensible to that kind of shame than the mean and illiterate fishermen of Galilee. The only other difference
Ghofl should conduct a

utation

ineffable things, and which were above the
prehension of man (2 Cor. xii. 2, 3, 4, and Acts xiii. 4, 5, 6, &c.)

Saul and Barnabas went first into Cyprus, where
they began to preach in the synagogues of the Jews.

When they had gone over the whole island, they there
found a Jewish magician called Bar-jesus, who was with
the proconsul Sergius Paulus; and who refuted them,
and endeavoured to prevent the proconsul from
embracing Christianity: whereupon St Paul struck
him with blindness; by which miracle the proconsul, being
blind for three days, said he was ignorant, no man will allege
that he was ignorant, no man will allege

That he had very attentively; and he was
and was deceived by the fraud of others: but this inquiry needs not be long, for
matters of indifference, to "become all things to all men," with the most pliant
condescension, bending his notions and manners to theirs, as far as his duty to
God would permit; a conduct
compatible neither with the stiffness of a bigot nor with the
violence and violence of fanaticical delusion.

That he was not melancholy, is plain from his conduct in embracing every method which prudence could suggest
to escape danger and thus persecution, when he could do it without betraying the duty of his office or the
honour of his God. A melancholy enthusiast courts persecution; and when he cannot obtain it, afflicts him-
self with absurd penances: but the holiness of St Paul consisted only in the simplicity of a godly life, and in the
unnarrowed performance of his apostolical duties. That he was ignorant, no man will allege who is not
grossly ignorant himself; for he appears to have been master not only of the Jewish learning, but also of the
Greek philosophy, and to have been very conversant even with the Greek poets. That he was not credulous,
is plain from his having refuted the evidence of all the miracles performed on earth by Christ, as well as those
that were afterward worked by the apostles; to the fame of which, as he lived in Jerusalem, he could not
possibly have been a stranger. And that he was as free from vanity as any man that ever lived, may be gathered
from all that we see in his writings, or know of his

...
course again on the same subject the next sabbath-day; and several, both Jews and Gentiles, followed them, to receive particular instructions more at leisure. On the Sabbath-day following, almost all the city met together to hear the word of God: but the Jews, seeing the concourse of people, were moved with envy at it: oppressed, with blasphemies, what St Paul said; and not being able to bear the happy progress of the gospel in this country, they raised a persecution against the two apostles: whereupon Paul and Barnabas, shaking off the dust upon their feet against them, came from Antioch in Pisidia to Iconium. Being come thereto, they preached in their synagogue, and converted a great number, both of Jews and Gentiles: and God confirmed their commission by a great number of miracles (Acts xiv. 1, 2, &c.). In the mean time, the unbelieving Jews, having incensed the Gentiles against Paul and Barnabas, and threatening to stone them, they were obliged to retire to Lystra and Derbe, cities of Lycaonia, where they preached the gospel. At Lystra, there was a man who had been lame from his mother's womb. The man fixing his eyes on St Paul, the apostle bid him rise, and stand upon his feet: whereupon he presently rose up, and walked; the people, seeing this miracle, cried out, that the gods were descended among them in the shape of men. They called Barnabas Jupiter, and Paul Mercury, because of his eloquence, and being the chief speaker. The priest of Jupiter brought a bull before the gate, to offer sacrifices to them: but Paul and Barnabas tearing their clothes, and cutting themselves into the middle of the multitude, cried out to them, Friends, what do you do? we are men as well as yourselves: and we are preaching to you to turn away from these vain superstitiouns, and to worship only the true God, who has made heavens and earth. But whatever they could say, they had much ado to restrain them from offering sacrifices to them.

In the mean time, some Jews of Antioch in Pisidia and of Iconium coming to Lystra, animated the people against the apostles. They flonned Paul, and drew him out of the city, thinking him to be dead. But the disciples gathering together about him, he rose up among them, entered again into the city, and the day after left it with Barnabas to go to Derbe. And having here preached the gospel also, they returned to Lystra, to Iconium, and to Antioch in Pisidia. Paffing throughout Pisidia, they came to Pamphylia, and having preached the word of God at Perga, they went down into Attalia. From hence they set sail for Antioch in Syria, from whence they had departed a year before. Being arrived there, they assembled the church together, and told them the great things God had done by their means, and how he had opened to the Gentiles a door to salvation; and here they continued a good while with th: disciples.

St Luke does not inform us of the actions of St Paul from the 45th year of Christ to the time of the council at Jerusalem, which was held in the 50th year of Christ. There is great likelihood that it was during this interval that St Paul preached the gospel from Jerusalem to Illyricum, as he informs us in his epistle to the Romans (xv. 19.) and this without making any stay in those places where others had preached before him. He does not acquaint us with the particulars of those journeys, nor with the success of his preaching; but he says in general, that he had suffered more labours than any other, and had endured more prisons. He was often very near death itself, sometimes upon the water and sometimes among thieves. He run great dangers, sometimes from the Jews and sometimes among false brethren and perverted Christians; he was exposed to great hazards, as well in the cities as in the deserts: he suffered hunger, thirst, nakedness, cold, floggings, watchings (2 Cor. xi. 23-27.), and the fatigues inseparable from long journeys, which were undertaken without any prospect of human succour; in this very different from the good fortune of others who lived by the gospel, who received subsistence from those to whom they preached it, and who were accompanied always by religious women, who ministered to them in their necessaries occasions. He made it a point of honour to preach gratis, working with his hands that he might not be chargeable to any (1 Cor. ix. 1-5.); for he had learned a trade, as was usual among the Jews, which trade was to make tents of leather for the ufe of those that go to war (Acts xviiii. 3.)

St Paul and St Barnabas were at Antioch when some persons coming from Judea (Acts xv 1, 2, &c.) pretended to teach, that there was no salvation without circumcision, and without the observation of the other legal ceremonies. Epiphanius and Philaster say, that he that maintained this was Cerinthus and his followers. Paul and Barnabas withdofl their new doctors; and it was agreed to send a deputation to the apostles and elders at Jerusalem about this question. Paul and Barnabas were deputed; and being arrived at Jerusalem, they reported to the apostles the subject of their commission. Some of the Pharisees that had embraced the faith, adhered, that the Gentiles, that were converted ought to receive circumcision, and to observe the rest of the law. But the apostles and elders assembled to examine into this matter, it was by them decreed, that the Gentiles, who were converted to Christianity, should not be obliged to submit to the yoke of the law, but only to avoid idolatry, fornication, and the eating of things strangled, and blood.

St Paul and St Barnabas were then sent back to Antioc'h with letters from the apostles, which contained the decision of the question, and the resolution of that angelical assembly. The apostles also deputed Jude surnamed Barfaba and Silas, who were principal brethren, to go to Antioch with Paul and Barnabas to give their testimony of what had been decreed at Jerusalem. Being arrived at Antioch, they assembled the faithful, read to them the apostles' letter, and acquainted them, that it had been resolved to discharge them from the yoke of the ceremonial law. Some time after this, St Peter coming to Antioch and joining himself to the converted Gentiles, he lived with them without scruple; but some brethren happening to arrive there from Jerusalem, he separated himself from the Gentile converts, and did no longer eat with them: for which conduct St Paul publicly cenfured him (Gal. ii. 11-16.) St Paul (id. ii. 2, 3, &c.) in the same journey to Jerusalem declared openly to the faithful there the doctrine he preached among the Gentiles; and besides disowned of it in private among the chief of them in presence of Barnabas and Titus.
Paul

St Peter, St James, and St John, with whom he had these conversations, could find nothing either to be added or amended in so pure and so sound a doctrine and manner. They saw with joy the grace that God had given him; they acknowledged that he had been appointed the apostle of the Gentiles, as St Peter had been of the circumcision. They concluded that Paul and Barnabas should continue to preach among the Gentiles; and only recommended to them to take care concerning the collections for the poor; that is to say, to exhort the converted Christians among the Gentiles, to afflict the faithful brethren in Judea, who were in necessity; whether it were because they had sold and distributed their goods, or because they had been taken away from them (Heb. x. 34).

After Paul and Barnabas had continued some days at Antioch, St Paul proposed to Barnabas to return and visit the brethren through all the cities wherein they had planted the gospel, to see in what condition they were. Barnabas consented to the proposal; but infilled upon taking John Mark along with them. This was opposed by Paul, which produced a separation between them. Barnabas and John Mark went together to Cyprus; and St Paul, making choice of Silas, crossed over Syria and Cilicia, and came to Derbe, and afterwards to Lystra (Acts xv. 1, 2, &c.) Here they found a disciple called Timothy, whom St Paul took with him, and circumcised him that he might not offend the Jews of that country. When therefore they had gone over the provinces of Lycaonia, Phrygia, and Galatia, the Holy Ghost would not allow them to preach the gospel in the proconsular Asia, which contained Iconium, Aeolia, and Lydia. They therefore went on to Myra, and coming to Troas, St Paul had a vision in the night. A man, habited like a Macedonian, presented himself before him, and said, Paul and Silas went into Macedonia and came and succour us. Immediately he set out on this journey, not doubting but that God had called him into this country.

Embarking therefore at Troas, they failed towards midnight, which it immediately followed. St Paul and Silas: but the greatest part of the Jews of that country. Hence they came to Philippi, where St Paul had a great ear. Thither he came and succour us. But it shall not be so, for you yourselves shall come to fetch us out. The magistrates hearing that they were Roman citizens, came to excuse themselves; and having brought them out of prison, they desired them to depart out of their city. Paul and Silas went first to the house of Lydia, where having visited and comforted the brethren, they departed from Philippi.

Then passing through Amphipolis and Apollonia, they came to Thessalonica the capital city of Macedonia, where the Jews had a synagogue (Acts xvii. 1, &c.) Paul entered therein, according to his custom, and there preached the gospel to them for three Sabbath days successively. Some Jews and several profylytes believed in Jesus Christ, and united themselves to Paul and Silas: but the greatest part of the Jews being led away by a false zeal, raised a tumult in the city, and went to the house of Jason, where St Paul lodged. But not finding him there, they took Jason and led him before the magistrates, where they accused him of harbouring in his house people that were disobedient to the ordinances of the emperor, and who affirmed that there was another king besides him, one Jesus whom they preached up. But Jason having given security to answer for the people who were accused, he was dismissed to his own house; and the night following the brethren conducted Paul and Silas out of the city, who went to Berea, where they began to preach in the synagogue. The Jews of Berea heard them gladly, and many of them were converted; as also several of the Gentiles and many women of distinction that were not Jews.

The Jews of Thessalonica being informed that Paul and Silas were at Berea, came thither and animated the mob against them; so that St Paul was forced to withdraw, leaving Silas and Timothy at Berea to finish the work he had so happily begun. Those who conducted St Paul embarked along with him, and brought him as far as Athens (Theod. in Thek.); where he arrived in the fifty-second year of Jesus Christ. As soon as he was got thither, he sent back those that had brought him, with orders to tell Jason and Timothy, that he desired them to follow him to Athens as soon as possible. In the mean time, he went into a synagogue of the Jews, and preached to them as often as he had opportunity; and disputing with the philosophers who were frequent in that place, they...
they last brought him before the Areopagus, accusing him of introducing a new religion. St Paul being come before the judges, pleaded in his own defence, that among other marks of superflition which he had found in that city, he had observed an altar inscribed, "To the unknown God." It was therefore this God whom they confessed that they knew not, that he came to make known to them. Afterwards he spoke to them of God the creator of heaven and earth, of the superintendence of a providence, of the last judgment, and of the resurrection of the dead. But after they had heard of the resurrection, some made scorn of him, and others desired to hear him another time. However some of them embraced the Christian faith, of which number was Dionysius a senator of the Areopagus, and a woman called Damarsis, and several others with them.

St Timothy came from Berea to Athens according to the request of St Paul, and informed him of the persecution with which the Christians of Thessalonica were then afflicted. This obliged the apostle to send him into Macedonia, that he might comfort them and keep them steadfast (1 Thess. iii. 1, 2, &c.) After this St Paul left Athens and went to Corinth, where he lodged with one Aquila a Jew, and by trade a tentmaker (Acts xviii. 1, 2, &c.) With this Aquila the apostle worked, as being of the same trade himself. But, however, he did not neglect the preaching of the gospel, which he performed every day in the synagogue, showing both to the Jews and Gentiles that Jesus was the Messiah. There he made several converts; and he tells us himself (1 Cor. i. 14-17. and he was exposed to wild troubles, or delivered from the devils that were by him; though some are of opinion, that the fight here mentioned by St Paul was nothing else but the feuds he had with Demetrius the silversmith and his companions, who were disappointed in their attempt of putting the apostle to death. It was during his abode at Ephesus that the apostle wrote his epistle to the Galatians.

After this St Paul proposed, at the instigation of the Holy Ghost, to pass through Macedonia and Achaia, and afterwards to go to Jerusalem. And then after he had been there, he must also see Rome; and having sent Timothy and Eratus before to Macedonia, he tarried some time in Asia. During this time, he received intelligence that dometie troubles had rived in the church of Corinth, and that abuses had begun to creep in; which made him resolve to write his first epistle to that church.

Soon after this, taking leave of the disciples, he departed for Macedonix (Acts xx. 1, 2, &c.), He embarked at Troas, took Timothy with him, and then passed into Macedonia (2 Cor. ii. 12, and vii. 5-15). Titus came thither to him, and acquainted him with the good effects that his letter had produced among the Corinthians; and told him, that the collections that had been made by the church of Corinth, for the faithful in Palestine were now ready; which engaged Paul to write a second letter to the Corinthians. St Paul, having paused through Macedonia, came into Greece or Achaia, and there continued three months. He visited the faithful of Corinth;
and having received their alms, as he was upon the point of returning into Macedonia, he wrote his epistle to the Romans.

At last he left Greece, and came into Macedonia, in the year of Christ 58, intending to be at Jerusalem at the feast of Pentecost. He fixed some time at Philippi, and there celebrated the feast of the passover. From hence he embarked and came to Troas, where he continued a week. On the first day of the week the disciples being assembled to break bread, as St Paul was to depart the day following, he made a discourse to them which held till midnight. During this time a young man called Eutychus, happening to fall in a window and fall asleep, fell down three stories high, and was killed by the fall. St Paul came down to him, and embraced him, and restored him to life again. Then he went up again, broke bread and eat it, and continued his discourse till day-break, at which time he departed. Those of his company took ship at Troas; but as for himself he went on foot as far as Assos, otherwife called Apollonia, and then embarked along with them at Mitylene. From hence he came to Miletus, whither the elders of the church of Ephesus came to see him; for he had not time to go to them, because he was desirous of being at Jerusalem at the feast of Pentecost.

When these elders were arrived at Miletus, St Paul discoursed with them, and told them that he was going to Jerusalem without certainly knowing what should happen to him; however he did not doubt but that he had much to suffer there, since in all cities the Holy Ghost had given him to understand, that chains and afflictions waited for him at Jerusalem. Nevertheless, he declared to them, that all this did not terrify him, provided he could but fulfill his ministry. After having inquired them to patience, and having prayed along with them, he went on board, going straight to Coos, thence to Rhodes, and thence to Patara (Acts xxii. 3, 2, &c.), where finding a ship that was bound for Phœnicia, they went on board and arrived safe at Tyre. Here they made a stay for seven days, and then going on, they arrived at Ptolemais, and thence at Cæsarea, where they found Philip the evangelist, who was one of the seven deacons. While St Paul was there, the prophet Agabus came thither also from Judea; and having taken St Paul's girdle, he bound his own hands and feet with it, saying, "Thus shall the Jews of Jerusalem bind the man that owns this girdle, and shall deliver him up to the Gentiles." But St Paul's constancy was not shaken by all these predictions; and he told them, that he was ready, not only to suffer bonds, but death itself, for the name of Christ.

When he was come to Jerusalem, the brethren received him with joy; and the day following he went to see St James the less, bishop of Jerusalem, at whose house all the elders assembled. Paul gave them an account of what God had done among the Gentiles by his ministry. Then St James informed him, that the converted Jews were strangely prejudiced against him, because they were informed he taught the Jews that lived among the Gentiles and out of Palestine, that they ought to renounce the law of Moses, and no longer circumcise their children. Therefore, continued St James, we must assemble them here together, where you may speak to them yourself, and undeceive them. Moreover do this, that your acts may verify your words: join yourself to four men that are here, and who have taken upon them a vow of Nazarite ship; and that you may share in the merit of their action, contribute to the charge of their purification, and purify yourself also, that you may offer with them the offerings and sacrifices ordained for the purification of a Nazarite. See Nazarite.

St Paul exactly followed this advice of St James, and on the next day went into the temple, where he declared to the priests, that in seven days the four Nazarites would complete their vow of Nazarite ship; and that he would contribute his share of the charges. But towards the end of the seven days, the Jews of Asia having seen him in the temple, moved all the people against him, laid hold of him, and cried out, "Help, ye Israelites, this is he that teaches every where against the law, and against the temple, and has brought Gentiles into the temple, and profaned this holy place." At the same time they laid hold on him, shut the gates of the temple, and would have killed him, had not Lyfias the tribune of the Roman garrison there run to his rescue, taken him out of their hands, and brought him into the citadel. St Paul being upon the steps, defied the tribune to suffer him to speak to the people, who followed him thither in a great multitude. The tribune permitted him, and St Paul, making a sign with his hand, made a speech in Hebrew (Acts xxii.), and related them the manner of his conversion, and his mission from God to go and preach to the Gentiles. At his mentioning the Gentiles, the Jews began to cry out, "Away with this wicked fellow out of the world, for he is not worthy to live."

Immediately the tribune made him come into the stocks, and ordered that he should be examined by whipping him, in order to make him confess the matter why the Jews were so incensed against him. Being now bound, he said to the tribune, "Is it lawful for you to whip a Roman citizen before you hear him?" The tribune hearing this, caused him to be unbound, and called together the priests and the senate of the Jews, he brought Paul before them, that he might know the occasion of this tumult of the people. Then Paul began to speak to them to this purpose, (Acts xxii.): "Brethren, I have lived in all good conscience before God until this day." At which words, Ananias, son of Nebedeus, who was the chief-priest, ordered the bystanders to give him a blow in the face. At which St Paul said to him, "God shall smite thee, thou witless whit; for fittest thou to judge me after the law, and commandest me to be smitten contrary to the law?" Those that were present said to him, "Revilest thou God's high-priest?" St Paul excused himself by saying, that he did not know he was the high priest, "For it is written, thou shalt not speak evil of the ruler of thy people." Then perceiving that part of the assembly were Sadducees and part Pharisees, he cried out, "Brethren, I am a Pharisee, the son of a Pharisee; of the hope and resurrection of the dead I am called in question."

Then the assembly being divided in interests and opinions, and the clamour increasing more and more, the tribune ordered the soldiers to fetch him away out of
of the assembly, and bring him into the castle. The
following night the Lord appeared to Paul, and said
to him, "Take courage, for as you have borne testi-
mony of me at Jerusalem, so must you also at Rome." 
The day following, more than 40 Jews engaged them-
selves by an oath, not to eat or drink till they had killed Paul. They came therefore, and made known their
design to the priests and chief of the people faying to
them, "To-morrow caufe Paul to appear before you, as if you would inquire more accurately into his affair, and before he can come to you, we will lie in wait for him and kill him." But St Paul, being inforined of this conspiracy by his father's son, ac-
quainted the tribune with it; who gave orders that the
night following he should be sent to Caesarea, to felices by
Felix the Governor, who had his ordinary resi-
tence there. Felix having received letters from Lyfus and been informed that St Paul was of Cilicia, he told
him he would hear him when his accusers should ar-
rive.

Five days after, Annanias the high priest and some
of the senators came to Caesarea, bringing with them
Tertullus the orator, to plead against Paul. Tertul-
lus accused him of being a seditious person, a distur-
er of the public peace; one who had put himself at the
head of a sect of Nazarenes, and who made no scruple
even to profane the temple, (id. xxiv.) But St Paul eas-
ily refuted these calumnies, and declcied his accusers
to prove any of the articles they had alleged against
him: he ended his discourse by saying, "That for
the doctrine of the resurrection from the dead, his adver-
saries would have him condemned," Felix put off the
further hearing of this cause till another time; and,
seven days after, came himself with his wife Druf-
illa to hear Paul: and being in hopes that the apo-
file would purchase his freedom with a sum of money,
he used him well, often sent for him, and had frequent
conversations with him.

Two years having passed thus away, Felix made
way for his successor Portius Felix; but being will-
ning to oblige the Jews, he left Paul in prison. Felix
being come to Jerusalem, the chief priests defircd to
send for Paul, with a defign to fall upon him by the
way. But Felix told them, they might come to Caes-
area, where he would do them justice. Hither the
Jews came, and accused Paul of several crimes, of
which he was able to prove nothing, (id. xxv.) Felix
then proffered to the apostle to go to Jerusa-
lem, and be tried there; but he answered, "That he
was now at the emperor's tribunal, where he ought to
be tried; and that he appealed to Caesar;" whereupon
Felix, having conferred with his council, told him, that
therefore to Caesar he should go.

Some days after, King Agrippa and his wife Beren-
icia coming to Caesarea, defircd to hear Paul; who
pleaded his caufe with such ability, that Agrippa ex-
claimed, "Almoft thou persuadest me to be a Chris-
lian." See AGrippa.

As soon, therefore, as it was resolved to send Paul into
Italy, he was put on board a ship at Adramyttium, a
city of Myfia; and having paflèd over the seas of Cilicia
and Pamphylia, the arrived at Myra in Lycia, where
having found a ship that was bound for Italy, they
went on board, (id. xxvii.) But the feafon being far
advanced (for it was at least the latter end of Septem-
ber), and the wind proving contrary, they with much
difficulty arrived at the Fair Haven, a port in the isle of
Crete. St Paul advised them to winter there: how-
ever, others were of opinion they had better go to Phe-
nicia, another harbour of the fame isle; but as they
were going thither, the wind drove them upon a little
island called Cauda, where the mariners, fearing to
strike upon some bank of sand, they lowered their
maft, and surrendered themfelves to the mercy of the
waves. Three days after this, they threw overboard
the sailing of the ship. Neither fun nor fars had
appeared now for 14 days. In this extreme danger an
angel appeared to St Paul, and {aid him, that God
had given him the lives of all that were in the ship with
him; which were in all 276 fouls. St Paul told them
of his vi fion, exhorted them to take courage, and pro-
nounced them that they fhould all come alive into an
island; and that the vessel only should be loft. On
the 14th night the fear was cast out the lead, and
thought by their founding that they approached near
to fome land. They were attempting to fave themfelves
by going into the boat; but St Paul told the centurion
and the soldiers, that except the sailors continued in
the ship, their lives could not be faved. Then the
soldiers cut the ropes of the boat, and let her drive.
About day break, St Paul persuaded them to take
some nourishment; affuring them that not a hair of
their heads fhould perifh. After his example, they
took fome food, and when they had eaten, they lighten-
ed their vessel, by throwing the corn into the fea.
A fhort time after, they perceived a fhore, where they
reached, if possible, to bring the fhip to. But the ves-
fel having struck against a neck of land that ran out
into the fea, fo that the head remained fixed, and the
ftern was exposed to the mercy of the waves; the sol-
diers, fearing left any of the prisoners, fhould make
their escape by swimming, were for putting them all to
the fword. But the centurion would not suffer them,
being willing to fave Paul; and he commanded them that
could swim to throw themselves fift out of the vefel:
and the reft got planks, fo that all of them came safe
to fhore. Then they found that the isle was called
Melita or Malta; the inhabitants of which received
them with great humanity, (Acts xxvii. 1, 2, 5, &c.)
They being all very wet and cold, a great fire was
lighted to dry them; and Paul having gathered up a
handful of fticks, and put them upon the fire, a viper
leaped out of the fire, and took hold of his hand. Then
the barbarous people faid to one another, "Without
doubt this man is a murderer; and though he has been
faved from the fhipwreck, yet divine vengeance will
pursue him, and will not suffer him to live." But
Paul, flaking the viper into the fire, received no in-
jury from it. The people, feeing this, changed their
opinion of him, and took him for a god; which opin-
ion of theirs was more confirmed, by his curing
the father of Publius, the chief man of the isle, of
a fever and bloody flux. After this miracle, they all
brought out their fick to him, and they were healed.
See Malta.

At the end of three months they embarked again,
and arrived, firft at Syracuse, then at Rhegium, and
lately at Puteoli. Here St Paul found some Christians,
who detained him for seven days; then he {et out
for Rome. The brethren of this city, having been in-
formed of St Paul's arrival came out to meet him as far as Appii forum, and the Three Taverns. And when he was come to Rome, he was allowed to dwell where he pleased, having a soldier to guard him, who was joined to him with a chain. Three days afterwards, St Paul defined the chief of the Jews there to come to him. He related to them in what manner he had been seized in the temple of Jerusalem, and the necessity he was under of appealing to Caesar. The Jews told him, that as yet they had received no information about his affair; and, as for Christianity, they knew nothing of it, but only that it was spoken against everywhere; however, that they should be very willing to have some account of that doctrine from him. A day was appointed for this purpose; when St Paul preached to them concerning the kingdom of God, endeavouring to convince them from Moses and the prophets, that Jesus was the Messiah. Some of them believed what he had said to them, while others disbelieved; so that they returned from him divided among themselves.

Paul dwelt for two whole years at Rome, from the year of Christ 61 to the year 63, in a lodging that he hired, where he received all that came to him, preaching the kingdom of God, and the religion of Jesus Christ, without any interruption.

Hitherto we have had the Acts of the Apostles for our guide, in compiling the history of St Paul; what we shall add hereafter, will be mostly taken from his own Epistles. His captivity did not a little contribute to the advancement of religion; for he converted several persons even of the emperor's court, (Phil. i. 12—18. and iv. 22.) The Christians of Philippi, in Macedonia, hearing that St Paul was a prisoner at Rome, sent Epaphroditus their bishop to him, to bring him money, and otherwise to affist him in their name, (Phil. ii. 25.) Epaphroditus fell sick at Rome; and when he went back to Macedonia, the apostle sent by him his Epistle to the Philipp ans.

It is not known by what means St Paul was delivered from his prison, and discharged from the accusation of the Jews. There is great probability that they durst not appear against him before the Emperor, as not having sufficient proof of what they laid to his charge. However that may be, it is certain that he was set at liberty, after having been two years a prisoner at Rome. He wrote also, during this imprisonment, his Epistles to Philemon and the Colossians.

He was ill in the city of Rome, or at least in Italy, when he wrote his Epistle to the Hebrews. St Paul, having got out of prison, went over Italy; and, according to some of the fathers, sailed into Spain; then into Judea; went to Ephesus, and there left Timothy (Heb. vii. 24. and 1 Tim. i. 3.) preached in Crete, and fixed there Titus, to take care to cultivate the church he had planted in that place. Probably he might also visit the Philippians, according to the promise he had made them, (Phil. i. 23. 26. and ii. 24.) and it is believed, that it was from Macedonia that he wrote the First Epistle to Timothy—Some time after, he wrote to Titus, whom he had left in Crete; he defines him to come to Nicopolis, from whence probably, he sent this letter. The year following, that is, the 63rd year of the Christian era, the apostle went into Asia, and came to Troas, (2 Tim. iv. 13.) Thence he went to visit Timothy at Ephesus, and from that to Mileitus, (2 Tim. iv. 20.) Lastly he went to Rome; and St Chrysostom says, that it was reported, that having converted a cup-bearer and a concubine of Nero, this fio provoked the Emperor, that he saufed St Paul to be apprehended, and clapped into prison. It was in this last place of confinement that he wrote his Second Epistle to Timothy, which Chrysostom looks upon as the apostle's last testament. See Timothy and Titus.

This great apostle at last conformed his martyrdom, the 29th of June, in the 66th year of Jesus Christ, by having his head cut off, at a place called the Salvian aquae. He was buried on the way of Oltium, and a magnificent church was built over his tomb, which is in being to this day. Calmet's Dict. &c.

Paul (St), Cave or Grotto of, in the island of Malta, where St Paul and his company took shelter from the rains when the viper fastened on his arm. Upon this spot there is a church built by the famed Alphonse de Vignacourt, grand master of the order, in the year 1606, a very handsomely built, but a small structure. On the altar piece is a curious painting, representing the apostle shaking off the viper, surrounded with men, women, and children, in attitudes of admiration and surprise, and in the Old Maltese garb; and the whole very well executed. On the top of the painting is the following inscription:

Viperis ignis aetna calore frustra Pauli
Manum invadit; is infule benedicens
Angulbus & herbis admitt omne virus.
M. D. C. V.

Paul, first bishop of Narbonne, or Sergius Paulus the proconsul, converted and made bishop by St Paul, was defended from one of the belt families of Rome. It is said the Apostle called himself Paul, from his name. The Spaniards will have him to be their apostle, which is not improbable; and it is said he died a martyr at Narbonne.

Paul V. by birth a Roman, was first clerk of the chamber, and afterwards nuncio to Clement VIII in Spain, who honoured him with a Cardinal's hat. He was advanced to the papal chair the 16th of May 1605, after Leo XI. The ancient quarrel between the secular and ecclesiastical jurisdictions, which in former times had occasioned so much bloodshed, revived in the reign of this pontiff. The senate of Venice had condemned by two decrees, 1. The new foundations of monasteries made without their concurrence. 2. The alienation of the estates both ecclesiastical and secular. The first decree passed in 1603, and the second in 1605. About the same time a canon and abbot, accused of rapine and murder, were arrested by order of the senate, and delivered over to the secular court; a circumstance which could not fail to give offence to the court of Rome. Clement VIII. thought it proper to dissemble or take no notice of the affair; but Paul V. who had managed the Genoese upon a similar occasion, flattered himself with the hopes that the Venetians would be equally plant. However, he was disappointed for the senate maintained that they held their power to make laws of God only; and therefore they refused to revoke their decrees and deliver up the ecclesiastical
P A U [ 59 ]

Paul. ecclesiastical prisoners into the hands of the nuncio, as
the pope demanded. Paul, provoked at this behaviour,
excommunicated the doge and senate; and threatened
to put the whole state under an interdict, if satisfac-
tion was not given him, within the space of 24
hours. The senate did no more than protest against
this menace, and forbid the publication of it through-
out their dominions. A number of pamphlets, from
both sides, soon announced the animosity of the two
parties. The Capuchins, the Theatins, and Jesu-
tis were the only religious orders who observed the
interdict. The senate shipped them all off for Rome,
and the Jesuits were banished for ever. Meanwhile his
holiness was preparing to make the refractory republic
submit to his spiritual tyranny by force of arms. He
levied troops against the Venetians; but he soon found
his design balked, as the cause of the Venetians ap-
tered to be the common cause of all princes. He
had recourse therefore to Henry IV. to settle the
problems; and this prince had all the honour of
bringing about a reconciliation between the contending
parties. His ambassadors at Rome and Venice be-
gan the negotiation, and Cardinal de Joyeuse finished
it in 1607. It was agreed upon, that this cardinal,
should declare at his entry into the senate, that the
censures of the church were to be taken off, or that
he would remove them; and that the doge should
at the same time surrender to him the deeds of revo-
cation and protest. It was also stipulated, that all the
religious who were banished, except the Jesuits, should
be restored to their former privileges. In fine, the
Venetians promised to lend an ambassador extraordinary
throughout to Rome, in order to thank the pope for the
favour he had done them; but they would not allow
the legate to speak of his holiness granting them ab-
fuon优惠。 Paul was wise enough to overlook the whole
matter, but endeavoured to put an end to another dif-
pute, which had been long agitated in the congregations
de auxilii. He caused it to be intimidated in form to the
disputants and counsellors, that, as the congregations
were now dissolved, it was his express order that the
contending parties should no longer continue to cen-
fure one another. Some authors have affirmed that
Paul V. had drawn out a bull against the doctrine of
Molin, which only wanted to be promulgated; but
for this fact there appears to be no other evidence
than the draught of this bull, which we meet with in
the end of the history of the above-menanted congregations.
Paul was strongly solicited, but in vain, to make the immaculate conception of the holy virgin, an
article of faith. He concealed himself with barest
attachment to the contrary doctrine, to be publicly taught, that he might not offend the Dominicans, who at that
time, maintained that she was conceived, like other hu-
nan creatures, in original sin. His holiness afterwards
applied himself to the establishing of Rome, and was
at great pains to collect the works of the most eminent
painters and engravers. Rome is indebted to him for
its most beautiful fountains, especially that where the
water spouts out from an antique vase taken from the
thermae or hot-baths of Vepachi, and that which
they call agger Pauli, an ancient work of Augustus,
repaired by Paul V. He brought water into it by an
aqueduct 33 miles in length, after the example of
Sixtus V. He completed the frontispiece of St Peter,
and the magnificent palace of Mount Cavallo. He
applied himself in a particular manner to the reco-
viving and repairing ancient monuments, which he
made to advance, as much as the nature of them
would admit, the honour of Christiinity; as appears
from an elegant inscription placed upon a column
of porphyry, taken from the temple of Peace, and bear-
ing a beautiful statue of the Virgin, at the side of
the church of St Mary the elder:

“Impera fulsi templam
Quondam numinis
Jubente moelde perierebam Cæsare :
Nunc laeta veri
Perferens matrem Dei
Te, Paulæ, nulla obiecto faculæ.”

His pontificate was honoured with several illustrious
ambassadors. The kings of Japan, Congo, and other
Indian princes, sent ambassadors to him. He took
care to supply them with missionaries, and to found
bishops and in these countries newly brought over to
the faith. He showed the same attention to the Ma-
ronites and other eastern Christians. He sent legates
to different orthodox princes, both to settle his eitement
for them, and to confirm them in their zeal for reli-
gion. He died the 28th of January 1621, aged 69;
after having confirmed the French oratory, the Uni-
tines, the Order of Charity, and some other institu-
tions. Bold in his claims, but of narrow views, he
distinguished himself more by his piety and and
knowledge than by his politics. It has been remarked, that
he never paid a single day of his papedom without
celebrating masses. He enjoined all the religious in the
profession of their studies to have regular profestors for
Latin, Greek, Hebrew, and Arabic; if there were
any among themselves properly qualified; or if that
was not the case, to take the assistance of laymen for
that purpose, until there were some of their own order
who had learning enough to instruct their brethren.
It was very difficult to carry this decree into execu-
tion; and indeed it was always very imperfectly ob-
vailed.

Paul (Father), whose name, before he entered
into the monastic life, was Peter Sarpi, was born at
Venice, August 14, 1552. His father followed mer-
chandise but with so little success, that at his death
he left his family very ill provided for; but under the
care of a mother whose piety was likely to bring the
blessing of providence upon them, and whose wife con-
duct supplied the want of fortune by advantages of
greater value. Happily for young Sarpi he had a
brother, master of a celebrated school, under whose
direction he was placed by her. Here he lost no time,
but cultivated his abilities, naturally of the first rate,
with unbounded application. He was born for study,
having a natural aversion to pleasure and gaiety, and
a memory so tenacious that he could repeat 30 verses
upon once hearing them. Proprietary to his capa-
city was his progress in literature: at 15, having made
himself master of school learning, he turned his studies
to philosophy and the mathematics, and entered upon
logic under Capella of Cremona, who, through a cele-
bated master of that science, confided himself in a
very little time unable to give his pupil any farther in-
structions.

H 2 As
As Capella was of the order of the Servites, his scholam was induced by his acquaintance with him to engage in the same profession, though his uncle and his mother represented to him the hardships and authority of that kind of life, and advised him with great zeal against it. But he was steady in his resolutions, and in 1566 took the habit of the order, being then only in his 14th year, a time of reflection, and not made him public professor of divinity in the cathedral, and reader of canonical divinity and canon law in that city, but honoured him with many proofs of his esteem. But father Paul finding a court life not agreeable to his temper, quitted it two years afterwards, and retired to his beloved privacy, being then not only acquainted with the Latin, Greek, Hebrew, and Chaldee languages, but with philosophy, the mathematics, cannon law, all parts of natural philosophy, and chemistry itself; for his application was uninterrupted, his head clear, his apprehension quick, and his memory retentive.

Being made a priest at 22, he was distinguished by the illustrious Cardinal Borromeo with his confidence, and employed by him on many occasions, not without the envy of persons of less merit, who were so far exasperated as to lay a charge against him before the Inquisition for denying that the Trinity could be proved from the first chapter of Genesis; but the accusation was too ridiculous to be taken notice of. After this he passed successively through the dignities of his order, of which he was chosen provincial for the province of Venice at the age of 25 years; and discharged this post with such honor, that in 1579 he was appointed, with two others, to draw up new regulations and statutes for his order. This he executed with great success; and when his office of provincial was expired, he retired for three years to the study of natural and experimental philosophy and anatomy, in which he is said to have made some useful discoveries. In the intervals of his employment he applied himself to his studies with so extensive a capacity, as left no branch of knowledge untouched. By him Acquapendente, the great anatomist, confesses that he was informed how vision is performed; and there are proofs that he was not a stranger to the circulation of the blood. He frequently converted up a attainment with mathematicians, upon anatomy with surgeons, upon medicine with physicians, and with chemists upon the analysis of metals, not as a superficial inquirer, but as a complete master. He was then chosen procurator general of his order; and during his residence at Rome was greatly esteemed by Pope Sixtus V. and contrived an intimate friendship with Cardinal Bellarmine and other eminent persons. But the hours of repose, that he employed so well, were interrupted by a new information in the Inquisition; where a former acquaintance produced a letter written by him in cyphers, in which he said, that no pretension was entertained there but by dishonest means. This accusation, however dangerous, was passed over on account of his great reputation; but made such impressions on that court, that he was afterwards denied a bishops see by Clement VIII. After these difficulties were surmounted, F. Paul again retired to his solitude; where he appears, by some writings drawn up by him at that time, to have turned his attention more to improvements in piety than learning. Such was the care with which he read the scriptures, that its being his custom to draw a line under every passage which he intended more nicely to consider, there was not a single word in his New Testament but was underlined. The same marks of attention appeared in his Old Testament, Psalter, and Breviary.

But the most active scene of his life began about the year 1615; when Pope Paul V., exasperated by some decrees of the Senate of Venice that interfered with the pretended rights of the church, laid the whole state under an interdict. The Senate, filled with indignation at this treatment, forbade the bishops to receive or publish the pope's bull; and, convening the reverend fathers of the churches, commanded them to celebrate divine service in the accustomed manner, with which most of them readily complied: but the Jesuits and some of others refusing, were by a solemn edict expelled the state. Both parties having proceeded to extremities, employed their ablest writers to defend their measures. On the pope's side, among others, Cardinal Bellarmine entered the lists, and, with his confederate authors, defended the papal claims with much severity of expression, and very sophistical reasoning; which were confuted by the Venetian apologists in much more decent language, and with much greater solidity of argument. On this occasion F. Paul was most eminently distinguished by his Defence of the Rights of the Supreme Magistrate, his Treatise of Excommunication, translated from Cerfoni, with an Apology, and other writings; for which he was cited before the Inquisition at Rome; but it may be easily imagined that he did not obey the summons.

The Venetian writers, whatever might be the abilities of their adversaries, were at least superior to them in the justice of their cause. The propositions maintained in the side of Rome were these: That the Pope is invested with all the authority of heaven and earth; that all princes are his vassals, and that he may annul their laws at pleasure; that kings may appeal to him, as he is temporal monarch of the whole earth, that he can discharge subjects from their oaths of allegiance, and make it their duty to take up arms against their sovereign, that he may depose kings without any fault committed by them, if the good of the church requires it; that the clergy are exempt from all tribute to kings, and are not accountable to them even in cases of high treason; that the pope cannot err; that his decisions are to be received and obeyed on pain of sin, though all the world should judge them to be false; that the pope is God upon earth; that his sentence and that of God are the same: and that to call his power in question is to call in question the power of God: maxims equally shocking,
weak, pernicious, and absurd; which did not require the abilities or learning of F. Paul to demonstrate their fallacious and destructive tendency. It may be easily imagined that such principles were quickly overthrown, and that no court but that of Rome thought it for its interest to favour them. The pope, therefore, finding his authors confuted and his cause abandoned, was willing to conclude the affair by treaty; which, by the mediation of Henry IV. of France, was accommodated upon terms very much to the honour of the Venetians. But the defenders of the Venetian rights were, though comprehended in the treaty, excluded by the Romans from the benefit of it: some, upon different pretences, were imprisoned; some sent to the galleys; and all debarred from preferment. But their malice was chiefly aimed against F. Paul, who soon found the effects of it; for as he was going one night to his convent, about six months after the accommodation, he was attacked by five ruffians armed with filettoes, who gave him no less than fifteen flaps, three of which wounded him in such a manner that he was left for dead. The murderers fled for refuge to the nuncio, and were afterwards received into the pope's dominions; but were purveyed by divine justice, and all, except one man who died in prison, perished by violent deaths.

This, and other attempts upon his life, obliged him to confine himself to his convent, where he engaged in writing the History of the Council of Trent; a work unequalled for the judicious disposition of the matter, and artful texture of the narration; commended by any historian, as on every other day of that affair, the men of the nation, and artists employed to relieve his has been for a time a very severe, and perhaps not unjust, censure of some other modern sects as well as of the Socinians.

PAULICANS, a branch of the ancient Manichees, so called from their founder, one Paulus, an Arminian, in the seventh century; who, with his brother John, both of Samosata, formed this sect: though others

are
are of opinion, that they were thus called from another Paul, an Armenian by birth, who lived under the reign of Julian II. In the seventh century a zealot called Constandine revived this drooping sect, which had suffered much from the violence of its adversaries, and was ready to expire under the severity of the imperial edicts, and that zeal with which they were carried into execution. The Paulicians, however, by their number, and the countenance of the emperor Nicephorus, became formidable to all the East.

But the cruel rage of persecution, which had for some years been unfed, broke forth with redoubled violence under the reigns of Michael Cupropalates and Leo the Armenian, who inflicted capital punishment on such of the Paulicians as refused to return into the bosom of the church. The empress Theodora, tutors of the emperor Michael, in 843, would oblige them either to be converted or to quit the empire; upon which several of them were put to death, and more retired among the Bulgarians; many of them, either from a principle of zeal for the propagation of their religion, or from a natural desire of flying from the persecution which they suffered under the Grecian yoke, retired, about the close of the eleventh century, from Bulgaria and Thrace, and formed settlements in other countries. Their first migration was into Italy; whence, in course of time, they sent colonies into almost all the other provinces of Europe, and formed gradually a considerable number of religious assemblies, who adhered to their doctrine, and who were afterwards persecuted with the utmost vehemence by the Roman pontiffs. In Italy they were called Patarini, from a certain place called Pataria, being a part of the city of Milan, where they held their assemblies; and Gaithari or Gaziari, from Gazaria, or the Lesser Tartary. In France they were called Albigenenses, though their faith differed widely from that of the Albigenenses whom Protestant writers generally vindicate. (See Albigenenses.) The first religious assembly the Paulicians had formed in Europe is said to have been discovered at Orleans in 1017, under the reign of Robert, when many of them were condemned to be burnt alive. The ancient Paulicians, according to Photius, expressed the utmost abhorrence of Manes and his doctrine. The Greek writers compute their errors under the following particulars: 1. They denied that this inferior and visible world is the production of the Supreme Being; and they disfigured the Creator of the world and of human bodies from the most High God who dwells in the heavens: and hence some have been led to conceive that they were a branch of the Gnostics rather than of the Manichaeans. 2. They treated contemptuously the Virgin Mary; or, according to the usual manner of speaking among the Greeks, they refused to adore and worship her. 3. They refused to celebrate the institution of the Lord's supper. 4. They loaded the cross of Christ with contempt and reproach; by which we are only to understand, that they refused to follow the absurd and superstitious practice of the Greeks, who paid to the pretended wood of the cross a certain sort of religious homage. 5. They rejected, after the example of the greatest part of the Gnostics, the books of the Old Testament; and looked upon the writers of that sacred history as inspired by the Creator of this world, and not by the supreme God. 6. They excluded prebys and elders from all part in the administration of the church.

Paulina, a Roman lady, wife of Saturnus governor of Syria, in the reign of the Emperor Tiberius. Her conjugal peace was disturbed, and violence was offered to her virtue, by a young man named Mundus, who fell in love with her, and had caused her to come to the temple of Isis by means of the priests of that god, who declared that Ambitus wished to communicate to her something of moment. Saturnus complained to the emperor, which had been offered to his wife; and the temple of Isis was overturned, and Mundus banished, &c. — There was besides a Paulina, wife of the philosopher Seneca. She attempted to kill herself when Nero had ordered her husband to die. The emperor, however, prevented her; and she lived some few years after in the greatest melancholy.

Paulinia, in botany: A genus of the trignia order, belonging to the oastaria class of plants; and in the natural method ranking under the 23rd order, Triglete. Its characters are these: the flower has a permanent emplacement, composed of four small oval leaves; it has four oblong oval petals, twice the size of the emplacement; and eight short staminas with a turbinated germen, having three short slender styles, crowned by spreading ligmas; the germen turns to a large three-cornered capsule with three cells; each containing one almost oval seed. Linnaeus reckons seven, and Miller nine, species, natives of the West Indies.

Paulinus, a bishop who flourished in the early part of the 7th century. He was the apostle of Yorkshire, having been the first archbishop of York. This dignity seems to have been conferred on him about the year 626. He built a church at Almonbury, and dedicated it to St Alban, where he preached and converted the Brigantes. Camden mentions a croos at Dewborough, which had been ered to him with this inscription, Paulinus hic predixit et celebravit. York was so small about this time, that there was not so much as a small church in it in which King Edwin could be baptized. Constantius is said to have made it a bishopric. Pope Honorius made it a metropolitan see. We are told that Paulinus baptized in the river Swale, in one day, 10,000 men, besides women and children, on the first conversion of the Saxons to Christianity, besides many at Halidon. At Wallstone, in Northumberland, he baptized Segbert king of the East Saxons. Bede says, "Paulinus coming with the king and queen to the royal manor called Ad-Gibrin (now Yeverin), laid there 26 days with them, employed in the duties of catechizing and baptizing. In all this time he did nothing from morning to night but instruct the people, who flocked to him from all the villages and places, in the doctrine of Christ and salvation; and, after they were instructed, baptizing them;}
to the fame Bed; "he preached the word in the province of Lindolfi; and first converted the governor of the city of Lindocollina, whose name was Blecca, with all his family. In this city he built a fine church of exquisite workmanship, whose roof being ruined by long neglect or the violence of the enemy, only the walls are now standing." He is also said to have founded a collegiate church of prebends near Southwell in Nottinghamshire, dedicated to the Virgin Mary. This church he is said to have built when he baptized the Coritani in the Trent.

PAULO (Marco), a celebrated traveller, was son to Nicholas Paulo, a Venetian, who went with his brother Matthew, about the year 1255, to Constantinople, in the reign of Baldwin II. Nicholas, at his departure, left his wife big with child; and the brought to the world the famous Marco Paulo, the subject of this memoir. The two Venetians, having taken leave of the emperor, crossed the Black Sea, and travelled into Armenia; whence they passed over land to the court of Barka, one of the greatest lords of Tartary, who loaded them with honours. This prince having been defeated by one of his neighbours, Nicholas and Matthew made the best of their way through the deserts, and arrived at the city where Kublai, grand khan of the Tartars, reigned. Kublai was entertained with the account which they gave him of the European manners and customs; and appointed them ambassadors to the pope, in order to demand of his holiness a hundred missionaries. They came accordingly to Italy, obtained from the Roman pontiff two Dominicans, the one an Italian the other an Afaite, and carried along with them young Marco, for whom Kublai expressed a singular affection. This young man, having learned the different dialects of Tartary, was employed in embassies which gave him the opportunity of traversing Tartary, China, and other eastern countries.

At length, after a residence of seventeen years at the court of the grand khan, the three Venetians returned to their own country in the year 1295, with immense fortunes. A short time after his return, Marco served his country at sea against the Genoese, his galley, in a great naval engagement was sunk, and himself taken prisoner, and carried to Genoa. He remained there many years in confinement; and, as well to amuse his melancholy as to gratify those who desired it from him, he sent for his notes from Venice, and composed the history of his own and his father's voyages in Italy, under this title, Delle Maraviglie del mondo da lui vedute, &c.; the first edition of which appeared at Venice, in 8vo, 1496. His work was translated into different languages, and inserted in various collections. The editions most esteemed are the Latin one published by Andrew Muller at Cologne, in 4to, 1671; and that in French, to be found in the collection of voyages published by Bergeron, at the Hague, 1735, in 2 vols. 4to. In the writings of Marco Paulo, there are some things true and others highly incredible. It is indeed difficult to believe, that as soon as the great khan was informed of the arrival of two Venetian merchants who were come to sell theriac (or treacle) at his court, he sent before them an escort of 40,000 men, and afterwards dispatched these Venetian ambassadors to the Pope, to beseech his holiness to send him a hundred missionaries. It is equally difficult to believe that the pope, who doubtless had an ardent zeal for the propagation of the faith, instead of a hundred, should have sent him only two missionaries. There are therefore some errors and exaggerations in Marco Paulo's narrative; but many other things which were afterwards verified, and which have been of service to succeeding travellers, prove that in several respects his relation is valuable. He not only gave better accounts of China than had been before received; but likewise furnished a description of Japan, of many of the islands of the East Indies, of Madagascar, and the coasts of Africa; so that from his work it might be easily collected, that a direct passage by sea to the Indies was not only possible but practicable. It may be worth while to add, that, in the opinion of the authors of the Universal History, what he wrote from his own knowledge is both curious and true, so that where he has erred his father and uncle must have deceived him.

PAULUS AEMLILUS. See AEMLUS vs Paulus.

PAVO, the peacock, in ornithology; a genus belonging to the order of gallinae. The head is covered with feathers which bend backwards; the feathers of the tail are very long, and beautifully variegated with eyes of different colours. Latham enumerates eight species:

1. The cristatus, or common peacock of England, is rather less than the male. The female has rather less than the male. The train is very short, being much shorter than the tail, and fearfully longer than its coverters; neither are the feathers furnished with eyes. The crest on the head is similar to that on the head of the male; the sides of the head have a greater portion of white: the throat and neck,
where they are black: the instructions for collecting their
infections. Lots come male, matrons, of fritters, common
in wheat.

care the cry is loud and inharmonious; a
for his land than

fot this

fame luxury, and fold

in St Helena, at

cold

lines, but growing yellowish towards
the ends where they are black: the upper tail covers
are fewer than those of the common peacock, but
much longer than the tail; they are of a cheetah brown,
with white shafts, and have at the end of each a large
spot gilded in the middle, then blue, and surrounded
with green: the legs are ash-coloured, and not
furrihied with spurs, or have they been overlooked
by those who have seen them.
The female is smaller than the male; and differs in
having the belly quite black, and the upper tail
covers much shorter: the tail is green, edged with
blue, and white shafts. It inhabits Japan, and is only
known to Europe by means of a painting, sent by
the emperor of Japan to the pope.

So beautiful a species of birds as the peacock could
not long remain a stranger in the more distant parts
in which they were produced; for so early as the days
of Solomon, we find, among the articles imported
in his Tarshish navies, apes, and peacocks. A
monarch so convenient in all branches of natural
history, "who spoke of trees from the cedar of Leba-
non, even unto the hyppoc that springeth out of the
wall; who spoke of beasts and of fowl," would
certainly not neglect furnishing his officers with
instructions for collecting every curiosity in the
countries they voyaged to, which gave him a knowledge
that distinguished him from all the princes of his time.

Heliian relates, that they were brought into Greece
from some barbarous country; and that they were held
in such high esteem, that a male and female were val-
ued at Athens at 1000 drachms, or 32l. 5s. 1od.
Their next step might be to Samos; where they were
preferred about the temple of Juno, being the birds fi-
cred to that goddess; and Celsus, in his Noct. Attic.,
c. 16. commends the excellency of the Samian pe-
cocks. It is therefore probable, that they were
brought there originally for the purposes of superflu-
itv, and afterwards cultivated for the uses of luxury.
We are also told, when Alexander was in India, he

(a) Taversier's Travels, vol. iii. p. 57. The inhabitants of the mountains on both sides of the Ganges
catch them with a birdlime, prepared from the milky
juice of two sorts of trees ficus religiosa & indica.—
Lam., boiled with oils into a confection; which proves sufficiently tenacious to entangle them, or the largest

(b) They must have been in plenty notwithstanding; or the emperor Vitellius could not have got sufficient
for his large dish, called the Bucale of Misserus, which, history says, was filled with the livers of stari, tongues
of flamingoes, and brains of pheasants and peacocks.
found vast numbers of wild ones on the banks of the
Hydoritis; and was so struck with their beauty, as to
at a point a severe punishment on any person that killed
them.

Peacocks crests, in ancient times, were among the
ornaments of the kings of England. Ernald de Ac-
lent was fined to king John in 140 falaries, with fack-
butts, lorains, gift spurs, and peacock crests, such as
would be for his credit. See plate CCCX. X.

5. The pavo bicoloratus, is larger than the common
pheasant. The bill is black, but from the nostrils to
the tip of the upper mandible red. The irides are yel-
low. The feathers on the crown of the head are suf-
ficiently long to form a crest, of a dull brown colour.
The space between the bill and eyes is naked, with a
few fatted hairs: the fides of the head are white:
the neck is bright brown, interated with dusky
brown: the upper parts of the back, scapulars, and
wing coverts, are dull brown, d-ted with paler brown
and yellowish; besides which, each feather near the end
with a roundish large spot of a gilded purple colour,
changing into blue and green in different lights: the lower
part of the back and rump are dotted with white: all the under parts are brown, flari-
ated transversely with black: the quills are dusky, the
secondaries are marked with the same spot at the root
of the wings; the upper tail coverts are longer than the
tail, and each marked at the end with a spot like
the wing feathers, each of which is surrounded first
with a circle of black, and ultimately with an orange
one: the legs and claws are brown, and on the back
part of each leg are two spurs, one above the other.

The female is a third smaller than the male. The head,
neck, and under parts are brown; the head smooth:
the upper parts are also brown, and the feathers mark-
ed with a dull blue spot, surrounded with dirty orange:
the feathers which cover the tail are similar; but
marked at the end with an obscure dull oval spot of
blue: the legs have no spurs.

This species is of Chinese origin, and some of them
have been brought from China to England alive, and
have been in some time in the possession of Mr James
Monro. The male is now in the Leverian Museum,
in the finest preservation.

Someone observes, that the bird from whence his
description was taken had two spurs on one leg, and
three on the other. This must surely be a supxis na-
ture; especially as he says, it is the same as that in
Eden, pl. 67.

6. The pavo tibetanus, is about the size of a pinta-
do, being about two feet and nearly two inches long.
The bill is above an inch and a half long, and cinere-
ous: the irides are yellow: the head neck and under
parts are ash coloured, marked with blackish lines:
the wing coverts, back and rump, are grey, with small
white dots; besides which, on the wing coverts and
back are large round spots of a fine blue, changing in
different lights to violet and green gold: the quills and
upar tail coverts are also grey, marked with black-
ishes; the quills have two round blue spots on each,
like those of the coverts; on the outer webs, and on
each tail feather, there are four of the same, two on
each side of the web; the middle coverts are the longest,
the others shorten by degrees: the legs are grey, fur-
nished with two spurs behind, like the tail species:
the claws are blackish. This species inhabits the
kingdom of Thibet. The Chinese give it the name of
Chin tibet. Khi.

Pavo, in ichthyology. See Persever. See.

Pavo, in astronomy, a constellation in the souther-
hemisphere, unknown to the ancients, and not visible
in our latitude. It consists of 14 stars, of which the
names and situations are as follow:

PAVOR, a Roman deity, whose worship was intro-
duced by Tullius Hostilius, who, in a panic, vowed a
shrine to him, and one to Pallor, Palens; and there-
fore they are found on the coins of that family.

PAUREDASTYLE, in natural history, the
name of a genus of perfect crystals with double py-
ramids, and no intermediate column, composed of
12 planes, or two hexagonal pyramids joined base to
base.

PAUSANIA, in Grecian antiquity, a festival in
which were solemn games, wherein nobody contend-
but free-born Spartans; in honour of Pausanias
the Spartan general, under whom the Greeks over-
came the Persians in the famous battle of Plataea.

PAUSANISUS, a Spartan king and general, who
signalled himself at the battle of Plataea against the
Persians. The Greeks, very sensible of his services,
rewarded his merit with a tenth of the spoils taken
from the Persians. He was afterwards appointed to
command the Spartan armies, and he extended his
conquests in Asia: but the haughtiness of his behavi-
our created him many enemies; and the Athenians
soon obtained a superiority in the affairs of Greece —
Pausanias, dissatisfied with his countrymen, offered to
betray Greece to the Persians, if he received in mar-
riage as the reward of his perfidy the daughter of
their king. His intrigues were discovered by means
of a young man who was intrusted with his letters to
Peri, and who refused to go, on recoiling that such
as had been employed in that office before had never
returned. The letters were given to the Ephori of
Sparta, and the perfidy of Pausanias was thus dis-
covered. He fled for safety to a temple of Minerva; and as the
fandity of the place screened him from the violence
VOL. XIV.
PAUSANIAS, a learned Greek historian and orator in the second century, under the reign of Antonius the philosopher, was the disciple of Herodotus Atticus. He lived for a long time in Greece; and afterwards went to Rome, where he died at a great age. He wrote an excellent description of Greece, in ten books; in which we find not only the situation of places, but the antiquities of Greece, and every thing most curious and worthy of knowledge. Abbé Gedoin has given a French translation of it, in 2 vols 4to.

PAUSE, a stop or cessation in speaking, finging, playing, or the like. One use of pointing in grammar is to make proper pauses, in certain places.——There is a pause in the middle of each verse; in an hemistich, it is called a ref or repeat. See POETRY, and READING.

PAW, in the manage. A horse is said to paw the ground, when, his leg being either tired or painful, it does not rest it upon the ground, and seems to hurt himself as he walks.

PAWN, a pledge or gage for security of payment of mony lent. It is said to be derived a pugno, quia res que pignori dantur, pugno vel manu traduntur. The party that pawns goods hath a general property in them; they cannot be forfeited by the party that hath them in pawn for any offence of his, nor be taken in execution for his debt; neither may they otherwise be put in execution till the debt for which they are pawned is satisfied.

If the pawn is laid up, and the pawnee robbed, he is not answerable; though if the pawnee use the thing, as a jewel, watch, &c. that will not be the worse for wearing, which he may do, it is at his peril; and if he is robbed, he is answerable to the owner, as the using occasioned the loss, &c.

If the pawn is of such a nature that the keeping is a charge to the pawnee, as a cow or a horse, &c. he may milk the one and ride the other, and this shall go in recompense for his keeping.

Things which will grow the worse by using, as apparel, &c. he may not use.

PEA, in botany. See PISUM.

PEACE (Temple of), a celebrated temple at Rome, which was consumed by fire A. D. 191; produced, as some writers suppose, by a flight earthquake, for no thunder was heard at the time. Dio Cassius, however, supposes that it began in the adjoining houses. Be that as it will, the temple, with all the surrounding buildings, were reduced to ashes. That magnificent structure had been raised by Vespasian after the destruction of Jerusalem, and enriched with the spoils and ornaments of the temple of the Jews. The ancients speak of it as one of the most lofty buildings in Rome. There men of learning used to hold their assemblies, and lodge their writings, as many others deposited their jewels, and whatever else they esteemed of great value. It was likewise made use of as a kind of magazine for the spices that were bought by the Roman merchants out of Egypt and Arabia; so that many rich persons were reduced to beggary, all their valuable effects and treasures being consumed in one night, with the temple.

PEACH, in botany. See AMYGDALUS.

PEACOCK, in ornithology See PAVO.

Peacock Fili. Pinna ani ruddis 55 caudalí falcata. The body of this fih is of various colours; the fin of the anus has 55 streaks, and its tail is in the form of a crenet. The head is without scales; it is brown upon the upper part, yellow above the eyes, and of a silver colour on the sides. The back is round, and adorned with beautiful blue streaks in a serpentine form; and the belly bright as silver. The fins of the breast are round, and, like those of the belly, have a yellow ground with a grey border; that of the back is of a violet colour; that of the anus is straw coloured; and, lastly, that of the tail is yellow on the sides, red towards the middle, and bordered with a deep blue.

There is a variety of this fish found only in the Indian seas, and therefore called the Indian peacock fih; which is thus described in the language of Linnaeus: Pavo pinna caudalí forcipata; pinna dorfa út 14: acela carcel ò pone oncele. It has the fin of its tail forked: 14 sharp points or prickles on the back, with around blue fire break behind the eyes.

The body of this fish is of an elliptical form; the head is covered with scales to the tip of the fin. The two jaws are armed with long and sharp teeth; the ball of the eye is black, and the iris of a white colour, with a mixture of green. At the infection of the fins of the belly is found a bony substance. The head, back, and sides, are of a yellow colour, more or less deep, and covered with lines or streaks of sky blue. These colours are so agreeably mixed, that they resemble the elegance of the peacock's tail.

PEAK OF DERBYSHIRE, a chain of very high mountains in the county of Derby in England, famous for the mines they contain, and for their remarkable caverns. The most remarkable of these are Pool's barn and Elen: the former is a cave at the foot of a high hill called Cottring, so narrow at the entrance that passengers are obliged to crawl on all fours; but it soon opens to a considerable height, extending to above a quarter of a mile, with a roof somewhat resembling that of an ancient cathedral. By the petrifying water continually dropping in many parts of the cave are formed a variety of curious figures and representations of the works both of nature and art. There is a column here as clear as alabaster, which is called The Queen of Scots Pillar, because Queen Mary is said to have proceeded thus far when she visited the cavern. It seems the curiosity of that princess had led her thus far into this dark abode; and indeed there are few travellers who care to venture farther; but others determined to see the end of all, have gone beyond it. After sliding down the rock a little way, is found the dreary cavity turned upwards; following its course, and climbing from crag to crag, the traveller arrives at a great height, till the rock, closing over his head.
on all sides, puts an end to any farther subterraneous journey. Just at turning to descend, the attention is caught by a chasm, in which is seen a candle glimmering at a vast depth underneath. The guides say, that the light is at a place near Mary Queen of Scots pillar, and no less than 80 yards below. It appears frightfully deep indeed to look down; but perhaps does not measure any thing like what it is said to do. It is pitch'd fire by the Queen of Scots pillar, it will make a report as loud as a cannon. Near the extremity, there is a hollow in the roof, called the Needle's Eye; in which if a candle is placed, it will represent a star in the firmament to those who are below. At a little distance from this cave is a small clear stream consisting of hot and cold water, so near each other, that the finger and thumb of the same hand may be put, the one into the hot water and the other into the cold.

Elden-hole is a dreadful chasm in the side of a mountain; which, before the latter part of the last century, was thought to be altogether unfathomable. In the time of Queen Elizabeth, a poor man was let down into it for 200 yards; but he was drawn up in a frenzy, and soon after died. In 1682, it was examined by Captain Collins, and in 1699 by Captain Sturmy, who published their accounts in the Philosophical Transactions. The latter defended by ropes fixed at the top of an old lead-ore pit, four fathoms perpendicular. At 200 yards, he found a rich mine; but immediately after came a violent head-ach, which after continuing four days abated a little; however, will probably never be accounted on account of its vast use.

Pearce, in heraldry, is when the field of a coat of arms is fable, and the powderings or. PEARCE, in botany. See Pyrus. pear- Glovis. See vitensis Lactuca. PEARCE (Dr.), lord bishop of Rochester, was the son of a distiller in High Holborn. He married Miss Adams, the daughter of a distiller in the same neighbourhood, with a considerable fortune, who lived with him 52 years in the highest degree of conjugal happiness. He had his education in Westminster school, where he was distinguished by his merit, and elected one of the king's scholars. In 1716, when he was 20 years old, he was elected to Trinity College, Cambridge. During the first years of residence at the university, he sometimes amused himself with lighter compositions, some of which are inserted in the Guardian and Spectator.

In 1716, he published his edition of Cicero De Oratione, and, at the desire of a friend, luckily dedicated it to Lord Chief Justice Parker (afterwards Earl of Macclesfield), to whom he was a stranger. This incident laid the foundation of his future fortune: for Lord Parker soon recommended him to Dr Bentley, Maller of Trinity, to be made one of the fellows; and the doctor consented to it on this condition, that his lordship would promise to unmake him again as soon as it lay in his power to give him a living. In 1717 Mr Pearce was ordained at the age of 27; having taken time enough, as he thought, to attain a sufficient knowledge of the sacred office. In 1718, Lord Parker was appointed chancellor, and invited Mr Pearce to live with him in his house as chaplain. In 1719, he was inducted into the rectory of Stapleford Abbot, in Essex; and in 1720 into that of St Bartholomew, behind the Royal Exchange, worth 400 l. per annum. In 1724, the lord chancellor presented him to St Martin's in the Fields. His Majesty, who was then at Hanover, was applied to in favour of St Claget who was then along with him, and the doctor actually kissed hands upon the occasion: but the chancellor, upon the king's return, disputed the point and was permitted to present Mr Pearce. Mr Pearce soon attracted the notice and esteem of persons in the highest stations and of the greatest abilities. Befide Lord Parker, he could reckon among his patrons or friends, Lord Macclesfield, Mr Pulteney (afterwards Earl of Bath), archbishop Potter, Lord Hardwicke, Sir Isaac Newton, and other illustrious personages. In 1724, the degree of doctor of divinity was conferred on him by archbishop Wake. The same year he dedicated to his patron, the earl of Macclesfield, his edition of Longinus on the Sublime, with a new Latin version and notes.

When the church of St Martin's was rebuilt, Dr Pearce preached a sermon at the consecration, which he afterwards printed, and accompanied with an Essay on the origin and progress of temples, traced from the rude flones of which were first used for altars to the noble structure of Solomon, which he considers as the first temple completely covered. His observations on that building which is called the Temple of Dagon removes part of the difficulty which prevents itself in the narration of the manner in which Solomon destroyed it.

The deanery of Winchester becoming vacant, Dr
Pearce was appointed dean in 1739; and in the year 1744 he was elected prolocutor of the lower house of convocation for the bishop of Canterbury. His friends now began to think of him for the episcopal dignity; but Mr Dean's language rather declined it. However, after several difficulties had been flourished and removed, he consented to accept the bishopric of Bangor, and promised Lord Hardwicke to do it with a good grace. He accordingly made proper acknowledgments of the royal goodnefs, and was consecrated Feb. 12, 1748.

Upon the declining state of health of Dr Wilcocks, bishop of Rochester, the bishop of Bangor was several times applied to by archbishop Herring to accept of Rochester, and the deanship of Welfminton, in exchange for Bangor; but the bishop then first signified his desire to obtain leave to resign and retire to a private life. His lordship, however, upon being pressed, suffered himself to be prevailed upon.—"My Lord (said he to the Duke of Newcastle), your grace offers these dignities to me in so generous and friendly a manner, that I promise you to accept them." Upon the death of Bishop Wilcocks he was accordingly promoted to the see of Rochester and deanery of Welfmite, on Feb. 1756. Bishop Sherlock died 1761, and Lord Bath offered his interest for getting the Bishop of Rochester appointed to succeed him in the diocese of London; but the bishop told his lordship, that he had determined never to be bishop of London or archbishop of Canterbury.

In the year 1763, his lordship being 73 years old, and finding himself left fit for the business of his stations as bishop and dean, informed his friend Lord Bath of his intention to resign both, and live in a retired manner upon his private fortune. Lord Bath undertook to acquaint his majesty; who named a day and hour, when the bishop was admitted alone into the closet. He told the king, that he wished to have some interval between the Engagements of business and eternity; and desired his majesty to consult proper persons about the propriety and legality of his resignation. In about two months the king informed him, that Lord Mansfield faw no objection; and that Lord Northington, who had been doubtful, on further consideration thought that the sequel might be complied with. Unfortunately for the bishop, Lord Bath applied for Bishop Newton to succeed. This alarmed the ministry, who thought that no dignities should be obtained but through their hands. They therefore opposed the resignation; and his majesty was informed that the bishop disliked the design. His majesty sent to him again; and at a third audience told him, that he must think no more of resigning. The bishop replied, "Sir, I am all duty and submission," and then retired.

In 1768 he obtained leave to resign the deanship; in 1773, he left his lady; and after some months of lingering decay, he died at Little Ealing, June 29, 1774. This eminent prelate distinguished himself in every part of his life by the virtues proper to his station. His literary abilities, and application to sacred and philological learning, appeared by his works; the principal of which are, A letter to the clergy of the church of England, on occasion of the bishop of Rochester's commitment to the Tower, 3d edit. 1722. Miracles of Jesus vindicated, 1727 and 1728. A review of the text of Milton, 1733. Two letters against Dr Middle-
The perch is very abominable in winter, and will seldom bite in this season of the year; if he does at all, it is in the middle of the day: at which time indeed all fish bite best at that season.

If the bait be a minnow, which is the bait that affords most diversion to the angler, it must be fastened to the hook alive, by putting the hook through the upper lip or back-fin; it must be kept at about mid-water, and the float must be a quill and a cork, that the minnow alone may be able to work. The float must be of flax, and strong; and the hook armed with a small and fine wire, that if a pike should take the bait, as is not unfrequently the case, he may be taken. The way to carry the minows or small gudgeons alive for baits is this: All of them in a quarter of an hour by the holes, with regular belay, and pearches.

As for the use of flax, and flax; and the hook armed with a small and fine wire, that if a pike should take the bait, as is not unfrequently the case, he may be taken. The way to carry the minows or small gudgeons alive for baits is this: All of them in a quarter of an hour by the holes, with regular belay, and pearches.

The perch, in natural history, a hard, white, shining body, usually roundish, found in a teataceous fish resembling an oyster.

Pearls, though esteemed of the number of gems by our jewellers, and highly valued not only at this time but in all ages, proceed only from a distemper in the creature that produces them, analogues to the bauxsas and other leprous concretions in several animals of other kinds.

The fish in which these are usually produced is the East Indian pearl oyster, as it is commonly called. Besides this shell there are many others that are found to produce pearls; as the common oyster, the mussel, and several others; the pearls of which are often very good, but those of the true Indian barbiet, or pearl-oyster, are in general superior to all. The small or seed pearls, also called, cooke pearls, from being fold by the ounce and not by tale, are vastly the most numerous and common: but, as in diamonds, among the multitudes of small ones, there are smaller numbers and larger found, so in pearls there are larger and larger kinds; but as they increase in size, they are proportionably less frequent; and this is one reason of their great price. We have Stotch pearls frequently as big as a little tare, some as big as a large pea, and some few of the size of a horse-bean; but these are usually of a bad shape, and of little value in proportion to their weight. Philip II. of Spain had a pearl perfect in its shape and colour, and of the size of a pigeon's egg. The first, and what is called the true shape of the pearl, is a perfect round; but if pearls of a considerable size are of the shape of a pear, as is not unfrequently the case, they are not less valued, as they serve for ear-rings and other ornaments. Their colour ought to be a pure white; and that not a dead and lifeless, but a clear and brilliant one: they must be perfectly free from any foulines, spot, or flaw; and their surfaces must be naturally smooth and glossy, for they bring their natural polish with them, which art is not able to improve.

All pearls are formed of the matter of the shell, and consist of a number of coats spread with perfect regularity one over another, in the manner of the several coats of an onion; or like the several strata of the stones found in the bladders or stomachs of animals, only much thinner.

Manner of Fishing for Pearls in the East Indies.—There are two seasons for pearl-fishing: the first is in March and April, and the last in August and September: and the more rain there falls in the year, the more plentiful are these fisheries. At the beginning of the season there are sometimes 250 barks on the banks; the larger barks have two divers, and the smaller one. As soon as the barks arrive at the place where the fish lies, and have cast anchor, each diver binds a stone, six inches thick and a foot long, under his body; which serves him as a ballast, prevents his being driven away by the motion of the water, and enables him to walk more steadily under the waves. They also tie another very heavy stone to one foot, by which they are very speedily sent to the bottom of the sea; and as the oysters are usually firmly fixed to the rocks, they arm their hands with leather mittens, to prevent their being wounded in pulling them violently off; but this task some perform with an iron rake.

In the last place, each diver carries down with him a large net in the manner of a sack, tied to his neck by a long cord, the other end of which is fastened to the side of the bark. This net is to hold the oysters gathered from the rock, and the cord is to pull up the diver when his bag is full, or when he wants air.

In this equipment he sometimes precipitates himself fifty feet under water, and as he has no time to lose, he no sooner arrives at the bottom than he begins to run from side to side, tearing up all the oysters he meets with, and cramming them into his bag.

At whatever depth the divers are, the light is so great, that they easily see whatever passes in the sea; and, to their great consternation, sometimes perceive monstrous fishes, from which all their address in muddying the water &c. will not always save them, but they unhappily become their prey; and of all the dangers of the fishery, this is one of the greatest and most usual. The best divers will keep under water near half an hour, and the rest do not stay less than a quarter. During this time they held their breath without the use of oils or any other liquors; only acquiring the habit by long practice. When they find themselves straitened, they pull the rope to which the bag is fastened, and hall fall by it with both hands: when these in the bark, taking the signal, hoist them up into the air, and unload them of
their fish; which is sometimes 500 oysters, and sometimes not above 50. Some of the divers need a moment's respite to recover breath; others jump in again instantly, continuing this violent exercise without intermission for several hours.

On the middle of the night, the boats being ready in the fand, or in five feet square, raising heaps of sand over them to the height of a man; and in this condition they are left till the rain, wind, and sun, have obliged them to open, which soon kills them: upon this the flesh rots and dries, and the pearls, thus diffiged, fall into the pit on their taking out the shells. After clearing the pits of the greater fish, they sift the sand several times in order to find the pearl; but whatever care they take they always lose a great many. After cleaning and drying the pearls they are passed through a kind of sieve, according to their sizes; the smallest are then sold as feed-pearls, and the rest put up to auction, and sold to the highest bidder.

Though those ornaments are met with in all quarters of the globe, the most esteemed have always been those of Asia, and the coast of Africa. In the kingdom of Madura, which lies on the coast of Malabar, there are many pearl fisheries. Tutukurin or Tutucorin is the principal, if not the only city, on the coast of Madura. At the time the Portuguese were masters of these parts, the taking of oysters in the straits between the island of Ceylon and the continent, was styled by way of excellence, the fishery, and very deservedly; for though some prefer the pearls taken near the island of Baharen in the Persian gulf, and others likewise found on the coast of China at Hainan, yet it might be very easily proved, from the comparison of the annual amount of those fisheries within this period, that they were very seldom superior to this of which we are speaking. It was one of the wise points in the Portuguese policy, that, though they were really in possession of this beneficial commerce, yet they chose to dissemble it, and took all imaginable precautions in order to make the natives believe that they were perfectly free, and that their interposition was not so much the effect of authority as of goodwill; it was for this reason that they never pretended to erect any fort either at Tutucorin or at Calicutnam, two towns upon the continent, from whence most of the fishers and their barks came, and that they suffered the ancient customs to take place.

The season of the fishery was the latter end of April or beginning of May, sometimes sooner, sometimes later, according to the weather. The direction of it was left entirely to the sovereign of the country, called the naik, and the Portuguese, in quality of the protectors of the sea, sent two frigates to defend the fishing-vessels from the Malabar and Maldive pirates. The time which this pearl-fishing lasted was about a fortnight, of the beginning of which the naik gave public notice; and, the day being come, there repaired to the place assigned several thousands of people of all ages, and an indefinite number of fishing vessels, and divers from five or six hundred to a thousand or more. Upon a signal given the boats put to sea; and, having chosen their proper stations, the divers plunged and brought up the oysters in little baskets upon their heads; with which the boats being sufficiently laden, they were carried on shore, where the people who remained there for that purpose bought them in the sand, till, by the heat of the sun, the fish was corrupted and congealed, and the pearls easily taken out. The whole produce of the first day's fishery belonged to the naik; and after that deduction, what was caught every day was separated, and particularly distinguished, but went to the common profit. The whole number of the people employed at sea and at shore amounted frequently to 50,000 or 60,000 souls; and the pavilions and tents set up for their accommodation made a fine appearance at a distance. When the pearls were extracted, cleaned, and dried, they passed them through a kind of sieves, by which their sizes were distinguished. When all was over, the naik appointed a time and place for the public market; in consequence of which there was a kind of fair, that lasted commonly from the close of June till the beginning of September. The smallest, which are what we call sifted pearls, they sold by weight, and all the rest according to their respective sizes and beauty, from a few shillings up to ten or twenty pounds, but there were few buyers, except the Portuguese merchants, who, bringing ready money, had got bargains, and thus all parties were pleased. The Portuguese assumed the protection of this fishery very soon after they settled in the Indies, and held it till the year 1658, when, in consequence of their losses in Ceylon and elsewhere, it fell into the hands of the Dutch, who have remained in possession of it ever since.

The Dutch have changed this method, as we are informed by a person very well acquainted with their affairs. The course into which they have put it is, in a few words, this: the camp is sometimes held on the coast of Madura, upon the continent; sometimes on the island of Manar, which is in the hands of the Dutch, who, notwithstanding, follow the example of the Portuguese, and lay claim to that of protectors of the fishery, in which quality their commissary is ever in the camp, as well as the naik or sovereign of the country, who is also the rajah of Tanjore. The oysters caught every day are put up in tons or barrels, of which, when a certain number are full, they put them up to sale by way of auction; and the merchants bid according as they have an opinion of the oysters for the season; but the middle price is between 30 and 40 shillings sterling per cask. When a merchant has bought such a lot as this, he carries it to his quarters; and after a certain number of days he proceeds to opening the oysters, but always in the air, for the French is to great as to be almost insupportable. They open them over tubs, into which they pour what comes out of the oyster, as also that muddy water that remains in the cask; next they draw it out into cullenders of several sizes, and at length perhaps they find four or five shillings worth of pearls, sometimes to the value of ten or twelve pounds; so that it is a perfect lottery, by which some few becoming rich, it betrays numbers into beggary. This pearl-fishery, we are told, brings the Dutch company an annual tribute of 20,000 l.

There are a variety of rivers great and small in Eastern Tartary considerable for pearl-fishery; but these
these pearls, though much esteemed by the Tartars, would be little valued by Europeans, on account of their defects in shape and in colour. The Emperor Kang-hi had several chaplets or strings of these pearls, each containing 100, which were very large, and exactly matched. There are many rivulets in Livonia which produce pearls almost equal in size and clearness to the Oriental ones. There are several fisheries both on the eastern and western coasts of Africa; the most considerable of which lie round some small islands, over against the kingdom of Sofala; but the people thus employed, instead of expelling the oysters to the water's edge, as in the East, would induce them to open, lay them upon the embers; by which absurd method, these pearls which they catch contract a dull kind of redness, which robs them of their natural lustre as well as of their value. Pearl fishing is performed by the women as well as the men; both being equally expert. In the sea of California also there are very rich pearl fisheries. In Japan likewise there are found pearls of great price. Pearls are met with in all parts of the Red Sea in the Indian Ocean, on the low part of the coast of Arabia Felix named Balsam, adjoining to the Persian Gulf. They are likewise found on the low coast about Gumbroon to the eastward of the Persian Gulf; and many of the finest kind are met with on the coasts of Ceylon. They are most plentiful in the Baharene, between the coast of Arabia Felix and Ormus, whence they are transported to Aleppo, then sent to Leghorn, and then circulated through Europe.

It has been very commonly supposed, that pearls are found in the sand of oysters; and such the pearl fishes are called in part of the above account extracted from the Universal History; but Mr Bruce absolutely denies this, and informs us that there is no such fish as an oyster to be met with in the Red Sea in particular. They are indeed found in bivalve shells, of which there are three kinds commonly sought after by the pearl-fishers. One of these is a kind of murex now very rare; but whether more plentiful former than at present is not known; they are principally found on the north end of the Red Sea and on the Egyptian side, and Mr Bruce informs us, that the only place in which he ever met with them was about Coiffair, and to the northward of it, where there was an ancient port called Mus Hermes, "which (says Mr Bruce) commentators have called the port of the Muse, when they should have translated it the harbour of the Muses."

The second fort of shell is called Plu-a. It is broad and lenticular at the top, decreasing gradually until it turns sharp at the lower end, where the hinge is. The outside is rough and figured, of a beautiful red colour, and sometimes three feet long, and extremely brittle; the inside lined with that beautiful substance called mother-of-pearl.

The third kind of shell is the only one which can be said to bear any resemblance to the oyster; though even this is evidently of a different genus. In a general view of the writings of Linnaeus by Richard Pulteney, M. D. p. 42, it is said that Linnaeus made a remarkable discovery relating to the generation of pearls, in the river pearl-muscle (Mya margaritifera) a shell shell found in several rivers of Great Britain and Ireland; that this shell will bear removal remarkably well; and that in some places they form reservoirs for the purpose of keeping it, and taking out the pearl, which in a certain period will be renewed again. The discovery was a method which Linnaeus found of putting these muscles into a state of producing pearls at his pleasure, though the final effect did not take place for several years; but that in five or six years after the operation, the pearl would have acquired the size of a vert. Dr Pulteney regrets that we are unacquainted with the means by which Linnaeus accomplished this extraordinary operation, which was considered as important, since it is certain the author was rewarded with a munificent premium from the states of the kingdom on that account.

The colours of pearls are different according to the shells in which they are found. The first kind often produces those of a fine shape and excellent lustre, but seldom of that very fine colour which enhances their price. The second kind produces pearls having the reddish cast of the inner shell of the pinnas, called mother of pearl, which seems to confirm the opinion of Reaumur, that the pearls are formed from the glutinous fluid which makes the first rudiments of the shell; and this kind of pearl is found to be more red as it is formed nearer the broad part of the shell, which is redder than the other end. Mr Bruce is of opinion, that the pearl found in this shell is the pinnas of Scripture; and that this name is derived from its redness. "On the contrary (says he), the word pinnas has been idly imagined to be derived from penna, a feather; as being broad and round at the top, and ending at a point, like a quill below. The English translation of the Sacred text is not accurate in many things more material, translates this pinnas by rubies, without any foundation or authority but because they were both red, as are bricks or tiles, and many other things of base materials. The Greeks have translated it literally pina or pinnas, and the shell they call pinnas; and many places occur in Strabo, Theophrastus, Elian, and Ptolemy, which are mentioned as famous or this kind of pearl. I should imagine also, that by Solomon saying it is the most precious of all productions, he means that this species of pearl was the most valued or the best known in Judea; for though we learn from Pliny that the excellency of pearls was their whiteness, yet we know that the pearls of a yellowish cast are those esteemed in India to this day, as the pinnas pearls, or reddish pearl, was in Judea in the days of Solomon. In Job, where all the variety of precious stones are mentioned, the translator is forced, as it were unwillingly, to render pinnas pearls, as he thought indeed to have done in many other places where it occurs."

The third kind of shell produces pearls of extreme whiteness, which, though sayso that Bochart says are called diva or dora in Arabic; which seems to be a general term for all kinds of pearls in Scripture, whereas pinnas is only in particular. The pinnas is the magnet; "wisdom is better (a better guide) than the polar stone." But though the character of this pearl be extreme whiteness, we are told by Pliny that there are shades or differences of it. The chlorine, he says, are those of the Red Sea; but the pearls of India have the colour of the flakes or divisions of the lapis specularis. The most excellent are those like a solution of
of alum, limpid, milky-like, and even with a certain almost imperceptible cast of a fiery colour. Theophrastus tells us, that these pearls are transparent, as the description of Pliny would lead us to imagine; but it is not so; and if there were, it is apprehended they would lose all their beauty and value, and approach too much to glass. The value of these commodities depends upon their size, regularity of form, whether round or not, weight, smoothness, colour, and the different shades of that colour. The pearl fishers say, that when the shell is smooth and perfect, they never expect to find any pearls, but always do so when it has begun to be deformed and distorted. Hence it would seem, that as the fish turned older the vessels containing the juice for forming the shell, and keeping it in its vigour, grew weak and ruptured; and thence, from this juice accumulating in the fish, the pearl was formed, and the shell brought to decay, as supposed by Mr. Reaumur. If this be the case, it ought to be known by the form of the shell whether the pearl is large or small: and thus the smaller ones being thrown back into the sea, a constant crop of large pearls might be obtained.

Pliny says that pearls are the most valuable and excellent of all precious stones; and from our Saviour’s comparing the kingdom of heaven to a pearl, it would seem that they really were held in such high estimation at that time. Mr. Bruce, however, is of opinion, that this extraordinary value was put only upon the very large kinds of which we are told, that Servilia, the Mother of Marcus Brutus, presented one to Caesar of the value of 50,000 l. of our money; and Cleopatra dissolved one worth 250,000 l. in vinegar, which she drank at a supper with Mark Antony.

It is generally said that the pearl shell grows on rocks, which, together with the method of catching them, we have already mentioned. Some say they are taken with nets; from whence Mr. Bruce converts the idea of their growing on rocks; for nobody, he says, would employ nets to gather fish from among rocks. He tells us, that all kinds of them are found in the deep, and shallow, and very shallow bottom; the parts of most of them being too fine to bear the agitation of the sea among the rocks. It is observed that they produce the most beautiful pearls in those places of the sea where a quantity of fresh water falls. Thus (says Mr. Bruce), in the Red Sea, they are very much esteemed that were fished from Suakim southward, that is, in those parts corresponding to the country anciently called Berberis and Asa-ritis on the Arabian Coast near the island Camaron, where there is abundance of fresh water; and in the island of Poofht. As it is a fish that delights in repose, I imagine it avoids this part of the Gulf, as lying open to the Indian Ocean, and agitated by variable winds.

Mr. Bruce mentions a muscle found in the salt springs of the Nubian desert; in many of which he found those excreta which might be called pearls, but all of them ill formed, foul, and of a bad colour, though of the same consistence, and lodged in the same part of the body as those in the sea. “The muscle, too (says our author), is in every respect similar, I think larger. The outer skin or covering of it is of a vivid green. Upon removing this, which is the epidermis, what next appears is a beautiful pink, without glos, and seemingly of a calcareous nature. Below this, the mother-of-pearl, which is undermoll, is a white without lustre, partaking much of the blue and very little of the red; and this is all the difference I observed between it and the pearl-bearing muscle of the Red Sea.”

“In Scotland, especially to the northward (A), in all rivers running from lakes, there are found muscles that have pearls of more than ordinary merit, though seldom of large size. They were formerly tolerably cheap, but lately the wearing of real pearls into fashion, those of Scotland have increased in price greatly beyond their value, and superior often to the price of oriental ones when bought in the East. The reason of this is, a demand from London, where they are actually employed in work, and fold as oriental. But the excellence of all glass or plate manufactories, it is likely, will keep the price of this article, and the demand for it, within bounds; when every lady has it in her power to wear in her ears, for the price of existence, a pearl as beautiful in colour, more elegant in form, lighter and easier to carry, and as much bigger as the pieces, than the famous ones of Cleopatra and Servilia. In Scotland, as well as in the east, the smooth and perfect shell rarely produces a pearl; the crooked and distorted shell seldom wants one.

The mother-of-pearl manufactory is brought to the greatest perfection at Jerusalem. The most beautiful shell of this kind is that of the peninnium already mentioned; but it is too brittle to be employed in any large pieces of workmanship; whence that kind named dora, is most usually employed; and great quantities of this are daily brought from the Red Sea to Jerusalem. Of these, all the fine works, the crucifixes, the wafer-boxes, and the beads, are made which are sent to the Spanish dominions in the New World, and produce a return incomparably greater than the staple of the greatest manufactory in the Old.

Very little is known of the natural history of the pearl fish. Mr. Bruce says, that, as far as he has observed, they are all very upright in the mud by an extremity: the muscle by one end, the pinna by the small sharp point, and the third by the hinge or square part which projects from the round. “In shallow and clear streams (says Mr. Bruce), I have seen small furrows or tracks upon the sandy bottom, by which you could trace the muscle from its last fixation; and these not straight, but deviating into traverses and triangles, like the course of a ship in a contrary wind laid down upon a map, probably in pursuit of food. The general belief is, that the muscle is constantly stationary in a state of repose, and cannot transfer itself from place to place.”
to place. This is a vulgar prejudice, and one of those false ideas that are mistaken for want of sufficient pains or opportunity to make more critical observations. Others, finding the first opinion a false one, and that they are endowed with power of changing place like other animals, have, upon the same foundation, gone into the contrary extreme, so far as to attribute swiftness to them, a property purely inconsistent with their being fixed to rocks. Pliny and Solinus say that the molecules have leaders, and go in flocks; and that their leader is endowed with great cunning to travel; and that, when he is taken, the others fall an easy prey. This, however, we may justly look upon to be a fable; some of the most accurate observers having discovered the motion of the molecule, which indeed is wonderful, and that they lie in beds, which is not at all so, have added the rite, to make their history complete." Our author informs us, that the molecules found in the salt springs of Nubia likewise travel far from home, and are sometimes surprised, by the leaking of the rains, at a greater distance from their beds than they have strength and moisture to carry them. He assures us, that none of the pearl-fish are edible; and that they are the only fish he saw in the Red Sea that cannot be eaten.

Artificial Pearls. Attempts have been made to take out flains from pearls, and to render the foul opaque-coloured one equal in lustre to the orient. Abundance of processes are given for this purpose in books of secrets and travels; but they are very far from answerring what is expected from them. Pearls may be cleaned indeed from any external foulneffes by washing and rubbing them with a little Venice soap and warm water, or with ground rice and salts, with starch and powder blue, plaster of vitriol; and the like substances; but a flain that reaches deep into the substance of pearls is impossible to be taken out. Nor can a number of small pearls be united into a mass similar to an entire natural one, as some pretend.

There are, however, methods of making artificial pearls, in such manner as to be with difficulty distinguished from the best orient. The ingredient used for this purpose was long kept a secret; but it is now discovered to be a fine silver-like substance found upon the under side of the scales of the blay or bleak fish. The scales, taken off in the usual manner, are washed and rubbed with fresh parcels of fair water, and the several liquors suffered to fettle; the water being then poured off, the pearly matter remains at the bottom, of the confluence of oil, called by the French eau d'orient. A little of this is dropped into a hollow head of bluish-glaafs, and shaken about fo as to line the internal surface; after which the cavity is filled up with wax, to give solidity and weight. Pearls made in this manner are distinguishable from the natural only by their having fewer blemishes.

Mother-of-Pearl, the shell, not of the pearl oyster but of the mytilis margaritifera. See Mytilus.

Pearl-ashes, a kind of fixed alkaline salt, prepared chiefly in Germany, Russia, and Poland, and America, by melting the salts out of the ashes of burnt wood; and having reduced them again to dryness, evaporating the moisture, and calcining them for a considerable time in a furnace moderately hot. The goodness of pearl-ashes must be distinguished by the uniform and white appearance of them: they are nevertheless subject to a common adulteration, not easily to be distinguished by the mere appearance, which is done by the addition of common salt. In order to find out this fraud, take a small quantity of the suspected salt; and after it has been softened by lying in the air, put it over the fire in a flovel: if it contains any common salt, a cracking and kind of light explosion will take place as the salt grows hot.

Pearl-ashes are much used in the manufacture of glafs, and require no preparation, except where very great transparency is required, as in the case of looking-glaafs, and the kind of window-glaafs. For this purpose dissolve them in four times their weight of boiling water: when they are dissolved, let the solution be put into a clean tub, and suffered to remain there 24 hours or more. Let the clear part of the fluid be then decanted off from the sediment, and put back into the iron pot in which the solution was made; in a few let the water be evaporated till the salts be left perfectly dry. Keep those that are not designed for immediate use in stone jars, well stuffed with moisture and air.

Mr Kirwan, who has tried a course of experiments on the alkaline substances used in bleaching, &c. (seetrijf Trains: for 1789), tells us, that in 100 parts of the Danzicz pearl ash, the vegetable alkali amounted to somewhat above 63. His pearl-ashes he prepares by calcining a ley of vegetable ashes dried into a salt to whiteness. In this operation, he says, "particular care should be taken that it should not melt, as the extractive matter would not be thoroughly consumed, and the alkali would form such an union with the earthy parts as could not be easily dissolved." He has "added this caution, as Dr Lewis and Mr Doffie have inadvertently directed the contrary." We apprehend, however, that here is a little inaccuracy; and that it was not for pearl-ashes, but for the unrefined pot-ash, that these gentlemen directed evaporation. The fact is, that the American pot-ash, examined by them, had unquestionably suffered fusion; which was effected in the fame iron pot in which the evaporation was finished, by rather increasing the fire at the end of the process: by this management, one of the most troublesome operations in the whole manufacture, the separation of the hard salt from the ashes with hammers and chisels, was avoided; and though the extractive matter was not consumed, it was burnt to an indissoluble coal: so that the salt, though black itself, produced a pale or colourless solution, and was uncommonly strong. Mr Kirwan has also given tables of the quantities of ashes and salt obtained from different vegetables; and he concludes from them, 1. "That in general weeds yield much more ashes, and their ashes much more salt, than woods; and that, consequently, as to salts of the vegetable alkali kind, neither America, Triend, nor the northern countries, produfs any advantage over England. 2. That of all weeds, sumintry produces most salt, and next to it wormwood; but if we attend only to the quantity of salt in a given weight of ashes, the ashes of wormwood contain most. Trileum fliruum also produces more ashes and salt than fern." See Potash.

PEARSON (John), a very learned English bishop.
in the 17th century, was born at Saoring in 1613. After his education at Eton and Cambridge, he entered into holy orders in 1639, and was the same year collated to the prebend of Netherhaven in the church of Sarum. In 1640 he was appointed chaplain to the lord keeper Finch, and by him presented to the living of Torrington in Suffolk. In 1650 he was made minifter of St Clement's, Eastcheap, in London. In 1652, he and Mr Gunning had a dispute with two Roman Catholics upon the subject of schisms; a very unfair account of which was printed at Paris in 1658. Some time after, he published at London, An Exposition of the Creed, in folio, dedicated to his parishioners of St Clement's, Eastcheap, to whom the substance of that excellent work had been preached several years before, and by whom he had been forced to make it public. The same year he likewise published The Golden Remains of the ever memorable Mr John Hales of Eton; to which he prefixed a preface, containing, of that great man, with whom he had been acquainted for many years, a character drawn with great elegance and force. Soon after the Restoration, he was prefixed by Juxton, then bishop of London, to the rectory of St Christopher's in that city; created doctor of divinity at Cambridge, in purtuance of the king's letters mandatory; installed prebendary of Ely; archdeacon of Surry; and made master of Jesus college in Cambridge: all before the end of the year 1660. March 25th, 1661, he was appointed Margaret professor of divinity in that university; and, the first day of the ensuing year, was nominated one of the commissioners for the review of the liturgy in the conference at the Savoy. April 14th, 1662, he was admitted master of Trinity college in Cambridge; and, in August, resigned his rectory of St Christopher's and prebend of Sarum. In 1667 he was admitted a Fellow of the Royal Society. In 1672 he published at Cambridge, in 4to, Vindiciæ Epistolæorum S. Ignatii, in answer to Mons. Dailié, to which is subjoined, Epistolæ duæ ad deum Davidum Blondellum. Upon the death of the celebrated Wilkins, Pearson was appointed his successor in the see of Chester, to which he was consecrated February 9th 1672-3. In 1682, his Annales Cypriani, sive tresdecem annorum, quibus S. Cyprian, inter Christophanos veris simplicem historia chronologica, was publishèd at Oxford, with Pell's edition of that Father's works. Pearson was disabled from all public service by ill health a considerable time before his death, which happened at Chester, July 16th 1686.

PEASANT, a kind, one whose business is in rural labour.

It is amongst this order of men that a philosopher would look for innocent and ingenuous manners. The situation of the peasantry is such as excludes them from the devalitations of luxury and licentiousness; for when the contagion has once reached the cottages of rural retirement, and corrupted the minds of habitual innocence, that nation has reached the summit of vice, and is hastening to that decay which has always been the effect of vicious indulgence. The peasantry of Britain still in a great measure retain that simplicity of manner and rustic innocence which ought to be the characteristic of this order of society; and, in many parts, their condition is such as, were all its advantages sufficiently known, would create envy in the minds of those who have toiled through life, amidst the bustle of the world, in quest of that happiness which it could not confer.

O fortunatus nimium, tua si bona noster, 
Agricolae.——
Virgil.

In other countries the peasants do not enjoy the same liberty as they do in our own, and are consequently not so happy. In all feudal governments they are abject slaves, entirely at the disposal of some petty despots. This was the case in Poland, where the native peasants were subject to the most horrid slavery, though those descended of the Germans, who settled in Poland during the reign of Bolshaus the Chaste and Calumni the Great, enjoyed very distinguished privileges. Among the native slaves, too, those of the crown were in a better condition than those of individuals. See Poland.

The peasants of Russia (Mr Coxe tells us) are a hardy race of men, and of great bodily strength. Their cottages are constructed with tolerable propriety, after the manner of those in Lithuania; but they are very poorly furnished. The peasants are greedy of money, and, as the same author informs us, somewhat inclined to thieving. They afford horses to travellers, and act the part of coachmen and pottilioners. "In their Travels in to Poland, Russia, Sweden, and Denmark, in their intercourse with each other; they take off their cap at meeting; bow ceremoniously and frequently, and usually exchange a salutation. They accompany their ordinary discourse with much action, and innumerable gestures; and are exceedingly servile in their expressions of deference to their superiors: in acknowledging a person of consequence, they prostrate themselves, and even touch the ground with their heads. We were often struck at receiving this kind of eastern homage, not only from beggars, but frequently from children, and occasionally from some of the peasants themselves."

"The peasants are well clothed, comfortably lodged, and seem to enjoy plenty of wholesome food. Their rye-bread, whose blackness at first disgusts the eye, and whose flour is the paste, of a delicate traveller, agrees very well with the appetite: as I became reconciled to it from use, I found it at all times no unpleasant relish, and when seasoned with hunger, it was quite delicious: they render this bread more palatable, by stuffing it with onions and groats, carrots or green corn, and seasoning it with sweet oil. The rye-bread is sometimes white, and their other articles of food are eggs, salt fish, bacon, and mustrooms; their favourite dish is a kind of hodge-podge, made of fat, or sometimes fresh meat, groats, flour, highly seasoned with onions and garlic, which latter ingredients are much used by the Russians. Besides, mushrooms are so exceedingly common in these regions, as to form a very essential part of their provisions. I seldom entered a cottage without finding great abundance of them; and in passing through the markets, I was often astonished at the prodigious quantity exposed for sale; their variety was no less remarkable than their number; they were of many colours, among which I particularly noticed white, black, brown, yellow, green, and pink. The common drink of the peasants is kvass, a fermented liquor, somewhat like sweet-wort, made by pouring warm water on rye.
They are extremely fond of whisky, a spirituous liquor distilled from malt, which the peasants can occasionally command, and which their inclination often leads them to use to great excesses."

These people are extremely backward in the mechanic arts, though, where they have much intercourse with other nations, this does not appear, and therefore does not proceed from natural inability; indeed we have already given an instance of one peasant of Russia, who seems to possess very superior talents. See Nevä.

The dress of these people is calculated for the climate in which they live: they are particularly careful of their extremities. On their legs they wear one or two pair of thick worsted stockings; and they envelop their legs with wrappers of coarse flannel or cloth several feet in length, and over these they frequently draw a pair of boots, so large as to receive their bulky contents with ease. The lower sort of people are grossly ignorant: of which we shall give a very surprising instance in the words of Mr. Coxe:

"In many families, the father marries his son while a boy of seven, eight, or nine years old, to a girl of a more advanced age, in order, as it is said, to procure an able-bodied woman for the domestic service: he cohabits with this person, now becomes his daughter-in-law, and frequently has several children by her. In my progress through Russia, I observed in some cottages, as it were, two mistresses of a family; one the peasant's real wife, who was old enough to be his mother; and the other, who was nominally the son's wife, but in reality the father's concubine. These intemperate marriages, sanctioned by invertebrate custom, and permitted by the parish priests, were formerly more common than they are at present; but as the nation becomes more refined, and the priests somewhat more enlightened; and as they have lately been discommoded by government, they are daily falling into disuse; and it is to be hoped, will be no longer tolerated."

The peasants of Russia, like those of Poland, are divided into those of the crown and those of individuals; the first of which are in the best condition; but all of them undergo great hardships, being subject to the despotic will of some cruel overlord. They may obtain freedom, 1. By manumission on the death of their master, or otherwise: 2. By purchase; and, lastly, by serving in the army or navy. The Emperors have redressed some of the grievances of this class of her subjects. The hardihood of the peasants arises in a great measure from their mode of education and way of life, and from the violent changes and great extremes of heat and cold to which they are exposed.

"The people of Finland differ widely from the Russians in their look and dress: they are for the most part fair complexions, and many of them red hair: they have their beards, wear their hair parted at the top, and hanging to a considerable length over their shoulders (a). We could not avoid remarking, that they were in general more civilized than the Russians; and that even in the smallest villages we were able to procure much better accommodation than we usually met with in the largest towns which we had hitherto visited in this empire."

The peasants of Sweden (Mr. Coxe informs us) are more honest than those in Russia; in better condition, and possessing more of the conveniences of life, both with respect to food and furniture. They are well clad in brown cloth of their own weaving. Their cottages, though built with wood, and only of one story, are comfortable and commodious. The room in which the family sleep is provided with ranges of beds in tiers (if I may so express myself), one above the other: upon the wooden tellers of the beds in which the women lie, are placed others for the reception of the men, to which they ascend by means of ladders. To a person who has just quitted Germany, and been accustomed to tolerable inns, the Swedish cottages may perhaps appear miserable hovels; to me, who had been long used to places of inferior accommodation they seemed almost palaces. The traveller is able to procure many conveniences, and particularly a separate room from that inhabited by the family, which could seldom be obtained in the Polish and Russian villages. During my course through those two countries, a bed was a phenomenon which seldom occurred, excepting in the large towns, and even then not always completely equipped; but the poorest huts of Sweden were never deficient in this article of comfort: an evident proof that the Swedish peasants are more civilized than those of Poland and Russia. After having witnessed the slavery of the peasants in those two countries, it was a pleasing satisfaction to find myself again among freemen, in a kingdom where there is a more equal division of property: where there is no vassalage; where the lowest order enjoy a security of their persons and property; and where the advantages resulting from this right are visible to the commonest observer."
The peatants of Holland and Switzerland are all in a very tolerable condition; not subject to the undisputed control of a hireling master, they are free men, and enjoy in their several situations the blessings of freedom. In Bohemia, Hungary, and a great part of Germany, they are legally slaves, and suffer all the miseries attending such a condition. In Spain, Savoy, and Italy, they are little better. In France, their situation was such as to warrant the Revolution; but whether by carrying matters too far, they are now worse than they were at any former period, remains to be ascertained.

PEAT, a well known inflammable substance, used in many parts of the world as fuel. There are two species:

1. A yellowish-brown or black peat, found in moorish grounds in Scotland, Holland, and Germany. When fresh, it is of a viscous consistence, but hardens by exposure to the air. It consists, according to Kirwan, of clay mixed with calcareous earth and pyrites; sometimes also it contains common salt. While soft, it is formed into oblong pieces for fuel, after the pyriticaceous and flaky matters are separated. By distillation it yields water, acid, oil, and volatile alkali; the ashes containing a small proportion of fixed alkali; and being either white or red according to the proportion of pyrites contained in the substance.

The oil which is obtained from peat has a very pungent taste; and an empyreumatic smell, less fetid than that of animal substances, more so than that of mineral bitumens; it congeals in the cold into a pitchy mass, which liquefies in a small heat: it readily catches fire from a candle, but burns less vehemently than other oils, and immediately goes out upon removing the external flame; it diffuses almost totally in a reticulated spirit of wine into a dark brownish red liquor.

2. The second species is found near Newbury in Berkshire. In the Philosophical Transactions for the year 1757, we have an account of this species; the difference of which is as follows.

PEAT is a composition of the branches, twigs, leaves, and roots of trees, with grases, saw plants, and weeds, which having lain long in water, is formed into a mass so soft as to be cut through with a sharp spade. The colour is a blackish brown, and it is used in many places for firing. There is a stratnum of this peat on each side the Kennet, near Newbury in Berks, which is from about a quarter to half a mile wide, and many miles long. The depth below the surface of the ground is from one foot to eight. Great numbers of entire trees are found lying irregularly in the true peat. They are chiefly oaks, elders, willows, and firs, and appear to have been torn up by the roots: many horse's heads, and bones of several kinds of deer; the horns of the antelope, the heads and tails of boars, and the heads of beavers, are also found in it. Not many years ago an urn of a light brown colour, large enough to hold about a gallon, was found in the peat-pit in Speen-moor, near Newbury, at about 10 feet from the river, and four feet below the level of the neighbouring ground. Just over the spot where the urn was found, an artificial hill was raised about eight feet high; and as this hill consisted both of peat and earth, it is evident that the peat was older than the urn. From the side of the river several semicircular ridges are drawn round the hill, with trenches between them. The urn was broken to thieves by the peat-diggers who found it, so that it could not be critically examined; nor can it be known whether any thing was contained in it.

With peat also may be classified that substance called in England stone-turf; which hardens after its first exposure to the air, but afterwards crumbles down. The other common turf consists only of mould interwoven with the roots of vegetables; but when these roots are of the bulbous kind, or in large proportion, they form the worst kind of turf. "Although it may appear incredible (says M. Magellan), it is nevertheless a real fact, that, in England, pit-turf is advantageously employed in Lancashire to smelt the iron-ore of that county. Mr Wilkinson, brother-in-law to Dr Priestley, makes use of pit-turf in his large smelting furnaces. I have seen in the possession of Mr S. More, secretary to the Society of Arts, a kind of black tallow, extracted by the said Mr Wilkinson from pit-turf. It was very soft, and nearly of the same consistence with butter. It burned very rapidly, with a smoky flame in the fire; but the smell was very disagreeable, like that of pit-turf." The great cause of the differences of peat most likely arises from the different mineral admixtures. Some sorts of peat yield in burning a very disagreeable smell, which extends to a great distance; whilst others are inoffensive.

Some burn into grey or white, and others into red ferruginous ashes. The ashes yield, on elixiation, a small quantity of alkaline salt, with sometimes one and sometimes another salt of the neutral kind.

The smoke of peat does not preserve or harden flax like that of wood; and the foot, into which it condenses, is more disposed to liquify in moister weather.

PEAT ashes, properly burnt for a manure, are noble improvers both of corn and grass land: but the substance from which they should be got is an under stratum of the peat, where the fibres and roots of the earth, with, &c. are well decayed. Indeed the very best are procured from the lowest stratum of all. This will yield a large quantity of very strong ashes, in colour (when burnt) like vermilion, and in taste very salt and pungent. Great care and caution should be used in burning these ashes, and also in preserving them afterwards. The method of burning them is much the same as burning charcoal. The peat must be collected into a large heap, and covered so as not to flame out, but suffer to consume slowly, till the whole substance is burnt to an ash. The ashes thus burnt are held in most esteem: but the peat-ashes burnt in common firing in many places are used for the same purposes, and sold at the same prices.

PEAT ashes are found excellent in sweetening four meadow land, destroying rubbish, and other bad kinds of grases, and in their ileal producing great quantities of natural grases. They burn great quantities of peat-ashes in some parts of Berkshire and Lancashire, and esteem them one of the best dressings for their spring crops.

The sulphureous and saline particles with which the ashes abound have a most happy effect in promoting vegetation; and if used with discretion, the increase procured by them is truly wonderful.
All ashes are of a hot, fiery, caustic nature: they must therefore be used with caution. With respect to peat-ashes, almost the only danger proceeds from laying them on the ground in quantities at improper seasons. Nothing can be better than they are for dressing low damp meadows, laying to the foundation of fifteen to twenty Winchester bushels on an acre: it is best to sow them by hand, as they will then be more regularly spread. This should be done in January or February, at the first, that the ashes may be washed in, towards the roots of the grass by the first rains that fall in the spring.

If they were spread more forward in the year, and a speedy rain should not succeed, being hot in their nature, they would be apt to burn up the grass, instead of doing it any service. The damper and finer the soil, the mire peat-ashes should be laid on; but in grass lands the quantity should never exceed thirty Winchester bushels, and on light warm lands less than half that quantity is fully sufficient.

On wheat crops these ashes are of the greatest service, but they must be laid on with the utmost discretion. Were they to be spread in any quantity before the winter, after the sowing the corn, they would make the wheat too rank, and do more harm than good; was the spreading this manure, on the contrary, deferred till the spring, the corn could not possibly winter-dress the field and the latter end of November, before the hard frosts set in, seems to be the proper season for this purpose: and it will found necessary to sow on every acre of heavy clayey wheat land about eight Winchester bushels of these ashes; on lighter warmer lands in wheat, four will be sufficient for this purpose. The winter dressing is thought by practical farmers to be of great service: trifling as the quantity may seem, it warms the root of the plant, brings it moderately forward, prevents its verdure, and disposes it to get into a growing state the first fine weather after Christmas.

About the latter end of February, or the beginning of March, on heavy lands in wheat, another dressing of ashes, by sowing of them on every acre, eight bushels more, will do much good; on light lands, in this second dressing, five bushels may be allowed.

These ashes laid on in the spring are of the greatest service, without any probability of danger; if rain falls within a few days after the dressing is laid on, it is washed in, and has a happy effect on the succeeding crop, cooperating with the manure that was laid on in November; if, on the contrary, dry weather for a week follows, the first winter-dressing has its full effect, and the quantity laid on in the spring is in fact too small, that there is very little probability of its burning or hurting the crop. This excellent manure is also of great use in the turnip husbandry on many accounts, particularly as it much contributes to preserve the young crop from being devoured by the fly.

But one of the principal advantages derived from these ashes, not yet mentioned, is the very great service they are of to every kind of artificial pasture. Saintfoué receives great benefit from this manure, and so does clover, rye grass, and trefoil, provided it is laid on with discretion; the proper season is about the month of February. The quantity must be regulated by the nature of the crop and soil; but it ought scarcely in any instance to exceed thirty Winchester bushels. Clover, with the help of this manure, grows with great luxuriance, insomuch that there are often two large crops of hay from the same field in a year, and good autumn feed afterwards. They have an excellent effect on tares or vetches: to please they seem to be hurtful.

The effects of this manure will be visible at least three years, nor does it, like some others, leave the land in an impoverished state, when its virtues are exhausted and spent. Peat-ashes are not, however, to obtain a manure for barley and oats as for the winter corn: for as these are quick growers, and occupy the land but a few months, this warm manure is often apt to push them forward too fast, and make them too much to coarse straw, yielding only a lean immature grain. Oats, however, are not so apt to be damaged by it as barley.

Peat-ashes approach, in their effects on the several crops on which they are laid, to coal-foot; but two-thirds of the quantity that is used of foot will be sufficient of the ashes, as they are in a much stronger degree impregnated with a vegetative power; and they are besides in most places easier procured in quantities, and at a cheaper rate.

Peat-ashes are almost, as we have already observed, a general manure suited to every soil. On cold clay they warm the too compact particles, disposes it to ferment, crumble, and of course fertilizes, and, in fine, not only affix it in discolours and dispersing its great vegetative powers, but also bring to its aid a considerable proportion of ready prepared aliment for plants. On light lands these ashes have a different effect; here the poros are too large to be affected, or farther separated by the salts or sulphur contained in them; but, being closely attached to the surfaces of the large particles of which this earth is generally composed, this manure disposes them, by means of its salts, to attract the moisture contained in the air: by this operation, the plants which grow on these porous soils are prevented from being scorched and burnt; and if they want, which they generally do, more nourishment than the land is of itself capable of affording, this is readily and abundantly supplied by this useful manure. In large farms it is very usual to see all the home-fields rich and well mended by the yard dung, &c. whereas the more distant lands are generally poor, impoverished, and out of heart, for want of proper manure being applied in time. See Chemistry, No. 1448.

PEAUCER, in anatomy, a name given by Winckel, in his Treatise on the Head, and by some of the French writers, to the muscles called by Albinus latissimus colli; and by others dentatus quadratus, and quadratus genu. Santorini has called the part of this which arises from the cheek muscleus riseros novus; and some call the whole platysma myoides.

PEBBLES, the name of a genus of foliis, distinguished from the flints and hornocera by their having a variety of colours. These are defined to be stones composed of a crystalline matter debased by earths of various kinds in the same species, and then subject to veins, clouds, and other variations, usually formed by incrustation round a central nucleus, but sometimes the effect of a simple concretion; and veined like the agates, by the disposition which the motion of the
the fluid they were formed in gave their differently coloured substances.

The variety of pebbles is so great, that an halily describer would be apt to make as many species as he saw specimens. A careful examination will teach us, however, to distinguish them into a certain number of essentially different species, to which all the rest may be referred as accidental varieties. When we find the same colours, or those resulting from a mixture of the same, such as nature frequently makes in a number of fones, we shall easily be able to determine that these are all of the same species, though of different appearances; and that whether the matter be disposed of in one or two, or in 20 crusts, laid regularly around a nucleus; or thrown irregularly, without a nucleus, into irregular lines; or lastly, if blended into an uniform mass.

There are the three states in which every pebble is found; for if it has been naturally and regularly formed by incrustation round a certain nucleus, we find that the same in the same species, and the crusts not less regular and certain. If the whole has been more hastily formed, and the result only of one simple concretion, that has happened while its different substances were all moist and thin, they have blended together and made a mixed mass of the joint colour of them all. But if they have been something harder when this has happened, and too far concreted to diffuse wholly among one another, they are found thrown together into irregular veins. These are the natural differences of all the pebbles; and having regard to these in the several variegations, all the known pebbles may be reduced to 34 species.

In all the strata of pebbles there are constantly found some which are broken, and of which the pieces lie very near one another; but as bodies of such hardness could not be broken without some considerable violence, their present situation seems to indicate that they have suffered that great violence in or near the places where they now lie. Befide these, we often meet with others which have as plainly had pieces broken off from them, though these pieces are nowhere to be found; whence it seems equally plain, that whatever has been the cause of their fracture, they have been brought broken, as we find them, from some other place, or else that the pieces broken from them must at some time or other have been carried from this place to some other distant one.

Several of these broken pebbles have their edges and corners so sharp and even, that it seems evident they never can have been tumbled about or removed since the fracture was made; and others have their sides and corners so rounded, blunted, and worn away, that they seem to have been rubbed together and rolled about among other hard bodies, either with great violence, or for a very long continuance; since such hard bodies could not have been reduced to the condition in which we now see them without long friction. It may be supposed by some, that these bones never were broken, but have been naturally formed of this shape; but it will be easily seen, by any one who accurately surveys their veins or coats, which surround the nucleus, like the annular circles of a tree, that they must have been originally entire; and this will be the more plain if they are compared with a bone broken by art. Such pebbles as are found in strata near the surface of the earth, are much more brittle than those which lie in deeper strata; and the more clear and transparent the sand is which is found among pebbles, the more beautiful the pebbles are generally observed to be.

The use of these stones, and their disposition in the earth, is a subject of great wonder; and may serve as one of the numerous proofs of an over-ruling Providence in the disposition of all natural bodies. The surface of the earth is composed of vegetable mould, made up of different earths mixed with the putrid remains of animal and vegetable bodies, and of the proper texture and compos ates for conducting the moisture to the roots of trees and plants. Under this are laid the sands and pebbles which serve as a fort of drain to carry off the redundant moisture deeper into the earth, where it may be ready to supply the place of what is constantly rising in exhalations; and left the strata of sand should be too thick, it is common to find thin ones of clay between, which serve to put a stop to the defcent of the moisture, and keep it from flowing off too soon; and left these thin strata of sand should yield and give way, and by their fracturing when wetted give leave to the particles of sand to blend themselves with, and even force their way through them, there are found in many places thin coats of a poor iron ore, placed regularly above and below the clay; and by these means not only strengthening and supporting the clay, but effectually keeping the sand from making its way into it.

There are many people of opinion, that the swallowing of pebbles is very beneficial to health, in helping the stomach to digest its food; and a pebble-potsh is an old woman's medicine in the colic in many parts of England. They usually order the small white stones to be picked out of gravel walks for this purpose, and eat them in large quantities in some sort of spoon meat, of which milk is an ingredient.

The thing that has given occasion to this practice seems to have been, that people observe the birds to pick up the gravel, and that they are never well unless they have frequent recourse to this to help their digestion: but this is no similiar cafe at all, for the gizzard or stomach of a bird is made very strong, because the creature hath no teeth to chew its food; and this gizzard is lined with a rough coat, by the help of which and these fones the food they swallow whole is so ground as to yield its juices to the nourishment of the animal. But the stomach of man is formed so very differently, that it can never require those affinities to the comminution of food. Many people have, however, accustomed themselves to swallow not only these small white stones, but large pebbles, even to the size of a walnut each; and these will often pass safely; and people who have long accustomed themselves to swallow them, boast of receiving no injury from them: we can never know, however, that the death of such persons is not owing to them at last; and as they can do no good, it is best always to avoid them. There are, indeed, infallacies on record in which they have undoubtedly done much mischief.

PECARY, in zoology. See TAJACU.

PECANT, in medicine, an epithet given to the humours of the body, when they offend either in quantity or quality, i. e. when they are either morbid, or in too great abundance. Moll diffuses arise from pecant humours,
Two years afterwards he took the degrees of B. and M. A. He published unfairly printed probably a poem, intitled, "The Beauty and Affection of the Creator of the World; containing the History of the Holy Scriptures, 1716, 8vo." In 1722, he had before this time obtained the rectory of Godeby near Melton Mowbray, written by Francis Hargrave, who, in his History and Antiquities of Leicestershire and Rutland, which were printed, about the time of her death in 1714. Two years afterwards he printed "TO TWO ATON ; or an Exercice on the Creation, and an Hymn to the Creator of the World; written in the express words of the sacred text, as an Attempt to shew the Beauty and Sublimity of the Holy Scriptures, 1716, 8vo." In 1721, being then curate of King's Clifton in Northamptonshire, he issued proposals for printing the History and Antiquities of his native town, which was published in 1727, in folio, under the title of "Academia teria Anglicana; or the Antiquarian Annals of Stamford in Lincoln, Rutland, and Northamptonshires; containing the History of the University, Monasteries, Guilds, Churches, Chapels, Hospitals, and Schools there, &c." inscribed to John Duke of Rutland. This work was heightened by "An Essay on the ancient and present State of Stamford, 1726, 4to." written by Francis Hargrave, who, in his pref. &c. mentions the difference which had arisen between him and Mr Peck, on account of the former's publication unfairly referring that intended by the latter. Mr Peck is also therein very roughly treated, on account of a small work he had formerly printed, intitled, "The History of the Stamford Bull-running." Mr Peck had before this time obtained the rectory of Godeby near Melton in Leicestershire, the only preferment he ever enjoyed. In 1722, he printed on a single sheet, "Queries concerning the Natural History and Antiquities of Leicestershire and Rutland," which were afterwards reprinted in 1742, but although the progress he had made in the work was very considerable, yet it never made its appearance. In 1732 he published the first volume of "Defectorata Caroja; or, a Collection of divers fearce and curious Pieces relating chiefly to Matters of English History; confuting of choice tracts, memoirs, letters, wills, epitaphs, &c. trancribed, many of them, from the originals themselves, and the rest from divers ancient MS. copies, or the MS. Collations of sundry famous antiquaries and other eminent persons, both of the last and present age; the whole, as nearly as possible, digested into order of time, and illustrated with ample notes, contents, additional discourses, and a complete index." This volume was dedicated to Lord William Manners, and was followed, in 1735, by a second volume dedicated to Dr Reynolds bishop of Lincoln. In 1735 Mr Peck printed in a 4to pamphlet, a comple catalogue of all the discourses written both for and against the poetry in the time of King James II. containing in the whole an account of 457 books and pamphlets, a great number of them not mentioned in the three former catalogues, with references after each title, for the more speedy finding a further account of the said discourses and their authors in sundry writers, and an alphabetical list of the writers on each side." In 1739 he was the editor of "Nineteen Letters of the truly reverend and learned Henry Hammond, D. D. (author of the Annotations on the New Testament, &c.) written to Mr Peter Stain­nough and Dr Nathaniel Angelo, many of them on curious subjects, &c." These were printed from the originals communicated by Mr Robert Mariden arch­deacon of Nottingham, and Mr John Worthington. The next year, 1740, produced two volumes in 4to, one of them intitled, "Memoirs of the Life and Actions of Oliver Cromwell, as delivered in three pamphlets of him written in Latin; the first, as said, by Don Juan Rodriguez de Saa Meneles, Conde de Penguiao, the Portugal ambassador; the second, as affirmed by a certain Jesuit, the lord ambassador's chaplain; yet both, it is thought, compos'd by Mr John Milton (Latin secretary to Cromwell), as was the third; with an English version of each. The whole illustrated with a large historical preface; many familiar passages from the Paradice Lost, and other works of Mr John Milton, and notes from the best historians. To all which is added, a collection of divers curious historical pieces relating to Cromwell, and a great number of other remarkable persons (after the manner of Defectorata Caroja, v. i. and ii.) The other, "New Memoirs of the Life and poetical Works of Mr John Milton; with, first, an examination of Milton's styie; and secondly, explanatory and critical notes on divers passages in Milton and Shakespeare, by the editor. Thirdly, Baptizes; a sacred dramatic poem in defence of liberty, as written in Latin by Mr George Buchanan, translated into English by Mr John Milton, and first published in 1641, by order of the house of commons. Fourthly, the Parallel, or Archibishop Laud and Cardinal Wolsey compared, a Vision by Milton. Fifthly, the Legend of Sir Nicholas Throckmorton, kn. chief butler of England, who died of poison, anno 1570, an historical poem by his nephew Sir Thomas Throckmorton, kn. Sixth, Herod the Great, by the editor. Seventh, the Resurrection, a poem in imitation of Milton, by a friend. And eighth, a Discourse on the Harmony of the Spheres, by Milton; with prefaces and notes." These were the first publications which he
PECORA, in zoology, the fifth order of the class mammalia, in the Linnaean system. See Zoology.

PECQUET (John), was a physician in Dieppe, and died at Paris in 1674. He was physician in ordinary to the celebrated Fouquet, whom he entertained at his spare hours with some of the most amusing experiments in natural philosophy. He acquired immortal honour to himself by the discovery of a lacteal vein, which conveys the chyle to the heart; and which from his name is called le Réserveur de Pecquet. This discovery was a fresh proof of the truth of the circulation of the blood; though it met with opposition from many of the learned, particularly from the famous Riouan, who wrote a treatise against the author of it, with this title: Allevius Pecquetum & Pecquetianos. The only works which we have of Pecquet, are, 1. Experientia unius Anastasis, published at Paris, 1654. 2. A Dissertation, De Thoracis Laetibus, published at Amsterdam, 1661. He was a man of a lively and active genius; but his sprightly lines sometimes led him to adopt dangerous opinions. He recommended, as a remedy for all diseases, the use of brandy. This remedy, however, proved fatal to himself, and contributed to shorten his days, which he might have employed to the advantage of the public.

PECTEN, the SCALLOP; a genus of shell-fish, the characters of which are these: The animal is a tethys; the shell bivalve and unequall; the hinge toothless, having a small ovated hollow. This shell-fish is one of the spinners, having the power of spinning threads like the mussels; but they are much shorter and coarser than even those of that fish; so that they can never be wrought into any kind of work like the longer and finer threads of the pinna marina. The use of the threads which are spun by the scallop is to fix the creature to any solid body near its shell. All these proceed, as in the mussels, from one common trunk. It is an evident proof that the fish has a power of fixing itself at pleasure to any solid body by means of these threads, that after forms the scallops are often found tossed upon rocks, where there were none the day before; and yet these are fixed by their threads, as well as those which had remained ever so long in their place. They form their threads in the very same manner as the mussels; only their organ which serves for spinning is shorter, and has a wider hollow, whence the threads are necessarily thicker and shorter.

Mr Barbut divides the genus offera into four families; which he thus names according to their characters. 1. The winged equilateral pectens. 2. The pectens, that have one ear inwardly, spring by being clisiated. 3. The pectens that have their valves more gibbous on one side than on the other. 4. The rough ones, commonly called offera. Of the locomotive powers of the pecten, we have already treated under the article Animal Motion, which see p. 411. col. 2.

The pectens, such as the folio pecten, the ducal mantle pecten, the knotted, and others, seem to be in general inhabitants of the Indian seas; some of them frequent those of Africa and the South Seas. The most remarkable species is the maximus or great scallop, being the same with what Barbut calls the ducal mantle pecten. It has 15 rays, very prominent and broad, and fitted both above and below. They are rugged and imbricated with scales. They grow to a large size; are found in beds by themselves; are dredged up, and barrelled for sale. The ancients say that they have a power of removing themselves from place to place by vast springs or leaps. This shell was used both by the Greeks and Latins as a food. When dressed with pepper and cummin, it was taken medicinally. The scallop was commonly worn by pilgrims on their hat, or the cape of their coat, as a mark that they had crossed the sea in their way to the Holy Land, or some distant object of devotion.

The name pecten seems to have been given to these animals, from the longitudinal flire with which their surface is covered, which resemble somewhat the teeth of a comb; and hence also the Greek name Pecch. By the general character of this shell, it evidently includes cockles as well as scallops, which are the pectens without cars, and having left flat or elated shells. They are called by all authors, by a name which is only a diminutive of pecten, pectinulus. The having ears indeed is the common mark of distinction between the pectens and the cockles, which last usually have none; yet the genera are not distinct, as some have imagined: for there are shells universally allowed to be pectens or scallops, which have no ears, and others as universally allowed to be pecctnules or cockles which have. Hence then appears the errors of Lifier, who made them two distinct genera, and gave the ears and the equal convexity of both shells as the great characters of them; which, though they be good marks to distinguish the species by, are far from being so unalterable as to found different genera upon.

Barbut, we have seen, ranks the pectens under the genus offera; but he says, that though the generic character of the hinge agrees in both, the animal inhabiting the pectens is very different from that of the oyster; for which reason Linnaus has divided the genus into fctenas. The pectes by some are esteemed as delicious a food as the oyster. They differ very materially in a variety of circumstances. The pectens, as we have already observed, fail on the surface of the water; and besides, if they are attacked by a foe, they let down the membrane which nature has provided them for a fail, and drop to the bottom. "Behold (says Barbut) the splendor of the pectines, which rival the glowing colours of the papilionaceous tribe, as numerous as they are beautiful, flitting from place to place, and may well be called the papiliones of the ocean. What superior qualities do not the pectines enjoy above the offera edulis, which, constantly confined to its native bed, seems wholly destined to afford food to other creatures, not having any means of defence, but its flily car, which is frequently attacked and formed by its numerous enemies? This creature is not only useful to man as a dainty food, but the shell being levigated
motion are exerted in vain. It is probable, however, that they have the faculty of operating their own relief from those circumstances, and that they may be accidentally afflicted by other bodies. It must, however, be acknowledged, that the means of relief cannot be numerous or considerable in such as are attached to other oysters, to a body heavier than themselves, or to a rock; but such situations are the most uncommon in the oyster-beds that I was acquainted with on the French coasts in the Channel. Perhaps, indeed, a very angular or heavy shell may be sufficient to render an oyster immovable. This is undoubtedly the case with such of them as have been obliged by worms, or other more formidable enemies, so to increase their shells as to make them thick and unwieldy. But we do not know whether these animals, in unfavourable circumstances, may not be able to supply these manoeuvres that I have mentioned, by others that I have not as yet been able to observe. An oyster that has never been attached, may fix itself by any part of the margin of either of its valves, and that margin will become the middle, or nearly so, if the oyster is young. I would not be surprised that oysters, which have been fixed to a rock from the beginning, should be able to detach themselves. I have seen them operate upon their shells in so many different ways, and with such admirable contrivance, when those shells have been pierced by their enemies (among whom I must be ranked), that I do not think it at all impossible for them to quit the place to which they are attached. It will easily be imagined how delicate and difficult such observations and experiments must be, considering the finiteness of the animal, the delicacy of its organs, the transparency of the matter that forms the layers of its shells, the opacity of the shells themselves, the villiatures of the sea, and the seas, &c. But it was of use to show, that, contrary to the opinion generally entertained by the learned as well as by navigators, oysters are endowed with a locomotive faculty, and by what means that faculty is exerted. I must add, that those which first flowed me these motions, were brought from the coasts of Bretagne, put into a bed at La Hogue, then at Coursolle, whence they were carried to Havre; and that, as all those transportations were made in a dry carriage, the oysters could not be in perfect vigour. It was necessary also to show, that these animals have much more sensibility and more industry than is generally attributed to them.

It is not often that a sagacious observer of nature is seduced from his object by the pride of appearing above it, or the desire of generalization. To think of grasping the whole of nature, when we are unable to consider in the whole the first and most interesting of her kingdoms, is a vain illusion. Yet some have endeavoured to confound the kingdoms, while they have taken the liberty of dividing the highest of them into beings differently animalized. Under the pretence of having a better idea of it, they leaped off all the extremities; that is to say, they rid themselves of every thing they were not well acquainted with, or that threw difficulties into their way. This, to be sure, was very convenient, but very injurious to the proceeding of an enlarged mind, and very unfit to inform us with regard to the economy of nature. The organization of the oyster, though very different from that...
PECULIAR, in the canon law, signifies a
form of freehold, that is, an estate or
property in land and personal effects, to
which the owner is entitled, and from
which he is free from the jurisdiction of
the church. It is derived from the Latin
peculium, meaning property or goods.

PECULAR, a peculiarity, is a
characteristic or feature that is unique
to a particular thing or person.

PECULATION, the act of using
property or goods for personal profit.

PECULIUM, a private estate, is
an asset or property that is
owned by an individual or
organization.

PECULIUS, a term used in
Latin to refer to a private or
personal estate.

PEDANTIC, pedantic is an
adjective that describes being
intense or overzealous in
learning or teaching.

PEDIATRY, pediatrics is the
branch of medicine that focuses
on the health and safety of infants
and children.

PEDANT is a person who
shows an excessive or
unreasoning love of learning.

PEDANTICAL, pertaining to
or having to do with pedantry.

PEDIATRICIAN, a pediatrician is
a doctor who specializes in the
health and care of infants and
children.

PEDESTAL, a pedestal is
a stand or base upon which
an object is placed.

PEDESTRIAN, a pedestrian is
a person who travels on foot.

PEDESTRIANISM, pedestrianism is
the practice of walking as a form
of transportation.

PEDESTRIANIZATION, the process
of converting an area into a
dedicated space for pedestrians.

PEDESTRIANIZED, pedestrianized is
an adjective that describes an area
that has been converted into a pedestrian
space.

PEDIMENT, a pediment is an
architectural feature that
consists of a triangular roof
or canopy.

PEDESTRIANIZATION, the process
of converting an area into a
dedicated space for pedestrians.

PEDESTRIANIZED, pedestrianized is
an adjective that describes an area
that has been converted into a pedestrian
space.
To swell up little and low things, to make a vain show of science, to heap up Greek and Latin, without judgment, to tear those to pieces who differ from us about a passage in Suetonius or other ancient authors, or in the etymology of a word, to stir up all the world against a man for not admiring Cicero enough, to be interested for the reputation of an ancient as if he were our next of kin, is what we properly call pedantry.

PEDARIAN, in Roman antiquity, those senators who signified their votes by their feet, not with their tongues; that is, such as walked over to the side of those whose opinion they approved of, in divisions of the senate.

Dr. Middleton thus accounts for the origin of the word. He says, that though the magistrates of Rome had a right to a place and vote in the senate both during their office and after it, and before they were put upon the roll by the censors, yet they had not probably a right to speak or debate there on any question, at least in the earlier ages of the republic. For this seems to have been the original distinction between them and the ancient senators, as it is plainly intimated in the formula of the consular edict, sent abroad to summon the senate, which was addresed to all senators, and to all those who had a right to vote in the senate. From this distinction, those who had only a right to vote were called in ridicule pedarian; because they signified their votes by their feet, not their tongues, and upon every division of the senate went over to the side of those whose opinion they approved. It was in allusion to this old culmum, which seems to have been wholly dropped in the latter ages of the republic, that the mute pedarian; as Cicero informs us, who in giving an account to Atticus of a certain debate and decree of the senate upon it, says that it was made with the eager and general concurrence of the pedarians, though against the authority of all the confuls.

PEDATURA, a term used, in Roman antiquity, for a space or proportion of a certain number of feet set out. This word often occurs in writers on military affairs: as in Hymenius de Castrisarmatione, we meet with meminerimus iuxta ad computationem cohortis equitata militarium pedaturn ad militcentos sesquinginta dari debet; which is thus explained: The pedatura, or space allowed for a cohors equitata or provincial cohort, consisting of both horse and foot, could not be the same as the pedatura of an uniform body of infantry, of the same number, but must exceed it by 360 feet; for the proportion of the room of one horsemann to one foot soldier he assigns as two and a half to one.

PEDASTAS, the same with sodomite.

PEDESTAL, in architecture, the lowest part of an order of columns, being that part which sustains the column, and serves it as a foot or stand. See COLUMN.

PEDEAN, in Grecian antiquity. The city of Athens was anciently divided into three different parts; one on the descent of an hill; another on the sea-shore; and a third in a plain between the other two. The inhabitants of the middle region were called pedians, Pedaietes, formed from pedon, 'plain,' or 'flat,' or as Aristotle will have it, Pedone: those of the hill, Diacrians; and those of the shore, Paralians.

These quarters usually composed so many different factions. Pisistratus made use of the Pedians against the Diacrians. In the time of Solon, when a form of government was to be chosen, the Diacrians chose it democratic; the Pedians demanded an aristocracy; and the Paralians a mixed government.

PEDICLE, among botanists, that part of a stalk which immediately sustains the leaf of a flower or a fruit, and is commonly called a footstalk.

PEDICULUS, the louse, in zoology, a genus of insects belonging to the order of aptera. It has six feet, two eyes, and a fort of fting in the mouth; the feelers are as long as the thorax; and the belly is def pressed and sublubated. It is an oviparous animal. They are not peculiar to man alone, but infet other animals, as quadrupeds and birds, and even fishes and vegetables; but these are of peculiar species on each animal, according to the particular nature of each, some of which are different from those which infest the human body. Nay, even insects are infest with vermian which feed on and torment them. Several kinds of beetles are subject to lice; but particularly that kind called by way of eminence the lowf bottle. The lice on this are very numerous, and will not be shook off. The earwig is often infested with lice, just at the feting on of its head; these are white, and shining like mites, but they are much smaller; they are round-backed, flat-bellied, and have long legs, particularly the foremost pair. Snails of all kinds, but especially the large naked sorts, are very subject to lice; which are continually seen running about them, and devouring them. Numbers of little red lice, with a very small head, and in shape resembling a tortoise, are often seen about the legs of spiders, and they never leave the animal while he lives; but if he is killed, they at once instantly forsake him. A fort of whitish lice is found on humble-bees; they are also found on ants; and fishes are not less subject to them than other animals.

Kircher tells us, that he found lice also on flies, and M. de la Hire has given an accurate account of the creature which he found on a common fly. Having occasion to view a living fly with the microscope, he observed on its head, back, and shoulders, a great number of small animals crawling very nimbly about, and often climbing up the hairs which grow at the origin of the fly's legs. He with a fine needle took up one of these, and placed it before the microscope used to view the animalculae in fluids. It had eight legs; four on each side. These were not placed very distant from each other; but the four towards the head were separated by a small space from the four towards the tail. The feet were of a particular structure, being composed of several fingers, as it were, and fitted for taking hold of any thing; but the two nearest the head were also more remarkable in this particular than those near the tail; the extremities of the legs for a little way above the feet were dry and void of flesh like the legs of birds, but above this part they appeared plump and fleshy. It had two small horns upon its head, formed of several hairs arranged close together; and there were some other clusters of hairs by the side of these
Just return the plain text representation of this document as if you were reading it naturally.
Pediculus. between the latitude of Madeira and the Indies, drown and destroy the lice; and have the same effect as the rubbing over the lousy heads of children with butter and oil. The sweat, in these hot climates, is not rank as in Europe, and therefore it is not apt to breed lice; but when people return into latitudes where they sweat rank again, their nativitie subjects them to the same visitations of these vermin as before. The people in general in the Indies are very subject to lice in their heads, tho' free from them on their bodies. The reason of this is, that their heads sweat less than their bodies, and they take no care to comb and clean them. The Spaniards wash their heads thoroughly once every week with soap, to prevent their being lousy. This makes them escape much better than the other negroes who are laves thare; for the lice grow to numerous in their heads, that they often eat large holes in them.

Cleanliness is doubtless the grand secret by which to keep clear from lice, especially when we wear woollen clothes. It is also necessary where there is any danger, to take nourishing, succulent food, and to use wholesome drink. J. Mercurial advises frequent purges as a cure in the pedicular disease: it is necessary also to rub with garlic and mustard, to take treacle inwardly, also salted and acid food, to bathe, and to foment the body with a decoction of lupines, or of gall-nuts; but the most effectual remedies are sulphur and tobacco, mercurial ointment, black pepper, and vinegar. Monkeys and some Hottentots, we are told, eat lice; and are thence denominated phthiraphages. On the coast of the Red Sea it is reported, that there is a nation of small stature and of a black colour, who use loculics for the greatest part of their food, prepared only with salt. On such food those men live till 40, and then die of a peculiar or lousy difeased. A kind of winged lice devour them, their body putrefies, and they die in great torment. It is also a fact that the negroes on the west coast of Africa take great delight in making their women clear their bodies of lice, and those latter devour them with greediness as fast as they find them.

In ancient medicine lice were esteemed an aperient febrifuge, and proper for curing a pale complexion. The natural repugnance to these ugly creatures (fays Lamery) perhaps contributed more to banish the fever than the remedy itself. In the jaundice five or six were swallowed in a soft egg. In the suppuration of urina, which happens frequently to children at their birth, a living leuca is introduced into the urethra, which by the tickling which it occasions in the canal, forces the sphincter to relax, and permits the urine to flow. A bug produces the same effect. Farriers have also a custom (fays M. Bourgeois) of introducing one or two lice into the urethra of horses when they are seized with a retention of urine, a difficile pretty common among them. But, according to the Continuation of the Materia Medica, to use the pedicular medicine with the greatest advantage, one would need to be in Africa, where these insects are carefulliy sought after and swallowed as a delicious morsel. The great difficult between those which infect mankind is into the head and body lute. The former is hard and high coloured, and the latter is compact and more of an athen colour. If it were possible to give a reason why some families of the same species stick to the head and others to the clothes, &c. it would also in all probability be possible to understand the nature of many contagious diseases.

Pediciluvium, or Bathing of the Feet. The uses of warm bathing in general, and of the pediluvium in particular, are so little understood, that they are often propperously used, and sometimes as injudiciously attained from.

In the Edinburgh Medical Essays, we find an ingenious author's opinion of the warm pediluvium, notwithstanding that of Borelli, Boerhaave, and Hoffman, to the contrary, to be, That the legs becoming warmer than before, the blood in them is warmed; this blood rarifying, dilutes the veifels; and in circulating impart a great degree of warmth to the rest of the mafs; and as there is a portion of it constantly pausing through the legs, and acquiring new heat there, which heat is in the course of circulation communicated to the rest of the blood, the whole mafs rarify, occupies a larger space, and of consequence circulates with greater force. The volume of the blood being thus increased, every veifel is diffended, and every part of the body feels the effects of it; the diffant parts a little later than those first heated. The benefit obtained by a warm pediluvium is generally attributed to its making a derivation into the parts im­merfed, and a revulsion from those affected because they are relieved; but the cure is performed by the direct contrary method of operating, viz. by a greater force of circulation through the parts affected, removing what was stagnant or moving too sluggishly there. Warm bathing is of no service where there is an irregu­lar obstruction, though, by its taking off from a pain in general, it may seem to give a moment's ease; nor does it draw from the other hand, warm bathing of any sort should never be used. On the other hand, where ob­structions are not of long standing, and the impeded matter is not obstinate, warm baths may be of great use to resolve them quickly. In recent colds, with flight humoral peripneumonies, they are frequently an immediate cure. This they effect by increasing the force of the circulation, opening the skin, and driving freely through the lungs that lentor which flagellated or moved slowly in them. As thus conducing to the resolution of obstructions, they may be considered as abort and false fevers; and in using them we imitate nature, which by a fever often carries of an obliterating caufe of a chronic ailment. Borelli, Boerhaave, and Hoffman, are all of opinion, that the warm pediluvium acts by driving a larger quantity of blood into the parts im­merfed. But arguments must give way to facts: the experiments related in the Medical Essays seem to prove a demonstration, that the warm pediluvium acts by rarifying the blood.

A warm pediluvium, when rightly tempered, may be used as a safe cordial, by which circulation can be rouz'd, or a gentle fever rais'd; with this advantage over the cordials and sudorifies, that the effect of them may be taken off at pleasure.
Pediluvia are sometimes used in the small-pox; but Dr Stevenson thinks their frequent tumultuous operations render them suspected, and at best of very doubtful effect; and he therefore prefers Mons. Martin of Laufranne's method of bathing the skin, not only of the legs, but of the whole body, with a soft cloth dipped in warm water, every four hours, till the eruption; by which means the pustules may become universally higher, and consequently more safe.

**PEDIMENT.** See Architecture, p. 240, &c.

**PEDLAR,** a travelling foot-trader. See Hawkers.

In Britain (and formerly in France) the pedlars are despised; but it is otherwise in certain countries. In Spanish America, the busines is so profitable, that it is thought by no means dishonourable; and there are many gentlemen in Old Spain, who, when their circumstances are declining, spend their sons to the Indies to retrieve their fortunes in this way. Almost all the commodities of Europe are distributed through the southern continent of America by means of these pedlars. They come from Panama to Paita by sea; and in the road from the port last mentioned, they make Peru their first voyage to Lima. Some take the road through Casamalia; others through Truxillo, along shore from Lima. They take their passage back to Panama by sea; and perhaps take with them a little cargo of brandy. At Panama they again stock themselves with European goods, returning by sea to Paita, where they are put on shore; there they hire mules and load them, the Indians going with them in order to lead them back. Their travelling expences are next to nothing; for the Indians are brought under such subjection, that they find lodging for them, and provender for their mules, frequently thinking it an honour done them for their service; and that they are sufficiently rewarded by this public testimony of their affections. The queen dowager wished to raise disturbances in Portugal by aiming to recover the regency to herself; but the readiness of the regent's administration, the attachment of the best part of the nobility to him, his having, in an absolute degree, the confidence of the people; not only secured the interior tranquillity of the state, but raised the credit likewise of the crown of Portugal to a very great height in the sentiments of its neighbours; for in the course of his regency he had made it his continual study to pursue the public good; to ease the people in general, and the inhabitants of Lisbon in particular, of several impositions; to maintain the laws in their full vigour; to give the king an excellent education; and that it had been at all practicable, to diffuse a perfect unanimity through the court, by affuaging the malice and envy of his enemies. The king when he came of age, and the cortes or parliament, expressed their entire satisfaction with the regent's administration; and all parties entirely approved of the king's marriage with Donna Isabella, the regent's daughter, which was celebrated in 1446. The enmity of his enemies, however, was not in the least abated by the regent's being out of office. They still persecuted him with their unjust calumnies, and unfortunately made the king hearken to their falsehoods. The unfortunate duke, when ordered to appear before the king, was advised to take with him an escort of horse and foot. In his passage he was proclaimed a rebel, and quickly after he was surrounded by the king's troops. Soon after he was attacked, and in the heat of action he was killed; nor was the envy of his enemies even then satisfied; his body was forbid burial; and was at length taken away privately by the peasants. His virtue, however hated in courts, was adored by the uncorrupted part of his countrymen. At length, thro' an inspection of his papers, the king saw, when it was too late, the injustice that had been done the man who had behaved so well in so high and difficult an office; and whose papers only discovered signs of further benefit...
beacuue, loyal subjects, Peduncle, Pebbles.

Henry Douglas of Cavers, gunner, and a great many terraces on the neighbouring hills, vestiges which five arches.

In the neighbourhood of Tweedale, a county of Scotland, extending 25 miles in length and 18 in breadth. It is bounded on the east by Ettrick Forest, on the south by Annandale, on the west by Clydestede, and on the north by Mid Lothian.

Tweedale is a hilly country, well watered with the Tweed, the Yarrow, and a great number of smaller streams that fertilize the valleys, which produce good harvests of oats and barley, with some proportion of wheat. All the rivers of any consequence abound with trout and salmon. The lake called Wylt. Watrs Loch swarms with a prodigious number of eels. In the month of August, when the west wind blows, they tumble into the river Yarrow in such flocks, that the people who wade in to catch them run the risk of being overturned.

There is another lake on the borders of Annandale, called Loch-gennan, which forms a catacaot over a precipice 230 paces high: here the water falls with such a momentum as to kill the fish underneath. About the middle of this country is the hill or mountain of Braidalbh, from the top of which the sea may be seen on each side of the island. Tweedale abounds with limestone and freestone. The hills are generally as green as the downs in Suffex, and feed innumerable flocks of sheep, that yield great quantities of excellent wool. The country is well shaded with woods and plantations, abounds with all the necessaries of life, and is adorned with many fine seats and populous villages. The earls of March were hereditary sheriffs of Tweedale, which bequests the title of marquis on a branch of the ancient house of Hay, earls of Errol, and hereditary high constables of Scotland. The family of Tweedale is, by the female side, descended from the famous Simon de Frazer, proprietor of great part of this country, who had a great share in obtaining the triple victory at Rolin. The chief, and indeed the only town of consequence in Tweedale, is Peebles, a small inconsiderable royal borough, and seat of a prebendary, pleasantly situated on the banks of the Tweed, over which there is at this place a lately built bridge of five arches. In the neighbourhood of Peebles, near the village of Romans, on the river Lene, we see the vestiges of two Roman castella, or stationary forts; and a great many terraces on the neighbouring hills, which perhaps have served as itinerant encampments.

In the shire of Tweedale there are many ancient and honourable families of the gentry. Amongst these, Douglas of Cavers, who was hereditary sheriff of the country, still preserves the standard and the iron mace of the gallant lord Douglas, who fell in the battle of Otterburn, just as his troops had defeated and taken Henry Percy, iurnamed Hotspur. In the churchyard of Drumalzier, belonging to an ancient branch of the Hay family, the famous Merlin is supposed to lie buried. There was an old traditional prophecy, that the two kings' sons should be united when the waters of the Tweed and the Tweed should meet at his grave. Accordingly, the country people observe that this meeting happened in consequence of an inundation at the accession of James VI. to the crown of England.

Peek, in the seas language, is a word used in various senses. Thus the anchor is said to be a-peek, when the ship being about to weigh comes over her anchor in such a manner that the cable hangs perpendicularly between the haufe and the anchor.

To heave a-peek, is to bring the peek so as that the anchor may hang a-peek. A ship is said to ride a-peek, when lying with her main and fore yards hoisted up, one end of her yards is brought down to the throuds, and the other raised up on end; which is chiefly done when the lies in rivers, left other ships falling foul of the yards should break them. Riding a-broad peek, denotes much the same, excepting that the yards are only raised to half the height.

Peek is also used for a room in the hold, extending from the bids forward to the scra: in this room men of war keep their powder, and merchant men their victuals.

Peel, in the Isle of Man, formerly Holm-town, has a fort in a small island, and a garnison well supplied with cannon. In it are the ancient cathedral, the lord's house, with some lodgings of the bishops, and some other remains of antiquity.

Peers, in general, signifies an equal, or one of the same rank and station; hence in the acts of some councils, we find these words, with the consent of our peers, bishops, abbots, &c. Afterwards the same term was applied to the vassals or tenants of the same lord, who were called peers, because they were all in equal condition, and obliged to serve and attend him in his courts; and peers in feft, because they all held sefs of the same lord.

The term peers is now applied to those who are impeached in an inquest upon a person for convicting or acquitting him of any offence laid to his charge; and the reason why the jury is so called, is because, by the common law and the custom of England, every person is to be tried by his peers or equals; a lord by the lords, and a commoner by commoners. See the article Jury.

Peel of the Realm, a noble lord who has a seat and vote in the House of Lords, which is also called the House of Peers.

These lords are called peers, because though there is a distinction of degrees in nobility, yet in public actions they are equal, as in their votes in parliament, and in trying any nobleman or other person impeached by the commons, &c. See Parliament.

House of Peers, or House of Lords, forms one of the three estates of parliament. See Lords and Parliament.

In a judicative capacity, the house of peers is the supreme court of the kingdom, having at present no original jurisdiction over causes, but only upon appeals and writs of error; to redress any injustice or mistake of the law committed by the courts below. To this authority they succeeded of course upon the dissolution of
of the Aula Regia. For as the barons of parliament were confiderr members of that court, and the rest of its jurisdiction was dealt out to other tribunals, over which the great officers who accompanied these barons were respectively delegated to preside, it followed, that the right of receiving appeals, and superintending all other jurisdictions, still remained in that noble assembly, from which every other great court was derived. They are therefore in all cafes the last resort, from whose judgment no farther appeal is permitted; but every subordinate tribunal must conform to their determinations: The law reposing an entire confidence in the honour and confidence of the noblepersons who compose this important assembly, that they will make themselves masters of those questions upon which they undertake to decide; since upon their decision all property must finally depend. See Lords, Nobility, &c.

Peers, in the anti-revolution government of France, were twelve great lords of that kingdom; of which five were dukes and five counts; and of these, five were ecclesiastics and five laymen: thus the archbishop of Rheims, and the bishop of Laon and Langres, were dukes and peers; and the bishops of Chartres, the Marquis of Noyons, and Beauvais, were counts and peers. The dukes of Burgundy, Normandy, and Aquitaine, were lay peers and dukes; and the counts of Flanders, Champaign, and Touloufe, lay peers and counts. These peers assist at the coronation of kings, either in person or by their representatives, where each performed the functions attached to his respective dignity: but as the fix lay peersages were all united to the crown, except that of the count of Flanders, six lords of the first quality were chosen to represent them: but the ecclesiastical peers generally assisted in person. The title of peer was last paid to every lord whose estate was erected into a peerage; the number of which, as it depended entirely on the king, was uncertain.

Petures, a woman's whip is noble by descent, creation, or marriage. For, there are the noblemen of several ranks, so there are noblewomen; thus king Henry VIII. made Anne Bullen marchioness of Pembroke; king James I. created the Lady Compton, wife to Sir Thomas Compton, countess of Buckingham, in the lifetime of her husband, without any addition of honour to him; and also the same king made the Lady Finch, vicountess of Maidstone, and afterwards countess of Winchelsea, to her and the heirs of her body: and king George I. made the Lady Schullenberg, duchess of Kendal.

If a peeress, by descent or creation, marries a person under the degree of nobility, she still continues noble: but if she obtains that dignity only by marriage, she loses it, on her afterwards marrying a commoner: yet by the courtesy of England, the generally retains the title of her nobility.

A countess or baroness may not be arabled for debt or treason; for though in respect of their sex, they cannot sit in parliament, they are nevertheless peers of the realm, and shall be tried by their peers, &c.

Pewit, in ornithology. See Larks.

Pegasus, among the poets, a horse imagined to have wings; being that whereon Bellerophon was fabled to be mounted when he engaged the Chimera. See Chimera.

The opening of the fountain Hippocrene on mount Helicon is ascribed to a blow of Pegasus's hoof. It was esteemed to have flown away to heaven, where it became a constellation. Hence,

Pegasus, in astronomy, the name of a constellation of the northern hemisphere, in form of a flying horse. See Astronomy, n o 406.

Pegmares, a name by which certain gladiators were distinguished, who fought upon moveable scaffolds called pegmatae, which were sometimes unexpectedly raised, and by this means surprized the people with gladiators in hot contention. They were sometimes suddenly lifted up as to throw the combatants into the air; and sometimes they were let down into dark and deep holes, and then set on fire, thus becoming the funeral piles of these miserable wretches; and roasting them alive to divert the populace.

Pegu, a very considerable kingdom of Asia, beyond the Ganges. The country properly so called is about 750 miles in length from north to south, and as much in breadth from east to west. It is situated on the eastern side of the bay of Bengal, nearly opposite to Arix, and on the north-east of the coast of Coromandel. It is bounded on the north by the kingdoms of Arakan and Ava; on the east by the Upper and Lower Siam; on the south by part of Siam and the Sea; and on the west by the sea and part of Arakan.

The kingdom of Pegu is said to have been founded about 1100 years ago. Its first king was a seaman; concerning whom and his successors we know nothing till the discovery of the East Indies by the Portuguese in the beginning of the 16th century. In 1518 the throne of Pegu was poise by one Brenfagukan, with whom Antony Correa the Portuguese ambassador solemnly concluded a peace in 1519. This monarch was poise by a very large and rich empire, nine kingdoms being in subjection to him, whose revenues amounted to three millions of gold. We have no further account of his transactions after the conclusion of the treaty with the Portuguese. In 1529 he was murdered on the following occasion: Among other princes who were his tributaries was Para Mandar, king of the Barmas. These people inhabited the high lands called Pangozowars, to the northward of the kingdom of Pegu. Their prince, by one of the terms of his vassalage, was obliged to furnish the king of Pegu with 36,000 Barmas, to labour in his mines and other public works. As the king used frequently to go and see how his works went forward, and in these journeys took along with him none but his women, the Barmas observing these visits frequently repeated, formed a design of robbing the queen and all the concubines of their jewels; and pursuant to this design, the next time the king visited the works, they murdered him, and having stripped the ladies, fled to their own country.

By this enormity all Pegu was thrown into confusion; but instead of revenging the death of their king, the people divided everywhere into factions; so that Daeha Rupi, the lawful heir to the crown, found himself unable to maintain his authority. Of these commotions, the king of the Barmas taking the advantage,
of conquering the kingdom of Pegu.

With this view he invaded the country with an army of more than a million of foot, and 3000 elephants; besides a great fleet which he sent down the river Ava towards Bagou or Pegu, the capital of the empire; while he himself marched thither by land. Juft at this time Ferdinand de Miraies arrived at Pegu from Goa with a large galleon richly laden on account of the king of Portugal. As soon as Dacha Rupi heard of his coming, he sent to desire his assistance against the enemy. This he obtained by great presents and promises; and Miraies, sitting out in a galliot, joined the king's ships. Had the numbers been anything near an equality, the superior skill of Miraies would undoubtedly have gained the victory: But the fleet of the Barma covered the whole river, though as large as the Ganges, while that of Dacha Rupi could scarce be observed in comparison with them. Miraies did every thing that man could do, and even held out alone after the natives had deferted him; but at last, oppressed and overwhelmed with numbers, he was killed, with all his men.

Thus Para Mandara became master of all Pegu; after which he attacked the tributary kingdoms. In 1544 he besieged Martavan, the capital of a kingdom of the same name, then very great and flourishing. The land-forces which he brought against it consisted of 700,000 men, while by sea he attacked it with a fleet of 1700 sail, of which were large galleys, and in them 700 Portuguese commanded by John Cayero, who had the reputation of being a valiant and experienced officer. The siege, however, continued seven months, during which time the Barma lost 120,000 men; but at last the besieged king, finding himself straitened for want of provisions, and unable to withstand so great a power, offered terms of capitulation. The besiegers would admit of no terms, upon which the disfavored king applied to the Portuguese in the service of his enemy; for by their alliance he doubted not to be able to drive away the Barma. Accordingly, he sent one Seixas to Cayero, intreating him to receive himself, his family, and treasure, on board the four ships he had under his command; offering, on that condition, to give half his riches to the king of Portugal, to become his vaiffal, and pay such tribute as should be agreed upon. Cayero consulted the principal officers, and in their presence asked Seixas what he thought the treaty might amount to. Seixas answered, that out of what he had seen, for he had not seen all, two ships might be loaded with gold, and four or five with silver. This proposal was too advantageous to be declined; but the rest of the officers envying the great fortune which Cayero would make, threatened to discover the whole to the king of Barma if he did not reject it. The unhappy king of Martavan had now no other recourse but to set fire to the city, make a sally, and die honourably with the few men he had with him; but even here he was disappointed; for by the defection of 4000 of his troops the enemy were apprised of his design, and prevented it. Thus betrayed; he capitulated with the Barma king for his own life and the lives of his wife and children, with leave to end his days in retirement. All this was readily granted, but the conqueror intended to perform no part of his promise.

This city was plundered and burnt, by which above 60,000 persons perished, while at least an equal number were carried into slavery. Six thousand cannon were found in the place; 100,000 quintals of pepper, and an equal quantity of other spices. The day after this destruction, 21 gibbets were erected on an hill adjoining to the city; on which the queen, her children, and ladies, were executed, by hanging them up alive by the feet: however, the queen expired with anguish before she suffered such a cruel indignity. The king, with 50 of his chief lords, was cast into the sea, with stones about their necks. This monstrous cruelty so provoked the tyrant's soldiers, that they mutinied, and he was in no small danger of suffering for it: however, he found means to pacify them; after which he proceeded to besiege Prom, the capital of another kingdom. Here he increased his army to 900,000 men. The queen by whom it was governed offered to submit to be his vaifal; but nothing would satisfy the Barma monarch less than her surrender at discretion, and putting all her treasure into his hands. This he, who knew his perfidy, refused to do; on which the city was fiercely assaulted, but greatly to the disadvantage of the Barma, who lost near 100,000 men. However, the city was at last betrayed to him, when Mandara behaved with his usual cruelty. Two thousand children were slain, and their bodies cut in pieces and thrown to the elephants; the queen was stripped naked, publicly whipped, and then tortured, till she died; the young king was tied to her dead body, and both together cast into a river, as were also 300 other people of quality.

While the tyrant was employed in fortifying the city, he was informed, that the prince of Ava had followed down the river Queniot with 400 rowing vessels having 30,000 soldiers on board; but that, hearing of the queen's disaster, he stopped at Melatay, a strong fortress about 12 leagues north of Prom, where he waited to be joined by his father the king of Ava with 80,000 men. On this news the Barma king sent his foster-brother Chauimigre along the river-side two thousand children were slain, and their bodies cut in pieces and thrown to the elephants; the queen was stripped naked, publicly whipped, and then tortured, till she died; the young king was tied to her dead body, and both together cast into a river, as were also 300 other people of quality.

A most desperate engagement ensued, in which only 800 of the prince's army were left, and 115,000 out of 220,000 Barma who opposed him were killed. The 800 Avans retired into the fort; but Mandara coming up soon after, and being enraged at the terrible havoc made in his army, attacked the fortresses most violently for seven days; at the end of which time, the 800, finding themselves unable to hold out any longer, rushed out in a dark and rainy night, in order to tell their lives at as dear a rate as possible. This last effort was fo extremely violent, that they broke through the enemy's troops in several places, and even preceeded so hard on the king himself that he was forced to jump into the river. However, they were at last all cut off, but not before they had destroyed 12,000 of their enemies.

Mandara having thus become master of the fort, commanded it to be immediately repaired; and sailed up the river to the port of Ava, about a league from the
In the neighborhood, the capital, where he burnt between 2000 and 3000 vehicles, and lost in the enterprise about 8000 men. The city itself he did not think proper to invest, as it had been newly fortified, was defended by a numerous garrison, and an army of 80,000 men was advancing to its relief. The king also apprehensive of Man dara's power, had implored the protection of the emperor of Siam; offering to become his tributary on the same terms of peace as those which the Barma monarch, fo that he dispatched an embassage to the Kalaminham or sovereign of a large territory adjacent, requesting him to divert the emperor from his purpose. On the embassadors return from this court, it appeared that the treaty had already taken effect; but as the season was not yet arrived for invading Ava, Chaumigrem, the king's elder-brother was sent with 150,000 men to reduce Sbadi or Savadi the capital of a small kingdom about 150 leagues north-east from Pegu. The general, however, failed in his attempt; and afterwards endeavouring to revenge himself on a town in the neighbourhood, he was surprized by the enemy and put to flight.

In the mean time, the empire of Siam fell into great distractions; the king, together with the heir to the crown, were murdered by the queen, who had fallen in love with an officer, whom she married after her husband's death. However, both of them were soon after killed at an entertainment; and the crown was given to a natural brother of the late king, but a coward and a tyrant. On this Mandara resolved to invade the empire of Siam; and, his principal courtiers concurring in the scheme, he collected an army of 800,000 men, with no fewer than 20,000 elephants. In this army were 1000 Portuguese, commanded by one James Suarez, who already had a pension of 200,000 ducats a-year from the king of Pegu, with the title of his brother, and governor of the kingdom. With this formidable army he set out in April 1548. His first achievement was the taking of a fortress on the borders of the enemy's country; before which, being several times repulsed, and having lost 3000 of his men, he revenged himself by putting all the women to the sword. He next besieged the capital itself; but though the siege was continued for five months, during which time the most violent attacks were made upon it, the assailants were constantly repulsed with great loss. However, it was still resolved to continue the siege, and a mount of earth was raised, on which were placed 40 pieces of cannon, ready to batter it anew, when, in October, advice was received of a rebellion having broke out in Pegu.

The person who headed the rebels on the present occasion was Shoripam Shuy, near a kin to the former monarch than twelve years before. He was a religious person, of great understanding, and esteemed a saint. As he was a famous preacher, he made a great son, in which he felt the tyranny of the Barmas in such a manner, that he was immediately taken out of the pulpit, and proclaimed king by the people, who, as a token of sovereignty, gave him the title of Shemindoo. The first act of sovereignty which he exerted was to cut in pieces 15,000 Barmas, and seize on the treasure; and so agreeable was this change of government to all ranks of people, that in three weeks time all the strong holds of Pegu fell into his hands.

On this news the king immediately raised the siege in which he was engaged, and in 17 days got to Martavan. Here he was informed, that Shemindoo had polled 500,000 men in different places, in order to intercept his passage; at the same time that he had the satisfaction to find 50,000 of his best troops deserted. To prevent a greater defection, after 14 days they, he departed from Martavan, and soon met Shemindoo at the head of 600,000 men. A desperate engagement followed: in which Shemindoo was entirely defeated, with the loss of 300,000 men. Of the Barma troops were slain 60,000; among whom were 280 Portuguese.

The morning after this victory, the tyrant marched to the city; the inhabitants of which surrendered, on condition of having their lives and effects spared. The kingdom being thus again brought under his subjection, his next step was to punish the principal personages concerned in the rebellion: their heads he cut off, and confiscate their estates, which amounted to no less than ten millions of gold. Others say, that he put all without distinction to the sword, excepting only 12,000, who took shelter in James Suarez's house, that alone affording an asylum from the general slaughter. The plunder was incredible, Suarez alone getting three millions. All these cruelties, however, were insufficient to secure the allegiance of the tyrant's subjects; for in less than three months news was brought that the city of Martavan had revolted; and that the governor had not only declared for Shemindoo, but murdered 2000 Barmas. Mandara then summoned all the lords of the kingdom to meet him with their forces, within 15 days, at a place called Mouchan, not far from his capital, whither he himself went with 300 men, to wait their arrival. But in the meantime he received intelligence that the shemin or governor of Zatan, a city of some consequence, had submitted to Shemindoo, and also lent him a large sum of gold. The shemin was immediately sent for in order to be put to death: but he, supposing Mandara's design, escaped himself by pretending sickness; after which, having consulted with his friends, he disguised himself, and, with about 600 men, and having with these privately advanced to the place where the king was, he killed him, with the few attendant that were about him at the time. The guards in the court being alarmed with the noise, a skirmish ensued with the shemin's men, in which about 800 were slain on both sides, most of them Barmas. The shemin then retreated to a place called Pontel; whither the people of the country, hearing of the death of the king, who was universally hated, returned to him. When he had assembled about 5000 men, he returned to seek the troops which the late king had had under his command and finding them dispersed in several places, easily killed them all. With the Barmas were slain 800 out of 300 Portuguese. The remainder surrendered, with Suarez their leader; and were spared, on condition of their remaining in the service of the shemin.

The shemin, now finding his forces daily increase, assumed the title of king; and, to render himself the more popular, gave out that he would exterminate
The air of Pegu is very healthy, and presently recovers sick strangers. The soil also is very rich and fertile in corn, rice, fruit, and roots; being enriched by the inundations of the river Pegu, which are almost incredible, extending above 30 leagues beyond its channel. It produces also good timber of several kinds. The country abounds with elephants, buffaloes, goats, hogs, and other animals, particularly game; and deer is so plenty in September and October, that one may be bought for three or four pence; they are very flythy, but have no fat. There is flora of good poultry; the cocks are vastly large, and the hens very beautiful. As for fish, there are many forts, and well salted. In Pegu are found mines, not only of gold, iron, tin, and lead, or rather a kind of copper or mixture of copper and lead, but also of rubies, diamonds, and sapphires. The rubies are the best in the world; but the diamonds are small, and only found in the craws of poultry and pheasants. Besides, only one family has the privilege of telling them; and none dare open the ground to dig for them. The rubies are found in a mountain in the province of Kablan, or Kaplan, between the city of Pegu and the port of Sirian.

The inhabitants are of an olive, or rather a tawny complexion. The women are branded by some traveller as having hooked off all modishly, on account of their exposing some parts of their bodies which ought to be concealed from sight. Some also tell us, that the men wear bells, which at a certain age, viz. 25 or 30, or, according to others, when they are capable of making use of women, are inflected on each side the virile member between the skin and the flesh, which is opened for that purpose, and healed in seven or eight days. The Peguans may be ranked among the most superstitious of all mankind. They maintain and worship crocodiles; and will drink nothing but the waters of the ditches where those monstrous animals harbour. By thus exposing themselves to the manifest hazard of their lives, they have frequently the misfortune to be devoured. They have five principal festivals in the year, called falans, which they celebrate with extraordinary magnificence. In one of them the king and queen make a pilgrimage about 12 leagues from the city, riding on a triumphal car, so richly adorned with jewels, that it may be said without an hyperbole that they carry about with them the value of a kingdom. This prince is extremely rich; and has in the chapel of his palace idols of inestimable value, some of them being of maffy gold and silver, and adorned with all sorts of precious stones. The talapous, or priests of this country, have no poffessions; but such is the respect paid them by the people, that they are never known to want. They preach to them every Monday not to commit murder; to take from no person any thing belonging to him; to do no hurt to give no offence; to avoid impurity and superstitious; but above all, not to worship the devil: but these duties have no effect in the last respect. The people, attached to manichém, believe that all good comes from God; that the devil is the author of all the evil that happens to men; and that therefore they ought to worship him, that he may not afflict them. This is a common notion among the Indian idolaters.

The inhabitants of Pegu are accused by some authors with being slovenly in their houses, and nasty in their...
Pegu, on account of their seasoning their virtuus with fidol, a composition made of flinking fish, reduced to a consistency like mustard, so nauseous and offensive that none but themselves can endure the smell of it. Balbi says, he could sooner bear the scent of flinking carron; and yet with this they feast their rice, and other soups, instead of oil or butter. As they have no wheat in this country, their bread is rice made into cakes. Their common drink is water, or a liquor distilled from cocoa-nut water. They are a spirited and warlike people; open, generous, and hospitable; and have neither the indolence nor the jealousy of most other eastern nations.

The men here, as in most eastern countries, buy their wives, or pay their parents a dowry for them. They have an odd custom; which is to offer their daughters to flangers, and hire them out for a time: some say they hire out their wives in the same manner. Their marriages for a time are well regulated, and often prove very beneficial to the family. In case of a separation, the father is obliged to take care of the boys, and the mother of the girls. We are told that no woman is looked upon as a wife, but rather the better, for she has had the virtue of European husbands: he is likewise the heir of all his children. The men here, as in these countries, according to the humour or interest of the parties, they hire out their wives in the same manner.

In Pegu, the inheritance of all land is in the king; he is likewise the heir of all his subjects who die without issue; but in case they have children, two-thirds go to them, and the reft to his majesty.

In the government of this country, despotism prevails in its full extent, and despotism too of the very worst kind; for the inhabitants are under the absolute power of a few petty tyrants, who are themselves nothing more than slaves to the king of Ava. As they have little or no emolument, except what they can raise by extortion, it is exercised in the most unlimited manner. They take cognizance of all disputes between individuals that come to their ears, without the cafe of being laid before them by either of the parties; and on whatever side the cause is determined, there is a never-failing charge brought in against both, for justice, as they exprefs it; and this price of justice is often three or four times greater than the value of the matter in agitation.

But the inconveniences that this government labours under are not only those of despotism; the unhappy subjects feel these of anarchy too. There are about twenty persons concerned in the government of Rangoon, who, though one is subordinate to another, and though matters of the first consequence are determined in a council of the whole, can yet act separately; and any one member of this body can by his own authority give orders, which no inhabitant of Pegu dares to disobey. Thofe orders may be contrary to the sense of the whole body; in which cafe, they are, indeed, revered in council: but then there are infinaces, and according to the sense of the whole body, in which cafe, they are, indeed, revered in council: but then there are infinaces, and

* Fuller's account of the kingdom of Pegu.

As to the religion of the Peguers, it is the same at bottom with that which prevails over the rest of India and Tibet; only varies in dress somewhat in different countries, according to the humour or interest of the priests. They hold the existence of one supreme God, of whom they make no image; but they have many inferior created gods, whose images are set up in the temples for the laity to worship. Not content with these, we are told they worship the devil alfo. Many are ftehn to run about the streets every morning, with rice in one hand and a torch in the other, crying "Hi, luul, hello," that he may not hurt them all the day. Besides the Manichean doctrine of two principles, one the author of good and the other of evil, from whence their worshipping the devil has its rise, they believe an eternal succession of worlds without creation. The Peguers hold the doctrine of the Metempsychotis, or transmigration of the human fouls, which, after passing through the bodies of various animals, shall attain to the perfection and felicity of their gods; which in effeét is no other than a flate of annihilation. They have a strong opinion of the faticity of apes and crocodiles, infomuch that they believe the perions to be perfectly happy who are devoued by them. Their temples are of a conical form, and some of them a quarter of a mile round. They obferve a great many festivals, some of which are called japaI. The images of their inferior gods are in a fitting posture, with their legs akimbo, and toes of equal length; their arms and hands very small in proportion to their bodies, their faces longer than human; their ears long, and the lappets very thick. The congregation bow to them when they come in and when
Travels into Dalmatia.

PEGUNTUM (anc. geog.), Ptolemy; Peguntius, (Pliny); a town or citadel of Dalmatia, on the Adriatic; opposite to the island Brattia, scarce five miles off, and 40 miles to the city of Salona. According to Porphyrion, a mountain, a large hollow, and submarine springs are seen here. "This hollow (says he) seems to have been excavated by some ancient river. The springs which bubble up under the sea are so considerable, that they might pass for the rising again of a river sunk under ground. Vuillia has the fame derivation of the word Viril, which in Slavonian signifies a continent; and this etymology, rendering the name of Vuillia the Berullia of Porphyrion harmless to that of Peguntum, since it is clear that Viril and Virile are synonymous, induces me to believe, that the cattle named Peguntium by ancient geographers was situated in this place, and not at the mouth of the Cettina. No remarkable vestiges of antiquity now exit on the spot; yet it is evident, by the quantity of fragments of vases, tiles, and sepulchral inscriptions now and then dug up, that this tract of coast was well inhabited in the Roman times. The principal cause why the tracts of ancient habitations cannot be discovered about Vuillia, is the steepness of the hill above it, and the quantity of stones brought down from thence by the waters. The mouth of the hollow of Vuillia is dredged by farmers, on account of the fudden impetuous gusts of wind that blow from thence, and in a moment raise a kind of hurricane in the channel between the Primorie and the island of Brazza, to the great danger of barks surprized by it."

PEIGNE FORT ET DURS, (Lat. pana fortis et dura), signifies a special punishment inflicted on those who, being arraigned for felony, refrain not to put themselves on the ordinary trial, but stubbornly stand mute; it is vulgarly called prosing to death. See ARRANGEMENT.

PEIRCE (James), an eminent dissenting minister, was born at Wapping, in London, in the year 1674, and was educated at Utrecht and Leyden; after which he spent some time at Oxford, in order to enjoy the benefit of frequenting the Bodleian library. He then for two years preached the Sunday evening's lecture at the meeting-house in Miles-Lane, London, and then settled at Cambridge. In 1713 he was removed to a congregation at Exeter, where he continued till the year 1718; when the Calvinists among the dissenters proposing a subscription to articles of faith to be signed by all the dissenting ministers in the kingdom, several articles were proposed to him and Mr John Hallet, another dissenting minister at Exeter, in order to their subscribing; they both refused, imagining this proceeding of their dissenting brethren to be an unworthy imposition on religious liberty and private judgment; for which they were ejected from their congregation. Upon this, a new meeting was opened for them at Exeter, of which Mr Peirce continued minister till his death, in 1726. He was a man of the strictest virtue, exemplary piety, and great learning. He wrote, 1. Exercitatio philosophica de Homoeomer. 2. Thirteen pieces on the Controversy between the Church of England and the Dissenters. 3. Ten pieces on the Controversy about the Ejection at Exeter. 4. Six pieces on the Doctrine of the Trinity. 5. A paraphrase and Notes on the Epistles of St Paul to the Colossians, Philippians, and Hebrews. 6. An Essay in favour of giving the Eucharist to Children. 7. Fourteen Sermons.

PEIRESC (Nicolas Claude Fabri), born in 1580, was descended from an ancient and noble family, seated originally at Pisa in Italy. At ten years of age, he was sent to Avignon, where he spent five years in the Jansen college, in the study of what in Scotland and on the Continent is called humanity. From Avignon he was, in 1595, removed to Aix, and entered upon the study of philosophy. In the interim, he attended the proper matters for dancing, riding, and handling arms; in all which, though he performed the lessons regularly, it was with reluctance: 'for this was done only to please an uncle whose heir he was to be, he never practiced by himself, eleminating all the time lost that was not spent in the pursuits of literature. During this period his father was presented with a medal of the emperor Arcadius, which was found at Belgenier, Peirese begg the favour of it; and, charmed with deciphering the characters in the exergue, and reading the emperor's name, he carried the medal with a transport of joy to his uncle; who for his encouragement gave him two more, together with some books upon the subject. This is the epoch of his application to antiquities, for which he became afterwards so famous. In 1596, he was sent to finish his course of philosophy under the Jesuits at Tourn, where he turned his attention particularly to cosmography, as being necessary to the understanding of hiliary, abating, however, nothing of his application to antiquity, in which he was much aided by Petrus Rogerus, one of the professors, and a skilful medallist: nor did he omit the study of humanity in general, wherein he was the master and instructor of a brother who was with him. But to do all this he was obliged to set up late at nights; and so much labour and attention, as he was naturally of a tender constitution, increased the weakness of his stomach formerly contracted, and for which he had used a kind of digestive powder. Being recalled by his uncle in 1597, he returned to Aix, and entered there upon the study of the law; which he prosecuted, however, so as to find leisure to visit and converse frequently with Peter A. R. Bagarr, a most skilful antiquary, who was afterwards made master of the jewells to Henry IV.

The following year he went again to Avignon, to carry on his course of law under one Peter David; who, being well skilled in rarities, was pleased to see Peiresc join this study to that of the law. But Ghibertus of Naples, auditor to Cardinal Aquaviva, fed his curiosity the most, in showing him some rarities, such as he had never seen before. Ghibertus also lent him Galtrius's Treatise upon Coins, and advs.
vited him to go into Italy, especially to Rome, where he would meet with curiosities to satisfy his most ardent wishes. Accordingly, his uncle having procured a proper governor, he and his brother set out upon that tour Sept. 1599; and passing through Florence, Bononia, and Ferrara, when he had stayed a few days at Venice, he fixed his residence at Padua, in order to complete his course of law. But once a quarter, going to Venice to get cash for bills of exchange, he took these opportunities of introducing himself to the most distinguished literati there; and was particularly careted by F. Contarin, procurator of St Mark, who was professed of a curious cabinet of medals; and other antiquities, without knowing the value of them. This was fully shown to him by Percièfe, who likewise explained the Greek inscriptions upon his medals, and the monumental stones. After a year's stay at Padua, he set out for Rome, and arrived there Oct. 1600, in order to be in time for seeing the Jubilee: to celebrate which, the Porta Santà would be opened in the beginning of the next year. He passed six months in this city, viewing the numberless curiosities there, and generally acknowledged, that he had taken the helm of learning into his hand, and began to guide the commonwealth of letters.

Having now spent almost three years in Italy, he began to prepare for his departure; and in the end of 1602, having packed up all the rarities, gems, &c. which he had procured, and put them into the road to Marseilleilles, he left Padua, and, crossin the Alps to Geneva, went to Lyons; where receiving money, he made a handom present to his governor, who took the route of Paris. From Lyons he went to Montpelier, to procure himself a passport for Italy; and from thence passed to Florence; and not long after presented himself in the city, where he had spent seven years and some months. He arrived at Aix in October; and not long after presented to the court a patent from the king for the ordering of the family affairs. In 1618, having procured a faithful copy of "the Acts of the Monastery of Maren in Switzerland," he published a second edition of that work. As it was written in defence of the royal line of France against Theodoric Peffordius, who had attempted to prove the title of the Austrian family to the French crown by right of succession, he was, upon this publication, nominated the fane year, by Louis XIII. abbot of Sancta Maria Aquilieriensis. He stayed in France till 1623; when, upon a message from his father, now grown old and sickly, he left Paris, where he had spent seven years and some months. He arrived at Aix in November; but, bringing Parius along with him, he obtained leave to return to Montpelier in a few days. He waited upon Parius back again, under whom he continued pursuing his studies till the end of 1603, when he returned to Aix, at the earnest request of his uncle, who, having resigned to him his senatorial dignity, had ever since the beginning of the year laboured to get the king's patent. The degree of doctor of law was a necessary qualification for that dignity. Parisèfe, therefore, having kept the usual exercises, took that degree Jan. 16, 1604, when the afoid patent was given in to the senate, and ordered to be recorded; yet Parisèfe procured leave not to be presently entered into the lift of senators. The bent of his inclination was not so much to business as to advance arts and sciences, and to affit all the promoters of learning. For this purpose, he resolved to lead a single life; so that when his father had concluded a match for him with a respectable lady, he begged to be excused.

In 1605, he accompanied G. Varius, first president of the senate at Aix, who was very fond of him, to Paris; whence, having visited every thing curious, he crost the water, in company with the king's ambaf- sador, 1606, to England. Here he was very grati- agiously received by king James I.; and having seen Oxford, and visited Camblen, Sir Robert Cotton, Sir Henry Savile, and other learned men, he passed over to Holland; and after visiting the several towns and universities, with the literati in each, he went through Antwerp to Brussels, and thence back to Paris, to see the ceremony of the Dauphin's baptism; which being solemnized Aug. 24, he returned home in September 1606, being expected for the ordering of the family affairs.

Priently after this, he purchased the barony of Rians; and at the solicitation of his uncle, having approved himself before that assembly, he was received a senator on the 1st of July 1607. Jan. 1608 he left his uncle; and the following year, falling himself into a dangerous fever, recovered by eating musk-melons before supper, for which he had conceived a longing. He was ordered by his physician to eat them before his meals without bread, and to drink a glafs of pure wine upon them. He continued this method all his life afterwards; and grew fond of them, that, though he could abstain from any other meat as he list, yet towards them he professed he was unable to miter himself. He frequently experienced, that in the musk- melon season he was never troubled with the gravel. In 1618, having procured a faithful copy of "the Acts of the Monastery of Maren in Switzerland," he published a second edition of that work. As it was written in defence of the royal line of France against Theodoric Peffordius, who had attempted to prove the title of the Austrian family to the French crown by right of succession, he was, upon this publication, nominated the same year, by Louis XIII. abbot of Sancta Maria Aquilieriensis. He stayed in France till 1623; when, upon a message from his father, now grown old and sickly, he left Paris, where he had spent seven years and some months. He arrived at Aix in October; and not long after presented to the court a patent from the king for the ordering of the family affairs. To this the court of parliament not affenting, decreed unanimously, that, being already admitted into the first rank, he should abide perpetually therein; not returning, as the custom of the court was, to the inferior auditory, wherein trials are usually had of criminal cases. In 1624, he buried his father, who had been long afflicted with the gout. In 1627, he prevailed with the archbishop of Aix to establish a polt thence to Lyons, and so to Paris and all Europe; by which the correspondence conftantly held with the literati every where was much facilitated. In 1629, he began to be much tormented with the strangury and hemorrhoids; and in 1631, having completed the marriage of his nephew Claudius with Margaret Alrefia, a noblewoman of the county of Avignon, he bestowed upon him the barony of Rianty, together with a grant of his senatorial dignity, only reserving the function to himself for three years. But the parliament not waiting his surrender of it, he retented that affront so heinously, that he procured, in 1635, letters patent from the king to be restored, and
the office for five years longer, which happened to be till his death: for being seized, June 1637, with a fever that brought on a flux of urine, this put an end to his life on the 24th of that month, in his 57th year.

The character of Peirefc may be summed up in a few words. His person was of a middle size, and of a thin habit: his forehead large, and his eyes grey; a little hawk-nosed; his cheeks tempered with red; the hair of his head yellow, as also his beard, which he used to wear long; his whole countenance bearing the marks of uncommon and rare courtly and affability. In his diet he affected cleanliness, and in all things about him; but nothing superfluous or costly. His clothes were suitable to his dignity; yet he never wore silk. His bed was exceedingly plain, holes: the lower part of it was furnished, and his table continually loaded and covered with papers, transcripts, notes, collections from books, epistles, and such like papers. His bed was exceeding plain, holes: the lower part of his bed was adorned according to his condition, and very well furnished; but he neglected his own chamber. Instead of tapestry, there hung the pictures of his chief friends and of famous men, besides innumerable bundles of commentaries, transcripts, notes, collections from books, epistles, and such like papers. His bed was exceeding plain, and his table continually loaded and covered with papers, books, letters, and other things; as also all the seats round about, and the greatest part of the floor.

These were so many evidences of the turn of his mind; in respect to which, the writer of his eulogium compares him to the Roman Atticus; and Bayle, considering his great stock, which ends here, is commanded by a passage, which he calls "the attorney-general of the literary republic." The works which he published are, "Historia provinciae Galliae Narbonensis;" "Nobilium ejusdem provinciarum Originals, et separatum Fabricicum;" "Commentarii rerum omnium memoria digitarum, in qua estate gestarum;" "Liber de ludicris naturae operibus;" "Mathematica et astronomia variarum Observationum mathematicarum;" "Epitome ad S. P. Urbanum VIII. cardinale Barberinum, &c.;" "Auctores antiqui Graeci et Latini de ponderibus et mensuris;" "Elogia et epistola;" "Inscriptiones antiquae et modernae;" "Genealogia domus Austricae;" "Catalogus libros bibliothecae Universitatis;" "Societatis regii Academiae Carolinae;" "Immacolati Saxoni, Britannici, &c.;" "Linguae orientales, Hebraea, Samaritana, Arabica, Egyiptica, et Indices librarium harum lingvarum;" "Observationes in varios auctores." It is remarkable, that though Peirefs bought more books than any man of his time, yet his collection left was not large. The reason was, that, as fast as he purchased, he kept continually making presents of them to such learned men as he knew they would be useful to.

PEKIN, the capital city of the empire of China, in Asia, where the emperor generally resides. It is situated in a very fertile plain, 20 leagues distant from the great wall. This name, which signifies the northern court, is given to it, to distinguish it from another considerable city called Nancking, or the southern court. The emperor formerly resided in the latter; but the Tartars, a restless and warlike people, obliged this prince to remove his court to the northern provinces, that he might more effectually repel the incursions of those barbarians, by opposing to them a numerous militia which he generally keeps around his person. It is an exact square, and divided into two parts; namely, that which contains the emperor's palace, which is in the new city, or, as it is called, the Tartar's city, because it is inhabited by Tartars ever since they conquered this empire; the other, called the Old City, is inhabited by the Chinese. The circuit of both these together is 52 Chinese miles, each of which contains 240 geometrical paces; being, without the suburbs, full six leagues in circumference, according to the most accurate measurement made by order of the emperor.

Those who have paid attention to the population of this place, reckon the number of inhabitants at 2,000,000, though there are others that double that number.

Grosier tells us, "that the height and enormous thicknefs of the walls of the Tartar city excite admiration; twelve horsemen might easily ride abreast upon them; they have spacious towers raised at intervals, a bow-shot distant from one another, and large enough to contain bodies of reserve in case of necessity. The city has nine gates, which are lofty and well arched. Over them are large pavilion-roofed towers divided into nine stories, each having several apertures or port-holes: the lower story forms a large hall for the use of the soldiers and officers who quit guard, and those appointed to relieve them. Before each gate a space is left of more than 360 feet: this is a kind of place of arms, inclosed by a semicircular wall equal in height and thickness to that surrounding the city. The great road, which ends here, is commanded by a pavilion-roofed tower like the first, in such manner, that as the cannon of the former can batter the houses of the city, those of the latter can sweep the adjacent country. The streets of Pekin are straight, about 120 feet wide, a full league in length, and bordered with shops. It is astonishing to see the immense concourse of people that continually fills them, and the confusion caused by the prodigious number of horses, camels, mules, and carriages, which cross or meet each other. Besides this inconvenience, one is every now and then stopped by crowds, who stand listening to fortune-tellers, jugglers, ballad-fingers, and a thousand other mountebanks and buffoons, who read and relate stories calculated to promote mirth and laughter, or distribute medicines, the wondrous effects of which they explain with all the eloquence peculiar to them. People of distinction oblige all their dependents to follow them. A mandarin of the first rank is always accompanied in his walks by his whole tribunal; and, to augment his equipage, each of the inferior mandarins in his suit is generally attended by several domestics. The nobility of the court, and princes of the blood, never appear in public without being surrounded by a large body of cavalry; and, as their presence is required in the palace every day, their train alone would be sufficient to create confusion in the city. It is very singular, that at all this prodigious concourse no women are ever seen: hence we may judge how great the population of China must be, since the number of females in this country, as well as everywhere else, is superior to that of the other sex.

"As there is a continual influx of the riches and merchandise of the whole empire into this city, the number of strangers that resort hither is immeasurable. They are carried in chairs, or ride on horsecback: the latter is more common: but they are always attended by a guide acquainted with the streets, and who knows,
Pekin knows the houses of the nobility and principal people of the city. They are also provided with a book, containing an account of the different quarters, squares, remarkable places, and of the residence of those in public offices. In summer there are to be seen small temporary shops, where people are served with water cooled by means of ice; and one finds everywhere cafes supplied with refreshments of tea and fruits. Each kind of provision has a certain day and place appointed for its being exposed to sale.

The governor of Pekin, who is a Mantchev Tartar, is styled Governor of the Nine Gates. His jurisdiction extends not only over the foldedors, but also over the people in every thing that concerns the police. No police can be more active; and it is surprising to see among an infinite number of Tartars and Chinese, mixed together, the greatest tranquillity prevail. It is rare, in a number of years, to hear of houses being robbed, or people assassinated. All the principal streets have guard-rooms, and foldedors patrol night and day, each having a sabre hanging from his girdle, and a whip in his hand, to correct, without distinction, those who excite quarrels or cause disputes. They are warned to make a continual noise, to shew one to walk through streets, where they are about to be seen. They are, the person to whom this indulgence is granted must carry a lantern, and give a sufficient reason for his going out. In the evening, as soon as the foldedors are warned to their quarters by beat of drum, two centinels go and come from one guard-room to another, making a continual noise with a kind of calafnet, to show that they are not asleep. They permit no one to walk abroad in the night-time. They even examine those whom the emperor dispatches on business, and if their reply gives the least cause of suspicion, they have a right to convey them to the guard-room. The foldedors in each of the guard-rooms are obliged to answer every time the centinels on duty call out.

"It is by these wise regulations, observed, with the greatest strictness, that peace, silence, and safety reign throughout the whole city. The governor is also obliged to go the round; and the officers stationed on the walls, and in the towers over the gates (in which are kept large kettle-drums that beat every time the guard is relieved), are continually dispatching batches to examine the quarters belonging to the gates where they are posted. The least neglect is punished next morning, and the officer who was on guard is cashiered. This police, which prevents nocturnal assemblies, would appear no doubt extraordinary in Europe, and in all probability would not be much relished by young men of fortune and ladies of quality. But the Chinese think justly; they consider it to be the duty of the magistrates of a city to prefer good order and public tranquillity to vain amusements, which generally occasion many attempts against the lives and property of the citizens. It is true, the support of this police costs the emperor a great deal; for part of the foldedors we have mentioned are maintained for this purpose only. They are all infantry, and their pay is generally very high. Their employment consists not only in watching for those who may occasion disturb-

dance in the day-time, or walk abroad during the night; they must also take care that the streets are kept clean and swept every day; that they are watered morning and evening in time of dry weather; and that every nuisance is removed. They have orders also to assist in this labour themselves; and to clear the kennels, that the water may have a free course."

The walls of the emperor's palace, including that and the gardens, are about two miles in length. "Although (says Groser) the Chinese architecture has no resemblance to that of Europe, the imperial palace of Pekin does not fail to strike beholders by its extent, grandeur, and the regular disposition of its apartments, and by the singular structure: its pavilion-roofs, ornamented at each corner with a carved plat-band, the lower extremity of which is turned upwards. These roofs are covered with varnished tiles of a beautiful yellow colour, that, at a distance, they make as splendid an appearance as if they were gilded. Below the upper roof there is another of equal brilliancy, which hangs drooping from the wall, supported by a great number of beams, daubed over with green varnish, and interspersed with glittering filkes. This upper roof, with the projection of the first, forms a kind of crown to the whole edifice. The palace is a small distance from the south gate of the Tartar city. The entrance to it is through a spacious court, to which there is a descent by a marble staiway, ornamented with two large copper lions, and a balustrade of white marble. This balustrade runs in the form of a hedge, along the banks of a rivulet, that winds across the palace with a serpentine course, the bridge over which are of marble. At the bottom of this first court arises a facade with three doors: that in the middle is for the emperor only; the mandarins and nobles pass through those on each side. These doors conduct to a second court, which is the largest of the palace: it is about 300 feet in length, and 50 in breadth. An immense gallery runs round it, in which are magazines, containing rich effects, which belong to the emperor as his private property; for the public treasure is entrusted to a sovereign tribunal called Hou-pou. The first of these magazines is filled with plate and vessels of different metals; the second contains the finest kinds of furs; the third, dresses lined with sable, ermine, miniver, and foxes' skins, which the emperor sometimes gives in presents to his officers; the fourth is the depository of jewels, pieces of curious marble, and pearls filled up in Tartary; the fifth, containing two stories, is full of wardrobes and trunks, which contain the silk fluts used by the emperor and his family; the rest are filled with bows, arrows, and other pieces of armour taken from the enemy or pretented by different princes."

"The royal hall, called Wei-botien, or the Hall of the Grand Union, is in this second court. It is built upon a terrace about 18 feet in height, inclosed with white marble, and ornamented with balustrades of excellent workmanship. Before this hall all the mandarins range themselves, when they go, on certain days, to renew their homage, and perform those ceremonies that are appointed by the laws of the empire. This hall is almost square, and about 130 feet in length. The ceiling is carved, varnished green, and loaded with gilt dragons. The pillars which support the roof
That the law qualified men for the office of a Flemish Jesuit, who caused a new set of instruments to be made, with extraordinary care, neatness, and precision.

"This fabric stands in a court of a moderate extent, and is built in the form of a square tower, contiguous to the city wall on the infidels', and raised but ten or twelve feet above its basework. The ascent to the top is by a very narrow staircase; and on the platform above were placed all the old instruments, which, though but few, took up the whole room, till Father Verbiest introduced his new apparatus, which he disposed in a more convenient order. These are large, well cast, and embellished; and were the neatness of the divisions answerable to the work, and the telescopes fashioned to them according to the new method, they would be equal to those of Europe; but the Chinefe artificers, it seems, either too negligent, or incapable of following his directions. As to the old instruments, they were, by order of the emperor Kang-hi, set aside as useless, and laid in the hall near the tower, where they may be seen through a cross-barred window, all covered with rust, and buried in oblivion.

"In this famed observatory there are five mathematicians employed night and day, each in a proper apartment on the top of the tower, to observe all that passes over their heads: one of them is gazing towards the zenith, and the other towards the four points of the compass, that nothing may escape their notice. Their observations extend not only to the motions of the heavenly bodies, but to fires, meteors, winds, rain, thunder, hail, storms, and other phenomena of the atmosphere; and these are carefully entered in their journals, and an account of them is brought every morning to the surveyor of the mathematicals, and registered in his office."

PELAGIUS, a Christian foe who appeared about the fifth or end of the fourth century. They maintained the following doctrines. 1. That Adam was by nature mortal, and, whether he had sinned or not, would certainly have died. 2. That the consequences of Adam's sin were confined to his own person. 3. That new-born infants are in the same situation with Adam before the fall. 4. That the law qualified men for the kingdom of heaven, and was founded upon equal promises with the gospel. 5. That the general resurrection of the dead does not follow in virtue of our Saviour's resurrection. 6. That the grace of God is given according to our merits. 7. That this grace is not granted for the performance of every moral act; the liberty of the will, and information in points of duty, being sufficient. &c. The founder of this sect was, PELAGIUS, a native of Great Britain; but whether of England, Scotland, or Wales, is as uncertain as it is immaterial (A). He was born towards the close of the fourth century, and educated in the monastery of Banchor near Chester, to the government of which he was advanced A.D. 404. He was long esteemed and loved by St Jerome and St Augulfus, who kept up a friendly correspondence with him by letters before

---

(A) Dr Henry thinks he was born in North Wales; that his real name was Morgan, of which Pelagius is a translation: and that he was born on the 13th of November A.D. 354, the same day with his great antagonist St Augulfus. The fame learned historian gives us the following account of Pelagius and his great coadjutor Celestius. "He received a learned education in his own country, most probably in the great monastery of Banchor near Chester, to the government of which he was advanced A.D. 404. He was long esteemed and loved by St Jerome and St Augulfus, who kept up a friendly correspondence with him by letters before..."

before they discovered the heretical pravity of his opinions; for Pelagius, being a cautious and useful man, for some time vened his peculiar notions as the sentiments of others, without discovering that they were his own. At length, however, he threw off the mask, and openly published and defended his doctrines at Rome about the beginning of the fifth century. This involved him in many troubles, and drew upon him the indignation of his former friends St. Jerome and St. Augustin, who wrote against him with great acrimony. He is acknowledged, even by his adversaries, to have been a man of good sense and great learning, and an acute disputant, though they load him with the most bitter reproaches for his abuse of these talents. His personal biblimies are painted in very strong colours; and he is represented by these good fathers, in the heat of their zeal, as a very ugly fellow, broad-shouldered, thick-necked, fat-headed, lame of a leg, and blind of an eye. Even the most northern parts of this island (Britain) has produced some men of learning in this period. Celestius, the disciple and friend of Pelagius, was a Scotman, who made a prodigious noise in the world by his writings and disputations about the beginning of the sixth century. He defended and propagated the peculiar opinions of his master Pelagius with so much learning, zeal, and acumen, that those who embraced these opinions were frequently called Celestians. Before he became a priest, he wrote several books, which were universally admired for their orthodoxy, learning, and virtuous tendency. After he had spent his youth in his own country in a studious privacy, he travelled for his further improvement to Rome, where he became acquainted with Rufinus and Pelagius, and was by them infected with their heresies. From that time he became the most indefatigable and undaunted champion of these heresies, and thereby brought upon himself the indignation of the orthodox fathers of these days, who gave him many very bad names in their writings. St. Jerome, whose commentaries on the Epistles he had premeditated to criticize, calls him an ignorant, stupid fool, having his belly swelled and diffused with Scots pottage; a great, corpulent, barking dog, who was fitter to kick with heels than to bite with his teeth; a Cerberus, who, with his master Pluto (Pelagius), deferred to be knocked on the head, that they might be put to eternal silence. Such were the flowers of rhetoric which these good fathers employed against the enemies of the orthodox faith! But candour obliges us to observe, that this was perhaps mere the vice of the age in which they lived than of the men. Both Pelagius and Celestius were very great travellers; having visited many different countries of Asia and Africa, as well as Europe, with a view to elude the persecutions of their enemies, and to propagate their opinions. It is no inconsiderable evidence of their superior learning and abilities, that their opinions gained great ground in all the provinces both of the eastern and western empire, in spite of the writings of many learned fathers, and the decrees of many councils against them. The Pelagian and Celestian heresy (says Photius) not only flourished in great vigour in the West, but was also propagated into the East.
PELAIAH, a Levite (Nehem. viii. 7. x. 10.) He was one of the principal Levites that returned from captivity, and was one of those that signed the covenant that Nehemiah renewed with the Lord.

PELALIAH, son of Amazi and father of Jeroham, of the family of Pahhar son of Machiah, of whom mention has been made; he was of the race of the priests (Nehem. xi. 12.)

PELASGUS. See Pelasgians.

PELASGIA (Pliny); the ancient name of Lefbos; from called from the Pelasgi, its first inhabitants (Diodorus Siculus.) Also the ancient name of Pelasgius, from Pelagus, a native of the country (Nicolaus Damascenus, Ephorus).

PELASGICUM (Paulianus, Pliny); the north wall of Athens, so called from the builders, the Pelasgi. There was an ecclesiastic pronounced on any that should build houses under this wall; because the Pelasgi, while dwelling there, entered into a conspiracy against the Athenians (Thucydides).

PELASGIIOTIS, a third part of Thebaly, (Strabo.) So called from a very ancient people, the Pelasgi, called Pelasgiotes (Ptolemy; who formerly, together with the Aiolians, occupied Thebaly, and thence that part was called Pelasgium Argos) befores many other parts of Greece. The poets extend the appellation to Greeks in general. Pelasgi, the epithet. Some of the inhabitants of Crete were called Pelagi (Homer;) who thus also calls the neighbouring people to the Cilicians in Troy. The Pelasgi were the descendants of Peleg, and inhabited Greece before the Ionians, the polity of Javan, possessed it, hence the Lacondemonians and Jews were related (1 Maccab. xii. 21.) The Pelasgiotes was situated between Pieria and Macedonia to the north and west, Thessaly to the south, and Magnesia to the east, (Strabo, Pliny.)

PELATAE, were free born citizens, among the Athenians, who by poverty were reduced to the necessity of serving for wages. During their servitude they had no voice in the management of public affairs, as having no vote in the election of those who called the laws; this restriction was removed whenever they had released themselves from their servile situation, which they were allowed to do when able to support themselves. While they continued servants, they had also a right to change their masters. We find them sometimes distinguished by the name of Theba.

PELATIAH, son of Hananiah, and father of Ishi, of the tribe of Simeon. He subdued the Amalekites upon the mountain of Soir (1 Chron. iv. 42.) The time of this action is unknown.

PELATH, son of Beniaiah, a prince of the people, who lived in the time of Zedekiah king of Judah, and opposed the wholesome advice given by Jeremiah, to humble his heart Nebuchadnezzar. Ezekiel (xxi, 2, 3, 4) being a captive in Medopotamia, had a vision, in which he saw five and twenty men at the door of the temple of Jerusalem, among which were Jazaniah the son of Azur, and Pelatiah the son of Beniaiah, who were the most remarkable. Then the Lord said to him, "Son of man, these are the men that have thoughts of iniquity, and who are forming pernicious designs against this city, saying: Have not the hordes been built a long time? Jerusalem is the pot, and we are the flesh. Thus faith the Lord, Ye have made a great havoc in this city, and have filled its streets with dead bodies. These men are the flesh, and the city is the pot. But as for you, I will make you come forth from the middle of this city, and I will make you perish by the hand of your enemies." As he was prophesying in this manner, Pelatiah the son of Beniah died.

PELE (Stephanus). There were two towns of this name in Tholosy; one subject to Euryphylus, the other to Achilles; both extinct. Pelas the gentilic name (id.)

PELEG, son of Eber, was born in the year of the world 1757. The scripture says his father gave him the name of Peleg, signifying division, because in his time the earth began to be divided (Gen. xi. 16. x. 23;) whether it was then that man had begun to distribute the earth among his descendants, some years before the building of Babel, or that Peleg came into the world the same year that Babel was begun, and at the division of languages, or that Eber by a spirit of prophecy gave his son the name of Peleg (some years before the tower of Babel was begun, is not absolutely certain. That which here perplexes the interpreters is, first, that Peleg came into the world not above 100 years after the deluge. But it should seem, that the number of men was not then sufficient for such an undertaking as that of Babel. Secondly, Joktan the brother of Peleg had already thirteen sons at the time of this dispersion, which happened after the confusion of Babel (Gen. x. 26, 27, 28, 8c.) Peleg being born in the thirty-fourth year of Eber (Gen. xi. 16.), it is impossible his brother Joktan should have such a number of children at the birth of Peleg. It seems therefore that he was not born at the time of the dispersion. To this may be answered, that Moses has there enumerated the names of the thirteen sons of Joktan (in Gen. x. 25,) by way of anticipation, though they were not born till a good while after the confusion of Babel; but as they possessed a very large country, it was convenient for them to take notice of them, and to name them among the other descendants of Noah, who divided the provinces of the east among themselves. However this may have been, at the age of thirty years Peleg begat Reu; and he died at the age of 239.

PELETHITES. The Pelethites and Cherethites were famous under the reign of King David. They were the most valiant men in the army of that prince, and had the guard of his person. See Ezekiel xxv. 16. Zophaniah ii. 5. 1 Samuel xxx. 14. 2 Samuel xv. 18. xx. 7. Patrick's Comn. Pool's Annot. and Delany's Hist. of the Life of David.

PELETHRONII, a name or epithet given to the Lapithes, either because they inhabited the town of Pelathonum at the foot of mount Pelion in Thesla, or because one of their number bore the name of Pelathonius. It is to them, we are told, that mankind are indebted for the invention of the bit with which they tamed their horses with so much dexterity.

PELETHONIUM (Nicander and Scholiais); a town of Thesaly, situated in a flowery part of mount Pellos; and hence the appellation throna, signifying a

N 2 of flowers.
PELEUS, in fabulous history, a king of Thessaly, son of Aeacus and Eridite, the daughter of Chiron. He married Thetis one of the Nereids, and was the only mortal man who ever married an immortal. He was concerned in the murder of his brother Phoeus, and was therefore obliged to leave his father's dominions. He fled to the court of Eurytus the son of Actor, who reigned at Phthias, or according to the opinion of Ovid, the truth of which is questioned, to Ceyx king of Trachinia. He was purified of his murder by Eurytus, with the usual ceremonies, and the king gave him his daughter Antigone in marriage. After this, as Peleus and Eurytus went to the chase of the Calydonian boar, the father-in-law was accidentally killed by an arrow which his son-in-law had aimed at the beast. This unfortunate accident obliged him to banish himself from the court of Phthia, and he went to Iolchos, where he was also purified of the murder of Eurytus by Acastus the king of the country. His residence at Iolchos was short: Alcydamia the wife of Acastus fell in love with him; but when the god found him insensible to her passionate declarations, he accused him of attempts upon her virtue. The king her husband partly believed the accusations of his wife; but not willing to violate the laws of hospitality, by putting him instantly to death, he ordered his officers to conduct him to Mount Pelion, on pretence of hunting, and there to tie him to a tree and to leave him a prey to the wild beasts of the place. The orders of Acastus were faithfully obeyed; but Jupiter knowing the innocence of his grandson Peleus, ordered Vulcan to set him at liberty. As soon as he had been delivered from danger, Peleus assembled his friends in order to punish the ill treatment which he had received from Acastus. He took Iolchos by force, drove the king from his possessions, and put to death the wicked Alcydamia.

On the death of Antigone, Peleus made love to Thetis, of whose superior charms Jupiter himself had been enamoured. His pretensions were rejected; for as he was but a mortal, the goddess fled from him with the utmost abhorrence, and the more effectually to evade his inquiries, she generally assumed the shape of a bird, or a tree, or of a tygress. Peleus's passion was fanned by refusal; he offered a sacrifice to the gods; and Proteus informed him, that to obtain Thetis he must surprise her while she was asleep in her grove, near the shores of Thessaly. This advice was immediately attended to; and Thetis, unable to escape from the grasp of Peleus, at last confented to marry him. Their nuptials were celebrated with the greatest solemnity, all the gods attending and making them each the most valuable presents. The goddess of Discord was the only one of the deities who was absent; and the prince filled this seeming neglect by throwing an apple into the midst of the assembly of the gods, with the inscription of Dexta pudbris. The celebrated Achilles was the fruit of this marriage, whose education was early entrusted to the Centaur Chiron, and afterwards to Phoönix, the son of Amyntor. Achilles, it is well known, went to the Trojan war, at the head of his father's troops; and Peleus gloriéd in having a son who was superior to all the Greeks in valor and intrepidity. His death, however, was the source of great grief to Peleus; but Thetis, to comfort her husband, promised him immortality, and ordered him to retire into the groves of the island of Leuce, where he should see and converse with the names of his son. Peleus had a daughter called Polydora, by Antigone.

PELEW ISLANDS, a cluster of small islands situated between the latitudes of 5° and 7° north, and the longitudes 134° and 136° east. Various conjectures have been formed respecting the time of their first discovery by Europeans. Mr Keate, the editor of the only voyage in which we have any account of their climate, soil, and produce, together with the manners of their inhabitants, thinks they were first noticed by the Spaniards from the Philippines, and by them named Palos from the number of trees growing in them resembling the masts of ships. This conjecture has been vehemently opposed by a critic, who affirms that the whole of Mr Keate's introduction is err· nous, and that the islands in question were first discovered by a French Jesuit named Per Park. The Jesuit, he imagines, was directed to them by one of the inhabitants, who had found his way to the Moluccas, where he was baptized. They are said to have been again noticed by P. Centova in 1724, who saw at Agdane, the capital of the Merian islands, some of the inhabitants; and from their account gives a description not very favourable of these harmless islanders. Centova's description is to be found in the 15th volume, and the relation of the discovery by P. Pepin in the 11th volume, of Lettres Edifiantes et Curieuses, published at Paris 1751.

The latest and most authentic account of them, however, is given from the Journals of Captain Wilson of the Antelope, a packet belonging to the East India company, which was wrecked upon one of them in August 1783. This ship was fitted out in England by the court of directors in the summer 1782, as was generally understood, for a secret expedition. Whatever may have been her destination, as she was proceeding from Macao in equable weather, the man who, on the night of the 10th of August, had the look out, suddenly called out Breakers! But the found of the word had scarce reached the ears of the officer on deck, before the ship struck and stuck fast; and in less than an hour bulged and filled with water. Having secured the gunpowder, small arms, bread and such other provisions as were liable to be spoiled by water, Captain Wilson, after many difficulties, effected a landing. The crew of the Antelope consisted of 33 Europeans beside the captain, and 16 Chinese; and the only possible means by which they could be delivered from an island, which at first appeared to them uninhabited, was by building a ship capable of transporting them to the nearest European settlement in that quarter of the globe. Whilts they were meditating upon this undertaking, the natives appeared on the second day after their arrival; and their intercourse with them was facilitated by means which appear
The natives are all of a deep copper colour, going perfectly naked. They are of a middling stature, very straight, muscular, and well formed; but their legs, from a little above their ankles to the middle of their thighs, are tattooed so very thick, as to appear dyed of a far deeper colour than the rest of their skin. Their hair is of a fine black, long, and rolled up behind, in a manner, close to the back of their heads, which appeared both neat and becoming; but few of them had beards, it being the general custom to pluck them out by the roots.

They were not of the same height, nor could that be readily explained by their different figures, but it was at least partly explained by their hair being longer and more thickly rolled. Their legs were tattooed so thick, as to be mistaken for swellings, or rather their wearing wide trousers; but having been thrown by a tempest upon this very spot, where they were not easy to account for. They ran in and out of the tents, of the natives picked up a bullet, which had been carelessly dropped on the ground, and immediately expressed his surprise, that a bullet so small to the eye should be so very ponderous to the touch; and on their entering the tent, a large Newfoundland dog, and a spaniel which had been tied up there to prevent their being lost, set up a most violent barking, and the natives a noise but little less loud, which at first it was not easy to account for. They ran in and out of the tent, and seemed to wish that they might be made to bark again. This the Malay soon explained to be the effect of their joy and surprise, as there were the first large animals they had ever seen, there being no quadrupeds of any species on these islands, except a very few grey rats in the woods.

After some time it was agreed on by Captain Wilson and his people, that some of the crew should be sent to the king of the place in order to solicit his friendship, and intreat his permission to build a vessel that might carry them back to their own country.

This business was allotted to the captain's brother; and during his absence, Raa Kook, the king's brother, and several of the natives, remained with our people. This amiable chief seemed to place an entire confidence in those he was among; he endeavoured to accommodate himself to their manners; would sit at table as they did, instead of squatting on his hams; and inquired particularly into the principles and causes of every thing he observed about him, lending his personal affidance in all that was going forward, and even defiring thecook to let him aid him in blowing the fire.

In order to conciliate their affections, Captain Wilson had presented Arna Kooker, another of the king's brothers, with a pair of trowlers; but having conceived a great passion for a white shirt, one was immediately given to him; which he had no sooner put on, than he began to dance and jump about with so much joy, that every body was diverted by his singular gesticulations, and the contrail which the linen formed with his skin. This prince was about 40, of a short stature, but so plump and fat that he was nearly as broad as he was long. He polished an abundant share of good humour, and a wonderful turn for mimicry; and had besides a countenance so lively and expressive, that though our people at this time were strangers to almost all he said, yet his face and gestures made them accurately comprehend whatever he was describing.

After three or four days, Abha Thulle the king arrived with a great retinue. He was received with every mark of respect by the ship's company, who were exercised before him, and fired three volleys in different postions. The surprize of the natives, their hooting, hallowing, jumping, and chattering, produced a noise almost equal to the discharge of the muskets; and when one of the men shot a bird, which was done to display the effect of their arms, the surprize occasioned was wonderful. Some of the natives ran for it, and carried it to the king, who examined it with great attention, but was unable to comprehend how it could be wounded, not having seen any thing pass out of the gun.

Raa Kook expressed great impatience to know the king whatever had impressed his own mind; and taking his brother by the hand, led him to a grindstone which was fixed behind one of the tents. He immediately put it in motion, as he had frequently done before; at the rapidity of which the king was greatly astonished, particularly when he was informed that it would sharpen iron. Captain Wilson ordered a hatchet to be brought and ground, that they might more readily perceive its operation, when Raa Kook eagerly seized the handle, and began turning it, appearing highly delighted to let his brother see how well he understood it. The whole appeared like something supernatural; but the circumstances which most bewildered their ideas was, how the sparks of fire could come, and how a stone so well wetted could become so sharp.

The king then visited the different tents, and inquired about every thing he saw: all was novelty, and of course interested his attention. When he got to the tent where the Chinese men were, who had been brought with them from Macao, Raa Kook, whose re-
tentative mind never lost a single trace of any thing he had been informed of, acquainting the king that these were people quite different from the English, and that he had learnt there were many other nations besides these intermixed throughout the world, some of which fought with guns and others with boarding-skees, an instrument which he held very cheap in comparison with the former.

When the king heard his brother disconcerting about a variety of nations, who all spoke differently, and had before him the example of the Chinese, whose language was not the same with the English, he appeared instantly thoughtful and serious, as if struck by conceptions which had never before crossed his mind. He remained a while pensive and bewildered; and this circumstance impressed on every one at the time an idea that there was every reason to imagine that there had never been a communication between those people and any other nation; and indeed it is evident, that if Pere Papin did really visit them in 1710, they had before 1783 lost the remembrance of every trace of European manners. This indeed is not surprising, as they had no other record than knots similar to the quipes of Peru at the landing of the Spaniards.

Raa Kook would now show his brother the kitchen, which was in the hollow of a rock, a little above the cove. It was at the time when the cook was preparing dinner; and though the implements were exceedingly scanty, an iron pot, a tea kettle, a tin sauce-pan, with a skimmer, a pair of tongs, and a frying-pan, were here of sufficient consequence to excite admiration; nor were the bellows now forgotten by Raa Kook, who taking them up, as he explained their use to the king, seemed ambitious to let his brother see what an adept he was at blowing. The little barb cook, who was always close shaven, and never wore any thing on his head, was likewise pointed out to the king as an object of merit and curiosity.

Sometime after this the king requested five of Captain Wilson's men to attend him in a war he was going to make against the inhabitants of a neighbouring island called Orokong, who, as he said, had done him an injury. But before this request was made known, he had long struggled with a delicacy of sentiment which no one would have expected to find in regions so disjoined from the rest of mankind. This was no other than that it might prove a temporary inconvenience to the unfortunate strangers, who had fought his protection, and might be considered by them as an ungenerous proceeding. It was, however, no sooner made known, than Captain Wilson instantly complied: and every face, which had before been clouded with doubt and apprehension, became immediately brightened and gay.

In this enterprise little more was done than braving their enemies, stripping some cocoanut trees of their fruit, and carrying off a number of yams and other provisions; but in another, which was undertaken against the island of Artingall, they were more successful, and marked signs of the same fanganiary disposition which some demon has infused into the whole human race. Nine prisoners of war who had been taken upon this occasion were cruelly put to death; and notwithstanding the English treaty renounced against this, reasoning, all the arguments they could use were of no avail. In justification of their conduct, they alleged the necessity of doing it for their own security, declaring that they had formerly only detained them as servile servants, but that they always found means to get back to their own country, and return with such a force as frequently made great depredations.

Having given this general account of the character and conduct of these hitherto unknown people we now proceed to lay before our readers what we have learned of their government, customs, manners, and arts, together with a description of the face of their country. In this the editor of Captain Wilson's voyage must be our guide; and if our narrative does not satisfy the man of science, it is to be observed, that the Antelope was not a ship sent out purposely to explore undiscovered regions, nor were there people on board properly qualified to estimate the manners of a new race of men; they had amongst them no philosophers, botanists, or draughtsmen, experienced in such scientific pursuits as might enable them to examine with judgment every object which presented itself. Diletta threw them upon these islands; and while they were there, all their thoughts were occupied on the means of liberating themselves from a situation of all others the most afflicting to the mind, that of being cut off for ever from the society of the rest of the world.

It, however, clearly appears, form their uniform testimony, that at Pelew the king was considered as the first person in the government.

"He was looked up to as the father of his people; and though divested of all external decorations of royalty, had every mark of distinction paid to his person. His rupacks or chiefs approached him with the greatest respect; and his common subjects, whenever they passed near him, or had occasion to address him, made his hand behind them, and crouched towards the ground. Upon all occurrences of moment, he convened the rupacks and officers of state; their councils were always held in the open air, where the king first flated the business upon which he had assembled them, and submitted it to their consideration. Each rupack delivered his opinion, but without rising from his feet; and when the matter before them was settled, the king standing up put an end to the council.

"When any message was brought him, whether in council or elsewhere, if it came by one of the common people, it was delivered at some distance in a low voice to one of the inferior rupacks, who, bending in a humble manner at the king's side, delivered it in the same manner with his face turned aside. His commands appeared to be absolute, though he acted in no important business without the advice of his chiefs; and every day in the afternoon, whether he was at Pelew or with the English, he went out in public for the purpose of hearing any request, or of adjusting any difference or dispute which might have arisen among his subjects."

But these, according to our editor, seldom happened; for as their real wants were but few, and they knew nothing to create artificial ones, every one was chiefly occupied with his own humble pursuits; and as far as the ship's crew, who remained among them about three months, could decide, they appeared to conduct themselves towards each other with the greatest civility and benevolence; never wrangling or entering into quarrels.
some contentions, as is customary among those who

call themselves a polished and enlightened people.

Even when children showed a disposition of this kind,
they strongly marked their displeasure, by filling with
rebuke their little amainities.

The character of the king is thus drawn by the ed-
iter: “The excellent man who reigned over these sons
of nature, showed himself in every part of his conduct
firm, noble, generous, and benevolent; there was a
dignity in all his deportment, a gentleness in all his
manners, and a warmth and tenderness about his heart
that won the love of all who approached him. Nature
had bestowed on him a contemplative mind, which he
had to his duty by those reflections that good fortune
decided and observation confirmed. The happiness of his
people seemed to be always in his thoughts. In order
to more effectually to stimulate them to useful labour,
he had himself learnt all the few arts they possessed,
and was looked on in some of them to be the best work-
man in his dominions. Placed as he was by Providence in
his obscure scenes, he lived beloved by his chiefs,
and revered by his people; over whom, whilst he pre-
erved a dignity which distinguished his superior station,
he reigned more as the father than the sovereign. The
eyes of his subjects beheld their naked prince with so
much awe and respect as those are viewed with by
governed polished nations, and are decorated with all
the dazzling parade and ornaments of royalty; nor was
the purple robe or the splendid diadem necessary to
point out a character which the matterly hand of na-
ture had rendered so perfect.”

Next in power to the king was his brother Raa
Kook, who was official general of all his forces. It
was his duty to summon the rupacks to attend the
king for whatever purpose they were wanted. He was
also his presumptive heir; the succession of Pelew not
go ing to the king’s children till it had passed through
his brothers; so that after the demise of Abba Thulle,
the sovereignty would have descended to Raa Kook;
on his demise to Aria Kooker; and on the death of
this last it would have reverted to Qui Bill, the king’s
elder son, when Lee Boo, his second son, of whom
we have much to say, would have become the heredi-
tary general.

The office of first minister is described as follows;

“King was always attended by a particular chief
or rupack, who did not appear to possess any heredi-
tary office, but only a delegated authority. He was
always near the king’s per ton, and the chief who was
always first consulted; but whether his office was
religious or civil, or both, our people could not learn
with any certainty. He was not considered as a war-
ner, nor ever b rearm, and had but one wife, whereas
as the other rupacks had two. The English were never
invited to his house, or introduced into it, although
they were conducted to those of almost every other
chief.

Of the rupacks it is observed, “That they could
only be regarded as chiefs or nobles; they were not
all of the same degree, as was plain by a difference in
the bone (a) they wore; they generally attended the
king, and were always ready at his command to ac-
company him on any expedition with a number of ca-
noes properly manned, and armed with darts and spears,
who were to remain with him till they had his per-
mition to return home with their dependents. In this
part of their government we may trace an outline of
the feudal system; but from the few opportunities our
people had of investigating points of internal govern-
ment, it appeared that the titles of rupacks were per-
sonal badges of rank and distinction; nor did they appre-
head they were hereditary honours, unless in the reign-
ing family, who must of necessity be of this class.”

As to property, it was understood, “That the people
possessed only such as arose from their work and la-
bour, but no absolute one in the soil, of which the king
appeared to be general proprietor. A man’s house,
furniture, or canoe, was considered as his private
property, as was also the land allotted him, as long as he
occupied and cultivated it; but whenever he removed
with his family to another place, the ground he held
reverted to the king, who gave it to whom he pleased,
or to those who solicited to cultivate it.”

All that part of the island which they had an op-
portunity of seeing is said to have been well cultivated.
It was covered with trees of various kinds and sizes,
many of which must have been very large, as they
made canoes of their trunks, some of which were
capable of carrying 28 or 30 men. Among the timber-
trees was noticed the ebony, and a tree which when
pierced or wounded yielded a thick white liquor of the
confidence of cream. “They had also a species of
the manchinel tree, in cutting down of which our
people frequently got blistered and swelled; the inha-
bitants pointed out the cause, saying it was owing to
their being sprinkled by the sap. This they reckoned
among the unlucky trees, and advised our people
against the use of it.”

But the most singular tree noticed at Pelew, was one
in its size and manner of branching not unlike our
cherry-tree, but in its leaves resembling the myrtle.
Its peculiarity was, that it had no bark, but only an
outward coat of about the thickness of a card, which
was darker than the infide, though equally close in
texture. Its colour was nearly that of mahogany, and
the wood was so extremely hard, that few of the tools
which the English had could work it. They also found
cabbage-trees, the wild bread fruit, and another tree
whose fruit something resembled an almond. But
yams and cocoa nuts, being their principal articles of
fruitfulness, claimed their chief attention.

The island Coorooara, of which Pelew is the capital,
likewise produced plantains, bananas, Seville oranges
and lemons, but neither of them in any considerable

quantity. None of the islands which the English vis-
ited had any kind of grain. As to birds, they had
plenty of common cocks and hens, which, though not
domesticated, kept running about near their houses
and plantations; and what appears extremely singular
is, that the natives had never made any use of them.

(a) This was a mark of rank worn upon the wrist,
with which Captain Wilson was invested by the king; but
what animal it came from our people could not learn.
till our people told them they were excellent eating. Pigeons they accounted a great dainty; but none but those of a certain dignity were permitted to eat of them. The English left them two geese, which were the only remains of their live flock.

From the description of the country it appears to be very mountainous; but some of the valleys are represented as extensive and beautiful, affording many delightful prospects. The soil being very rich, produces a great abundance of graps, which, as there are no cattle to eat it, grows very high, and was scorched and burnt up by the sun. Our people saw no river at Pelew; their supplies of fresh water being obtained from small streams and ponds, of which there are a great many.

From this account of the scanty produce of these islands, it is evident that no luxury reigned among their inhabitants, whose principal article of food appears to be fish; they had no salt, nor did they make use of sauce or any seasoning in any thing they eat. Their drink was also as simple as their diet; it principally consisted of the milk of the cocoa nut; but upon particular occasions they used a kind of sweeter drink and sherbet, which latter had the addition of some juice of orange.

The islands appeared to be populous, though to what extent could not be ascertained. Their houses were raised about three feet from the ground, upon stumps which appeared as if hewn from the quarry. The interior part of them was without any division, the whole forming one great room, which roofed in a ridge like our barns, the outside being thatched thick and close with bamboos or palm leaves. All their implements, utensils, weapon of war, and canoes, are much of the same kind with those which were found in the South Sea islands.

In their marriages they allow a plurality of wives, though in general not more than two. When a woman is pregnant, the utmost attention is paid to her; but upon other occasions no more respect is shown to one fel than the other. "One of our people endeavoured to make himself agreeable to a lady belonging to one of the rupacks, by what we should call a marked affiduity, Arra Kooker, with the greatest civility, gave him to understand that it was not right to do so."

They have places particularly appropriated to sepulture; their graves being made nearly the same as they are in our country churchyards. The corpse is attended only by women, who at the place of interment make a great lamentation. The men, however, assemble round the body before it is carried to the grave, on which occasion they prefer a solemn silence; their minds, from principles of fortitude or philosophy, being armed to meet the events of mortality with manly sublimity, divested of the external testimony of human weakness."

On the article of religion our editor observes, "That, among all the race of men whom navigation has brought to our knowledge, few appear to be without a sense of something like religion, however it may be mixed with idolatry or superstitition. And yet our people, during their continuance with the natives of Pelew, never saw any particular ceremonies, or observed anything that had the appearance of public worship, But though there was not found on any of the islands they visited any place appropriated to religious rites, it would perhaps be going too far to declare that the people of Pelew had absolutely no idea of religion. Independent of external testimony, there may be such a thing as the religion of the heart, by which the mind may in awful silence be turned to contemplate the God of Nature; and though unblest by those lights which have pointed to the Christian world an unerring path to happiness and peace, yet they might, by the light of reason only, have discovered the efficacy of virtue, and the temporal advantages arising from moral rectitude.

"Superstition is a word of great latitude, and vaguely defined; though it hath in enlightened ages been called the offspring of ignorance, yet in no time hath it existed without having some connection with religion. Now the people of Pelew had beyond all doubt some portion of it, as appeared by the with expressed by the king when he saw the ship building, that the English would take out of it some particular wood, which he perceived they had made use of, and which he observed was deemed an omen, or prophetic. "They had also an idea of an evil spirit, that often counteracted human affairs. A very particular instance of this was seen when Mr Barker, a most valuable member in the English society, fell backwards from the side of the vessel, whilst he was on the rocks: Raa Kook, who happened to be present, observed that it was owing to the unlucky wood our people had suffered to remain in the vessel, that the evil spirit had occasioned this misfortune."

They likewise appear to entertain a strong idea of divination, as was evident from the ceremonies they practised before they undertook any enterprise of moment. A few occurrences which are mentioned in the course of the narrative, would also lead us to believe that they could not be altogether unacquainted with the nature of religious worship; for when they were present at the public prayers of the English, they expressed no surprise at what was doing, but seemed desirous to join in them, and constantly preferred the most profound silence. The general even were in the habit of receiving a message from the king which arrived during divine service. And upon another occasion, when Captain Wilfon told Lee Boo, that good men would live again above, he replied, with great earnestness, "All fame Pelew, bad men stay in earth; good men go into sky; become very beautiful," holding his hand up, and giving a fluttering motion to his fingers. Some later voyagers, however, have affirmed, that these people, notwithstanding their superstitious, have no notion whatever of a Deity; a circumstance to which it is extremely difficult to give full credit."

The most wonderful circumstance in the history of this people, excepting that last mentioned, are the acute-ness of their understanding, their hospitality, and the implicit confidence which they placed in utter strangers. That their manners were pleasing, and their society not disagreeable, is evident from the conduct of Madan Blanchard, one of the seamen, who, when the vessel was built and ready to take her departure with his Captain and companions, was left behind at his own particular request. That they had the fullest confidence in Captain Wilfon and his crew, is put beyond
yond a doubt by the behaviour of the king and Raa
Kook when their guests were to leave them. Raa
Kook solicited his brother's permission to accompany
the English, but from prudential motives was refused.
The sovereign, however, resolved to entrust his second
son Lee Boo to Captain Wilton's care, that he might
improve his mind, and learn such things as at his return
would benefit his country.

The instructions which he gave the young man, and
the fortitude which he showed upon this occasion,
would have done honour to the most enlightened mind.
Upon delivering him to Captain Wilton, he used these
expressions: "I would wish you to inform Lee Boo
of all things which he ought to know, and make him
an Englishman. The subject of parting with my son
I have frequently revolved; I am well aware that the
distant countries he must go through, differing much
from his own, may expose him to dangers, as well as
diseases, that are unknown to us here, in consequence
of which he may die; I have prepared my thoughts to
this; I know that death is to all men inevitable; and
whether my son meets this event at Pelew or elsewhere
is immaterial. I am satisfied, from what I have ob-
served of the humanity of your character, that if he is
sick you will be kind to him; and should that happen,
which your utmost care cannot prevent, let it not hin-
der you, or your brother, or your son, or any of your
countrymen, returning here; I shall receive you, or any
of your people, in friendship, and rejoice to see you
again." How noble is this the language of a king, a father,
and a philosopher, who would have been delighted to see his son with European accom-
plishments. But alas! the fabulous history of this
amiable youth must force a tear from the eye of every
reader whose heart is not callous to the genuine feel-
ings of nature and humanity. As soon as they ar-

PEL [105] PELE

rived at Macao, the house into which he first entered,
and the different articles of furniture, fixed him in
silent admiration; but what struck his imagination most
was the upper walk and flat ceilings of the rooms,
being utterly unable to comprehend how they could be
so formed. When he was introduced to the ladies of
the family, his deportment was so easy and polite, that
it could be exceeded by nothing but his abundant good
nature; and at his departure, his behaviour left on the
mind of every one present the impression, that, how-
ever great the surprise might be which the scenes of a
new world had awakened in him, it could hardly be
exceeded by that which his own amiable manners and
native politeness would excite in others.

They were now conducted to the house of an Eng-
lish gentleman, who introduced them into a large hall,
which was lighted up, with a table in the middle, cov-
ered for supper, and a sideboard handsomely decor-
ated. Here a new scene burst at once upon Lee Boo's
mind; he was all eye, all admiration. The vessels of
glass particularly riveted his attention; but when he
surveyed himself in a large pier glass at the upper end
of the hall, he was in raptures with the deception.
It was in truth, to him, a scene of magic, a fairy
tale.

Soon after the people of the vessel came on shore, some
of them went to purchase things they were in want of;
in doing which they did not forget Lee Boo, who was
a favourite with them all. Among the trinkets they
brought him was a string of large glass beads, the first
of which almost threw them into an ecstacy; he
hugged them with a transport which could not have
been exceeded by the interested poltroonry of a string of
original pearls. His imagination suggested to him
that he held in his hand all the wealth the world
could afford him. He ran with eagerness to Captain
Wilton to show him his riches, and begged he would
get him a Chinese vessel to carry them to the king
his father, that he might see what the English had done
for him; adding, that if the people faithfully exe-
cuted their charge, he would at their return present
them with one or two beads as a reward for their ser-
ices.

Having no quadrupeds at Pelew, the sheep, goats,
and other cattle, which he met with at Macao, were
viewed with wonder; but soon after, seeing a man pass
the house on horseback, he was so much affected
that he wanted every one to go and look at the strange
animal. After the matter, however, was explained to
him, he was easily persuaded to get upon horsecback
himself; and when he was informed what a noble, do-
cile, and useful animal it was, he besought the cap-
tain to send one to his uncle Raa Kook, as he was sure
it would be of great service to him.

Omitting a number of other particulars of this kind,
which excited his curiosity and showed the excellent
disposition of his heart, we shall follow him to Eng-
land, the country from which he was never to return.
Here he had not been long before he was sent to an
academy to be instructed in reading and writing, which
he was extremely eager to attain, and most assiduous
in learning. His temper was mild and compassionate
in the highest degree; but it was at times governed
by discretion and judgment. If he saw the young
asked for relief, he would rebuke them with what little
English he had, telling them it was a shame to beg
when they were able to work; but the intreaties of old
age he could never withstand, saying, "Must give
poor old man, old man able to work."

He always addressed Mr. Wilton by the name of
Captain, but never would call Mrs. Wilton by any
other name than mother, looking on that as a mark of
the greatest respect; and such was the gratitude of
his heart for the kindness they showed him, that if
any of the family were ill, he always appeared unhap-
py, would creep softly up to the chamber, and sit fi-
lent by the bedside for a long time together without
moving, peeping gently from time to time between the
curtains, to see if they slept or lay still.

He was now proceeding with hasty strides in gaining
the English language, reading, and accounts, when
he was overtaken by that fatal disease, the small-pox,
which the greatest pains had been taken to guard him
against; and not withstanding the utmost care and at-
tention of his physician he fell a victim to this scourge
of the human race.

Upon this trying occasion, his spirit was above com-
plaining, his thoughts being all engrossed by the kind-
ness of his benefactors and friends. He told his at-
tendant, that his father and mother would grieve very
much, for they knew he was sick. This he repeated
several times, and begged him to go to Pelew, and
tell Abba Thulie that Lee Boo take much drink to
make small-pox go away, but he die; that the captain
O
and mother very kind; all English very good men; much sorry he could not speak to the king the number of fine things the English had got." Then he reckoned up the presents which had been given him, deeming that they might be properly distributed among the chiefs, and requesting that particular care might be taken of two glass pedestals, which he begged might be presented to his father.

We have given this short history of Lee Boon, because it exhibits in a strong light the manners of the natives of the Pelew islands, to which we know nothing similar in the history of man from the savage state to that of civilization. They appear to have had no communication with any other people, and were yet neither treacherous, cruel, nor cowardly. They are a striking instance of the weakness of all the philosophic theories by which mankind are usually traced from their origin through the several stages of savagery, barbarism, and civilization, down to the period of refinement, ending in effeminacy.

Since the publication of Captain Wilson's voyage we have some further accounts of these islands, all confirming what we were first told of the gentleness of the people. Two armed ships were, by order of the court of directors, fitted out at Bombay in 1790, for the purpose of surveying the islands of Pelew, and furnishing the natives with domestic animals, and such other things as might add to the comforts of life. Among the presents to the king were swords and other European implements of warfare, of which it is at least possible that he and his people might have been equally happy had they remained for ever in total ignorance. The foundation of a town was likewise laid on one of the islands, and possession of it taken in the name of the English; we trust with no remote view of enslaving the people, or of driving them from their native country. It has been likewise announced in a late publication, that Captain M'Culloch, who commanded the armed ships, was so delighted with the manners of the king and his subjects, that he has resolved to pass the remainder of his days on these islands at the early age of 34; and we hope he will prove a father to the people.

PELIAE (fab. hist.) twin-brother of Nereus, was son of Neptune by Tyro, daughter of Alcmenes. His birth was concealed by his mother, who wished her father to be ignorant of her incontinence. He was exposed in the woods, but his life was preserved by shepherds; and he received the name of Pelias, from a spot of the colour of lead in his face. Some time after Tyro married Cretheus, son of Aeolus, king of Iolcos, and became mother of three children, of whom Aeoleon was the eldest. Pelias vitiated his mother, and was received in her family; and after the death of Cretheus, he unjustly feized the kingdom, which belonged not to him, but to the children of Tyro by the deceased king. To strengthen himself in his usurpation, Pelias conferred the oracle; and when he was told to beware of one of the descendants of Aeolus, who should come to his court with one foot shod and the other bare, he privately removed the son of Aeoleon, after he had openly declared that he was dead. These precautions proved vain. Jason, the son of Aeoleon, who had been educated by Chiron, returned to Iolcos, when come to years of maturity; and having left one of his shoes in crossing the river Ananus or the Evenus, Pelias immediately perceived that this was the person whom he had so much dreaded. His unpopularity prevented him from acting with violence to a stranger, whose uncommon drefs and commanding aspect had raised admiration in the people. But his asseveration was greatly excited, when he saw Jason arrive at his palace, with his friends and his relations, and boldly demanded the kingdom which he had usurped. Pelias, conscious that his complaints were well founded, endeavoured to divert his attention, and told him that he would voluntarily resign the crown to him, if he went to Colchis to avenge the death of Phryxus, the son of Athamas, whom Aeoleon had cruelly murdered. He further declared, that the expedition would be attended with the greatest glory, and that nothing but the infirmities of old age had prevented himself from vindicating the honour of his country, and the injuries of his family, by punishing the afflains. This so warmly recommended, was with equal warmth accepted by the young hero, and his intended expedition was made known all over Greece. While Jason was absent in the Argonautic expedition, Pelias murdered Aeoleon and all his family; but, according to the more received opinion of Ovid, Aeoleon was still living when the Argoauts returned, and he was restored to the flower of youth by the magic of Medea. This change in the vigour and the constitution of Aeoleon astonished all the inhabitants of Iolcos; and the daughters of Pelias, who have received the patronymic of Pelaiades, expressed their desire to see their father's infirmities vanished by the same powerful magic. Medea, who wished to avenge the injuries which her husband Jason had received from Pelias, raised the defiles of the Pelaiades, by cutting an old ram to pieces, and boiling the flesh in a cauldron, and then turning it into a fine young lamb. After they had seen this successful experiment, the Pelaiades cut their father's body to pieces, after they had drawn all the blood from his veins, on the assurance that Medea would replenish them by her wonderful power. The limbs were immediately put into a cauldron of boiling water; but Medea suffered the flesh to be totally consumed, and refused to give the promised ailhance, and the bones of Pelias did not even receive a burial. The Pelaiades were for number, Alcate, Pitidice, Polape, and Hippothoe, to whom Hyginus adds Medua. Their mother's name was Anaxibia, the daughter of Bias or Philomachus, the daughter of Amphion. After this parricide, the Pelaiades fled to the court of Aedemus, where Acaeus, the son-in-law of Pelias, purified them, and took their protector prisoner. The Pelaiades died, and were buried in Arcadia.

PELICAN, in ornithology. See PELICANUS.

PELICAN, in chemistry, is a glass alembic consisting of one piece. It has a tubulated capital, from which two opposite and crooked beaks pull out and enter again at the belly of the cucurbit. This vessel has been contrived for a continued distillation and coagulation, which chemists call circulation. The volatile parts of substances put into this vessel rise into the capital, and are obliged to return through the crooked beaks into the cucurbit; and this without interruption, or luting and unluting the vessels. Although the pelican seems to be a very convenient instru.
PELICANUS, inornithology, a genus belonging to the order of anseres. The bill is straight, without teeth, and crooked at the point; the face is naked, and the feet are palmated. Mr. Latham enumerates no less than 30 different species of this genus, besides varieties. The most remarkable seem to be the following:

1. The carbo, or corvornant, sometimes exceeds seven pounds in weight; the length three feet four; the extent four feet two; the bill duckly, five inches long, deliquit of nostrils; the base of the lower mandible is covered with a naked yellow skin, that extends under the chin, and forms a fort of pouch; a loose skin of the same colour reaches from the upper mandible round the eyes and angles of the mouth; the head and neck are of a dark blackness, but under the chin of the male the feathers are white; and the head in that face is adorned with a short, loose, pendant crest; in some the crest and hind-part of the head are streaked with white. The coverts of the wings, the scapulars, and the back, are of a deep green, edged with black, and glossed with blue; the quill-feathers and tail duckly; the legs are short, strong, and black; the middle claw ferrated on the inside; the irides are of a light ash-colour.

These birds occupy the highest parts of the cliffs that jut over the sea; they make their nests of sticks, sea-tang, grafts, &c., and lay fix or seven white eggs of an oblong form. In winter they disperse along the shores, and visit the fresh waters, where they make great havoc among the fish. They are remarkably voracious, having a most flen-then digestion, promoted by the infinite quantity of small worms that fill their intestines. The corvornant has the rankest and most disagreeable smell of any bird, even when alive. Its form is disagreeable; its voice hoarse and croaking, and its qualities base. These birds, however, have been trained to fish, and are called falvo. Whitelock tells us, that he had a call of them manned like hawks, and which would come to hand. He took much pleasure in them; and relates, that the beak he had was one presented him by Mr. Wood, master of the corvornants to Charles I. It is well known that the Chinese make great use of these birds, or a congnerous sort, in fishing; and that not for amusement, but profit.

2. The granicus, or flag, called in the north of England the crane, is much inferior in size to the corvornant: the length is 27 inches; the breadth three feet six; the weight three pounds three quarters. The bill is four inches long, and more slender than that of the preceding: the head is adorned with a crest two inches long, pointing backward; the whole plumage of the upper part of this bird is of a fine and very shining green; the edge of the feathers a purplish black; but the lower part of the back, the head, and neck, wholly green; the belly is duckly; the tail of a duckly hue, tinged with green; the legs are black, and like those of the corvornant.

Both these kinds agree in their manners, and breed in the same places; and, what is very strange in web-footed birds, will perch and build in trees; both swim with their head quite erect, and are very difficult to be shot; for, like the grebes and divers, as soon as they see the flash of the gun, they pop under water, and never rise but at a considerable distance.

3. The bannus, gannet, or solan goose, weighs seven pounds; the length is three feet one inch; the breadth six feet two inches. The bill is six inches long, straight almost to the point, where it inclines down; and the irides are irregularly jagged, that it may hold its prey with more security; about an inch from the base of the upper mandible is a sharp process pointing forward; it has no nostrils; and in their place a long faw, that reaches almost to the end of the bill. The whole is of a dirty white, tinged with ash-colour. The tongue is very small, and placed low in the mouth; a naked skin of a fine blue surrounds the eyes, which are of a pale yellow, and are full of vivacity; this bird is remarkable for the quickness of its fight. Martin tells us, that solan is derived from an Irish word expressive of that quality.

From the corner of the mouth is a narrow slip of black bare skin, that extends to the hind-part of the head; beneath the chin is another, that, like the pouch of the pelican, is dilatable, and of size sufficient to contain five or six entire herrings; which in the breeding season it carries at once to its mate or young.

The young birds, during the first year, differ greatly in colour from the old ones; being of a duckly hue, speckled with numerous triangular white spots; and at that time resemble in colours the speckled diver. Each bird, if left undisturbed, would only lay one egg in the year; but if that be taken away, they will lay another; if that be also taken then a third; but never more that afeon. Their egg is white, and rather less than that of the common goose; the nest is large, and formed of any thing the bird finds floating on the water, such as grafts, sea-plants, flavings, &c. These birds frequent the Isle of Alifa, in the Frith of Clyde; the rocks adjacent to St. Kilda; the Stalls of Soultkerry, near the Orkneys; the Skelgyl Isles, off the coasts of Kerry, Ireland; and the Bays of the Frith of Edinburgh: the multitudes that inhabit these places are prodigious. Dr Harvey's elegant account of the latter, will serve to give some idea of the numbers of these, and of the other birds that annually migrate to that little spot.

There is a small island, called by the Scotch Basi Island, not more than a mile in circumference; the surface is almost wholly covered during the months of May and June with nests, eggs, and young birds; so that it is scarcely possible to walk without treading on them; and the flocks of birds in flight are so prodigious as to darken the air like clouds; and their noise is such, that you cannot without difficulty hear your next neighbour's voice. If you look down upon the sea from the top of the precipice, you will see it on every side covered with infinite numbers of birds of different kinds, swimming and hunting for their prey.
The Pelican

P E L [ 103 ]

The pelican

The pelican is a large water bird that is found in many parts of the world. It is known for its distinctive pouch under its beak, which it uses to catch fish. The pelican is often depicted in works of art and literature, symbolizing various qualities such as wisdom, knowledge, and longevity. In this text, the pelican is mentioned in the context of its habitat and behavior, highlighting its role in the ecosystem and its adaptability to different environments. The pelican's presence in various regions underscores its importance in the biodiversity of the areas it inhabits.
Pelicans. Kind are taught to choose the properest habitations and feeding places, and to shift their quarters feasably, by the unerring hand of God.

"From the account given above of the multitudes of sea-fowls that feed their food on this coast, we may justly conclude that there must be inexhaustable stores of fish there. Let us for a moment confine our attention to the consumption made by a single species of fowls. The Solan goose is almost infallibly voracious; he flies with great force and velocity, toils all the day with very little intermission, and digests his food in a very short time; he digests to eat any thing worse than herring or mackerel, unless it be in a very hungry place, which he takes ear to avoid or abandon. We shall take it for granted that there are 100,000 of that kind around the rocks of St Kilda; and this calculation is by far too moderate, as no less than 20,000 of this kind are destroyed every year, including the young ones. We shall suppose, at the same time, that the folan goose fijourn in these seas for about seven months of the year; that each of them destroys five herring in a day; a subsistence infinitely poor for so greedy a creature, unless it were more than half supported at the expense of other fishes. Here we have 100,000,000 of the finest fish in the world devoured annually by a single species of the St Kilda sea-fowls.

"If, in the next place, it be considered, that much the greatest part of the other tribes have much the same appetite for herring, and partake it from place to place, in the several migrations it makes from one sea to another, the consumption must be prodigiously great. Taking these into the account, and allowing them the same quantity of food, and of the same kind, by reason of their vast superiority in numbers of those, their stomachs are considerably weaker; we see there are no less than 200,000,000 of herrings swallowed up every year by the birds of a very small district of rocks, which occupy to inconsiderable a space in the Deucalidian ocean.

"Should all the articles of this account be fulfilled, articles which seem no less just than plain, and should our curiosity lead us into a new calculation, allowing between 600 and 700 to every barrel, it is evident that more than 350,000 barrels are annually carried away by such creatures."

The birds are well known on most of the coasts of England, but not by the name of the Solan goose. In Cornwall and in Ireland they are called gannets; by the Welsh, gann. Mr Ray supposed the Cornish gannet to be a species of large gull: a very execusable mistake; for during his six months residence in Cornwall, he never had an opportunity of seeing that bird, except flying; and in the air it has the appearance of a gull. On that supposition he gave us the title of a genus, which admirably expresses the rapid descent of this bird on its prey. Mr Moyle first detected this mistake; and the Rev. Dr William Borlase, by presenting us with a fine specimen of this bird, confirms the opinion of Mr Moyle; at the same time giving the following natural history of the bird.

"The gannet comes on the coasts of Cornwall in the latter end of summer, or beginning of autumn; hovering over the hollar of pilchards that come down to us through St George's Channel from the northern coast of Spain. The gannet seldom comes near the land, but is constant to its prey, a sure sign to the fishermen that the pilchards are on the coast; and when the pilchards retire, generally about the end of November, the gannets are seen no more. The bird now went was killed at Chandour, near Mountbatten, Sept. 30, 1762, after a long struggle with a water-fowl, affixed by the beakmen; for it was strong and pugnacious. The person who took it observed that it had a transparent membrane under the eye-bird, with which it covered at pleasure the whole eye, without obfuscating the sight or shutting the eye lid; a gracious provision for the security of the eyes of so weighty a creature, whose method of taking its prey is by darting headlong on it from a height of 50 feet or more into the water. About four years ago, one of these birds flying over Penzance, (a thing that rarely happens,) and seeing some pilchards lie on a fir-plant, in a cellar used for curing fish, darting itself down with fierce violence, that it struck its bill quite through the board (about an inch and a quarter thick), and broke its neck."

These birds are sometimes taken at sea by a deception of the like kind; the fishermen fastening a pillow to a board, as in St Kilda: they catch herrings, and which in the same manner decoys the unwary gannet to its own destruction.

In the Cataracta of Juba may be found many characters of this bird: he says, that the bill is toothed; that its eyes are fiery; and that its color is white; and in the very name is expressed its furious devent on its prey. The rest of his account favours of table. We are uncertain whether the gannet breeds in any other parts of Europe besides our own islands; except, as Mr Ray suspects, the fula (described in Clusius's Exotics, which breeds in Feroe Isles) be the same bird.

4. The fula, or booby, is somewhat less than a goose; the basis of the bill yellow, and bare of feathers; the eyes of a light grey color; the lower part of the bill of a light brown. The colours of the body are brown and white; but varied so in different individuals, that they cannot be described by them. Their wings are very long; their legs and feet pale yellow, flapped like the feet of corvants. They frequent the Bahama islands, where they breed all months in the year, laying one, two, or three eggs, on the bare rock. While young, they are covered with a white down, and continue so till they are almost ready to fly. They feed on fish like the rest of this genus; but have a very troublesome enemy of the man-of-war bird which lives on the spoils obtained from other sea-birds, particularly the booby. As soon as this rapacious enemy perceives that the booby has taken a fish, he flies furiously at him, upon which the former dives to avoid the blow; but as he cannot swallow his prey below water, he is soon obliged to come up again with the fish in his bill as before, when he suffers a new affault; nor does his enemy cease to persecute him till he lets go the fish, which the other immediately carries off.

5. The great booby, called by Linnaeus pelicanus Bozanius pufius, frequents the rivers and sea-coasts of Florida, pursuing and devouring fishes like others of the genus. Mr Catsey informs us, that he has several
PEL

Pelicanus.

The pelican or man-of-war bird, is in the body

synopsis of the size of a large fowl; in length three feet,

and breadth 1.4. The bill is flender, five inches long,

and much curved at the point; the colour is dusky;

from the base a reddish dark coloured skin

spreads on each side of the head, taking in the eyes;

from the under mandible hangs a large membranaceous

bag attached some way down the throat, as in

the pelican, and applied to the same uses; the colour

of this is a fine deep red, sprinkled on the sides with

a few scattered feathers; the whole plumage is brownish-

black, except the wing coverts, which have a rufous

tinge; the tail is long, and much forked; the outer

feathers are 18 inches or more in length; the middle

ones from seven to eight: the legs are small, all the

toes are webbed together, and the webs are deeply in-

dented; the colour of them is dusky red.

The female differs in wanting the membranaceous

pouch under the chin; and in having the belly white:

in other things is greatly like the male.

The frigate pelican, or man-of-war bird (a), as it

is by some called, is chiefly, if not wholly, met with

between the tropics, and ever out at sea, being only

seen on the wing. It is usual with other birds, when

fatigued with flying, to rest themselves on the surface

of the water; but nature, from the exceeding length

of wing ordained to this, has made the flitting there

from utterly impossiible, at least writers not only to in-

form us, but every one whom we have talked with

avers the same: though perhaps this is no defect of

nature, as it fiercely seems to require much rest: at

least, from the length of wing, and its apparent easy

gliding motion (much like that of the kite), it appears

capable of fulfilling very long flights; for it is often

seen above 100, and not unfrequently above 200, leagues

from land. It has indeed been known to settle on the masts of ships; but this is not a frequent

circumstance, though it will often approach near, and

hover about the top-mast flag. Sometimes it soars so

high in the air as to be scarcely visible, yet at other

times approaches the surface of the sea, where, hovering

at some distance, the moment it spies a fish, it darts down on it with the utmost rapidity, and feld-m

without success, flying upwards again as quick as it

defended. It is also seen to attack* gulls and other

birds which have caught a fish, when it obliges them

to disgorge, and then takes care to seize it before it falls

into the water. It is an enemy to the flying fish;

for, on being attacked beneath by the dolphin

and other voracious fish, to escape their jaws, these

fiem-volatiles leap out of the water in clusters, making

use of their long fins as wings to buoy them up in the

air, which they are enabled to do as long as they re-

main wet; but the men they become dry are use-

less, and drop into their proper element again: during

their flight, the frigate darts in among the fish, and

seizes one or two at a look. These birds know the ex-

act place where the fish are to rise from the bubbling

of the water, which directs them to the spot; in this they

are accompanied by gulls and other birds, who act in

conest with them.

These birds, which, though not uncommon every-

where within the tropics, yet are less frequent in some

places than others, were seen by Cook in 1740 deg. In

the old route of navigators, they are mentioned fre-

quently as being met with at Ascension Island, Ceylon,

Eait Indies, and China. Dampier saw them in great

plenty in the island of Aves in the West Indies. Our

later navigators talk of them frequenting various

places of the South Sea, about the Marquesas, Easter

Isles, and New California, also at Otaheite, though at

this last place not in such plenty as in many others.

They are said to make nails on trees, if there be any

within a proper distance; otherwise on the rocks. They

lay one or two eggs of a flesh colour, marked with crip-

son spots. The young birds are covered with greyish

white down: the legs are of the same colour, and the

bill is white. There is a variety of this species, which

is less, measuring only two feet nine inches in length;

the extent from wing to wing is five feet and a half. The

bill is five inches long, and red; the base of it, and bare

space round the eye, are of the same colour; the noftrils

are sufficiently apparent, and appear near the base; the

shape of the bill is as in the larger one: the head, bind

part of the neck, and upper parts of the body and wings,

are ferrugious brown; the throat, fore part of the

neck, and breast, are white; the tail is greatly forked as

in the other; the legs are of a dirty yellow.

In my collection (says Latham) is a bird very fa-

miliar to this, if not the same; general colour of the

plumage full black; breast and belly mottled with ash-

colour; the inner ridge of the wing the same; the bill

has the long narrow, as is seen in the greater one; but

the nostrils are sufficiently apparent, being about half

an inch in length, rather broader at that part than the

base. This has a large red pouch at the chin and

throat, as in the former species. It is most likely that

mine is the male bird, as others, suspected to be of

the opposite sex, have little or no traces of the jugular

pouch. This supposition seems justified from a pair

in the Hunterian museum, in both of which the plum-

age is wholly black; the one has a large pouch, the

other

(a) It is also called tislur, or tailor, by the French, from the motion of its tail representing a pair of shears

when opened; and when on the wing, it opens and shuts them frequently, in the manner of using that infor-

ment.—Olsen, Vmp. ii. p. 304.

(c) Thought by Obeck to be one of the sorts of birds used in fishing by the Chinese.
Pelicans, other definite of it. Some have supposed that the greater and leffer frigates are the fame bird, in different periods of age."

7. The oncorhynthus, or pelican of Asia, Africa, and America; though Linnaeus thinks that the pelican of America may possibly be a different variety. This creature, in Africa, is much larger in the body than a cormorant, and somewhat of the same shape and colour. Its four toes are all webbed together; and its neck in some measure resembles that of a cormorant: but that singularity in which it differs from all other birds is in the bill and the great pouch underneath. This enormous bill is 15 inches from the point to the opening of the mouth, which is a good way back behind the eyes. At the base the bill is somewhat greenish, but varies towards the end, being of a reddish blue. It is very thick in the beginning, but tapers off to the end, where it hooks downwards. The under chap is still more extraordinary; for to the lower edges of it hang a bag, reaching the whole length of the bill to the neck, which is said to be capable of containing 15 quarts of water. This bag the bird has a power of wrinkling up into the hollow of the under-chap; but by opening the bill, and putting one's hand down into the bag, it may be diffused at pleasure. The skin of which it is formed will then be seen of a bluish ash colour, with many fibres and veins running over its surface. It is not covered with feathers, but with a short downy fulstance as smooth and as soft as fatin, and is attached all along to the under edges of the chap, is fixed backward till its head by proper ligaments, and reaches near half way down. When this bag is empty, it is not seen; but when the bird is filled with fishes, it is then incredible to what an extent it is often filled. For the first thing the pelican does in fishing is to fill up the bag; and then it returns to digest its burden at leisure. When the bill is opened to its widest extent, a person may run his hand into the bird's mouth, and conceal it in this monstrous pouch, thus adapted for very singular purposes. Yet this is nothing to what Ruyfch affures us, who avers that a man has been seen to hide his whole leg, boot and all, in the monstrous jaws of one of these animals. At first appearance this would seem impossible, as the sides of the under chap, from which the bag depends, are not above an inch in width when the bird's bill is first opened; but then they are capable of great separation; and it must necessarily be so, as the bird prey upon large fishes, and hides them by dozens in its pouch. Tertius affirms, that it will hide as many fish as will serve 60 hungry men for a meal.

This pelican was once also known in Europe, particularly in Russia; but it seems to have deferted those coasts. This is the bird of which so many fabulous accounts have been propagated: such as its feeding its young with its own blood, and its carrying a provision of water for them in its great reservoir in the defert. But the absurdity of the first account answers itself; and as for the latter, the pelican uses its bag for very different purposes than that of filling it with water.

Clavigero, in his History of Mexico, says that "there are two species, or rather varieties, of this bird in Mexico; the one having a smooth, bill, the other a notched one. Although the Europeans are acquainted with this bird, I do not know whether they are equally well acquainted with the singular circumstance of its afflicting the sick or hurt of its own species; a circumstance which the Americans at times take advantage of to procure fish without trouble. They take a live pelican, break its wing, and after tying it to a tree, conceal themselves in the neighbourhood; there they watch the coming of the other pelicans with their provisions, and as soon as they see these throw up the fish from their pouch, run in, and take a little for the captive bird, they carry off the rest."

This amazing pouch may be considered as analogous to the crop in other birds; with this difference, that as theirs lie at the bottom of the gullet, so this is placed at the top. Thus, as pigeons and other birds macerate their food for their young in their crops, and then supply them; so the pelican supplies its young by a more ready contrivance, and macerates their food in its bill, or stores it for its own particular sustenance.

The ancients were particularly fond of giving this bird admirable qualities and parental affections: Struck, perhaps, with its extraordinary figure, they were willing to supply it with as extraordinary appetites; and having found it with a large resevoir, they were pleased with turning it to the most tender and parental uses. But the truth is, the pelican is a very heavy, sluggish, voracious bird, and very ill fitted to take its flight, or to make those cautious provisons for a distant time; which we have been told they do.

The pelican, says Labar, has strong wings, furnished with thick plumage of an ash-colour, as are the rest of the feathers over the whole body. Its eyes are very small, when compared with the size of its head; there is a narrowness in its countenance, and its whole air is melancholy. It is as dull and reluctant in its motions as the flamingo is sprightly and active. It is flow of flight, and when it rises to fly, performs it with difficulty and labour. Nothing, as it were, but the spur of necessity, could make these birds change their situation, or induce them to ascend into the air: but they must either starve or fly.

They are torpid and inactiv to the last degree, so that nothing can exceed their indolence but their gluttony; it is only from the stimulations of hunger that they are excited to labour; for otherwise they would continue always in fixed repose. When they have raised themselves about 30 or 40 feet above the surface of the sea, they turn their head with one eye downwards, and continue to fly in that posture. As soon as they perceive a fish sufficiently near the surface, they dart down upon it with the swiftness of an arrow, seize it with unreeling certainty, and stow it up in their pouch. They then rise again, though not without great labour, and continue hovering and fishing, with their head on one side as before.

This work they continue with great effort and industry till their bag is full, and then they fly to land to devour and digest at leisure the fruits of their industry. This, however, it would appear, they are not long in performing; for towards night they have another hungry call, and they again reluctantly go to labour. At night, when their fishing is over, and the toil of the day crowned with success, these lazy birds retire a little way from the shore; and, though with the webbed feet and clumsy figure of a goose, they will be contented to perch nowhere, but upon trees among the light and airy.  

Plate xcclxxi.
pany and conversation of men, and in music both vocal and instrumental; for it would willingly stand," says he, "by those that sung or sounded the trumpet; and stretching out its head, and turning its ear to the music, listened very attentively to its harmony, though its own voice was little pleasanter than the braying of an ass." Gefner tells us, that the emperor Maximilian had a tame pelican which lived for above 80 years, and that always attended his army on their march. It was one of the largest of the kind, and had a daily allowance by the emperor's orders. As another proof of the great age to which the pelican lives, Aldrovandus makes mention of one of those birds that was kept several years at Meclhin, and was w'ely believed to be 50 years old. - We often see these birds at our shows about town.

Mr Edwards, in his History of Birds, describes the pelican of America from one, the body of which was fent him stuffed and dried. From the point of the bill to the angles of the mouth measured 13 inches, and the wing when closed measured 18 inches. The pouch when dry appeared of the confi'ance and colour of a brown dry ox's bladder, having fibres running its whole length, and blood vessels crossing them; and proceeding from the sides of the lower part of the bill, which opened into this pouch, its whole length. The greater bone of the wing being broken, was found to be light, hollow, void of marrow, and the sides of it thin as parchment. Sir Hans Sloane writes thus of it (see Naut. Hist. of Jamaica, vol. ii. p. 322.): "This seems to be the same with the white pelican, only of a darker colour. They are frequent in all the seas of the hot West Indies. They fish after the same manner as man-of-war birds, and come into the sheltered bays in stormy weather, where they very often perch on trees: they fly over the seas as gulls, and take the fish when they sly them, by falling down upon them, and then rise again and do the like. They are not reckoned good food. When they are seen at sea, it is a sign of being near land." Water, in his voyage and description of the islands of America, says, "The pelican is not found on the South Sea side of the line from which they abound on the northern side; they are of a dark grey colour, and under the throat hangs a bag: the old ones are not eaten, but the young are good meat." Mr Edwards, in another place, gives the description of a pelican, which he says is double the biggest of the largest swan. His drawing was made from the pelican shown at London in 1745, which was brought by Capt. Pelly from the Cape of Good Hope, where they are larger than anywhere else. The body, legs, and feet, very much resemble the pelican of America; and it differs little but in the head and neck, which last is very long, like a swan's; the bill is slimmer, and the upper part only hooked at the end: the pouch is shaped something different, hanging more down in the middle. Mr Edwards thus describes it. "From the point of the bill to the angle of the mouth is 20 inches of our English measure, which is six inches more than any natural historian has found it; the academy of Par is having measured one which was about 14 inches, Paris measured I suppose; and our countryman, Wiltoughby, measured one brought from Russia, which he makes 14 inches English. I thought it something incredible in Wiltoughby's description, that a man should
Pelican

should put his head into the pouch under the bill, but
I saw it performed in this bird by its keeper, and am
ture a second man’s head might have been put in with
it at the same time.”

The Academy of Paris think the bird they have de-
cribed is the pelican of Aristotle, and the Onocrotalus
of Pliny. They are also confirmed in the opinion
that this is a long-lived bird; for, out of a great num-
ber kept at Verailles, none had died for more than 12
years, being the only animis kept in the menageriy
of which some have not died in that time. Some au-
tors say they live 60 or 70 years.

Capt. Keeling, in his voyage to Sierra Leon, says
the pelicans there are as large as swans, of a white
colour with exceeding long bills t and M. Thevenot,
in his travels to the Levant, observes, that the pelicans
about some part of the Nile near the Red Sea swim
by the bank side like geese, in such great numbers that
they cannot be counted. Father Morella, in his voy-
age to Congo, says pelicans are often met with in the
road to Singa, and are all over black, except on their
breast, which is of a flesh colour like the neck of a
turkey. He adds further, that father Francisco de Pa-
via informed him, that on his journey to Singa he ob-
erved certain large white birds, with long beaks, necks,
and feet, which, whenever they heard the least sound
of an instrument, began immediately to dance, and
leap about the rivers, where they always reside, and
whereof they were great lovers; this, he said, he took
a great pleasure to contemplate, and continued often
upon the banks of the rivers to observe.

It would extend our article beyond all proportion,
were we to touch on each individual species of this ex-
tensive genus, together, with their accidental varieties.
But as the genus is unquestionably very curious, we
shall here subjoin a list of books, which such of our
readers as desire it may have recourse to for further
information: Edward’s History of Birds: Natural His-
tory of Jamaica: Mem. de l’Académie Royale des Sciences,
deépuis 1665 jusqu’a 1699. tom. 3, troisième partie, p.
186; Willoughby’s Pennant’s British and Arctic Zoology;
and Latham’s Synopsis of Birds: the last of which is the
fullest and most scientific of any we have yet seen.

PELION (Diodorus Siculus, &c.), Pelion mons, un-
derwood, (Mela, Virgil, Horace, Seneca), a moun-
tain of Thessaly, near Olla, and hanging over the Sinus
Pelaicus, or Pegaeicus; its top covered with pines,
the fides with oaks, (Ovid). Said also to abound in
wild ash, (Val. Plancy). From this mountain was
cut the spear of Achilles, called pelius, which none
but himself could wield, (Homer). Dicareus, Ari-
Stote’s scholar, found this mountain 1250 paces higher
than any other of Thessaly, (Pliny). Pelius, Cicero;
Pellucem, (Carullus), the epithet.

PELLA (anc. geog.), a town situated on the confines
of Emathia, a district of Macedonia, (Ptolemy); and
therefore Herodotus allot it to Botina, a maritime
district on the Sinus Thermaicus. It was the royal re-
fidence, situated on an eminence, verging to the south-
west, encompassed with unpassable marshes summer and
winter: in which, next the town, a citadel like an
island rise, placed on a bank or dam, a prodigious
work, both supporting the wall and securing it from
any hurt by means of the circumambient water. At a
distance, it seems close to the town, but is separated
from it by the Ludias, running by the walls, and joined
to it by a bridge, (Liv.); distant from the sea 120
Stadia, the Ludias being far navigable, (Strabo).
Mela calls the town Pelis, though most Greek authors
write Pella. The birth place of Philip, who enlarged
it; and afterwards of Alexander, (Strabo, Melcl). Con-
tinued to be the royal residence down to Pericles, (Li-
v.). Called Pella Colonii, (Pliny); Colonia Julia
Augusta, (Coin). It afterwards came to decline, with
but few and mean inhabitants, (Lucian). It is now
called Των Παπαρών, The Little Palace, (Hollinrux).

Pellane, both the gentilicium name and the epithet,
(Lucian, Juvenal, Martial.)—Another Pella; (Po-
ylus, Pliny); a town of the Decapoli, on the other
side the Jordan; abounding in water, like its cognomi-
tual town in Macedonia; built by the Macedonians,
(Strabo); by Seleucus, (Eusebius): anciently called
Butis, (Stephanus); Agamas, (Strabo); situated 35
miles to the north-east of Gerasa, (Ptolemy). Thir-
ther the Christians, just before the siege of Jerusa-
lem by Titus, were divinely admonished to fly, (Eu-
senius). It was the utmost boundary of the Perea, or
Transjordan country, to the north, (Josephus).

PELLETIER (James), a doctor of physic, and an
eminent mathematician, was born at Mans in 1517,
and died at Paris in 1582. He was an excellent Latin
and French poet, a good orator, physician, and gram-
marian. He wrote Oeuvres Politiques, Commentaires La-
ties, etc.

PELLITS, in heraldry, those roundles that are
black; called also opristes and gunflames, and by the
French torteaux de fable.

PELLICLE, among physicians, denotes a thin
film or fragment of a membrane. Among chemists it
signifies a thin surface of crystals uniformly spread over
a small liquor evaporated to a certain degree.

PELLISON, or PELSON FONTANIER, (Paul),
one of the finest geniuses of the 17th century, was the
son of James Pellisson counsellor at Caftres. He was
born at Beziers in 1624, and educated in the Protestant
religion. He studied with faccaces the Latin, Greek,
French, Spanish, and Italian tongues, and applied
himself to the reading the best authors in these lan-
guages; after which he studied the law at Caftres with
reputation. In 1652 he purchased the post of secre-
tary to the king, and five years after became first de-
puty to M. Fouquet. He suffered by the disgrace of
that minister; and in 1661 was confined in the Bastile,
from whence he was not discharged till four years after.
During his confinement he applied himself to the study
of controversy; and in 1670 abjured the Protestant
religion. Louis XIV. beloowed upon him an annual
pension of 2000 crowns: and he likewise enjoyed se-
veral polit. In 1676 he had the abbey of Giment,
and some years after the priory of St Orens at Auch.
He died in 1693. His principal works are, 1. The
History of the French Academy. 2. Reflections on
religious Disputes, &c. in 4 vols 12mo. 3. The History
of Louis XIV. 5. Historical Letters and Miscellanies,
in 3 vols 12mo.

PELOPIA, a festival observed by the Eleans in
honour of Pelops. A ram was sacrificed on the occa-
sion, which both priests and people were prohibited
from...
from partaking of, on pain of excommunication from Jupiter's temple; the neck only was allotted to the officer who provided wood for the sacrifice. This officer was called 

PELOPONNESUS, (Dionysius,) a large peninsula to the south of the reit of Greece; called, as it were, Peloponnisus or infula, though properly not an island, but a peninsula; yet wanting but little to be one, viz. the ithmus of Corinth, ending in a point like the leaf of the plantane or plane-tree. Anciently called Apis and Paeloja; a peninsula second to no other country for nobleness; situated between two seas, the Egean and Ionian, and resembling a plantane-leaf, on account of its angular recesses or bays. (Pliny, Strabo, Mela.) Strabo adds from Homer, that one of its ancient names was Argo, with the epithet Achaticum, to distinguish it from Thesaly, called Pela
gicum. Divided into six parts; namely, Argolis, Laconica, Meglena, Elis, Achaea, and Arcadia, (Mela.) Now called the Morea.

PELOPS, in fabulous history, the son of Tantalus king of Phrygia, went into Elis, where he married Hippodamia the daughter of Oenomaus king of that country; and became so powerful, that all the territory which lies beyond the Ithmus, and composes a considerable part of Greece, was called Peloponnesus, that is, the island of Pelops, from his name and the word Next.

PELTIA, a small, light, manageable buckler, used by the ancients. It was worn by the Amazons. The pelta is said by some to have resembled an ivy leaf in form; by others it is compared to the leaf of the plantane or plane-tree. Anciently called 

PELTARIA, in botany: A genus of the siliqua order, belonging to the tetradasyma clafs of plants; and in the natural method ranking under the 39th order, Siliquea. The siliqua is entire, and nearly orbicular, compressed plane, and not opening.

PELUSIUM (anc. geog.), a noble and strong city of Egypt, without the Delta, distant 20 statas from the sea; situated amidst marshes; and hence its name and its strength. Called the key or inte of Egypt (Diodorus, Hirtius); which being taken, the rest of Egypt lay quite open and exposed to an enemy. Called Sin (Ezekiel). Pelasgius the epithet (Virgil, Diodorus.) From its ruins arose Damietta. E. Long. 32°. N. Lat. 31°.

Mr Savary gives us the following account of this place: "The period of its foundation, as well as that of the other ancient cities of Egypt, is lost in the obscurity of time. It flourished long before Herodotus. As it commanded the entrance of the country on the side of Asia, the Pharaohs rendered it a considerable forbos, one of them raised a rampart of 30 leagues in length from the walls of this town to Helopolis. But we find from the history of nations that the long wall of China, which the weakness of the Greek emperors led them to build round Constantinople, and many others, built at an immense expense, were but feeble barriers against a warlike people; these examples have taught us, that a flate, to be in security against a foreign yoke, must form warriors within itself, and that men must be opposed to men. This rampart, which covered Pelusium, did not stop Cambyses, who attacked it with a formidable army. The feeble character of the Son of Amasis, unable to prevent the defeition of 200,000 Egyptians, who went to found a colony beyond the cataracts, had not force sufficient to oppose that torrent which broke in upon his country. Cambyses, after a bloody battle, wherein he cut his enemies to pieces, entered Pelusium in triumph. That memorable day, which saw the defeition of one part of the Egyptian militia and the ruin of the other, is the true epoch of the subjugation of that rich country. Since that period, it has paused under the yoke of the Persians, the Macedonians, the Romans, the Greeks, the Arabs, and the Turks. A continued slavery of more than 2000 years seems to secure them an eternal bondage.

"Herodotus, who visited Pelusium some years after the conquest of Cambyses, relates an anecdote which I cannot omit: 'I surveyed (says he) the plain where the two armies had fought. It was covered with human bones collected in heaps. Tho' of the Persians were one side, tho' of the Egyptians on the other, the inhabitants of the country having taken care to separate them after the battle. They made me take notice of a fact which would have appeared very alarming to me without their explanation of it. The skulls of the Persians, which were light and fragile, broke on being lightly struck with a stone; tho' of the Egyptians, thicker and more compact, resisted the blows of flint. This difference of solidity they attributed to the custom the Persians have of covering their heads from their infancy with the tiara, and to the Egyptian custom of leaving the heads of their children bare and shaven, exposed to the heat of the sun. This explanation appeared satisfactory to me.' Mr Savary affirms us that the same customs still subsist in Egypt, of which he frequently had ocular demonstration."

"Pelusium (continues he), after passing under the dominion of Persia, was taken by Alexander. The brave Antony, general of cavalry under Gabinius, took it from his succours, and Rome restored it to Ptolemy Auletes. Pompey, who credit had established this young prince on the throne of Egypt, after the fatal battle of Pharamaia took refuge at Pelusium. He landed at the entrance of the harbour and, on quitting his wife Cornelia and his son, he repeated the two following verses of Sophocles, 'The free man who seeks an asylum at the court of a king will meet with flavery and chains.' He thers found death. Scarcely had he landed on the shore, when Theodore the rhetorician, of the isle of Chio, Septimius the courtier, and Achilles the eunuch, who commanded his troops, wishing for a victim to present to his conqueror, flaved him with their swords. At the sight of the affrays Pompey covered his face with his mantle, and died like a Roman. They cut off his head, and embalmed it, to offer it to Caesar, and left his body naked on the shore. It was thus that this great man, whose warlike talents had procured the liberty of the hea, for the Romans, and added whole kingdoms to their extended empire, was basely slain in letting foot on the territory of a king who owed to him his crown. Philip his freedman, collecting together, under favour of the night, the wreck of a boat, and stripping of his own cloak to cover the sad remains of his master, burnt them.
PELVIS, in anatomy. See here, n° 3—43.

PEMBROKE (Mary Countess of). See HERBERT.

PEMBROKE, in Pembroke-shire, in England, is the principal town in the county. It is situated upon a creek of Milford-Haven, and in the most pleasant part of Wales, being about 256 miles distant from London. It is the county-town, and has two handsome bridges over two small rivers which run into a creek, forming the west side of a promontory. It is well inhabited, has several good houses, and but one church. There is also a custom-house in it. There are several merchants in it, who, favoured by its situation, employ near 200 sail on their own account; so that, next to Caermarthen it is the largest and richest town in South Wales. It has one long street, upon a narrow part of a rock; and the two rivers seem to be two arms of Milford-Haven, which ebb and flows close up to the town. It is governed by a mayor, bailiffs, and burgesses; and was in former times fortified with walls, and a magnificent castle seated on a rock at the west end of the town. In this rock, under the chapel, is a natural cavern called Wegan, remarked for having a very fine echo: this is supposed to have been a store-room for the garrison, as there is a circular leading into it from the castle: it has also a wide mouth towards the river. This structure being burnt a few years after it was eroded, it was rebuilt. It is remarkable for being the birth-place of Henry VII., and for the brave defence made by the garrison for Charles I.

PEMBROKESHIRE, a county of Wales, bounded on all sides by the Irish sea, except on the east, where it joins to Caermarthenshire, and on the north-east to Cardiganshire. It lies the nearest to Ireland of any county in Wales; and extends in length from north to south 35 miles, and from east to west 29, and is about 140 in circumference. It is divided into seven hundreds, contains about 420,000 acres, one city, eight market towns, two foresters, 145 parishes, about 2300 houses, and 25,900 inhabitants. It lies in the province of Canterbury, and diocese of St. David's. It sends three members to parliament, viz. one for the shire, one for Haverfordwell, and one for the town of Pembroke.

PEMBROKESHIRE, considering its situation, is good; but it is in general better the farther from the sea. As there are but few mountains, the soil is generally fruitful, especially on the sea-coasts; nor are its mountains altogether unprofitable, but produce pasture sufficient to maintain great numbers of sheep and goat. Its other commodities are corn, cattle, pit-coal, murl, fish, and fowl. Among these last are falcoms, called here peregrins. Amongst the birds common here are migratory sea-birds, that breed in the

Isle of Ramsey, and the adjoining rocks called The Bishops and the Cliffs. About the beginning of April flocks of birds, of several sorts, resort to these rocks, as appear incredible to those who have not seen them. They come to them in the night-time, and also leave them then; for, in the evening, the rocks may be seen covered with them, and the next morning not one be seen at all. In like manner, not a single bird shall appear in the evening, and the next morning the rocks shall be covered with them. They also generally make a visit about Christmas, staying a week or longer; and then take their leave till breeding-time. Among these birds are the eider, razor-bill, puffin, and harry-bird. The eider lays only one egg, which, as well as those of the puffin and razor-bill, is as big as a duck's, but longer and smaller at one end. She never leaves it till it is hatched, nor then till the young one is able to follow her; and she is all this time fed by the male. This and the razor-bill breed upon the bare rocks, without any kind of nest. The puffin and harry-bird breed in holes, and commonly in the holes of rabbits; but sometimes they dig holes for themselves with their beaks. The harry-birds are never seen on land but when taken. All the four kinds cannot raise themselves to fly away when they are on land, and therefore they creep or waddle to the cliffs, and throwing themselves off, take wing. The eider is the tame bird which they call in Cornwall (England) a kidow, and in Yorkshire a scoul. The razor-bill is the merre of Cornwall. The puffin is the arctic duck of Clusius, and the harry-bird the flire-water of Sir Thomas Brown. The inhabitants of this county make a very pleasant durable fire of culm, which is the dust of coal made up into balls with a third part of mud. The country is well watered by the rivers Clethy, and in English Black-butter. Having washed it clean, they lay it to sweat between two flat flones, then fired it small, and kned it well, like dough for bread, and then make it up into great balls or rolls, which is by some eat raw, and by others fried with oatmeal and butter. It is accounted excellent against all distempers of the liver and spleen; and some affirm that they have been relieved by it in the sharpflits of the nose.

PEN, a town of Somersetshire in England, on the north-east side of Wincanton, where Kenwold a West Saxon king, so totally defeated the Britons, that they were never after able to make head against the Saxons; and where, many ages after this, Edmund Ironside gained a memorable victory over the Danes, who had before, i.e. in 1001, defeated the Saxons in that same place.

PEN, a little instrument usually formed of a quill, serving to write withal.
PEN

Pens are also sometimes made of silver, brass, or iron.

Dutch Pens are made of quills that have paffed through hot ashes, to take off the grofer fat and moisture, and render them more transparent.

Fountain Pen, is a pen made of silver, brass, &c. contrived to contain a confiderable quantity of ink, and let it flow out by gentle degrees, fo as to supply the writer a long time without being under the neceffity of taking fresh ink.

The fountain pen is compos'd of several pieces, as in Plate CCCLXXII, where the middle piece F carries the pen, which is screwed into the infide of a little pipe which again is foldered to another pipe of the fame bignefs as the lid G; in which lid is folderd a male screw, for screwing on the cover, as alfo for floppling a little hole at the place and hindering the ink from paffing through it. At the other end of the piece F is a little pipe, on the outside of which the top-cover H may be screwed. In the cover there goes a port-crayon, which is to be screwed into the other mathematical figures, may be defcribed in the fimple form. We fhall give proper firft:

A port-crayon, which is to be screwed into the other mathematical figures, may be described in the fimple form.

The radius of $EG$ (fig. 11.) muft be to that of $FG$ as 10 to 5 nearly; their velocities, or the number of teeth in the wheels, to be equal; the motion to be in the fame direction.

If the length of $FG$ be varied, the looped figure delineated at fig. 12. will be produced. A circle may be defcribed by equal wheels, and any radius but the bars muft move in contrary directions.

To define by this circular motion a right line and an ellipse. For a right line, equal radii, the velocity as 1 to 2, the motion in a contrary direction; the fame data will give a variety of ellipses, only the radii muft be unequal; the ellipses may be defcribed in any direction. See fig. 13.

PEN, or Penflock. See Penstock.

See Pen. See Penatula.

PENANCE, a punithment either voluntary or imposed by authority, for the faults a perfon has committed. Penance is one of the seven sacraments of the Romish church. Besides fasting, alms, abstinence, and the like, which are the general conditions of penance, there are others of a more particular kind; as the repeating a certain number of ave-marys, pater-nothers, and credos, wearing a hair-shirt, and giving one's self a certain number of stripes.

In Italy and Spain it is ufual to see Christians almost naked, loaded with chains and a crofs, and lashing themselves at every step.

PENATES, in Roman antiquity, a kind of tutelar deities, either of countries or particular houses; in which laft fente they differed in nothing from the lares. See Lakes.

The penates were properly the tutelar gods of the Trojans, and were only adopted by the Romans, who gave them the title of penates.

PENCIL, an instrument used by painters for laying on their colours. Pencils are of various kinds, and made of various materials; the largest forts are made of boar's bristles, the thick ends of which are bound to a ftick, bigger or lefs according to the uses they
Pencils, are designed for: these, when large, are called

The finer sorts of pencils are made of camels, badgers, and squirrels hair, and of the down of swans; these are tied at the upper end with a piece of strong thread, and inclosed in the barrel of a quill.

All good pencils, on being drawn between the lips, come to a fine point.

Pencils, is also an instrument used in drawing, writing, &c. made of long pieces of black-lead or red-chalk, placed in a groove cut in a flp of cedar; on which other pieces of cedar being glued, the whole is planed round, and one of the ends being cut to a point, it is fit for use.

Black-lead in fine powder, purred into moulds, unites with black-lead itself, and in such quantity, in virtue perhaps of its abounding with sulphur, that though the compound remains fluid enough to be poured into moulds, it looks nearly like the coarser phur, unites a mould, so as to serve for black-lead again, consisted in mixing with it sulphur or sulphureous bodies.

On this principle the German black-lead pencils are made to be used; and many of those which are hawked about by certain perons amongst us are prepared in the same manner: their melting or softening, when held to a candle, or applied to a red-hot iron, and yielding a bluish flame, with a strong smell like that of burning brimstone, betrays their composition; for black-lead itself yields no smell or fume, and fuffers no apparent alteration in that heat. Pencils made with such additions are of a very bad kind; they are hard, brittle, and do not cut or make a mark freely either on paper or wood, rather cutting or scratching them than leaving a coloured stroke.

The true English pencils (which Vogel in his mineral history, and some other foreign writers, imagine to be prepared also by melting the black-lead with some additional substances, and casting it into a mould) are formed of black-lead alone sawed into slips, which are fitted into a groove made in a piece of wood, and another slip of wood glued over them: the fairest wood, as cedar, is made choice of, that the pencil may be the easier cut; and a part at one end, too short to be conveniently used after the reft has been worn and cut away, is left unfilled with the black-lead: that there may be no waste of so valuable a commodity. These pencils are greatly preferable to the others, though seldom to perfect as could be wished, being accompanied with some degree of the fame incoherencies, and being very unequal in their quality, on account of different sorts of the mineral being fraudulently joined together in one pencil, the fore-part being commonly pretty good, and the reft of an inferior kind. Some, to avoid these imperfections, take the finer pieces of black-lead itself, which they saw into slips, and fix for use in part-rayons: this is doubtless the surest way of obtaining black-lead rayons, whose goodness can be depended on.

Pendant, an ornament hanging at the ear, frequently composed of diamonds, pearls, and other jewels.

Pendants, in heraldry, parts hanging down from the label, to the number of three, four, five, or six at most, resembling the drops in the Doric froze; when they are more than three, they must be specified in blazoning.

Pendants, of a Ship, are those funnels, or long colours, which are split and divided into two parts, ending in points, and hung at the head of masts, or at the yard-arm ends.

PENDENIS, in Cornwall, at the mouth of Fal-mouth haven, is a peninsula of a mile and a half in compass. On this Henry VIII erected a castle, opposite to that of St Maw's, which he likewise builded. It was fortified by Queen Elizabeth, and served then for the governor's house. It is one of the largest castles in Britain, and is built on a high rock. It is stronger by land than St Maw's, being regularly fortified, and having good outworks.

PENDULOUS, a term applied to any thing that bends or hangs downwards.

PENDULUM, a vibrating body suspended from a fixed point. For the history of this invention, see the article Clock.

The theory of the pendulum depends on the inclined plane. Hence, in order to understand the nature of the pendulum, it will be necessary to premise some of the properties of this plane; referring, however, to Inclined Planes, and Section VI. in the article Mechanics, for the demonstration.

I. Let AC (fig. 1.) be an inclined plane, AB its perpendicular height, and D any heavy body; then the force which impels the body D to descend along the inclined plane AC, is to the absolute force of gravity as the height of the plane AB is to its length AC; and the motion of the body will be uniformly accelerated.

II. The velocity acquired in any given time by a body descending on an inclined plane AC, is to the velocity acquired in the same time by a body falling freely and perpendicularly as the height of the plane AB to its length AC. The final velocities will be the same; the spaces described will be in the same ratio; and the times of description are as the spaces described.

III. If a body descend along several contiguous planes, AB, BC, CD, (fig. 2.) the final velocity, namely, that at the point D, will be equal to the final velocity in descending through the perpendicular AE, the perpendicular heights being equal. Hence, if these planes be supposed indefinitely short and numerous, they may be conceived to form a curve; and therefore the final velocity acquired by a body in descending through any curve AB, will be equal to the final velocity acquired in descending through the planes AB, BC, CD, or to that in descending through AE, the perpendicular heights being equal.

IV. If from the upper or lower extremity of the vertical diameter of a circle a cord be drawn, the time of descent along this cord will be equal to the time of descent through the vertical diameter; and therefore...
If a pendulum vibrates in the small arc of a circle, the time of one vibration is to the time of the pendulum, a body's falling perpendicularly through half the length of the pendulum as the circumference of a circle is to its diameter.

Let PE (fig. 5.) be the pendulum which describes the arch ANC in the time of one vibration; let PN be perpendicular to the horizon, and draw the cords AC, AN; take the arc EF infinitely small, and draw EFG, efg perpendicular to PN, or parallel to AC; describe the semicircle BGN, and draw ef g perpendicular to EG; now let t be time of describing through the diameter 2PN, or through the cord AN; then the velocities gained by falling through 2PN, and by the pendulum's describing through the arch AE, will be as √2PN and √BF; and the space described in the time t, after the fall through 2PN, is 4PN. But the times are as the spaces divided by the velocities.

Therefore $\frac{4PN}{\sqrt{2PN} \times 2\sqrt{2PN}} \times t = \frac{E e}{\sqrt{BF}},$ time of describing $E e = \frac{2\sqrt{2PN} \times BF}{\sqrt{2PN} \times 2\sqrt{2PN}}.$ But in the similar triangles PEF, Efr, and KGF, Ggs.

As PE=PN : EF : Ee : er = $\frac{PN \times E e}{\sqrt{BF}}$ and KG = KD : FG : Gs : $G = \frac{KD \times G s}{\sqrt{EF} \times \sqrt{FG}}$

But $er = G s = \frac{PN \times E e}{\sqrt{EF} \times \sqrt{FG}}$ Hence $E e = \frac{KD \times EF \times G s}{\sqrt{EF} \times \sqrt{FG}}.$

And by substituting this value of $E e$ in the former equation, we have the time of describing $E e = t \times PN \times G g.$

But by the nature of the circle FG = $\sqrt{BF} \times FN,$ and $EF = \sqrt{PN \times PF} \times FN.$

Hence, by substitution, we obtain the time of describing $t \times PN \times \sqrt{BF} \times FN \times G g.$

$E e = \frac{2KD \times EF \times \sqrt{BF} \times 2PN}{t \times PN \times G g}$

And $2KD \times \sqrt{PN \times PF} \times FN \times \sqrt{BF} \times 2PN = t \times PN \times G g = \frac{2KD \times \sqrt{PN \times PF} \times FN \times \sqrt{BF} \times 2PN}{t \times \sqrt{2PN \times G g}}$

$= \frac{2BD \times \sqrt{2PN} - NF \times G g}{t \times \sqrt{2PN} \times G g}$

But NF, in its mean quantity for all the arches $G g$ is nearly equal to NK; for if the semicircle described on the diameter BN, which corresponds to the whole arch $AN,$ be divided into an indefinite number of equal arches $G g,$ &c., the sum of all the lines NF will be equal to as many times NK as there are arches in the same circle equal to $G g$ and the time of describing $E e = \frac{2BN \times \sqrt{2PN} - NK}{2BN \times \sqrt{2PN} - NK} \times G g.$

Whence the time of describing the arch AED $t \times \sqrt{2PN} = \frac{2BN \times \sqrt{2PN} - NK}{2BN \times \sqrt{2PN} - NK} \times BGN;$ and the time of describing the whole arch ADC, or the time of one vibration, is $t \times \sqrt{2PN}$ $= \frac{2BN \times \sqrt{2PN} - NK}{2BN \times \sqrt{2PN} - NK} \times 2BGN.$ But when the arch ANC is very small, NK vanishes, and then
Pendulum, then the time of vibration in a very small arc is

\[
\frac{1}{2} x \sqrt{2 \cdot PN} = \frac{1}{2} \sqrt{2 \cdot BGN} = \frac{1}{2} \sqrt{2 \cdot PN}.
\]

be the time of descent through \(2 \cdot PN\); then since the spaces described are as the squares of the times, \(t\) will be the time of descent through \(PN\); therefore the diameter \(BN\) is to the circumference \(2 \cdot BGN\), as the time of falling through half the length of the pendulum is to the time of one vibration.

Prop. IV. The length of a pendulum vibrating seconds is twice the space through which a body falls in one second, as the square of the diameter of a circle is to the square of its circumference.

Let \(d\) be the time of falling through half the length of the pendulum. Let \(s\) be the space described by a body falling perpendicularly in the first second; then since the spaces described are in the subduplicate ratio of the times of description, therefore

\[
d = \sqrt{d^2} = \sqrt{s^2}.
\]

It has been found by experiment, that in latitude \(\phi\) a body falls about \(16.11\) feet in the first second; hence the length of a pendulum vibrating seconds in that latitude is

\[
\frac{22.22}{3.14159} = 3 \text{ feet} \; 3.174 \text{ inches}.
\]

Prop. V. The times of vibrations of two pendulums in similar arcs of circles are in a subduplicate ratio of the lengths of the pendulums.

Let \(PN, PO\) (fig. 6.) be two pendulums vibrating in the similar arcs \(AB, CD\); the time of a vibration of the pendulum \(PN\) is to the time of a vibration of the pendulum \(PO\) in a subduplicate ratio of \(PN\) to \(PO\).

Since the arcs \(AN, CO\) are similar and similarly placed, the time of descent through \(AN\) will be to the time of descent through \(CO\) in the subduplicate ratio of \(AN\) to \(CO\): but the times of descent through the arcs \(AN\) and \(CO\) are equal to half the times of vibration of the pendulums \(PN, PO\) respectively. Hence the time of vibration of the pendulum \(PN\) in the arc \(AB\) is to the time of vibration of the pendulum \(PO\) in the similar arc \(CD\) in the subduplicate ratio of \(AN\) to \(CO\): and since the radii \(PN, PO\) are proportional to the similar arcs \(AN, CO\), therefore the time of vibration of the pendulum \(PN\) will be to the time of vibration of the pendulum \(PO\) in a subduplicate ratio of \(PN\) to \(PO\).

If the length of a pendulum vibrating seconds be \(39.174\) inches, then the length of a pendulum vibrating half seconds will be \(9.793\) inches. For

\[
\frac{\sqrt{39.174}}{\sqrt{2} \cdot 39.174} = \frac{1}{2} \sqrt{2} = \frac{1}{2} \times 1.414 = \frac{1}{2} \times 1.414 = \frac{1}{2} \times 1.414 = 0.707.
\]

\[
x = \frac{1}{2} \times 0.707 = 0.354.
\]

Prop. VI. The lengths of pendulums vibrating in the same time, in different places, will be as the forces of gravity.

For the velocity generated in any given time is directly as the force of gravity, and inversely as the quantity of matter *. Now the matter being supposed the same in both pendulums, the velocity is as the force of gravity; and the space passed through in a given time will be as the velocity; that is, as the gravity.

Cor. Since the times of pendulums vibrating in the same time in small arcs are as the gravitating forces, and as gravity increases with the latitude on account of the spherical figure of the earth and its rotation about its axis; hence the length of a pendulum vibrating in a given time will be variable with the latitude, and the same pendulum will vibrate slower the nearer it is carried to the equator.

Prop. VII. The time of vibrations of pendulums of the same length, acted upon by different forces of gravity are reciprocally as the square roots of the forces.

For when the matter is given, the velocity is as the force and time; and the space described by any given force is as the force and square of the time. Hence the lengths of pendulums are as the forces and the squares of the times of falling through them. But these times are in a given ratio to the times of vibration; hence the lengths of pendulums are as the forces and the squares of the times of vibration. Therefore, when the lengths are given, the forces will be reciprocally as the square of the times, and the times of vibration reciprocally as the square roots of the forces.

Cor. Let \(p\) be the length of pendulum, \(g\) the force of gravity, and \(t\) the time of vibration. Then since \(p = g \times t^2\), and \(t = \sqrt{g/p}\),

\[
g \times t^2 = \sqrt{g/p}.
\]

That is, the forces in different places are directly as the lengths of the pendulums, and inversely as the square roots of the times of vibration; and the times of vibration are directly as the square roots of the lengths of the pendulums, and inversely as the square roots of the gravitating forces.

Prop. VIII. A pendulum which vibrates in the arch of a cycloid describes the greatest and least vibrations in the same time.

This property is demonstrated only on a supposition that the whole mass of the pendulum is concentrated in a point: but this cannot take place in any really vibrating body; and when the pendulum is of finite magnitude, there is no point given in position which determines the length of the pendulum; on the contrary the centre of oscillation will not occupy the same place in the given body, when describing different parts of the tract it moves through, but will continually be moved in respect of the pendulum itself during its vibration. This circumstance has prevented any general determination of the time of vibration in a cycloidal arc, except in the imaginary case referred to.

There are many other obstacles which concur in rendering the application of this curve to the vibration of pendulums designed for the measures, of time the source of errors far greater than those by which its peculiar property it is intended to obviate; and it is now wholly diluted in practice.

Although the times of vibration of a pendulum in
PENDULUM.

Different arches be nearly equal, yet from what has been said, it will appear, that, if the ratio of the height of these arches to the greatest be considerable, the vibrations will be performed in different times; and the difference, though finally, will become sensible in the course of one or more days. In clocks used for astronomical purposes, it will therefore be necessary to observe the arc of vibration; which if different from that described by the pendulum when the clock keeps time, there a correction must be applied to the time shown by the clock. This correction, expressed in seconds of time, will be equal to the half of three times the difference of the square of the given arc, and of that of the arc described by the pendulum when the clock keeps time, these arcs being expressed in degrees; and so much will the clock gain or lose according as the first of these arches is less or greater than the second.

Thus, if a clock keeps time when the pendulum vibrates in an arch of $3^\circ$, it will lose 10$\frac{2}{3}$ seconds daily in an arch of $4^\circ$.

For $3^\circ = 3 \times 360^\circ = 7 \times \frac{3}{4} = 10\times \frac{3}{4}$ seconds.

The length of a pendulum rod increases with heat, and the quantity of expansion answering to any given degree of heat is experimentally found by means of a thermometer, and the degree of heat at any given time is shown by a thermometer: hence that instrument should be placed within the clock-case at a height nearly equal to that of the middle of the pendulum, and its height, for this purpose, should be examined at least once a day. Now by a table constructed to exhibit the daily quantity of acceleration or retardation of the clock answering to every probable height of the thermometer, the corresponding correction may be obtained. It is also necessary to observe, that the mean height of the thermometer during the interval ought to be used. In Six's thermometer this height may be easily obtained; but in thermometers of the common construction it will be more difficult to find this mean.

It had been daily by repeated experiments, that a brass rod equal in length to a second pendulum will expand or contract $1^\circ$ part of an inch by a change of degree temperature of one degree in Fahrenheit's thermometer; and since the times of vibration are in a subduplicate ratio of the lengths of the pendulum, hence an expansion or contraction of $1^\circ$ part of an inch will answer nearly to one second daily: therefore a change of one degree in the thermometer will occasion a difference in the rate of the clock equal to one second daily. Whence, if the clock be so adjusted as to keep time when the thermometer is at $55^\circ$, it will lose 10 seconds daily when the thermometer is at $65^\circ$, and gain as much when it is at $45^\circ$.

Hence the daily variation of the rate of the clock from summer to winter will be very considerable. It is true indeed that most pendulums have a nut or regulator at the lower end, by which the bob may be raised or lowered a determinate quantity; and therefore, while the height of the thermometer is the same, the rate of the clock will be uniform. But since the state of the weather is ever variable, and as it is impossible to raising or lowering the bob of the pendulum at every change of the thermometer, therefore the correction formerly mentioned is to be applied. This correction, however, is in some measure liable to a small degree of uncertainty; and in order to avoid it pendulum, altogether, several contrivances have been proposed by constructing a pendulum of different materials, and so disposing them that their effects may be in opposite directions, and thereby counterbalance each other; and by this means the pendulum will continue of the same length.

Mercurial Pendulum. The first of these inventions is Mercurial that by the celebrated Mr George Graham. In this, the rod of the pendulum is a hollow tube, in which a sufficient quantity of mercury is put. Mr Graham first used a glass tube, and the clock to which it was applied was placed in the most exposed part of the house. It was kept continually going, without having the hands of pendulum altered, from the 9th of June 1723 to the 14th of October 1725, and its rate was determined by trials of fixed bars. Another clock made with extraordinary care, having a pendulum about 60 pounds weight, and not vibrating above one degree and a half from the perpendicular, was placed beside the former, in order the more readily to compare them with each other, and that they might both be equally exposed. The result of all the observations was this, that the irregularity of the clock with the quicksilver pendulum exceeded not, when greatest, a sixth part of that of the other clock with the common pendulum, but for the greatest part of the year not above an eighth or ninth part; and even this quantity would have been lessened, had the column of mercury been a little shorter: for it differed a little the contrary way from the other clock, going fuller with heat and flower with cold. To confirm this experiment more, about the beginning of July 1725 Mr Graham took off the heavy pendulum from the other clock, and made another with mercury, but with this difference, that instead of a glass tube he used a brass one, and varnished the inside to secure it from being injured by the mercury. This pendulum he used afterwards, and found it about the same degree of exactness as the other.

The Gridiron Pendulum is an ingenious contrivance for the same purpose. Instead of one rod, this pendulum is composed of any convenient odd number of rods, as five, seven, or nine; being so connected, that the effect of one set of them counteracts that of the other; and therefore, if they are properly adjusted to each other, the centres of suspension and oscillation will always be equidistant. Fig. 7 represents a gridiron pendulum composed of nine rods, fixed and braced alternately. The two outer rods, AB, CD, which are of steel, are fastened to the cross piece AC, BD by means of pins. The next two rods, EF, GH, are of brass, and are fastened to the lower bar BD, and to the second upper bar EG. The two following rods are of steel, and are fastened to the cross bars EG and IK. The two rods adjacent to the central rod of brass, are fastened to the cross pieces IK and LM; and the central rod, to which the ball of the pendulum is attached, is suspended from the cross piece LM, and passes freely through a perpend bar in each of the cross bars IK, BD. From this disposition of the rods, it is evident that, by the expansion of the extreme rods, the cross piece BD, and the two rods attached to it, will defend: but since those rods are expanded by the same heat, the cross piece BD will consequently...
Angular Pendulum.

Pendulum, if be raised and therefore also the two next rods; but because these rods are also expanded, the cross bar IK will descend; and by the expansion of the two next rods, the piece LM will be raised a quantity sufficient to counteract the expansion of the central rod. Whence it is obvious, that the effect of the steel rods is to increase the length of the pendulum in hot weather, and to diminish it in cold weather; and that the brass rods have a contrary effect upon the pendulum. The effect of the brass rods must, however, be equivalent not only to that of the steel rods, but also to the part above the frame and spring, which connects it with the cock, and to that part between the lower part of the frame and the centre of the ball.

M. Thiout

Another excellent contrivance for the same purpose is described in a French author on clock-making. It was used in the north of England by an ingenious artist about forty years ago. This invention is as follows: A bar of the same metal with a rod of the pendulum and of the same dimensions, is placed against the back part of the clock-case: from the top of this a part projects, to which the upper part of the pendulum is connected by two fine pliable chains or filk en stringings, which just below pass between two plates of brass, which lower ends will always make the length of the pendulum at the upper end. These plates are supported on a pedestal fixed to the back of the case. The bar rests upon an immovable base at the lower part of the case; and is inserted into a groove, by which it is always retained in the same position. From this construction, it is evident that the extension or contraction of this bar, and of the rod of the pendulum, will be equal, and in contrary directions. For suppose the rod of the pendulum to be expanded any given quantity by heat; then, as the lower end of the bar rests upon a fixed point, the bar will be expanded upwards, and raise the upper end of the pendulum just as much as its length was increased, and hence its length below the plates will be the same as before.

Of this pendulum, somewhat improved by Mr. Crosthwaite watch and clock-maker, Dublin, we have the following description in the Transactions of the Royal Irish Academy, 1778. - A and B (fig. 8.) are two rods of steel forged out of the same bar, at the same time, of the same temper, and in every respect familiar. On the top of B is formed a gibbet C; this rod is firmly supported by a steel bracket D, fixed on a large piece of marble E, firmly set into the wall F, and having liberty to move freely upwards between crosstables of brass, 1, 2, 3, 4, which touch only in a point in front and rear (the staples having been carefully formed for that purpose); to the other end is firmly fixed by its centre the lens G; of 24 pounds weight, although it should in strictness be a little below it. This pendulum is suspended by a short steel spring on the gibbet at C; all which is entirely independent of the clock. To the back of the clock-plate are firmly screwed two cheeks nearly cycloidal at K, exactly in a line with a centre of the verge L. The maintaining power is applied by a cylindrical steel Rod, in the usual way of regulators, at M. Now, it is very evident, that any expansion or contraction that takes place in either of these exactly similar rods, is instantly counteracted by the other: whereas in all composition pendulums composed of different materials, however just a calculation may seem to be, that can never be the case, as not only different metals, but also different bars of the same metal that are not manufactured at the same time, and exactly in the same manner, are found by a good pyrometer to differ materially in their degrees of expansion and contraction, a very small change affecting one and not the other.

The expansion or contraction of straight-grained fir is prejudicial to pendulum rods, but is much less injurious to wood length wise, by change of temperature, is so small that it is found to make very good pendulum rods. The wood called *spiculito* is said to be still better. There is good reason to believe, that the previous baking, varnishing, gilding, or soaking of these woods in any melted matter, only tends to impair the property that renders them valuable. They should be simply rubbed on the outside with wax and a cloth. In pendulums of this construction the error is greatly diminished, but not taken away.

Angular Pendulum, is formed of two pieces or legs angular like a sector, and is suspended by the angular point, Pendulum. This pendulum was invented with a view to diminish the length of the common pendulum, but at the same time to preserve or even increase the time of vibration. In this pendulum, the time of vibration depends on the length of the legs, and on the angle contained between them conjointly, the duration of the time of vibration increasing with the angle. Hence a pendulum of this construction may be made to oscillate in any given time. At the lower extremity of each leg of the pendulum is a ball or bob as usual. It may be easily shown, that in this kind of pendulum, the figures of the times of vibration are as the seconds of half the angle contained by the legs: hence if a pendulum of this construction vibrates half seconds when its legs are close it will vibrate whole seconds when the legs are opened, so as to contain an angle equal to 121° 24'.

The Conical or Circular Pendulum, is so called from the figure described by the string or ball of the pendulum. This pendulum was invented by Mr. Huygens, and is also claimed by Dr. Hook.

In order to understand the principles of this pendulum Conical, it will be necessary to premise the following Lemma.

*Lemma* 1. If a pendulum, the heavy globular body, revolving within an inverted hollow paraboloid, will be equal whatever be the radii of the circles described by that body.

In order therefore, to construct the pendulum so that its ball may always describe its revolutions in a paraboloid surface, it will be necessary that the rod of the pendulum be flexible, and that it be suspended in such a manner as to form the evolute of the given paraboloid. Hence, let KH (fig. 9.) be an axis perpendicular to the horizon, having a pinion at K moved by the shaft wheel in the train of the clock; and a hardened steel point at H moving in an agate pivot, to render the motion as free as possible. Now, let it be required that the pendulum shall perform each revolution in a second, then the paraboloid surface it moves in must be such whose latus rectum is double the length of the common half second pendulum. Let O be the focus of the paraboloid MEC, and MC, the latus rectum; and make $AE=MO=MC$ the length of a common half second pendulum. At the point A of the verge, let a thin plate $AB$ be fixed at one end, and at the other end $B$ let it be fastened to the bar or arm $BD$ perpendi-
The pendulum is perpendicular to DH, and to which it is fixed at the point D. The figure of the plate AB is that of the evolute of the parabola MEC.

The equation of this evolute, being also that of the semicubical parabola, is \( \frac{27}{16} x^2 = y^3 \). Let \( \frac{27}{16} = P \); then \( P \sqrt{\frac{16}{x^2}} = y \), and in the focus \( P = 2y \). In this case

\[
\sqrt{\frac{16}{t^2}} = \text{the distance of the focus from the vertex A.}
\]

By affuming the value of \( x \), the ordinates of the curve may be found; and hence it may be easily drawn.

The string of the pendulum must be such a length that when one end is fixed at B, it may lie over the plate AB, and then hang perpendicular from it, so that the centre of the bob may be at E when at rest.

Now, if the verge KH being put in motion, the ball of the pendulum will begin to gyrate, and thereby conceive a centrifugal force which will carry it out from the axis to some point F, where it will circulate seconds or half seconds, according as the line AE is 89, inches, or \( \frac{1}{2} \) inches, and AN answerable to it.

One advantage possessed by a clock having a pendulum of this constitution is, that the second hand moves in a regular and uniform manner, without being subject to those jerks or starts as in common clocks; and the pendulum is entirely silent.

Theory has painted out several other pendulums, known by the names of Elliptic, Horizontal, Rectangular, \&c. pendulums. These, however, have not as yet attained that degree of perfection as to supplant the common pendulum.

Besides the use of the pendulum in measuring time, it has also been suggested to be a proper standard for measures of length. See the article MEASURE.

PENEAS, in botany: A genus of the monogynia order, belonging to the tetrandra class of plants; and in the natural method ranking with those of which the order is doubtful. The calyx is diphylous; the corolla campanulated; the style quadrangular; the capsule tetragonal, quadrilocular, and obovate.

PENELOPE, in fabulous history, the daughter of Learns, married Ulysses by whom she had Telemaechus. During the absence of Ulysses, who was gone to the siege of Troy, and who lived 20 years from his dominions, several princes, charmed with Penelope's beauty, told her that Ulysses was dead, offered to marry her, and pressed her to declare in their favour. She promised compliance on condition they would give her time to finish a piece of tapestry she was weaving; but at the same time she said in the night what she had done in the day, and by this artifice eluded their importunity till Ulysses's return.

PENELOPE, in ornithology: A genus of birds of the order of Gallina, the characters of which are: The beak is bare at the base; the head is covered with feathers: the neck is quite bare; the tail consists of twelve principal feathers; and the feet are for the most part bare. Linnæus, in the Systema Naturæ, enumerates six species. 1. Meleagris gallopavo, or horned pheasant. Latham calls it the horned turkey. This species is larger than a fowl, and smaller than a turkey. The colour of the bill is brown; the nostrils, forehead, and space round the eyes, are covered with slender black hairy feathers; the top of the head is red. Behind each eye there is a fleshy callous blue substance like a horn, which tends backward. On the fore part of the neck and throat, there is a loose flap of a fine blue colour, marked with orange spots, the lower part of which is becketed with a few hairs; down the middle it is somewhat looser than on the sides, being wrinkled. The breast and upper part of the back are of a full red colour. The neck and breast are inclined to yellow. Some of the plumage and tail are of a rufous brown marked all over with white spots, encompassed with black. The legs are somewhat white, and furnished with a spur behind each. A head of this kind, Mr. Latham tells us, was sent to Dr. Mead from Bengal, together with a drawing of the bird, which was called napaul phasianus. It is a native of Bengal.

2. The meleagris cristata, called by Ray penelope, auro-pene, and by Edwards the guan, or guan, is about the size of a fowl, being about two feet six inches long. - The bill is two inches long, and of a black colour; the irides are of a dirty orange colour; the sides of the head are covered with a naked purplish blue skin, in which the eyes are placed: beneath the throat, for an inch and a half, the skin is loose, of a fine red colour, and covered only with a few hairs. The tip of the head is furnished with long feathers, which the bird can erect as a crest at pleasure; the general colour of the plumage is brownish black, glossed over with copper in some lights, but the wing covert has a greenish and violet gloss. The quills are mostly inclining to a purple colour; the fore-part of the neck, breast, and belly, are marked with white spots; the thighs, under tail coverts, and the tail itself, are brownish black, the legs are red; the claws black. Some of these birds have little or no crest, and are thence supposed to be females. - They inhabit Brazil and Guiana, where they are often seen on trees. It frequently makes a noise not unlike the word jaeu. Their flesh is much esteemed.

3. Crax Campanus, called by Latham, &c. yacou. It is bigger than a common fowl. The bill is black; the head feathers are long, pointed, and form a crest, which can be erected at pleasure. The irides are of a pale rufous colour: the space round the eyes is naked, similar to that of a turkey. It has also a naked membrane, or kind of wattles, of a dull black colour. - The blue skin comes forward on the bill but is not liable to change colour like that of the turkey. The plumage has no much variation; it is chiefly brown, with some white markings on the neck, breast, wing coverts, and belly; the tail is composed of twelve feathers, pretty long, and even at the end; the legs are red. This species inhabits Cayenne, but is a very rare bird, being met with only in the inner parts, or about the Amazon's country, though in much greater plenty up the river Oyapoc, especially towards Camopi; and indeed those which are seen at Cayenne are mostly tame ones, for it is a familiar bird, and will breed in that state, and mix with other poultry. It makes the neft on the ground, and hatches the young there; but is at other times moftly seen on trees. It frequently creeds the crest, when pleased, or taken notice of, and likewise spreads the tail upright like a fan, in the manner of the turkey. It has two kinds of cry; one like
that of a young turkey, the other lower and more plaintive; the first of these is thought by the Indians to express the word crowedit, the other yacou.

4. The pipe$, or as it is called, ecras pige$, is black in the belly, and the back brown stained with black. The flesh on the neck is of a green colour. It is about the bigness of the former, and has a diving medicine$.

The head is partly black and partly white, and is adorned with a short crest. The space about the eyes, which are black, is white; the feet are red. It inhabits Guiana.

5. The marail is about the size of a fowl, and shaped somewhat like it. The bill and irides are blackish; the space round the eyes is bare, and of a pale red; the chin, throat, and fore part of the neck, are scarcely covered with feathers; but the throat itself is bare, and the membrane elongated to half an inch or more; both this and the skin round the eyes change colour, and become deeper and thicker when the bird is irritated. The head feathers are longish, so as to appear like a crest when ruffled up, which the bird often does when agitated; at which time it also crefts those of the whole body, and so disfigures itself as to be scarce known: the general colour of the plumage is a greenish black; the fore-part of the neck is tipped with white; the wings are short; the tail is long, consisting of 12 feathers, which are even at the end, and commonly pendent, but can be lifted up and spread out like that of the turkey; the legs and toes are of a bright red; the claws are crooked, and somewhat sharp. In a collection (says Latham) from Cayenne was a bird, I believe, of this very species. It was 28 inches long, the bill is like that of a fowl, brown, and rather hooked; round the eye bare; the head is crested; the feathers of the fore-part of the neck are tipped with white; the breast and belly are rufous brown; the rest of the plumage is greenish brown; the tail is 11 inches long, and rounded at the end: the quills just reach beyond the rump; the legs are brown, and claws hooked. This species is common in the woods of Guiana, at a distance from the sea, though it is much less known than could be imagined; and found, in small flocks for the most part, except in breeding time when it is only seen by pairs, and then frequently on the ground, or on low bushes; at other times on high trees, where it roosts at night.

The female makes her nest on some low bushy tree, as near the trunk as possible, and lays three or four eggs. When the young are hatched, they defend with their mother, after 10 or 12 days. The mother acts as other fowls scratching on the ground like a hen, and brooding the young, which quit their nest the moment they can shift for themselves. They have two broods in a year; one in December or January, the other in May or June. The belt time of finding these birds is morning or evening, being then met with on such trees whose fruit they feed on, and are discovered by some of it falling to the ground. The young birds are easily tamed, and seldom forsake the places where they have been brought up: they need not be houset, as they prefer the roosting on tall trees to any other place. Their cry is not inharmonious, except when irritated or wounded, when it is harsh and loud. Their flesh is much esteemed.

Bunham supposes this bird to be the female of the yacou, or at least a variety; but that this cannot be, the anatomical inspection will at once determine. The windpipe of this bird has a singular construction, passing along the neck to the entrance of the breast, where it rises on the outside of the flesh, and, after going a little way downwards, returns, and then passes into the cavity of the lungs. It is kept in its place on the outside by a muscular ligament, which is perceptible quite to the breast bone. This is found to be the case in both male and female, and plainly proves that it differs from the yacou, whose windpipe has no such circumvolution in either sex.

If this be the bird mentioned by Fermor, in his History of Guiana, p. 176. he says that the crest is cuneiform, and of a black and white colour; and observes that they are scarce at Surinam; but it does not seem quite certain whether he means this species or the yacou.

Bancroft mentions a bird of Guiana by the name of Marmole, which he says is wholly of a brownish black: the bill the same; and the legs grey. Thence, he says, are common, and make a noise not unlike the name given it, perching on trees. The Indians imitate their cry as exactly, as to lead to the discovery of the place the birds are in, by their answering it. The flesh of them is like that of a fowl: it is therefore most likely the marail.

6. The vociferating penelope. The bill of this bird is of a greenish colour; the back is brown, the breast green, and the belly is of a whitish brown. Latham calls it the crying curaffaw. It is about the bigness of a crow.

PENEOSTICA, (Antonine), a town of the Helvetii, situated between the Lacus Laufonius and Salodurum; called Petenfca by Peutinger. Thought now to be Briel, (Cluverius); the capital of a small territory in Switzerland.

PENEUS, (Strabo); a river running through the middle of Thessaly, from west to east, into the Sinus Thermaicus, between Olympus and Offa, near Tempa of Thefaly, rising in mount Pindus, (Ovid, Val. Flaccus).

PENETRAlE, a facred room or chapel in private houses, which was fet apart for the worship of the household gods among the ancient Romans. In temples also there were penelrea, or apartments of distinguished sanctity, where the images of the gods were kept, and certain solemn ceremonies performed.

PENGUIN, or PINGUIN. See PINGUIN.

PENCILLUS, among surgeons is used for a tent to be put into wounds or ulcers.

PENIEL, or PENHEL, a city beyond Jordan near the ford of the brook Jabbok. This was the occasion of its name. Jacob, upon his return from Mesopotamia, (Gen. xxxii. 24, &c.) made a stop at the brook Jabbok: and very early the next morning, after he had sent all the people before, he remained alone, and beheld an angel came, and wrestled with him till the day began to appear. Then the angel said to Jacob, Let me go for the morning begins to appear. Jacob answered, I shall not let you go from me till you have given me your blessing. The angel blessed him then in the same place, which Jacob thence called Peniel, saying, I have seen God face to face, yet continue alive.

In following ages the Israelites built a city in this place, which was given to the tribe of Gad. Gideon, returning

Penitent.

Penitent.

Penitents of penitents distinguished by the different shape and colour of their habits. These are secular societies who have their rules, statutes, and churches, and make public processions under their particular crosses or banners. Of these, there are more than a hundred, the most considerable of which are as follows: the white penitents of which there are several different forts at Rome, the most ancient of which was constituted in 1264; the brethren of this fraternity every year give portions to a certain number of young girls in order to their being married: their habit is a kind of white fackcloth, and on the shoulder is a circle, in the middle of which is a red and white cross. Black penitents the most considerable of which are the brethren of mercy, instituted in 1488 by some Florentines, in order to afflict criminals during their imprisonment, and at the time of their death; on the day of execution, they walk in procession before them, flogging the seven penitential psalms and the litanies; and after they are dead, they take them down from the gibbet and burn them; their habit is black fackcloth. There are others whose business is to bury such persons as are found dead in the streets; these wear a death's head on one side of their habit. There are also blue, grey, red, green, and violet penitents; all which are remarkable for little else besides the different colours of their habits.

Mabillon tells us, that at Turin there are a set of penitents kept in pay to walk through the streets in procession, and cut their shoulders with whips, &c.

Penitents of Convicts of the name of Jifus, a congregation of religious at Seville in Spain, consisting of women who had led a licentious life, founded in 1550. This monastery is divided into three quarters: one for professed religious; another for novices; a third for those who are under correction. When these last give signs of a real repentance, they are removed into the quarter of the novices, where, if they do not behave themselves well, they are remanded to their correction. They observe the rule of St. Augustine.

Penitents of Orvieto, are an order of nuns, instituted by Antony Simoncelli, a gentleman of Orvieto in Italy. The monastery he built was at first designed for the reception of poor girls, abandoned by their parents, and in danger of losing their virtue. In 1662 it was erected into a monastery, for the reception of such as having abandoned themselves to impurity, were willing to take up, and consecrate themselves to God by solemn vows. Their rule is that of the Carmelites. These religious have this in peculiar, that they undergo no novitiate. All required is, that they continue a few months in the monastery in a secular habit; after which they are admitted to the vows.

Penitentiary, an ecclesiastical book retained among the Romanists; in which is prescribed what relates to the imposition of penance and the reconciliation of penitents. See Penance.

There are various penitentials, as the Roman penitentiary, that of the venerable Bede, that of Pope Gregory III., &c.
Penitentiary

Penitentiary, at the court of Rome, is an office in which are examined and delivered out the secret bulls, graces, or dispensations relating to cases of conscience, confessions, &c.

Penitentiary, is also an officer in some cathedrals, vested with power from the bishop to absolve, in cases referred to him. The pope has at present his grand penitentiary, who is a cardinal, and the chief of the other penitentiary priets established in the church or Rome, who consiult him in difficult cases. He presides in the penitentiary, dispatches dispensations, absolutions, &c. and has under him a regent and 24 proctors, or advocates of the sacred penitentiary.

PENMAN-MAVR, a mountain in Caernarvonshire, 1400 feet high. It hangs perpendicularly over the sea, at so vast a height, that few spectators are able to look down the dreadful deep. On the side which is next the sea, there is a road cut out of the side of the rock, about six or seven feet wide, which winds up a steep ascent, and used to be defended on one side only by a wall built in some parts about a yard high, and in others by only a bank, that scarce rose a foot above the road. The sea was seen defiance its wave: 40 fathoms below, with the mountain rising as much above the traveller's head. This dangerous road was a few years ago secured by a wall built high, to the building of which the city of Dublin largely contributed, it being in the High road to Holyhead.

PENN (Sir William), was born at Bristol in 1621, and inclined from his youth to maritime affairs. He was made captain at 21 years of age, rear-admiral of Ireland at 23, vice-admiral at 25, admiral of Ireland to the Straits at 29, vice-admiral of England at 31, and General in the first Dutch war at 32. Whence returning in 1655, he was chosen representative for the town of Weymouth; and in 1660 was made commissioneer of the admiralty and navy, governor of the town and fort of Kinsale, vice-admiral of Munster, and a member of that provincial council. In 1664 he was chosen great captain-commander under the duke of York, and distinguished himself in an engagement against the Dutch fleet; after which he took leave of the sea, but continued in his other employments till 1669. He died in 1670.

Penn (William), an eminent writer among the Quakers, and the planter and legislator of Pennsylvania, was the son of the above Sir William Penn, and was born at London in 1644. In 1660, he was entered a gentleman-commoner of Christ-church, in Oxford; but having before received an impression from the preaching of one Thomas Lee a Quaker, withdrew with his other students from the national worship, and held private meetings, where they preached and prayed among themselves. This, owing great offence to the heads of the college, Mr Penn, though but 16 years of age, was fined for nonconformity; and continuing his religious exercise, was at length expelled his college. Upon his return home, he was, on the same account, treated with great severity by his father, who at last turned him out of doors; but his repentment afterwards abating, he sent him to France in company with some persons of quality; where he continued a considerable time, and returned not only well skilled in the French language, but a polite and accomplished gentleman. About the year 1666, his father committed to his care a considerable estate in Ireland. Being found in one of the Quaker meetings in Cork, he, with many others was thrown into prison; but, on his writing to the earl of Orrery, was soon discharged. However, his father being informed he still adhered to his opinions, sent him to England, and finding him inflexible to all his arguments, turned him out of doors a second time. About the year 1668, he became a public preacher among the Quakers: and that year was committed close prisoner to the Tower, where he wrote several treatises. Being discharged after seven months imprisonment, he went to Ireland, where he also preached amongst the Quakers. Returning to England, he was in 1670 committed to Newgate, for preaching in Gracechurch street meeting-house, London; but being tried at the sessions-house in Old Bailey, he was acquitted. In September the same year, his father died; and being perfectly reconciled to him, left him both his paternal blessing and a plentiful estate. But his persecutions were not yet at an end: for in 1671 he was committed to Newgate for preaching at a meeting in a Wheeler-street, London; and during his imprisonment, which continued six months, he also wrote several treatises. After his discharge, he went into Holland and Germany; and in the beginning of the year 1672, married and settled with his family at Rickmanworth in Hertfordshire. The same year he published several pieces; and particularly one against Reeve and Muggleton. In 1677, he again travelled into Holland and Germany in order to propagate his opinions: and had frequent conversations, with the princes Elizabeth, daughter to the queen of Bohemia and sister to the princess Sophia, mother to king Geo. I. In 1681, king Charles IL, in consideration of the services of Mr Penn's father, and several debts due to him from the crown at the time of his decease, granted Mr Penn and his heirs the province lying on the west side of the river Delaware in North America, which from thence obtained the name of Pennsylvania. Upon this Mr Penn published a brief account of that province, with the king's patent; and proposing an easy purchase of land, and good terms of settlement for such as were inclined to remove thither, many went over. These having made and improved their plantations to good advantage, the governor, in order to secure the planters from the native Indians, appointed commissioners to purchase the land he had received, from the king of the native Indians, and concluded a peace with them. The city of Philadelphia was planned and built; and he himself drew up the fundamental constitutions of Pennsylvania in 24 articles. In 1681, he was elected a member of the Royal Society, and the next year embarked for Pennsylvania, where he continued about two years and returned to England in August 1684. Upon the accession of King James to the throne, he was taken into a great degree of favour with his Majesty, which exposed him to the imputation of being a Papist; but from which he fully vindicated himself. However, upon the Revolution, he was examined before the council in 1688, and obliged to give security for his appearance on the first day of next term, which was afterwards continued. He was several times discharged.
charged and examined; and at length warrants being
issued out against him, he was obliged to conceal him-
selt for two or three years. Being at last permitted to
appear before the king and council, he represented his
innocence so effectually that he was acquitted. In Au-
t. 1699, he, with his wife and family, embarked for
Pennsylvania; whence he returned in 1701, in order to
vindicate his proprietary right, which had been attack-
ded during his absence. Upon Queen Anne’s accession
to the crown, he was in great favour with her, and was
often at court. But in 1707, he was involved in a law-
suit with the executors of a person who had been for-
merly his received: and though many thought him
ag-
grieved, the court of chancery did not think proper to
relieve him; upon which account he was obliged to live
within the rules of the Fleet for several months, till
the matter in dispute was accommodated. He died in
1718.

At one period of his life, Mr Penn lodged in a house
in Norfolk-street in the Strand. In the entrance to it
he had a peeping-hole, through which he could see
any person that came to him. A creditor one day
sent in his name, and having been made to wait more
than a reasonable time, he knocked for the servant
whom he asked, “Will not thy master see me?”
“Friend (answered the servant) he has been thee, but
he does not like thee.”

Mr Penn’s friendly and pacific manner of treating
the Indians produced in them an extraordinary love
for him and his people; so that they have maintained
a perfect amity with the Quakers in Pennsylvania ever
since. He was the greatest bulwark of the Quakers,
in whose defence he wrote numberless pieces. Besides
the above works, he wrote a great number of
others of which are,

1. His primitive Christianity revived. 2. His defence of a paper, inti-
tiled "Gospel Truths against the Exceptions of the Bi-

His Good advice to the Church of England, Ro-
man Catholic, and Protestant Differenters. 5. The Sandy
Foundation shaken. 6. No Cross, no Crown. 7. The
great Case of Liberty of Conscience debated. 8. The
Christian Quaker and his Testimony stated and vind-
cated. 9. A discourse on the general rule of Faith
and Practice, and Judge of Controversy. 10. Eng-
land’s present Interest considered. 11. An Address
to Protestants. 12. His Reflections and Maxims
13. His advice to his Children. 14. His Rise and
Progress of the People called Quakers. 15. A Treat-
ise on Oaths. Most of these have passed several ed-
tions, some of them many. The letters between Wil-
liam Penn and Dr Tillotson, and William Penn and
William Pople, Esq.; together with Penn’s letters to
the princes Elizabeth of the Rhine, and the coun-
tefs of Hornes, as also one to his wife on his going to
Pennsylvania, are inserted in his works, which were first
printed in 3 folio vol.; and the parts fine printed and abridged into 1 vol folio, are very
much and deservedly admired for the good sense they
contain.

PENNATULA, or Sea-Pen, in natural history, a
genus of zoophytes, which, though it swarms about
freely in the sea, approaches near to the gorgonia.
This genus hath a bone along the middle of the in-
side, which is its chief support; and this bone re-
Peels the supply of its 10aceous matter by the same
Polype mouthes that furnish it with nourishment.
Linnaeus reckons seven species. The name zoophytes
under which this genus is ranked, is well known sig-
nificantly, that the creature partakes of both the animal
and vegetable nature; but some have supposed it to be
nothing more but a focus or sea plant. It is cer-
tainly an animal, however, and as such is free or loco-
motive. Its body generally expands into processes on
the upper parts, and these processes or branches are
furnished with rows of tubular denticles; they have a
polype head proceeding from each tube.

The Sea-Pen is not a coraline, but distinguished
from it by this specific difference, corals, corallines,
aleomaria, and all that order of beings, adhere simply
by their bases to submarine substances, but the sea-
pen, either swims about in the water or floats upon
the surface.

The Honourable Dr Coote Moleworth lately lent
one of these animals to the ingenious Mr Ellis, the
author of many curious papers on the nature of cora-
llines, which was taken in a trawl to 72 fathoms water,
the same species are frequently found in the ocean from the coast
of Norway to the Mediterranean sea, sometimes at con-
derable depths, and sometimes floating on the surface.
Mr Ellis’s description of that sent him by Dr Mole-
worth is as follows:

Its general appearance greatly resembles that of a quill
feather of a bird’s wing (See Plate CCCCXXXVIII, fig. 1.) it is about four inches long, and of a reddish
colour; along the back there is a groove from the quill
part to the extremity of the feathered part, as there is
in a pen; the feathered part consists of fins proceeding
from the same, as expressed in the figure. The fins
move the animal backward and forward in the water,
and are furnished with suckers or mouths armed with
filaments, which appear magnified as fig. 2. There is
no perforation at the bottom, and therefore Mr Ellis is
of opinion that the exuvia of the animals upon which it
feeds are discharged by the same aperture at which the
food is taken in; and in this it is not singular, Nature
having observed the fame economy in the Greenland
polype, described by Mr Ellis in his Essay on Coral
lines. Each sucker has eight filaments, which are
protruded when prey is to be caught; but at other
times they are drawn back into their cases, which
are furnished at the end with spicula, that close together
round the entrance, and defend this tender part from
external injuries.

Dr Bohadish, of Prague, had an opportunity of ob-
serving one of these animals alive in the water, and
he gives the following account of what he saw: “A
portion of the item contracted, and became of a strong
purple colour, fo as to have the appearance of a ligat-
ure round it: this apparent ligature, or zone, moved
upwards and downwards successively through the
whole length of the item, as well the feathered as the
naked part; it began at the bottom, and moving up-
wards to the other extremity, it there disappeared,
and at the same instant appeared again at the bottom,
and ascended as before; but as it ascended through the
feathered or pinnated part, it became paler. When
this zone is much constricted, the trunk above it
swells and acquires the form of an onion; the con-
striction
Pennatula. Friction of the trunk gives the colour to the zone, for the intermediate parts are paler in proportion as the zone becomes deeper. The end of the naked trunk is sometimes curved like a hook; and at its extremity there is a finus or chink, which grows deeper while the purple ring is ascending, and shallower as it is coming down. The fins have four motions, upward and downward, and backward and forward, from right to left, and from left to right. The feathery filaments, or claws, move in all directions; and with the cylindrical part from which they proceed are sometimes protruded from the fins, and sometimes hidden with them.

Upon dissecting this animal the following phenomena were discovered. When the trunk was opened lengthwise, a saltish liquor flowed out of it, fo viscous as to hang down an inch. The whole trunk of the item was found to be hollow, the outward membrane being very strong, and about a tenth part of an inch thick: within this membrane appeared another much thinner; and between these two membranes, in the pinnated part of the trunk, innumerable little yellowish eggs, about the size of a white poppy seed, were seen floating in a whitish liquor; about three parts of the cavity within the inner membrane is filled by a kind of yellowish bone: this bone is about two inches and an half long, and one twentieth of an inch thick; in the middle it is four square, but towards the ends it grows round and very taper, that end being finest which is next the pinnated part of the trunk. This bone is covered in its whole length with a clear yellowish skin, which at each end runs out into a ligament; one is inserted in the top of the pinnated trunk, and the other in the top of the naked trunk: by the help of the upper ligament the end of the bone is either bent into an arch, or dilated in a straight line. The fins are composed of two skins; the outward one is strong and leathery, and covered over with an infinite number of crimson streaks; the inner skin is thin and transparent: the suckers are also in the same manner composed of two skins, but the outward skin is something finer. Both the fins and suckers are hollow, so that the cavity of the suckers may communicate with those of the fins, as the cavity of the fins does with that of the trunk.

Dr Shaw, in the History of Algiers, says, that these animals are so luminous in the water, that in the night the fishermen discover fishes swimming about in various depth of the sea by the light they give: From this extraordinary quality Linnaeus calls this species of the sea pen, Pennatula phosphorea, and remarks, after giving the synonyms of other authors, Habitat in oceano fundum illuminans.

There are other kinds of sea-pens, or species of this animal, which have not a resemblance to a pen. There is the kidney shaped sea pen (see fig. 3), the feather of the peacock fin (see fig. 4), the penatula filosa of Linnaeus (see fig. 5), his penatula retigata (see fig. 6), his penatula mirabilis (see fig. 7), and the finger-shaped sea pen (see fig. 8). The kidney shaped sea pen was discovered some time ago on the coast of South Carolina, and sent to Mr Ellis by John Gregg, Esq: of Charlestown. It is of a fine purple colour; the kidney part is about an inch from end to end, and about half an inch wide in the narrowest part; a tail proceeds from the middle of the body, which is roundish, and about an inch long; it is also full of rings like an earth-worm, and along the middle both of the upper and under part of it there is a small groove which runs from one end to the other, but there is no perforation at either extremity. The upper part of the body is convex, and about an inch thick; the whole surface is covered with small yellow starry openings, through which little suckers are protruded, each furnished with fix tentaculas, or filaments, like what are observed on some corals; the under part of the body is quite flat, and is full of ramifications of feathery fibres, which proceeding from the termination of the tail, as a common centre, branch out so as to communicate with the starry openings on the exterior edge and upper surface of the animal. Of all the penatulae yet known the feather shaped one, or as it is called the siluer sea pen (see fig. 1), is the largest as well as the most specious in its appearance. It is of a beautiful silver white, elegantly frizzled on each of the feather-like processes with lines or streaks of the deepest black. It is very rare, and is a native of the Indian seas. There is a very fine specimen of this species in the British Museum.

PENNI (Giovanni Francischi), born at Florence in 1488, was the disciple of Raphael, who observing his genius and integrity, intrusted his domestic concerns entirely to his management; by which means he got the appellation of il fature, or the "favorid," which he retained ever after. The genius of Penni was universal; but his greatest pleasure was in painting landscapes and buildings: he was an excellent designer, and coloured extremely well in oil, distemper, and trefco. He painted portraits in an exquisite style; and had such happy natural talents, that Raphael left him heir to his fortune in partnership with Julius Romano his fellow-disciple. After Raphael's death, Penni painted many pictures at Rome, particularly in the palace of Chigi, so exactly in the style of his master, that they might not underduly have been imputed to him: he finished, in conjunction with Julio and Pierino del Vaga, the celebrated designs of the battles of Constatine, and others which Raphael had left imperfect; but differing with them about a copy of the transfiguration, which the pope intended for the king of France, they separated. Penni went to Naples; but the air of that country, disagreeing with his constitution, he died soon after in 1528. He had a brother called Luca, Penni, who worked at Genoa and other parts of Italy in conjunction with Pierino del Vaga, who married his sister; he went thence to England, where he worked for Henry VIII. and for several merchants; was employed by Francis I. at Fountainbleau; but at last quitted the pencil and devoted himself to engraving.

PENNY, or Penny, in commerce, an ancient English coin, which had formerly considerable course; but is now generally dwindled into an imaginary money, or money of account. Camden derives the word from the Latin pennis, "money."

The ancient English penny, penig, or pening, was the first silver coin struck in England; nay, and the only one current among our Saxon ancestors; as is agreed by Camden, Spelman, Dr Hicks, &c.

The penny was equal in weight to our three-pence; five of them made one shilling, or shilling Saxon; so a mark or mancuse, equal to our 7½ d.

Till the time of King Edw. I. the penny was struck with a cross so deeply indented in it, that it might be easily
PEN [ 128 ]

PENROSE (Thomas), was the son of the Reverend Mr Penrose, rector of Newbury, Berks, a man of high character and abilities, descended from an ancient Cornish family, beloved and respected by all who knew him. Mr Penrose, jun. being intended for the church, pursued his studies with success, at Christ-church, Oxon, until the summer of 1762, when he moved to the naval and military line overpowering his attachment to his real interest, he left his college, and embarked in the unfortunate expedition against Nova Colonia, in South America, under the command of Captain Macnamara. The issue was fatal. The Clive (the largest vessel) was burnt; and though the Ambuscade escaped (on board of which Mr Penrose, acting as lieutenant of marines, was wounded), yet the hardships which he afterwards sustained in a prize vessel, in which he was stationed, utterly ruined his constitution. Returning to England with ample testimonials of his gallantry and good behaviour, he finished, at Hertford College Oxon, his course of studies; and having taken orders accepted the curacy of Newbury, the income of which, by the voluntary subscription of the inhabitants, was considerably augmented. After he had continued in that station about nine years, it seemed as if the clouds of disappointment, which had hitherto overshadowed his prospects, and tinctured his poetical essays with gloom, were clearing away; for he was then presented by a friend, who knew his worth and honoured his abilities, to a living worth near 500 l. per annum. It came, however, too late; for the state of Mr Penrose's health was now such as left little hope except in the abstinence of the waters of Brtilt. Thither he went; and there he died in 1779, aged 36 years. In 1768 he married Miss Mary Slocock of Newbury, by whom he had one child, Thomas, who was educated at Winton College.

Mr Penrose was respected for his extensive erudition, admired for his eloquence, and equally beloved and esteemed for his social qualities. By the poor towards whom he was liberal to his utmost ability, he was venerated to the highest degree. In oratory and composition his talents were great. His pencil was ready as his pen, and on subjects of humour had uncommon merit. To his poetical abilities the public, by their recep-
PEN [ 129 ]

reception of his Flights of Fancy, &c. have given a favourable testimony. To sum up the whole, his figure and address were as pleasing as his mind was ornamented.

PENRYN, a town of Cornwall, in England, seated on a hill at the entrance of Falmouth-haven by Pen-dennis castle. It consists of about 300 houses; and the streets are broad and well paved. There are so many gardens and orchards in it, that it refembles very much a town in a wood. It is well watered with rivulets, and has an arm of the sea on each side of it, with a good cullomhouse and quay, and other neat buildings. It drives a considerable trade in pilchards, and in the Newfoundland fishery. It was anciently governed by a portreeve; but James I. made it a corporation, confiding of a mayor, 11 aldermen, 12 common-council-men, with a recorder, steward, &c. an office of record every three weeks, with a prison, and power to try felons in their jurisdiction. And he granted, that the mayor and two aldermen should be justices of the peace, and that they should have a guildhall. There was once a monastery in this place, which was a cell to Kirton; and there are still to be seen a tower, and part of the garden walls, the ruins of a collegiate church. It has neither church nor chapel, but belongs to the parish of Gluvias, a quarter of a mile off. It has sent members to parliament ever since the first year of Queen Mary; and James II. granted it a new charter, whereby their election was vested in the mayority only; but it was never made use of, all the inhabitants that pay foot and lord, who are not much above 100, being the electors. Mr. Rymer gives a very remarkable account how Penryn was once saved by a company of strolling players. He says, that towards the latter end of the 16th century the Spaniards were landing to burn the town just as the players were setting Sampson upon the Philistines; which performance was accompanied with such drumming and shouting, that the Spaniards thought some ambush was laid for them, and scampered back to their ships. Queen Elizabeth founded a free-school in this place. W. Long, 57. N. Lat. 50. 23.

PENSACOLA, a settlement in North America, situated at the mouth of a river on the gulf of Mexico, it was established by the French, and ceded to Great Britain in 1763. Its first discoverer was Sebastian Cabot in 1497.

The year 1781, so disastrous to Britain in other respects, was also remarkable for the reduction of Pensacola by the Spaniards under Don Bernardo Galvez. Great preparations for this expedition had been making at the Havannah; but it was for some time retarded by a dreadful hurricane which attacked the Spanish fleet, and by which four ships of the line, besides others of inferior note, were lost, together with the people on board, to the amount of more than 2000. By this disaster the remainder were obliged to put back to the Havannah to repair; but as soon as the fleet was again judged capable of putting to sea, an embarkation was made of near 8000 men, with Don Bernardo at their head, together with five ships of the line, who arrived at Pensacola on the 9th of March 1781. This force was soon augmented by ten ships of the line and frigates; while General Campbell, the British governor, could oppose such a formidable armament with few more than 1000 men, consisting of some regulars and seamen, with the inhabitants. The entrance of the harbour, which was the principal object of defence, was guarded by two small armed vessels, but they were insufficient to second the batteries that had been erected for its protection; and the Spaniards, without the assistance of some ships of force, were incapable of refilling a vigorous attack. Notwithstanding this prodigious odds, however, the Spaniards met with the most determined opposition. Every inch of ground was disputed with the greatest resolution. The harbour was not forced without the greatest difficulty, nor could the vessels be taken that defended it; the companies belonging to them, after setting them on fire, retired on shore.

The Spaniards, now in possession of the harbour, invested the place in form, and made their approaches in a cautious and regular manner; while, on the other hand, the besieged were no less active and vigilant in their own defence. Sallies were made occasionally with great success, at the same time that an uninterrupted fire was kept up in such a manner as not only greatly to annoy, but even to strike the besiegers with alonement. This incensed the Spanish general the more, as he knew that the garrison could expect no relief, and therefore that all their efforts could only prolong the date of their surrender. The resistance was the more mortifying, as he was perfectly conscious of the bravery of his troops; and he had artillery fit, as his officers expressed themselves, "to be employed against Gibraltar." With all these advantages, however, so resolute was the defence of the garrison, that the siege had continued for two months, very little hope could be entertained of its speedy termination. As they despaired therefore of making any effectual impression by means of their cannon, they erected a battery of mortars, with which they bombarded a fortress, and in this way they were favoured by an unexpected accident. On the 9th of May a shell burst open the door of the powder magazine under the redoubt, by which it was blown upon the lots of near 100 men killed and wounded. Fortunately for the garrison, however, two flank-works still remained entire, from both which heavy a fire was kept up, that though an assault was immediately given, the assailants were repulsed with great slaughter. This afforded leisure to the garrison to carry off the wounded men, with some of the artillery, and to spike up the rest. As the enemy, however, soon recovered themselves, and prepared for a general storm, it was thought proper to abandon the flank works, and retire into the body of the place. The possession of these outworks, however, gave the enemy such advantages, that the place was no longer tenable. Their situation, on a rising ground, enabled them to command the battery opposite to their chief approach with small arms, and to single out the men at their guns. A capitulation therefore became absolutely necessary, which was obtained on honourable terms. The town, with the whole province of West Florida, was confirmed to the Spaniards by the treaty of 1783. W. Long, 87. 20. N. Lat. 30. 22.

PENSANCE, a town of Cornwall, in England, at the bottom of Mountbay, about ten miles from the Land's End. It was burnt in 1595 by the Spaniards, who,
who, with four galleys, surprized this part of the coast, and set fire to several villages and farms; but it was soon after rebuilt, made one of the coinage towns, and has now a considerable trade. It lies in the parish of Madern noted for its restorative spring, very effectual in the cure of lamenefs as well as the cholick, &c. It is well built and populous, and has many ships belonging to it. The shore abounds so with lead, tin, and copper ore, that the veins thereof appear on the utmost extent of land at low-water mark.

PENSILES NORTH, Hanging Gardens, in antiquity. See Babylon, n° 5.

PENNSYLVANIA, or Pennsylvania, is one of the United States of North America; formerly called the Province of Pennsylvania. It was named from its honorable founder, the first proprietary and governor, William Penn, to whom it was granted by King Charles the Second, anno 1682. (See William Penn.) It is bounded on the east, by the river Delaware; which separates it from New Jersey; on the south, by an east and west line; which divides it from the States of Delaware and Maryland and a part of Virginia, at the distance of about fifteen miles south, from the parallel of its capital, PHILADELPHIA, extending westward, from the fild river, 5° of Longitude; and from thence northward to the beginning of the 43° of North Lat. which separates it from part of the State of New York, on the north. It extends about 320 miles east and west, and 155 north and south; containing about 41,000 square miles, and near 26 millions of acres of land.

It was intended, by charter, to contain 3° of Lat. between the parallels of 39° and 45° N. and between about 70° and 76° of Long. West from London; but the grant being afterwards found to encroach upon that of Maryland, to lord Baltimore, which was prior to the grant of Pennsylvania, the boundary between them was afterwards, by agreement, settled, as above. William Penn likewise, in 1682, obtained of the Duke of York, afterwards James II. of England, &c. the three lower counties on Delaware river and bay; which were in consequence, called the Territories of Pennsylvania; but since, the State of Delaware.

The first proprietor William Penn, being one of the people called Quakers, the province was consequently settled at first, mostly by people of that religious society; and in the first year arrived between 20 and 30 ships, with about 3000 settlers, or new colonists; and within the two next succeeding years, about as many more, which afterwards were annually succeeded by many others.

Besides a few families of English, there were many Dutch and Swedes in the country before; who were the first European settlers before it, with what is, now called the State of New York, was taken from the Dutch by the English, in 1664. It is likewise said to have included about ten Indian nations, containing many thousands of those Aborigines: all which the proprietor treated with such prudence, justice, and kindness, on his first arrival, in 1682, and afterwards, that he very remarkably attracted and engaged their love and affection; and his memory has ever since been revered among the Indians, even after their residence has been entirely removed without the limits of the province, or state; for though the country was granted to him by the king, yet he always agreed with, and gave them full satisfaction for their lands, before he settled them; and the heat of advice, for their real happiness, which they remained not only sensible of, but also frequently acknowledged in their public treaties afterwards, and demonstrated by a long continued friendship, a conduct of great advantage to the future settlement and prosperity of the province.

Pennsylvania enjoys a pleasant and salubrious air; though the transition from heat to cold, and vice versa, in the extreme, is sometimes very sudden and injurious. The winter is longer, and more severe than in England; the summer hotter and dryer; the spring very short; the autumn long and mild; but, notwithstanding the length and severity of the winter, it is generally more clear, agreeable, and healthy, than in England, but the summer less so: by reason of its more intense heat, fudden, and greater changes, than are usual in that country; which sometimes cause fevers, lingering and putrid fevers, in the latter part of summer, &c. The snows, in winter, are frequently very deep; and the frosts so intense, that sometimes the river Delaware, even nigh Philadelphia, where it is near a mile broad, has been so hard frozen over, in one night, as to bear people walking upon it the next morning; hence, in that season, its navigation is frequently obstructed; and sometimes for many weeks together successively; and the spring commences near a month later, at Philadelphia, than about London; yet the corn harvest in Pennsylvania, is near a month earlier than in England.

The nature of the land and soil must necessarily be various, in a country so extensive; but there is more of a similarity, in this respect, through the whole of it, than is to be found in the same extent in England, and it is well watered by rivers and springs. It is more of a middling, improvable kind, than very rich;—And, if the whole be divided into three parts, viz. grazing, arable, or least useful, the first, or, what may be called very rich land, is but a small proportion, compared with the second; which is a middling kind, and comprises the greater part of the late, or present improved lands, in Pennsylvania;—which, in many places, abounds with great plenty of iron ore, as well as with limestone, marble, &c. in others; from the first of which are made large quantities of pig and bar iron, hollow-ware, &c.

Most of the land, if not all, which is capable of improvement, is now suppos’d to be taken up, or surveyed to private persons; though much of it still remains unsettled, or in a wilderness state. All the improved parts of Pennsylvania, before the revolution, were divided into eleven counties, and since into twenty-two.

As to the face of the country, it abounds with hills, valleys, woods, and plains, and is crossed by several ranges, or chains, of mountains, running from N. E. to S. W.; as the South, North, or Endless Mountains, so called; which in different places, take different names; as the Kittatinny, and Alleghany mountains, &c. It is mostly covered with woods, and timber of various kinds, where not improved, or entirely barren; among which, has been said, there are above seventeen species, or varieties, of oak.

The principal rivers are the Delaware and Susquehanna; each several hundred miles in length; which have
have many large navigable branches, for boats, barges, and small vessels; besides the Alleghany, which waters the N. W. part of the state, and joins the Monongahela, at Pittsburg; where they form the Ohio; which from thence proceeds out of the bounds of the state, to the Mississippi. These three rivers take their rise in the state of New York, a little northward of Pennsylvania; but the rivers generally, in this country, are broader and shallower, than in some other parts of the world.

The Delaware, on the west side of which stands the flourishing city of Philadelphia, in N. Lat. 40° is navigable for ice vessels, thirty miles above the city, where it is near a mile broad; and about 130 from the sea, along the course of the river and bay of Delaware; above which are rocks, or falls, in several places; tho' passable for boats, barges, rafts, &c. at certain times, above 100 miles further. The Schuylkill is a large branch of the Delaware; which it joins about four miles below Philadelphia, after having replenished the interior parts of the country; but its navigation, for large vessels, is obstructed by a sand bar, at its mouth; and, in some places above, it has rocks or falls; though at certain times, they are passable for boats, flats, rafts, and canoes, for many miles.

The Susquehanna waters much of the interior parts of the state, being in some places, very crooked, broad and shallow. It empties into the head of Chesaapeake bay, in Maryland; but its navigation is much obstructed by falls, or rocks and shallows, in divers places.

The chief towns in Pennsylvania, next after the city of Philadelphia, besides the two old boroughs of Chester and Bristol, (which have long seemingly been on the decline) are Lancaster, York, Carlisle, Reading, Germantown, Harrisburg, and Pittsburg, the last of which is situated above 260 miles westward from Philadelphia, at the junction of the rivers Alleghany and Monongahela; and each of them may probably contain from about 2000 to 6000 inhabitants. Besides, there are many other considerable towns in the state: —but, in a country, like Pennsylvania, where, so long as the chief employment continues to be agriculture, many large towns are neither so proper, convenient nor common, as where the inhabitants, for want of land, become more engaged in manufacturing, &c.

As to the produce of Pennsylvania, Indian corn is an original, and strawberries, with grapes of various kinds, grow naturally in the woods, as well as mulberries. Deer among the quadrupeds, and wild turkeys, among the winged tribe, were formerly very plentiful, but now scarce. But molt kinds of European grain and fruits, as well as domestic, or tame animals have been naturalized there; some of the fruits have been melliorated by the change, while others degenerate. But the principal staple of Pennsylvania, and its vicinity, is wheat, flour, rye, and Indian corn. And the quantity of grain, of different kinds, manufactured and unmanufactured, exported from the port of Philadelphia, in 1774, before the revolution, has been computed, above two millions of bushels; and in 1775, the quantity of flour alone, exported from thence, amounted to above 325,000 barrels each containing 14 cwt. In which year, the value of the exports from the port of Philadelphia, when the chief staple or principal of them, was only at about half the price, to which it has since advanced, was estimated at near 800,000l. sterling; which employed near 800 sea vessels. And in the year 1775, were built 5480 tons of shipping, or new vessels; which employment afterwards, as well as before, was constantly upon the increase every year. —But the province was very early famed for the finenes of its flour and bread, and the goodness of its beer, &c.

Reflecting the produce and trade of Pennsylvania, in a judicious Treatise, published in London, anno 1731, among other things, is the following account, though they have since greatly increased both in quantity and variety. viz.—"The produce of Pennsylvania, for exportation, is wheat, flour, biscuit, barrelled beef, and pork, bacon hams, butter, cheese, cider, apples, soap, myrtle-wax and tallow candles, strong beer, refined oil, strong waters, deer-skin, and other peltry, hemp, some little tobacco, limer; (i. e. sawed boards, and timber, for building houses, cypress wood, fingles, cafe-flakes and heading, masts, and other ship timber) also drugs of various sorts; (as sassafras, calamus aromaticus, snake root, &c.) Lastly, the Pennsylvanians build about 2000 tons of shipping a year, for sale, over and above what they employ in their own trade; which may be about 6000 tons more. They send great quantities of corn to Portugal and Spain, and frequently sell their ships, as well as cargo; and the produce of both is sent thence to England, where it is always laid out in goods, and sent home to Pennsylvania. They receive no less than from 4000 to 6000 100 l. from the Dutch trade of Curacoa alone, for provisions and liquors. And they trade to Surinam, in the like manner, and to the French part of Hispaniola, as also to the other French islands; from whence they bring back molasses, and also some money. From Jamaica they sometimes return with all money, and no goods; because their rum and molasses are too dear there. And all the money they can get from all parts; as also sugar, rice, tar, pitch, &c. is brought to England, to pay for the manufactures, &c. They carry home from us, which has been for many years past, 250,000 l. per annum. They trade to our provinces of New England, Virginia, Maryland, Carolina, and to all the islands, in the west Indies, (excepting the Spanish ones) as also to the Canaries, Madeira, and the Azores Islands; likewise to Newfoundland for fish; which they carry to Spain, Portugal, and up the Mediterranean; and remit the money to England; which, one way or other, may amount to 60,000l. yearly."

Hence, as the trade of Pennsylvania, particularly its exports, as well as the number of its inhabitants, before the revolution, in 1776, usually doubled, at least, every twenty years, some idea of its great increase, improvement and prosperity, before that time, as well as since, may be formed; which, in the space of forty-five years, between these two periods, must consequtently, at least, have been doubled twice; besides the advancement made since the revolution.

The first constitution and government of Pennsylvania, under William Penn, was formed on such a generous plan of liberty and prudent religious toleration; and the moderation and manners of the early settlers and inhabitants were so remarkably amiable and inviting, that the province was so settled...
Pennsylvania,settled and improved, with very extraordinary rapidity; and in a manner almost unparalleled in any other country, where force, or compulsion, has not been used: for it was founded entirely upon the pacific plan. It affords a very remarkable example of the happy effects of the peaceable principle of forbearance, justice and moderation, as well as good policy of that people (the Quakers) who first established, and for so many years directed and conducted the government and public affairs, &c. Reflecting which says the tract, last quoted "That Pennsylvania, which has not any peculiar staple, (like Carolina, Virginia, and Maryland), and was begun to be planted so late as 1680) should at present, in 1731, have more white people in it, than all Virginia, Maryland, and both the Carolinas, is extremely remarkable! And although the youngest colony on the continent, they have by far, the finest capital city of all British America."

By the last constitution of Pennsylvania, since the revolution, established in September 1790, and, as at present existing in 1795, all legislative powers are vested in a senate, and house of representatives; elected by the citizens of Philadelphia, and the several counties in the state, in proportion to their number of taxable inhabitants. The representatives can never be fewer than sixty, nor more than one hundred. The state is divided into districts, (each consisting of one or more contiguous counties) for the choice of senators; who cannot be more than one third, nor less than one fourth of the number of the representatives. The present house of representatives consists of 78 members, and the senate of 40. The qualifications of the electors are full age, and two years residence in the state, with payment of taxes, assessed at least six months before exercising the rights of an elector; but the sons of freeholders are entitled to vote for senators and representatives without any qualification except full age (a). The supreme executive power is lodged in a governor, chosen every three years by the people; he must be, at least, thirty years of age, and have been a citizen or inhabitant of the state for seven years next preceding his election; and no one person can be governor more than nine years in twelve (a). The governor has the appointment of all officers, not otherwise provided for by the constitution; which exclusion only applies to the state treasurer, who is appointed by the legislature; and the sheriffs and coroners, who are elected by the people of the respective counties once in three years.

The inhabitants of Pennsylvania mostly consist of such people as have removed thither from Europe, and of their descendants; many of whom still have customs and manners of the different countries from which they originally came, according to their rank in life. The first and early settlers, or colonists, for many years, as before observed, were mostly Friends, or the People called Quakers, a sober, industrious, and peaceable people; but they have since been long exceeded, in number, by those of other religious societies; and the Presbyterians alone, are now suppos'd to be more numerous than they. The Germans, and their descendants, were suppos'd, before the revolution, to compose near one third part of the inhabitants. They were an honest and industrious people; and have contributed much to cultivate and improve the country. In the year 1749, about twenty-five sail of ships arrived with German passengers alone which brought about 12,000 souls; and in some other years near as many came annually. Before the year 1776, when their importation was suspended, it appears near 40,000 of them, at different times, had arrived in the province, since the first settlement of it; and their internal increase has been very great. Besides, the people, who arrived from Ireland, were very numerous, before the revolution, sometimes about 10,000 in a year. Before which period, the inhabitants were thought to double, in number, at least, every twenty years. They were computed at above 360,000, prior to that time; and since, in the year 1795, they are suppos'd to be about 450,000, in number: for it cannot be reasonably expected they should long continue to increase in so great proportion as they have done. As to the Aborigines or Indians, there have been few, or none of them, resident within the state for many years past: For, as the country advances, and becomes more occupied, they remove further back into the wilderness. The Negroes, or black people, were never very numerous in the province: as the Quakers were always adverse to the debatable traffic in those people; and at present, the total abolition of holding them in bondage is fast advancing, among all sorts of people in the state; the importation of them, for sale, having long since ceased; so that there are but few, or no slaves, now in the country, except such as are introduced by strangers.

The Dutch and Swedes, who were settled here before Mr. Penn became proprietor, choosing still to reside in this country, as they did in New York and the Jerseys, obtained the same privileges as the rest of his majesty's subjects; and their descendants are now in a manner the same people with the English, speaking their language, and being governed by their laws and customs. Mr. Penn, however, not satisfied with the title granted him by King Charles II. and his brother, bought the lands also of the Indians for a valuable consideration, or what they esteemed cash (though 20 miles were purchased, at first, for less than an acre about Philadelphia would pay now), paying them in cloth, tools, and

---

(a) The qualifications of a representative, so far as they differ from those of an elector, are, that the former shall have been a citizen, or inhabitant of the state, three years next preceding his election, and the last year thereof an inhabitant of the city or county for which he shall be chosen. Every senator must have attained to the age of twenty-five years, and have been a citizen or inhabitant of the state four years next before his election; and the last year thereof an inhabitant of the district for which he shall be chosen.

(b) He has a negative on every bill; but if after such negative, two thirds of each house agree to pass the bill, it shall be a law; and if any bill sent to the governor, be not returned within ten days, it shall be a law.
Pennsylvania and utensils, to their entire satisfaction; for they had not hands to cultivate the hundredth part of their lands. and if they could have raised a product, there was nobody to buy; the purchase, therefore, was all clear gain to them; and, by the coming of the English, their peltry trade became so profitable, that they soon found their condition much altered for the better; and are now as well clothed and fed as the European paupers in many places.

Pennsylvania was one of the most flourishing colonies in North America, having never had any quarrel with the natives. Whenever they desired to extend their settlements, they purchased new lands of the French, never taking any by force; but the Indians now let a very high price upon their lands, in comparison of what they did at first, and will hardly part with them at any rate. In an estimate of the proprietary estate of the province, published above 40 years ago, we find, that the proprietaries, who alone could purchase lands here from the natives, had bought seven millions of acres for no more than 750 l. sterling, which the proprietaries afterwards sold at the rate of 15 l. for every 100 acres. The Indian council at Onandago, however, disapproved of their deputies parting with so much land; and, in the year 1755, obliged the proprietaries to reconvey great part of the same to the Indians.

A dispute subsisted a long time between the proprietors of this province and Lord Baltimore, proprietary of Maryland, about the right to certain lands; which was at last amicably adjudged, though greatly in favour of the Penns.

About the year 1704 there happened some alteration in the constitution of the province. The establishment that took place, and subsisted till the American war broke out, consisted of an governor, council, and assembly, each with much the same power and privileges as in the neighbouring colony of New York. The lieutenant governor and council were appointed by the proprietors Thomas and Richard Penn, with his majesty's approbation; but the laws enacted here were not repealed within six months after they had been presented to the king for his approbation or disallowance, they were not repealable by the crown after that time.

As to the different religious societies, in Pennsylvania, they are numerous. They consist of the Friends or Quakers; who were the first settlers of the province as before observed; and have ever since flourished in the free enjoyment of their religion. They neither give titles nor use compliments in their conversation or writings, believing that whatsoever is more than yes, no, and may, may, come of evil. They conscientiously avoid, as unlawful, kneeling, bowing, or uncovering the head to any person. They discard all superfluities in drest or equipage; all games, sports, and plays, as unbecoming the Christian. Swear not at all, is an article of their creed literally observed in its utmost extent. They believe it unlawful to fight in any cause whatever; and think that if their enemy finite them on the one cheek, they ought to turn to him the other also. They are generally honest, punctual, and even punctilious in their dealings; provident for the necessities of their poor; friends to humanity, and of course enemies to slavery; strict in their discipline; careful in their observance even of the punctilios in drest, speech, and manners, which their religion enjoins; faithful in the education of their children; industrious in their several occupations. In short, whatever peculiarities and mistakes those of other denominations have supposed they have fallen into, in point of religious doctrines, they have proved themselves to be good citizens. The Episopalians, according to the manner of the Church of England, with the German and Swedifh Lutherans; the Presbyterians, with the German Calvinists; the Church of Rome, and the Jews; the Baptists, with those among the Germans, called Mennonists and Dunkards; the Moravians, or United Brethren, and Schwenkfelders; besides the Methodists, &c all of which have generally lived there always in much friendship and harmony, notwithstanding their different religious opinions. (All which fice in their proper places.)

In the Philosophical Transactions for 1757, there is an account of a copper spring in Pennsylvania. This spring rises from a copper mine, and will diffuse iron in less time by three-fourths than the waters of Wicklow in Ireland, lately described by Dr William Henry and Dr Bond. From the solution of iron in these waters, about half the quantity of pure copper is procured by melting it in a crucible: but though these waters melt iron sooner than the Irish waters, yet the solution does not produce so great a proportion of copper; for the pure copper procured from the solution of iron in the Irish waters is to the solution as 16 to 20. In the neighbourhood of this spring, which supplies 800 hds. in 24 hours, are many ores of vitriol and sulphur; the water is of a pale green colour, of an acid, sweet, astringent, inky, and nauseous taste. It is very heavy; for the hydrometer, which was immersed in it, stood at the same height as in a solution of one ounce of vitriol in a quart of water. A very small quantity of the solution of pot ashes instantaneously precipitates the metallic parts of this water in three different colours; ochre at the top, green in the middle, and white at bottom; a clean knife kept in it for a few minutes, is covered with a bright copper colour. But besides a large proportion of copper, this water contains also a large proportion of vitriol of iron. A pint of it exhausted by a flow fire left 400 grains of solid contents, which appeared to be chiefly sulphate; for 196 grains of it, dissolved and filtered, did not leave above four grains of indissoluble matter. It appears therefore, that the proportion of vitriolic parts in this water is in direct ratio of a pint; consequently it is a stronger solution of vitriol than sea-water is of marine salt. So that, besides the copper to be obtained from a solution of iron, it will afford great quantities of vitriol, and the great plenty of water and fuel will make the establishment of copperworks extremely cheap and commodious. This water mixed with common water is frequently used as an emetic and cathartic by the country people, and is found very efficacious in the cure of cutaneous disorders and fomes.

Amongst the other curiosities of this state may be reckoned another spring about 14 feet deep and about 100 square, in the neighbourhood of Reading. A full mill stream issues from it. The waters are clear and full of filies. From appearances it is probable that
PENSION, a sum of money paid annually for services or considerations already past. The yearly payment of each member to the houses of the ins of courts is likewise named pensions; and the yearly assembly of the society of Gray's Inn, to consult on the affairs of the house, is also called a pENSION.

PENSIONARY, or PENSIONER, a person who has an appointment or yearly sum, payable during life, by the office of his chapel, company, or particular person.

Grand Pensionary, an appellation given to the first minister of the states of Holland. The grand pensionary is chairman in the assemblies of the states of that province: he proposes the matters to be consulted on; collects the votes; forms and pronounces the resolutions of the state; opens letters; confers with foreign ministers, &c. His business is also to inspect the finances, to maintain the authority of the states, and to see that the laws are observed; and he is perpetual deputy of the states general of the United Provinces. His commission is, however, given him only for five years: after which it is deliberated whether or not it shall be renewed; but there is no instance of its being revoked; therefore death only puts an end to the functions of this important minister.

Pensionary, is also the first minister of the regency of each city in Holland. His office is to give his advice in affairs relating to the government, either of the state in general, or of the city in particular; and in assemblies of the states of the province, he is speaker in behalf of his city. The function, however, of these pensionaries is not everywhere alike; in some cities they give only their advice, and are never found in assemblies of the magistrates, except when expressly called thither: in others they attend constantly; and in others they make the propositions on the part of the burgomasters, draw up their conclusions, &c. They are called pensionaries, because they receive an appointment or pension.

Pensioner, in general, denotes a person who receives a pension, yearly salary, or allowance. Hence the ban of gentlemen pensioners, the noblesse of guard to the king's person, conists of 40 gentlemen, who receive a yearly pension of 100l.

This honourable band was first instituted by King Henry VIII. and their office is to attend the king's person, with their battle-axes, to and from his chapel royal, and to receive him in the presence-chamber, or coming out of his privy-lodging; they are also to attend at all great solemnities, as coronations, St George's feast, public audiences of ambassadors, at the sovereign's going to parliament, &c.

They are each obliged to keep three double horses and a servient, and so are properly a troop of horse. They wait half at a time quarterly; but on Christmas-day, Easter-day, Whitunday, &c. and on extraordinary occasions, they are all obliged to give their attendance. They have likewise the honour to carry up the sovereign's dinner on the coronation-day and St George's feast; at which times the king or queen usually confer the honour of knighthood on two such gentlemen of the band as their captain presents.

Their arms are gilt battle-axes; and their weapons, on horseback, in time of war, are cuirassiers' arms, with sword and pistols. Their standard in time of war is, argent, a cross gules. Their captain is always a nobleman, who has under him a lieutenant, a standard-bearer, a clerk of the check, secretary, paymaster, and harbinger.

Pensioner, in the university of Cambridge and in that of Dublin, has a very peculiar meaning; for those students, either under graduates or bachelors of arts, are called pensioners who live wholly at their own expense, and who receive no emolument whatever from the college of which they are members. They are divided into two kinds, the greater and the less; the former of which are generally called fellow-commoners, because they eat with the fellows of their college; the latter are always called pensioners, and eat with the scholars, who are those students of the college, either under-graduates or bachelors who are upon the foundation, who receive emoluments from the society, and who are capable of being elected fellows. See Servitor and Sizar.

Penstock, a sluice or flood-gate, serving to retain or let go at pleasure the water of a mill-pond, or the like.

Pentarctylos, in national history, a name given by Linnius and some other authors to a kind of fella marina or tea flar-fish, composed of five principal rays, with several transverse hairy or downy processes.

Pentachord (compounded of omnit five, and signifying five), an ancient musical instrument with five strings. The invention of the pentachord is referred to the Seychians; the strings were of bullock's leather, and they were thruck with a placcum made of goats-horn.

Pentacrostic, in poetry, a set of verses so disposed, as that there are always five acrostics of the same name, in five divisions of each verse. See Acrostic.

Pentactinodos, in national history, a name given by some authors to those species of star-fish which are composed of a body divided into five rays.

Pentadactylon, five fingers, in botany, a name given by some authors to the viscous or palma Chryphi, from the figure of its leaf.

Pentadactylos, the five-fingered fish, in ichthology, the name of a fish common in all the seas about the East Indies, and called by the Dutch there vif vinger vish.

It has this name from five black stripes which it has on each side, resembling the prints of five fingers. Its head is flat, convex at the bottom, plain in the sides, and inclined in the fore part. The finot is thick, obtuse, and round; the lower jaw at its extremity bent and
and rounded; the nostrils are double; the balls of the eyes oval; the iris of a silver colour; the first fin of the back is small, the second is more elevated; those of the breath are infected obliquely, that of the anus is greatly extended, and that of the tail much floped. The whole body is covered with scales of a moderate size, thin, flexible, and slightly indented on their hinder edge; the back is red-dull, the sides of a silver colour, and the fins white. The fish is described by some as about nine inches long; by others as a foot and a half. It is a dry but not ill-tailed fish.

PENTÆDROSTYLA, in natural history, the name of a genus of spars: (See Sfars). The bodies of this genus are spars in form of pentagonal columns, terminated by pentagonal pyramids at one end, and regularly affixed at the other to some solid body.

PENTAGON, in geometry, a figure of five sides and five angles. See Geometry.

In fortification, pentagon denotes a fort with five bastions.

PENTAGONOTHECA, in botany, the name given by Vaillant to the plant called by Linnaeus, Plu-nier, Houtouin, and others, pisonia.

PENTAGRAM, an instrument designed for drawing figures in what proportion you please, without any skill in the art.

The instrument is otherwise called a parallelogram.

The common pentagram (Plate CCC.LXXXIII. fig. 14.) consists of four brass or wooden rulers, two of them from 15 to 18 inches long, the other two half that length. At the ends, and in the middle, of the longer rulers, as also at the ends of the shorter, are holes, upon the exact fixing whereof the perfection of the instrument chiefly depends. Those in the middle of the long rulers are to be at the same distance from those at the end of the long ones and those of the short ones; so that when put together they may always make a parallelogram.

The instrument is fitted together for use by several little pieces, particularly a little pillar, No. 1, having at one end a screw and nut, whereby the two long rulers are joined; and at the other a little knot for the instrument to slide on. The piece, No. 2, is a rivet with a screw and nut, wherewith each short ruler is fastened to the middle of each long one. The piece, No. 3, is a pillar, one end whereof, being hollowed into a screw, has a nut fitted to it. At the other end is a worm to screw into the table; when the instrument is to be used, it joins the ends of the two short rulers. The piece, No. 4, is a pen, portcroyan, or pencil, screwed into a little pillar. Lastly, the piece, No. 5, is a brass point, moderately blunt, screwed likewise into a little pillar.

Use of the Pentagram, or Parallelogram. 1. To copy a design in the same scale or bigness as the original: screw the worm No. 3 into the table; lay a paper under the pencil No. 4, and the design under the point No. 5. This done, conducting the point over the several lines and parts of the design, the pencil will draw or repeat the same on the paper.

2. If the design be to be reduced—e. g., into half the space, the worm must be placed at the end of the long-ruler, No. 4, and the paper and pencil in the middle. In this situation conduct the brads point over the several lines of the design, as before; and the pencil at the same time will draw its copy in the proportion required; the pencil here only moving half the lengths that the point moves.

Hence, on the contrary, if the design be to be enlarged by one half, the brads point, with the design, must be placed in the middle, at No. 3, the pencil and paper at the end of the long ruler, and the worm at the other.

3. To enlarge or reduce in other proportions, there are holes drilled at equal distances on each ruler, viz. all along the short ones, and half way of the long ones, in order for placing the brads point, pencil, and worm, in a right light therein; i.e., if the piece carrying the point be put in the third hole, the two other pieces must be put in its third hole:

If, then, the point and design be placed at any hole of the great rulers, and the pencil with the paper at any hole of the short ruler, which forms the angle therewith, the copy will be less than half the original. On the contrary, if it be placed at one of the holes of that short ruler, which is parallel to the long ruler, the copy will be greater than half the original.

The construction of this instrument requires a degree of accuracy which most of our instrument-makers are strangers to; for which reason there are very few of the instruments that succeed. Few will do any thing tolerably but straight lines; and many of them not even those.

In order to prove that the figure described by a pentagram is similar to the given figure, let C (fig. 15.) be the fixed centre of motion; P the pencil for tracing the given figure PP, and p the pencil which traces the other figure pp; p, &c. must be so adjusted, that p, C, and P, may lie in one straight line; then, since Bp: A p : : BP: AC, whatever be the situation of the pentagram, the angles PCP and P C P are vertical; and therefore PCP will in every position of the instrument be a right line: but PC: : C : : BA: A P, in each of the two positions in the figure, and consequently the triangles PCP, P C P are similar; and PP: pp (:: PC: : C) : : BA: A P, or in a given ratio. Hence it appears, that, by moving the pencil p, A P, may be equal to BA, or less in any proportion; and consequently p p may be equal to PP, or less, in the same proportion.

PENTAMETER, in ancient poetry, a kind of verse, consisting of five feet, or metres, whence the name. The two first feet may be either dactyls or spondees at pleasure; the third is always a spondee; and the last anapestis: such is the following verse of Ovid.

1. Carminibus uivos tempos in omne meis.

2. A pentameter verse subjoined to an hexameter, constitutes what is called elegiac. See Elégiac.

PENTANDRIA (from πεντάνταρχον, and αν a man or husband): the name of the fifth class in Linnaeus's sexual method, consisting of plants which have hermaphrodite flowers, with five stamina or male organs. See Botany, p. 430.

PENTAPETALOUS, an appellation given to flowers which consist of five petals or leaves.

PENTAPETES, in botany: A genus of the dodecandria order, belonging to the monadelphia class of plants; and in the natural method ranking under the
Pelletier. There is but one species known in the gardens of this country, viz. the phacienia, with half-pointed, spear-shaped, fawed leaves. It is an annual plant, a native of India, and rises to the height of two or three feet, adorned with fine scarlet flowers, consisting of one petal cut into five segments. In the centre of the flower arises a short thick column, ... to which it is adhered. It is a tender plant, and must be brought up in the hot-house.

PENTAPOLIS. This name is given to the five cities, Sodom, Gomorrah, Admah, Zeboim, and Zoar (Wisd. x. 6.). They were all five condemned to utter destruction, but Lot interceded for the preservation of Zoar, otherwise called Baal. Sodom, Gomorrah, Admah, and Zeboim, were all consumed from fire and heaven, and in the place where they flooded was made the lake Asphaltites, or the lake of Sodom.

PENTAPOLIS (Ptolemy), a district of Cyrenaica; situated on the Mediterranean; denominated from its five cities; namely, Berenice, Arinone, Polemais, Cyrene, and Appollonia.

PENTAPHILINES (Josephus); taking name from five principal cities, Gaza, Gath, Azeton, Azor, and Ekron.

PENTATEUCH. This word, which is derived from the Greek πεντατέυχος, from πέντε, five, and τέυχος, an instrument or volume, signifies the collection of five instruments, or books of Moses, which are Genesis, Exodus, Leviticus, Numbers, and Deuteronomy: each of which books we have given an account of under their several names.

There are some modern critics who have disputed Moses's right to the pentateuch. They observe that the author always speaks in the third person. "Now the man Moses was very meek above all the men which were upon the face of the earth. The Lord spake unto Moses, saying, &c. Moses said to Pharaoh, &c." Thus they think he would never have spoken of himself; but would at least sometimes have mentioned himself in the first person. Besides this, say they, the author of the pentateuch sometimes abridges his narrative like a writer who collected from some ancient memoirs. Sometimes he interrupts the thread of his discourse; for example, he makes Lamech the bigamist to say (Gen. iv. 23.), "Hear my voice, ye wives of Lamech, hearken unto my speech; for I have slain a man to my wounding, and a young man to my hurt," without informing us before hand to whom this is related. These observations, for example (Gen. xii. 6.), "And the Canaanite was then in the land," cannot be reconciled to the age of Moses, since the Canaanites continued to be the masters of Palestine all the time of Moses. The passage out of the book of the wars of the Lord, quoted in the book of Numbers (xxi. 14.), seems to have been changed in afterwards, as also the first verses of Deuteronomy. The account of the death of Moses, which is at the end of the same book, cannot certainly belong to this legislator; and the fame judgment may be made of other passages, wherein it is said, that the places mentioned lay beyond Jordan; that the bed of Og was at Ramah to this day; that the havoth of Jair, or the cities of Jair, were known to the author, though probably they had not that name Pentateuch till after Moses's time (Num. xxxii. 41, Deut. iii. 14.).

It is observed also in the text of the pentateuch, that there are some places that are defective; for example, in Exodus (xii. 8.), we see Moses speaking to Pharaoh, where the author omits the beginning of his discourse. The Samaritan differs in the same place what is wanting in the Hebrew. In other places, the same Samaritan copy adds what is deficient in the Hebrew text; and what it contains more than the Hebrew seems so well connected with the rest of the discourse, that it would be difficult to separate them. Lastly, they believe that they observe certain strokes in the pentateuch which can hardly agree with Moses, who was born and bred in Egypt; as what he says of the earthly paradise, of the rivers that watered it, and ran through it; of the five cities, Babylon, Erech, Reph, and Calneh; of the gold of Pifon, of the Bdelium, of the stone of Sopher, or onyx-stone, which was to be found in that country. These particulars, observed with such curiosity, seem to prove, that the author of the pentateuch lived beyond the Euphrates. Add what he says concerning the ark of Noah, of its judgment may be made of other places, the same which was brought--up in this country. Thefe particulars, observed with such curiosity, seem to prove, that the author of the pentateuch lived beyond the Euphrates. Add what he says concerning the ark of Noah, of its

PENTATHLON, in antiquity, a general name for the five exercises performed at the Grecian games, viz. wrestling, boxing, leaping, running, and playing at the discus.

PENTECOST, a solemn festival of the Jews; so called, because it was celebrated on the 50th day after the 16th of Nisan, which was the second day of the passover. The Hebrews called it the feast of weeks, because it was kept seven weeks after the passover. They then offered the first fruits of the wheat harvest, which was then completed; besides which they presented at the temple seven lambs of that year, one calf, and two rams, for a burnt offering; two lambs for a peace offering; and a goat for a sin offering (Levit. xix. 15, 16. Exod. xxxiv. 22, and Deut. xvi. 9, 10.) The feast of the pentecost was instituted among the Israelites, first to oblige them to repair to the temple of the Lord, there to acknowledge his absolute dominion over the whole country, and to offer him the first-fruits of their harvest; and, secondly, that they might call to mind, and give thanks to God, for the law which he had given them from mount Sinai, on the 50th day after their coming out of Egypt.
The modern Jews celebrate the pentecost for two days. They deck the synagogue and their own houses with garlands of flowers. They hear a sermon or oration in praise of the law, which they suppose to have been delivered on this day. The Jews of Germany make a very thick cake, consisting of seven layers of paste, which they call Sina. The seven layers represent the seven heavens, which they think God was obliged to reassend from the top of this mountain. See Leo of Modena et Bostorf's Syag Jud.

It was on the feast of pentecost that the Holy Ghost miraculously descended on the apostles of our Lord, cv. 28.

PENTHESILEA, queen of the Amazons, succeeded Ortygia, and gave proofs of her courage at the siege of Troy, where she was killed by Achilles. Pliny says that she invented the battle-axe.

PENTHORUM, in botany; a genus of the pentagynia order, belonging to the pentandria class of plants. The calyx is quinqued; there are either five petals or none; the capsule is five-pointed and quinqued-ocular.

PENTLAND or PICTLAND EIRTH, is a narrow strait of six miles between the main land of Scotland and the Orkney isles. This strait is the great thoroughfare of shipping between the eastern and western seas, the terror of the boldest mariners, and the grave of thousands; where the winter's storms afford many natives on the opposite shores a better livelihood than they could obtain by fishing or husbandry. They search from place to place, and from one cavern to another, in the hopes of finding timber, caiks, and other floating articles; of the wrecked vessels, of whom six or eight are thus sacrificed sometimes in one night. The navigation of this pass is rendered more dangerous by the island of Strom, and two rocks called the Skerries, lying near the middle of it.

PENULA, among the ancient Romans, was a coarse garment or cloak worn in cold or rainy weather. It was shorter than the lacerna, and therefore more proper for travelers. It was generally brown, and succeeded the chlamys after that became monastic. Clovis III. Childebert, and Dagobert, the power of these mayors in France was so great, that they left the sovereign only the empty title, and in the end seized on the throne itself. See PIPER.

PEPIN DE HERISTAL, or LE GROS, mayor of the palace under Clovis III. Childerbert, and Dagobert. The power of these mayors in France was so great, that they left the sovereign only the empty title, and in the end seized on the throne itself. See PIPER.

PEPLUM, in botany: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 17th order Calyceal: hema. The perianthium is campanulated; the mouth cleft in 12 parts; there are five petals inserted into the calyx: the capsule is bilocular.

PEPLUS, a long robe worn by the women in ancient times, reaching down to the feet, without sleeves, and so very fine, that the shape of the body might be seen through it. The Athenians used much ceremony in making the peplos, and dressing the statue of Minerva with it. Homer makes frequent mention of the peplos of that goddess.

PEPPER, Pipers, in natural history, an aromatic berry of a hot dry quality, chiefly used in seasoning. We have three kinds of pepper: 1. Present used in the shop, the black, the white, and the long pepper. Black pepper is the fruit of the piper, and is brought from the Dutch settlements in the East Indies. See PIPER.

The common white pepper is fictitious, being prepared from the black in the following manner: they steep this in sea-water, exposed to the heat of the sun for several days, till the rind or outer bark looses; they then take it out, and, when it is half dry, rub it till the rind falls off; then they dry the white fruit, and the remains of the rind blow away like chaff. A great deal of the heat of the pepper is taken off by this process, so that the white kind is more fit for many purposes than the black. However, there is a sort of native white pepper produced on a species of the same plant; which is much less the fictitious, and indeed little inferior to the black.

The long pepper is a dried fruit, of an inch or an inch and an half in length, and about the thickness of a large goose quill; it is of a brownish grey color,
cyindrical in figure, and said to be produced on a plant of the fame genus.

Pepper is principally used by us in food, to affift digestion; but the people in the East Indies esteem it as a stomachic, and drink a strong infusion of it in water by way of giving them an appetite; they have also a way of making a fiery spirit of fermented fresh pepper with water, which they use for the same purposes. They have also a way of preserving the common and long pepper in vinegar, and eating them afterwards at meals.

Jamaica Pepper, or Pimento. See Pimenta.

Pepper-Mint. See Mentha.

Pepper-Pot. See Capsicum.

Pepper-Water, a liquor prepared in the following manner, for microscopical observations: put common black pepper, grossly powdered, into an open vessel to as to cover the bottom of it half an inch thick, and put to it rain or river-water, till it covers it an inch; shake or stir the whole well together at the first mixing, but never disturb it afterwards: let the vessel be exposed to the air uncovered; and in a few days there will be seen a pellicle or thin skin swimming on the surface of the liquor, looking of several colours.

This is a congregation of multitudes of small animals; and being examined by the microscope, will be seen all in motion: the animals, at first sight, are so small as not to be distinguishable, unless to the greatest magnifiers; but they grow daily till they arrive at their full size. Their numbers are also continually increasing, till the whole surface of the liquor is full of them, to a considerable depth. When dilatated, they will sometimes all dart down to the bottom; but they soon return up to the surface again. The skin appears from time to time in warm weather, and the animals grow the quickest; but in the severest cold it would succeed, unless the water freezes.

About the quantity of a pin's head of this scum, taken up on the nib of a new pen, or the tip of a hair-pencil, is to be laid on a plate of clear glass; and if applied first to the third magnifier, then to the second, and finally to the first, will show the different animals it contains, of several kinds and shapes as well as sizes.

PEPPERMINT-TREE, in botany; the Eucalyptus piperita.

In a journal of a voyage to New South Wales, by John White, Esq; we have a plate of this tree, with the following account of it: "This tree grows to the height of more than 100 feet, and is about 30 feet in circumference. The bark is very smooth, like that of the poplar. The young branches are long and slender, angulated near the top; but as they grow older, the angles disappear. Their bark is smooth, and of a reddish brown. The leaves are alternate, lanceolate, pointed, very entire, smooth on both sides, and remarkably unequal or oblique at their base; the veins alternate, and not very conspicuous. The whole surface of both sides of the leaves is marked with numerous minute reticulate spots, in which the essential oil resides. The footstalks are about half an inch in length, round on the under side, angular above, quite smooth. The flowers we have not seen. What Mr White has sent as the ripe capsules of this tree (although not attached to the specimens of the leaves) grow in clusters, from six to eight in each, fiddle and conglomerated. These clusters are supported on angular alternate footstalks, which form a kind of panicle. Each capsule is about the size of an hawthorn berry, globular, but as it was cut off at the top, rugged on the outside, hard and woody, and of a dark-brown colour. At the top is a large orifice, which shows the internal part of the capsule divided into four cells, and having a square column in the centre, from which the partitions of the cell arise. These partitions extend to the rim of the capsule, and terminate in four small projections, which look like the teeth of a calyx. The seeds are numerous, small, and angular.

"The name of peppermint tree has been given to this plant by Mr White, on account of the very great resemblance between the essential oil drawn from its leaves and that obtained from the peppermint (mentha piperita) which grows in England. This oil was found by Mr White to be much more efficacious in removing all cholicky complaints than that of the English peppermint, which he attributes to its being less pungent and more aromatic. A quart of the oil has been sent by him to Mr Wifion.

"The tree above described appears to be undoubtedly the same genus with that cultivated in some greenhouses in England, which Mr L'Héritier has described in his Species AU. ficum by the name of Eucalyptus obliqua, though it is commonly called in the gardens Micropteris obliqua; but we dare not assert it to be the same species, nor can this point be determined till the flowers and every part of both be seen and compared; we have compared the best specimens we could procure of each, and find no specific difference. The eucalyptus obliqua has, when dried, an aromatic flavour, somewhat similar to our plant. We have remarked, indeed, innumerable minute white spots, besides the numerous ones, on both surfaces of the leaves in some specimens of the garden plant, which are not to be seen in ours; and the branches of the former are rough, with small scaly tubercles. But how far these are constant, we cannot tell. The obliquity in the leaves, one side being shorter at the base than the other, as well as a narrowness all the way up, as in the Brigham mitida of the Hortus Kewensis, is remarkable in both plants."

The figure represents a branch of the peppermint tree in leaf; on one side of it part of a leaf separate, bearing the gall of some insect; on the other the fruit above described."

PERA, one of the suburbs of Constantinople, where embassadors and Christians usually reside. See Constantiopolis.

PERAMBULATOR, in surveying, an instrument for measuring distances, called the pedometer, way-wifdr and surveying-wheel. See Pedometer.

It consists of a wheel AA, two feet seven inches in diameter, and a half in diameter; consequently half a pole, or eight feet three inches, in circumference. On one end of the axis is a nut, three quarters of an inch in diameter, and divided into eight teeth; which, when moving the wheel round, fall into the eight teeth of another nut, fixed; and this turn the rod once round in the time the wheel makes one revolution. This rod, lying along a groove in the side of the carriage of the instrument, under the dotted line, has at its other end a square hole, into which is fitted the end B of a small cylinder P. This cylinder
The cylinder is disposed under the dial-plate of a movement, at the end of the carriage, in such a manner as to be moveable about its axis: its end is cut into a peptural screw, which, falling into the 32 teeth of a wheel perpendicular thereon, upon driving the instrument forward, that wheel makes a revolution each 16th pole. On the axis of this wheel is a pinion with fixed teeth, which, falling into the teeth of another wheel of 60 teeth, carries it round every 15th pole, or half a mile.

This last wheel, carrying a hand-or index round with it over the divi of a dial-plate, whose outer limb is divided into 160 parts, corresponding to the 160 poles, points out the number of poles passed over.

Again, on the axis of this last wheel is a pinion, containing 20 teeth, which, falling into the teeth of a third wheel which hath 40 teeth, drives it once round in 320 poles, or a mile. On the axis of this wheel is a pinion of 12 teeth, which, falling into the teeth of a fourth wheel having 72 teeth, drives it once round in 12 miles.

This fourth wheel, carrying another index over the inner limb of the dial-plate, divided into 12 for miles, and each mile subdivided into halves, quarters, and sixteens, serves to register the revolutions of the other hand, and to keep account of the half miles and miles passed over as far as 12 miles.

The use of this instrument is obvious from its construction. Its proper office is in the surveying of roads and large distances, where a great deal of expedition, and not much accuracy is required. It is evident, that driving it along and observing the hands, has the same effect as dragging the chain and taking account of the chains and links.

Its advantages are its hardness and expedition; its contrivance is such, that they may be fitted to the wheel of a coach, in which rate it performs its office, and measures the road without any trouble at all.

PERCA, the perch; a genus of fishes belonging to the order of Thoryctico. The head is furnished with a peptural screw, which, falling into the teeth of a third wheel, drives it once round in 320 poles, or a mile. On the axis of this wheel is a pinion of 12 teeth, which, falling into the teeth of a fourth wheel having 72 teeth, drives it once round in 12 miles.

This wheel, carrying another index over the inner limb of the dial-plate, divided into 12 for miles, and each mile subdivided into halves, quarters, and sixteens, serves to register the revolutions of the other hand, and to keep account of the half miles and miles passed over as far as 12 miles.

The use of this instrument is obvious from its construction. Its proper office is in the surveying of roads and large distances, where a great deal of expedition, and not much accuracy is required. It is evident, that driving it along and observing the hands, has the same effect as dragging the chain and taking account of the chains and links.

Its advantages are its hardness and expedition; its contrivance is such, that they may be fitted to the wheel of a coach, in which rate it performs its office, and measures the road without any trouble at all.

PERCA, the perch; a genus of fishes belonging to the order of Thoryctico. The head is furnished with a peptural screw, which, falling into the teeth of a third wheel, drives it once round in 320 poles, or a mile. On the axis of this wheel is a pinion of 12 teeth, which, falling into the teeth of a fourth wheel having 72 teeth, drives it once round in 12 miles.

This wheel, carrying another index over the inner limb of the dial-plate, divided into 12 for miles, and each mile subdivided into halves, quarters, and sixteens, serves to register the revolutions of the other hand, and to keep account of the half miles and miles passed over as far as 12 miles.

The use of this instrument is obvious from its construction. Its proper office is in the surveying of roads and large distances, where a great deal of expedition, and not much accuracy is required. It is evident, that driving it along and observing the hands, has the same effect as dragging the chain and taking account of the chains and links.

Its advantages are its hardness and expedition; its contrivance is such, that they may be fitted to the wheel of a coach, in which rate it performs its office, and measures the road without any trouble at all.

Perception

the cognizance of objects distant and apart from ourselves, and learn that we are but a small part in the system of nature. By what process the senses give us this information, we have endeavoured to show elsewhere, (See Metaphysics, Part I. Chap. i.) and we should not again introduce the subject, but to notice a singular opinion of a very able writer, whose work has been given to the public since our article alluded to had issued from the press.

Dr. Sayers, who is an ornament to that school in which we are strongly inclined to enlist ourselves, has endeavoured to prove that no man can perceive two objects, or be conscious of two ideas at the same instant. If this be true, not only our theory of time (See Metaphysics, Part II. Chap. viii.) is grossly absurd, but even memory itself seems to be an imaginary faculty. If a man be not conscious of his present existence, at the very instant when he thinks of a past event, or reviews a series of past transmutations, it is difficult, to us indeed impossible, to conceive what idea he can have of time, or what he can mean when he fays that he remembers a thing. But let us examine the reasoning by which the ingenious author endeavours to establish his opinion.

If we reflect (fays he;) upon the surprising velocity with which ideas pass through the mind, and the remarkable rapidity with which the mind turns itself; or is directed from one object of contemplation to another, this might alone give us some suspicion that we may probably be mistaken in supposing ideas to be synchronously perceived. Other arguments may be adduced to strengthen this suspicion. It will be granted, I believe, that the mind, whether immaterial or the result of organization, has certainly a wholeness or unity belonging to it, and that it is either not composed of parts, or that no one of the parts from which it originates is itself mind: in this case, it is difficult to conceive how two ideas should be impressed upon the mind at the same instant; for this would be supposing that part of the mind could receive one idea, and part another, at the same time; but if the parts do not perceivedly fign:flly, this is evidently impossible. If, on the other hand, this self-division of the mind does not take place, then if two ideas are nevertheless to be perceived at the same instant, it should appear that these ideas must be fo blended with each other, that neither of them could appear distinct. If we examine the manner in which a complex idea is perceived, we shall find very clearly, that the whole of such an idea is never present to the mind at once. In thinking of a centaur, for instance, can we at the same moment be thinking of the parts of a man and the parts of a horse? Can we not almost detect the gliding of the mind from the one to the other? In contemplating the complex idea of gold, are the ideas of its colour, ductility, hardness, and weight, all present to the mind at the same instant? I think, if we accurately attend to it, we shall find a perceptible time has elapsed before this complex idea has been perfectly formed in our mind; but if all the parts of a complex idea cannot be recalled at the same instant, is it not reasonable to infer that these parts are also fingly impressed, and not all originally perceived at the same instant?"?

This reasoning is plausible, but perhaps not convincing. Surely we have all been conscious of bodily pain or pleasure with our eyes open, and been affected by perception of disagreeable smells at the very infant that we looked at objects beautifully coloured. That our ideas pass through the mind with great velocity, and that the mind can rapidly turn itself from one subject of contemplation to another, are truths which cannot be controverted; but instead of leading us to suppose that two or more objects cannot be synchronously perceived, or two or more ideas synchronously apprehended, they appear to furnish a complete proof of the reverse of all this. For we beg leave to ask how we come to know that ideas pass with velocity through the mind, if we be not all the while conscious of something that is permanent? If we can contemplate but one idea at once, it is plainly impossible that two or more can be compared together; and therefore we cannot possibly say that any particular train has passed through the mind with a degree of velocity greater or less than that which we have usually experienced; nay, we cannot say that we have ever experienced a train of ideas at all, or even been conscious of a single idea, besides the immediate object of present apprehension. That the mind is an individual, we most readily grant; but that it should therefore be incapable of having two ideas synchronously excited in it, is a proposition for which the author has brought no evidence. That it is difficult to conceive how this is done, we acknowledge; but not that it is more difficult than to conceive how a single idea is excited in the mind; for of the mode in which mind and matter mutually operate upon each other, we can form no conception. We know that objects make an impression on the organs of sense: that this impression is by the nerves communicated to the brain, and that the agitation of the brain excites sensation in the mind: but in what way it excites sensation we know not; and therefore have no reason to suppose that two or more different agitations may not excite two or more synchronous sensations, as well as one agitation excites one sensation. That the agitation given to the brain operates on the mind, is known by experience; but experience gives us no information respecting the mode of that operation. If the mind be, as our author and we suppose it to be, an individual mind, it cannot, as mind, be either divisible or extended; and therefore it is certain that the operation in question cannot be, in the proper sense of the word, impression. Hence we have no right to infer, if two objects be perceived at once, either that the idea of the one must be impressed on a part of the mind different from that which receives the impression of the other, or that the two impressions must be so blended with each other, that neither of them could appear distinct; for this would be to reason from one mode of operation to another; with which, upon acknowledged principles, it can have nothing in common.

By far the greater part of our ideas are relics of vivid sensations; and of every thing which we can actually see at once, we may at once contemplate the idea. That he could at once perceive a centaur, if such a being were presented us, cannot surely be doubted by any one who has ever looked at a horse in close proximity; and therefore that we can at the same moment contemplate the whole idea of a centaur, is a fact of which consciousness will not permit us to doubt.

If, indeed, we choose to analyze this complex idea in-
PERCEPTION, if we examine the term, is self-evident that the mind
must glide from the one to the other, because the very
analysis consists in the separation of the parts, of which,
if after that process we think of them, we must think in
succession: but that we may have at the same in-
stant, either an actual or ideal view of all the parts of
the centaur united, is a proposition so evident as to
admit of no other proof than an appeal to experience.
In contemplating what the author calls the complex
idea of gold, it cannot be denied that the ideas of its
colour, ductility, hardness, and weight, are never all
prent to the mind at the same instant: but the reason
is obvious. There is no whole in the particular
parts of the word, but some of them are ideas, and some
notions, acquired by very different processes and very
different faculties. Colour is an idea of sensation, im-
mediately suggested through the organ of sight; duct-
ility is a relative notion, acquired by repeated experi-
ments; and gold might be made the object of every
sense, without suggesting any such notion. The writ-
er of this article never found an experiment made on the
ductility of gold, and has therefore a very obscure and
indistinct notion of that property of the metal; but he
is conscious, that he can perceive, at the same in-
stant, the yellow colour an irregular figure of a guinea,
and have a very distinct, though relative notion, of
its hardness.

We conclude, therefore, that the mind is capable
of two or more simultaneous perceptions, or synchronous
ideas; that, during every train which passes through it,
it is conscious of its own permanent existence; and
that if it were limited to the apprehension of one idea at
once, it could not be said in the future or anticipated
of the future, but would appear to it-
self, could it make any comparison, to pass away like
a flash of lightning.

PERCH, in land-measuring, a rod or pole of 16½
feet in length, of which 40 in length and 4 in breadth
make an acre of ground. But, by the customs of fe-
veral counties, there is a difference in this measure.
In Staffordshire it is 24 feet; and in the forest of
Sherwood 23 feet; the foot being there 18 inches
long; and in Hertfordshire a perch of ditching is 21
feet, the perch of walling 16½ feet, and a pole of
denihed ground is 12 feet, &c.

PERCHE, a territory of Orleans in France,
35 miles long, and 30 broad; bounded on the north
by Normandy; on the south, by Maine and Dauphiné,
on the east, by Brabant; and on the west, by Maine.
It takes its name from a forest, and is pretty fertile.
The inhabitants carry on a pretty good trade; and
the principal town is Bellefle.

PERCULATION, the same with FILTRATION.
See CRYSTALLIZATION, no. 568.

PERCUSSION, in mechanics, the impression a
body makes in falling or striking upon another; or
the shock of two bodies in motion.

PERDICIUM, in botany; A genus of the poly-
gamia superflua order, belonging to the fynomena
class of plants; and in the natural method ranking
under the 49th order, Compuestas. The receptacle is
naked; the pappus is simple; the florets bilabiate.
PERDIX. See TETRADO
PEREASLA, a strong populous town of Po-
land, in the palatinate of Klavin, situated on the river
Perea, in Lat. 53° 44°, N. Long. 49° 46.

PERENNIALS, or PERENNIAL FLOWERS, in bot-
any; a term applied to those plants whose roots will
abide many years, whether they retain their leaves in
winter or not. Those which retain their leaves are
called evergreen; but such as cast their leaves are
named deciduous, or perennials.

PERFECT, something to which nothing is want-
ing, or that has all the requisites of its nature and
kind.

PERFECT Cadence, in music. See Cadence.

PERFECT Tense, in grammar. See PRETERITE.

PERFECTION, the state or quality of a thing
PERFECT.

Perfection is divided, according to Chauvinus, into
physical, moral, and metaphysical.

Physical or natural perfection, is that whereby a
thing has all its powers and faculties, and those too
in full vigour; and all its parts both principal and se-
condary, and those in their due proportion, constitu-
tion, &c., in which sense man is said to be perfect
when he has a found mind in a found body. This
perfection is by the schools frequently termed perfectu-
num, because a thing is enabled thereby to perform all its
operations.

Moral perfection is an eminent degree of virtue or
moral goodness, to which men arrived by repeated acts
of piety, beneficence, &c. This is usually subdivided
into absolute or inherent, which is actually in him to
whom we attribute it; and imputative, which exists in
some other, and not in him it is attributed to.

Metaphysical, transcendental, or essential perfection,
is the possession of all the essential attributes, or of all
the parts necessary to the integrity of a substance; or it is
that whereby a thing has or is provided of every thing
belonging to its nature. This is either absolute, where all
imperfectness is excluded, such is the
perfection of God; or secundum quid, and in its
kind.

PERFORANS MANUS,
PER FORANUS MANUS,
PERFORATUS MANUS,
PERFORATUS PEDIS,
PERFORATUS PEDIS,
PER FORATUS PEDIS,
See Anatomy, Table of the Muscles.

PERFUME, denotes either the volatile effluvia,
from any body affecting the organ of smelling, or the
substance emitting those effluvia; in which last sense
the word is most commonly used. The generality of
perfumes are made up of musk, ambergris, civet, rose
and cedar woods, orange-flowers, jaffamines, jonquils,
tuberose, and other odoriferous flowers. Those drugs
commonly called aromatics, such as tobacco, frankin-
calls, clove, nutmeg, &c., enter the composition
of a perfume; some are also compounded of aromatic
herbs or leaves, as lavender, marjoram, sage, thyme,
hyssop, &c.

The use of perfumes was frequent among the He-
brews, and among the orientals in general, before it was
known to the Greeks and Romans. In the time of Mo-
ses perfumes must have been known in Egypt, since he
speaks of the art of the perfumer, and gives the com-
position of two kinds of perfumes (Exod. xxx. 25.), of
which one was to be offered to the Lord upon the
golden altar, which was in the holy place; and the
other.
other was appointed for the anointing of the high priest and his sons (ibid. 34, &c.), as also of the tabernacle, and all the vessels that were used in divine service.

The Hebrews also perfumes which they made use of in embalming their dead. The composition is not known, but it is certain that they generally made use of myrrh, aloes, and other strong and aromatic drugs, proper to prevent putrefaction (John xix. 49.) See the article Embalming.

Besides the perfumes for these purposes, the Scripture mentions other occasions wherein the Hebrews used perfumes. The spoule in the Canticles (i. 3.) commends the scent of the perfumes of her lover; and her lover in return says, that the scent of the perfumes of his spoule surpasses the most excellent odours (ibid. iv. 10, 14.) He names particularly the spikenard, the calamus, the cinnamon, the myrrh, and the aloes, as making a part of these perfumes. The voluptuous woman described by Solomon (Prov. vii. 17.) says, that she had perfumed her bed with myrrh, aloes, and cinnamon. The epicures in the book of Wisdom (vi. 27) encourage another to the luxuriant use of odours and costly perfumes.

Idub (vii. 9.) reproaches Judah, whom he describes as a spoule faithless to God, with being painted and perfumed to please strangers, "Thou wentest to the king with ointment, and didst increase thy perfumes." Ezekiel (xxii. 41) laments to the Jews with having profaned the odours and perfumes, the use of which was reserved to sacred things, by applying them to their own use.

They came afterwards to be very common among the Greeks and Romans, especially those composed of musk, ambergris, and civet. The nardus and melabathrum were held in much estimation, and were imported from Syria. The unguentum nardusum was very much prepared, and contained many ingredients. Melabathrum was an Indian plant. Perfumes were also used at sacrifices to regain the gods; at feasts, to increase the pleasures of sensual; at funerals, to overpower nauseous smells, and please the manes of the dead; and in the theatres, to prevent the offensive effluvia, proceeding from a crowd, from being perceived.

Since people are become sensible of the harm they do to the head, perfumes are generally diluted among us; however, they are still common in Spain and Italy.

PERGAMA (Virgil), the citadel of Troy; which, because of its extraordinary height, gave name to all high buildings (Servius). Others say the walls of Troy were called Pergamus.

PERGAMUS (Pliny); also called Pergamum, (Virgil); Pergamum (Plutarch); a town of Crete, built by Agamemnon in memory of his victory, (Velleius). Here was the burying-place of Lycurgus, (Aristopenes, quoted by Plutarch). It was situated near Cydonia (Servius); to what point not said: but Scylax helps us out, who places the Daedalymenae temple of Diana, which stood near Cydonia (Strabo), to the north of the territory of Pergamum.—Another PERGAMUM (Pliny, Strabo); a town of Myia, situated on the Cucus, which runs by it. It was the royal residence of Eumenes, and of the kings of the Attali (Livy). There an ancient temple of Aesculapius stood; an asylum (Tacitus). The ornament of Pergamum was the royal library, yea with that of Alexandria in Egypt; the kings of Pergamum and Egypt rivaling each other in this respect (Pliny). Strabo ascribes this rivalry to Eumenes. Plutarch reckons up 200,000 volumes in the library at Pergamum. Here the membrana pergaminea, whence the name parchment, were invented for the use of books, (Varro, quoted by Pliny). The country of Galen, and of Oribasius chief physician to Julian the Apostate (Euapius), called by some the age of Galen. Here P. Scipio died (Cicero). Attalus son of Eumenes dying without issue, bequeathed his kingdom to the Roman people, who reduced it to a province, (Strabo). Pergamum, the epiphlet (Martial). Here was one of the nine conventus juridici, or assemblies of the Aphia Romana, called Pergamum, and the ninth in order (Pliny); which he also calls jurisdictio Pergamum.

PERGAMUS, an ancient kingdom of Aphi, formed out of the ruins of the empire of Alexander the Great. It commenced about the year 283. The first sovereign was one Philoerus an eunuch, by birth a Paphlagonian, of a mean condition; and in his youth a servile servant to Antigonus one of Alexander's captains. He afterwards served Lyssimachus king of Macedon and Thrace, who appointed him keeper of his treasures. He digged in Pergamum. While he held this employment, having fallen under the displeasure of Arinoe wife to Lyssimachus, the found means to make a quarrel between him and his master; upon which Philoerus seized on the castle of Pergamum, together with the treasures entrusted to his care, amounting to 90,000 talents. At first he offered his service together with his treasures, to Seleucus king of Syria: but both Seleucus and Lyssimachus dying soon after, he kept possession of the town and treasure aloft till his death; which happened 20 years after his revolt from Lyssimachus.

Philetarus left the city of Pergamum to his brother, or, according to some, to his brother's son Eumenes I., and he, laying hold of the opportunity offered by the discontents among the Seleucides, polled himself of many strong-holds in the province of Aphi; and having hired a body of Galatians, defeated Antiochus, as he was returning from a victory gained over his brother Seleucus Callinicus. By this victory he obtained possession of the greater part of Aphi; however, he did not long enjoy his acquisitions; for he died next year of immoderate drinking, a vice to which he was greatly addicted.

Eumenes was succeeded by Attalus I., nephew of Philoerus, and the first who took upon him the title of king of Pergamum. He defeated the Gauls, who were desirous of settling in his territory; and, according to Livy, was the first of the Attalic princes who refused to pay a contribution to the barbarians. When Seleucus Cerammon was engaged in other wars, he invaded his territories, and conquered all the provinces on this side of Mount Taurus; but was soon driven out of his new acquisitions by Seleucus and his grandson Achaus, who entering into an alliance against him, deprived him of all his newly acquired territories, and even befeiged him in his capital. Upon his death...
Pergamus. Attalus invited to his assistance the Gauls who had settled in Thrace; and with their help not only obliged the enemy to raise the siege of Pergamus, but quickly recovered all the provinces he had lost. After this he invaded Ionia and the neighbouring provinces, where several cities voluntarily submitted to him. The Teians, Colonians, with the inhabitants of Egea and Lemnos, sent duplities declaring themselves ready to acknowledge him for their sovereign; the Carianas, on the other side the river Lykos, opened their gates to him, having first expelled the governor set over them by Achaeus. From thence he advanced to Apia, and encamping on the banks of the river Megeithus, received homage from the neighbouring nations. But here the Gauls, being frightened by an eclipse of the moon, refused to proceed farther; which obliged Attalus to return to the Hellespont, where he allowed his allies to settle, giving them a large and fruitful territory, and promising that he would always afford and protect them to the utmost of his power.

Attalus having thus settled his affairs with equal honour and advantage to himself, entered into an alliance with Rome, and afterwards joined them in their war against Philip king of Macedon. Here he had the command of the Rhodian fleet; with which he not only drove the Macedonians quite out of the seas, but having landed his men, he, in conjunction with the Athenians, invaded Macedon, and obliged Philip to raise the siege of Athens, which he had greatly diversified; for which services the Athenians not only heaped on him all the favours they could, but called one of their tribes by his name; an honour they had never before bestowed on any foreigner before.

Attalus, not contented with all he had yet done against Philip, attempted to form a general confederacy of the Greeks against him. But while he was haranguing the Bœotians to this purpose, and exhorting them with great vehemence to enter into an alliance with the Romans against their common enemy, he fell down speechless. However, he came to himself again, and desired to be carried by sea from Thessob to Pergamus, where he died soon after his arrival, in the 72d year of his age and 43d of his reign.

This prince was a man of great generosity, and such an enthusiastic in learning and learned men, that he caused a grammarian named Daphidus to be thrown into the sea from the top of a high rock, because he spoke disrespectfully of Homer.

Attalus was succeeded by his eldest son Eumenes II. He was exceedingly attached to the Romans, inasmuch that he refused the daughter of Antiochus the Great in marriage, lest he should thus have been led into a difference with that people. He also gave notice to the Roman senate of the transgressions of Ariarathes king of Cappadocia, who was making great preparations both by sea and land. Nor did Eumenes stop here; for when he saw the war about to break out between Antiochus and the Romans, he sent his brother Attalus to Rome to give information of the proceedings of Antiochus. The senate heaped honours both on Eumenes and his brother; and in the war which followed, gave the command of their fleet to the king of Pergamus in conjunction with C Livius Salinator. The victory gained on this occasion was in great measure owing to Eumenes, who boarded some of the enemy's ships in person, and during the whole action behaved with uncommon bravery. Some time afterwards Eumenes, entering the territories of Antiochus with a body of 5000 men, ravaged all the country about Thyatira, and returned with an immense booty. But in the mean time Antiochus invading Pergamus in his turn, ravaged the whole country, and even laid siege to the capital. Attalus, the king's brother, held out with an handful of men till the Achaean, who were in alliance with Eumenes, sent 1000 feet and 100 horse to his assistance. As this small body of auxiliaries were all chosen men, and commanded by an experienced officer, they behaved with such bravery that the Syrians were obliged to raise the siege. At the battle of Magnesia it, Eumenes behaved with the greatest bravery; not only fulfilling the first attack of the enemy's elephants, but driving them back again on their own troops, which put the ranks in disorder, and gave the Romans an opportunity of giving them a total defeat by attacking them opportunistly with their horse. In consequence of this defeat, Antiochus was obliged to conclude a peace with the Romans on such terms as they pleased to prescribe; one of which was, that he should pay Eumenes 400 talents, and a quantity of corn, in recompense for the damage he had done him.

Eumenes now thought of obtaining some reward from the Romans equivalent to the services he had done them. Having gone to Rome, he told the senate, that he was come to beg of them that the Greek cities which had belonged to Antiochus before the commencement of the late war, might now be added to his dominions; but his demand was warmly opposed by the ambassadors from Rhodes, as well as by deputies from all the Greek cities in Asia. The senate, however, after hearing both parties, decided the matter in favour of Eumenes, adding to his dominions all the countries on this side of Mount Taurus which belonged to Antiochus; the other provinces lying between that mountain and the river Meander, excepting Lycia and Caria, were bestowed on the Rhodians. All the cities, which had paid tribute to Attalus, were ordered to pay the same to Eumenes; but such as had been tributary to Antiochus were declared free.

Soon after this Eumenes was engaged in a war with Prusias king of Bithynia, who made war upon him by the advice of Hannibal the celebrated Carthaginian general. But Eumenes, being affiled by the Romans, defeated Prusias in an engagement by sea, and another by land; which so disheartened him, that he was ready to accept of peace on any terms. However, before the treaty was concluded, Hannibal found means to draw Philip of Macedon into the confederacy, who sent Philocles, an old and experienced officer, with a considerable body of troops to join Prusias. Hereupon Eumenes sent his brother Attalus to Rome with a golden crown, worth 15,000 talents, to compel Prusias for making war on the allies of the Roman people without any provocation. The senate accepted the present, and promised to adjut all every thing to the satisfaction of their friend Eumenes, whom they looked upon to be the most ready ally they had in Asia. But in the mean time Prusias, having ventured another sea-fight, by a contrivance of Hannibal's, gained a complete
complete victory. The Carthaginian commander adviced him to fill a great many earthen vessels with various kinds of serpents and other poisonous reptiles, and in the heat of the light with an appliance for setting them on fire, and let the serpents loose. All the soldiers and seamen were commanded to attack the ship in which Eumenes was, and only to defend themselves as well as they could against the reft; and that they might be in no danger of misfiring the ship, an herald was sent before the engagement with a letter to the king. As soon as the two fleets drew near, all the ships of Prusias, singling out that of Eumenes, discharged such a quantity of serpents into it, that neither folders nor sailors could do their duty, but were forced to fly to the shore, left they should fall into the enemy's hands. The other ships, after a faint resistance, followed the king's example, and were all driven ashore with great slaughter, the officers being no less annoyed by the stings of the serpents, than by the weapons of the enemy. The greatest part of the ships of Eumenes were burnt, several taken, and the others so much shattered that they became quite unserviceable. The fame year Prusias gained two remarkable victories over Eumenes by land, both of which were entirely owing to stratagems of Hannibal. But, while matters were thus going on to the disadvantage of Eumenes, the Romans interfered, and by their deputies not only put an end to the differences between the two kings, but prevailed on Prusias to betray Hannibal; upon which he inflicted himself, as hath been related under the article Hannibal.

Eumenes being thus freed from such a dangerous enemy, engaged in a new war with the kings of Cappadocia and Pontus, in which also he proved victorious. His friendship for the Romans he carried to such a degree of enthusiasm, that he went in person to Rome to inform them of the machinations of Perseus king of Macedon. He had before quarrelled with the Rhodians, who sent ambassadors to Rome to complain of him. But as the ambassadors happened to arrive while the king himself was present in the city, the Rhodian ambassadors could not obtain any hearing, and Eumenes was disgraced with new marks of censure. This journey, however, had almost proved fatal to him; for, on his return, as he was going to perform a sacrifice at Delphi, two serpents, sent by Perseus, rolled down two great stones upon him as he entered the straits of the mountains. With one he was dangerously wounded on the head and with the other on the shoulder. He fell with the blows from a steep place, and thus received many other bruises; so that he was carried on board his ship when it could not well be known whether he was dead or alive. His people, however, soon finding that he was still alive, conveyed him to Corinth, and from Corinth to Eginia, having cauaged their vessels to be carried over the Ilissus.

Eumenes remained at Eginia till his wounds were cured, which was done with such secrecy, that a report of his death was spread all over Asia, and even believed at Rome; nay, his brother Attalus was so convinced of the truth of this report, that he not only assumed the government, but even married Stratonice the wife of Eumenes. But in a short time Eumenes convinced them both of his being alive, by returning Pergamus to his kingdom. On the receipt of this news, Attalus resigned the fovereignty in great haste, and went to meet his brother; carrying an helmet, as one of his guards. Eumenes received both him and the queen with great tenderness, nor did he ever fay any thing which might tend to make them uneasy; only it is said he whispered in his brother's ear when he first saw him, "Be in no haste to marry my wife again till you are sure that I am dead."

The king being now more than ever exasperated against Perseus, joined the Romans in their war against him; but during the course of it he suddenly cooled in his affections towards those allies whom he had hitherto served with so much zeal, and that to such a degree, that he admitted ambafladors from Perseus, and offered to band neuter if he would pay him 1000 talents, and for 1500, to influence the Romans to grant him a safe and honourable peace. But those negotiations were broke off without effect, by reason of the distrust which the two kings had of one another. Eumenes could not trust Perseus unless he paid him the money beforehand; while, on the other hand, Perseus did not care to part with the money before Eumenes had performed what he promised; neither could he be induced to pay the sum in question, though the king of Pergamus offered to give hostages for the performance of his promise. What the reason of such a sudden change in the disposition of Eumenes was, is nowhere told; however, the fact is certain. The negotiations above-mentioned were concealed from the Romans as long as possible; but they soon came to be known; after which the republic began to entertain no small jealousy of their old friend, and therefore heaped favours on his brother Attalus, without taking any notice of the king himself. Eumenes had sent him to Rome to congratulate the senate on the happy issue of the war with Perseus, not thinking that his practices had been discovered. However, the senate, without taking any notice of their dissatisfaction to Eumenes at first, entertained Attalus with the greatest magnificence; then several of the senators who visited him proceeded to acquaint him with their suspicions of the king, and desired Attalus to treat with him in his own name, assuring him, that the kingdom of Pergamus would be granted him, if he demanded it, by the senate. These speeches had at first some effect; but Attalus, being of an honest disposition, and afficted by the advice of a physician called Stratus, a man of great probity, resolved not to comply with their desire. When he was admitted to the senate, therefore, he first congratulated them on the happy issue of the Macedonian war, then modestly recounted his own services; and lastly, acquainted them with the motive of his journey; intreated them to send ambafladors to the Gauls, by whom their authority might secure his brother from any danger of their hostilities; and he requested them also, that the two cities of Thessalonica and Maronea might be bestowed on him; felf. The senate, imagining that Attalus designed to choose some other day to sue for his brother's kingdom, not only granted all his requests, but fent him richer and more magnificent presents than they had ever done before. Upon this Attalus immediately set out on his return to Pergamus; which so provoked the senators, that they declared
AttaIus, thus rendering ineffectual their promise which they were ashamed openly to revoke; and as for the Gauls, who were on all occasions ready to invade the kingdom of Pergamus, they sent ambassadors to them, with instructions to behave in a manner as would rather tend to encourage them in their design than dissuade them from it.

Eumenes, being alarmed at these proceedings, resolved to go in person to Rome, in order to justify himself. But the senate, having already condemned him in their own minds, resolved not to hear his vindication. For this reason, as soon as they heard of his design, they made an act that no king should be permitted to enter the gates of Rome. Eumenes, however, who knew nothing of this act, set forward on his journey, and landed at Brundusium; but no sooner did the Roman senate get intelligence of his arrival there, than they sent a few senators and princes to the decree of the senate, and telling him at the same time, that if he had any business to transact with the senate he was appointed to hear it, and transmit it to them; but if not, that the king must leave Italy without delay. To this Eumenes replied, that he had no business of any consequence to transact, and that he did not stand in need of any of their assistance; and without saying a word more, went on board his ship, and returned to Pergamus.

On his return home, the Gauls, being encouraged by the cold reception which he had met with at Rome, invaded his territories, but were repulsed with great loss by the king, who, afterwards invaded the dominions of Prusias, and possessed himself of several cities. This produced new complaints at Rome; and Eumenes was accused, not only by the ambassadors of Prusias, but also by those of the Gauls and many cities in Asia, of keeping a secret communication with Perseus king of Macedon. This last charge was confirmed by some letters which the Romans themselves had intercepted; so that Eumenes found it impossible to keep up his credit any longer at Rome, though he sent his brothers Athenaeus and Attalus thither to intercede for him. The senators, in short, had conceived the most implacable hatred against him, and feared absolutely bent on his destruction, when he died, in the 39 year of his reign, leaving his kingdom and his wife to his brother Attalus. He left one son, but he was an infant, and incapable of governing the kingdom; for which reason Eumenes chose rather to give the present possession of the crown to his brother, reserving the succession to his son, than to endanger the whole by committing the management of affairs to his son's tutors.

Attalus, in the beginning of his reign, found himself greatly diffraeted by Prusias king of Bithynia, who not only overthrew him in a pitched battle, but advanced to the very walls of Pergamus, ravaging the country as he marched along; and at last reduced the royal city itself. The king, however, saved himself by a timely flight, and dispatched ambassadors to Rome, complaining of the bad usage of Prusias. The latter endeavoured to defend himself, and to throw the blame on Attalus. But, after a proper inquiry was made into the matter, Prusias was found to be entirely in the wrong; in consequence of which, he was at last obliged to conclude a peace with his adversary on the following terms. 1. That he should immediately deliver up to Attalus 20 ships with decks. 2. That he should pay 500 talents to Attalus within the space of 20 years. 3. That he should pay 100 talents to some of the other Asiatic nations by way of reparation for the damages they had sustained from him. And, 4. Both parties should be content with what they had before the beginning of the war.

Some time after this, Prusias having made an unnatural attempt on the life of his son Nicomedes, the latter rebelled, and, with the assistance of Attalus, drove his father from the throne, and, as is said, even murdered him in the temple of Jupiter. The Romans took no notice of these transactions, but showed the same kindness to Attalus as formerly. The last enterprise in which we find Attalus engaged, was against Andrianus the pretended son of Perseus king of Macedon, when he afflicted the Romans; after which he gave himself up entirely to ease and luxury, committing his affairs entirely to his ministers; and thus continued to his death, which happened in the 82d year of his age, about 138 B.C.

Attalus II. was succeeded by Attalus III. the son of Eumenes; for the late king, considering that he only held the crown as a truft for his nephew, passed by his own children in order to give it to him, tho' he appears to have been by no means worthy of it. He is said to have been deprived of his sences throu' the violence of his grief for his mother's death; and indeed, throughout his whole reign, he behaved more like a madman than anything else. Many of his subjects of the highest quality were cut off with their wives and children, upon the most groundless suspicions; and for these executions he made use of mercenaries hired out from among the most barbarous nations. Thus he proceeded till he had cut off all the best men in the kingdom; after which he fell into a deep melancholy, imagining that the ghosts of those whom he had murdered were perpetually haunting him. On this he flung himself up in his palace, put on a mean apparel, let his hair and beard grow, and seducled himself from all mankind. At last he withdrew from the palace, and retired into a garden, which he cultivated with his own hands, and filled with all sorts of poisonous herbs. These he used to mix with wholesome pulate, and send packets of them to such as he suspected. At last, being weary of his amusements, and living in solitude, because no body durst approach him, he took it in his head to follow the trade of a foundry, and make a brazen monument. But, while he laboured at melting and casting the brass, the heat of the sun and furnace threw him into a fever, which in seven days put an end to his tyranny, after he had sat on the throne five years.

On the death of the king, a will was found, by which he left the Roman people heirs of all his goods; upon which they seized on the kingdom, and reduced it to a province of their empire by the name of Asia Proper. But Arilonicus, a son of Eumenes by an Ephesian courtean reckoning himself the lawful heir to the crown, could by no means be satisfied with this usurpation of the Romans, and therefore assembled a considerable army to maintain his pretensions. The people in general, having been accustomed to a mon-
Pergamus, narchy, dreaded a republican form of government; in consequence of which, they afflicted Arilonicus, and soon put him in a condition to reduce the whole kingdom. The news, however, were soon carried to Rome; and Licinius Craflus, the pontifex maximus, was sent into the caft, with orders to enforce obedience to the king's will. Historians take no notice of any forces which were sent along with this commander; whence it is supposed, that he depended on assistance from the Asiatics, who were in alliance with Rome, or from the Egyptians. But when he came thither, he found both the Syrians and Egyptians so reduced, that he could not expect any assistance from them. However, he was soon supplied with troops in plenty by Bithynia, Cappadocia, and Phaphagonia; but managed matters so ill, that he was entirely defeated and taken prisoner. Those who took him, designed to carry him to Arilonicus; but, he not able to endure the disgrace, would have laid violent hands on himself if he had not been disarmed. However, being allowed to keep a rod for managing the horse on which he fat, he struck a Thracian soldier who stood near him fo violently with it, that he beat out one of his eyes; upon which the other drew his sword, and ran him thro' on the spot. His head was brought to Arilonicus, who exposed it to public view; but the body was honourably buried.

Arilonicus had no great time to enjoy the fruits of his victory. Indeed he behaved very improperly after it; for, instead of preparing to oppose the next army, which he might have been assured the Romans would send against him, he spent his time in feasting and revelling. But he was soon routed out of his lethargy by Perpenna the new confull, who having assembled with incredible expedition the troops of the allies, came unexpectedly upon him, obliged him to venture an engagement at a disadvantage, and entirely defeated him. Arilonicus fled to a city called Stratonic; but was so closely pursued by the conqueror, that the garrifon, having no method of supplying themselves with provisions, delivered up their leader, as well as a philosopher named Biflours, who had been the companion and counsellor of Arilonicus. The philosopher behaved with great resolution after being taken, and openly defended his siding with Arilonicus, because he thought his cause just. He exhorted the latter to prevent the disgrace and misery of captivity by a voluntary death; but Arilonicus, looking upon death as a greater misery than any captivity, suffered himself to be treated as his conquerors pleased.

In the mean time, a new confull, named Manius Aquilinus, being arrived from Rome, sent a moft haughty message to Perpenna, requiring him immediately to deliver up Arilonicus, as a captive belonging to his triumph when the war should be ended. With this demand Perpenna refused to comply, and his refusal had almost produced a civil war. However, this was prevented by the death of Perpenna, which happened soon after the dispute commenced. The Pergame¬nians, notwithstanding the defeat and captivity of their leader, still held out with much obstinacy that Aquilinus was obliged to besiege, and take by force, almost every city in the kingdom. In doing this, he took a very effectual, though exceeding cruel method. Most of the cities in the kingdom had no other water than what was brought from a considerable distance in Pergunnah aqueducts. These Aquilinus did not demolish but poisoned the water, which produced the greatest abhorrence of him throughout all the caft. At last, however, the whole country being reduced, Aquilinus triumphed, the unhappy Arilonicus was led in chains before his chariot, and probably ended his miserable life in a dungeon. The country remained subject to the Romans while their empire lasted, but is now in the hands of the Turks. The city is half ruined, and is still known by the name of Pergamus. It is inhabited by about 3000 Turks, and a few families of poor Christians.

E. Long. 27, 27. N. Lat. 30. 3.

PERGUNNAH, in the language of Hindoostaan, means the largest subdivision of a province, whereas the revenues are brought to one particular head Cuthbery, from whence the accounts and cash are transmitted to the general Cuthery of the province.

PERIAGOGE, in rhetoric, is used where many things are accumulated into one period which might have been divided into several.

PERIAGUA, a fort of large canoe made ufe of in the Leeward islands, South America, and the gulf of Mexico. It is composed of the trunks of two trees hollowed and united together; and thus differs from the canoe, which is formed of one tree.

PERIANDER, tyrant of Corinth and Corcyra, was reckoned among the seven wise men of Greece; though he might rather have been reckoned among the most wicked men, since he changed the government of his country, deprived his countrymen of their liberty, usurped the sovereignty, and committed the most shocking crimes. In the beginning of his reign he behaved with mildness; but after his having sent to the tyrant of Syracuse to consult him on the safest method of government, he abandoned himself to cruelty. The latter, having heard Periander's envoys, took them into a field, and, instead of answering them, pulled up before them the ears of corn which exceeded the reit in height. Periander, on being told of this action, understood what was meant by it. He first secured himself by a good guard and then put the most powerful Corinthians to death. He abandoned himself to the most enormous crimes; committed incest with his mother, killed to death his wife Melitta, daughter of Procles king of Epidaurus, notwithstanding her being with child; and was so enraged at Lycophon, his second son, for lamenting his mother's death, that he banished him into the island of Corcyra. Yet he pafled for one of the greatest politicians of his time; and Heraclides tells us, that he forbade voluptuousness; that he imposed no taxes, contenting himself with the custom arising from the sale and the import and export of commodities; that, tho' wicked himself, he hated the wicked, and caused all pimps to be drowned; lastly, that he established a female, and settled the expence of its members. He died 585 B.C.

PERIANTHIUM, (from πειραθιον, "round," and ἄθος, "the flower,") the flower cup properly so called, the most common species of calyx, placed immediately under the flower, which is contained in it as in a cup. See BOTANY, p. 433, col. 1.

PERICARDIUM, in anatomy, a membranous bag filled with water, which contains the heart in man and...
and many other animals. It is formed by a duplicature of the median tum, or membrane which divides the thorax into two unequal parts. See Anatomy, n. 121.

PERICARPIUM, (from περικερύς “round,” and καρπός “fruit,”) the feed vesel; an entral of the plant big with feeds, which it discharges when ripe. The feed-vesel is in fact the developed seed bud, and may very properly be compared to the fecundated ovary in animals; for it does not exist till after the fertilizing of the feeds by the male dust, and the consequent fall of the flower. All plants, however, are not furnished with a feed-vesel; in such as are deprived of it, the receptacle or calyx performs its functions by inclining the feeds, as in a matrix, and accompanying them to perfect maturity.

PERICHORUS, in antiquity, a name given by the Greeks to their profane games or combats, that is, to such as were not consecrated to any of the gods.

PERICLES, was one of the greatest men that ever flourished in Greece. He was educated with all imaginable care; and besides other matters, he had for his tutors Zeno, Eleates, and Anaxagoras. He learned from the laft of these to fear the gods without superstition, and to account for an eclipse from a natural cause. Many were unjust enough to suspect him of atheism, because he had perfectly studied the doctrine of that philosopher. He was a man of undoubting courage; and of such extraordinary eloquence, supported and improved by knowledge, that he gained almost as great an authority under a republican government as if he had been a monarch; but yet he could not escape the satirical frokes of the comic poets. His discourses with the women were one of the vices with which he was chiefly charged. He died the third year of the Peloponnesian war, after long sickness, which had weakened his understanding. Aephaia, Pericles's favourite, was a learned woman of Miletus; she taught Socrates rhetoric and politics. As Pericles cared not much for his wife, he willingly gave her up to another, and married Aephaia, whom he passionately loved.

PERICRANIUM, in anatomy, a thick solid coat or membrane covering the outside of the cranium or skull. See Anatomy, n. 4.

PERIGEE, in astronomy, that point of the sun or moon's orbit wherein they are at the least distance from the earth, in which sense it flands opposed to apogee.

PERIGEUX, an ancient episcopal town of France, capital of the province of Perigord, seated on the river Isle, in E. Lon. o. 53. N. Lat. 45. 18. It is remarkable for the ruins of the temple of Venus, and an amphitheatre.

PERIGORD, a province of France, which makes part of Guienne, bounded on the north by Angoumois and a part of Marne, and on the ealt by Quercy and Limousin; on the south by Agenois and Baza-
dois; and on the west, by Bourledois, Angoumois, and a part of Saintonge. It is about 83 miles in length, and 60 in breadth. It abounds in iron mines, and the air is pure and healthy. Perigex is the capital town.

PERIGORD-Stone, an ore of mangaenite, of a dark grey colour, like the bafaltes or trappe. It may be scraped with a knife, but is extremely difficult to be broken. It is found of no regular figure, is very compact, heavy, and as black as charcoal. Its appearance is glittering and flinted, like the ore of antimonii; its particles being disposed in the form of needles, crossing one another without any agglutination, infomuch that some are loose as iron-shot; when fluck to a lodestone; resembling the scoria from a blacksmith's furnace. By calcination it becomes harder and of a reddish-brown colour, but is not attracted by the magnet. It has a considerable specific gravity, does not melt per /, but with borax runs into a glass of the colour of an amethyst. It is scarcely affected by nitrous acid without the addition of sugar. It seems also to contain some argil and iron. It is met with in Gascony and Dauphiny in France, and in some parts of England. It is employed by the French potters and enamellers in the glazy varnish of their earthen wares.

PERIGRAPHE, a word usually understood to express a careless or inaccurate delineation of anything; but in Vellus it is used to express the white lines or impressions that appear on the musculus rectus of the abdomen.

PERIHELION, in astronomy, that part of a planet or comet's orbit wherein it is in its least distance from the sun, in which sense it stands in opposition to aphelium.

PERIMETER, in geometry, the bounds or limits of any figure or body. The perimeters of surfaces or figures are lines; those of bodies are surfaces. In circular figures, instead of perimeter, we say circumference, or periphery.

PERINEUM, or PERINEUM, in anatomy, the space between the anus and the parts of generation, divided into two equal lateral divisions by a very distinct line, which is longer in males than in females.

PERINSKIOLD (John), a learned Swedish writer, born at Stredniva in Suederania, in 1654, studied under his father, who was professor of eloquence and poetry, and afterwards became well skilled in the antiquities of the north. He was made professor at Upsal, secretary antiquary of the king of Sweden, and councillor of the chancery of antiquities. He died in 1720. His principal works are; 1. A History of the Kings of Norway. 2. A History of the Kings of the North. 3. An Edition of John Meffenius on the Kings of Sweden, Norway, and Denmark, in 14 vols folio, &c. All Perinskiold's works are excellent, and highly esteemed.

PERIOD, in astronomy, the time taken up by a star or planet in making a revolution round the sun; or the duration of its course till it return to the same part of its orbit. See Planet.

The different periods and mean distances of the several plants are as follow:

<table>
<thead>
<tr>
<th>Planet</th>
<th>Days</th>
<th>h</th>

There is a wonderful harmony between the distances of...
of the planets from the sun, and their periods round
him; the great law whereof is, that the squares of the
periodical times of the primary planets, are to each
other as the cubes of their distances from the sun:
and likewise, the squares of the periodical times of the
secondaries of any planet are to each other as the cubes
of their distances from that primary. This harmony
among the planets is one of the greatest confirmations
of the Copernican hypothesis. See Astronomy, n°
414.

For the periods of the moon, see Astronomy, n°
422, and observe Index to astronomy.

Period, in chronology, denotes a revolution of a
certain number of years, or a series of years, whereby,
in different nations, and on different occasions, time is
measured; such are the following.

Calippic Period, a system of seventy-six years. See
Calippic, and Astronomy, n° 1, &c.

Dionysian Period, or Victorian Period, a system of
532 lunae-solem and Julian years; which being eclipsed,
the characters of the moon fall again upon the same
day and era, and revolve in the same order, accord-
ing to the opinion of the ancients.

This period is otherwise called the great paschal
cycle, because the Christian church first used it to find
the true time of the pascha or Easter. The sum of these
years arise by multiplying together the cycles of the
sun and moon.

Hipparchus’s Period, is a series of 304 solar years,
returning in a constant round, and restoring the new
and full moons to the same day of the solar year, ac-
cording to the sentiment of Hipparchus. This period
arises by multiplying the Calippic period by four.

Hipparchus assumed the quantity of the solar year
to be 365 days 5 hours 55; 10"; and hence con
duced, that in 104 years Calippus’s period would err a whole
day. He therefore multiplied the period by four, and
from the product cast away an entire day. But
even this does not restore the new and full moons to the
same day throughout the whole period; but they are
sometimes anticipated 1 day 8 hours 234 29" 20".
See Astronomy, n° 14.

Julian Period. See Julian.

Period, in grammar, denotes a small compass of
discourse, containing a perfect sentence, and distinc-
ted at the end by a point, or full stop, thus (.); and
in members of division marked by commas, col-
ons, &c.

Father Buffier observes two difficulties in the use of the
period, or point; i.e. in distinguishing it from the
colon, or double point; and in determining justly the
end of a period, or perfect sentence. It is remarked,
that the supernumerary members of a period, separated
from the real by colons and semicolons, usually com-
 mencement with a conjunction: yet it is true these same
conjunctions sometimes rather begin new periods than
supernumerary members of old ones. It is the sense of
things, and the author’s own discretion, that must
make the proper distinction which of the two in effect
it is. No rules will be of any service, unless this be ad-
mitted as one, that when what follows the conjunctive
is of as much extent as what precedes it, it is usually
a new period; otherwise not.

The second difficulty arises hence, that the sense
appears perfect in several short detached phrases, where-
in it does not seem there should be periods; a thing
frequent in free discourse: as, We are all in sufpen-
s: make your proposals immediately: you will be to blame for
detaining us longer. Where it is evident, that simple
phrases have perfect senses like periods, and ought to
be marked accordingly; but the shortness of the dis-
course making them easily comprehended, the point
is neglected.

De Colonius defines period a short but perfect sen-
tence, consisting of certain parts or members, depend-
ing one on another, and connected together by one com-
mon vinculum. The celebrated definition of Aristotle
is, a period is a discourse which has a beginning, a
middle, and an end, all visible at one view. Rhetorici-
ens consider period, which treats of the structure of
sentences, as one of the four parts of composition.
The periods allowed in oratory are three: A period of
two members, called by the Greeks δίοδος, and by the
Latins binembris; a period of three members, τριοδος,
trimembris; and a period of four, quadrinembris, tetra-
colos. See Punctuation.

Period, in numbers, is a distinction made by a point
or comma, after every sixth place, or figure; and is
used in numeration, for the easier distinguishing and
naming the several figures or places; which see under
Numeration.

Period, in medicine, is applied to certain diseases
which have intervals, and returns, to denote an entire
curse or circle of such disease; or its progress from
one state through all the rest till it return to the same
again.

Galen describes period as a time composed of an in-
tention and remission, wherein it is usually divided into
two parts, the paroxytm or exacerbation, and remis-
ion.

In intermittitent fevers, the periods are usually flated
and regular; in other diseases, as the epilepsy, gout,
&c. they are vague or irregular.

Period, in oratory. See there, n° 47.

PERIODIC, or Periodical, fomething that ter-
minalizes and comprehends a period; such is a periodic
mouth; being the space of time wherein the moon
dispatches her period.

PERIOECT, επιπέδος, in geography, such inhabi-
tants of the earth as have the same latitude, but
opposite longitudes, or live under the same parallel; and
the same meridian, but in different semicircles of that
meridian, or in opposite points of the parallel. Thence
have the same moon seasons throughout the year,
and the same phenomena of the heavenly bodies; but
when it is noon-day with the one, it is midnight with
the other, there being twelve hours in an east and west
direction. Thence are found on the globe by the hour
index, or by turning the globe half round, that is, 180
degrees either way.

PERIOSTEUM, or Periostium, in anatomy, a
nervous vascular membrane, endued with a very quck
sense, immediately surrounding, in every part, both
the internal and external surfaces of all the bones in the
body, excepting only fo much of the teeth as stand
above the gums, and the peculiar places on the bones,
in which the muscles are inserted. It is hence divided
into the external and internal periostium; and where
it
it externally surrounds the bones of the skull, it
is generally called the periocranium. See Anatomy, p. 4.

PERIPATETICS, philosophers, followers of Ari-
totle, and maintainers of the peripatetic philosophy; called also Aristotelians. Cicero says, that Plato left
two excellent disciples, Xenocrates and Aristotle, who
founded two sects, which only differed in name: the
former took the appellation of Academicians, who were
those that continued to hold their conferences in the
Academy, as Plato had done before; the others, who
followed Aristotle, were called Peripatetics, from
peri-\patetikos, "I walk," because they disputed walking
in the Lyceum.

Ammonius derives the name Peripatetic from Plato
himself, who only taught walking; and adds, that the
disciples of Aristotle, and those of Xenocrates, were
equally called Peripatetics; the one Peripatetics of the
Academy, the other Peripatetics of the Lyceum; but
that in time the former quitted the title Peripatetic for
the sake of Academic, on account of the place where
they assembled; and the latter retained simply that of
Peripatetic. The greatest and last part of Aristotle's
philosophy was borrowed from Plato. Sertorius affirms,
and says he could demonstrate, that there is nothing
exquisite in any part of Aristotle's philosophy, dialectics,
ethics, politics, physics, or metaphysics, but is
found in Plato. And of this opinion are many of the
ancient authors, such as Clemens Alexandrinus, &c.
Gale attempts to show, that Aristotle borrowed a good
deal of his philosophy, both physical and metaphysical,
about the first matter, and metaphysical about the first being, his affec-
tions, truth, unity, goodness, &c. from the Scriptures;
and adds from Clesarchus, one of Aristotle's scholars,
that he made use of a certain Jew, who
affiliated him therein.

Aristotle's philosophy preferred itself in paris natura-
ibus for a long time; in the earlier ages of Christianity,
the Platonic philosophy was generally preferred; but
this did not prevent the doctrine of Aristotle from
taking its way into the Christian church. Towards the
end of the fifth century, it rose into great credit; the
Platonics interpreting in their schools some of the
writings of Aristotle, particularly his dialectics, and
recommending them to young persons. This appears
to have been the first step to that universal dominion
which Aristotle afterwards obtained among the learned,
which was at the same time much promoted by the
controversies which Origen had occasioned. This
father was zealously attached to the Platonic system;
and therefore, after his condemnation, many, to avoid
the imputation of his errors, and to prevent their being
counted among the number of his followers, openly
adopted the philosophy of Aristotle. Nor was any
philosophy more prone for furnishing those weapons of
subtle distinctions and captious sophisms, which were
used in the Neotanians, Arians, and Euchistian contro-
versies. About the end of the sixth century, the
Aristotelian philosophy, as well as science in general, was
almost universally decried; and it was chiefly owing to
Bozthius, who explained and recommended it, that
it obtained a higher degree of credit among the La ins
than it had hitherto enjoyed. Towards the end of the
seventh century, the Greeks abandoned Plato to the
monks, and gave themselves up entirely to the direc-
tion of Aristotle; and in the next century, the Peri-
patetic philosophy was taught every where in their pub-
lic schools, and propagated in all places with consider-
able success. John Damascenus very much contributed
to its credit and influence, by compiling a concise,
plain, and comprehensive view of the doctrines of the
Stagirite, for the instruction of the more ignorant, and
in a manner adapted to common capacities. Under
the patronage of Photuss, and the protection of Bardes,
the study of philosophy for some time declined, but
was revived again about the end of the ninth century.
About the middle of the 11th century, a revolution
in philosophy commenced in France; when several fa-
mous logicians, who followed Aristotle as their guide,
took nevertheless the liberty of illustrating and modell-
ing anew his philosophy, and extending it far beyond
its ancient limits. In the 12th century, three methods
of teaching philosophy were in use by different doc-
tors: the first was the ancient and primitive system, which
confined its researches to the philosophical notions of
Porphyry, and the dialectical system, commonly attri-
buted to St Augustine, and in which was laid down
this general rule, that philosophical inquiries were to
be limited to a small number of subjects, left, by their
becoming too extensive, religion might suffer by a pro-
fuse mixture of human futility with its divine wisdom.
The second method was called the Aristotelian, because
it confided in explications of the works of that philo-
osopher, several of which books, being translated into
Latin, were almost everywhere in the hands of the
learners. The third was termed the tree method, em-
ployed by such as were bold enough to search after
truth, in the manner the most adapted to render their
inquiries successful, without rejecting the success of
Aristotle and Plato. A reformed system of the Peri-
patetic philosophy was first introduced into the schools
in the university of Paris, from whence it soon spread
throughout Europe; and has subsisted in some universi-
ties even to this day, under the name of schol. philos.
Y.

The foundation thereof is Aristotle's doctrine, often
misunderstood, but other misapplied: whence the ret-
tainer thereof may be denominated Reformed Peri-
patetics. Out of these have sprung, at various times, sev-
eral branches; the chief are, the Thomists, Scotchists,
and Nominalists. See these articles.

The Peripatetic system, after having prevailed with
great and extensive dominion for many centuries, be-
gan rapidly to decline towards the close of the 17th
when the disciples of Ramus attacked it on the one
hand, and had still more formidable adversaries to
encounter, in Descartes, Gassendi, and New. See
Philosophy.

PERIPATON, in antiquity, the name of that walk
in the Lyceum where Aristotle taught, and whence the
name of Peripatetics given to his followers.

PERIPETIA, in the drama, that part of a trage-
dy wherein the action is turned, the plot unravelled,
and the whole concludes. See Catastrophe.

PERIPHERY, in geometry, the circumference of
circle, ellipse, or any other regular curve, or line.
See Geometry.

PERIPHERIAS, circumstance, formed of peri-
about,” and same “I speak;” in rhetoric, a circuit-
or tour of words, much affected by orators, and a resid-
common and trite manners of expression. The peri-
phrases.
**PER** [150] **PER**

**PERIPLOCA,** Virginian silk, in botany: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 30th order, Contorta. The neoflora surrounds the genitals, and feeds out five filaments. There are five species, four of which are natives of warm climates, and can only be raised there. The fifth, however, is sufficiently hardy for this climate. The propagation of this climber is very easy; for if they are laid down in the ground, or a seed is sown, they will strike root at the joints, and two of the shoots, they are succeeded by a long taper pod, with compressed seeds, having down to their tops.

The propagation of this climber is very easy; for if the cuttings are planted in a light moist soil, in the autumn or in the spring, they will readily strike root. Three joints at least should be allowed to each cutting; they should be the bottom of the preceding summer's shoot; and two of the joints should be planted deep in the soil. Another, and a never-failing method, is by layers; for if they are laid down in the ground, or a little foil only loosely thrown over the young preceding summer's shoots, they will strike root at the joints, and be good plants for removing the winter following.

**PERINEUM,** derived from *peri* "about," and *neum* "lungs," in medicine, an inflammation of some part of the thorax, properly of Perizhantrium, a vessel of bone or brafs which was filled with holy water, and with which all those were sprinkled who were admitted by the ancients to their sacrifices. Beyond this vessel no profane person was allowed to pass. We are told by some, that it was placed in the Aduam, or in the recess of the temple; others say it was placed at the door, which indeed seems to be the most likely opinion. It was used both by Greeks and Romans, and has been evidently borrowed, like many other Pagan ceremonies, by the Church of Rome. The Hebrews had a vessel for purification.

**PERISCIIL**, in geography, the inhabitants of either frigid zones, between the polar circles and the poles, where the sun, when in the summer signs, moves only round about them, without setting; and consequently their shadows in the same day turn to all the points of the horizon.

**PERISTALTIC,** a vermicular spontaneous motion of the intestines, performed by the contraction of the circular and longitudinal fibres of which the fleshy coats of the intestines are composed; by means whereof the chyle is driven into the orifices of the lacteal veins, and the faces are protruded towards the anus.

**PERISTYLE,** in ancient architecture, a building encompassed with a row of columns on the infide.

**PERITONÆUM,** in anatomy, is a thin, smooth, and lebruous membrane, investing the whole internal surface of the abdomen, and containing most of the vifera of that part as it were in a bag. See Anatomy, No. 59.

**PERITROCHIUM,** in mechanics, denotes a wheel, or circle, concentric with the base of a cylinder, and moveable together with it about its axis. See Mechanics.

**PERJURY,** in law, is defined by Sir Edward Coke to be a crime committed when a lawful oath is administered, in some judicial proceeding, to a person who swears willfully, absolutely, and falsely, in a matter material to the issue or point in question. In ancient times it was in some places punished with death; in others it made the false swearer liable to the punishment due to the crime he had charged the innocent person with; in others a pecuniary mulct was imposed. But though it escaped human, yet it was thought, amongst the ancients in general, that the divine vengeance would most certainly overtake it; and there are many severe infirmities from the hand of God upon record, as monuments of the abhorrence in which this atrocious crime is held by the Deity. The souls of the deceased were supposed to be employed in punishing perjured persons. Even the inanimate creation was thought to take revenge for this crime. The Greeks supposed that no perfon could swear falsely by Styx without some remarkable punishment; and that no person guilty of perjury could enter the cave of Palemon at Corinth without being made a memorable example of divine justice. In Sicily, at the temple of the Palici, there were fountains called Delfi, from which infued boiling water, with flames and balls of fire; and we are told that if any person swore falsely near them, he was instantly struck dumb, blind, lame,
Perjury, or dead, or was swallowed up by the waters. But although perjury was thus held in general abhorrence, notwithstanding the credit which was given to such accounts of divine inflictions, it was so much practised by the Greeks, that Græc. ἔλος became a proverb. Lovers perjuries, however, were supposed to pass unnoticed, or to be very lightly punished with blackness of the nails, a decayed tooth, or some small diminution of beauty.

The ancient philosophers, however, were so afraid of perjury, that even an oath before a judge was never admitted but for want of other proof. Plato's precept was, "Not to administer an oath wantonly, but on deep grounds, and with the strictest caution." Ulpian gives his opinion thus: "Some are forward to take oaths from a contempt of religion; others, from an extraordinary awe of the Divine Majesty, carry their fear to an unreasonable superstition; so make an equitable decision of a judge necessary." "No man will perjure himself (says Anitote) who apprehends vengeance from Heaven and disgrace among men." Climias was so very ferulous, that rather than take an oath (though lawfully), he suffered the loss of three talents. Perjury, in the time of Philo Judeus, was abominated and capital punishment among the Jews; though since they have much degenerated, having been poisoned with the books of the Talmud, which says, "He who breaks his promissory oath, or any vows he enters into by the year, if he has a mind to make in the year following, let him rise foro, and void, and of no effect." Tract. iii. part 3. of the Talmud, in the treatife Nedharim, ch. 4. And the modern Jews use the same artifice, thinking they may thus lawfully deceive the Christians. See Hieron. ex Ditiis Talmud, c. 3. and Magister Ioannes de Concor. Legum, tit. iv. c. 7. In our law, no notice is taken of any perjury but such as is committed in some court of justice having power to administer an oath; or before some magistrate or proper officer invested with a similar authority, in some proceedings relative to a civil suit or a criminal prosecution: for it esteems all other oaths unnecessary at least, and therefore would not punish the breach thereof. For which reason it is much to be questioned, how far any magistrate is justifiable in taking a voluntary affidavit in any extrajudicial matter, as is now too frequent upon every petty occasion; since it is more than possible that, by such idle oaths, a man may frequently, in foro conscientiæ, incur the guilt, and at the same time evade the temporal penalties of perjury. The perjury must also be corrupt (that is, committed mala anima), wilful, positive, and absolute; not upon surprize, or the like: it also must be in some point material to the question in dispute; for if it only be in some trifling collateral circumstance, to which no regard is paid, it it no more penal than in the voluntary extrajudicial oaths before mentioned. Subornation of perjury is the offence of procuring another to take such a false oath, as constitutes perjury in the principal. The punishment of perjury and subornation, at common law, has been various. It was anciently death; afterwards banishment, or cutting out the tongue; then forfeiture of goods; and now it is fine and imprisonment, and never more to be capable of bearing testimony. But the statute 5 Eliz. c. 9. (if the offender be prosecuted thereon) inflicts the penalty of perpetual infamy, and a fine of 40 l. on the fabommer; and in default of payment, imprisonment for six months, and to stand with both ears nailed to the pillory. Perjury itself is thereby punished with six months imprisonment, perpetual infamy, and a fine of 20 l. or to have both ears nailed to the pillory. But the prosecution is usually carried on for the offence at common law; especially as, to the penalties before inflicted, the statute 2 Geo. II. c. 25. supraedes a power for the court to order the offender to be sent to the house of correction for a term not exceeding seven years, or to be transported for the same period; and makes it felony, without benefit of clergy, to return or escape within the time. It has sometimes been wilful, i.e. that perjury, at least upon capital accusations whereby another's life has been or might have been destroyed, was also rendered capital, upon a principle of retaliation; as it was universally by the laws of France. And certainly the odiousness of the crime pleads strongly in behalf of the French law. But it is to be considered, that there they admitted witneses to be heard only on the side of the prosecution, and used the rack to extort a confession from the accused. In such a constitution, therefore, it was necessary to throw the dread of capital punishment into the other scale, in order to keep in awe the witneses for the crown; on whom alone the prisoner's fate depended: so naturally does one cruel law beget another. But corporal and pecuniary punishments, exile, and perpetual infamy, are more suited to the genius of the English law; where the fact is openly discussed between witneses on both sides, and the evidence for the crown may be contradicted and disproved by those of the prisoner. Where indeed the death of an innocent person has actually been the consequence of such wilful perjury, it falls within the guilt of deliberate murder, and deserves an equal punishment; which our ancient law in fact inflicted. But the mere attempt to deploy life by other means not being capital, there is no reason that an attempt by perjury should; much less that this crime should, in all judicial cases, be punished with death. For to multiply capital punishments lessens their effect, when applied to crimes of the lesser dyes; and, detestable as it is, it is not by any means to be compared with some other offences, for which only death can be inflicted; and therefore it seems already (except perhaps in the instance of deliberate murder by perjury) very properly punished by our present law; which has adopted the opinion of Cicero, derived from the law of the twelve tables, Perjurì peccavit, divina, exitial, humana, deducit. See Oath. PERIWIG. See PERUK. PERIZONIUS (James), a very learned and laborious writer, was born at Dam in 1651. He became profeffor of history and eloquence at the university of Franeker, when, by his merit and learning, he made that university flourish. However, in 1695, he went to Leyden, where he was made profeffor of history, eloquence, and the Greek tongue; in which employment he continued till his death, which happened in 1715. He wrote many Differtations, and other learned and curious works, particularly Origines Babylonica et Egypiae.
children of a sanguine habit and delicate constitution; Perones.

and may be prevented or removed by such remedies as

invigorate the system, and are capable of removing any
tendency to gangrene in the constitution.

Perones, is an epithet applied to

some of the muscles of the perone or fibula. See

Anatomy, Table of the Muscles.

Perones, a sort of high shoes which were worn

not only by country people, but by men of ordinary

rank at Rome. In the early times of the common-

wealth they were worn even by senators: but at last

they were diffused by persons or figure, and confined
to ploughmen and labourers. They were very rudely

formed, confisting only of hides undressed, and reaching
to the middle of the leg. Virgil mentions

the perones as worn by a company of rustic soldiers on one

foot only.

Peronne, a strong town of France, in Picardy,
capital of Santerre. It is said never to have been
taken, though often beleaguered. It is seated on the river
Somme, in L. Long. 51. N. Lat. 44. 50.

Peroration, in rhetoric, the epilogue or last
part of an oration, wherein what the orator had insinu-
ated throughout his whole discourse is urged afresh with

greater vehemence and passion. The peroration con-

sists of two parts. 1 Recapitulation; wherein the

substance of what was diffused throughout the whole
speech is collected briefly and cursorily, and summed
up with new force and weight. 2. The moving the

passions; which is so peculiar to the peroration, that

the masters of the art call this part fides affiectum. The

passions to be roused are various, according to the va-
rious kinds of oration. In a panegyrick, love, admiration,
emulation, joy, &c. In an invective, hatred, contempt, &c.
In a deliberation, hope, confidence, or fear. The qualities required in the peroration are,
that it be very vehement and passionate, and that it be
short; because, as Cicero observes, tears soon dry up.
These qualities were well observed by Cicero, who
never had an equal in the management of this part of
an orator's province; for peroration was his master-

piece.

"Concerning peroration (says Dr Blair), it is need-

less to say much, because it must vary so considerably

according to the strain of the preceding discourse.

Sometimes the whole pathetic part comes in most pro-

perly at the peroration. Sometimes, when the dis-

course has been entirely argumentative, it is fit to con-
clude with summing up the arguments, placing them

in one view, and leaving the impression of them full and
strong on the mind of the audience. For the great rule of
a conclusion, and what nature obviously suggests, is
to place that last on which we choose that the strength
of our cause should rest.

"In all discourses, it is a matter of importance to
hit the precise time of concluding, so as to bring our
discourse just to a point; neither ending abruptly and
unexpectedly, nor disappointing the expectation of the
hearers when they look for the close, and continuing
to hover round and round the conclusion till they be-
come heartily tired of us. We should endeavour to

go off with a good grace; not to end with a languish-

ing and drawn-out sentence, but to close with dignity
and spirit, that we may leave the minds of the hearers

warm;
was universally admired: that intitled La fée de Louis d'Grand, in which he exalted the modern authors above the ancients, was a prelude to a style with all the learned style. After he had engaged himself from this content, he applied himself to draw up eulogies of several great men of the 17th century, with their portraits, of which he has collected 102. There are other esteemed works of Perrault.—Besides these there were two other brothers, Petru and Nicholas, who made themselves known in the literary world.

PERRON (James Davy Du.) a cardinal distinguished by his abilities and learning, was born in the canton of Bern in 1556. He was educated by Julian Davy, his father, a very learned Calvinist, who taught him Latin and the mathematics; after which, he by himself became acquainted with the Greek and Hebrew, philosophy, and the poets. Philip Delportes, abbot of Tyron, made him known to Henry III. king of France, who conceived a great esteem for him. Some time after, Du Perron abjured Calvinism, and afterwards embraced the ecclesiastical function; and having given great proofs of his wit and learning, he was chosen to pronounce the funeral oration of Mary que n Scotts. After the murder of Henry III. he retired to the house of Cardinal de Bourbon, and took great pains in bringing back the Protestants to the church of Rome. Among others, he gained over Henry Spandanus, afterwards bishop of Pamiers. He also chiefly contributed to engage Henry IV. to change his religion; and that prince sent him to negotiate his reconciliation to the holy see, in which he succeeded. Du Perron was consecrated bishop of Evereaux while he resided at Rome. On his return to France, he wrote, preached, and disputed against the reformed; particularly against Du Plessis Mornay, with whom he had a public conference in the presence of the king at Fontainebleau. He was made cardinal in 1654 by pope Clement VIII. at the solicitation of Henry IV. who afterwards nominated him to the archbishopric of Sens. The king at length sent him to Rome with Cardinal Joyeuse in order to terminate the disputes which had arisen between Paul V. and the Venetians. It is said that this pope had such an high opinion of the address of the cardinal Du Perron, that he used to say, "Let us pray to God to inspire the cardinal Du Perron, for he will persuade us to do whatever he pleases." After the death of Henry IV. he retired into the country, where he put the last hand to his works; and, setting up a printing-house, corrected every sheet himself. He died at Paris in 1611. His works were collected after his death, and published at Paris in 3 vols. folio.

PERROT (Nicholas), Sieur d'Aubracourt, one of the first geniuses of his age, was born at Coulons in 1666. After studying philosophy about three years, he was sent to Paris to follow the law. At eighteen years of age he was admitted advocate of parliament, and frequented the bar: but he soon conceived a desire for it, and therefore discontinued his practice. This displeased an uncle, but whose favour he recovered by quitting the protestant religion. He could not, however, be prevailed upon to take orders in the Romish church; and some years after, he had a desire to return to the religion he had abjured. But, that he might not do any thing rashly, he resolved to study philosophy and divinity. For that purpose he
chose for his master Mr Stuart a Scotfman and Luth-}

Perruker, a man of great learning. Almost three years he
spent in the most affluous study; and then set out
from Paris to Champagne, where he abjured the
Roman Catholic, and once more embraced the Protestant
religion. In 1637 he was admitted a member of the
French Academy; a little after which he undertook a
translation of Tacitus. While he was engaged in that
labours task, he retired to his small estate of Ablan-
court, and lived there till his death in 1664. He
was a man of fine understanding, of great piety and
integrity, and of universal learning. Morerit has
given a catalogue of his works, the greatest part of
which consist of translations, which seemed rather
originals.

Perruker, Perrue, or Perwige, was anciently
a name for a long head of natural hair; such, particu-
larly, as there was care taken in the adjusting and
trimming of. Menage derives the word rather fanci-
fully from the Latin pilus, 'hair.' It is derived, ac-
cording to this critic, thus, pilus, pelas, pelate, pelatius; pelatia, periwique, peruke, perruke. The Latins call it co-
ma; whence part of Gaul took the denomination of
Gallia Comata, from the long hair which the inhabitants
were as a sign of freedom. An ancient author says,
that Abafalon's peruke weighed 200 shekels.

The word is now used for a set of false hair, curled,
buckled, and feved together on a frame or cawl; an-
ciently called copilamentum or "false peruke." It is
doubted whether or not the use of perukes of this kind
was known among the ancients. It is true, they used
false hair: Martial and Juvenal make merry with the takers had

Nothing can be more ridiculous than the description
Lampridius gives of the emperor Commodus's peruke:
its was powdered with scrapings of gold, and oiled (if we
may use the expression) with glutinous perfumes
for the powder to hang by. In effect, the use of per-
ukes, at least in their present mode, is not much more
than 160 years old; the year 1629 is reckoned the
epocha of long perukes, at which time they began to
appear in Paris; from whence they spread by degrees
through the rest of Europe. At first it was reputed
a scandal for young people to wear them, because the
loins of their hair at that age was attributed to a dif-
ease the very name whereof is a reproach; but at
length the mode prevailed over the scruple, and per-
sions of all ages and conditions have worn them, fore-
going without any necessity the conveniences of their
natural hair. It was, however, some time before the
clothes, which were in the manner of the French clergy,
in the year 1660; nor is the practice yet well author-
ized. Cardinal Grimaldi in 1684, and the bishop of
Lyon in 1688, prohibited the use of the peruke to
all priests without a dispensation or necessity. M. Thierry
has an express treatise, to prove the peruke indecent
in an ecclesiastic, and directly contrary to the decrees
and canons of councils. A priest's head, embellished
with artificial hair curiously adjusted, he efeems a
monster in the church, nor can he conceive any thing
so scandalous as an abbot with a florid countenance,
heightened with a well-curled peruke.

Perry (Captain John), was a famous engineer,
who refided long in Russia, having been recommended
to the czar Peter while in England, as a perfon ca-
pable of serving him on a variety of occasions relating
to his new design of establlishing a fleet, making his
rivers navigable, &c. His salary in this service was
300l. per annum, besides travelling expenses and sub-
fidence money on whatever service he should be em-
ployed, together with a further reward to his fatis-
faction at the conclusion of any work he should fini.sh.
After some conversation with the czar himself, parti-
cularly respecting a communication between the river
Volga and Don, he was employed on that work for
three summers successively; but not being well sup-
pplied with men, partly on account of the ill success
of the czar's arms against the Swedes at the battle of
Navra, and partly by the discouragement of the gover-
nor of Altaii, he was ordered at the end of 1707 to
stop, and next year was employed in refitting the ships
at Veronife, and 1709 in making the river of that
name navigable; but after repeated disappointment,
and a variety of fruitless applications for his salary, he,
at last quitted the kingdom, under the protection of
Mr Whitworth, the English ambassador, in 1712: (See
his narrative in the Preface to The State of Russia). In
1721 he was employed in stopping with success the
breach at Dagenham, in which several other under-
takers had failed; and the same year abut the harbour
at Dublin, to the objections against which he then
published an answer. He was author of The State of
Russia, 1716, 8vo, and an account of the stopping
of Dagenham Breach, 1721, 8vo; and died Feb. 11,
1733.

Perry, the name of a very pleasent and wholesome
liqour extracted from pears, in the same manner as cy-
der is from apples. See the article Cyder and Hus-
bandry, pages 227-238.

The best pears for perry, or at least the sorts which
have been hitherto deemed the fittest for making this
liqour, are so excessively tart and harsh, that no mortal
can think of eating them as fruit; for even hungry
swine will not eat them, nay hardly so much as smell
them. Of these the Boisbury pear, the Bareland pear,
and the holfie pear, are the most esteemed for perry in
Worceftershire; and the squaith pear, as it is called,
in Glouceftershire, England; in both which counties,
as well as in some of the adjacent parts, they are planted
in the hedge-rows and most common fields. There is
this advantage attending pear-trees, that they will
thrive on land where apples will not so much as live,
and that some of them grow to such a size, that a
single pear-tree, particularly of the Boisbury and the
squaith kind, has frequently been known to yield,
in one season, from one to four longheads of perry. The
Boisbury pear is thought to yield the most lasting and
most vinous liqour. The John pear, the Harpury
pear, the Drake pear, the Mary pear, the Lulum
pear, and several others of the hardest kinds, are
esteemed the best for perry, but the redder or more tawny
they are, the more they are preferred. Pears as well
as apples, should be full ripe before they are ground.

Dr
PER

Dr. Beale, in his general advertisements concerning cyder, subjoined to Mr. Evelyn's Pomona, disapproves of Palladius's saying, that perry will keep during the winter, but that it turns four as soon as the weather begins to be warm; and gives, as his reason for being of a contrary opinion, that he had himself tasted at the end of summer, a very brisk, lively and vinous liquor, made of horse pears; that he had often tried the juice of the Bobury pear, and found it both pleasanter and richer the second year, and still more for the third, though kept only in common hogheads, and in but indifferent cellars, without being bottled; and that a very honest, worthy, and ingenious gentleman in his neighbourhood, assured him, of his own experience, that it will keep a great while, and grow much the stronger for keeping, if put into a good cellar and managed with due care. He imputes Palladius's error to his possibly speaking of common eatable pears, and to the perry's having been made in a very hot country; but he would have ascribed it to a more real cause, perhaps, had he pointed out the want of a thorough regular fermentation, to which it appears plainly that the ancients were entire strangers; for all their vinous liquors were medicated by boiling before they were laid up in order to be kept.

PERSECUTION, is any pain or affliction which a person deservedly inflicts upon another: and in a more restrained sense, the sufferings of Christians on account of their religion.

Historians usually reckon ten general persecutions, the first of which was under the emperor Nero, 31 years after our Lord's ascension; when that emperor having set fire to the City of Rome, shewed the odium of that execrable action on the Christians, who under that pretence were wrapped up in the skins of wild beasts, and worried and devoured by dogs; others were crucified, and others burnt alive. The second was under Domitian, in the year 95. In this persecution St. John the apostle was sent to the isle of Patmos, in order to be employed in digging in the mines.

The third began in the third year of Trajan, in the year 100, and was carried on with great violence for several years. The fourth was under Antoninus the philosopher, when the Christians were banished from their houses, forbidden to show their heads, reproached, beaten, hurried from place to place, plundered, imprisoned, and flogged. The fifth began in the year 197, under the emperor Severus. The fifth began with the reign of the emperor Maximus in 225. The seventh, which was the most dreadful persecution that had ever been known in the church, began in the year 250, in the reign of the emperor Decius, when the Christians were in all places driven from their habitation, stripped of their estates, tormented with racks, &c. The eighth began in the year 257, in the fourth year of the reign of the emperor Valerian. The ninth was under the emperor Aurelian, A.D. 274; but this was very inconsiderable: and the tenth began in the 19th year of Diocleian, A.D. 303. In this dreadful persecution, which lasted ten years, houses filled with Christians were set on fire, and whole droves were tied together with ropes and thrown into the fire. See TOLERATION.

PERSEES, the descendants of a colony of ancient Persians, who took refuge at Bombay, Suid, and in the vicinity of those cities, when their own country was conquered 1100 years ago by the Mahometan Arabs. They are a gentle, quiet, and industrious people, loved by the Hindoos, and living in great harmony among themselves. The consequence is, that they multiply exceedingly, whilst their countrymen in the province of Kerman are visibly diminishing under the yoke of the Mahometan Persians. Of the manners and customs of this amiable race, we have the following account in Heron's elegant translation of Nisbin's Tales.

"The Persians (says he) make common contributions for the aid of their poor, and suffer none of their number to ask alms from people of a different religion. They are equally ready to employ their money and credit to screen a brother of their fraternity from the abuses of justice. When a Persees behaves ill, he is expelled from their communion. They apply to trade, and exercise all sorts of professions.

"The Persians have as little knowledge of circumcision as the Hindoos. Among them a man marries only one wife, nor ever takes a second, unless when the first happens to be barren. They give their children in marriage at six years of age; but the young couple continue to live separate, in the houses of their parents, till they attain the age of puberty. Their dress is the same as that of the Hindoos, except that they wear under each ear a tuft of hair, like the modern Persians. They are much addicted to astrology, although very little skilled in astronomy.

"They retain the singular custom of expelling their dead to be eaten by birds of prey, instead of interring or burning them. I saw (continues our author) a hill at Bombay a round tower, covered with plants of wood, on which the Persians lay out their dead bodies. When the flesh is devoured, they remove the bones into two chambers at the bottom of the tower.

"The Persians, followers of the religion of Zerdruft or Zoroaster, adore one God only, eternal and almighty. They pay, however, a certain worship to the sun, the moon, the stars, and to fire, as visible images of the invisible divinity. Their veneration for the element of fire induces them to keep a sacred fire constantly burning, which they feed with odoriferous wood, both in the temples and in the houses of private persons, who are in easy circumstances. In one of their temples at Bombay, I saw a fire which had burnt unextinguished for two centuries. They never blow out a light, lest their breath should pollute the purity of the fire. See POLYTHEISM.

"The religion of the Persians enjoins purifications as strictly as that of the Hindoos. The disciples of Zerdruft are not, however, obliged to abstain from animal food. They have accustom ed themselves to refrain from the flesh of the ox, because their ancestors promised the Indian prince who received them into his dominions never to kill burned cattle. This promise they continue to observe under the dominion of Christians and Mahometans. The horse is by them considered as the most impure of all animals, and regarded with extreme aversion.

"Their festival, denominated Ghumbals, which return frequently, and last upon each occasion five days, are all commemorations of some part the work of creation. They celebrate them not with splendour, or
with any particular ceremonies, but only dress better during those five days, perform some act of devotion in their houses, and visit their friends."

The Persees were till lately but very little known; the ancients speak of them but seldom, and what they say seems to be distorted by prejudice. On this account, Dr. Hyde, who thought the subject both curious and interesting, about the end of last century attempted a deeper investigation of a subject which till then had been but very little attended to. He applied to the works of Arabian and Persian authors, from whom, and from the relations of travellers, together with various letters from persons in India, he compiled his celebrated work on the religion of the Persees. Other accounts have been given by different men, as accident put information in their way. But the most distinguished is by M. Anquetil du Perron, who undertook a voyage to discover and translate the works attributed to Zoroaster. Of this voyage he drew up an account himself and read it before the Royal Academy of Sciences at Paris in May 1761. A translation of it was made and published in the Gentleman's Magazine for 1762, to which we refer our readers. The account begins at p. 573, and is concluded at p. 614. Remarks were afterwards made on du Perron's account by a Mr. Yates. See the same Magazine for 1766, p. 529.

PERSEPOLIS, formerly the capital of Persia, situated in N. Lat. 30° 50', E. Long. 84°, now in ruins, but remarkable for the most magnificent remains of a palace or temple that are to be found throughout the world.—This city stood in one of the finest plains in Persia, being 18 or 19 leagues in length, and some places two, in some four, and in others six leagues in breadth. It is watered by the great river Araxes, now Bendersir, and by a multitude of rivulets beside. Within the compass of this plain, there are between 1000 and 1500 villages, without reckoning those in the mountains, all adorned with pleasant gardens, and planted with shady trees. The entrance of this plain on the west side has received as much grandeur from nature, as the city it covers could do from industry or art. It consists of a range of mountains steep and high, four leagues in length, and about two miles broad, forming two flat banks, with a rising terrace in the middle, the summit of which is perfectly plain and even, all of native rock. In this there are such openings, and the terraces are so fine and so even, that one would be tempted to think the whole the work of art, if the great extent, and prodigious elevation thereof, did not convince one that it is a wonder too great for nature to produce. Undoubtedly these banks were the very place where the advanced guards from Persepolis took post, and from which Alexander found it so difficult to dislodge them. One cannot from hence defy the ruins of the city, because the banks are too high to be overlooked; but one can perceive on every side the ruins of walls and of edifices, which heretofore adorned the range of mountains of which we are speaking. On the west and on the north this city is defended in the like manner; so that, considering the height and evenness of these banks, one may fairly say, that there is not in the world a place so fortified by nature.

The mountain Relmount, in the form of an amphitheatre, circumscribes the palace, which is one of the noblest and most beautiful pieces of architecture remaining of all antiquity. Authors and travellers have been exceedingly minute in their descriptions of their ruins; and yet some of them have expressed themselves so differently from the others, that had they agreed, with respect to the latitude and longitude of the place, one would be tempted to suspect that they had visited different ruins. These ruins have been described by Garcias de Silva Figueroa, Pietro de la Valle, Char­dìn, Le Brun, and Mr. Franc­klin. We shall adopt the latest description, as being exceedingly distinct, and given by a traveller intelligent and unalarming. The ascent to the columns is by a grand staircase of blue stone containing 154 steps.

"The first object that strikes the beholder on his entrance, are two portals of stone, about 50 feet in height each; the sides are embellished with two sphinxes of an immense size, dressed out with a profusion of head-work, and, contrary to the usual method, they are represented standing. On the sides above are inscriptions in an ancient character, the meaning of which no one hitherto has been able to decipher."

"At a small distance from these portals you afford another flight of steps, which lead to the ground hall of columns. The sides of this staircase are ornamented with a variety of figures in baso relief; most of them have veils in their hands; here and there a camel appears, and at other times a kind of triumphal car, made after the Roman fashion; besides there are several led horses, oxen and rams, that at times inter­vene and diversify the procession. At the head of the staircase is another baso relief, representing a lion seizing a bull; and close to this are other inscriptions in ancient characters. On getting to the top of this staircase, you enter what was formerly a most magnificent hall; the natives have given this the name of ebal minir, or forty pillars; and though this name is often used to express the whole of the building, it is more particularly appropriated to this part of it. Although a vast number of ages have elapsed since the foundation, 15 of the columns yet remain entire; they are from 70 to 80 feet in height, and are stately pieces of masonry: their pedestals are curiously worked, and appear little injured by the hand of time. The shafts are encased up to the top, and the capitals are adorned with a profusion of fret work.

From this hall you proceed along eastward, until you arrive at the remains of a large square building, to which you enter through a door of granite. Most of the doors and windows of this apartment are still standing they are of a black marble, and polished like a mirror: on the sides of the doors, at the entrance, are baso reliefs of two figures at full length; they represent a man in the attitude of slaving a goat: with one hand he seizes hold of the hump of the beast, and throws a dagger into his heart with the other; one of the goat's feet rests upon the breast of the man, and the other upon his right arm. This device is common throughout the palace. Over another door of the same apartment is a representation of two men at full length; behind them stands a domestic holding a spread umbrella: they are supported by large round shafts, ap­
PER

At the fourth well-entrance of this apartment are two large pillars of stone, upon which are carved four figures; they are dressed in long garments, and hold in their hands spears 10 feet in length. At this entrance also the remains of a stair-case of blue stone are still visible. Various numbers of broken pieces of pillars, shafts, and capitals are scattered over a considerable extent of ground, some of them of such enormous size, that it is wonderful to think how they could have been brought whole, and set up together. Indeed, all the remains of these noble ruins indicate their former grandeur and magnificence, truly worthy of being the residence of a great and powerful monarch."

These noble ruins are now the shelter of hawks and birds of prey. Besides the information above mentioned, there are others in Arabic, Persian and Greek. Dr. Hyde observes, that the inscriptions are very rude and unartful; and that some, if not all of them, are in praise of Alexander the Great; and therefore are later than that conqueror. See the article Ruins.

PERSEVERANCE, in theology, a continuance in a state of grace to a state of glory. About this subject there has been much controversy in the Christian church. All doctors, except Unitarians, admit, that no man can ever be in a state of grace without the co-operation of the spirit of God; but the Calvinists and Arminians differ widely as to the nature of this co-operation. The former, at least such as call themselves the true disciples of Calvin, believe, that those who are once under the influence of divine grace can never fall totally from it, or die in mortal sin. The Arminians, on the other hand, contend, that the whole of this life is a state of probation; that without the grace of God we can do nothing that is good, that the Holy Spirit afflicts, but does not overpower, our natural faculties; and that a man, at any period of his life, may repent, grieve, and even quench the Spirit. See Theology.

PERSEUS, in astronomy. See there. n° 406.

PERSIA, a most ancient and celebrated empire of Asia, extending in length from the mouth of the river Araxes to that of the river Indus, about 1840 of miles; and in breadth from the river Oxus, to the Persian gulf, about 1089 of the same miles. It is bounded on the north by the Caspian Sea, the river Oxus, and mount Caucasus; on the east, by the river Indus and the dominions of the Great Mogul; on the south by the Persian gulf and the Indian ocean, and on the west, by the dominions of the Grand Signior. We learn from Sir William Jones, the illustrious president of the Asiatic Society, that Persia is the name of only one province of this extensive empire, which by the present natives, and all the learned Musulmans who reside in the British territories in India, is called Iran. It has been a practice not uncommon in all ages to denominate the whole of a country from that part of it, with which we are best acquainted; and hence have the Europeans agreed to call Iran by the name of that province of which Shiraz is the capital; See Shiraz. The same learned writer is confident that Iran, or Persia in its largest extent, comprehended within its outline the lower Asia, which, says he, was unquestionably a part of the Persian, if not of the old Assyrian empire. Thus may we look on Iran as the noblest peninsula on this inhabitable globe; and if M. Bailly had fixed on it as the Atlantis of Plato, he might have supported his opinion with more strong arguments than any that he has adduced in favour of Nova Zelandia. If, indeed the account of the Atlantis be not purely an Egyptian fable, I should be more inclined, says Sir William, to place them in Iran than in any region with which I am acquainted.

The most ancient name, however, of this country was that of Elam, or, as some write it, Alam, from Alam the son of Shem, from whom its inhabitants are descended. Herodotus calls its inhabitants Calphents; and in very ancient times the people are said to have called themselves Arati, and the country in which they dwelt Arabia. In the books of Daniel, Ezra, and from the time of Cyrus who learned riding in Media, and introduced it, it is called by the name of Perses Pharaos, which signifies a horsemans or rider, equus; whence the modern name of Persia.

That Persia was originally peopled by Elam, the opinion of Sir William has been very generally admitted; but there is the truth is, that of the ancient history of this distinguisht empire very little is perfectly known. For this ignorance, which at first seems strange, satisfactory reasons may easily be assigned: of which the principal are the superficial knowledge of the Greeks and Jews, and the loss of Persian archives or historical compositions. That the Grecian writers before Xenophon had no acquaintance with Persia, and that their accounts of it are wholly fabulous, is a paradox too extravagant to be seriously mentioned; but (says Sir William) their connection with it in war or peace had been generally confined to bordering kingdoms under feudatory princes: and the first Persian emperor, whose life and character they seem to have known with tolerable accuracy, was the great Cyrus. Our learned author, however, is so far from considering Cyrus as the first Persian monarch, that he thinks it evident a powerful monarchy had subsisted in Iran for ages before the accession of that hero; that this monarch was called the Medebidian dynasty; and that it was in fact the oldest monarchy in the world. The evidence upon which the learned writer rests this opinion, is the work of a Mahometan traveller, compiled from the books of such Persians as fled from their country upon the innovation in religion made by Zoroaster; and if these books, of which a few still remain, be genuine, and the Mahometan a faithful compiler, facts of which Sir William has not the smallest doubt, the evidence is certainly sufficient to bear the superstructure which he has raised upon it.

If the Persian monarchy was thus ancient, it is natural to suppose that Persia or Iran was the original seat of the human race, whence colonies were sent out or emigrated of themselves to people the rest of the human habitable globe. This supposition is actually made by race, our ingenious author, who strongly confirms it by remarks.
marks on the most ancient language of Persia, which he showed to have been the parent of the Sanscrit, as well as of the Greek, Latin, and Gothic (see Philology). He therefore holds, as a proposition firmly established, "that Iran or Persia, in its largest sense, was the true centre of population, of knowledge, of languages, and of arts; which instead of travelling westward only, as it has been fancifully supposed, or eastward, as might with equal reason have been asserted, were expanded in all directions to all the regions of the world." He thinks it is from good authority that the Saxon Chronicle brings the first inhabitants of Britain from Armenia; that the Goths have been concluded to come from Persia; and that both the Irish and old Britons have been supposed to have proceeded from the borders of the Caspian; for all these places were comprehended within the ancient Iran.

Of this first Persian monarchy we have no historical accounts; and must therefore, after having thus mentioned it, descend at once to the era of Cyrus. This prince is celebrated both by sacred and profane historians; but the latter are at small variance concerning his birth and accession to the throne. According to Herodotus, Abyages, the last king of the Medes being warned in a dream, that the son who was to be born of his daughter Mandane, should one day be lord of Asia, resolved to marry her, not to a Mede, but to a Persian. Accordingly he chose for her husband one Cambyses, a man of a peaceable disposition, and of no very high station. However, about a year after they were married, Abyages was frightened by another dream, which made him resolve to dispatch the infant as soon as it should be born. Hereupon the king sent for his daughter and put her under confinement, where she was soon after delivered of a son. The infant was committed to the care of one Harpagus, with strict orders to destroy it in what manner he thought proper. But he, having acquainted his wife with the command he had received, by her advice gave it to a shepherd, defiring him to let it perish by exposure. But the shepherd, out of compulsion, exposed a full-born child which his wife happened to be then delivered of, and brought up the son of Mandane as his own, giving him the name of Cyrus.

When the young prince had attained the age of ten years, as he was one day at play with other children of the same age, he was seized by his companions; and having, in virtue of that dignity, divided them into several orders and classes, the son of Artabares, a lord of eminent dignity among the Medes, refused to obey his orders; whereupon Cyrus caused him to be seized, and whipped very severely. The boy ran crying to his father; and he immediately hasted to the king's palace, loudly complaining of the affront his son had received from the son of a slave, and intreating Abyages to revenge, by some exemplary punishment, the indignity offered to him and his family. Abyages, commanding both the headman and his son to be brought before him, asked the latter, how he, who was the son of so mean a man, had dared to abuse the son of one of the chief lords of the kingdom? Cyrus replied, that he had done no more than he had a right to do; for the boys of the neighbourhood having chosen him king, because they thought him most worthy of that dignity, and performed what he, vested with that character, had commanded, the son of Artabares alone had slighted his orders, and for his disobedience had suffered the punishment he deserved. In the course of this conversation Abyages happening to recollect, that his grandson, whom he had ordered to be destroyed, would have been about the same age with Cyrus, began to question the shepherd concerning his supposed son, and at last obtained from him a confession of the whole truth.

Abyages having now discovered Cyrus to be his grandson, sent for Harpagus, who also confessed that he had not seen Mandane's son destroyed but had given him to the shepherd; at which Abyages was so much incensed, that, having invited Harpagus to an entertainment he caused him to be served with the flesh of his own son. When he had done, the king asked him whether he liked his viands; and Harpagus answering, that he had never tasted any thing more delicious, the officers appointed for that purpose brought in a basket, containing the head, hands, and feet of his son, defiring him to uncover the basket, and take what he liked best. He did as they desired, and beheld the mangled remains of his only child without betraying the least concern, so great was the command which he had over his passions. The king then asked him, whether he knew what kind of meat he had been entertained. Harpagus replied, that he knew very well, and was always pleased with what his sovereign thought fit to order; and having thus replied, with a surpining temper he collected the mangled parts of his innocent son, and went home.

Abyages having thus vented his rage on Harpagus, began next to consult what he should do with Cyrus. The magi, however, took him of his fears with regard to him, by assuring him, that as the boy had been once chosen king by his companions, the dream had been already verified and that Cyrus, never would reign in any other fene. 'The king, being well pleased with this answer, called Cyrus, and, owning how much he had been wanting in the affection which he ought to have had towards him, defired him to prepare for a journey into Persia, where he would find his father and mother in circumstances very different from those of the poor shepherd and his wife with whom he had hitherto lived. Cyrus, on his arrival at his father's house, was received with the greatest joy. When he grew up, he soon became popular on account of his extraordinary parts; till at last his friendship was courted by Harpagus, who had never forgot the cruel treatment he received from Abyages. By his means a conspiracy was formed against Abyages; who being overthrown in two succeeding engagements, was taken prisoner and confined for life.

The account given by Xenophon of the rise of Cyrus is much more conformant to Scripture: for he tells us, that Babylon was conquered by the united forces of the Medes and Persians. According to him, Cyrus was the son of Cambyses king of the Persians, and Mandane the daughter of Abyages king of the Medes. He was born a year after his uncle Cyaxares, the brother of Mandane. He lived till the age of twelve with his parents in Persia, being educated after the manner of the country, and inured to fatigues and military exercises. At this age he was taken to the court of Abyages, where he resided four years; when the revolt
While Cyrus was employed in the Babylonish war, before he attacked the metropolis itself, he reduced all the nations of Aha Minor. The most formidable of these were the Lydians, whose king Croesus assembled a very numerous army, composed of all the other nations in that part of Aha, as well as of Egyptians, Greeks and Thracians. Cyrus being informed of their vast preparation, augmented his forces to 196,000 men, and with them advanced against the enemy, who were assembled near the river Pactolus. After long marches, he came up with them at Thym-bra, not far from Sardis, the capital of Lydia. Besides the horse and foot, which amounted to 196,000 as already observed, Cyrus had 300 chariots armed with scythes, each chariot drawn by four horses abreast, covered with trappings that were proof against all sorts of missile weapons; he had likewise a great number of chariots of a larger size, upon each of which was placed a tower about 18 or 20 feet high, and in each tower were lodged 20 archers. These towers were drawn by 16 oxen yoked abreast. There was moreover a considerable number of camels each mounted by two Arabian archers, the one looking towards the head, and the other towards the hinder parts of the camel. The armies of Croesus consisted of 420,000 men. The Egyptians, who alone were 120,000 in number, being the main strength of the army, were placed in the centre. Both armies were drawn up in an immense plain, which gave room for the extending of the wings on either side; and the design of Croesus, upon which alone he founded his hopes of victory, was to surround and hem in the enemy's army.

When the two armies were in fight of each other, Croesus, observing how much his front exceeded that of Cyrus, made the centre halt, but commanded the two wings to advance, with a design to inclose the Persian army, and begin the attack on both sides at once. When the two detached bodies of the Lydian forces were sufficiently extended, Croesus gave the signal to the main body, which marched up to the front of the Persian army, while the two wings attacked them in flank; so that Cyrus' army was hemmed in on all sides, and, as Xenophon expresses it, was included like a small square drawn within a great one. This motion, however, did not at all alarm the Persian commander; but, having his troops the signal to face about, he attacked in flank those forces that were going to fall upon his rear so vigorously, that he put them to great disorder. At the same time a squadron of camels was made to advance against the enemy's other wing, which consisted mostly of cavalry. The horses were so frightened at the approach of these animals, that most of them threw their riders and trod them under foot; which occasioned great confusion. Then Artagezes, an officer of great valour and experience, at the head of a small body of horse, charged them so briskly, that they could never afterwards rally; and at the same time the chariots, armed with scythes, being driven in among them, they were entirely routed. Both the enemy's wings being thus put to flight, Cyrus commanded his chief favourite Abradates to fall upon the centre with the large chariots above-mentioned. The first ranks, consisting mostly of Lydians, not being able to stand so violent a charge, immediately gave way; but the Egyptians, being covered with their bucklers, and marching so close that the chariots had not room to penetrate their ranks, a great slaughter of the Persians ensued. Acharates himself was killed, his chariot overthrown, and the greatest part of his men were cut in pieces. Upon his death, the Egyptians advancing boldly, obliged the Persian infantry to give way, and drove them back quite to their engines. There they met with a new shower of darts and javelins from their machines; and at the same time the Persian rear advancing sword in hand, obliged their spearmen and archers to return to the charge. In the mean time Cyrus, putting to flight both the horse and foot on the left of the Egyptians, pushed on to the centre, where he had the misfortune to find his Persians again giving ground: and judging that the only way to stop the Egyptians, who were pursuing them, would be to attack them in the rear, he did so; and at the same time the Persian cavalry coming up to his assistance, the fight was renewed with great slaughter on both sides. Cyrus himself was in great danger; for his horse being killed under him, he fell among the midst of his enemies: but the Persians, alarmed at the danger of their general, threw themselves headlong on their opponents, rescued him and made a terrible slaughter; till at last Cyrus, admiring the valour of the Egyptians, offered them honourable conditions: letting them know at the same time that all their allies had abandoned them. They accepted the terms offered them: and having agreed with Cyrus that they should not be obliged to carry arms against Croesus, they engaged in the service of the conqueror, and continued faithful to him ever after.

The next morning Cyrus advanced towards Sardis, and Croesus marched out to oppose him at the head of the Lydians only; for his allies had all abandoned him. Their strength consisted mostly in cavalry; which being well apprised of, he ordered his camels to advance; by whom the horses were so frightened, that they became quite ungovernable. However the Lydians dismounted, and for some time made a vigorous resistance on foot; but were at last driven into the city, which was taken two days after; and thus the Lydian empire was totally destroyed.

After the conquest of Sardis, Cyrus turned his arms against Babylon itself, which he reduced in the manner related under that article. Having settled the civil government of the conquered kingdoms, Cyrus took a review of all his forces, which he found to consist of 600,000 foot, 120,000 horse, and 2000 chariots armed with scythes. With these he extended his dominion all over the nations to the confines of Ethiopia, and to the Red Sea; after which he continued to reign peaceably over his vast empire till his death, which happened about 329 before Christ. According to Xenophon, he died a natural death; but others tell us, that having engaged in a war with the Scythians, he was by them overthrown and cut in pieces with his whole army, amounting to 200,000 men. But this is very improbable, seeing all authors agree that the tomb of Cyrus was extant at Paphragada in Persia in the time of Alexander the Great; which it could not have been
PER  [ 160 ]

PER

if his body had remained in the possession of the
Seythians, as these authors assert.

In the time of Cyrus, the Persian empire extended
from the river Indus to the Caegean Sea. On the north
it was bounded by the Euxine and Caspian Seas, and
on the South by Ethiopia and Arabia. That monarch
kept his refidence for the seven cold months at Baby-
lion, by reason of the warmth of that climate: three
months in the spring he spent at Susa, and two at Ec-
batan during the heat of summer. On his death bed
he appointed his son Cambyses to succeed him in the
empire; and to his other son, Smerdis, he gave several
considerable governments. The new monarch imme-
diately set about the Conquest of Egypt, which he
accomplished in the manner related in the history of
that country.

Having reduced Egypt, Cambyses next resolved to
turn his arms against the Carthaginians, Hammonians,
and Ethiopians. But he was obliged to drop the frist
of these enterprises, because the Phoenicians refused
to supply him with ships against the Carthaginians,
who were a Phoenician colony. However, he sent
ambassadors to Ethiopia with a design to get intelli-
gence of the state and strength of the country. But
the Ethiopian monarch, being well apprised of the
condition on which they came, treated them with great
contempt. In return for the presents sent him by
Cambyses, he sent his own bow; and advised the Per-
ians to make war upon the Ethiopians when they could
bend such a strong bow as easily as he did, and to
thank the gods that the Ethiopians had no ambition
to extend their dominions beyond their own country.

Cambyses was no sooner informed of this answer by
his ambassadours than he flew into a violent passion;
and ordered his army immediately to begin their march,
without considering that they were neither furnished
with provisions nor any other necessary. When he
arrived at Thebes in Upper Egypt, he detached
50,000 men, with orders to destroy the temple of Ju-
piter Ammon: but all these perished in the defect;
not a single person arriving either at the oracle, or
returning to Thebes. The rest of the army, led by
Cambyses himself, experienced incredible hardships;
for not being provided with any necessaries, they had
not marched a fifth part of the way when they were
obliged to kill and eat the beasts of burden. When
these failed, the soldiers fed on grass and roots, as
long as any could be found; and at last were reduced
to the dreadful necessity of eating one another; every	enth man, on whom the lot fell, being condemned to
serve as food for his companions. The king, however,
obstinately perished in his design; till, being appro-
hehensive of the danger he himself was in, he retreated
to Thebes, after having lost the greatest part of his
army.

Cambyses was a man of a very cruel and suspicious
temper, of which he gave many instances; and the
following proved indubitably the cause of his death.—
We have already observed that the king of Ethiopia
sent his bow in return for the presents brought to him
by the ambassadours of Cambyses. The only man in
the Persian army who could bend this bow was Smei-
dis the king's brother; and this instance of his personal
strength so alarmed the tyrant, that, without any
crimes alleged, he caused him to be murdered. This
gave occasion to one Smerdis, a magician, who greatly
resembled the other Smerdis in looks, to assume the
name of the deceased prince, and to raise a rebel lion
against Cambyses, who was generally hated for his
cruelty; and this he could do the more easily, as the
chief management of affairs had been committed to
this Smerdis during the king's absence. Cambyses, on
receiving the news of this revolt, immediately ordered
his army to march, in order to suppress it; but as he
was mounting his horse, his sword, falling out of its
scabbard, wounded him in the thigh. On this acci-
dent, he asked the name of the city where he was;
and being told that it was Ecbatan, he said in the
presence of his attendants, "Pace has decreed that
Cambyses the son of Cyrus shall die in this place."
For, having consulted the oracle of Butus, which was
very famous in that country, he was told that he
should die at Ecbatan. This he had always understood
of Ecbatan in Media, and had therefore resolved to
avoid it. Being now, however, convinced that his
end was near, he assembled the chief Persian lords
who served in the army, and having told them that his
brother was certainly dead, he exhorted them never
to submit to the impostor, or suffer the sovereignty
again to pass from the Persians to the Medes, to which
nation Smerdis belonged, but to use their utmost
efforts to place one of their own blood on the
throne.

As the king's wound mortified, he lived but a few days
after this; but the assembly supposing that he
had spoken only out of hatred to his brother, quietly
submitted to the impostor, who was thus for a time
established on the throne. Indeed from his conduct
during the short time which he enjoyed the kingdom,
he appears to have been not at all deserving of a
crown. He began with granting to all his subjects an
imposing exemption from taxes and military service for three Smerdis
years, and treated all of them in the most beneficent
manner. To secure himself on the throne the more
effectually, he married Atotfa the daughter of Cyrus;
thinking, that in a case of discovery he might hold
the empire by her title. She had before been married to
her brother Cambyses, on a deceitful pretense, that a
man of Peris might die; as he pleased; and by virtue of
this decision Smerdis also married her as his brother.
The extreme caution of Smerdis, however, promoted
the discovery of his imposture. He had married all
his predecessor's wives, among whom was one Phedy-
yna, the daughter of Otanes, a Persian nobleman of the
first rank. Otanes, who suspected that the king was
not Smerdis the son of Cyrus, sent a true messenger
to his daughter, desiring to know whether he was
or not; but Phedyyna, having never seen this Smerdis,
could not give any answer. Her father then desired
to enquire at Atotfa, who could not but know her
own brother. However, he was again disappointed;
for Phedyyna acquainted him that all the king's wives
were lodged in distinct and separate apartments,
without allowing to see each other. This greatly
increased the suspicions of Otanes; upon which he sent
his daughter a third message, desiring her, the next
time, he should be admitted to the king's bed, to take
an opportunity of feeling whether he had ears or not;
for Cyrus had formerly caussed the ears of Smerdis the
magician to be cut off for some crime of which he had
been
A conspiracy formed against him.

In the mean time Smerdis and his brother had by great promises prevailed on Prenaspe (the executioner of the true Smerdis) to bind himself by an oath not to discover the fraud they had put on the Persians, and even to make a public speech, declaring that the present king of Persia was really the son of Cyrus. At the time appointed, he began his discourse with the genealogy of Cyrus, putting his hearers in mind of the great favours the nation had received from that prince. After having extolled Cyrus and his family, to the great amazement of all present, he confided the whole transaction with regard to the death of Smerdis: telling the people, that the apprehensions of the danger he must inevitably run by publishing the imposture had constrained him to conceal it for long; but, now, not being able any longer to act such a dishonourable part, he acknowledged that he had been compelled by Cambyses to put his brother to death with his own hand, and that the perfon who professed the throne was Smerdis the magian. He then begged pardon of the gods and men for the crime he had committed; and fulminating many imprecations against the Persians if they failed to recover the sovereignty, he threw himself headlong, from the top of the tower on which he stood, and died on the spot.

In the mean time the conspirators, who were advancing towards the palace, were informed of what had happened: and Ota­nes was again for deferring the execution of their enterprize; but Darius infulting upon the danger of delay, they proceeded boldly to the palace; and being admitted by the guards, who did not suspect them, they killed both the usurper and his brother; after which they ex­posed their heads to the people, and declared the whole imposture. The Persians at this were so enraged, that they fell on the whole feet, and killed every one of the magi they could meet with; and had not the slaughter been stopped by night, not one of the order would have been left alive.

The day on which this slaughter happened was afterwards celebrated by the Persians with the greatest solemnity, and called by the name of Magophonia, or the slaughter of the Magi. On that festival the magi durst not appear abroad, but were obliged to flint themselves up in their houses. Smerdis the magian reigned only eight months.

When the tumult was a little subdued, the conspirators, who were fe ven in number met together in order to elect a new king, or to determine what form of government they should next introduce. Ota­nes was for a republic: but being over-rulled by the rest, he declared, that as he was determined not to be a king, neither would he be ruled by one: and therefore infulted that he and his family should ever afterwards remain free from subjection to the royal power. This was not only granted, but it was further agreed by the other six, that whoever should every year present Ota­nes with a Median veil, a mark of great distinction among the Persians, because he had been the chief author of the enterprize. They farther agreed to meet at a certain place next morning at nine o'clock on horseback, and that he whose horse first neighed should be king. This being overheard by Ochobres, who had the care of Darius’s horses, he led a mare over night, and took it to the place, and brought his master’s horse to her, and the next morning the horse remembering the place, immediately neighed for the mare; and the five lords dismounting, saluted Darius as their king.

Darius Hystaspes was elected king of Persia in the year 522 B.C. Immediately after his accession, he promoted the other conspirators to the first employments in the kingdom, married the two daughters of Cyrus, Atossa and Artaytona, Parmys the daughter of the true Smerdis, and Phedyma the daughter of Ota­nes, who had detected the imposture of the magian. He then divided the whole empire into 20 satrapies or governments, and appointed a governor over each division, ordering them to pay him an annual tribute. The inhabitants of Colchis, with some others, were enjoined only to make annual presents, and the Arabsians to furnish every year such a quantity of frankincense as equalled the weight of 1000 talents. Thus Darius received the yearly tribute of 14,560 Euboeic talents, upwards of 250,000 pounds sterling.

Under Darius, the building of the temple of Jeru­salem, which had been obstructed by Cambyses and Smerdis, went on successfully, and the Jewish state was entirely restored. The most remarkable of Darius’s other trans­actions were his expeditions against Babyl­on; against Sis­tya, India, and Greece. The expedi­tion against Babylon took place in the year 517 B.C. when the people unable to bear the oppression of the Persians, and likewise discontented because the seat of Ionian government was removed from their city to Susa in Persia, took the opportunity of the troubles which happened in the reigns of Cambyses and Smerdis, to fo­lore their city with all kinds of provis­ions sufficient to serve them for many years; after which they broke out into an open rebellion, and this quickly brought upon them Darius with all his forces. The Babylonians perceiving themselves shut up by a numerous army, turned all their thoughts towards the supporting of a long siege, which they imagined would tire out the king’s troops. To prevent the con­sumption of their provis­ions, they took the most barbarous and cruel re­solution that ever was put in execution by any nation: they agreed among themselves to get rid of all unne­
cayinary mouths; and therefore gathering together all the old men, women, and children, they instigated them without distinction; every one being allowed only to keep the wife he liked best, and a maid servant to do the work of the house. The siege continued for a year and eight months; nor was there any likelihood of its being ended, when Zopyrus, one of Darius's chief commanders, put him in possession of it by the following stratagem. He cut off his nose and ears, and having mangled his body with stripes in a most cruel manner, he fled to the Babylonians thus disfigured, pretending that he had been so treated by Darius for advising him to raise the siege. Being intrusted with the command of some forces, he cut off several parties of the Persian army, whom Darius thus sacrificed in order to raise the character of Zopyrus the higher among the Babylonians. In this manner he so much established his credit, that at last he was made commander in chief of all the Babylonian forces, and the guard of the city committed entirely to his care; and so soon was this done than he delivered up Darius, who, to prevent their rebelling a second time beat down the walls of that metropolis to the height of 50 cubits. Three thousand of the most active in the rebellion were impaled; the rest pardoned. As they had destroyed most of their women, the neighbouring nations were commanded to furnish them with wives, and 50,000 women were sent to that city, by which means it was prevented from being depopulated. Zopyrus was rewarded with the highest honours, and had the whole revenues of Babylon bestowed on him for life.

After the reduction of Babylon Darius undertook a Scythian expedition, directed against those nations which lie between the Danube and the Tanaus. His pretext for this war was, to revenge the calamities which those nations had brought upon Achaia about 120 years before, when they invaded and subdued Media; keeping it in subjection for the space of 28 years, as we have related under the article. In this expedition he was attended with an army of 700,000 men. With these he marched to the Thraian Bosphorus: which having passed on a bridge of boats, he reduced all Thrace. From Thrace he advanced to the Danube, where he had appointed his fleet to meet him. This river he passed on another bridge of boats, and entered Scythia. His enemies, however, were too wise to oppose such a formidable power in the open field; and therefore retired before him, wafting the country as they went along, till at last the king, sensible of the danger he was in, resolved to give over the enterprise and return home. In order to do so with safety, he lighted a great number of fires in the night-time, and decamped; leaving behind him the old men and the sick, who fell into the hands of their enemies. The Scyths perceiving that Darius was gone, detached a considerable body to the bridge over the Danube; and as they were well acquainted with the roads, they got thither before the Persians. The Scyths had sent express messengers before hand to persuade the Ionians, whom Darius had left to guard the bridge, to break it down and retire to their own country; and this they prevailed the more easily, that as the time performed by Darius was now expired, they were at liberty to return home, without breaking their word or being wanting in their duty. Miltiades, prince of the Chersonese of Thrace, was for embracing fo favourable an opportunity of cutting of Darius's retreat, and shaking off the Persian yoke at once; all the other commanders agreed with him, except Hyllius prince of Miletus; who represented to the Ionian chiefs, that their power was connected with that of Darius, since it was under his protection that each of them was lord in his own city; and that the cities of Ionia would not fail to depose them and recover their liberty, if the Persian power should sink or decline. This speech made a deep impression on the rest, and it was at last determined that they should wait for Darius; and in order to deceive the Scyths, they began to break down the bridge, but advised them to return back and defeat Darius. They did so, but misused him; and he having thus safely escaped so great a danger, immediately repeated the Bosphorus, and took up his winter-quarters at Sardis, leaving Megabyzus, one of his chief generals, to complete the conquest of Thrace.

The king having sufficiently refreshed his troops, who had suffered extremely in the Scythian expedition, began to think of extending his dominions eastward; and, in order to facilitate his design, resolved in the first place to discover those countries. With this view, he caused a fleet to be built and equipped at Cephalus, a city on the river Indus. The command of this fleet he gave to one Scylax, a Grecian of Caria, who was well versed in maritime affairs. Him he ordered to sail down the current, and make the best discoveries he could of the country lying on either side of the river, till he arrived at the southern ocean; from whence he was to steer his course westward, and that way return to Persia. Scylax, having exactly observed his instructions, and sailed down the river Indus, entered the Red Sea by the straits of Babelmande1, and on the 30th month from his first setting out, landed at the same place from whence Necho king of Egypt formerly sent out the Phoenicians who circumnavigated Africa. From hence Scylax returned to Susa, where he gave a full account of his discoveries; upon which Darius, marching into India at the head of a powerful army, reduced that large country, and made it a province of the Persian empire drawing from thence an annual tribute of 360 talents of gold.

Soon after the expedition of Darius against India, the revolt of the Ionians, which gave occasion to his expedition into Greece, an account of which is given under the articles Attica, Greece, Sparta, &c. The ill success which attended him here, however, was so far from making him drop the enterprise, that it only made him the more intent on reducing the Grecians; and he resolved to head his army in person, having attributed his former bad success to the inexperience of his generals. But while he was employed in making the necessary preparations for this purpose, he received intelligence that the Egyptians had revolted, so that he was obliged to make preparations for reducing them also; and before this could be done, the king died, after having reigned 36 years, leaving the throne to his son Xerxes.

This prince ascended the throne of Persia in the year 485 B. C.; and his first enterprise was to reduce the Egyptians; which he effectually did, bringing
them into a worse state of slavery than they ever had experienced before. After this he resolved on an expedition into Greece; theVarious event of which is related under the article Artaxerxes. By his misfortunes in the Greek expedition, he became at last so dispirited, that he thereupon abandoned all thoughts of war and conquests: but growing tyrannical, and oppressing his subjects, he was murdered in his bed, in the year 464 B.C. and 418 of his reign, and was succeeded by his third son Artaxerxes Surnamed Longimanus on account of the great length of his arms.

This prince is named Ahasuerus, in Scripture, and is the name of the father of Esther, and from the whole of his reign showed the greatest kindness to the Jewish nation.

In the beginning of his reign he was opposed by Hytypates the second son of Xerxes, whom, however, he overcame, though not without considerable difficulty. After this he applied himself to the settlement of the affairs of government, and reforming many abuses which had crept in; and then, being fully established on the throne, he appointed feasts and rejoicings to be made for 160 days in the city of Susa: at one of which he resolved to divorce his queen for disobedience, and afterwards married Esther, as we find it recorded in the sacred writings.

In the fifth year of the reign of Artaxerxes the Egyptians revolted anew, and, being aided by the Athenians, held out for six years; but were again obliged to submit, and continued in subjection during the whole of his reign. Nothing else remarkable happened during the life of Artaxerxes Longimanus, who died in the 418th year of his reign; and was succeeded by Xerxes II. the only son he had by his queen, though by his concubines he had 17. Xerxes having drunk immoderately at an entertainment immediately after his accession, retired to a chamber in order to refresh himself with sleep; but here he was murdered by Sogdianus, the son of Artaxerxes by one of his concubines, after he had reigned 45 days.

Sogdianus was scarce seated on the throne when he put to death Bagorazus, the most faithful of all his father's eunuchs; by which, and the murder of his sovereign, he became generally odious. Upon this, fear of the dangerous situation in which he was, he sent for one of his brothers named Ochus, whom he supped with, with a design to murder him the moment he arrived. Ochus, however, understanding his design, put off, by several pretences, his coming, till he had drawn together a powerful army, with which he advanced to the confines of Persia. Here he openly declared, that his design was to revenge his brother's death; which brought over to him many of the nobility and governors of provinces, by whom he was immediately proclaimed king. Sogdianus, seeing himself thus deserted, contrary to the advice of all his friends, came to an accommodation with Ochus; who no sooner had him in his power than he cauffed him to be suffocated among aspers; a punishment invented on purpose for him.

Ochus being firmly settled on the throne by the death of Sogdianus, changed his name to Darius; and is by historians commonly called Darius Nabon or, The Bafard. But Arsites, another of the brothers being in what manner Sogdianus had got the better
the rear of the Greek battalions; but this advice he rejected with indignation, saying, that he should thus render himself unworthy of the crown for which he was fighting. As the king's army drew near, the Greeks fell upon them with such fury, that they routed the wing opposite to them almost at the first onset; upon which Cyrus was with loud shouts proclaimed king by those who fled next to him. But he, in the mean time, perceiving that Artaxerxes was wheeling about to attack him in flank, advanced against him, having 600 choien horse, killed Artagefes captain of the king's guard with his own hand, and put the whole body to flight. In this encounter, discovering his brother, he spurred on his horse, and coming up to him, engaged him with great fury; which in some degree turned the battle into a single combat. Cyrus killed his brother's horse, and wounded him on the ground; but he immediately mounted another horse, when Cyrus attacked him again, gave him a second wound, and had already lifted up his hand to give him a third, when the guards, perceiving the danger in which their king was, discharged their arrows at once against his antagonist, who at the same time throwing himself headlong upon his brother, was pierced through by his javelin. He fell dead upon the spot; and all the chief lords of his court, resolving not to survive him, were slain in the same place.

In the mean time, the Greeks having defeated the enemy's left wing commanded by Tissaphernes, and the king's right wing having put to flight Cyrus's left, both parties, being ignorant of what had passed elsewhere, imagined that they had gained the victory. But Tissaphernes acquainting the king, that his men had been put to flight by the Greeks, he immediately rallied his troops, in order to attack them. The Greeks, under the command of Clearchus, easily repulsed them, and pursued them to the foot of the neighbouring hills. As night was drawing near, they halted at the foot of the hill, much surprised that neither Cyrus himself, nor any messenger from him, had appeared; for as yet they knew nothing of his death, and the defeat of the rest of the army. They determined, therefore, to return to their camp, which they did accordingly; but found there that the greatest part of their baggage had been plundered, and all their provisions taken, which obliged them to pass the night in the camp without any sort of refreshment. The next morning, as they were still expending to hear from Cyrus, they received the news of his death, and the defeat of that part of the army. Whereupon they sent deputies to Ariœus, who was commander in chief of all the other forces of Cyrus, offering him, as conqueror, the crown of Perse. Ariœus rejected the offer, and acquainting them that he intended to set out early in the morning on his return to Ionia, advised them to join him in the night. They followed his directions, and, under the conduct of Clearchus, began their march, arriving at his camp about midnight, whence they set out on their return to Greece. They were at a vast distance from their own country, in the very heart of the Persian empire, surrounded by a victorious and numerous army, and had no way to return again but by forcing their way through an immense track of the enemy's country. But their valour and resolution mastered all these difficulties; and in spite of a powerful army, which pursued and harassed them all the way, they made good their retreat for 2325 miles through the provinces belonging to the enemy, and got safe to the Greek cities on the Euxine sea. This retreat (the longest that was ever made through an enemy's country) was conducted at first by Clearchus; but he being cut off through the treachery of Tissaphernes, Xenophon was chosen in his room, who at last brought his men safe into Greece; but for a full account of that famous retreat, see the article Xenophon.

The war with Cyrus was scarce ended, when another broke out with the Lacedemonians, on the following account. Tissaphernes being appointed to succeed Cyrus in all his power, to which was added all which he himself possessed formerly, began to oppress the Greek cities in Asia in a most cruel manner. On this they sent ambassadors to Sparta defiring the assistance of that powerful republic. The Spartans having ended their long war with the Athenians, willingly laid hold of the present opportunity of breaking again with the Persians, and therefore sent against them an army under the command of Thimbro, who, being strengthened by the forces which returned under Xenophon, took the field against Tissaphernes. But Thimbro being soon recalled upon some complaints, Dercyllidas, a brave officer and experienced engineer, was appointed to succeed him; and he carried on the war much more advantage than his predecessor. On his arrival in Asia, finding that Tissaphernes was at variance with another governor named Pharnabazus, he concluded a truce with the former, and marching against Pharnabazus, drove him quite out of Æolis, and took several cities in other parts. The latter, however, immediately repaired to the Persian court, where he made loud complaints against Tissaphernes, but gave the king a most salutary advice, which was to equip a powerful fleet, and give the command of it to Conan the Athenian, the best sea officer of his time, by which means he would obstruct the passage of further recruits from Greece; and thus soon put an end to the power of the Lacedemonians in Asia. This advice being approved of, the king ordered 700 talents for the equipment of a fleet, with directions to give Conan the command of it.

In the mean time, Dercyllidas, with all his valour and fame, fitted himself to be drawn into such a disadvantageous situation, that he must inevitably have been destroyed with his whole army, had it not been through the cowardice of Tissaphernes, who, having experienced the Grecian valour at the battle of Cuiza, could not by any means be induced to attack them. The Lacedemonians, however having heard that the Perian monarch was fitting out a great fleet against them, resolved to put on the war as vigorously as possible; and for this purpose, sent over Agesilaus one of their kings, and a most experienced commander, into Asia. This expedition was carried on with such secrecy, that Agesilaus arrived at Ephesius before the Persians had the least notice of his design. Here he took the field with 10,000 foot and 4000 horse, and falling upon the enemy while they were totally unprepared, carried every thing before him. Tissaphernes deceived him into a truce till he had leisure to assemble his forces, but gained little by his treachery.
Peri.

ery; for Ageilaus deceived him in his turn, and while Tissaphernes marched his troops into Caria, the Greeks invaded and plundered Phrygia.

Early in the spring, Ageilaus gave out that his design was to invade Lydia; but Tissaphernes, who remembered the last year's stratagem, now taking it for granted that Ageilaus would really invade Caria, made his troops again march to the defence of that province. But Ageilaus now led his army into Lydia as he had given out, and approached Sardis; upon which Tissaphernes recalled his forces from their former rout, with a design to relieve the place. But Caria being a very mountainous country, and unfit for horse, he had marched thither only with the foot, and left the horse behind on the borders of that province. Whence, on their marching back to the relief of Sardis, the horse being some days march before the foot, Ageilaus, took the advantage of so favourable an opportunity, and fell upon them before the foot could come to their assistance. The Persians were routed at the very first onset; after which Ageilaus over-ran the whole country, enriching both himself and his army with the spoils of the conquered Persians.

By this continued ill fortune Artaxerxes was so much provoked against Tissaphernes, that he soon after caused him to be put to death.

On the death of Tissaphernes, Tithraustes, who was appointed to succeed him, sent large presents to Ageilaus, in hopes of persuading him to abandon his conquests; but finding that commander was not by any means to be induced to relinquish the war, he sent Timocrates of Rhodes into Greece, with large sums of money to corrupt the leading men in the cities; and rekindle a war against the Lacedemonians. This stratagem produced the intended effect; for the cities of Thebes, Argos, Corinth, and others, entering into a confederacy, obliged them to recall Ageilaus, to the defence of his own country.

After the departure of Ageilaus, which happened in the year 354 B.C. the Lacedemonian power received a severe blow at Cnidus, where their fleet was entirely defeated by that of Artaxerxes under Conon, 50 of their ships being taken in the engagement; after which Conon and Pharnabazus being masters of the sea, failed round the islands and coasts of Asia, taking the cities there which had been reduced by the Lacedemonians. Sebota and Abydos only held out, and refilled the utmost efforts of the enemy, though they had been besieged both by sea and land.

Next year Conon having assembled a powerful fleet, again took Pharnabazus on board, and reduced the island of Melos, from whence he made a descent on the coasts of Lydia, plundering all the maritime provinces, and loading his fleet with an immense booty. After this, Conon obtained leave of him to repair to Athens with 80 ships and 50 talents, in order to rebuild the walls of that city; having first convinced Pharnabazus, that nothing could more effectually contribute to the weakening of the power of Sparta than putting Athens again in a condition to rival its power. He no sooner arrived at Piraeus the port of Athens, but he began to work; which as he had a great number of hands, and was seconded by the zeal of all those that were well inclined to the Athenians was soon completed, and the city not only restored to its former splendor, but rendered more formidable than ever. The Lacedemonians were now reduced to the necessity of accepting such terms of peace as they could procure. The terms were, that all the Greek cities in Asia should be subject to the king of Persia, peace with as also the islands of Cyprus and Clesomena; that the Persians should be restored to the Athenians, and all the cities of Greece, whether small or great, should be declared free; and by the same treaty, Artaxerxes engaged to join those who accepted the terms he proposed, and to affit them to the utmost of his power against such as should reject them.

Artaxerxes, being now disengaged from the Greek war, turned his arms against Evagoras, king of Cyprus. This man was defended from the ancient kings of Salamis, the capital city of the island of Cyprus. His ancestors had held that city for many ages in quality of overmen; but were at last driven out by the Persians, who, making themselves masters of the whole island, reduced it to a Persian province. Evagoras, however, being a man of an enterprising genius, soon became weary of living in subjection to a foreign power, drove out the Persian governor, and recovered his paternal kingdom. Artaxerxes attempted to drive him out of it; but being diverted by the Greek war, was obliged to put off the enterprise. However, Conon, by means of Ctesias, chief physician to Artaxerxes, got all differences accommodated, and Artaxerxes promised not to molest him in the possession of his small kingdom. But Evagoras soon becoming discontented with such a narrow possession, gradually reduced under his subjection almost the whole of the island. Some, however, there were who held out against him, and these immediately applied to Artaxerxes for assistance; and he, as soon as the war with Greece was at an end, bent all his force against Evagoras, intending to drive him quite out of the island. The Athenians, however, not withholding the favours lately conferred upon them by the king of Persia, could not forbear affisting their old ally in such a dreadful emergency. Accordingly, they sent him ten men of war under the command of Philocrates; but the Lacedemonian fleet, commanded by Talentias brother of Ageilaus, falling in with them near the isle of Rhodes, surrounded them so that not one ship could escape. The Athenians, determined to assist Evagoras at all events, sent Chabrias with another fleet and a considerable body of land forces; and with the assistance of these he quickly reduced the whole island. But in a short time, the Athenians being obliged, in consequence of the treaty concluded with the Persians, to recall Chabrias, Artaxerxes attacked the island with an army of 300,000 men, and a fleet of 300 ships. Evagoras applied to the Egyptians, Lybians, Arabians, Tyrians, and other nations, from whom he received supplies both of men and money; and fitting out a fleet, with which he ventured an engagement with that of Artaxerxes. But being defeated, and obliged to quit him self up in Salamis, he was closely besieged by sea and land. Here at last he was obliged to capitulate, and abandon to the Persians the whole of the island except Salamis, which he held as a king tributary to Artaxerxes.

The Cyprian war being ended, Artaxerxes turned,
The last years of the reign of Artaxerxes were greatly disturbed by dissensions in his family; which at last ended by bringing the two sons named Oebus, who behaved with such cruelty, that almost one half of his dominions revolted as soon as he came to the throne. But by reason of the dissensions of the rebels among themselves, all of them were reduced, one after another; and among the rest, the Sidonians, finding themselves betrayed, burnt themselves to the number of 40,000, together with their wives and children.

Oebus, having quelled all the insurgents, immediately set himself about reducing Egypt, and for this purpose procured a reinforcement of other 10,000 mercenaries from Greece. On his march, he lost a great number of his men drowned in the lake Serbonis, which lies between Phoenice and Egypt, extending about 32 miles in length. When the south wind blows, the whole surface of the lake is covered with sand, in such a manner that no one can distinguish it from the firm land. Several parties of Oebus’s army were lost in it for want of proper guides; and it is said that whole armies have sometimes perished in the same place. When he arrived in Egypt, he detached three bodies to invade the country in different parts: each being commanded by a Persian and a Greek general. The first was led by Lachares the Theban, and Rosaces governor of Lydia and Ionia; the second by Nicotiratus the Theban and Artizanes; the third by Mentor the Rhodian and Bagoas an eunuch. The main body of the army he kept with himself, and encamped near Pelium, with a design to watch the events of the war there. The event was successful, as we have related under the article Egypt; and Oebus having reduced the whole country, dismantled the strong holds, plundered the temples, and returned to Babylon loaded with booty.

The king, having ended this war with such success, conferred very high rewards on his mercenaries and others who had distinguished themselves. To Mentor the Rhodian he gave 100 talents, and other presents to a great value; appointing him also governor of all the coasts of Asia, and committing to his care the whole management of the war which he was still carrying on against some provinces that had revolted in the beginning of his reign; and all these either by firatages, or by force, he at last reduced; restoring the king's authority in all these places. Oebus then, finding himself free from all troubles, gave his attention to nothing but his pleasures, leaving the administration of affairs entirely to Bagoas the eunuch, and to Mentor. These two agreed to share the power between them in consequence of which the former had the provinces of Upper Asia, and the latter all the rest. Bagoas, having arms against the Cadutiens, whose country lay between the Euxine and Caucasian seas. But these nations were too well accustomed to war to be overcome by the Persians; and therefore the king was obliged to abandon the project, after having lost a great number of his troops and all the horses which he took with him. In his Egyptian expedition, which happened immediately after the Caduian war, he was attended with little better success; which, however, was owing to the bad conduct of his general Pharnabazus. This commander being entrusted with the management of the Egyptian war, sent an ambassador to Athens, complaining that Chabrias had engaged in the service of his king, with whom the state of Athens was in alliance, and threatening the republic with his master's resentment if proper satisfaction was not given: at the same time he demanded Iphicrates, another Athenian, and the gulf general of his time, to command the Greek mercenaries in the Persian service. This the Athenians complied with; and Iphicrates having mutilated his troops, so exercised them in all the arts of war, that they became afterwards very famous among the Greeks under the name of Iphicratian fathers. Indeed he had sufficient time to instruct them; for the Persians were so slow in their preparations, that two whole years elapsed before they were ready to take the field. At the same time Artaxerxes, that he might draw the more mercenaries out of Greece, sent ambassadors to the different states in it, declaring it to be his will and pleasure that they should live at peace with each other, on the terms of the treaty lately concluded: which declaration was received with pleasure by all the states except Thebes, who aspired to the sovereignty of Greece; and accordingly refused to conform to it. All things, however, at last being ready for the expedition, the troops were mutinied at the city then called Aes, and since Ptolomaiis where they were found to consist of 200,000 Persians under the command of Pharnabazus, and 20,000 Greeks led by Iphicrates. The fleet consisted of 300 galleys, besides a vast number of other vessels which followed with provisions. The fleet and army began the same time; and that they might act in concert they separated as little as possible. It was proposed, that the war should begin with the siege of Pelium; but Neocles, the revolting king of Egypt, had provided so well for the defence of the place, that it was thought expedient to drop the enterprise, and make a defence at one of the mouths of the Nile. In this they succeeded; for the Egyptians not expecting them at that place, had not taken such care to fortify it as at Pelium. The fortresses of conqunence was easily taken, and all the Egyptians in it put to the sword. After this, Iphicrates was for embarking the troops without loss of time, and attacking Memphis the capital of Egypt. Had this opinion been followed before the Egyptians recovered from the consternation into which they were thrown, it is highly probable that the whole country might have been reduced at once; but Pharnabazus would undertake nothing before the rest of the forces were come up. Iphicrates then, in the utmost vexation at losing so favourable an opportunity, pressed Pharnabazus to allow him to attack the place with the Greek mercenaries only; but he refused this also, from a mean jealousy of the honour which Iphicrates might acquire; and in the mean time the Egyptians recovered sufficient courage to put themselves in such a posture of defence, that they could not be attacked with any probability of success; and at the same time the Nile overflowing as usual, obliged them to return to Phoenice. The expedition was again undertaken 12 years after, but without success.

The last years of the reign of Artaxerxes were greatly disturbed by dissensions in his family; which at last ended by bringing the two sons named Oebus, who behaved with such cruelty, that almost one half of his dominions revolted as soon as he came to the throne. But by reason of the dissensions of the rebels among themselves, all of them were reduced, one after another; and among the rest, the Sidonians, finding themselves betrayed, burnt themselves to the number of 40,000, together with their wives and children.

Oebus, having quelled all the insurgents, immediately set himself about reducing Egypt, and for this purpose procured a reinforcement of other 10,000 mercenaries from Greece. On his march, he lost a great number of his men drowned in the lake Serbonis, which lies between Phoenice and Egypt, extending about 32 miles in length. When the south wind blows, the whole surface of the lake is covered with sand, in such a manner that no one can distinguish it from the firm land. Several parties of Oebus’s army were lost in it for want of proper guides; and it is said that whole armies have sometimes perished in the same place. When he arrived in Egypt, he detached three bodies to invade the country in different parts: each being commanded by a Persian and a Greek general. The first was led by Lachares the Theban, and Rosaces governor of Lydia and Ionia; the second by Nicotiratus the Theban and Artizanes; the third by Mentor the Rhodian and Bagoas an eunuch. The main body of the army he kept with himself, and encamped near Pelium, with a design to watch the events of the war there. The event was successful, as we have related under the article Egypt; and Oebus having reduced the whole country, dismantled the strong holds, plundered the temples, and returned to Babylon loaded with booty.

The king, having ended this war with such success, conferred very high rewards on his mercenaries and others who had distinguished themselves. To Mentor the Rhodian he gave 100 talents, and other presents to a great value; appointing him also governor of all the coasts of Asia, and committing to his care the whole management of the war which he was still carrying on against some provinces that had revolted in the beginning of his reign; and all these either by firatages, or by force, he at last reduced; restoring the king’s authority in all these places. Oebus then, finding himself free from all troubles, gave his attention to nothing but his pleasures, leaving the administration of affairs entirely to Bagoas the eunuch, and to Mentor. These two agreed to share the power between them in consequence of which the former had the provinces of Upper Asia, and the latter all the rest. Bagoas,
The religion of his country, and endeavoured, on the conquest of Egypt, to influence the king in favour of the Egyptian ceremonies; but in spite of all his endeavours, Ochus not only refused to comply, but killed the sacred bull, the emblem of the Egyptian god Apis, plundered the temples, and carried away their sacred records. This Bagas supposed to be the highest guilt which a human creature could commit; and therefore poisoned his master and benefactor in the 21st year of his reign. Nor did his revenge stop here; for he kept the king's body, cau(ing another to be buried in its stead; and because the king had caused his attendants eat the flesh of Apis, Bagas cut his body in pieces, and gave it so mangled to be devoured by cats, making handles for swords of his bones. He then placed Aries the youngest of the deceased king's sons on the throne, that he might the more easily preserve the whole power to himself.

Aries did not long enjoy even the shadow of power which Bagas allowed him, being murdered in the second year of his reign by that treacherous enmity, who now conferred the crown on Darius Codemanus, a distant relation of the royal family. Neither did he incline to let him enjoy the crown much longer than his predecessor; for finding that he would not suffer himself to be guided by him, in all things, the treacherous Bagas brought him a poisonous potion; but Darius got rid of him by his own artifice, cau(ing Darius in the throne as far as security from internal enemies could do so; but in a very little time his dominions were invaded, and we may say, the same moment conquered, by Alexander the Great. The particulars of that hero's conquest are related under the article Macedon; we shall therefore here only take notice of the fate of Darius himself, with which the Persian empire concluded for many ages.

After the death of Artibes, which was decisive in favour of Alexander, the latter took and plundered Persepolis, from whence he marched into Media, in order to pursue Darius, who had fled to Ecbatan, the capital of that province. This unhappy prince had an army of 50,000 foot, among whom were 4000 Greeks, who continued faithful to the king. Besides these, he had 4000 slingers and 5000 horse, most of them Bactrians, and commanded by Bessus governor of Bactria. When Darius heard that Alexander was marched to Ecbatan, he retired into Bactria, with a design to raise another army; but soon after, changing his mind, he determined to venture a battle with the forces he still had left. On this Bessus governor of Bactria, and Bellerus a Persian lord of great distinction, formed a conspiracy against him, proposing to seize his person, and if Alexander purposed them, to gain his friendship and protection by betraying their master into his hands; but if they escaped, their design was to murder him, and usurp the crown. The troops were easily gained over, by representing to them the desperate situation of Darius's affairs; but Darius himself, though informed of their proceedings, and solicited to trust his person among the Greeks, refused to give credit to the report, or follow such a fatal change. The consequence of this was, that he was in a few days seized by the traitors, who, out of respect to the royal dignity, bound him with golden chains, and shutting him up in a covered cart, fled with him towards Bactria. The cart was covered with skins, and strangers appointed to drive it without knowing who the prisoner was. Bessus was proclaimed commander in chief in the room of Darius by the Bactrian horse; but Artabazus and his sons with the forces they commanded, and the Greeks under the command of one Patron, retired from the body of the army under Bessus, and marched over the mountains towards Parthia. In the mean time Alexander arriving at Ecbatan, was informed that Darius had left the place five days before. He then dispatched orders to Clitus, who had fallen sick at Sufa, to repair, as soon as he recovered, to Ecbatan, and from thence to follow him into Parthia with the cavalry and 6000 Macedonians, who were left in Ecbatan. Alexander himself with the rest of the army pursed Darius; and the 11th day arrived at Rhages, having marched in that space of time 3300 furlongs. Most of those who accompanied him died through the fatigue of so long a march; insomuch that, on his arrival at Rhages, he could scarce multer 60 horsemen. Finding that he could not come up with Darius, who had already passed the Caspian straits, he fix'd five days at Rhages, in order to refresh his army and settle the affairs of Media. From thence he marched into Parthia and encamped at a small distance from the Caspian straits, which he passed the next day without opposition. He had scarce entered Parthia, when he was informed that Bessus and Nabarzanes had conspired against Darius, and designed to seize him. Hereupon leaving the main body of the army behind with Craterus, he advanced with a small troop of horse lightly armed; and having marched day and night without ever halting, except for a few hours, he came on the third day to a village where Bessus with his Bactrians had encamped the day before. Here he understood that Darius had been seized by the traitors; that Bessus had caused him to be shut up in a close cart, which he had sent before that he might be the more sure of his person; and that the whole army except Artabazus and the Greeks, who had taken another rout, obeyed Bessus. Alexander therefore taking with him a small body of light armed horse, for the others could not possibly proceed further, at last came in sight of the barbarians, who were marching in great confusion. His unexpected appearance struck them though far superior in number, with such terror, that they immediately betook themselves to flight, and because Darius refused to follow them, Bessus and those who were about him discharged their darts at the unfortunate prince, leaving him wallowing in his blood. After this they all fled different ways and were pursued with great slaughter by the Macedonians. In the mean time the horaces that drew the cart in which Darius was, flopped of their own accord, for the drivers had been killed by Bessus, near a village about four furlongs from the highway. Thither Polyrattus a Macedonian, being pref'd with thirst in the pursuit of the enemy, was directed by the inhabitants to a fountain to refresh himself, not far from the place where they flopped. As he was filling his helmet with water, he heard the groans of a dying man; and looking round, he discovered a cart with a team of horses, unable to move.
move by reason of the many wounds they had received. When he drew near, he perceived Darius lying in the cart and very near his end, having several darts sticking in his body. However, he had strength enough left to call for some water, which Polytarus readily brought him. Darius, after drinking, turned to the Macedonian, and with a faint voice told him, that, in the deplorable state to which he was reduced, it was no small comfort to him that his last words would not be lost; he then charged him to return his hearty thanks to Alexander for the kindn

His muttering with the flower!

Having uttered these words, he expired in the arms of Polytarus. Alexander coming up a few minutes after, bewailed his death, and caused his body to be in terred with the highest honours. The traitor Bessus being at last reduced to extreme difficulties, was delivered up by his own men naked and bound into the hands of the Macedonians; on which Alexander gave him up to Oeaxmes, the brother of Darius, to suffer what punishment he should think proper. Plutarch tells us, that he was executed in the following manner: Several trees being by main force bent down to the ground, and one of the traitor's limbs tied to each of them, the trees, as they were suffer'd to return to their natural position, flew back with such violence, that each carried with it the limb that was tied to it.

Thus ended the empire of Persia, 209 years after it had been founded by Cyrus. On the death of Alexander the Persian dominion became the object of Seleucus Nicator, and continued subject to him for 62 years, when the Parthians revolted, and conquered the greatest part of them. To the Parthians they continued subject for 475 years, when the sovereignty was again restored to the Persians, as related under the article PARTHIA.

The reforer of the Persian monarchy was Artaxerxes, or Artaxares, who was not only a private person, but of spurious birth. However, he possessed great abilities, by which means he executed his ambitious projects. He was no sooner feated on the throne than he took the pompous title of king of kings, and formed a design of reforing the empire to its ancient glory. He therefore gave notice to the Roman governors of the provinces bordering on his dominions, that he had a just right, as the successor of Cyrus, to all the Left. As; which he there commanded them immediately to quit, as well as the provinces on the frontiers of the ancient Persian kingdom, which were already his. The consequence of this was a war with Alexander. Severus the Roman emperor. Concerning the event of this war there are very different accounts. It is certain, however, that, on account of his exploits against Artaxerxes, Alexander took the titles of Par-
and having an army superior to them in numbers, employed them continually in skirmishes, which were sometimes favourable to him and sometimes otherwise. But Sâd, perceiving that this lingering war would destroy his army, determined to halt forward, and force the enemy to a general engagement. The Periâns declined this for a long time; but at length, finding a convenient plain where all their forces might act, they drew up in order of battle and resolved to wait for the Arabs. Sâd having disposed his men in the belt order he could, attacked the Periâns with the utmost fury. The battle lasted three days and three nights; the Periâns retiring continually from one point to another, till at last they were entirely defeated; and thus the capital city, and the greatest part of the dominions of Periâ, fell into the hands of the Arabs. The conquerors seized the treasures of the king; which were formidable, that, according to a Mahometan tradition, their prophet gave the Saracen army a miraculous view of those treasures before the engagement, in order to encourage them to fight.

After the loss of this battle, Jezdegerd retired into Chorâfan, where he maintained himself as king, having under his subjection two other provinces, named Kerman and Seyffian. But after he had reigned in this limited manner for 19 years, one of the governors of the few towns he had left, betrayed it, and called in the Turks. This place was called Merv, seated on the river Ghîn or Odus. Jezdegerd immediately marched against the rebels and their allies. The Periâns were defeated; and the unfortunate monarch, having with much difficulty reached the river, found there a little boat, and a fisherman to whom it belonged. The king offered him a bracelet of precious stones; but the fellow, equally brutal and stupid, told him that his fare was five farthings, and that he would neither take more nor less. While they disputed, a party of the rebel horse came up, and knowing Jezdegerd, killed him in the year 652.

Jezdegerd left behind him a son named Firouz, and a daughter named Dara. The latter espoused Bolesnay, whom the rabbinical writers have dignified with the title of the har of the capityary; and who, in fact, was the prince of the Jews settled in Chaldea. As for Firouz, he still preferred a little principality; and when he died, left a daughter named Mab Afiir, who married Wâlid the son of the caliph Abdalm-lek, by whom she had a son named Tâzid, who became caliph, and consequently sovereign of Periâ; and so far was this prince from thinking himself above claiming the title derived from his mother, that he contemptuously styled himself the son of Khoufou, king of Periâ, the descendant of the caliph Manouen, and among whose ancestors on the side of the mother were the Roman emperor and the khâcan.

Periâ continued to be subject to the Arabs till the decline of the Saracen empire, when it was seized by various usurpers, till the time of Jenghiz Khan, who conquered it as well as almost all the rest of Asia. After his death, which happened in the year 1227, Periâ, together with the neighbouring countries, were governed by officers appointed by his successors, who reigned at Karakorom, in the eastern parts of Tartary, till the year 1253, when it became once more the seat of a mighty empire under Hulaku the Mogul, who in 1256 abolished the khalifate, by taking the city of Bâdad, as related under that article. After the death of Hulaku, his son Abaka succeeded to his extensive dominions; and his first care was to shut up all the avenues of his empire against the other princes of the race of Jenghiz Khan, who reigned in different parts of Tartary. His precautions, however, were of little avail; for in the very beginning of his reign he was invaded by Burkan Khan, of the race of Jagatay the son of Jenghiz Khan, from Great Bakhuria, with an army of 300,000 men. Abaka was but indifferently prepared to oppose such a formidable power; but, happily for him, his antagonist died before the armies came to an engagement, and the invaders disappeared and returned to Tartary. In the year 1264, Armenia and Anatolia were ravaged by the Mamlûks from Egypt, but they were obliged to fly from Abaka, who thus seemed to be established in the possession of an empire almost as extensive as that of the ancient Persian kings.

His tranquillity, however, was of short duration; for in 1268 his dominions were invaded by Borak Khan, a prince likewise of the race of Jagatay, with an army of 100,000 men. He quickly reduced the province of Chorâfan, where he met with little opposition, and in 1269 advanced as far as Aderbijan, where Abaka had the bulk of his forces. A bloody battle ensued; in which Abaka was victorious, and Borak obliged to fly into Tartary, with the loss of all his baggage and great part of his army. Abaka died in 1282, after a reign of 17 years, not without suspicion of being poisoned; and was succeeded by his brother Ahmed Khan. He was the first of the family of Jenghiz Khan who embraced Mahometanism; but neither he nor his successors appear to have been in the least verified in the arts of government; for the Periân history, from this period, becomes only an account of insurrections, murders, rebellions, and poisonings, till the year 1335, when it split all to pieces, and was possessed by a great number of petty princes; all of whom were at perpetual war with each other till the period of Timur Beg, or Tamerlane, who once more reduced them all under one jurisdiction.

After the death of Tamerlane, Periâ continued to be governed by his son Shah Rukh, a wife and valiant prince: but immediately after his death fell into the same confusion as before; being held by a great number of petty tyrants, till the beginning of the 16th century, when it was conquered by Shah Ismael Safi, or Sefi; of whose family we have the following account. His father was Sheykh Hayder or Hayder Safi, the son of Sultan Juneyd, the son of Sheykh Ibrahim, the son of Sheykh Ali, the son of Sheykh Mufti, the son of Sheykh Sefi; who was the 13th in a direct line from Ali the fon-in-law of the prophet MahOMET. When Tamerlane returned from the defeat of Bajazet the Turkish sultan, he carried with him a great number of captives out of Karamania and Anatolia, all of whom he intended to put to death on some remarkable occasion; and with this resolution he entered Ardebil, or Ardevil, a city of Aderbijan, about 25 miles to the east of Taurus, where he continued for some days. At this time lived in that city the Sheykh Safi or Sefi abovementioned, reputed by the inhabitants to be a saint; and, as such, much revered by them. The fame of Sefi's sanctity so much moved Tamerlane, that he paid him frequent visits; and, when he was about to depart, promised to grant whatever favour he should ask. Sheykh Safi, who had been informed of Tamerlan's
The reigns of the succeeding princes afford nothing remarkable till the time of Shah Abbas I. surnamed the Great. He ascended the throne in the year 1584; and his first care was to recover from the Turks and Tartars the large provinces they had seized which formerly belonged to the Persian empire. He began with declaring war against the latter, who had seized the finest part of Chorassan. Accordingly, having raised a powerful army, he entered that province, where he was met by Abdallah Khan the chief of the Ubeek Tartars. The two armies lay in fight of each other for six months; but at length Abbas attacked and defeated his enemies, forcing them, for that time, to abandon Chorassan. Here he continued for three years; and on his leaving that place, fixed the seat of government at Isfaham, where it has continued ever since.

His next expedition was against the Turks. Understanding that the garrison of Tauris was in no expectation of an enemy, he formed a design of surprizing the place; and having privately assembled a few forces, he marched with such celerity, that he reached a pass called Shihk, very near Tauris, in six days, though it is usually 18 or 20 days journey for the caravans. Here the Turks had posted a few soldiers, rather for the purpose of collecting the customs on such commodities as were brought that way, than of defending the pass against an enemy. Before they came in fight of this pass, Abbas and some of his officers left the rest of the army, and rode briskly up to the turnpike. Here the secretary of the customhouse, taking them for merchants, demanded the usual duties. Abbas replied, that the person who had the purfe was behind, but at the same time ordered some money to be given him. But while the secretary was counting it, he was suddenly robbed by the Shah's order; and the officers who were with him suddenly falling upon the few soldiers who were there, obliged them to submit; after which he entered the pass with his army. The governor of Tauris marched out with all the troops he could collect on so short a warning: but being inferior to the Persians, he was utterly defeated, and himself taken prisoner; after which the city was obliged to submit, as also a number of places in the neighbourhood. One city only, called Orumie, being very strongly fortified, refused all the efforts of Abbas; but was at last taken by the assistance of the Curds, who he gained over by promising to share the plunder of the place with them. But instead of this, he formed a design to cut them all off at once; fearing that they might at another time do the Turks a service of the same nature that they had done to him just now. For this reason he invited their chiefs to dine with him; and having brought them to a tent, the entrance to which had several turnings, he stationed on the inside two executioners, who cut off the head of the guests as soon as they entered.

After this Shah Abbas considerably enlarged his dominions, and repelled two dangerous invasions of the Turks. He attempted also to promote commerce, and civilize his subjects; but failed all his great actions by his abominable cruelties, which he practised on every one who gave him the least caufe of offence; nay, frequently without any caufe at all. He took the Isle of Ormus from the Portugese, who had kept it since 1507, by the assistance of some English ships in 1622; and died six years after, aged 70.

The princes who succeeded Shah Abbas the Great, were remarkable only for their cruelties and debaucheries, which occasioned a revolution in 1716, when the Shah Husein was dethroned by the Afghans, a people inhabiting the country between Perlia and India; who being oppressed by the mini fters, revolted under the conduct of one Merewell. The princes of the Afghan race continued to enjoy the sovereignty of Khoul Khan; and during this time, when Ashraf the reigning Shah was dethroned by one of his officers, the country continued to be governed by the Afghans, till the year 1760, when the Emperor of Perlia, taking advantage of the confusion among the Persians, sent an army to Chorassan, and compelled the Sultan of the Afghan race to acknowledge the suzerainty of Perlia. A few years after, he was murdered by the Afghans, on whom the empire of Perlia was seized. On this occasion, the Afghans made a league with the Ottoman and Persia, against the Turks; but the latter, as usual, forced their way into Chorassan, when Shah Shujah, the son of the late Sultan, fled to the Ottoman, and by their assistance recovered the provinces of Chorassan and Isfaham, and established Shah Shujah on the throne of Perlia. This Shah Shujah died in the year 1772, and was succeeded by his son Shah Jum-Ali Khan Shuja, who continued on the throne until 1777, when he was dethroned by his great uncle, the Shah Fathollah, who was assassinated the following year. Thus, after a reign of about 40 years, the throne of Perlia was restored to its legitimate owner. The next ruler of Perlia was a person named Hassam-Ala-ul-Mulk, who reigned 5 years, and was succeeded in 1783 by his son and successor, Afshar Khan, who reigned 9 years, and was followed by Shah Shujah II., grandson of the late Shah Shujah. This Shah Shujah was assassinated in 1798, and the throne was seized by his son, with the assistance of the Russians, who, in 1798, sent an army into Perlia. This army, however, was defeated by the forces of the British, and the Shah Shujah was restored to the throne by them. He reigned 2 years, and was succeeded by his son, who reigned 8 years, when he was succeeded by his cousin, the present Shah, named Shah Shujah III., who has reigned 25 years, and is considered as one of the most able and just rulers of Perlia.
Perfia.

Thamasp, otherwise called Prince Thamas, the only survivor of the family of Abbas, assembling an army, invited into his service Nadir Khan, who had obtained great reputation for his valor and conduct. He was the son of a Persian nobleman, on the frontiers of Ubeck Tartary; and his uncle who was his guardian, keeping him out of possession of the castle and estate, which was his inheritance, took to robbing the caravans; and, having increased his followers to upwards of 5,000 men, became the terror of that part of the country, and especially of his uncle, who had seized his estate. His uncle therefore resolved to make peace with him, and with that view invited him to the castle, where he entertained him in a splendid manner; but Nadir Khan ordered his troops to be cut next night, and all his people to be turned out of the castle. No sooner had Nadir Khan got the command of the Persian army, than he attacked and defeated the usurper Etriff, put him to death, as is supposed; after which, he seemed to be well treated, and had his life, or at least his freedom, restored to him. He was in the possession of immense wealth, and pretenders to the throne of Persia.

Nadir Khan, who had made themselfs masters of the country, and then prince Thamas seemed to be established on the throne; but Nadir Khan, to whom Thamas had given the name of Thama Kouti Khan, that is, the Slave of Thamas, thinking his services not sufficiently rewarded, and pretending that the king had a design against his life, or at least to fet him aside, confined against his will, and put him to death, as is supposed; after which, he usurped the throne, flying himself shab Nadir, or King Nadir.

He afterwards laid siege to Candabor, of which a son of Merewies had possesed himself. While he lay at this siege, the court of the Great Mogul being divided in factions, one of the parties invited Shah Nadir to come to their assistance, and betrayed the Mogul into his hands. He thereupon marched to Delhi, the capital of India, and summoned all the viceroys and governors of provinces to attend him, and bring with them all the treasures they could raise; and those that did not bring as much as he expected, he tortured and put to death. Having thus amassed the greatest treasure that ever prince was master of, he returned to Persia, giving the Mogul his liberty, on condition of his resigning the provinces on the west side of the Indus to the crown of Persia. He afterwards made a conquest of Ubeck Tartary, and plundered Bohara the capital city. Then he marched against the Dagillian Tartars; but left great part of his army in their mountains, without fighting. He defeated the Turks in several engagements; but lying siege to Bagdad, was twice compelled to raise the siege. He proceeded to change the religion of Persia to that of Oman, hanged up the chief priests, put his own son to death, and was guilty of such cruelty, that he was at length assassinated by his own relations, anno 1747. A contest upon this ensued between these relations for the crown, which has rendered Persia a scene of the most horrible confusions for upwards of 40 years.

The reader will form some notion of the troubles of this unhappy country from the following series of pretenders to the throne between the death of Nadir and the accession of Kerim Khan. We give it from Francklin's Observations. 1st, Adil Shah.—2d, Ibrahim Shah.—3d, Shah Rokh Shah.—4th, Suleeman Shah.—5th, Ismael Shah.—6th, Azad Khan Afghan.—7th, Hiffun Khan Kejar.—8th, Ali Merdan Khan Bakhteari.—9th, Kerim Khan Zund.

"Their reigns, or more properly the length of time they respectively governed with their party, were as follows: Adil Shah, nine months. Ibrahim Shah, six months. Shah Rokh Shah, after a variety of revolutions, at length regained the city of Meshid: he is now alive (1787), and above 80 years of age, reigning in Khorasan, under the direction of his son Nadir Ullah Meerza. Suleeman Shah and Ismael Shah in about forty days were both cut off, almost as soon as they were elevated. Azad Khan Afghan, one of Kerim Khan's most formidable rivals and competitors, was subdued by him, brought prisoner to Shiraz, and died there of a natural death. Hiffun Khan Kejar, another of Kerim Khan's competitors, was believing Shiraz, when his army suddenly mutinied and deserted him. Their mutiny was attributed to their want of pay. A party sent by Kerim Khan took him prisoner. His head was instantly cut off, and presented to Kerim Khan. His family were brought captives to Shiraz. They were well treated, and had their liberty given them soon after, under an obligation not to quit the city. Ali Merdan Khan was killed by a musket-shot as he was walking on the ramparts of Meshid encouraging his men. Kerim Khan Zund, by birth a Curdian, was a most favourite officer of Nadir Shah, and at the time of his death was in the southern provinces. Shiraz and other places had declared for him. He found means at last, after various encounters with doubtful success, completely to subdue all his rivals, and finally to establish himself as ruler of all Persia. He was in power about 50 years; the latter part of which he governed Persia under the appellation of vakeel or regent, for he never would receive the title of Shah. He made Shiraz the chief city of his residence, in gratitude for the assistance he had received from its inhabitants and those of the southern provinces. He died in the year 1779, regretted by all his subjects, who esteemed and honoured him as the glory of Persia.

"When the death of Kerim Khan was announced in Twenty-six, much confusion arose; two and twenty of the principal officers of the army, men of high rank and station, took possession of the ark, or citadel, with a resolution to acknowledge Abul Fittah Khan (the eldest son of the late Vakeel) as their sovereign, and to defend him against all other pretenders; whereupon Zikea Khan, a relation of the late Vakeel by the mother's side, who was possessed of immense wealth, enlisted a great part of the army into his pay, by giving them very considerable bounties. Zikea Khan was of the tribe of Zund (or the Lackeries); a man remarkably proud, cruel, and unrelenting. Having assembled a body of troops, he immediately marched them to the citadel, and laid close siege to it for the space of three days; at the expiration of which, finding he could not take it by force, he had recourse to treachery. To each of the principal khans he sent a written paper, employing treacherous means to entice the officers out, and was successful in taking them; and it appeared that they could not withstand many days longer, they agreed to
surrender themselves, firmly relying on the promises that had been made them. Zikea Khan, in the mean time, gave private orders for the khans to be seized, and brought separately before him as they came out of the citadel. His orders were strictly obeyed, and these deluded men were all massacred in his presence: he was seized in the meantime, feeding his eyes on the cruel spectacle.

"Zikea Khan's tyranny became soon intolerable, and he was cut off by his own body-guard, when Abul Futtah Khan, who was at the time in the camp, was proclaimed king by the unanimous voice of the troops, whom he immediately led back to Shiraz. On his arrival he was acknowledged as sovereign by all ranks of people, and took quiet possession of the government.

"Mahomed Sadick Khan, only brother of the late Kerim Khan, who had during that prince's life filled the high office of beglerbeg of Fars, and had been appointed guardian of his son Abul Futtah Khan, was at this period governor of the city of Busfora, which had been taken by the Persians, previous to the vakeel's venture. On the eve of the battle which he has fought with Sadick Khan, as in 1788, Mr. Franklin, from whose excellent Observations on a Tour made in the years 1786-7, these particulars are mostly extracted, says that Jaafar Khan is the most likely, in case of success against his opponent Akau Mahomed Khan; and for this purpose marched with his army towards Shiraz: the two armies met near Yezdekhail; when a battle ensued, and Akau Mahomed Khan's superior fortune again prevailing, Jaafar Khan was defeated, and retired to Shiraz, which he quitted on the 23rd of June 1787, and shortly after marched his army to the northward, but returned in October without having effected anything." Such was the state of Persia in 1788.

Which he effects.

67
Akau Mahomed Khan-collects troops, and is proclaimed at Mazanderan and Ghilan.

The news of Sadick Khan's approach threw the inhabitants of Shiraz into the greatest consternation: their minds were variously agitated on the occasion: some, from his known public character, expected he would honestly fulfill the commands of his deceased brother; others, who had been witnesses to the confusion of former times, on similar occasions, rightly imagined that he would set up for himself; and indeed this proved to be the case: for having entered Shiraz a very few days after, he caused Abul Futtah Khan to be seized and deprived of life, and put into close confinement.

"At this event, Sadick Khan openly assumed the government. As soon as the intelligence reached Ali Murad Khan, who was at Isphahan, that lord instantly rebelled: deeming himself to have an equal right to the government with Sadick Khan, as in fact he had, he could ill brook the thought of being obedient to him, and openly declared himself a competitor for the empire. Persia was by this means again involved in all the horrors of a civil war. Ali Murad Khan indeed took possession of Shiraz, assumed the government, and gave to the empire the flattering prospect of being settled under the government of one man; but this prospect was soon obscured by the power and credit acquired by Akau Mahomed Khan."

On the night following Kerim Khan's death, this man found means to make his escape from Shiraz, and fled to the northward, where, collecting some troops, he soon made himself master of Mazanderan and Ghilan, and was proclaimed nearly about the time that Ali Murad Khan had taken Shiraz. "It is remarkable (says our author), that from his first entering into competition for the government, he has been successful in every battle which he has fought. He is an eunuch, having been made so whilst an infant, by the command of Nadir Shah, and possesses great personal bravery."

Ali Murad Khan, hearing of the success of Akau Mahomed Khan, determined to go against him, but as he was previously proceeding to Isphahan to suppress a rebellion, he fell suddenly from his horse and expired on the spot.

"At this period Jaafar Khan, the eldest and only surviving son of Sadick Khan, was governor of Khums: he deemed this a favourable opportunity to assert his pretensions to the government, and immediately marched with what few troops he had to Isphahan; soon after his arrival he was joined by the greater part of the malcontents, who were then in arms. In this situation he remained some time; but Akau Mahomed Khan coming down upon him with his army, he was obliged to risk his fate in a battle, and being defeated, fled with the small remains of his troops, taking the road to Shiraz. Soon after finding himself strengthened by an increase of his army, he determined to venture a second engagement with his opponent Akau Mahomed Khan; and for this purpose marched with his army towards Isphahan: the two armies met near Yezdekhail, when a battle ensued, and Akau Mahomed Khan's superior fortune again prevailing, Jaafar Khan was defeated, and retired to Shiraz, which he quitted on the 25th of June 1787, and shortly after marched his army to the northward, but returned in October without having effected anything." Such was the state of Persia in 1788.

Mr. Franklin, from whose excellent Observations on a Tour made in the years 1786-7, these particulars are mostly extracted, says that Jaafar Khan is the most likely, in case of success against his opponent, to restore the country to a happy and reputable state; but it will require a long space of time to recover it from the calamities into which the different revolutions have brought it:—a country, if an oriental metaphor may be allowed, once blooming as the garden of Eden, fair and flourishing to the eye;—now, sad reverse! despoiled and leafless by the cruel ravages of war, and defolating contention."

As to the air and climate of this country, considering the great extent thereof, it cannot but be very different, according to the situation of its several parts; some being frozen with cold, whilst others are burnt, with heat at the same time of the year. The air, wherever it is cold, is dry; but while it is extremely hot, it is sometimes moist. All along the coast of the Persian Gulf, from west to east, to the very mouth of the river Indus, the heat of four months is so excessive, that even those who are born in this country, unable to bear it, are forced to quit their houses, and retire to the mountains; so that such as travel in these parts, at that season, find none in the villages but wretched poor creatures, left there to watch the effects of the rich, at the expense of their own health. The extreme heat of the air, as it is insupportable, so to it makes it prodigiously unwholesome; strangers frequently falling sick there, and seldom escaping. The eastern provinces of Persia, from the river Indus to the borders of Tartary, are subject to great heats, though not quite so unwholesome as on the coasts of the Indian Ocean and the Persian Gulf; but in the northern provinces, on the coast of the Caspian Sea, the
heat is full as great, and, though attended with moisture, as unwholesome as on the coast before mentioned. From October to May, there is no country in the world more pleasant than this; but the people carry indelible marks of the malign influence of their summers, looking all of them of a faint yellow, and having neither strength nor spirits; though, about the end of April, they abandon their houses, and retire to the mountains, which are 25 or 30 leagues from the sea. But this moistnes in the air is only in these parts; the rest of Persia enjoys a dry air, the sky being perfectly serene, and hardly so much as a cloud seen to fly therein.

Though it seldom rains, it does not follow that the heat admits of no mitigation: for in the night, notwithstanding there is not a cloud to be seen, and the sky is so clear, that the stars alone afforded a light sufficient to travel by, a brisk wind springs up, which lasts until within an hour of the morning, and gives such a coolness to the air, that a man can be attended with tolerable warm garments. The seasons in general, heat admits of no mitigation: for in the night, the heat is found as great, and though the sky is being perfectly serene, and hardly so much as a cloud seen to fly therein.

During the spring, the face of the country appears uncommonly beautiful. The flowers, of which they have a great variety, and of the brightest hues, the fragrant herbs, shrubs, and plants, the rose, the sweet basil, water-hyacinth, and the myrtle, all here contribute to refresh and perfume the natural mildness of the air. The nightingale of the garden (called by the Persians boodul bezar dafaars), the goldfinch, and the linnet, by their melodious warblings at this delightful season of the year, serve to add to the satisfaction of the mind, and to inspire it with the most pleasing ideas. The beauties of nature are here depicted in their fullest extent; the natural historian and the botanist would here meet with ample scope for pursuing their favourite investigations. With the great advantages of the salubrity of the air, how can it be wondered at that the inhabitants of Shiraz should so confidently assert the pre-eminence of their own city to any other in the world; or that such beauties should fail of calling forth the poetical exertions of a Hafiz, a Sadí, or a Jamí? Their mornings and evenings are cool, but the middle of the day is very pleasant. In summer the thermometer seldom rises above 7 in the day-time, and at night it generally sinks as low as 2.

The autumn is the worst season of the year, that being the time when the rains begin to fall, and during the autumnal months it is considered by natives as the most unhealthy; colds, fluxes, and fevers being very general. In winter a vast deal of snow falls, and very thick; but ice is rarely to be found, except on the summits of the mountains, or towards Ispahan, and the more northern parts of Persia. One thing which is most to be thanked in this country, and renders it preferable to any other part of the world, is the nights, which are always clear and bright; and the dew, that in moist places is so pernicious and dangerous a nature, is not of the least ill consequence here; there is none at all in summer, and in the other seasons it is of such a nature, that if the brightlest incimitar should be exposed to it all the night, it would not receive the least rust; a circumstance I have myself experienced. This dryness in the air causes their buildings to last a great while, and is undoubtedly one of the principal reasons that the celebrated ruins of Persepolis have endured for so many ages, and, comparatively speaking, in so perfect a state. The great dryness of the air exempts Persia from thunder and earthquakes. In the spring, indeed, there sometimes falls hail; and, as the harvest is then pretty far advanced, it does a great deal of mischief. The rain-bow is seldom seen in this country, because there rise not vapours sufficient to form it; but in the night there are seen rays of light flitting thro' the firmament, and followed as it were by a train of smoke. The winds, however brisk, seldom swell into storms or tempests; but, on the other hand, they are sometimes poisonous and infectious on the shores of the Gulf, as all travellers agree. Mr Tavernier says, that at Gombroon people often find themselves struck by a south wind, in such a manner that they cry, "I burn!" and immediately fall down dead. M. le Brun tells us, that he was affured while he was there, that the weather was sometimes so excessive as to melt the sheets of letters. At this time the people go in their shirts, and are continually sprinkled with cold water; and some even lie several hours naked in the water. Among the inconveniences consequent from this malign disposition of the air, one of the most terrible is the engendering, in the arms and legs, a kind of long small worms, which cannot be extracted without great danger of breaking them; upon which a mortification ensues.

The foil of Persia is in general stony, sandy, barren and everywhere so dry, that, if it be not watered, it produces nothing, not even grass; but, where they can turn the water into their plains and valleys, it is not Unfruitful. There is a great difference in point of fertility in the different provinces of the empire; and those of Media, Iberia, Hyrcania, and Bactria, are now in a great measure what they were formerly, and surpass most of the other parts of the world. All along the Perian Gulf, the soil is still more barren, cattle less plenty, and every thing in a worse condition than anywhere else.

Though there is scarce a province in Persia which produces, does not produce wine, yet the wine of some provinces is much more esteemed than that of others; but Shiraz, or, as it is written by Mr. Franklin, Shiravass, wine is universally allowed to be the very best in Persia; insomuch, that it is a common proverb there, That to live happy one must eat the bread of Yezd, and drink the wine of Shiraz.

The grain most common in Persia is wheat; which is wonderfully fair and clean. As for barley, rice, and millet, they only make bread of them in some places, as in Courdestan, when their wheat-bread is exhausted before the return of harvest. They do not cultivate in this country either oats or rye; except where the Armenians are settled, who make great use of the latter in Lent. Rice is the universal aliment of all sorts of people in Persia; for this reason they are extremely careful in its cultivation; for, after they have lown it...
in the same manner as other grain, they in three months time transplant it, root by root, into fields, which are well watered, otherwise it would never attain that perfection in which we find it there; since it is softer, sooner boiled, and more delicious, than the same grain in any other part of the world. Perhaps its taste is, in some measure heightened by a practice they make use of to give it a glossy whiteness, viz. by cleansing it, after it is beaten out of the husks, with a mixture of flour and salt. Corn ripens exceedingly in the country; so that in some parts they have threefold crop in the year. The Persian bread is generally very thin, white, and good; and commonly cheap enough. Though none can be carried out of the kingdom with a master, as cooing little or nothing to keep. They travel without halter or reins; grazing on the road from time to time, notwithstanding their load. They are managed entirely by the voice; those who direct them making use of a kind of song, and the camel moving bricker, or at its ordinary pace, as they keep a quicker or slower time. The camels shed their hair so quickly or slower time. The camels shed their hair so clean in the spring, that they look like seamed skin; but then they are pitched over, to keep the flies from biting them. The camel hair is the most profitable fleece of all the tame beasts: fine fluffs are made of it; and in Europe, hats, with a mixture of a little beaver.

As beef is little eaten in Persia, their oxen are generally employed in ploughing, and other sorts of labour. Hogs are nowhere bred in Persia, if we except in a province or two on the borders of the Caspian Sea. Sheep and deer are very common throughout all Persia.

Of wild beasts, the number is not great in that country, because there are few forests; but where there are any, as in Hyrcania, now called Tbrizian, abundance of lions, bears, tigers, leopards, porcupines, wild boars, and wolves, are to be found; but the last are not so numerous as any of the other species.

There are but few insects in this country; which may be ascribed to the dryness of the climate. In some provinces, however, there is an infinite number of locusts or grasshoppers, which fly about in such clouds as to darken the air. In certain parts of the Persian dominions they have large black scorpions, so venomous, that such as are stung by them die in a few hours. In others they have lizards, frightfully ugly, which are so long and as thick as a large toad, their skins being as hard and tough as that of the fea dog: they are said to attack and kill men sometimes; but that may be doubted. The southern provinces are infested with gnats; some with long legs, like those we call midges; and some white, and as small as fleas, which make no buzzing, but stung suddenly, and so mortally, that the sting is like the prick of a needle. Among the reptiles is a long square worm, called by the inhabitants hazar-pas, i.e. "thousand feet," because its whole body is covered with feet; it runs prodigiously fast; and its bite is dangerous, and even mortal, if it gets into the ear.

There are in Persia all the several sorts of fowls which we have in Europe, but not in such great plenty; excepting, however, wild and tame pigeons, of which vast numbers are kept all over the kingdom, chiefly on account of their dung, which is the best manure for melons. It is a great diversion among the lower order of people in town and country to catch pigeons, though it be forbidden: for this purpose they have pigeons taught, that, flying in one flock, they surround such wild ones as they find in the field, and bring them back with them to their masters. The partridges of this country are the largest and finest in the world, being generally of the size of our fowls. Geese, ducks, cranes, herons,
Perfia. beRNas, and many other forts of water-fowl, are common here; as are likewise nightingales which are heard all the year, but chiefly in the spring. martlets, which learn whatever words are taught them; and a bird called naura, which chatters incessantly, and repeats whatever it hears. Of birds of a larger size, the most remarkable is the pelican, by the Persians called t.ectal, i. e. “water-carrier” and also n. i. e. “sheep”, because it is as large as one of these animals *. There are in Persia various birds of prey. Some of their falcons are the largest and finest in the world: the people take great pains to teach them to fly at game; the Persian lords being great lovers of falconry, and the king having generally 800 of this sort of birds, each of which has a perfon to attend it.

There is perhaps no country in the world which, generally speaking, is more mountainous than Persia; but many of them yield neither springs nor metals, and but few of them are shaded with trees. It is true, some of the chief of them are situated on the frontiers, and serve as a kind of natural ramparts, or bulwarks, to this vast empire. Among the latter are the mountains of Caucasus and Ararat, sometimes called the mountains of Baghshan, which, with all the space between the Euxine and Caspian seas, is called Tartary, and the several branches thereof, run through Persia from Natolia to India, and fill all the middle of the country.

As to rivers, except the Araxes, which runs in the mountains of Armenia, and falls into the Kur or Cyrus before it reaches the Caspian Sea, there is not one navigable stream in this county. The Oxus divides Persia on the north-east from Usbeck Tartary. The Indus also may now be reckoned among the rivers of Persia, as the provinces lying to the west of that river are now in possession of that crown; this river is said to have a course of more than 1000 miles, and overflows all the low grounds in April, May, and June.

The seas on the south of Persia are, the Gulph of Persia or Baffora, the Gulph of Ormus, and the Indian Ocean. The only sea on the north is the Caspian, or Hyrcan Sea; which is more properly a lake, having no communication with any other sea. The Persians, together with the lakes and rivers, supply Persia with plenty of fish. The Caspian sea contains very fine fish on one side; and the Persian Gulph on the other is believed to have more fish than any other sea in the world. On the coasts of this gulph is taken a sort of fish, for which they have no particular name; its flesh is of a red colour, very delicious, and some of them weigh 200 or 300 pounds. The river fish are chiefly barbels; but far from being good. Those of the lakes are carps and flads. In the river at Spahuan are a great number of crabs, which crawl up the trees, and live night and day under the leaves, where they are taken; and are esteemed very delicious food.

In his voyage from Gombroon up the Persian Gulph, Mr. Ives makes mention of several islands, named Kifme, Poloor, Vey, Tiberabie, Shitewar, and Baffora. Some of these were quite barren; on others there were a few trees and bushes, with little fishing towns, and a few small vessels lying along shore. The date trees were thinly scattered among the hills; but the small portion of green might here and there be discovered, yet fish was the barrengest of these islands in general, that it was for some time a matter of surprise how sheep and goats could possibly subsist upon them. On closer examination, however, it was found, that the soil produced a kind of small-leaved juicy madows, on which these animals principally feed. The Persian could, as they fell along, afford a most romantic prospect, appearing at first to be one continued rock, rent and torn asunder by earthquakes; but it was afterwards discovered, that some part of it was only sand hardened by the rains and sun.

Narban Point terminates in a long and low piece of land, which runs off into the gulph from the foot of the Persian hills. Between this point and the main land is a channel, in which a ship of 600 tons burden might easily ride. The Portuguese had formerly a settlement here, the remains of which are still to be seen. A large river empties itself into the sea at this place; and Mr. Ives observes, that "Providence seems here to have allotted a spot of ground amidst inhospitable rocks and deserts, capable of affording the kind production of vegetables for man and beast."

Through all the Persian Gulph Mr. Ives remarks, that the spring-water on the islands is much better than that on the continent; and the water near the sea on the islands has greatly the advantage over that which is found in the middle parts. This holds good however, only in those parts which are near the sea; for about 12 miles up the country, both on the Persian and Arabian side of the gulph, the water is very good. At the island called Bareen or Bahren, divers go down to the bottom of the sea, at certain known depths, and come up again with their vessels filled with fresh water. This fresh water is found in holes or little natural wells, some fathoms below the surface of the sea. The Arabs have certain marks on the island to teach them where to dive for the fresh water. Mr. Ives was assured by an Arabian merchant, that he himself had discovered a spring upon the shore, by which one of those wells was served. He put into this spring a bit of a heavy flock; and in two or three days an Arabian diver brought it to him again from the bottom of one of these holes.

The English and other nations, trade with the Persians several ways, particularly by the gulph of Ormus at Gombroon, and by the way of Turkey. A trade also was not many years since opened by the English with Persia through Russia and the Caspian Sea; but that is now discontinued, having been prohibited by the court of Russia, who were apprehensive that the English would teach the Persians to build ships, and dispute the navigation of the Caspian Sea with them. The principal commodities and manufactures of Persia are, raw and wrought silk, mohair camels, carpets, leather; for which, and some others, the European merchants exchange chiefly woolen manufactures; but the trade is carried on altogether in European shipping, the Persians having scarce any ships of their own, and the Russians the sole navigation of the Caspian Sea. There is not a richer or more profitable trade in the world, than that which is carried on between Gombroon and Surat in the East Indies; and the English East India Company frequently let out their ships to transport the merchandise of the Banians and Armenians from Persia to India. The itah, or forage,
PER

Money.

The most current money of Persia are the abashees, worth about 1s. 4d. sterling; they are of the finest silver. An abass is worth two mahmoudes; a mahmoud, two fahees; and a fahee, ten single or five double casbehes; these last pieces are of brass, the others of silver; for gold is not current in trade. The fahees are not very common; but mahmoudes and casbehes are current everywhere. Horses, camels, houses, &c. are generally sold by the toman, which is an imaginary coin, worth 200 fahees, or 50 abassees; and they usually reckon their edates that way. Such a one, they say, is worth 200 many tormans, as we say pounds in this country.

Peria is an absolute monarchy, the lives and estates of the people being entirely at the disposal of their prince. The king has no council established, but is advised by such ministers as are most in favour; and the resolutions taken amongst the women of the harem frequently defeat the best laid designs. The crown is hereditary, excluding only the females. The sons of a daughter are allowed to inherit. The laws of Persia exclude the blind from the throne; which is the reason that the reigning prince usually orders the eyes of all the males of the royal family, of whom he has any jealousy, to be put out. The king has generally a great many wives, which it would be death for any one, besides the eminents, who have the superintendence of them, to look at, or even see by accident; wherefore, when he travels, notice is given to all men to quite the road, nay their very houses, and to retire to a great distance.

The prime minister is called attainat doulet, which signifies the director of the empire, and also visir iwan, or the great supporter of the empire; as he alone almost fulfils the whole weight of the administration. This minister's chief study is to please his master, to secure to himself an ascendancy over his mind, and to avoid whatever may give him any uneasiness or umbrage. With this view, he never fails to flatter him, to extol all above the princes upon earth, and to throw a thick veil over every thing that might help to open his eyes, or discover to him the weakness of the state. He even takes particular care to keep the king in utter ignorance, to hide from him, or at least to soften, all unwelcome news; and, above all, to exalt immediately every the least advantage he obtains over his enemies. As he takes these methods, which indeed are and must be taken, more or less, by the ministers of every despotic prince, to secure the favour and confidence of his master; so, for the inferior officers and governors of provinces are obliged to employ all the means in their power to secure the prime minister's, they depending no left upon him then he does upon the king. There is a gradation of despotism and flattery, down from the prime minister to the lowest retainer to the court, or dependent on the government. Children are sometimes in Persia required by the king to cut off the ears and nose, and even to cut the throats of their parents; and these orders cannot be objected to, without endangering their own lives. Indeed their baseness and mercenary is such, that they will perpetrate such atrocious deeds without the least scruple or difficulty, when they have a promise or expectation of poffessing their places.

The prime ministers, notwithstanding the precarious footing on which they stand, in effect of their abilities or good fortune, sometimes continue in their employments during life; or, if removed, are only banished to some city, where they are allowed to spend the remainder of their days in a private station.

Next to the prime minister are the nadirs, or grand masters of the household; the master, or groom of the chambers, who is always a white eunuch; the mir-akbar-balhe, or master of the helmet; the mir-shakar-balhe, or great huntsman and falconer; the divan-beggh, or chief justice, to whom there lies an appeal from the draga, or the lieutenant of police, in every town; the vakka-nuviez, or recorder of events, or first secretary of state; the musulauk-nulumaleck, or master of the accounts and finances of the kingdom; the numes hamhuses, or the king's chief physicians; the shickada-balhe, or inspector of the palace, and regulator of rank at court; and the khan, or governors of provinces, under whom are other governors, called ultans, appinted also by the king.

Civil matters are all determined by the cazi, and ecclesiastical ones (particularly divorces) by the sheick-elfaleum, or head of the faith; an officer answering to the multi among the Turks; under him are the sheick-elfeleum, and cadi, who decide in all matters of religion, and make all contracts, testaments, and other public deeds, being appointed by the king in all the principal towns; and next to these are the pachnams, or directors of the prayers; and the moullahs, or doctors of the law.

Justice is carried in Persia in a very summary manner; the sentence, whatever it may be, being always put into execution on the spot. Theft is generally punished with the loss of nose and ears; robbery on the road, by ripping up the belly of the criminal, in which situation he is exposed upon a gibbet in one of the most public parts of the city, and there left until he expires in torment.

There is no nobility in Persia, or any respect shown to a man on account of his family, except to those who are of the blood of their great prophet or patriarchs; but every man is esteemed according to the poll he pollutes; and when he is dismissed, he loses
With respect to the forces of Persia, these two bodies, called the Kortbies and Goulans, that serve on horseback, are well kept and paid, and may amount, the former to about 22,000, and the latter to about 18,000. The Kortbies are descended from an ancient but foreign race; and the Goulans are either Georgian renegades or slaves, or the children of slaves or all nations. The infantry, called Tangtches, are picked out from among the most robust and vigorous of the peasants, and compose a body of 40,000 or 50,000. The Persians have few fortified towns, and had no ships of war, till Koul Khan built a royal navy, and among them had a man of war of 80 guns; but since the death of that usurper, we hear no more of their all but foreign race; and all Mahometan nations, wine being prohibited; but of all Mahometan countries, wine being prohibited; but of all Mahometan nations, they pay the least regard to this prohibition. Many of them drink wine publicly, and almost all of them in private (excepting those who have performed the pilgrimage to Mecca, and men of religion); they also are very liable to be quarrelsome when intemperately exceeding their custom, which is often attended with fatal consequences. They eat opium, but in much less quantity than the Turks; and indeed in everything they say or do, eat or drink, they make a point to be as different from this nation as possible, whom they detest to a man, beyond measure; esteeming Jews and Christians superior to them, and much nearer to salvation.

Every one knows, that the religion of the Persians is Mahometan; and that they are of the sect of Ali, of their religious prejudices so very prevalent in every other Mahometan nation; they are fond of inquiring after the manners and customs of Europe, and in return very readily afford any information in respect of their own country. The practice of hospitality is with them so grand a point, that a man thinks himself highly honoured if you will enter his house and partake of what the family affords; whereas, going out of a house without making a calen, or taking any other refreshment, is deemed in Persia a high affront.

Their usual drink is water and sherbet, as in other Mahometan countries, wine being prohibited; but of all Mahometan nations, they pay the least regard to this prohibition. Many of them drink wine publicly, and almost all of them in private (excepting those who have performed the pilgrimage to Mecca, and men of religion); they also are very liable to be quarrelsome when intemperately exceeding their custom, which is often attended with fatal consequences. They eat opium, but in much less quantity than the Turks; and indeed in everything they say or do, eat or drink, they make a point to be as different from this nation as possible, whom they detest to a man, beyond measure; esteeming Jews and Christians superior to them, and much nearer to salvation.

The Persians, before the conquest of Alexander, are known to have been exceedingly voluptuous and effeminate. After that event, the Greek discipline and martial spirit being in part communicated to them, they became much more formidable; and hence the Parthians were found to be a match not only for the Syro-Macedonian princes, but even for the Romans. Of their manners we know little or nothing, but that to their valour and military skill they joined in a surprising degree all the luxury and dissipation of the ancient Persians.

The modern Persians, like the Turks, plundering all the adjacent nations for beauties to breed by, are noted for good nature, haud and complexion; but the Gouras, or ancient Persians, are homely, ill-hosped, and clumsy, with a rough skin, and olive complexion. In some provinces, not only the complexion but the constitutions of the inhabitants, suffer greatly by the extreme heat and unwholesomeness of the air. The Persian women, too, are generally handsome and well-shaped, but much inferior to those of Georgia and Circassia. The men wear large turbans on their heads, some of them very rich, interwoven with gold and silver; a vext, grit with a fait; and over it a loose garment, something shorter; with sandals, or flippers, on their feet. When they ride, which they do every day, if it be but to a house in the same town, they wear plant boots of yellow leather; the furniture of their horses is extremely rich, and the hussars generally of silver; whether on horseback or on foot they wear a broad sword and a dagger in their safr. The dress of the women does not differ much from that of the men; only their veils are longer, and they wear twilled caps on their heads, and their lining down.

With respect to outward behaviour, says an intelligent traveller, "The Persians are certainly the Persians of the East. Whilst a rude and insolent demeanour peculiarly marks the character of the Turkish nation towards foreigners and Christians, the behaviour of the Persians, on the contrary, is honour to the most civilized nations: they are kind, courteous, civil, and obliging, to all strangers, without being guided by those religious prejudices so prevalent in every other Mahometan nation; they are fond of inquiring after the manners and customs of Europe, and in return very readily afford any information in respect of their own country. The practice of hospitality is with them so grand a point, that a man thinks himself highly honoured if you will enter his house and partake of what the family affords; whereas, going out of a house without making a call, or taking any other refreshment, is deemed in Persia a high affront."
they then wash their hands, which is an invariable custom with the Persians both before and after eating. They eat very quick, conveying their food to their mouths with their fingers; the use of knives and forks being unknown in Persia. Sherbets of different sorts are introduced, and the meal concludes with a dessert of delicious fruit. The supper being finished, the family sit in a circle, and entertain each other by relating pleasant stories (of which they are excessively fond), and also by repeating passages from the works of their most favourite poets, and amusing themselves at various kinds of games. The fifth and last prayer is styled maw son akhir; the last prayer, or sometimes numah fith, or the night prayer, repeated about an hour after supper.

The most remarkable law among the Persians respecting marriage. A man may divorce his wife when he chooses, without assigning any other reason for the divorce than that it is his pleasure. If he should change his mind, he may again marry her, divorce her a second time, and a third time marry her; but here this privilege stops. No man is allowed to marry the woman whom he has thrice divorced. A widow is obliged to mourn four months for her deceased husband before she can be married to another; but a concubine may form a new connection the infant that her keeper expires.

At the naming of children in Persia, Mr. Francklin informs us that the following ceremony is observed: “The third or fourth day after the child is born, the friends and relations of the woman who has lain in at her house, attended by music, and dancing girls hired for the occasion; after playing and dancing some time, a mullah or priest is introduced, who, taking the child in his arms, demands of the mother what name she chooses the infant should be called by; being told, he begins praying, and after a short time applies his mouth close to the child’s ear, and tells him distinctly three times (calling him by name) to remember and be obedient to his father and mother, to venerate his Koran and his prophet, to abstain from those things which are unlawful, and to practice those things which are good and virtuous. Having repeated the Mahometan profession of faith, he then redeems the child to his mother; after which the company are entertained with sweet meats and other refreshments, a part of which the females present always take care to carry away in their pockets, believing it to be the invariable means of their having offspring themselves.”

The Persians excel more in poetry than in any other sort of literature; and allrologers are now in as great reputation in Persia as the magi were formerly. Their books are all manuscripts, the art of printing having not yet been introduced among them: they excel indeed in writing, and have eight different hands. They write from the right hand to the left, as the Arabs do. In their short hand, they use the letters of the alphabet; and the same letters, differently pointed, will have 20 different significations. In short, the Persians are here, with as good natural parts as any people in the East, but make a bad use of them; being great dummies, cheats, liars, and flatterers, and having a strong propensity to voluptuousness, luxury, idleness, and indolence; vices in general to which the Atlatics in general are much addicted.

PERSIAN WHEEL. See HYDROSTATICS.

PERSICA, the Peach, is by Linæus referred to the same class and genus with Amygdalus; however, as they are so commonly reckoned to be different genera, we have thought proper to distinguish them. There are a great variety of peach-trees planted in the gardens, some of which are preferred only for the beauty of their flowers, but most of them for the sake of the fruit. Of those remarkable for the beauty of their flowers, the principal are, 1. The vulgaris, or common peach-tree, with double flowers, which is a very great ornament in gardens, producing very large double flowers of a beautiful red or purple colour, and growing to a considerable size. 2. The humilis, or dwarf-almond. 3. The Africana, or double-flowing dwarf-almond. These two reach not above the height of three or four feet, though their flowers are of equal beauty with the former.

Of the peach-trees cultivated for the sake of their fruit there are a great number, to describe which particularly would exceed the proper bounds of this article. They are rained from the stones of the fruit, which should be planted in autumn on a bed of light dry earth, about three inches deep and four inches an under. In the winter the beds should be covered with much to protect them from the frost. In this bed they should remain for a year; when they are to be taken up and planted in a nursery, where they are to remain one or two years; after which they must be removed to the places where they are to continue.

PERSICANA, in botany. See POLYGONUM.

PERSICUS SINUS, in anc. geog. (Mela, Piny); a part of the sea which the Romans called Mare Rubrum, and the Greeks Mare Erythreum; waiting Aрабia Felix on the east, between which and Carmania, entering into the land, it washes Persis on the south. Its large mouth consists of straight sides, like a neck, and then the land retiring equally a vaat way, and the sea surrounding it in a large compass of shore, there is exhibited the figure of a human head (Mela). Theophratus calls this bay Great Persia, which name is equally claims with Periacus, only for distinction fake Periacus is appropriated to it by others.

PERSIMON. See Diospyros.—From the perimmon is made a very palatable liquor in the following manner: As soon as the fruit is ripe, a sufficient quantity is gathered, which is very easy, as each tree is well stocked with them. These perimmon apples are put into a dough of wheat or other flour, formed into cakes, and put into an oven, in which they continue till they are quite baked and sufficiently dry, when they are taken out again: then, in order to brew the liquor, a pot full of water is put on the fire, and some of the cakes are put in: these become soft by degrees as the water grows warm, and crumble in pieces at last; the pot is then taken from the fire, and the water in it well stirred about, that the cakes may mix with it; till all is then poured into another vessel, and they continue to steep and break as many cakes as are necessary for a brewing; the malt is then infused, and they proceed as usual with the brewing. Beer thus prepared is reckoned much preferable to other beer. They like-

83 Intellectual excellence.
Ternefs. He wrote but seldom; and it is evident that he was incalculably charmed with his verses, that he was insensibly affected by them in the judgments of which the critics are so justly pleased. Volterra; and afterwards continued his studies at Rome and all the labours of Horace; but after some time he was nothing left but to be underediting of the composition of his verses. He was a man of perfect rank. He was a most licentious, and full of lewdness. When the persimmon trees get once the cold, they are not fermented, but have a most agreeable and elegant smell. Some persons are ripe at the end of November and December, and are not before No-vember and December. The word Persius, or Persin, of a weak constitution, and all the labours of Phalaris, who has written a most learned and elaborate commentary upon him, cannot make him equal to either of them as a satirist, though in virtue of his learning he exceeded them both. He was a professor imitator of Horace; yet he had little of Horace's wiry, concise, and talent in ridicule. His style is grand, figurative, poetical, and suitable to the dignity of the Stoic philosophy; and hence he shines most in recommending virtue and integrity: here it is that satire begets him. He was too grace to court the muses with success; but he had a great soul, susceptible of noble sentiments, which gave a grace but to indifferent poetry. His cotemporaries thought highly of him. Quintilian allows, that Persius, although he wrote but one book of satires, acquired a great deal of true glory, Mul sum et vera gloria quamvis uno libro Persius meruit: and Martial says much the same thing, Sapientia in libros memorat Persius uno, etc.

Persis, a Roman lady, whom St Paul salutes in his epistle to the Romans (xvi. 12.), and whom he calls his beloved sister. He says she has laboured much for the Lord, and still labours. Nothing else of her life is come to our knowledge, nor do we know that she is honoured by any church; which is something singular.

Persius (Flaccus Aulus), a Latin poet in the reign of Nero, celebrated for his satires. He was born, according to some, at Volterra in Tuscany; and according to others, at Tignula, in the gulf of Della Specia, in the year 34. He was educated till 12 years old at Volterra; and afterwards continued his studies at Rome under Paëmon the grammarian, Virgil the rhetorician, and Cornutus the Stoic philosopher, who contracted a friendship for him. Persius confided that illustrious friend in the composing of his verses. Lucian also studied with him under Coratinus; and appeared to be charmed with his verses, that he was incessantly breaking out into exclamations at the beautiful passages in his satires: an example rarely seen in poets of equal rank. He was a steady friend, a good son, an affectionate brother and parent. He was chaste, meek, and modest: which shows how wrong it is to judge of a man's morals by his writings; for the satires of Persius are not only licentious, but sharp and full of bitterness. He wrote but seldom; and it was some time before he applied himself regularly to it.

Persius was of a weak constitution, and troubled with a bad stomach, which was the cause of his death in the 50th year of his age. Six of his satires remain; in their judgments of which the critics have been much divided, excepting as to their obscurity, Persius being indeed the most obscure of all the Latin poets. As a poet, he is certainly inferior to Horace and Juvenal; and all the labours of Irae Caelus, who has written a most learned and elaborate commentary upon him, cannot make him equal to either of them as a satirist, though in virtue and learning he exceeded them both. He was a professor imitator of Horace; yet had little of Horace's wiry, concise, and talent in ridicule. His style is grand, figurative, poetical, and suitable to the dignity of the Stoic philosophy; and hence he shines most in recommending virtue and integrity: here it is that satire begets him. He was too grace to court the muses with success; but he had a great soul, susceptible of noble sentiments, which gave a grace but to indifferent poetry. His cotemporaries thought highly of him. Quintilian allows, that Persius, although he wrote but one book of satires, acquired a great deal of true glory, Mul sum et vera gloria quamvis uno libro Persius meruit: and Martial says much the same thing, Sapientia in libros memorat Persius uno, etc.

Persia, an individual substantive of a rational nature. Thus we say, an ambassador represents the person of his prince; and that, in law, the father and son are reputed the same person.

The word person, persona, is thought to be borrowed from personando, from personating or counterfeiting; and is supposed to have first signified a mask; because, as Boethius informs us, in Tares concursus sonus voluptatir: and hence the actors who appeared mask'd on the stage were sometimes called pergamini, and sometimes persona. He likewise says, that as the several authors represented each a single individual person, sinum Celipus, or Chremes, or Hecuba, or Medea; for this reason, other people, who were at the same time distinguished by something in their form, character, &c. whereby they might be known, came likewise to be called by the Latin personae, and by the Greeks πρόσωποι. Again, as actors rarely represented any but great and illustrious characters, the word came at length to import the mind, as being that whole disposition constituting the character. And thus men, angels, and even God himself, were called personas. This is merely corporeal, as a stone, a plant, or a horse, were called ψυχα, or ψυχή, but never personas. Hence the learned suppose, that the same name persona came to be used to dignify some dignity, whereby a person is distinguished from another; as a father, husband, judge, magistrate, &c. In this sense we are to understand that of Cicero: "Cæsar, who speaks of Pompey but in terms of honour and respect; he does many hard and injurious things, however, against his person." Person we have already defined to mean an individual substantive of a reasonable nature. Now a thing may be individual in two ways: 1. Logically, because it cannot be predicated of any other; as Cicero, Plato, &c. 2. Physically; in which sense a drop of water, separated from the ocean, may be called an individual. Person is an individual nature in each of these senses: logically, according to Boethius, because persona is not spoken of universals, but only of singulars and individuals; we do not say the person of an animal or a man, but of Cicero and Plato; and physically, since Socrates's hand or foot are never considered as personas. This last kind of individual is denominated two ways: poëtically, when the person is said to be the whole principle of acting; for to whatever thing action is attributed, that the philosopher calls a persona: and negatively, when we say, with the Thomists, &c. that a person consists in this, that it does not consist in other as a more perfect being. Thus a man, though he consists of two different things, viz. body and spirit, is not two personas; because neither part of itself is a complete principle of action, but one persona, since the manner of his consisting of body and spirit is such as constitutes one whole principle of action; nor does he exist in any other as a more perfect being; as, for example,
example, Socrates's foot does in Socrates, or a drop of water in the ocean.

PERSON, in grammar, a term applied to such nouns or pronouns as, being either prefixed or underlaid, are the nominatives in all inflections of a verb; or it is the agent or patient in all finite or personal verbs. See GRAMMAR.

PERSONAL, any thing that concerns, or is referred to, the person: thus it is a maxim in ethics, that all faults are personal.

PERSONAL Action, in law, is an action levied directly and solely against the person; in opposition to a real or mixed action. See ACTION.

PERSONAL Goods, or Chattels, in law, signifies any moveable thing belonging to a person, whether alive or dead. See CHATTLES.

PERSONAL Identity. See METAPHYSICS, Part III.

PERSONAL Verb, in grammar, a verb conjugated in all the three persons; thus called in opposition to an impersonal verb, or that which has the third person only.

PERSONALITY, in the schools, is that which constitutes an individual a distinct person.

PERSONATE, is the name of the 40th order in Linnæus's Fragments of a Natural Method, consisting of a number of plants whose flowers are furnished with an irregular gaping or gnawing petal, which in figure somewhat resembles that of an animal. The bulk of the genera of this natural order range themselves under the clas's and order didynamia angiosperma of the Sexual Method.

The real, although they cannot enter into the artificial clas's just mentioned, for want of the classic character, the inequality of the stamens; yet, in a natural method, which admits of greater latitude, may be arranged with those plants which they resemble in their habit in general appearance, and particularly in the circumference expressed in that title.

PERSONIFYING, or PERSONALIZING, the giving an inanimate being the figure, sentiments, and language of a person.

Dr Blair, in his Lectures on Rhetoric, gives this account of personification. "It is a figure, the use of which is very extensive, and its foundation laid deep in human nature. At first view, and when considered abstrafly, it would appear to be a figure of the utmost boldness, and to border on the extravagant and ridiculous. For what can seem more remote from the track of reasonable thought, than to speak of ftones and trees, and fields and rivers, as if they were living creatures, and to attribute to them thought and feeling, affections and actions? One might imagine this to be no more than childish conceit, which no person of taste could relish. In fact, however, the case is very different. No such ridiculous effect is produced by personification when properly employed; on the contrary, it is found to be natural and agreeable, nor is any very uncommon degree of passion required in order to make us relish it. All poetry, even in its most gentle and humble forms, abounds with it. From profé it is far from being excluded; nay, in common conversation, very frequent approaches are made to it. When we say, the ground bleshis for rain, or the earth shrills with plenty; when we speak of ambition's being red, or a dicefe being deceitful; such expresfions show the facility with which the mind can accommodate the properties of living creatures to things that are inanimate, or to abstract conceptions of its own forming.

"Indeed, it is very remarkable, that there is a wonderful proneness in human nature to animate all objects. Whether this arises from a fort of assimilating principle, from a propension to spread a resemblance of ourselves over all other things, or from whatever other cause it arises, so it is, that almost every emotion which in the least agitates the mind belongs upon its object a momentary idea of life. Let a man, by an unwary step, forain his ankle, or hurt his foot upon a stone, and in the ruffled discomposed moment he will sometimes feel himself disposed to break the stone in pieces, or to utter passionat expressive against it, as if it had done him an injury. If one has been long accustomed to a certain set of objects, which have made a strong impression on his imagination; as to a house, where he has passed many agreeable years; or to fields, and trees, and mountains, among which he has often walked with the greatest delight; when he is obliged to part with them, especially if he has no prospect of ever seeing them again, he can scarce avoid having somewhat of the same feeling as when he is leaving old friends. They seem endowed with life. They become objects of his affection; and, in the moment of his parting, it scarce seems absurd to him to give vent to his feeling in words, and to take a formal adieu.

"So strong is that impression of life which is made upon us, by the more magnificent and striking objects of nature especially, that I doubt not in the least of this having been one cause of the multiplication of divinities in the heathen world. The belief of dryads and naiads, of the genius of the wood and the god of the river, among men of lively imaginations, in the early ages of the world, easily arose from this turn of mind. When their favourite rural objects had often been animated in their fancy, it was an easy transition to attribute to them some real divinity, some unseen power or genius which inhabited them, or in some peculiar manner belonged to them. Imagination was highly gratified, by thus gaining somewhat to rest upon with more stability; and when belief coincided so much with imagination, very light causes would be sufficient to establish it.

"From this deduction may be easily seen how it comes to pass that personification makes so great a figure in all compositions where imagination or passion have any concern. On innumerable occasions it is the very language of imagination and passion; and therefore deserves to be attended to, and examined with peculiar care. There are three different degrees of this figure, which it is necessary to remark and distinguish, in order to determine the propriety of its use. The first is, when some of the properties or qualities of living creatures are ascribed to inanimate objects; the second, when those inanimate objects are produced as acting like such as have life; and the third, when they are represented either as speaking to us, or as listening to what we say to them."

The ingenious professor goes on to investigate the nature of personification at considerable length. We shall
PERSPECTIVE

Perspective is the art of drawing on a plane surface true resemblances or pictures of objects, as the objects themselves appear to the eye from any distance and situation, real or imaginary.

It was in the 16th century that Perspective was revived, or rather reinvented. It owes its birth to painting and particularly to that branch which was employed in the decorations of the theatre, where landscapes were properly introduced, and which would have looked unnatural and horrid if the size of the objects had not been nearly proportioned to their distance from the eye. We learn from Vitruvius, that Agatharchus, instructed by Scopilus, was the first who wrote upon this subject, and that afterwards the principles of this art were more diligently taught by Democritus and Anaxagoras, the disciples of Agatharchus. Of the theory of this art, as described by them, we know nothing; since none of their writings have escaped the general wreck that was made of ancient literature in the dark ages of Europe. However, the revival of painting in Italy was accompanied with a revival of this art.

The first person who attempted to lay down the rules of perspective was Pietro del Borgo, an Italian. He supposed objects to be placed beyond a transparent tablet, and endeavoured to trace the images which rays of light, emitted from them, would make upon it. But we do not know what success he had in this attempt, because the book which he wrote upon this subject is not now extant. It is, however, very much commended by the famous Egnazio Dante; and, upon the principles of Borgo, Albert Durer contrived a machine, by which he could trace the perspective appearance of objects.

Baldazzar Purcell studied the writings of Borgo, and endeavoured to make them more intelligible. To him we owe the discovery of points of distance, to which all lines that make an angle of 45 degrees with the ground-line are drawn. A little time after, Guido Ubaldi, another Italian, found that all the lines that are parallel to one another, if they be inclined to the ground-line, converge to some point in the horizontal line; and that through this point also, a line drawn from the eye, parallel to them, will pass. These principles put together enabled him to make out a pretty complete theory of perspective.

Great improvements were made in the rules of perspective by subsequent geometers; particularly by professor Gravelpande, and still more by Dr Brook Taylor, whose principles are in a great measure our own, and far more general than any before him.

In order to understand the principles of perspective, it will be proper to consider the plane on which the representation is to be made as transparent, and interpolated between the eye of the spectator and the object to be represented. Thus, suppose a person at a window looks through an upright pane of glass at any object beyond it, and, keeping his head steady, draws the figure of the object upon the glass with a black lead pencil, as if the point of the pencil touched the object itself; he would then have a true representation of the object in perspective as it appears to his eye.

In order to this two things are necessary: first, that the glass be laid over with strong gum-water, which, when dry, will be fit for drawing upon, and will retain the traces of the pencil; and, secondly, that he looks through a small hole in the glass, fixed about a foot from the glass, between it and his eye, and that he keep his eye close to the hole; otherwise he might shift the position of his head, and consequently make a false delineation of the object.

Having traced out the figure of the object, he may go over it again with pen and ink; and when that is dry, put a sheet of paper upon it, and trace it thereon with a pencil; then taking away the paper and laying it on a table, he may finish the picture by giving it the colours, lights, and shades, as he sees them in the
PERSPECTIVE.

the object itself, and then he will have a true reference of the object.

To every person who has a general knowledge of the principles of this, must be self-evident: For as vision is occasioned by pencils of rays coming in straight lines to the eye from every point of the visible object, it is plain that, by joining the points in the transparent plane, through which all these pencils respectively pass, an exact representation must be formed of the object, as it appears to the eye in that particular position, and at that determined distance: and were pictures of things to be always drawn on transparent planes, this simple operation, with the principle on which it was founded, would compose the whole theory and practice of perspective. As this, however, is far from being the case, rules must be deduced from the sciences of optics and geometry for drawing representations of visible objects on opaque planes; and the application of these rules constitutes what is properly called the art of perspective.

Previously to our laying down the fundamental principles of this art, it may not be improper to observe, that when a person stands right against the middle of one end of a long avenue or walk, which is straight and equally broad throughout, the sides thereof seem to approach nearer and nearer to each other as they are further and further from his eye; or the angles, under which their different parts are seen, become less and less as the distance from his eye increases; and if the avenue be very long, the sides of it at the farther end will seem to meet: and there an object that would cover the whole breadth of the avenue, and be of a height equal to that breadth, would appear only to be a mere point. See Offices, §219, 220.

Having made these preliminary observations, we now proceed to the practice of perspective, which is built upon the following

(Fundamental) Theorem I.

Let a b c d (fig. 1, Plate CCCLXXXIII.) represent the ground-plan of the figure to be thrown into perspective, and e f g h the transparent plane through which it is viewed by the eye at E. Let these planes intersect in the straight line k l. If B be any point in the ground-plan, and B E a straight line, the path of a ray of light from that point to the eye. This will pass through the plane e f g h in some point b; or B will be seen through that point, and b will be the picture, image, or representation of B.

If B A be drawn in the ground-plan, making any angle B A K with the common intersection, and E V be drawn parallel to it, meeting the picture-plane or perspective plane in V, and V A be drawn, the point b is in the line V A so situated that B A is to E V as b A to V b.

For since E V and B A are parallel, the figure B A V E V B is in one plane, cutting the perspective-plane in the straight line V A; the triangles B A b, E V b, are similar, and B A : E V = b A : b b.

Cor. 1. If B be the point of the picture, its picture b is above the intersection b b; but if B be between the eye and the picture as at B', its picture b' is below b b.

2. If two parallel lines B A', E S, be drawn, and A', S, be joined, the picture of B is in the intersection of the lines A V and A S.

3. The line B A is represented by k A, or b A is the picture of B A; and if A B be infinitely extended, it will be represented by A V. V is therefore called the vanishing point of the line A B.

4. All lines parallel to A B are represented by lines converging to V from the points where these lines intersect the perspective plane; and therefore V is the vanishing point of all such parallel lines.

5. The pictures of all lines parallel to the perspective plane are parallel to the lines themselves.

6. If through V be drawn H V parallel to k l, the angle E V H is equal to B A K.

Remark. The proposition now demonstrated is not limited to any inclination of the picture-plane to the ground-plane; but it is usual to consider them as perpendicular to each other, and the ground-plane as horizontal. Hence the line k l is called the ground line, and O H the horizon line; and V K, perpendicular to both, is called the height of the eye.

If E S be drawn perpendicular to the picture-plane, it will cut it in a point S of the horizon line directly opposite to the eye. This is called the point of f S b, or principal point.

7. The pictures of all vertical lines are vertical, and the pictures of horizontal lines are horizontal, because these lines are parallel to the perspective plane.

8. The point of sight S is the vanishing point of all lines perpendicular to the perspective plane.

The above proposition is a sufficient foundation for the whole practice of perspective, whether on direct or inclined pictures, and serves to suggest all the various practical constructions, each of which has advantages which suit particular purposes. Writers on the subject have either confined themselves to one construction, from an affection of simplicity or fondness for symmetry; or have multiplied precepts, by giving every construction for every example, in order to make a great book, and give the subject an appearance of importance and difficulty. An ingenious practitioner will avoid both extremes, and avail himself of the advantage of each construction as it happens to suit his purpose. We shall now proceed to the practical rules, which require no consideration of intersecting planes, and are all performed on the perspective plane by means of certain substitutions for the plane of the eye and the original figure. The general substitution is as follows:

Let the plane of the paper be first supposed to be the ground-plan, and the spectator to stand at F (fig. 2.) Let it be proposed that the ground-plan is to be represented on a plane surface, standing perpendicularly on a line G K L of the plan, and that the point K is immediately opposite to the spectator, or that K F is perpendicular to G L; then K F is equal to the distance of the spectator's eye from the picture.

Now suppose a piece of paper laid on the plan with its straight edge lying on the line G L; draw on this paper K S perpendicular to G L, and make it equal to the height of the eye above the ground-plan. This may be much greater than the height of a man, because the spectator may be floating on a plane much raised above the ground-plan. Observe also that K S...
must be measured on the same scale on which the ground-plan and the distance FK were measured. Then draw HSO parallel to GL. This will be a horizontal line, and (when the picture is set upright on GL) will be on a level with the spectator's eye, and the point S will be directly opposite to his eye. It is therefore called the principal point, or point of sight. The distance of his eye from this point will be equal to FK. Therefore make SP (in the line SK) equal to FK, and P is the projecting point or substitute for the place of the eye. It is sometimes convenient to place P above S, sometimes to one side of it on the horizontal line, and in various other situations; and writers, ignorant of, or inattentive to, the theory, have given it different denominations, such as point of distance, point of view, &c. It is merely a substitute for the point E in fig. 1. and its most natural situation is below, as in this figure.

The art of perspective is conveniently divided into Ichnographia, which teaches how to make a perspective draught of figures on a plane, commonly called the ground-plan; and Scenography, which teaches how to draw solid figures, or such figures as are raised above this plan.

**Fundamental Prob. I. To put into perspective any given point of the ground-plan.**

First general construction.

Plate 

From B and P (fig. 2.) draw any two parallel lines A'C, and AV, cutting the ground-line and horizon-line in A and V, and draw BP, AV, cutting each other in b; b is the picture of B.

For it is evident that BA, PV, of this figure are analogous to BA and EV of fig. 1. and that BA: PV:: BA: bV.

If BA be drawn perpendicular to GL, PV will fall on PS, and need not be drawn. AV will be A'S. — This is the most easy construction, and is nearly the same with Ferguson's.

Second general construction.

Draw two lines BA, BA', and two lines PV, PD, parallel to them, and draw AV, A'D, cutting each other in b; b is the picture of B by Cor. 2. — This construction is the foundation of all the rules of perspective that are to be found in the books on this subject. They appear in a variety of forms, owing to the ignorance or inattention of the authors to the principles. The rule most generally adhered to is as follows:

Draw BA (fig. 3.) perpendicular to the ground-line, and AS to the point of sight, and let off A'S equal to BA. Set of SD equal to the distance of the eye in the opposite direction from S that S is from A, where B and E of fig. 1. are on opposite sides of the picture; otherwise they form the same way. D is called the point of distance. Draw D'S, cutting AS in B'. This is equivalently equivalent to drawing BA and PS perpendicular to the ground line and horizon-line, and BS and PD making an angle of 45° with these lines, with the additional puzzle about the way of setting of A'S and SD, which is avoided in the construction here given.

This usual construction, however, by a perpendicular and the point of distance, is extremely simple and convenient; and two points of distance, one on each side of S, serve for all points of the ground plan. But the first general construction requires still fewer lines, if BA be drawn perpendicular to GL, because PV will then coincide with PS.

Third general construction.

Draw BA from the given point B perpendicular to the ground-line, and AS to the point of sight. From the point of distance D set off D'E equal to BA, on the same or the contrary side as S, according as B is on the same or the contrary side of the picture as the eye. Join d A, and draw D'b parallel to DA. b is the picture of B. For SD, D's, are equal to the distances of the eye and given point from the picture, and SD: D's = b'S: bA.

This construction does not naturally arise from the original lines, but is a geometrical consequence from their position and magnitude; and it is of all others the most generally convenient; as the perpendicular distances of any number of points may be arranged along SD without confusion, and their direct situations transferred to the ground-line by perpendiculars such as BA; and nothing is easier than drawing parallel, either by a parallel ruler or a bevel-square, used by all who practice drawing.

**Prob. 2. To put any straight line BC (fig. 4.) of the ground plan in perspective.**

Find the points b, c, of its extreme points by any of the foregoing constructions, and join them by the straight line b c. Perhaps the following construction will be found very generally convenient.

Produce CB till it meet the ground-line in A, and draw PV parallel to it, and AV, and PB, PC, cutting AV in b, c. V is its vanishing point, by Cor. 3. of the fundamental theorem.

It must be left to the experience and sagacity of the draftsman to select such constructions as are most suitable to the multiplicity of the figures to be drawn.

**Prob. 3. To put any inclined figure of the ground-plan in perspective.**

Put the bounding lines in perspective, and the problem is solved.

The variety of constructions of this problem is very great, and it would fill a volume to give them all. The most generally convenient is to find the vanishing points of the bounding lines, and connect these with the points of their intersection with the ground-line. For example, to put the figure ABCD (fig. 5.) into perspective.

Draw from the projecting point PV, PW, parallel to AB, BC, and let AB, BC, CD, DA, meet the ground-line in a, s, b, c, and draw AV, aV, aW, bW, cutting each other in a b c d, the picture of the figure ABCD. The demonstration is evident.

This construction, however, runs the figure to great distances on each side of the middle line when any of the lines of the original figure are nearly parallel to the ground-line.

The following construction (fig. 6.) avoids this inconvenience.

Let D be the point of distance. Draw the perpendiculars A's, B's, C's, D's, and the lines A's, B's, C's, D's, parallel to PD. Draw S's, S, s, s, and D's, D's, D's, D's, cutting the former in a, b, c, d, the angles of the picture.

It is not necessary that D be the point of distance, only the lines A's, B's, C's, and D's must be parallel to PD.

**Remark.**
Perspective.

Remark. In all the foregoing constructions the necessary lines (and even the finished picture) are frequently confounded with the original figure. To avoid this great inconvenience, the writers on perspective direct us to transpose the figure; that is, to transfer it to the other side of the ground line, by producing the perpendiculars $A_{5}$, $B_{5}$, $C_{5}$, $D_{5}$, till $A_{5}$, $B_{5}$, $C_{5}$, $D_{5}$ are respectively equal to $A$, $B$, $C$, $D$, and instead of the original figure, to use only its transposed sublitude $A'B'C'D'$. This is an extremely proper method. But in this case the point $P$ must also be transposed to $P'$ above $S$, in order to retain the first or most natural and simple construction, as in fig. 7; where it is evident, than when $BA=AB$, and $bA=$ the height of the eye, and $b'd$ is the distance of the horizon-line from the point $b$, which is the picture of the foot of the line. Therefore (Theor. 2) $b'e$ is the required picture of the vertical line.

This problem occurs frequently in views of architecture; and a comprehensible method of solving it would be peculiarly convenient. For this purpose, draw a vertical line $XZ$ at the margin of the picture, or on a separate paper, and through any point $V$ of the horizon-line draw $VX$. Set off $XY$, the height of the vertical line, and draw $VY$. Then from any points $b$, $r$, on which it is required to have the pictures of lines equal to $XY$, draw $bS$, $rS$, parallel to the horizon line, and draw the verticals $S_m$, $r_v$, these have the lengths required, which may be transferred to $b$ and $r$. This, with the third general construction for the base points, will save all the confusion of lines which would arise from constructing each line apart.

Prob. 6. To put any sloping line in perspective.

From the extremities of this line, suppose perpendiculars making the ground plane in two points, which we shall call the base points of the sloping line. Put these base points in perspective, and draw, by last problem, the perpendiculars from the extremities. Join these by a straight line. It will be the picture required.

Prob. 7. To put a square in perspective, as seen by a person not standing right against the middle of either of its sides, but rather near with one of its corners.

In fig. 9. let $ABCD$ be a true square, viewed by an observer, not standing at $a$, directly against the middle of its side $AD$, but at $O$ almost even with its corner $D$, and viewing the side $AD$ under the angle $AOD$; the angle $AOD$ (under which he would have seen $AD$ from $a$) being 60 degrees.

Make $AD$ in fig. 10. equal to $AD$ in fig. 9, and draw $SP$ and $OP$ parallel to $AD$. Then, in fig. 10, let $O$ be the place of the observer's eye, and $SO$ be perpendicular to $SP$; then $S$ shall be the point of sight in the horizon $SP$.

Take $SO$ in your compasses, and set that extent from $S$ to $P$; then $P$ shall be the true point of distance, taken according to the foregoing rules.

From $A$ and $D$ draw the straight lines $AS$ and $DS$; draw also the straight line $AP$, intersecting $DS$ at $C$.

Lastly, to the point of intersecion $C$ draw $BC$ parallel to $AD$; and $ABCD$ in fig. 10, will be a true perspective representation of the square $ABCD$ in fig. 9. The point $M$ is the centre of each square, and $AMC$ and $BMD$ are the diagonals.

Prob. 8. To put a reticulated square in perspective, as seen by a person standing opposite to the middle of one of its sides.

A reticulated square is one that is divided into several little squares, like network, as fig. 11. Each side of which is divided into four equal parts, and the whole surface into four times four (or 16) equal figures.

Having divided this square into the given number of little squares, draw the two diagonals $AX$ and $BX$; through $AD$ in fig. 12. equal to $AD$ in fig. 11, and divide it into four equal parts, as $AE$, $EG$, $GI$, and $ID$. Draw $SP$ for the horizon, parallel to $AD$, and, through
through the middle point $g$ of $AD$, draw $OS$ perpendicular to $AD$ and $SP$.—Make $S$ the point of sight, and $O$ the place of the observer's eye.

Take $SP$ equal to $SO$, and $P$ shall be the true point of distance.—Draw $AS$ and $DS$ to the point of fight, and $AP$ to the point of distance, intersecting $DS$ in $C$; then draw $BC$ parallel to $AD$, and the outlines of the reticulated square $ABCD$ will be finished.

From the division points $e, f, g, i, k$, draw the straight lines $e, f, g, h, i, k$, tending towards the point of fight $S$; and draw $BD$ for one of the diagonals of the square, the other diagonal $AC$ being already drawn.

Through the points $r$ and $x$, where these diagonals cut $e, f, i, k$, draw $lm$ parallel to $AD$. Through the centre-point $x$, where the diagonals cut $g, l$, draw $no$ parallel to $AD$. Lastly, through the points $v$ and $w$, where the diagonals cut $e, f, i, k$, draw $pq$ parallel to $AD$; and the reticulated perspective square will be finished.

This square is truly represented, as if seen by an observer standing at $O$, and having his eye above the horizontal plane $ABCD$ on which it is drawn; as if $OS$ was the height of his eye above that plane; and the lines which form the small squares within it have the same letters of reference with those in fig. 11, which is drawn as it would appear to an eye placed perpendicularly above its centre $x$.

Prob. 9. To put a circle in perspective.

If a circle be viewed by an eye placed directly over its centre, it appears perfectly round, but if it be obliquely viewed, it appears of an elliptical shape. This is plain by looking at a common wine glass set upright on a table.

Make a true reticulated square, as fig. 11. Plate CCCLXXXIII. of the same diameter as you would have the circle; and setting one foot of your compasses in the centre $x$, describe as large a circle as the sides of the square will contain. Then, having put this reticulated square into perspective, as in fig. 12, observe through what points of the cross-lines and diagonals of fig. 11. the circle passes; and through the like points in fig. 12. draw the ellipsis, which will be as true a perspective representation of the circle, as the square in fig. 12. is of the square in fig. 11.

This is Mr. Ferguson's rule for putting a circle in perspective; but the following rules by Wolf are perhaps more universal.

If the circle to be put in perspective be small, describe a square about it. Draw first the diagonals of the square, and then the diameters $b, a$ and $d, e$ (fig. 1. Plate CCCLXXXIV.) cutting one another at right angles; draw the straight lines $f, g$ and $h, c$ parallel to the diameter $d, e$. Through $b$ and $f$ and likewise $c$ and $g$ draw straight lines meeting $DE$, the ground line of the picture in the points $3$ and $4$. To the principal point $V$ draw the straight lines $1V, 3V, 4V, 2V$, and to the points of distance $L$ and $K$, $2L$ and $1K$. Lastly, join the points of intersection $a, b, d, f, h, g, c, t$, by the arcs $a, b, d, f$, and $a, b, d, f, h, g, c, t$ will be the circle in perspective.

If the circle be large so as to make the foregoing practice inconvenient, bisect the ground line $AB$, describing, from the point of vision as a centre, the semicircle $AGB$ (fig. 2. Plate CCCLXXXIV.), and from any number of points in the circumference $C, F, G, H, I$, &c. draw to the ground line the perpendiculars $Cf, Fg, Gh, Hi$, &c. to the point of sight as a centre, the semicircle $AGB$. From the points $A, 1, 2, 3, 4, 5, B$, draw straight lines to the principal point or point of sight $V$, like wise straight lines from $B$ to $A$ to the points of distance $L$ and $K$. Through the common intersections draw straight lines as in the preceding case; and you will have the points $a, c, d, f, g, h, i, j$, &c. as formerly directed, and you have the perspective circle $a, c, d, f, g, h, i, j$.

Hence it is apparent how we may put not only a circle but also a pavement laid with stones of any form in perspective. It is likewise apparent how useful the square is in perspective; for, in the second case, a true square was described round the circle to be put in perspective, and divided into several smaller squares, so in this third case we make use of the semicircle only for the sake of brevity instead of that square and circle.

Prob. 10. To put a reticulated square in perspective, as seen by a person not standing right against the middle of either of its sides, but rather nearly even with one of its corners.

In fig. 13. Plate CCCLXXXIII, let $O$ be the place of an observer, viewing the square $ABCD$ almost even with its corner $D$.—Draw at pleasure $SP$ for the horizon, parallel to $AD$, and make $SO$ perpendicular to $SP$: then $S$ shall be the point of sight, and $P$ the true point of distance; if $SP$ be made equal to $SO$.

Draw $AS$ and $DS$ to the point of sight, and $AP$ to the point of distance, intersecting $DS$ in the point $C$; then draw $BC$ parallel to $AD$, and the outlines of the perspective square will be finished. This done draw the lines which form the letters squares, as taught in Prob. 8. and the work will be completed.—You may put a perspective circle in this square by the same rule as it was done in fig. 12.

Prob. 14. To put a cube in perspective, as if viewed by a person standing almost even with one of its edges, and seeing three of its sides.

In fig. 16. Plate CCCLXXXIII. let $AB$ be the breadth of either of the fix equal square sides of the cube $ABG$; $O$ the place of the observer, almost even with the edge $CD$ of the cube, $S$ the point of sight, $SP$ the horizon parallel to $AD$, and $P$ the point of distance taken as before.

Make $ABCD$ a true square; draw $BS$ and $CS$ to the point of sight, and $BP$ to the point of distance, intersecting $CS$ in $G$.—Then draw $FG$ parallel to $BC$, and the uppermost perspective square side $BFGC$ of the cube will be finished.

Draw $DS$ to the point of sight, and $AP$ to the point of distance, intersecting $DS$ in the point $I$; then draw $GI$ parallel to $CD$; and, if the cube be an opaque one, as of wood or metal, all the outlines of it will be finished; and then it may be shaded as in the figure.

But if you want a perspective view of a transparent glass cube, all the sides of which will be seen, draw $AH$ toward the point of sight, $FH$ parallel to $BA$, and $HI$ parallel to $AD$; then $AHID$ will be the square base of the cube, perpendicularly parallel to the top $BFGC$; $ABFH$ will be the square side of the cube, parallel to $CGID$, and $FGIH$ will be the square side parallel to $ABCD$.

As to the shading part of the work, it is such mere children's play, in comparison of drawing the lines

A a
which form the shape of any object, that no rules need be given for it. Let a person sit with his left side toward a window, and he knows full well, that if any solid body be placed on a table before him, the light will fall on the left-hand side of the body, and the right-hand side will be in the shade.

**Prob. 15.** To put any solid in perspective.

Put the base of the solid, whatever it be, in perspective by the preceding rules. From each bounding point of the base, raise lines representing in perspective the altitude of the object; by joining these lines and shading the figure according to the directions in the preceding problem, you will have a scenographic representation of the object. This rule is general; but as its application to particular cases may not be apparent, it will be proper to give the following example of it.

**Prob. 16.** To put a cube in perspective as seen from one of its angles.

Since the base of a cube standing on a geometrical plane, and seen from one of its angles, is a square seen from one of its sides, draw first such a perspective square: then raise from any point of the ground-line DE (Fig. 3, Plate CCCLXXXIV.) the perpendicular HI equal to the side of the square, and draw to any point V in the horizontal line HR the straight lines VI and VH. From the angles db and c draw the dotted lines d 2 and e 1 parallel to the ground line DE. Perpendicular to these dotted lines, and from the points 1 and 2, draw the straight lines L 1 and M 2. Lastly, since HI is the altitude of the intended cube in a, L 1 in c, and b, M 2 in d, draw from the point a the straight line fa perpendicular to a E, and from the points b and c, bg and ce, perpendicular to b c 1, and a b d c being according to rule, make a f = HI, b g = e c = L 1, and b d = M 2. Then, if the points g, b, e, f, be joined, the whole cube will be in perspective.

**Prob. 17.** To put a square pyramid in perspective, as standing upright on its base, and viewed obliquely.

In fig. 4, no. 1, of Plate CCCLXXXIV. let AB be the breadth of either of the four sides of the pyramid ATCD at its base ABCD; and MT its perpendicular height. Let O be the place of the observer, S his point of sight, SE his horizon, parallel to AD and perpendicular to OS; and let the proper point of distance be taken in SE produced toward the left hand, as far from S as OS is from S.

Draw AS and DS to the point of sight, and DL to the point of distance, intersecting AS in the point B. Then, from B, draw BC parallel to AD; and ABCD shall be the perspective square base of the pyramid.

Draw the diagonal AC, intersecting the other diagonal BD at M, and this point of intersection shall be the centre of the square base.

Draw MT perpendicular to AD, and of a length equal to the intended height of the pyramid; then draw the straight lines AT, CT, and DT; and the outlines of the pyramid (as viewed from O) will be finished; which being done, the whole may be so shaded as to give it the appearance of a solid body.

If the observer had stood at e, he could have only seen the side ATD of the pyramid; and two is the greatest number of sides that he could see from any other place of the ground. But if he were at any height above the pyramid, and had his eye directly over its top, it would then appear as in No. 2, and he would see all its four sides E, F, G, H, with its top just over the centre of its square base ABCD; which would be a true geometrical and not a perspective figure.

**Prob. 18.** To put two equal figures in perspective, one of which shall be directly over the other, at any given distance from it, and both of them parallel to the plane of the horizon.

In fig. 5, Plate CCCLXXXIV. let ABCD be a perspective square on a horizontal plane, drawn according to the foregoing rules, S being the point of sight, SP the horizon (parallel to AD), and P the point of distance.

Suppose AD, the breadth of this square, to be three feet; and that it is required to place just such another square EFGH directly above it, parallel to it and two feet from it.

Make AE and DH perpendicular to AD, and two thirds of its length: draw EH, which will be equal and parallel to AD; then draw ES and HS to the point of sight, S, and EP to the point of distance P, intersecting HS in the point G: this done, draw FG parallel to EH; and you will have two perspective squares ABCD and EFGH, equal and parallel to one another, the latter directly above the former, and two feet distant from it; as was required.

By this method shelves may be drawn parallel to one another, at any distance from each other in proportion to their length.

**Prob. 19.** To put a truncated pyramid in perspective.

Let the pyramid to be put in perspective be quinquangular. If from each angle of the surface whence the top is cut off, a perpendicular be supposed to fall upon the base, these perpendiculars will mark the bounding points of a pentagon, of which the sides will be parallel to the sides of the base of the pyramid, within which it is inscribed. Join these points, and the interior pentagon will be formed with its longest side parallel to the longest side of the base of the pyramid. From the ground-line EH (Fig. 6, Plate CCCLXXXIV.) raise the perpendicular IH, and make it equal to the altitude of the intended pyramid. To any point V draw the straight lines IV and HV, and by a process similar to that in Problem 16 determine the scenographic altitudes a, b, c, d, e. Connect the upper points j, g, i, k, by straight lines; and draw 1k, f, m, g, n, and the perspective of the truncated pyramid will be completed.

Cor. If in a geometrical plane two concentric circles be described, a truncated cone may be put in perspective in the same manner as a truncated pyramid.

**Prob. 20.** To put in perspective a hollow prism lying on one of its sides.

Let ABDEC (Fig. 7, no. 1) be a section of such a prism. Draw HI parallel to AB, and distant from it the breadth of the side on which the prism rests; and from each angle internal and external of the prism let fall perpendiculars to HI. The parallelogram will be thus divided by the ichnographical process below the ground-line, so as that the side AB of the real prism will be parallel to the corresponding side of the ichnographic view of it.—To determine the altitude of the internal and external angles. From H (no. 2.) raise HI perpendicular to the ground-line, and on it mark
mark off the true altitudes $H_1$, $H_2$, $H_3$, $H_4$, and $H_5$. Then if from any point $V$ in the horizon be drawn the straight lines $VH_1$, $V_1$, $V_2$, $V_3$, $V_4$, $V_5$ or $V_1$; by a process similar to that of the preceding problem, will be determined the height of the internal angles, viz. $1 = a$, $2 = b$, $3 = c$, $4 = d$; and of the external angles, $3 = e$, and $5 = r$; and when these angles are formed and put in their proper places, the figure of the prism is complete.

**Prob. 21.** To put a square table in perspective, standing on four upright square legs of any given length with respect to the breadth of the table.

In fig. 5, Plate CCCLXXXIV. let $ABCD$ be the square part of the floor on which the table is to stand, and $EFGH$ the surface of the square table, parallel to the floor.

Suppose the table to be three feet in breadth, and its height from the floor to be two feet; then two thirds of $AD$ or $EH$ will be the length of the legs $i$ and $m$ of the other two ($l$ and $n$) being of the same length in perspective.

Having drawn the two equal and parallel squares $ABCD$ and $EFGH$, as shown in Prob. 10, let the legs be square in form, and fixed in the table at a distance from its edges equal to their thickness. Take $Aa$ and $Dd$ equal to the intended thickness of the legs, and $a$ and $d$ also equal thereto. Draw the diagonals $AC$ and $BD$, and draw straight lines from the points $a$, $b$, $c$, $d$, toward the points of sight $S$, and terminating at the side $BC$. Then, through the points where these lines cut the diagonals, draw the straight lines $n$ and $p$, $q$, parallel to $AD$; and you will have formed four perspective squares (like $ABCD$ in fig. 4 no. 1.) for the bases of the four legs of the table: and then it is easy to draw the four upright legs by parallel lines, all perpendicular to $AD$; and to have them as in the figure.

To represent the intended thickness of the table-board, draw $e$, $f$, parallel to $EH$, and $HG$ toward the point of sight $S$; then shade the spaces between these lines, and the perspective figure of the table will be finished.

**Prob. 22.** To put five square pyramids in perspective, standing upright on a square pavement composed of the surfaces of 81 cubes.

In fig. 8, Plate CCCLXXXIV. let $ABCD$ be a perspective square drawn according to the foregoing rules; $S$ the point of sight, $P$ the point of distance in the horizon $PS$, and $AC$ and $BD$ the two diagonals of the square.

Divide the side $AD$ into 9 equal parts (because 9 times 9 is 81), as $Aa$, $ab$, $bc$, etc., and from these points of division, $a$, $b$, $c$, $d$, etc., draw lines toward the point of sight $S$, terminating at the furthest part of $BC$ of the square. Then, through the points where these lines cut the diagonals, draw straight lines parallel to $AD$, and the perspective square $ABCD$ will be subdivided into 81 smaller squares, representing the upper surfaces of 81 cubes, laid close to one another, $a^2$ in a square form.

Draw $AK$ and $DL$, each equal to $Aa$, and perpendicular to $AD$; and draw $LN$ toward the point of sight $S$: then draw $KL$ parallel to $AD$, and its distance from $AD$ will be equal to $Aa$.—This done, draw $a$, $b$, $c$, $d$, etc., $e$, $f$, $g$, $h$, and $i$; all parallel to $AK$; and the space $ADLK$ will be subdivided into nine equal squares, which are the upper outward surfaces of the nine cubes in the side $AD$ of the square $ABCD$.

Draw $LN$ toward the point of sight $S$; and from the points where the lines, which are parallel to $AD$ in this square, meet the side $CD$ thereof, draw short lines to $LN$, all parallel to $DL$, and they will divide that side into the outer upward surfaces of the nine cubes which compose it; and then the outsides of all the cubes that can be visible to an observer, placed at a proper distance from the corner $D$ of the square, will be finished.

As taught in Prob. 17, place the pyramid $AE$ upright on its square base $Aa$, making it as high as you please; and the pyramid $DH$ on its square base $b$, equal to $AD$, of equal height with $AE$.

Draw $EH$ from the top of one of these pyramids to the top of the other; and $EH$ will be parallel to the other.

Draw $ES$ and $HS$ to the point of sight $S$, and $HP$ to the point of distance $P$, intersecting $ES$ in $F$.

From the point $F$, draw $FG$ parallel to $EH$; then draw $EG$, and you will have a perspective square $EFGH$ (parallel to $ABCD$) with its two diagonals $EG$ and $FH$, intersecting one another in the centre of the square at $I$. The four corners of this square, $E$, $F$, $G$, $H$, give the perspective heights of the four pyramids $AE$, $BF$, $CG$, and $DH$; and the intersection of the diagonals gives the height of the pyramid $MI$, the centre of whose base is the centre of the perspective square $ABCD$.

Lastly, place the three pyramids $BF$, $CG$, $MI$, upright on their respective bases at $B$, $C$, and $M$; and the required perspective representation will be finished, as in the figure.

**Prob. 23.** To put upright pyramids in perspective, on the side of an oblong square or parallelogram; so that their distances from one another shall be equal to the breadth of the parallelogram.

In most of the foregoing operations we have considered the observer to be so placed, as to have an oblique view of the perspective objects; in this, we shall suppose him to have a direct view of fig. 8. Plate CCCLXXXIV. that is, standing right against the middle of the end $AD$, which is nearest to his eye, and viewing $AD$ under an angle of 60 degrees.

Having cut $AD$ in the middle, by the perpendicular line $S$, take $S$, therein at pleasure, for the point of sight, and draw $ES$ for the horizon, parallel to $AD$.

Here $S$, must be supposed to be produced downward, below the limits of the plate, to the place of the observer; and $SE$ to be produced towards the left hand beyond $E$, far enough to take a proper point of distance therein, according to the foregoing rules.

Take $Aa$ at pleasure, and $DG$ equal to $Aa$, for the breadths of the square bases of the two pyramids $AE$ and $DF$ next the eye; then draw $AS$ and $DS$, and likewise $DS$ and $SS$, to the point of sight $S$; and $DG$ on to the point of distance, intersecting $AS$ in $G$; then, from $G$ draw $GI$ parallel to $AD$, and you will have the first perspective square AGID of the parallelogram $ABCD$.

From I draw $IH$ (or toward) the point of distance, intersecting $AS$ in $H$; then, from $H$ draw $Aa$.
Perspective.

HK parallel to AD, and you will have the second perspective square GHKL of the parallelogram.—Go on in this manner till you have drawn as many perspective squares up towards S as you please.

Through the point e, where DG intersects g S, draw k f parallel to AD; and you will have formed the two perspective squares A b c d and e f D g of the two pyramids at A and D.

From the point f (the upper outward corner of e f D g) draw f b toward the point of distance, till it meets AS in h; then, from this point of meeting, draw b m parallel to GI, and you will have formed the two perspective squares G h i k and l m n o for the square bases of the two pyramids at G and I.

Proceed in the same manner to find the bases of all the other pyramids, at the corners of the ret of the perspective squares in the parallelogram ABCD, as shown by the figure.—Then

Having placed the first two pyramids at A and D upright on their square bases, as shown in Prob. 9, and made them of any equal heights at pleasure, draw ES and FS from the tops of these pyramids to the point of sight S; place all the rest of the pyramids upright on their respective bases, making their tops touch the straight lines ES and FS; and all the work, except the shading part, will be finished.

Prob. 24. To put a square pyramid of equal sized cubes in perspective.

Fig. 2. Plate CCCLXXXV. represents a pyramid of this kind: confinishing as it were of square tables of cubes, one table above another; 8 t in the lowest, 49 in the next, 25 in the third, 9 in the fourth, and 1 in the fifth or uppermost. These are the square numbers of 9, 7, 5, 3, and 1.

If the artist is already master of all the preceding operations, he will find less difficulty in this than in attending to the following description of it; for it cannot be described in a few words, but may be executed in a very short time.

In fig. 1, having drawn PS for the horizon, and taken S for the point of sight therein (the observer being at O) draw AD parallel to PS for the side (next the eye) of the first or lowermost table of cubes. Draw AS and DS to the point of sight S, and DP to the point of distance P, intersecting AS in the point B. Then, from B, draw BC parallel to AD, and you will have the surface ABCD of the first table.

Divide AD into nine equal parts, as A a, a b, b c, c d, &c. and make AK and DL equal to A a, and perpendicular to AD. Draw KL parallel to AD, and from the points of equal division at a, b, c, &c. draw lines to KL, all parallel to AK. Then draw b S to the point of sight S, and from the division-points a, b, c, &c. draw lines with a black lead pencil, all tending toward the point of sight, till they meet the diagonal BD of the square.

From these points of meeting draw black lead lines to DC, all parallel to AD; then draw the parts of these lines with black ink which are marked 1, 2, 3, 4, &c. between E and D. Then draw DC parallel to DL; and all the visible lines between the cubes in the first table will be finished.

Make IC equal and perpendicular to p 5, and q M equal and parallel to IC; then draw GM, which will be equal and parallel to q. From the points k, l, m, n, &c. draw k n, l o, m p, &c. all parallel to IC, and the outsides of the seven cubes in the side G o of the second table will be finished.

Draw GS and MS to the point of sight S, and MP to the point of distance P, intersecting GS in H; then, from the point of intersection H, draw HI parallel to AD; and you will have the surface GHIM of the second table of cubes.

From the points n, o, p, q, &c. draw black lead lines towards the point of sight S, till they meet the diagonal MH of the perspective square surface GHIM; and draw JM, with black ink, toward the point of sight.

From those points where the lines drawn from n, o, p, q, &c. meet the diagonal MH, draw black lead lines to MJ, all parallel to AD; only draw the whole first line q 1 with black ink, and the parts 2, 3, 4, &c. and n t, o u, v, &c. of the other lines between N and M, and GM and q 1, with the same; and rub out all the rest of the black lead lines, to avoid further confusion. Then, from the points where the short lines 1, 2, 3, &c. meet the line MI, draw lines down to q E, all parallel to MQ, and the outer surfaces of the seven cubes in the side ME will be finished; and all these left lines will meet the former parallels 2, 3, 4, &c. in the line q E.

Make IO equal and perpendicular to q 1, and P equal and parallel to IO; then draw OP, which will be equal and parallel to q y.—This done, draw OS and PS to the point of sight S, and PP to the point of distance P in the horizon. Lastly, from the point Q, where PP intersects OS, draw QR parallel to OP, and you will have the outlines QQRP of the surface of the third perspective table of cubes.

From the points w, v, w, n, s, take up the points of sight, and draw up the outlines of the five cubes in the side O Y of this third table.

From the points where these upright lines meet OP, draw lines toward the point of sight S, till they meet the diagonal PQ 1; and from these points of meeting draw lines to PR, all parallel to OP, making the parts 2, 3, 4, 5, of these lines with black ink which lie between ZY and PR. Then, from the points where these lines meet PR, draw lines down to y N 1, which will bound the outer surface of the five cubes in the side PN of the third table.

Draw the line y 1 with black ink; and, at a fourth part of its length between y and Z, draw an upright line to S, equal in length to that fourth part, and another equal and parallel thereto from Z to V; then draw SV parallel to ZZ, and draw the two upright and equidistant lines between ZZ and SV, and you will have the outer surfaces of the three cubes in the side SZ of the fourth table.

Draw SS and VS to the point of sight S in the horizon, and VP to the point of distance therein, intersecting
Perspective

To represent a double crofs in perspective.

In fig. 3, Plate CCCCLXXXV, let ABCD and EF GH be two perspective squares, equal and parallel to one another, the uppermost part of the cross; made figure. — From R, draw MO, and RS, and when the whole is properly laid down, and as far asunder as is equal to the given height of the upright part of the cross; S being the point of fight, and P the point of distance, in the horizon PS taken parallel to AD.

Draw AE, DH, and CG; then AE HD and DH GC shall be the two visible sides of the upright part of the cross; of which, the length, AE, is here made equal to three times the breadth EH.

Divide DH into three equal parts, HI, IK, and KD. Through these points of division, at I and K, draw MN, and MN parallel to AD; and make the parts MN, IO, PQ, KR, each equal to HI; then draw MP and OR parallel to DH.

From M, draw MS, and OS to the point of fight S; and from the point of distance D, P, draw PN cutting MS in T: from T draw TU parallel to MO, and meeting OS in U; and you will have the uppermost surface MTUO of one of the crosf pieces of the figure. — From R, draw RS to the point of fight S; and from U draw UV parallel to OR; and OUVR shall be the perspective square end next the eye of that crosf part.

Draw PM (as long as you please) from the point of distance P, through the corner M: lay a ruler to N and S, and draw XN from the line PX:—then lay the ruler to I and S, and draw YZS. — Draw XY parallel to MO, and make XW and YB equal and perpendicular to XY: then draw WB parallel to XY, and WX YB shall be the square visible end of the other crosf-part of the figure.

Draw BK towards the point of sight S; and from U draw US to the point of distance D, interfacing YS in Z; then, from the Interference Z, draw ZA parallel to MO, and ZB parallel to HD, and the whole delineation will be finished.

This done, shade the whole, as in fig. 4, and you will have a true perspective representation of a double crosf.

PROB. 26. To put three rows of upright squares in perspective, equal in size, and at equal distances from each other, on an oblong plane, the breadth of which shall be of any assigned proportion to the length thereof.

Fig. 5. Plate CCCCLXXXV, is a perspective representation of an oblong plane, three times as long as it is broad, having a row of nine upright squares on each side, and one of the same number in the middle; all equally high, and at equal distances from one another, both long and crosswise, on the same plane.

In fig. 6, PS is the horizon, S the point of sight, P the point of distance, and AD (parallel to PS) the breadth of the plane.

Draw AS, NS, and DS, to the point of sight S; the point N being in the middle of the line AD; and draw DP to the point of distance P, interfacing AS in the point B: then, from B draw BC parallel to AD, and you have the perspective square ABCD.

Through the point i, where DB interfices NS, draw a B parallel to AD; and you will have subdivided the perspective square ABCD into four lesser squares, as A i N, N i D, a B k i, and i k C. From the point C (at the top of the perspective square ABCD) draw CP to the point of distance P, interfacing AS in E; then, from the point E draw EF parallel to AD; and you will have the second perspective square BEFC.

Through the point l, where CE interfices NS, draw b f parallel to AD; and you will have subdivided the square BEFC into four lesser squares, b f k l, k l f c, b e m l, and I m F f.

From the point F (at the top of the perspective square BEFG) draw EP to the point of distance P, interfacing AS in I; then from the point I draw IK parallel to AD; and you will have the third perspective square EIKF.

Through the point n, where FI interfices NS, draw e g parallel to AD; and you will have subdivided the square EIKF into four lesser squares, E c n m, m n g F, c e m, and n e K g.

From the point K (at the top of the third perspective square EIKF) draw KP to the point of distance P, interfacing AS in I; then from the point L draw LM parallel to AD; and you will have the fourth perspective square IL MK.

Through the point p, where KL interfices NS, draw d b parallel to AD; and you will have subdivided the square IL MK into the four lesser squares, I d p o, o p b K, d L q p, and p q M b.

Thus we have formed an oblong square ALMD, whose perspective length is equal to four times its breadth, and it contains 16 equal perspective squares.

If greater length was still wanted, we might proceed further on toward S.

Take A 3, equal to the intended breadth of the side of the upright square objects AQ (all the other sides being of the same breadth), and AO for the intended height. Draw O 1 8 parallel to AD, and make D 8 and 4 7 equal to A 3; then draw g S, 4 S, 7 S, and 8 to the point of sight S; and among them we shall have the perspective square bases of all the 27 upright objects on the plane.

Through the point q, where DB interfices 8 S, draw 1 10 parallel to AD, and you have the three perspective square bases A 1 2 3, 4 5 6 7, 8 9 10 D, of the three upright square objects at A, N, and D.

Through the point 21, where e B interfices 8 S, draw 1 4, 11 parallel to AD; and you will have the three perspective squares a 1 4 15 16 17 18 19 20, and 21 1 2 22, for the bases of the second cross row of objects; namely, the next beyond the first three at A, N, and D.

Through the point s, where CE interfices 8 S, draw a line parallel to BC; and you will have three perspective squares, at B, A, and C, for the bases of the third row of objects; one of which is set up at B.

Through the point x, where f e interfices 8 S, draw a line parallel to P's f; and you will have three perspective squares, at A, k, and x, for the bases of the fourth cross row of objects.

Go on in this manner, as you see in the figure, to find:
find the reft of the fquare bafes, up to LM; and you
will have 27 upon the whole oblong fquare plane, on
which you are to place the like number of obje¢ts, as in
fig. 6.

Having affumed AO for the perpective height of
the three obje¢ts at A, N, and D (fig. 6.) next the
observer's eye, and drawn O 18 parallel to AD, in
order to make the obje¢ts at N and D of the fame
height as that at O; and having drawn the upright
lines 4, 15, 7 W, 8 X, and D 22, for the heights N
and D; draw OS and RS, 15 S and WS, XS and
22 S, all to the point of fight S: and these lines will
determine the perpective equal heights of all the
reft of the upright obje¢ts, as shown by the two placed
at a and B.

To draw the fquare tops of these obje¢ts, equal and
parallel to their bafes, we need only give one example,
which will serve for all.

Draw 9 R and 2 Q parallel to AO, and up to the
line RS; then draw PQ parallel to OR, and OPQR
shall be the top of the obje¢t at A, equal and parallel
to its fquare bafe A 3. In the fame easy way the
tops of all the other obje¢ts are formed.

When all the reft of the obje¢ts are delineated, shade
them properly, and the whole perpective fcheme will
have the appearance of fig. 5.

Prob. 27. To put a fquare box in perpective, containing
a given number of fquare boxes of a depth equal
to their width.

Let the given number of little fquare boxes or cells
be 16, then 4 of them make the length of each fide
of the four outer fides ab, bc, cd, da, as in fig. 7.
and the depth a is equal to the width ab. Whoever
can draw the reft of the fquare box, by the rules laid down
towards the beginning of this article, will be at no
loss about putting this perpective fcheme in pradice.

Prob. 28. To put stairs with equal and parallel fides
in perpective.

In fig. 1. of Plate CCCLXXXVII. let ab be the
given breadth of each ftep, and a the height thereof.
Make 5, 6, 7, 8, &c. each equal to a b; and draw
all the upright lines a, b, l, c, d, &e. perpendicular
to a b (to which the horizon S is parallel); and
from the points i, l, n, p, r, &c. draw the equidistant
lines i B, J C, n D, &c. parallel to a b; these distances
being equal to that of i B fr m a.

Draw $x$ touching all the corner points $i$, $l$, $p$, $r$
de &c. from it as far as you want the length of the fteps to be.

Towards the point of fight S draw the lines a 1, i 2,
k 3, l 4, &c. and draw 16 15, 14 13, 12 11, 10 9,
8 7, 6 5, 4 3, and 2 1, all parallel to Ab, and meeting
the lines $v 15, u 14, t 13, i 12, &c. in the points 15,
14, 13, 12, 11, 10, 9, 8, 7, 6, 5, 4, 3, and 2 1,
all parallel to a b; a and the outlines of the fteps will
be finated. From the point 16 draw 16 A parallel
to b a, and A x 16 will be part of the flat at the top of
the upper ftep. This done, shade the work as
in fig. 2. and the whole will be finated.

Prob. 29. To put fairs with flats and openings in perpective,
standing on a horizontal pavement of fquares.

In fig. 3. of Plate CCCLXXXVII. having made S the
point of fight, and drawn a reticulated pavement AB
with black lead lines, which may be rubbed out again,
at any distance from the fide AB of the pavement
which is nearest to the eye, and at any point where
you choose to begin the fair at that distance, as a,
draw Ga parallel to BA, and take a b at pleafure for
the height of each ftep.

Take a b in your compaffes, and set that extent as
many times upward from F to E as is equal to the
fift required number of fteps O, N, M, L, K; and
from there points of division in EF draw b d, e f,
and Ek all equidistant from one another, and
parallel to Fa: then draw the equidistant upright lines
a b, t d, u f, v h, w k, and I m, all perpendicular to
Fa: then draw m b, touching the outer corners of
these fteps at m, n, o, d, and b; and draw n parallel
to m b, as far from it as you want the length of the
fteps K, L, M, N, O to be.

Towards the point of fight S draw m n, l 5, k, i 6,
b, f, g, d, and v 8. Then (parallel to the bottom
line BA) through the points m, n, p, q, r, s, draw
e, f, g, d, and h, &c. as in the figure. Whoever
can draw the upright lines 29, 30, 31, &c. in the
points where these short fteps meet CD draw lines
parallel to GE, and the short lines marked
32, 33, &c. just even with the parallel lines 1, 2, &c.
From the points where these short fteps meet CD
draw lines toward the point of fight S till they meet
DE; then from the points where the lines 58, 39, 40,
&c. of the pavement meet C, draw upright lines
parallel to CD, and the lines which form the opening
will be finated.

The fteps P, Q, R, S, T, and the flat U above
the arch V are done in the fame manner with thofe
in fig. 1. as taught in Prob. 28 and the equidistant
parallel lines marked 18, 19, &c. are directly even
with thofe on the left-hand fide of the arch V, and
the upright lines on the right hand fide are equidistant
with thofe on the left.

From the points where the lines 18, 19, 20, &c.
meet the right-hand fide of the arch, draw lines toward
the point of fight S; and from the points where the
pavement lines 29, 30, 31, &c. meet the line drawn
from A towards the point of fight, draw upright lines
toward the top of the arch.

Having done the top of the arch, as in the figure,
and the few fteps to the right hand thereof, shade the
whole as in fig. 4. and the work will be finated.

Prob. 30. To put upright conical obje¢ts in perpective,
as if standing on the fides of an oblong square, at diftan-
ces from one anor her equal to the breadth of the oblong.

In fig. 5. of Plate CCCLXXXVI. the bases of the
upright cones are perpective circles inscribed in fquares
of the fame diameter; and the cones are fet upright

Fig. 7.

Perspective Plate CCCXXXV
on their bases by the same rules as are given for pyramids, which we need not repeat here.

In most of the foregoing operations we have considered the observer's eye to be above the level of the tops of all the objects, as if he viewed them when standing on high ground. In this figure, and the first and second of the next plate, we shall suppose him to be standing on low ground, and the tops of the objects to be above the level of his eye.

In fig. 5, let AD be the perspective breadth of the oblong square ABCD; and let AA and DD (equal to Aa) be taken for the diameters of the circular bases of the two cones next the eye, whose intended equal heights shall be AE and DF.

Having made S the point of sight in the horizon parallel to AD, and found the proper point of distance therein, draw AS and aS to contain the bases of the cones on the left-hand side, and DS and dS for those on the right.

Having made the two first cones at A and D of equal height at pleasure, draw ES and ES from their tops to the point of sight, for limiting the perspective heights of all the rest of the cones. Then divide the parallelogram ABCD into as many equal perspective squares as you please; find the bases of the cones at the corners of these squares, and make the cones thereon, as in the figure.

If you would represent a ceiling equal and parallel to ABCD, supported on the tops of these cones, draw EF, then EFGH shall be the ceiling; and by drawing ef parallel to EF, you will have the thickness of the floor-boards and beams, which may be what you please.

This shows how any number of equidistant pillars may be drawn of equal heights to support the ceiling of a long room, and how the walls of such a room may be represented in perspective at the backs of these pillars. It also shows how a street of houses may be drawn in perspective.

Para. 31. To put a square hollow in perspective, the depth of which shall bear any assigned proportion to its width.

Fig. 1. of Plate CCCLXXXVII. is the representation of a square hollow, of which the depth AG is equal to three times its width AD; and S is the point of sight over which the observer's eye is supposed to be placed, looking perpendicularly down into it, but not directly over the middle.

Draw AS and DS to the point of sight S; make ST the horizon parallel to AD, and produce it to such a length beyond T that you may find a point of distance therein not nearer S than if AD was seen under an angle of 60 degrees.

Draw DU to the point of distance, intersecting AS in B; then from the point D draw DC parallel to AD; and you shall have the first perspective square ABD, equal to a third part of the intended depth.

Draw CV to the point of distance, intersecting AS in E; then from the point E draw EF parallel to AD; and you will have the second perspective square BEFC, which, added to the former one, makes two-thirds of the intended depth.

Draw FW to the point of distance, intersecting AS in G; then from the point G draw GH parallel to AD; and you will have the third perspective square EGHF, which, with the former two, makes the whole depth AGHD three times as great as the width AD, in a perspective view.

Divide AD into any number of equal parts, as suppose 8; and from the division-points a, b, c, d, &c. draw lines toward the point of sight S, and ending at GH; then through the points where the diagonals BD, EC, GF, cut these lines, draw lines parallel to AD; and you will have the parallelogram AGHD reticulated, or divided into 192 small and equal perspective squares.

Make AI and DM equal and perpendicular to AD; then draw IM, which shall be equal and parallel to AD; and draw IS and MS to the point of sight S.

Divide AI, IM, and MD, into the same number of equal parts as AD is divided; and from these points of division draw lines toward the point of sight S, ending respectively at GK, KL, and LH.

From those points where the lines parallel to AD meet AG and DH draw upright lines parallel to AI and DM; and from the points where these lines meet IK and LM draw lines parallel to IM; then shade the work, as in the figure.

Para. 32. To represent a semicircular arch in perspective, as it were standing on two upright walls, equal in height to the height of the observer's eye.

After having gone through the preceding operation, this will be more easy by a bare view of fig. 2. in Plate CCCLXXXVII. than it could be made by any description; the method being so much like that of drawing and shading the square hollow.—We need only mention, that ALBEA and DFST are the upright walls on which the semicircular arch is built; that S is the point of sight in the horizon T, taken in the centre of the arch; that d in fig. 1. is the point of distance; and that the two perspective squares ABCD and BEFC make the parallelogram AEFD of a length equal to twice its breadth AD.

Para. 33. To represent a square in perspective, as viewed by an observer standing directly even with one of its corners.

In fig. 3. of Plate CCCLXXXVII. let AG BC be a true square, viewed by an observer standing at some distance from the corner C, and just even with the diagonal C G.

Let RS be the horizon, parallel to the diagonal AB; and S the point of sight, even with the diagonal C G. Here it will be proper to have two points of distance p and P, equidistant from the point of sight S.

Draw the straight line 17 parallel to AB, and draw A 8 and B 10 parallel to CS: Take the distance between 8 and 9 in your compasis, and set it off all the way in equal parts from 8 to 1, and from 10 to 17. The line 17 should be produced a good way further both to right and left hand from 9, and divided all the way in the same manner.

From these points of equal division, 8, 9, 10, &c. draw lines to the point of sight S, and also to the two points of distance p and P, as in the figure.

Now it is plain, that a c b 9 is the perspective representation of A9BC, viewed by an observer even with the corner C and diagonal C G.—But if there are other such squares lying even with this, and having the same position with respect to the line 17, it is evident that the observer, who stands directly even with the corner,
corner C of the first square, will not be even with the like corners G and K of the others; but will have an oblique view of them, over the sides FG and IK, which are nearest his eye: and their perspective representations will be g f 6 and b k i 3, drawn along the lines in the figure; of which, the spaces taken up by each side lie between three of the lines drawn toward the point of distance p, and three drawn to the other point of distance P.

Prob. 34. To represent a common chair, in an oblique in perspective.

The original lines to the point of sight S, and points of distance p and P, being drawn as in the preceding operation, choose any part of the plane, as l m n 13, on which you would have the chair L to stand.—There are just as many lines (namely two) between 1 and m or 13 and n, drawn toward the point of distance p, at the left hand, as between l and 13, or m and n, drawn to the point of distance P on the right: so that l m, m n, n 13, and 13 l, form a perspective square.

From the four corners l, m, n, 13, of this square raise the four legs of the chair to the perspective perpendicular height you would have them: then make the seat of the chair a square equal and parallel to l m n 13, as taught in Prob. 18, which will make the two sides of the seat in the direction of the lines drawn toward the point of distance p, and the fore and back part of the seat in direction of the lines drawn to the other point of distance P. This done, draw the back of the chair leaning a little backward, and the cross bars therein tending toward the point of distance P. Then shade the work as in the figure; and the perspective chair will be finished.

Prob. 35. To present an oblong square table in an oblique perspective view.

In fig. 3. of Plate CCCXXXVII. M is an oblong square table, as seen by an observer standing directly even with C 9 (see Prob. 33.) the side next the eye being perspective parallel to the sides a c of the square a b c d. The forementioned lines drawn from the line 1 7 to the two points of distance p and P, form equal perspective squares on the ground plane.

Choose any part of this plane of squares for the feet of the table to stand upon; as at p, q, r, and s, in direction of the lines o p and r s for the two long sides, and t and q r for the two ends; and you will have the oblong square or parallelogram q r and t for the part of the floor or ground-plane whereon the table is to stand: and the breadth of this plane is here taken in proportion to the length as 6 to 10, so that, if the length of the table be ten feet, its breadth will be six.

On the four little perspective squares at q r, s t, and t, place the four upright legs of the table, of what height you please, so that the height of the two next the eye, at o and p, shall be terminated by a straight line w o drawn to the point of distance P. This done, make the leaf of the table an oblong square, perspective equal and parallel to the oblong square q r s t on which the feet of the table stands. Then shade the whole, as in the figure, and the work will be finished.

If the line 1 7 was prolonged to the right and left hand, and equally divided throughout (as it is from 1 to 17), and if the lines which a d drawn from p and to the right and left hand sides of the plate were prolonged till they came to the extended line 1 7, they would meet it in equal points of division. In forming large plans of this fort, the ends of slips of paper may be pasted to the right and left edges of the sheet on which the plan is to be formed.

of the Anamorphosis, or reformation of distorted images.

By this means pictures that are so mithapen, as to exhibit no regular appearance of any thing to the naked eye, shall, when viewed by reflection, present a regular and beautiful image. The inventor of this ingenious device is not known. Simon Stevin, who was the first that wrote upon it, does not inform us from whom he learned it. The principles of it are laid down by S. Vauzelard in his Perspectiva Conique et Cycloides, and Gaifer Schott professes to copy Marius Bettinus in his description of this piece of artificial magic.

It will be sufficient for our purpose to copy one of the simplest figures of this writer, as by this means the mystery of this art will be sufficiently unfolded. Upon the cylinder of paper, or palteboard, ABCD, draw whatever is intended to be exhibited, as the letters IHS. Then with a needle make perforations along the whole outline; and placing a candle, G, behind this cylinder, mark upon the ground plane the shadow of them, which will be distorted more or less, according to the position of the candle plane or the plane, &c. This being done, let the picture be an exact copy of this distorted image, let a metallic speculum be substituted in the place of the cylinder, and let the eye of the spectator have the same position before the cylinder that the candle had behind it. Then looking upon the speculum, he will see the distorted image restored to its proper shape. The reformation of the image, he affirms, will not easily be made exact in this method, but it will be sufficiently so to answer the purpose.

Other methods, more exact and geometrical than this, were found out afterwards: so that these pictures could be drawn by certain rules, without the use of a candle. Schott quotes one of these methods from Bettinus, another from Heironius, and another from Kircher, which may be seen in his Magia, vol i. p. 162, &c. He also gives an account of the methods of reforming pictures by speculums of conical and other figures.

Instead of copying any of these methods from Schott or Bettinus, we shall present our readers with that which Dr Smith hath given us in his Optics, vol i. p. 250, &c. He there gives an account of the more simple methods of reformation of distorted images. He speaks of two mirrors, one of which, fig. 7, is convex, and the other, fig. 8, is concave. In order to paint upon a plane a deformed copy ABCDEKIGHF of an original picture, which shall appear regular, when seen from a given point O, elevated above the plane, by rays reflected from a polished cylinder, placed upon the circle l p, equal to its given base; from the point R, which must be supposed to lie perpendicularly under O, the place of the eye, draw two lines R a R e, which shall either touch the base of the cylinder, or else cut off two small equal segments from the sides of its, according as the copy is intended to be more or less deformed. Then, taking the eye, raised above R, to the given height RO, and...
somewhat greater than that of the cylinder for a luminous point, describe the shadow $a e k f$ (of a square $a e k e$, fig. 36. or parallelogram standing upright upon its base $a e$, and containing the picture required) anywhere behind the arch $l n p$. Let the lines drawn from $R$ to the extremities and divisions of the base $a, b, c, d, e$ cut the remotest part of the shadow in the points $f, g, h, i, k$, and the arch of the base in $l, m, n, o, p$; from which points draw the lines $l A F, m B G, n C H, o D I, p E K$, as if they were rays of light that came from a focus, $K,$ and were reflected from the base $l n p$; so that each couple, as $l A, l R,$ produced, may cut off equal segments from the circle. Lastly, transfer the lines $l a f, m b g, o c i, a l n, b m r,$ and all their parts, in the same order, upon the respective lines $l A F, m B G, n C H, o D I, p E K,$ and having drawn regular curves, by elimination, through the points $A, B, C, D, E,$ through $F, G, H, I, K,$ and through every intermediate order of points; the figure $A C E K H F,$ so divided, will be the deformed copy of the square, drawn and divided upon the original picture, and will appear similar to it, when seen in the polished cylinder, placed upon the base $l n p,$ by the eye in its given place $O$.

The practical methods of drawing these images seem to have been carried to the greatest perfection by J. Leopold, who, in the Acta Lipsiensia for the year 1712, has described two machines, one for the images to be viewed with a cylindrical, and the other with a conical mirror. The person possessed of this instrument has nothing to do but to take any print he pleases, and while he goes over the outlines of it with one pen, another traces the anamorphosis. The merit of the invention has nothing to do but to take any print he pleases, and while he goes over the outlines of it with one pen, another traces the anamorphosis.

By methods of this kind, groves of trees may be cut, so as to represent the appearance of men, horses, and other objects from some one point of view, which are not at all discernible in any other. This might easily be effected by one person placing himself in any particular place, and having directed a person what trees to plant, and in what manner. In the same method it has been contrived, that buildings of circular and other forms, and also whole groups of buildings, consisting of walls at different distances, and with different positions to one another, should be painted so as to exhibit the exact representation of particular objects, which could only be perceived in one situation. Bettinus has illustrated this method by drawings in his Apiaria.

It may appear a bold assertion to say, that the very short sketch now given of the art of perspective is a sufficient foundation for the whole practice, and includes all the expeditious rules peculiar to the problems which most generally occur. It is, however, true, and the intelligent reader will see, that the two theorems on which the whole rests, include every possible cafe, and apply with equal facility to pictures and originals in any position, although the examples are selected of perpendicular pictures, and of originals referred to horizontal planes, as being the most frequent. The scientific foundation being so simple, the structure need not be complex, nor swell into volumes which, by their size deter from the perusal, and give the simple art the appearance of intricate mystery; and,

by their prices, defeat the design of their authors, viz. the dissemination of knowledge among the practitioners. The treatises on perspective acquire their bulk by long and tedious discourses, minute explanations of common things, or by great numbers of examples; which indeed do make some of these books valuable by the variety of curious cuts, but do not at all instruct the reader by any improvements made in the art itself. For it is evident, that most of those who have treated this subject have been more conversant in the practice of designing than in the principles of geometry; and therefore when, in their practice, the cafcs which have offered have put them on trying particular expedients, they have thought them worth communicating to the public as improvements of the art; and each author, fond of his own little expedient (which a scientific person would have known for an easy corollary from the general theorem), have made it the principle of a practical system—and in this manner narrowing instead of enlarging the knowledge of the art; and the practitioner, tired of the bulk of the volume, in which a single maxim is tedioufly spread out, and the principle on which it is founded kept out of his sight, contents himself with a remembrance of the maxim (not understood), and keeps it slightly in his eye, to avoid gross errors. We can appeal to the whole body of painters and draughtsmen for the truth of this assertion; and it must not be considered as an imputation on them of remissness or negligence, but as a necessary consequence of the ignorance of the authors from whom they have taken their information. This is a strong term, but it is not the least just. Several mathematicians of eminence have written on perspective, treating it as the subject of pure geometry, as it really is; and the performances of Dr Brook Taylor, Gravevande, Wolf, De la Caille, Emerson, are truly valuable, by prefenting the art in all its perpicious simplicity and universality. The works of Taylor and Emerson are more valuable, on account of the very ingenious and expeditious constructions which they have given, suited to every possible cafe. The merit of the first author has been universally acknowledged by all the British writers on the subject, who never fail to declare that their own works are composed on the principle of Dr Brook Taylor: but any man of science will see that these authors have either not understood them, or aimed at pleasing the public by fine cuts and uncommon effects; for, without exception, they have omitted his favourite constructions, which had gained his predilection by their universality, and attached themselves to inferior methods, more usually expeditious perhaps, or inventions (as they thought) of their own. What has been given in this article is not professed to be according to the principles of Dr Brook Taylor, because the principles are not peculiar to him, but the necessary results of the theory itself, and incorporated by every mathematician who has taken the trouble to consider the subject. They are sufficient not only for directing the ordinary practice, but also for fogging modes of construction for every case out of the common track. And a person of ingenuity will have a laudable enjoyment in thus, without much stretch of thought, inventing rules for himself; and will be better pleased with fruit's of his own ingenuity, than in reading the tedious explanations of examples devised...
PERSPECTIVE.

The art of painting, taken in its full extent, consists of two parts; the inventive, and the executive. The inventive part is common with poetry, and belongs more properly and immediately to the original design (which it invents and divides in the most proper and agreeable manner) than to the picture, which is only a copy of that design already formed in the imagination of the artist. The perfection of this art of painting depends upon the thorough knowledge the artist has of all the parts of his subject; and the beauty of it consists in the happy choice and disposition that he makes of it: And it is in this that the genius of the artist discovers and shows itself, while he indulges and humour his fancy, which here is not confined. But the other, the executive part of painting, is wholly confined and strictly tied to the rules of art, which cannot be dispensed with on any account; and therefore in this the artist ought to govern himself entirely by the rules of art, and not to take any liberties whatever. For any thing that is not truly drawn according to the rules of perspective, or not truly coloured or truly shaded, does not appear to be what the artist intended, but something else. Therefore, if at any time the artist happens to imagine that his picture would look the better, if he should twice a little from these rules, he may assure himself, that the fault belongs to his original design, and not to the strictness of the rules; for what is perfectly agreeable and just in the real original objects themselves, can never appear defective in a picture where those objects are exactly copied.

Therefore to offer a short hint of thoughts we have some time had upon the method which ought to be followed in instructing a scholar in the executive part of painting; we would first have him learn the most common effects of practical geometry, and the first elements of plain geometry and common arithmetic. When he is sufficiently perfect in these, we would have him learn perspective. And when he has made some progress in this, so as to have prepared his judgment with the right notions of the alterations that figures must undergo when they come to be drawn on a flat, he may then be put to drawing by view, and be exercised in this along with perspective, till he come to be sufficiently perfect in both. Nothing ought to be more familiar to a painter than perspective; for it is the only thing that can make the judgment correct, and will help the fancy to invent with nine times the ease that it could do without it.

We earnestly recommend to our readers the careful perusal of Dr Taylor's Treatise, as published by Colson in 1749, and Emerson's published along with his Optics. They will be surprised and delighted with the instruction they will receive; and will then truly estimate the splendid volumes of other authors and see their frivolity.

Perspective is also used for a kind of picture or painting, frequently seen in gardens, and at the ends of galleries; designed expressly to deceive the sight by representing the continuation of an alley, a building, landscape, or the like.

Aerial PERSPECTIVE, is sometimes used as a general deno-
denomination for that which mere restrictedly is called _aerial perspective_, or the art of giving a due diminution or degradation to the strength of light, shade, and colours of objects, according to their different distances, the quantity of light which falls upon them, and the medium through which they are seen; the _chiare obscuro_, or _clair obscur_, which consists in expressing the different degrees of light, shade, and colour of bodies, arising from their own shape, and the position of their parts with respect to the eye and neighbouring objects, whereby their light or colours are affected; and keeping, which is the observance of a due proportion in the general light and colouring of the whole picture, so that no light or colour in one part may be too bright or strong for another. A painter, who could succeed in _aerial perspective_, ought carefully to study the effects which distance, or different degrees or colours of light, have on each particular original colour, to know how its hue or strength is changed into the several colours of the picture, to which all the same colours at several distances must have a proportional degradation in like circumstances.

_Bird's eye view in Perspective_, is that which supposes the eye to be placed above any building, etc. as in the air at a considerable distance from it. This is applied in drawing the representations of fortifications, when it is necessary not only to exhibit one view as seen from the ground, but so much of the several buildings as the eye can possibly take in at one time from any situation. In order to this, we must suppose the eye to be removed a considerable height above the ground, and to be placed as it were in the air, so as to look down into the building like a bird that is flying. In representations of this kind, the higher the horizontal line is placed, the more of the fortification will be seen, and vice versa.

_Perceptive Machine_ is an instrument by which any person, without the help of the rules of art, may delineate the true perspective figures of objects. Mr Fergusson has described a machine of this sort of which he ascribes the invention to Dr Bevis.

Fig. 4. of Plate CCCLXXXVII. is a plane of this machine, and fig. 5. is a representation of it when made use of in drawing distant objects in perspective.

In fig. 4. _a b e f_ is a oblong square board, represented by _ABEF_ in fig. 5. _x y_ and _X Y_ are two hinges on which the part _c l d_ (CLD) is moveable. This parts consists of two arches or portions of circles _c m l_ (CML) and _d n l_ (DNL) joined together at the top _l_ (L), and at bottom to the cross bar _d e_ (DC), to which one part of each hinge is fixed, and the other part to a flat board, half the length of the board _a b e f_ (ABEF), and glued to its uppermost side. The centre of the arch _c m l_ is at _d_, and the centre of the arch _d n l_ is at _e_.

On the outer side of the arch _d n l_ is a sliding piece _n_ (much like the nut of the quadrant of altitude belonging to a common globe), which may be moved to any part of the arch between _d_ and _l_; and there is such another slider _o_ on the arch _c m l_, which may be fitted to any part between _e_ and _l_. A thread _e p n_ (CPN) is stretched tight from the centre _c_ (C) to the slider _n_ (N), and such another thread _e q_ is stretched from the centre _d_ (D) to the slider _o_ (O); the ends of the threads being fastened to these centres and sliders.

Now it is plain, that by moving these sliders on their respective arches, the intersecion _p_ (P) of the threads may be brought to any point of the open space within the arches.—In the groove _k_ (K) is a straight sliding bar _l_ (1), which may be drawn further out, or pushed further in at pleasure.

To the outer end of this bar _l_ (fig. 5.) is fixed the upright piece _H Z_, in which is a groove for receiving the sliding piece _Q_. In this slider is a small hole _r_ for the eye to look through, in using the machine; and there is a long slit in _H Z_, to let the hole _r_ be seen through when the eye is placed behind it at any height of the hole above the level of the bar _l_.

_How to delineate the perspective figure of any distant objects, or objects, by means of this machine._

Suppose you wanted to delineate a perspective representation of the house _g r p_ (which we must imagine to be a great way off without the limits of the plate), place the machine on a ready flat board, with the end _E F_ of the horizontal board _ABEF_ toward the house, so that when the Gothic-like arch _ABEF_ is set upright, the middle part of the open space (about _P_ within it may be even with the house when you place your eye at _Z_ and look at the house through the small hole _r_. Then fix the corners of a square piece of paper with four wafers on the surface of that half of the horizontal board which is near to the house; and all is ready for drawing.

Set the arch upright, as in the figure; which it will be when it comes to the perpendicular side _r_ of the upright piece _l_ fixed to the horizontal board behind _D_. Then place your eye at _Z_, and look through the hole _r_ at any point of the house, as _q_, and move the sliders _N_ and _O_ till you bring the intersection of the threads at _P_ directly between your eye and the point _q_; then put down the arch flat upon the paper on the board, as at _ST_, and the intersection of the threads will be at _W_. Mark the point _W_ on the paper with the dot of a black lead pencil, and set the arch upright again as before: then look through the hole _r_, and move the sliders _N_ and _O_ till the intersection of the threads comes between your eye and any other point of the house, as _a_; then put down the arch again to the paper, and make a pencil mark thereon at the intersection of the threads, and draw a line from that mark to the former one at _W_; which line will be a true perspective representation of the corner _p q_ of the house.

Proceed in the same manner, by bringing the intersection of the threads successively between your eye and other points of the outlines of the house, as _r s_ &c. and put down the arch to mark the like points on the paper, at the intersection of the threads: then connect these points by straight lines, which will be the perspective outlines of the house. In like manner find points for the corners of the door and windows, top of the house, chimneys, &c. and draw the finishing lines from point to point; then shade the whole, making the lights and shades as you see them on the house itself, and you will have a true perspective figure of it.—

_Great care must be taken, during the whole time, that_
Perspicuity, properly signifies the property which any thing has of being easily seen; hence it is generally applied to such writings or discourses as are easily understood.

Perspicuity, in composition. See Oratory, p. 43.

Perth, a county of Scotland, including Montech, Braithibin, Athol, Stratherne, part of Gowrie, and Perth Proper; is bounded by Badenoch and Lochabar on the north and north west; by Mar on the north-east; by Argyle and Lennox on the west and south-west; having Clackmannanshire, part of Stirling-shire, and the Forth to the south; the shires of Kinroofs and Fife to the south east, and Angus to the east. It extends above 70 miles in length, and near 60 at its greatest breadth, exhibiting a variety of Highlands and Lowlands; mountains, hills, dales, and straths, diversified with pasture-grounds, corn fields, and meadows; rivers, lakes, thores, waterfalls, plantations, and closeries, towns, villages, and a great number of elegant feats, beautifully situate, belonging to noblemen and gentlemen. The chief rivers of Perthshire are the Tay, the Teith, and the Erne, besides a great number of subordinate streams. The river Teith is famous for its salmon-fishery, and its steep cataract, near the Blair of Drummond, the noise of which is so loud, as to deafen those who approach it. The river Erne rises from Loch Erne, a lake seven miles long, in the mountainous country of Stratherne; this river, after a course of 34 miles from west to east, during which it receives many streams and rivulets, falls into the Tay at Abernethy.

Freetone, lead, iron, and copper ores, with some lapis calaminaris, are found in different parts of Perthshire. The soil, being generally rich and well manured, produces excellent wheat, and all kinds of grain. The hilly country abounds with pasture for the black cattle, horses, sheep, goats, and deer. The heaths, woods, and forests, are stored with variety of game; the rivers teem with salmon and trout; the gardens and orchards, are stored with all kinds of herbs, roots, apples, pears, cherries, plums, and almost every species of fruit found in South Britain. The houses and towns, even of the commonalty, are neat and decent; and every peasant can produce a good quantity of linen, and great store of blankets, made in his own family. Indeed, this is the case through all the Lowlands of Scotland. Flax is reared by every husbandman; and being dressed at home, is spun by the females of his family into thread for linen; this is woven by country weavers, of whom there is a great number through all the Low Country, and afterwards bleached or whitened by the good-wife and her servants; so that the whole is made fit for use at a very small expense. They likewise wash, card, spin, and weave their wool into tartan for plaids, kerseys, and coarse stuff-cloth, for common wearing, besides great part of which is knitt into caps, stockings, and mitts. Plaids, made of the finest worsted, are worn either plain or variegated, as veils, by women of the lower, and even of the middle rank; nay, some years ago, ladies of fashion wore flikken plaids with an undress; this

**PERSPIRATION, in medicine, the evacuation of the juices of the body through the pores of the skin. Perpiration is distinguished into sensible and insensible; and here sensible perpiration is the name with sweating, and insensible perpiration that which Perspicuity escapes the notice of the senses; and this last is the idea affixed to the word perspiration when used alone.**
Mr Camden was too good a courtier to speak.

The Lowlanders of Perthshire are civilized, hospitable, and industrious: the commerce of the country consists chiefly in corn, linen, and black cattle; there are, moreover, some merchants who trade to foreign countries.—For an account of the different divisions of this country above-mentioned, see the articles as they occur in the order of the alphabet.

PERTH, the capital of the county of that name, is an agreeable, populous town, situated 20 miles within land, on the south bank of the river Tay. It was otherwise called St John’s, from a church dedicated to St John, as the patron of the place. It is a royal borough, second in dignity to the metropolis, the seat of a large prebendary, and gave the title of Earl to the family of Drummond, which is now forfeited. James Drummond, 4th Earl, was created Duke of Perth by James II. for adhering to whose interests he was outlawed. His two grandsons were attainted 1651, created Lord Ruthven: but the honour, on the death of his son David in 1659, was restored to his family. By James’s known hatred to the Lowings, towards the southern end of the town of Perth by James II. for adhering to the family of Lyon.

North-eastward from Perth to Bridge of Strathmore, one of the most fertile districts in Scotland, which gives the title of Earl to the noble family of Lyon.

The castle of Perth stood on the red bridge, which terminated the narrow street called Skinner-gate. At the end of the Castle-street another narrow street leads west to the Blak-friers called Cowper-row, where the Curfew bell was. The streets of Perth before James II. were crown’d at Scone, and refited at Perth as the metropolis of the nation. James refited and was educated in the castle of Edinburgh, and was crowned there 1437. The parliaments and courts of justice were removed from Perth to Edinburgh, but Perth kept its priority till 1742.

The church in which John Knox harangued is still standing, and is now divided into three; named the east, the middle, and the west kirk. The east kirk was lately very handomely modernized within. There is an old hospital, a considerable building, the foundling of which is ascribed to James VI. The town is thus vis., the eastern end of the High-street. A monastery of Carthusians was here established by King James I. of Scotland, who left his life on the very spot by the treachery of Athol and his accomplices. The king was buried in a very stately monument in this place, which was called monasterium valtis virtutis, one of the most magnificent buildings in the kingdom, which with the rest was destroyed by the populace. James VI. created George Hay commenda-
The city of Perth was once the capital of the kingdom, and was completed at the expense of King Robert. It is built, now greatly decayed. The royal boroughs of Perth, St. Andrews, and the city of Dunkeld, are truly a noble river. It flows through the large river of Tummel. Here it bends to the north, and its waters are diffused into the famous Loch Tay, which flows hither by a more direct line, and receives several small rills. Soon after, it discharges itself into the ocean, Perth is advantageously situated. A person acquainted with the general character of great rivers, and with their influence in determining the aspect and fertility of the districts through which they pass, might readily without farther knowledge of the local circumstances than what is conveyed in this account of the course of the Tay, and of the situation of Perth upon it, conclude the city to be amid delightful scenery, and to enjoy all the advantages which natural circumstances afford, for the promotion of trade and industry.”

For Pertinax, the emperor after the death of Commodus, he was descended of a mean family; and like his father, who was either a slave or the son of a manumitted slave, he for some time followed the employment of drying wood and making charcoal. His poverty did not, however, prevent him from receiving a liberal education.

The trade of Perth is considerable. It exports annually 150,000 L. worth of linen, from 24,000 to 30,000 bolls of wheat and barley to London and Edinburgh, and a very large quantity of cured salmon. That fish is taken there in vast abundance; 30,000 have been caught in one morning; weighing one with another, 16 pounds; the whole capture 48,000 pounds. The fisheries amount to considerably upwards of 3000 L. per annum. Salmon come up this river in May and June. See Pear's W. Long. 3. 27. N. Lat. 56. 22.

Pertinax, the emperor after the death of Commodus, was an illustrious Roman emperor after the death of Commodus. He was descended of a mean family; and like his father, who was either a slave or the son of a manumitted slave, he for some time followed the employment of drying wood and making charcoal. His poverty did not, however, prevent him from receiving a liberal education. For some time he was employed in teaching a number of pupils the Greek and the Roman languages in Egypt.

The rents of the fisheries amount to considerably upwards of 3000 L. per annum. Smelts come up this river in May and June. See Pear's W. Long. 3. 27. N. Lat. 56. 22.
Pertinax was taken prisoner on the plea of old age and increasing infirmities, did not prevent his being called an emperor and Augustus. He complied with reluctance; but his meekness, his economy, and popularity, convinced the Senate and the people of the prudence and the justice of their choice. He forbade his name to be inscribed on such places or effigies as were part of the imperial domains, and affirmed that they belonged not to him but to the public. He melted all the silver statues which had been raised to his predecessor, and he exposed to sale all his conculines, horses, arms, and all the instruments of his pleasure and extravagance. With the money raised from these relics he enriched the empire, and was enabled to subsidize all the taxes which Commodus had laid on the rivers, ports, and highways, throughout the empire. These patriotic actions gained him the affection of the worthy and most discerning of his subjects; but the extravagant, luxurious, and vicious, raised their clamour against him; and when the emperor attempted to introduce among the praetorian guards such discipline as was absolutely necessary, to preserve the peace and tranquility of Rome, the flames of rebellion were kindled, and the minds of the soldiers totally alienated. Pertinax was apprized of their mutinying, but he refused to fly at the hour of danger. He learned the advice of such of his friends as wished him to withdraw from the impending storm: and he unexpectedly appeared before the ferous troops, and without fear or concern boldly asked them, whether they were bound by duty to defend the person of their prince and emperor, or come to betray him and to shed his blood? His undaunted courage and intrepidity would have had the defined effect, and the soldiers had begun to retire when one of the most ferious of them advanced and darted his javelin at the emperor's breast, exclaiming, The soldiers fend you this. The respect instantly followed the example; and Pertinax muffi: g up his head, and calling upon Jupiter to avenge his death, remained unmoved, and was immediately dispatched. His head was cut off and carried upon the point of a spear in triumph to the camp. This abominable murder happened in the 103d year of the Christian era.

It was no sooner known that Pertinax had been murdered, than the enraged populace flockt from all quarters of the city; and uttering dreadful menaces against the authors of his death, ran up and down the streets in quest of them. The senators were more less concerned for his death than the people; the more, because they were now convinced, that the soldiers would suffer none to reign but tyrants. However, as they had more to lose than the common people, they did not offer to revenge his death; but either shut themselves up in their own houses, or in those of the followers of their acquaintance, thinking themselves the more safe. Such was the unfortuate and much-lamented end of Publius Helvius Pertinax, after he had lived 66 years 7 months and 26 or 28 days: and reigned, according to Dio Cassius, 87 days, that is, from the 1st of January to the 28th of Mar.h. His body, together with his head, was interred with great pomp by Didius Julianus, his successor, in the burying place of his wife's family. The emperor Septimius Severus, with the title of emperor, assumed the name of Pertinax, which he knew would above any thing else recommend him to the army in Illyricum; and to the Roman people. He punished with great severity all those who had been accessory to his death, disband ed the praetorian guards, honoured his memory with a most magnificent funeral, at which was carried the effigies of the deceased prince, pronounced his panegyric, and caused him to be ranked in the number of the gods, appointing the son chief-priest to his father. The day of his accension to the empire was yearly celebrated with the Circensian games; and his birth-day for many years after, with other sports. He performed great things, says Herodian, during his short administration, and would have restored the empire to its former lustre, had he been indulged with a longer reign.

PERTINENT OF LANDS, in Scots law. See Law, No. clvii. 6 p. 670.

PERU, a country of South America, is bounded on the north by Popayan, on the east by Amazonia, on the south by Chili, and on the west by the Pacific ocean; extending from 1° 40' north to 26° 10' south latitude, and between 56° and 81° west longitude from Greenwich; being about 1800 miles in length, but its greatest breadth does not much exceed 390.

This country was discovered by the Spaniards; and the first intelligence they had of it was on the following occasion. Nunez de Balboa having sailed to the government of the small colony at Santa Maria in Darien by the suffrages of his companions, was very defirous of having that authority confirmed by the court of Spain. For this purpose he endeavoured to recommend himself to the Spanish ministry by some important service; that is, by extorting from the Indians as much gold and silver as he could. He therefore made frequent inroads into the adjacent country, subdued several of the caciques or pretty princes, and collected a considerable quantity of gold. In one of these expeditions, the Spaniards contended so violently about the division of some gold which they had taken, that they were on the point of coming to blows with one another. A young cacique who was present, astonished at such contention about a thing of which he knew not the value, tumbled the gold out of the balance with indignation, and turning to the Spaniards, told them, that since they valued gold so highly, he would conduct them to a country where the most common utensils were made of that metal. The Spaniards eagerly caught at this hint; and upon further questioning the cacique, were informed, that at the distance of six days' journey, towards the south, from the place where they were at that time, they should discover another ocean, near which this desirable country was situated; but if they intended to attack that powerful state, they must assemble a much greater number of forces than had hitherto appeared on the continent.

Balboa was transported at the news. He immediately concluded, that the ocean mentioned by the cacique was that which Columbus had so long sought for in vain, and that the rich territory described to him must be part of the East Indies. He was therefore impatient till he should arrive at that happy country, in comparison with the discovery of which all former exploits almost vanished into nothing. In order therefore to procure a force sufficient to ensure face of
in his enterprise, he first secured the friendship of the neighbouring caciques, and then dispatched some of his officers to Hispaniola, with a large quantity of gold as a proof of his pacific intentions, and an earnest of what he expected. By this means he secured the friendship of the governor, and procured a considerable reinforcement. But though he now imagined himself sufficiently strong to attempt the discovery, there were still prodigious difficulties to be surmounted.

This isthmus of Darien, though not above 60 miles in breadth, has a chain of lofty mountains running through its whole extent. Being situated between two vast oceans, the Atlantic and Pacific, the climate is excessively moist, in some places; that it rains for two thirds of the year. In consequence of this the valleys are marshy, and so frequently overflowed, that the inhabitants find it necessary in some places to build their houses upon trees, in order to be elevated from the damp soil, and the odious reptiles engendered in the waters. There are also many large rivers very difficult to be crossed; and as the country at that time was only inhabited by a few wandering savages, the enterprise of Balboa was looked upon as the most difficult that had been undertaken by any Spanish adventurer.

On this arduous task Balboa set out on the 1st day of September 1513, at the time that the periodical rains began to abate. He had only 190 Spaniards along with him; but all of them were hardy veterans, inured to the climate of America, and very much attached to their leader. A thousand Indians attended in order to carry their provvisions and other necessaries; and they had along with them some fierce dogs to terrify the natives of America.

Balboa proceeded by sea, and without difficulty, to the territories of a cacique whose friendship he had gained; but as soon as he began to advance into the interior parts of the country, he met with all the difficulties above-mentioned. Some of the caciques also, at his approach, fled with all their people to the mountains, carrying off or destroying whatever could afford subsistence to an army. Others collected their force in order to oppose him; however, Balboa continued unmoved in spite of all difficulties; and at last, after a most painful journey of 25 days, he arrived at the South Sea, when with the most extravagant transports of joy, he went into it up to the middle, and took possession of the ocean in his master's name, vowing to defend it against all the enemies of Spain.

That part of the South Sea which Balboa now discovered, he called the Gulf of St Michael; which name it still retains, and is situated to the east of Panama. From some of the neighbouring caciques he extorted provisions and gold by force; others sent him presents voluntarily; and he had the satisfaction to hear, that the adjacent coasts abounded with pearl-oysters. The inhabitants were also unanimous in declaring, that there was to the southward a very rich and populous country where the people had tame animals, which they endeavoured to describe to him, meaning the Peruvian sheep. But however impatient he might be to visit this empire, he considered it as highly improper to venture thither with a handful of men exhausted by labour and disease. He therefore led back his followers to Santa Maria, in order to refresh them after their fatigues; and from thence he sent an account to the court of Spain of the important discovery he had made, demanding a reinforcement of 1000 men in order to conquer the country he had newly discovered. But here his hopes were all blasted at once.

The king indeed determined to prosecute the discovery, but refused to continue Balboa in his government, appointing Pedrarias Davila in his stead, and giving him the command of 15 stout vessels, with 1200 soldiers, to ensure his success.

Balboa, though much mortified by his disgrace, submitted to the king's pleasure without repining. It was not long, however, before he met with an additional misfortune; the new governor tried him for some pretended irregularities committed before his arrival, and fined him of almost all he was worth. In the mean time the Spaniards, paying no regard to the treaties concluded by Balboa with the Indians, plundered and destroyed all indiscriminately, infomuch that the whole country, from the gulf of Darien to the like Nicaragua, was desolated. The new comers had also arrived at the most unlucky time of the year, namely, about the middle of the wet season, when the excessive rains produced the most violent and fatal diseases. To this was joined an extreme scarcity of provisions; so that in the space of a month above 600 Spaniards perished in the utmost misery.

Balboa failed not to send violent remonstrances to Spain against the conduct of the new governor; and he, on the other hand, accused his antagonist of having deceived the king by false accounts of the country, and magnifying his own exploits beyond measure. At last the king, sensible of his error in superfluously promoting Balboa, appointed him adelantado, or lieutenant-governor of the countries on the South Sea, with very extensive privileges and authority; enjoining Pedrarias to support him in all his enterprises, and to confide with him in everything which he himself undertook. It was impossible however, to extinguish the envy of Pedrarias; and therefore, though a reconciliation took place in appearance, even to far, that Pedrarias agreed to give his daughter in marriage to Balboa, yet he soon after had him condemned and executed on preference of disloyalty, and an intention to revolt from the to death.

On the death of Balboa, the thoughts of conquering Peru were for a time laid aside; however, it still remained an object of desire to all the Spanish adventurers in America. Accordingly, several armaments were fitted out with a design to explore and take possession of the countries to the east of Panama; but, either through the difficulties which attended the undertaking itself, or the bad conduct of the adventurers, all of them proved unsuccessful, until at last it became a general opinion, that Balboa's scheme had been entirely visionary.

Still, however, there were three persons settled at A new enterprise of Spain on the common opinion made no little impression, that they determined to go in quest of this country, looked upon to be chimerical by the generality of their neighbours. Their names were Francisco Pizarro, Diego de Almagro, and Hernando Luque. Pizarro and Almagro were soldiers of fortune, and Luque was an ecclesiastic, who acted both as priest and schoolmaster at Panama. Their confederacy was authorized by
by Pedrarius governor of Panama; and each engaged to employ his whole fortune in the adventure. Pizarro, being the least wealthy of the three, engaged to take upon himself the greatest share of the fatigue and danger, and to command in person the armament which was to go first upon the discovery. Almagro offered to conduct the supplies of provisions and reinforcement of troops which might be necessary; and Luque was to remain at Panama, in order to negotiate with the governor, and to superintend whatever was carrying on for the general interest.

In 1524, Pizarro set sail from Panama with a single vessel of small burden, and 12 men; and so little was he or his countrymen at that time acquainted with the climate of America, that the most improper season of the whole year was chosen for his departure; the periodical winds, which were then set in, being directly opposite to the course which he proposed to steer. The consequence of this was, that after beating about for 70 days, with much danger and fatigue, he had advanced scarce as far to the south-east as a skillful navigator will now make in three days. He touched at several places of Terra Firma; but finding that country exceedingly inhospitable and unhealthy, he was obliged to retire to Chuchama, opposite to the Pearl Islands, where he hoped to receive some reinforcements from Panama. Here he was found by Almagro, who had set out in quest of him with a reinforcement of 70 men, and had suffered difficulties very much resembling those of Pizarro himself. In particular, he had lost an eye in a combat with the Indians. However, he had advanced as far as the river of St Juan in the province of Popayan, where the country showing a better aspect, and the inhabitants more friendly, our projector again began to indulge themselves in hopes, and determined by no means to abandon their scheme.

Almagro returned to Panama, in hopes of recruiting their scattered troops. But the bad accounts of the service gave his countrymen such an unfavourable idea of it, that Almagro could levy no more than 80 men, and these with great difficulty. slender as this reinforcement was, however, the adventurers felt happy in renewing their enterprise. The difficulties and disappointments they met with in this new attempt, were scarcely inferior to those they had already experienced, when part of the armament at last reached the bay of St Matthew on the coast of Quiro, and landed at Tacames, to the south of the river of Emeralds, where they met with a more fertile and campagna country than any they had yet seen; the natives also were more civilized, and clothed in garments of cotton or woolen stuff, adorned with trinkets of gold and silver. But notwithstanding these favourable appearances, Pizarro did not think fit to attack such a powerful empire with a handful of followers already exhausted; and therefore retired to a small island called Gallo, with part of the troops; from whence he dispatched Almagro to Panama, in hopes of obtaining a reinforcement.

The reception which Almagro met with was by no means agreeable. Some of the adventurers had informed their friends of the many dangers and losses which they had sustained; which not only disheartened people from engaging in the service, but weighed so much with Pedro de los Ruis, the succesor of Pedra-
not only in honour of the sun, but of their first Inca, Manco Capac, and Coya Mama Oclolo, his wife and sister, whom the Incas considered as their first parents, descended immediately from the sun, and sent by him into the world to reform and polt his kind. At this festival, all the viceroys, generals, governors, and nobility, were assembled at the capital city of Cuzco; and the emperor, or Inca, officiated in person as high-priest; though on other occasions the erlic-dotal function was discharged by the regular pontiff, who was usually either the uncle or brother of the Inca.

The morning of the festival being come, the Inca, accompanied by his near relations, drawn up in order according to their seniority, went barefoot in procession, at break of day, to the market-place, where they remained looking attentively towards the east in expectation of the rising sun. The luminary no sooner appeared, than they fell prostrate on their faces in the most profound veneration, and universally acknowledged it to be their god and father.

The vassal princes, and nobility, that were not of the blood royal, assembled in another square, and performed the like ceremony. Out of a large flock of sheep the priests then chose a black lamb, which they offered in sacrifice, first turning its head towards the east. From the entrails of the victim, on this occasion, they superstitiously drew prognostics relating to peace and war, and other public events.

That the Peruvians believed in the immortality of the soul, appears from the practice of the Incas, who constantly inclosed to the people, that on leaving this world, they should enter into a state of happiness provided for them by their god and father the sun.

Before the arrival of the Spaniards in America, the Peruvians were acquainted with some points of astronomy. They had observed the various motions of the planet Venus, and the different phases of the moon. The common people divided the year only by the seasons; but the Incas who had discovered the annual revolution of the sun, marked out the summer and winter solstices by high towers, which they erected on the east and west of the city of Cuzco. When the sun came to rise directly opposite to four of those towers, on the east side of the city, and to set against the west of the city, it was then the summer and winter solstices; and in like manner, when it rose and set against the other towers, it was the winter solstice. They had also erected marble pillars in the great square before the temple of the sun, by which they observed the equinoxes. This observation was made under the equinox, when the sun being directly vertical, the pillars cast no shade. At these times they crowned the pillars with garlands of flowers and adorifere herbs, and celebrating a festival, offered to their adored luminary rich presents of gold and precious stones.

They distinguished the months by the moon, and their weeks were called quarters of the moon; but the days of the week they marked only by the ordinal numbers, as first, second, &c. They were also informed at the eclipses of the sun and moon. When the former hid his face, they concluded it was on account of their sins, imagining that this phenomenon...
PER

non pretended famine, war, and pestilence, or some other terrible calamity. In a similar fate of the moon, they apprehended that she was sick, and when totally obscured, that she was dying. At this alarming crisis they sounded their trumpets, and endeavoured by every kind of noise to rouse the lunar planet from her supposed lethargy; teaching their children to cry out, and call upon mama quilla, or "mother moon," that she would not die and leave them to perish.

They made no predictions from any of the stars, but considered dreams, and the entrails of beasts which they offered in sacrifice, as instructive objects of divination. When they saw the fun set, they imagined that he plunged into the ocean, to appear next morning in the east.

Amidst a people wholly void of letters, the speculative essays of the understanding must have been very rude and imperfect. They had, however, among them amenas, or philosophers, who delivered moral precepts, and likewise cultivated poetry. Comedies and tragedies composed by those bards were acted on their festivals before the king and the royal family, the performers being the great men of the court, and the principal officers of the army. The amenas also composed songs and ballads; but if we may judge from the rudeness of the music with which they are said to have been accompanied, they were far from being agreeable to a polished ear.

That the Peruvians were not acquainted with painting and statuary, appears from the furniture and ornaments of their temples and palaces; but in all the implements of mechanic arts they were extremely deficient. Though many goldsmiths were constantly employed, they had never invented an anvil of any metal, but in its head made use of a hard flone. They beat their plate with round pieces of copper in place of hammers; neither had they any files or graving tools. Instead of bellows for melting their metals, they used copper pipes, of a yard long, almost of the form of a trumpet. Having no tongues to take their heated metal out of the fire, they made use of a flick or copper bar. The carpenters had no other tools than hatchets made of copper or flint; nor had they learned the use of iron; though the country affords mines of that metal. Instead of nails, they fastened their timber with cords or the rough twigs of trees. A thorn, or a small bone, served them for a needle; and instead of thread, the finewool of animals, or the spines of some plant. Their knives were made of flint or copper.

When the Spaniards first visited this country, they found it agitated by a civil war. Huana Capac, the 12th monarch from the founder of the state, was feated on the throne; who is represented as a prince no less conspicuous for his abilities in war than for his pacific virtues. By him the kingdom of Quito was subdued, which almost doubled the extent of the dominions and power of the Peruvian empire. Notwithstanding the ancient and fundamental law against polluting the blood of the Inca with any foreign alliance, Huana married the daughter of the conquered monarch, by whom he had a son named Atabalipa, commonly written Achibalipa, to whom, at his death in 1529, he left the kingdom of Quito, beseeving the rest of his dominions upon Huascar his eldest son by a mother of the royal race. This produced a civil war, in which Atabalipa proved victorious, and afterwards attempted to secure himself on the throne by putting to death all the descendants of Manco Capac, styled the children of the Sun, whom he could seize either by force or stratagem; however, from a political motive, he spared the life of his rival Huascar, who had the misfortune to be taken prisoner in an engagement, that, by suffering out orders in his name, he might more easily establish his own authority, and cover the illegality of his birth.

This contest had so much engaged the attention of the Peruvians, that they never once attempted to check the progress of the Spaniards. It was some time, however, before Pizarro was informed of this contest, so much in his favour. The first intelligence which he received of it was a message from Huascar, asking his assistance against Atabalipa, whom he represented as a rebel and an usurper. Pizarro perceived the importance of the intelligence, and therefore determined to push forward, while intelligence discord put it out of the power of the Peruvians to attack him with their whole force. Being obliged to divide his troops, in order to leave a garrison in St Michael, which might serve for a place of retreat in case of a disaster, he began his march with only 62 horsemen and 102 foot-soldiers, 20 of whom were armed with cross-bows, and only three with muskets. He directed his course towards Caxamala, a small town at the distance of 12 days' march from St Michael, where Atabalipa was encamped with a considerable body of troops. Before he had proceeded far, an officer dispatched by the Inca met him with a valuable present from that prince, accompanied with a promise of his alliance, and his assurance of a friendly reception at Caxamala. Pizarro, according to the usual artifice of his countrymen in America, pretended to come as the ambassador of a very powerful monarch and declared that he was now advancing with intention to offer Atabalipa his aid against those enemies who disputed his title to the throne.

As the object of the Spaniards in entering their country was altogether incomprehensible to the Peruvians, they had formed various conjectures concerning it, without being able to decide whether they should consider their new guests as beings of a superior nature, who had visited them from some beneficent motive, or as formidable avengers of their crimes, and enemies to their repose and liberty. The continual professions of the Spaniards, that they came to enlighten them with the knowledge of truth, and lead them in the way of happiness, favoured the former opinion; the outrages which they committed, their rapaciousness and cruelty, were awful confirmations of the latter. While in this state of uncertainty, Pizarro's declaration of his pacific intentions to far removed all the Inca's fears, that he determined to give him a friendly reception. In consequence of this resolution, the Spaniards were allowed to march in tranquility across the sandy desert between St Michael and Motupé, where the most feasible effort of an enemy, added to the unavoidable difficulties which they suffered in passing through that uncomfortable region, must have proved fatal to them. From Motupé they advanced towards the mountains which encompass the low country of Peru, and passed
ed through a defile so narrow and inaccessible, that a few men might have defended it against a numerous army. But were likewise, from the fame inconsiderate credulity of the Incas, the Spaniards met with no opposition, and took quiet possession of a fort erected for the security of that important station. As they now approached near to Caxamalca, Atabali pa renewed his professions of friendship; and, as an evidence of his sincerity, sent them presents of greater value than the former.

On entering Caxamalca, Pizarro took possession of a large court, on one side of which was a house which the Spanish historians call a palace of the Incas, and on the other a temple of the sun, the whole surrounded with a strong rampart or wall of earth. When he had posted his troops in this advantageous station, he dispatched Hernando Soto, and his brother Ferdinand, to the camp of Atabali pa, which was about a league distant from the town. He instructed them to confirm the declaration which he had formerly made of his pacific disposition, and to deliberate an interview with the Inca, that he might explain more fully the intention of the Spaniards in visiting their country. They were treated with all the respectful hospitality usual among the Peruvians in the reception of their most cordial friends, and Atabali pa promised to visit the Spanish commander next day in his quarters. The decent deportment of the Peruvian monarch, the order of his court, and the reverence with which his subjects approached his person and obeyed his commands, all united to excite the Spaniards, who had never met in America with anything more dignified than the petty caciques of a barbarous tribe. But their eyes were still more powerfully attracted by the vast profusion of wealth which they observed in the Inca's camp. The rich ornaments worn by him and his attendants, the vessels of gold and silver in which the repast offered to them was served up, the multitude of utensils of every kind formed of those precious metals, opened prospects far exceeding any idea of opulence that a European of the 16th century could form.

On their return to Caxamalca, while their minds were yet warm with admiration and desire of the wealth which they had beheld, they gave such a description of it to their countrymen, as confirmed Pizarro in a resolution which he had already taken. From his own observation of American manners during his long services in the New World, as well as from the advantages which Cortes had derived from showing Montezuma, he knew of what consequence it was to have the Inca in his power. For this purpose, he formed a plan as daring as it was pernicious. Notwithstanding the character he had assumed of an ambassador from a powerful monarch, who courted an alliance with the Inca, and in violation of the repeated offers which he had made to him of his own friendship and affiance, he determined to avail himself of the unsuspicious simplicity with which Atabali pa relied on his professions, and to seize his person during the interview to which he had invited him. He prepared for the execution of his scheme with the same deliberate arrangement, and with as little compunction, as if it had reflected no disgrace on himself or his country. He divided his cavalry into three small squadrons, under the command of his brothers Ferdi-
he reigned by hereditary succession; and added, that he could not conceive how a foreign priest should pretend to dispose of territories which did not belong to him; that if such a preposterous grant had been made, he, who was the rightful possessor, refused to consent to it; that he had no inclination to renounce the religious institutions established by his ancestors; nor would he forsake the service of the sun, the immortal divinity whom he and his people revered, in order to worship the God of the Spaniards, who was subject to death; that with respect to other matters contained in his discourse, as he had never heard of them before, and did not now understand their meaning, he defined to know where he had learned things so extraordinary. "In this book," answered Valverde, reaching out to him his breviary. The Inca opened it eagerly; and turning over the leaves, lifted it to his ear: "This," says he, "is a silent; it tells me nothing," and threw it with disdain to the ground. The enraged monk, running towards his countrymen, cried out, "To arms, Chullians, to arms; the word of God is insulted; avenge this profanation on these impious dogs."

Pizarro, who during this long conference had with difficulty restrained his soldiers, eager to seize the rich spoils of which they had so far seen a view, immediately gave the signal of assault. At once the martial music struck up, the cannon and muskets began to thunder, the horse fell out fiercely to the charge; the infantry rushed on sword in hand. The Peruvians, astonished at the suddenness of an attack which they did not expect, and dismayed by the destructive effects of the fire-arms, and the irresistible impulsion of the cavalry, fled with universal consternation on every side, without attempting either to annoy the enemy or to defend themselves. Pizarro, at the head of his chosen band, advanced directly towards the Inca; and though his nobles crowded around him with efficacious zeal, and fell in numbers at his feet, while they cried one with another in facilitating their own lives, that they might cover the sacred person of their sovereign, the Spaniards soon penetrated to the royal seat; and Pizarro seizing the Inca by the arm dragged him to the ground, and carried him as a prisoner to his quarters. The view of the monarch increased the galling frowns of his followers. The Spaniards purified them towards every quarter, and, with deliberate and unrelenting barbarity, continued to slaughter wretched fugitives, who never once offered at resistance. The carnage did not cease until the close of day. Above 4000 Peruvians were killed. Not a single Spaniard fell, nor was one wounded but Pizarro himself, whose hand was slightly hurt by one of his own followers, while struggling eagerly to lay hold on the Inca.

The plunder taken on this occasion was immense, but the Spaniards were still unsatisfied; which being observed by the Inca, he endeavoured to apply himself to their ruling passion, avarice, in order to obtain his liberty; and therefore offered such a ransom as astonished them, even after all they knew concerning the opulence of the country. The apartment in which he was confined was 22 feet in length and 16 in breadth; and all this space he engaged to fill with vessels of gold as high as he could reach. This proposal was eagerly caught by Pizarro, and a line was drawn upon the walls to mark the stipulated height.

Atabalipa, charmed with the thoughts of liberty, immediately set about performing his part of the agreement, and dispatched messengers into all parts of the empire, in order to collect the immense quantity of gold which he had promised; and though the unfortunate monarch was now in the hands of his enemies, such was the veneration which his subjects had for him, that his orders were obeyed with as great alacrity as though he had been at full liberty; while he, in the mean time flattering himself with the hopes of being soon released, made no preparations for expelling the invaders from his dominions.

In a short time Pizarro received intelligence that Almagro was arrived at St. Michael with a reinforcement equal to the force he had with him. This was a matter of great joy to the Spaniards, and no small vexation to Atabalipa, who now considered his kingdom as in danger of being totally over-run by these strangers, whose force he neither knew, nor the means they had of transporting themselves. For this reason he determined to put his brother Huascar to death, lest he should join the strangers against him. To this he was the rather inclined, as he had got information that the captive prince had been making applications to them and had offered them, a much larger sum than what was stipulated for the Inca's ransom; and in consequence of this determination the unfortunate prince lost his life.

In the mean time the Indians daily arrived at Casamalca with vast quantities of treasure; the fight of which so much inflamed the Spaniards, that they insisted upon an immediate division; and this being complied with, there fell to the share of each horseman 8000 pesos, at that time not inferior to the value of as many pounds of silver in the present century, and half as much to each foot-soldier, Pizarro and his officers receiving shares proportional to their dignity. A fifth part was reserved for the emperor, together with some vessels of curious workmanship as a present. In consequence of this immense acquisition of wealth, many of the Spaniards became clamorous for their discharge; which was readily granted by their general, as well knowing that the display of their riches would not fail to allure adventurers more hardly, though less opulent, to his standard.

After this division of the spoil, Atabalipa was very importunate with Pizarro in order to recover his liberty; but the Spaniard, with unparalleled treachery and cruelty, had now determined to put him to death. To this he was urged by Almagro's soldiers, who thought they had received an equal share with the rest, were still unsatisfied. The Inca's ransom had not been completed; and they were apprehensive, that whatever sums might afterwards be brought in, the troops of Pizarro would appropriate them to themselves as part of that ransom. They insulted with Pizarro, therefore, to put him to death, that all the adventurers might for the future be on an equal footing. Accounts were likewise received that troops were assembling in the remote provinces of the empire, which Pizarro suspected to be done by the Inca's orders. These accounts were heightened by one Philippo an Indian interpreter, who had conceived a passion for one of the unhappy monarch's wives; and for that reason wished to have him put to death. Atabalipa himself,
two, had the misfortune to hasten his own ruin by his conceiving a contemptuous notion of Pizarro, which he had not the precaution to conceal. He had, since they were first discovered by him, admired the European arts of reading and writing, and wished much to know whether he should regard it as a natural or acquired talent. In order to determine this, he defined one of the folders who guarded him to write the name of God upon the nail of his thumb. This he showed to several Spaniards successively, asking its meaning; and, to his surprise, they all returned the same answer. At length Pizarro entered; and, on presenting it to him, he blushed, and was obliged to own his ignorance, which inspired the Inca with the contemptuous notion of him above mentioned.

In order, however, to give some show of justice to such a detestable action, and that he might be exempted from standing singly as the perpetrator, Pizarro resolved to accuse the Inca of some capital crime, and institute a court of judicature for the purpose of trying him. For this purpose, he appointed himself and Almagro, with two assistants, as judges, with full powers to acquit or condemn; an attorney-general was named to carry on the prosecution in the king's name; counsellors were chosen to assist the prisoner in his defence; and clerks were ordained to record the proceedings of court. Before this strange tribunal a charge was exhibited still more amazing. It consisted of various articles: that Atahalipa, though a bafillard, had dispossessed the lawful owner of the throne, and usurped the regal power; that he had put his brother and lawful sovereign to death; that he was an idolater, and had not only permitted, but commanded the offering up of human sacrifices; that he had a great number of concubines; that since his imprisonment, he had waited and embezzled the royal treasures, which now belonged of right to the conquerors; and that he had excited his subjects to take up arms against the Spaniards. On these heads of accusation they proceeded to try the sovereign of a great empire; over whom they had no jurisdiction. To all these charges the Inca pleaded not guilty. With respect to the death of his brother, he alleged, that the Spaniards could take no cognizance of the fact. With regard to the taxes which he had levied, and the wars he had carried on, they were nothing to the Spaniards; and as to the conspiracy against the Spaniards, he utterly denied it. He called heaven and earth to witness the integrity of his conduct, and how faithfully he had performed his engagements, and the perjury of his accusers. He desired to be sent over to Spain to take his trial before the emperor; but no regard was paid to his intreaties. He was condemned to be burnt alive; which cruel sentence was mitigated, as a great favour, to strangling; and the unhappy monarch was executed without mercy.

The death of the Inca was followed by a revolution in the Spanish affairs, who now became generally called. HIDEOUS cries were set up by his women as the funeral procession passed by their apartment; many offered to bury themselves alive with him; and on being hindered, strangled themselves out of grief and vexation. The whole town of Caxamalca was filled with lamentation, which quickly extended itself over the whole kingdom. Friends and enemies accused the Spaniards of inhumanity and treachery. Loads of gold that were coming to Caxamalca by order of the deceased Inca were now stopped; and the loss of the treasure was the first unfortunate consequence which the Spaniards felt from their late iniquitous conduct. The two factions of Indians united against Pizarro; and many of the Spaniards not only excused against the cruelty of the judges, but would even have mutilated, had not a sense of the impending danger kept them quiet. At Cuzco the friends of the emperor Huascar proclaimed Manco Capac the legitimate brother of the late Inca, determining to support him to the last against all the machinations of his enemies. Pizarro, in the mean time, set up Tapatapa, the son of Atahalipa, causing him to be treated with all the honours due to an emperor. Immediately he set out for Cuzco, the gaining of which was absolutely necessary for his design. An army of Indians occupied the pales, and refused to dispute his progress. The council, however, was soon decided; the Spanish cavalry bore down everything before them, and great numbers of Indians were slain. The conquerors gained a considerable booty; and Pizarro dispatched Almagro to reduce Cuzco, while he himself founded a new colony in the fruitful valley of Xaua; which, however, was not permanent, being afterwards removed to the place where Lima now stands.

While Pizarro was thus employed, another commander, named Ferdinand de Soto, was detached with 60 horse to make the best of his way to Cuzco, and clear the road for the march of the remainder of the army. He was opposed by a formidable collection of Indians, who had fortified themselves in order to defend a pass against him; for which reason, fearing lest his strength might be unequal, he sent a message to Pizarro, desiring that the Inca might join him, thinking that his presence would awe the Peruvians, and prevent the further effusion of blood; but his expectations were frustrated by the death of the Inca, which happened about this time; so that there was now a necessity for having recourse to arms; for as the Spaniards set up no person in his room, the title of Manco Capac was universally acknowledged.

In the mean time, a new supply of soldiers arriving from Spain, Benalcazar, governor of St Michael, undertook an expedition against Quito, where, according to the report of the natives, Atahalipa had left the greatest part of his treasure. He accomplished his purpose with very great difficulty, having a country covered with rocks and mountains to pass, and being opposed by large bodies of the natives. But when he got possession of the city, to his extreme mortification he found that the inhabitants had carried off all their gold and silver; for they were now acquainted with the ruling passion of the Spaniards, had taken care to disappoint it, by removing the treasures which they knew very well had been the cause of the expedition.

About the same time Alvarado governor of Guatimotoca invaded the province of Chile. In this expedition his troops endured such hardships, and suffered so much from the cold among the Andes, that a fifth of the men and all the horses died, and at the same time the rest were so much dispirited and emaciated, that they became quite unfit for service. What
was worth of all, when they had arrived at the end of their journey, they met with a body of Spaniards drawn up in hostile array to oppose them. There had been sent against him by Pizarro, who claimed Chili as part of his jurisdiction, and were now joined by Benalcazar, with the troops under his command. Alvarado, however, advanced boldly to attack them, on the interpolation of five moderate men in each party, the difference was accommodated. Alvarado engaged to return to his government, upon his being paid 100,000 pesos to depray the essence of his armament. However, most of his followers remained in the country, and enlisted in the service of Pizarro.

In the meantime Ferdinand Pizarro, the brother of the general, had landed in Spain, where he produced such immense quantities of gold and silver as astonished the court, even after all they had been of the wealth of their new discovered territories. The general's authority was confirmed to him with new powers and privileges, and the addition of 70 leagues extending along the coast, to the southward of the territory granted in his former patent. Almagro had the title of adelantado or governor conferred upon him, with jurisdiction over 200 leagues of country lying southward from the province allotted to Pizarro; he himself was made a knight of the order of St. Jago.

Of these transactions some accounts were received at Peru before the arrival of Ferdinand Pizarro himself; and no sooner did Almagro hear that he had obtained the royal grant of an independent government, than, pretending that Cuzco, the capital of all Peru, lay within his jurisdiction, he attempted to seize it. Pizarro was not less ready to oppose him, and a very dangerous civil war was about to take place, when the quarrel, was made up, on condition that Almagro should attempt the conquest of Chili; and if he did not find there an establishment equivalent to his expectations, Pizarro should yield up to him part of Peru.

By this reconciliation Pizarro was left at liberty to settle the internal policy of his province, which, though little qualified for a legislator, he accomplished, by dividing the country into various districts, appointing magistrates to preside in each, and establishing such regulations concerning the administration of justice, the royal revenue, &c., as occurred to him. The fact of government he removed from Cuzco to Lima, which he named Ciudad de los Reyes, and which name it still retains among the Spaniards in all legal and formal deeds. Its other name, Lima, is a corruption of Rima, the name of the valley in which the city stands.

In the mean time Almagro had set out on his expedition to Chili; the event of which has been related under the article Chili; and while he was thus employed, Pizarro encouraged some of his most distinguished officers to invade those provinces of the empire which had not yet been visited by the Spaniards. This he did with a view to keep them employed, and prevent tumults; but it was attended with very terrible consequences. No sooner did Manco Capac the Inca perceive the fecurity of the Spaniards in thus dividing their forces, than he seized the opportunity of making a vigorous effort to redress the wrongs of himself and his countrymen, and expel the invaders, who had tyrannized in such a cruel manner. Though strictly guarded by the Spaniards, he found means to communicate his intentions to the chief men of his nation, whom he joined in the year 1536, under pretence of celebrating a festival which he had obtained liberty from Pizarro to attend. Upon this the standard of war was immediately erected, and a most formidable army, according to the Spanish historians, of 200,000 men, collected. Many Spaniards were massacred in their habitations, and several detachments entirely cut off; and while this vast army laid siege to Cuzco, another formidable body invested Lima, and kept the governor closely shut up. The greatest effort, however, was made against Cuzco, which was defended by Pizarro and his two brothers, with only 170 men. The siege lasted nine months; many of the Spaniards were killed; among whom was Juan Pizarro, the general's brother, and the best beloved of them all. The remnant were reduced to the most desperate situation, when Almagro appeared suddenly in the neighborhood of Cuzco. He had received such accounts of the insurrection in Peru, as would at any rate have determined him to return to the assistance of Pizarro; but besides this, he had now received the royal patent, creating him governor of Chili, and deemed it certain beyond all contradiction, that Cuzco lay within his jurisdiction; for which reason he had hastened to prevent it from falling into the hands of the Peruvians. On his arrival his assistance was solicited by both parties. The Inca made many advantageous proposals, but at length despairing of obtaining any cordial union with a Spaniard, he attacked him in the night by surprise with a great body of chosen troops. But the Spanish soldiers and discipline prevailed against all the numbers of defeated their enemies; and the Peruvians were repulsed with such slaughter, that a great part of the remainder dispersed, and Almagro advanced to the gates of Cuzco without opposition. Pizarro's brothers took measures to oppose his entrance; but prudence for the present restrained both parties from entering into a civil war while they were surrounded with enemies; and therefore each leader endeavored to corrupt the followers of his antagonist. In this Almagro had the advantage, and so many of Pizarro's troops deserted the night, that Almagro was able to march towards the city, where he surprised the capitales and investing the houses where the two brothers were lodged, he compelled them, after an obstinate defence, to surrender at discretion; and Almagro's authority over Cuzco was immediately recognized as authentic.

In this fray only two or three persons were killed.

Civil war but matters soon began to wear a more serious aspect, between Francisco Pizarro, having dispersed the Peruvians who invested Lima, and received considerable reinforcements from other provinces, ordered 500 men, under the command of Alonso de Alvarado to march to Cuzco, in hopes of relieving his brothers, if they were not already cut off. They advanced to a small distance from the capital, before they knew that they had a more formidable enemy than the Indians to encounter. When they saw the Indians drawn up on the banks of a river to oppose them, they were greatly surprised; however, Alvarado, who wished rather to gain them than to fight, began with attempting to induce their leader. Alvarado could not by any means be gained over.
over; but being inferior in military skill, Almagro attacked him by surprise, entirely defeated and dispersed his army, taking himself and some of his principal officers prisoners.

This victory seemed decisive; and Almagro was advised to make it so by putting to death Gonzalo and Ferdinand Pizarro, Alvarado, and some others whom he could not hope to gain. This advice, however, he declined from motives of humanity, and a desire of making his adversary appear the aggressor. For these reasons, instead of marching directly against Pizarro, he retired quietly to Cuzco; which gave his adversary time to recollect himself from the disorder into which the news of so many disasters had thrown him. He began again to practise upon Almagro those arts which had before proved successful; and Almagro again suffered himself to be deceived by pretended offers of pacification. The negotiations for this purpose were protracted for several months; and while Almagro was employed in detecting and elucidating the fraudulent intentions of the governor, Gonzalo Pizarro and Alvarado found means to corrupt the soldiers who guarded them, and not only made their own escape, but persuaded 60 of Almagro's men to accompany them. There now remained only Ferdinand Pizarro in the hands of Almagro; and he was delivered by another act of treachery. The general proposed that all points of controversy should be submitted to the decision of their sovereign; and that Ferdinand Pizarro should be instantly set at liberty, and return to Spain, together with some other officers whom the general proposed to send over to show the justice of his claims. Though the intention of Pizarro by making this proposal was evident, Almagro was deceived by it, and released those whom Pizarro wanted: which he had no sooner done, than the latter threw off all disguises, and openly declared, that arms alone must now decide the matter between them. He therefore immediately set out for Cuzco with an army of 700 men, to which Almagro had only 500 to oppose. From the weakness of his forces, probably, Almagro did not attempt to guard some strong passes, through which Pizarro had to march, but waited patiently for his adversary in a plain open country.

In the meantime, Pizarro advanced without any obstruction from his enemy; and an engagement soon happened, in which Almagro was defeated and taken prisoner. The conquerors behaved with great cruelty, massacring a great number of officers, and treating Almagro himself with great severity. The Indians had assembled in great numbers to see the battle, with an intention to join the vanquished party; but were so much overawed by the Spaniards, that they retired quietly after the battle was over, and thus lost the only opportunity they ever had of expelling their tyrants.—Almagro, after having for some months languished in prison, was at length formally tried, and condemned to die by Pizarro. Notwithstanding his confummate bravery, for which he was remarkable, this hardy veteran could not bear the deliberate approach of death, but confounded to use intimacies to save his life. The Pizarrs, however, continued inflexible; and he was first strangled in prison, and then publicly beheaded. He left one son by an Indian woman, whom he appointed his successor, by virtue of a power granted him by the emperor.

As during these divisions all intercourse with Spain ceased, it was some time before the accounts of the civil war were received at court. The first intelligence was given by some of Almagro's soldiers, who had left America on the ruin of their cause; and they did not fail to represent the injustice and violence of Pizarro in the strongest colours, which strongly prejudiced the emperor against him. In a short time, however, Ferdinand Pizarro arrived, and endeavoured to give matter a new turn. The emperor was uncertain which of them he ought to believe; and therefore thought it necessary to send over some person with ample powers to inquire into the merits of the case, and to determine certainly who was in the wrong. If he found the governor still alive, he was to assume only the title of judge, in order to have the appearance of acting in concert with him; but if he was dead, the viceroy might then produce his commission appointing him Pizarro's successor in the government. This complaisance to Pizarro, however, proceeded more from a dread of his power than from any other thing; for in the mean time, his brother Ferdinand was arrested at Madrid, and confined to a prison, where he remained above 20 years. The person nominated to this important trust was Chiribogo Vaca de Castro.

While this gentleman was preparing for his voyage, Peru, now Pizarro, considering himself as the unrivalled master of the kingdom of Peru, proceeded to parcel out its territories among the conquerors, and had this division been made with any degree of impartiality, the extent of country which he had to bestow was sufficient to have gratified his friends, and to have gained his enemies. But Pizarro conducted this transaction, not with the equity and candour of a judge attentive to discover and to reward merit, but with the illiberal spirit of a party leader. Large districts, in parts of the country most cultivated and populous, were set apart as his own property, or granted to his brothers, his adherents, and favourites. To others, lots less valuable and inviting were allotted. The followers of Almagro, amongst whom were many of the original adventurers, to whose valour and perseverance Pizarro was indebted for his success, were totally excluded from any portion in those lands, towards the acquisition of which they had contributed so largely. As the vanity of every individual sets an immoderate value upon his own services, and the idea of each, concerning the remuneration due to them, rose gradually to a more exorbitant height, in proportion as their conquests extended; all who were disappointed in their expectations exclaimed loudly against the rapaciousness and partiality of the governor. The partisans of Almagro murmured in secret, and meditated revenge.

Rapid as the progress of the Spaniards in South America had been since Pizarro landed in Peru, their avidity of dominion was not yet satisfied. The officers to whom Ferdinand Pizarro gave the command of different detachments, penetrated into several new provinces; and though some of them were exposed to great hardships in the cold and barren regions of the Andes, and others suffered ditfrefs not inferior amid the woods and marshes of the plains, they made disco-
33

E. Peru.

planes and conquests which extended their knowledge of the country, as well as added to their power. Pedro de Valdivia re-affumed Almagro's scheme of invading Chili; and, notwithstanding the fortitude of the natives in defending their possessions, made such progress in the conquest of the country, that he founded the city of St Jago, and gave a beginning to the establishment of the Spanish dominion there. But of all the enterprises undertaken about this period, that of Gonzales Pizarro was the most remarkable. The governor, who seems to have resolved that no peril in Peru should possess any station of distinguished eminence or authority but those of his own family, had deprived Benalcazar, the conqueror of Quito, of his command in that kingdom, and appointed his brother Gonzales to take the government of it. He instructed him to attempt the discovery and conquest of the country to the eait of the Andes; which, according to the information of the Indians, abounded with cinnamon and other valuable spices. Gonzales, not inferior to any of his brothers in courage, and no less ambitious of acquiring distinction, eagerly engaged in this difficult service. He set out from Quito at the head of 340 soldiers, near one half of whom were horsemen, with 4000 Indians to carry their provisions. In forcing their way through the defiles, or over the ridges of the Andes, excelsof cold and fatigue, to neither of which they were accustomed, proved fatal to the greater part of the wretched attendants. The Spaniards, tho' more robust, and imured to a variety of climates, suffered considerably, and lost some men; but when they defended into the low country, their distress increased. During two months it rained incessantly, without any interval of fair weather long enough to dry their clothes. The vah plains upon which they were now entering, either altogether without inhabitants, or occupied by the rudest and least industrious tribes in the New World, yielded little subsistence. They could not advance a step but as they cut a road through woods, or made it through marshes. Such incessant toil, and continual scarcity of food, seem more than sufficient to have exhausted and dispirited any troops. But the fortitude and perseverance of the Spaniards in the 16th century were innumerable. Allured by frequent but false accounts of rich countries before them, they perished in struggling on, until they reached the banks of the Coca or Napo, one of the larger rivers whose waters pour into the Maragnon, and contribute to its grandeur. There, with infinite labour, they built a bark, which they expected would prove of great utility, both in conveying them over rivers, in procuring provisions, and in exploring the country. This was manned with 50 soldiers, under the command of Francis Orellana, the eldest in rank to Pizarro. The stream carried them down with such rapidity, that they were soon far ahead of their countrymen, who followed slowly and with difficulty by land.

At this distance from his commander, Orellana, a young man of an aspiring mind, began to fancy himself independent; and, transported with the predominant passion of the age, he formed the scheme of distinguishing himself as a discoverer, by following the course of the Maragnon until it joined the ocean, and by surveying the vah regions through which it flows. This scheme of Orellana's was as bold as it was treacherous. For, if he be chargeable with the guilt of having vio-

34

Orellana fails down the river Maragnon and defeats Pizarro.

lated his duty to his commander, and with having abandoned his fellow-soldiers in a pathless desert, where they had hardly any hopes of success, or even of safety, but what were founded on the service which they expected from the bark, his crime is, in some measure, balanced by the glory of having ventured upon a navigation of near 2000 leagues, through unknown nations, in a vessel halfly contructed with green timber, and by very unskilful hands, without provisions, without a compass, or a pilot. But his courage and alacrity supplied every defect. Committing himself fearlessly to the guidance of the stream, the Napo bore him along to the south, until he reached the great channel of the Maragnon. Turning with it towards the coast, he held on his course in that direction. He made frequent descents on both sides the river, sometimes leading by force of arms the provisions of the fierce savages seated on its banks, and sometimes procuring a supply of food by a friendly intercourse with more gentle tribes. After a long series of dangers, which he encountered with amazing fortitude, and of distresses which he supported with no less magnanimity, he reached the ocean, where new perils awaited him. These likewise surprised, and got safe to the Spanish settlement in the island Cubagua; from thence he failed to Spain. The vanity natural to travellers who visit regions unknown to the rest of mankind, and the art of an adventurer, solicitous to magnify his own merits, concurred in prompting him to mingle an extraordinary proportion of the marvellous in the narrative of his voyage. He pretended to have discovered nations so rich, that the roofs of their temples were covered with plates of gold; and described a republic of women so warlike and powerful, as to have extended their dominion over a considerable tract of the fertile plains which he had visited. Extravagant as those tales were, they gave rise to an opinion, that a region abounding with gold, distinguished by the name of El Dorado, and a community of Amazons, were to be found in this part of the New World; and such is the propensity of mankind to believe what is wonderful, that it has been flowly, and with difficulty, that reason and observation have exploded those fables. The voyage, however, even when stripped of every romantic embellishment, deserves to be recorded, not only as one of the most memorable occurrences in that adventurous age, but as the first event that led to any certain knowledge of those immense regions that stretch eastward from the Andes to the ocean.

No words can describe the confederation of Pizarro, when he did not find the bark at the confuence of the Napo and Maragnon, where he had ordered Orellana to wait for him. He would not allow himself to suffer that a man, whom he had entrusted with such an important command, should be so base and so unfeeling as to defeat him at such a juncture. But imputing his absence from the place of rendezvous to some unknown accident, he advanced above 50 leagues along the banks of the Maragnon, expecting every moment to see the bark appear with a supply of provisions. At length he came up with an officer whom Orellana had left to perish in the desert, because he had the courage, to renounce against his peridy. From him he learned the extent of Orellana's crime; and his followers perceived at once their own desperate situation, when deprived of their only resource. The spirit of the flout-
But, of heart veteran sunk within him; and all demanded to be led back instantly. Pizarro, though he affirmed an appearance of tranquility, did not oppose their inclination. But he was now 1200 miles from Quito; and in that long march the Spaniards encountered hardships greater than those they had endured in their progress outward, without the alluring hopes which then foothered and animated them under their sufferings. Hunger compelled them to feed on roots and berries, to eat all their dogs and horses, to devour the most loathsome reptiles, and even to gnaw the leather of their saddles and sword belts. Four thousand Indians, and 210 Spaniards, perished in this wild and disfurbous expedition, which continued near two years; and as 30 men were aboard the bark with Orellana, only 80 got back to Quito. These were naked like savages, and fo emaciated with famine, or worn out with fatigue, that they had more the appearance of spears than of men.

But, instead of returning to enjoy the repose which his condition required, Pizarro, on entering Quito, received accounts of a fatal event that threatened calamities more dreadful to him than those through which he had passed. From the time that his brother made that partial division of his conquests which has been mentioned, the adherents of Almagro, considering themselves as proscribed by the party in power, no longer entertained any hope of bettering their condition. Great numbers in despair, referred to Lima, where the house of young Almagro was always open to them; and the flender portion of his father's fortune, which the governor allowed him to enjoy, was spent in affording them subsistence. The warm attachment with which every person who served under him as their incitement; and the affections of all the qualities which captivate the affections of soldiers. Of a graceful appearance, dexterous at all martial exercises, bold, open, generous, he seemed to be formed for command; and as his father, conscious of his own inferiority from the total want of education, had been extremenotative to have him instructed in every science becoming a gentleman, the accomplishments which he had acquired heightened the respect of his followers, as they gave him distinction and eminence among illiterate adventurers. In this young man the Almagrians found a point of union which they wanted; and looking up to him as their head, were ready to undertake any thing for his advancement. Nor was affection for Almagro their only incitement; they were urged on by their own diftresses. Many of them, delirium of common necessities, and weary of lottering away life, a burden to their chief, or to such of their associates as had faved some remnant of their fortune from pillage and confiscation, longed impatiently for an occasion to exert their activity and courage, and began to deliberate how they might be avenged on the author of all their misery. Their frequent cabals did not pass unobserved; and the governor was warned to be on his guard against men who meditated some desperate deed, and had resolution to execute it. But, either from the native intrepidity of his mind, or from contempt of persons whose poverty rendered their machinations of little consequence, he disregarded the admonitions of his friends. “Be in no pain (said he carelessly) about my life; it is perfectly safe, as long as every man in Peru knows that I can in a moment put him to death who dares to harbour a thought against it.” This security gave the Almagrians full leisure to digest and ripen every part of their scheme; and Juan de Herrera, an officer of great abilities, who had the charge of Almagro’s education, took the lead in their consultations, with all the zeal which that connection inspired, and with all the authority which the attendant that he was known to have over the mind of his pupil gave him.

On Sunday, the 26th of June, at mid-day, the sensation of tranquillity and repose in all sultry climates, Herrera, at the head of 18 of the most determined conspirators, fell out of Almagro’s house in complete armour; and drawing their swords, as they advanced hastily towards the governor’s palace, cried out, “Long live the king, but let the tyrant die.” Their associates, warned of their motions by a signal, were in arms at different stations ready to support them. Though Pizarro was usually surrounded by such a numerous train of attendants as suited the magnificence of Peru, all was known to have over the progress of the palace unobserved. They were at the bottom of the stair case, before a page in waiting could give the alarm to his master, who was convering with a few friends in a large hall. The governor, whose steady mind no form of danger could appall, started up, called for arms, and commanded Francisco de Chaves to make fast the door. But that officer, who did not retain so much prefeice of mind as to obey this prudent order, running to the top of the staircase, wildly asked the conspirators what they meant, and whither they were going? Instead of anfvering, they flabb’d him to the heart, and buried into the hall. Some of the perons who were there threw themselves from the windows; others attempted to fly; and a few drawing their swords, followed their leader into an inner apartment. The conspirators, animated with having the object of their vengeance now in view, rushed forward after them. Pizarro, with no other arms than his sword and buckler, defended the entry, and supported by his half-brother Alcantara and his little knot of friends, maintained the unequal contest with intrepidity worthy of his past exploits, and with the vigour of a youthful combatant. “Courage (cried he), companions, we are yet enow to make these traitors repent of their audacity.” But the armour of the conspirators protected them, while every thrill they made took effect. Alcantara fell dead at his brother’s feet; his other defenders were mortally wounded. The governor, so weary that he could hardly wield his sword, and no longer able to parry the many weapons furiously aimed at him, received a deadly thrust full in his throat, sunk to the ground, and expired.

As soon as he was slain, the assailants ran out into the streets, and waving their bloody swords, proclaimed the death of the tyrant. Above 200 of their associates having joined them, they conducted young Almagro in solemn procession through the city; and assembling the magistrates and principal citizens, compelled
Young Almagro heads the rebels.

The licentiate Vaca di Castro, who had been sent from Europe to try the murderers of old Almagro, arrived at Peru. As he was appointed to assume the government in place of Pizarro it was more to all who had not folded themselves to the tyrant hastened to acknowledge him. Uncertainty and jealousy, which had for too long a time kept them dispersed, were no longer an obstacle to their re-union. Castro, who was as resolute as if he had grown old in the service, did not suffer their impatience to languish, but instantly led them against the enemy. The two armies engaged at Chapas on the 16th of September 1542, and fought with inexplicable obstinacy. Victory, after having wavered a long time, at the close of the day decided in favour of that party whose cause was the most just. Those among the rebels who were most guilty dreadful to languish under disgraceful provocation, provoked the conquerors to murder them, crying out, like men in despair, if we are not Relief Pizarro. Their chief was taken prisoner, and died on the scaffold.

While these scenes of horror were transpiring in America, the Spaniards in Europe were employed in finding out expedients to terminate them; though no measures had been taken to prevent them. Peru had only been made subject to the audience of Panama, which was too remote to superintend the maintenance of good order, and had too little influence to make its decrees respected. A supreme tribunal was then established at Lima for the dispensation of justice, which was to be invested with authority sufficient to enforce and to reward a due obedience to the laws. Blasco Nunez Vela, who professed in it as viceroy, arrived in 1544 attended by his subordinates in office, and found every thing in the most dreadful disorder.

To put an end to these tumults which now subsisted, would have required a profound genius, and many other qualities which are seldom united. Nunez had none of these advantages. Nature had only given him probity, firmness, and arduous; and he had taken no pains to improve these gifts. With these virtues, which were almost defects in his situation, he began to fulfil his commission, without regard to places, persons, or circumstances.

Contrary to the opinion of all intelligent persons who wished that he should wait for fresh instructions from Europe, he published ordinances, which declared that the lands the conquerors had seized should not pass to their descendants, and which disfranchised those who had taken part in the civil commotions. All the Peruvians who had been enflaved by monks, bishops, and persons belonging to the government, were declared free. Those who belonged to other matters were to be freed from their shackles at the death of their oppressors. They could no longer be compelled to bury themselves in the mines, nor could any kind of labour be exacted from them without payment. Their tribute was fixed. The Spaniards who travelled on foot were deprived of the right of taking three Indians to carry their baggage; and those who travelled on horseback, of the right of taking five. The caciques were drenched from the obligation of furnishing the traveller and his retinue with provisions gratis. Other tyrannical establishments also would soon have been prohibited; and the conquered people were on the eve of being sheltered under the protection of laws, which would at least have tempered the rigours of the right of conquest, if even they had not entirely repaired the injustice of them; but it should seem that the Spanish government was only to be unfortunate in the good it attempted to effect.

A change so unexpected filled those with confirmation who saw their fortunes wrested from them, or who left the flattering hope of transmitting them to their posterity. Even those who were not affected by these interrelated views, being accustomed to look upon the Indians as the instruments and victims of their avarice, had no conception that any other ideas could prevail concerning them. From altercation they proceeded to indignation, murmuring, and sedition. The viceroy was degraded, put in irons, and banished to a desert island, till he could be conveyed to Spain.

Gonzales Pizarro was then returned from his hazardous expedition, which had employed him long enough to prevent him from taking a part in those revolutions which had so rapidly succeeded each other. The anarchy he found prevailing at his return, inspired him with the idea of seizing the supreme authority. His fame and his forces made it impossible that this should be refused him; but his usurpation was marked with so many enormities, that Nunez was regretted. He was recalled from exile, and soon collected a sufficient number of forces to enable him to take the field. Civil commotions were then renewed with extreme fury by both parties. No quarter was asked or given on either side. The Indians took part in this as they had done in the preceding wars; some ranged themselves under the standard of the viceroy, others under the banners of Gonzales. From 15,000 to 20,000 of these unhappy wretches, who were scattered about in each army, dragged up the artillery, levelled the roads, carried the baggage, and destroyed one another. Their conquerors had taught them to be frugal. After a variety of advantages for a long time alternately obtained, fortune at length favoured the rebellion under Gonzales. Pizarro.
the walls of Quito in the month of January, in the year 1545; and Nunez with the greatest part of his men were killed.

Pizarro took the road of Lima, where they were deliberating on the ceremonies with which they should receive him. Some officers wished that a canopy should be carried for him to march under, after the manner of kings. Others, with adulation still more extravagant, pretended that part of the walls of the town, and even some houses, must be pulled down; as was the custom at Rome, when a general obtained the honours of a triumph. Gonzales contented himself with making his entrance on horseback, preceded by his lieutenant, who marched on foot. Four bishops accompanied him, and he was followed by the magistrates. The streets were filled with flowers, and the air resounded with the noise of bells and various musical instruments. This homage totally turned the head of a man naturally haughty, and of confined ideas. He spoke and acted in the most despotic manner.

Had Gonzales possessed judgment and the appearance of moderation, it would have been possible for him to render himself independent. The principal persons of his party wished it. The majority would have beheld this event with indifference, and the rest would have been obliged to conform to it. Blind cruelties, infatiable avarice, and unbounded pride, altered these dispositions. Even those, whose interests were connected with those of the tyrant, wished for a deliverer.

Such a deliverer arrived from Europe in the person of the licentiate Pedro di la Gafea. The squadron and the provinces of the mountains immediately declared for a person who was invested with a lawful authority to govern them. Those who lived concealed in deferts, caverns, and forests, quitted their retreats to join him. Gonzales, who saw no resource left to support him but in some great achievement, took the road of Cuzco, with a resolution to give battle. At some leagues distance from this place he met the royal army, and attacked it on the 9th of June 1548. One of his lieutenants, seeing him abandoned at the first charge by his belted soldiers, advised him to throw himself into the enemy's battalions, and perish like a Roman; but this weak man chose rather to surrender, and end his life on a scaffold. Carvajal, a more able warrior, and more ferocious than himself, was quartered. This man, when he was expiring, boasted that he had massacred with his own hand 1400 Spaniards and 20,000 Indians.

Such was the last scene of a tragedy, of which every act has been marked with blood. The government was moderate enough not to continue the proscriptions; and the remembrance of the horrid calamities they had suffered kept the Spaniards in the bounds of submission. What still remained of that commotion that had been raised in their minds, intolerably sunk into a calm; and the country hath remained in quiet ever since.

With regard to the Peruvians, the most cruel measures were taken to render it impossible for them to rebel. Tupac Amaru, the heir of their late king, had taken refuge in some remote mountains, where he lived in peace. There he was so closely surrounded by the troops which had been sent out against him, that he was forced to surrender. The viceroy Francis de Toledo caused him to be accused of several crimes that he had not committed, and for which he was beheaded in 1571. All the other defenders of the Incas shared the same fate, under pretence that they had conspired against their conquerors. The horror of these enormities excited so universal an indignation both in the Old and the New World, that Philip II thought himself obliged to disapprove them; but the infamous policy of this prince was so notorious, that no credit was given to this appearance of his justice and humanity.

The empire of Peru, at the time it was subdued, extended along the South Sea, from the river of the empire, Emeralda to Chili, and on the land side to Popayan, according to some geographers. It contained within its extent that famous chain of mountains which rises in the Terra Magica; and the greatest part of Mexico, in order to unite, as it should seem, the southern parts of America with the northern.

It is now divided into three grand divisions or audiences; Quito, Lima, or Los Reyes, and Los Charcos. As to its climate, mines, soil, and produce, they differ greatly in different parts of the country.

The extensive province of Quito is bounded on the north by Popayan, and includes a part of that government, also by Santa Fe de Bogota; on the south by the governments of Piura and Chachapoyas; on the east it extends over the whole government of Maynas and the river of the Amazons to the meridian, which divides the Spanish from the Portuguese dominions; and on the west it is bounded by the South Sea, extending, according to Antonio de Ulloa, 600 leagues in length, and about 200 in its greatest breadth; but this greatly exceeds the computation of all other geographers. He however observes, that it must be owned a great part of these vast dominions are either inhabited by nations of Indians, or have not hitherto been sufficiently peopled by the Spaniards, if indeed they have been thoroughly known; and that all the parts that can properly be said to be peopled, and actually subject to the Spanish government, are those intercepted by the two Cordilleras of the Andes, which, in comparison to the extent of the country, may be termed a street or lane, 15 leagues, or sometimes more, from east to west; to this must be added several detached governments, separated by the very extensive tracts inhabited by free Indians.

The climate of Quito differs from all others in the Climate the same parallel, since even in the centre of the torrid zone, or although under the equinoctial, this government is very tolerable, but even in some places the cold is painful; while others enjoy all the advantages of a perpetual spring, the fields being constantly covered with verdure, and enamelled with flowers of the most lively colours. The mildness of the climate, free from the extremes of heat and cold, and the constant equality of the day and night, render this country, which from its situation might be thought to be parched by the constant heat of the sun, and strongly inhabited, both pleasant and fertile; for nature has here dispersed her bounties with so liberal a hand, that this country in several respects surpasses those of the temperate zones, where the vicissitudes of winter and summer, and the change
change from heat to cold, cause the extremes of both to be more feebly felt. However, in different parts of the country, the air is very different; in one part are mountains of a stupendous height and magnitude, with their summits covered with snow. The plains are temperate, the valleys hot, and, according to the high or low situation of the country, are found all the variety of gradations in temperature possible to be conceived between the extremes of heat and cold.

Quito, the capital, in 0° 13' south latitude, and 77° 50' west longitude from Greenwich, is so happily situated, that neither heat nor cold are troublesome, though both may be felt in its neighbourhood; and what renders this equality more delightful is that it is constant throughout the whole year, the difference between the feasons being scarce perceptible. Indeed the mornings are cool, the remainder of the day warm, and the nights of an agreeable temperature. See Quito.

The winds, which are pure and balmy, blow for the most part from north to south, but never with any violence, though they sometimes shift their quarters, but without any regard to the season of the year. Such signal advantages resulting from the climate, soil, and aspect of this country, would be sufficient to render it the most enviable spot upon earth, as it is supposed to be the most elevated, if, whilst enjoying these delights, the inhabitants were not harassed by terror, and exposed to continual danger; for here tremendous tempests of thunder and lightning prevail, which are sufficient to appall the stoutest heart; whilst earthquakes frequently spread universal apprehensions, and sometimes bury cities in ruins.

The distinction of winter and summer consists in a very minute difference; the interval between the month of September and that of April, May, or June, is here called the winter season, and the other months compose the summer. In the former season the rains chiefly prevail, and in the latter the inhabitants frequently enjoy whole days of fine weather; but whenever the rains are discontinued for above fortnight, the inhabitants are in the utmost confusion, and public prayers are offered up for their return. On the other hand, when they continue a short time without intermission, the like fears prevail, and the churches are again crowded with supplicants to obtain fine weather; for a long drought produces dangerous diseases, and a continual rain, without intervals of sunshine, destroys the fruits of the earth. The city of Quito, however, enjoys one peculiar advantage in being free from musketoes and other troublesome insects, such as flies and venomous reptiles, except the sigua, or pique, which is a very small insect shaped like a fly, but hardly visible to the sight. See Chagas.

The fertility of the soil here is incredible, for the fruits and beauties of the several seasons are visible at the same time; and the curious European observer with a pleasing admiration, that whilst some herbs of the field are fading, others of the same kind are springing up; while some flowers lose their beauty, others blow to continue the enamelled profuse; thus, when the fruits of the trees have attained their maturity, and the leaves begin to change their colour, fresh leaves blossom, and fruits are seen in their proper gradations in size and ripeness on the same tree. The same incessant fertility is conspicuous in the corn, both reaping and fowing being carried on at the same time; so that the declivities of the neighbouring hills exhibit all the beauties of the four seasons in one assemblage. Though all this is generally seen, yet there is a settled time for the grand harvest; yet sometimes the most favourable season for fowing in one place is a month or two after that of another, though their distance does not exceed three or four leagues. Thus in different spots, and sometimes in one and the same place, fowing and reaping are performed throughout the whole year, the forwardness or retardment naturally arising from the different situations, such as mountains, rivulets, plains, and valleys; and the temperature being different in each, the best times for performing the several operations of husbandry must also differ.

The chirimoya is considered as one of the most delicious fruits of the world. Its dimensions are various, being from one to five inches in diameter. Its figure is imperfectly round, flattened towards the flanks, where it forms a kind of navel; but all the other parts are nearly circular. It is covered with a thin soft shell, which adheres so closely to the pulp as not to be separated from it without a knife. The outward coat is green, variegated with prominent veins, forming all over it a kind of net-work. The pulp is white, and contains a large quantity of juice resembling honey, of a sweet taste, mixed with a gentle acid of a most exquisite flavour. The seeds are formed in several parts of the pulp, and are somewhat flat. The tree is high and tufted, the stem large and round, but with some inequalities, full of elliptic leaves, terminating in a point. The blossom differs little from the colour of the leaves, which is a darkish green; and though far from being beautiful, is remarkable for its incomparable fragrance. The granadilla in its shape resembles an hen's egg, but is larger. The outside of the shell is smooth, glossy, and of a faint carnation colour, and the inside white and soft. The shell contains a viscid liquid substance full of very small and delicate grains, left behind on the outside of the pomegranate. This medullary substance is separated from the shell by a fine and transparent membrane. Its fruit has a delightful sweetness blended with acidity, very cordial and refreshing, and so wholesome, that there is no danger of eating to excess.

The frutilla, or Peruvian strawberry, is very different from that of Europe in size; for though they are here generally not above an inch in length, they are much larger in other parts of Peru; but their taste, though juicy, and not unpalatable, is not equal to those in Europe.

The country is observed to abound more in women inhabiting than in men, which is the more remarkable, as those taints cause which induce men to leave their country, as travelling, commerce, and war, naturally bring over more men from Europe than women. But there are many families in which there are a number of daughters, without one son among them. The women enjoy a better state of health than the men, which may be owing in some measure to the climate, and more particularly to the early intemperance and voluptuousness of the other sex.

The Creoles are well made, of a proper stature and of a lively and agreeable countenance. The Mestizos are also in general well made, often taller than the ordinary

The fumptuous manner of performmg the
habit is capable of prevailing over reason and prudence; for their obstinacy is so great in this particular, that many families of credit are ruined by preposterously endeavouring to excite others; and the people here may be said to till and scheme to lay up wealth, to enable their successors to lavish honours upon a body infensible of all pageantry.

The commerce of the province of Quito is chiefly carried on by Europeans settled here, and others who occasionally arrive. The manufactures of this province are only cottons, some white and striped batiks, and cloths, which meet with a good market at Lima, for supplying the inward provinces of Peru. The returns are made partly in silver, and partly in fringes made of gold and silver thread, and wine, brandy, oil, copper, tin, lead, and quicksilver. On the arrival of the galleons at Cartagena, these traders resort thither to purchase European goods, which, at their return, they confign to their correspondents all over the province. The coasts of New Spain supply this province with indigo, of which there is a very considerable consumption at the manufactures, blue being universally the colour which this people adopt for their apparel. They also import, by way of Guayaquil, iron and steel both from Europe and the coast of Guatemala.

The disposition of the Indians in the province of Quito is extremely remarkable, and they appear to have no resemblance to the people found there by those who first discovered the country. They are prudent, peaceable, and not to be disturbed either by fortunate or unfortunate events. In their mean state and condition they are as contented as a prince clothed in the most splendid robes. They show the fame disregard to riches; and even the authority and grandeur within their reach is little the object of their ambition, that to all appearances it seems to be the fame to an Indian whether he be created an alcalde or obliged to perform the office of a common executioner. Their sloth is so great, that scarcely any thing can induce them to work. Whatever therefore is necessary to be done is left to the Indian women, who are much more active; they spin and make the half shirts and drawers which form the only apparel of their husbands; they cook the provisions, grind barley, and brew the beer called chicha; while the husband sits squatting on his hams, the usual posture of the Indians, looking at his busy wife. The only domestic service they do is to plough their little spot of land, which is fowed by the wife. When they are once seated on their hams, no reward can induce them to stir; so that if a traveller has lost his way, and happens to come to one of their cottages, they charge their wives to lay that they are not at home. Should the passenger alight and enter the cottage, the Indian would fill be safe; for having no light but what comes through a hole in the door, he could not be discovered; and should the stranger even see the Indian, neither entreaties nor rewards would prevail on him to flee a step with him.

They are lively only in parties of pleasure, rejoicings, entertainments, and especially dancing; but in all these the liquor must circulate briskly, and they continue drinking till they are entirely deprived both of sense and motion.

It is remarkable that the Indian women, whether maid's or married, and Indian young men before they are of an age to contract matrimony, are never guilty of this vice: it being a maxim among them, that drunkenness is the privilege of none but masters of families, who, when they are unable to take care of themselves, have others to take care of them.

The women present the chicha (a) to their husbands in calabashes, till their spirits are raised; then one plays on a pipe and tabor, while others dance. Some of the bell voices among the Indian women sing songs in their own language, and those who do not dance, squat down in the usual posture till it comes to their turn. When tired with intemperance, they all lie down together, without regarding whether they are near the wife of another or their own sister or daughter. These festivities sometimes continue three or four days, till the priest coming among them, throws away all the chicha, and disperses the Indians, lest they should procure more.

Their funerals are likewise solemnized with excessive drinking. The house is filled with jugs of chicha, for the solace of the mourners and other visitors; the latter even go out into the streets, and invite all the nation who happen to pass by to come in and drink to the honour of the deceased. This ceremony lasts four or five days, and sometimes more, strong liquor being their supreme enjoyment.

The Indians in the audience of Quito are said to act contrary to all other nations in their marriages; for they never make choice of a woman who has not been first enjoyed by others, which they consider as a certain indication of her personal attractions. After a young man has made choice of a woman, he asks her of her father, and having obtained his consent, they begin to cohabit together as man and wife, and assist the father in law in cultivating the land. At the end of three or four months, and frequently of a year, the husband leaves his bride or wife without any ceremony; and perhaps expostulates with his father-in-law for endeavouring to deceive him, by imposing upon him his daughter, whom nobody else had thought worthy of making a bedfellow. But if no dissuasions arise in the man on this account or any other, after passing three or four months in this commerce, which they call amansatas, or to habituate one's self, they then marry. This custom is still very common, though the whole body of the clergy have used all their endeavours to put a stop to it. Accordingly they always

---

(a) This is a liquor made from maize by the following process. The maize, after being soaked in water till it begin to grow, is dried in the sun, then parched a little, and at last ground. The flour, after it has been well kneaded, is put with water into a large vessel, and left for two or three days to ferment. Its tincture is nearly that of the most indifferent kind of cider. It is a refreshing, nourishing, and aperitive liquor, but it will not keep above eight days without turning four.
It has been observed, that the dependencies of the summit of Cotopaxi, and that of Sangay, which is of a prodigious height, and the far greater part of it covered with snow; yet from its summit issue a continental fire, attended with explosions which are plainly heard at 40 leagues distance. The country adjacent to this volcano is entirely barren, being covered with cinders ejected from its mouth. In this mountain rises the river Sangay, which being joined by the Upano, forms the Paya, a large river which discharges itself into the Maranon.

Pichincha, though famous for its great height, is 1778 yards lower than the perpendicular height of Cotopaxi, and was formerly a volcano, but the mouth or crater on one of its sides is now covered with sand and calcined matter; so that at present neither smoke nor fire issue from it. When Don George Juan and Don Antonio de Ulloa were stationed on it for the purpose of making astronomical observations, they found the cold on the top of this mountain extremely intense, the wind violent, and they were frequently involved in a thick fog, or, in other words, a cloud, that an object at six or eight paces distance was scarcely discernible. The air grew clear, by the clouds moving nearer to the earth, and on all sides surrounding the mountain to a vast distance, representing the sea with the mountain: looking like an island in the centre. When this happened, they heard the dreadful noise of the tempests that discharged themselves on Quito and the neighbouring country. They saw the lightning issue from the clouds, and heard the thunder roll far beneath them. While the lower parts were involved in tempests of thunder and rain, they enjoyed a delightful serenity; the wind was abated, the sky clear, and the evening rays of the sun moderated the severity of the cold. But when the clouds rose, their thickness rendered respiration difficult, snow and hail fell continually, and the wind returned with all its violence; so that it was impossible entirely to overcome the fear of being, together with their hut, blown down the precipice on whose edge it was built, or of being buried in it by the constant accumulations of ice and snow. Their fears were likewise increased by the fall of enormous fragments of rocks. Though the smallest crevice visible in its hut was stopped, the wind was so piercing that it penetrated through; and though the hut was small, crowded with inhabitants, and had several lamps constantly burning, the cold was so great, that each individual was obliged to have achaing-dish of coals, and several men were constantly employed every morning to remove the snow which fell in the night. By the severities of such a climate their feet were swelled, and fat tender that walking was attended with extreme pain, their hands covered with chilblains, and their lips so swelled and chapped that every motion in speaking drew blood.

The next division of Peru is the audience of Lima, province of which is bounded on the north by Quito, on the east by Lima, the Cordilleras of the Andes on the south by the audience of Los Charcos, and on the west by the Pacific Ocean, it being about 770 miles in length from north to south, but of an unequal breadth.

The climate and soil of this country is uncommonly various; in some places it is exceedingly hot, in others cool, and insupportably cold, and in the city of Lima, where in this present age all rains never falls, it is always temperate. The seasons vary within the compass of a few miles, and in certain parts of the audience all the vicissitudes of weather are experienced in 24 hours. It is extremely remarkable that no rains fall or rivers flow on the sea coasts, tho'...
the country is refreshed by thick fogs, and the heat abated by dense clouds that never condense into flowers. This phenomenon, has drawn the attention of many naturally, without their being able satisfactorily to account for it.

Spring begins toward the close of the year, that is about the end of November or the beginning of December, when the vapours which fill the atmosphere during the winter fables, and the sun, to the great joy of the inhabitants, again appears, and the country then begins to revive, which, during the absence of his rays, had continued in a state of languor. This is succeeded by summer, which, though hot from the perpendicular direction of the sun's rays, is far from being insufferable; the heat, which indeed would otherwise be excessive, being moderated by the fourth winds, which always blow at this season, though with no great force. Winter begins at the latter end of June or the beginning of July, and continues till November or December, when the fourth winds begin to blow stronger, and to produce a certain degree of cold, not indeed equal to that in countries where ice and snow are known, but so keen that the light dresses are laid by, and cloth or other warm fluffs worn. During the winter the earth is covered with so thick a fog, as totally to intercept the rays of the sun; and the winds, by blowing under the shelter of this fog, retain the particles they contracted in the frozen zone. In this season only the vapours dissolve into a very small dew, which everywhere equally moistens the earth; by which means all the hills, which during the other parts of the year offer nothing to the traveler, are clothed with verdure and enamelled with flowers of the most beautiful colours. These dews never fall in such quantities as to impair the roads or incommodate the traveler; a very thin stuff will not soon be wet through; but the continuance of the mists during the whole winter, without being exhaled by the sun, fertilizes every part of the country.

Lima is as free from tempests as from rain; so that those of the inhabitants who have withstood the mountains nor travelled into other parts, are absolute strangers to thunder and lightning, and are therefore extremely terrified when they first hear the former or see the latter. But it is very remarkable, that what is here entirely unknown should be so common 30 leagues to the east of Lima; it being no farther to the mountains, where violent rains and tempests of thunder and lightning are frequent as at Quito.

But though the capital is freed from the terror of these tempests, it is subject to what is much more dreadful. Earthquakes happen here so frequently, that the inhabitants are under continual apprehensions of being, from their suddenness and violence, buried in the ruins of their own houses: yet they earthquakes, though so sudden, have their prefaces, one of the principal of which is a rumbling noise in the bowels of the earth about a minute before the shocks are felt, that seems to pervade all the adjacent subterraneous part; this is followed by dismal howlings of the dogs, who seem to prefigure the approaching danger. The breasts of burden pulling the freets stop, and by a natural instinct spread upon their legs, the better to secure themselves from falling. On these portents the terrified inhabitants fly from their houses into the freets with such precipitation, that if it happens in the night they appear quite naked; the urgency of the danger, once begun, all sense of delicacy or shame. Thus the freets exhibit such odd and singular figures as might afford matter of diversion, were it possible to be diverted in so terrible a moment. This sudden concourse is accompanied with the cries of children waked out of their sleep, blended with the lamentations of the women, whose agonizing prayers to the saints increases the common fear and confusion. The men are also too much afflicted to refrain from giving vent to their terror; so that the whole city exhibits a dreadful scene of confusion and horror.

The earthquakes that have happened at the capital are very numerous. The first since the establishment of the Spaniards was in 1582; but the damage was much less considerable than in some of the succeeding.

Six years after Lima was again visited by another earthquake, so dreadful, that it is still fearfully commemorated every year. In 1609 another happened, which overturned many houses. On the 27th of November 1630, such prodigious damage was done in the city by an earthquake, that, in acknowledgment of its not having been entirely demolished, a festival on that day is annually celebrated. Twenty-four years after, on the 3d of November, the most lately edifices in the city, and a great number of houses, were destroyed by an earthquake; but the inhabitants retiring, few of them perished. Another dreadful one happened in 1783; but one of the most terrible was on the 28th of October 1687. It began at four in the morning, and destroyed many of the finest public buildings and houses, in which a great number of the inhabitants perished: but this was little more than a prelude to what followed; for two hours after the shock returned with such impetuous concussions, that all was laid in ruins, and the inhabitants felt themselves happy in being only spectators of the general devastation, by having saved their lives, though with the loss of all their property. During this second shock, the sea retiring unconsiderably, and then returning in mountainous waves, entirely overwhelmed Callao, which is only nine miles distant from Lima, and all the adjacent country, together with the miserable inhabitants. From that time six earthquakes have happened at Lima previous to that of 1746. This last was on the 28th of October, at half an hour after ten at night, when the concussions began with such violence, that in little more than three minutes the greatest part, if not all the buildings in the city, were destroyed, burying under their ruins those inhabitants who had not made sufficient haste into the freets and squares, the only places of safety. At length the horrible effects of the first shock ceased; but the tranquillity was of short duration, the concussions swiftly succeeding each other. The sea of Callao also sunk into ruins; but what it suffered from the earthquake in its building was inconsiderable, when compared to the dreadful catastrophe which followed; for the sea as is usual on such occasions, receding to a considerable distance, returned in mountainous waves, foaming with the violence of the agitation, and suddenly buried Callao and the neighbouring country under its flood. This, however, was not entirely effected by the first swell of the waves; for the sea retiring farther, returned with still greater impetuosity, and covered both
In this bishopric are several mines of gold and silver, that are extremely rich.

The fourth diocese of the audience of Lima is Arequipa, which contains the city of the same name, one of the largest in all Peru. It is delightfully situated in a plain, the houses are well built of stone, and are generally lofty, commodious, finely decorated on the outside, and neatly furnished within. The temperature of the air is extremely agreeable, the cold being never excessive, nor the heat troublesome; so that the fields are always clothed with verdure, and enamelled with flowers, as in a perpetual spring. But these advantages are alloyed by its being frequently exposed to dreadful earthquakes; for by these convulsions of nature it has been four times laid in ruins. The city is, however, very populous, and among its inhabitants are many noble families.

In this bishopric are several gold and silver mines, and in some parts are large vineyards, from which considerable quantities of wine and brandy are made. Among the other productions is Guinea pepper, in which the jurisdiction of Africa in this diocese carries on a very advantageous trade, the annual produce of these plantations bringing in no less than 60,000 dollars per annum. The pods of this pepper are about a quarter of a yard in length, and when gathered are dried in the sun and packed up in bags of rushes, each bag containing an aroba or a quarter of a hundred weight, and thus they are exported to all parts. Other places of this jurisdiction are famous for vast quantities of large and excellent olives, far exceeding the finest produced in Europe, they being nearly the size of a hen's egg.

The audience of Charcas, the last diocese of Peru, is equal in extent to that of Lima; but many of its parts are not so well inhabited, some being full of vall valleys, deserts and impenetrable forests, whilst others have extensive plains intercepted by the stupendous height of the Cordilleras; the country is inhabited only in such parts as are free from those inconveniences. It is bounded on the north by the diocese of Cusco, and reaches southward to Buenos Ayres; on the east it extends to Brazil; and on the west it reaches to the Pacific Ocean, particularly at Atacama. The remainder of the province borders on the kingdom of Chili.

This audience is divided into the archbishopric of Plata, and five bishoprics. We shall begin with the first.

The famous mountain of Potosi is known all over the commercial world for the immense quantity of silver it has produced. The discovery of this amazing treasure happened at the commencement of the year 1545, by a mere accident, which we shall mention afterwards. At a small distance from it are the hot medicinal baths, called Don Diego, whether some resort for health and others for diversion.

At the time when the first conquests were made, when emigrations were most frequent, the country of the Incas had a much greater reputation for riches than New Spain; and, in reality, for a long time much settled by more considerable treasuries were brought away from it, the Spanish the desire of partaking of them must necessarily draw towards thither, as was really the case, a greater number of Castilians. Though almost all of them went over thither with the hope of returning to their country to enjoy
Fewer errors have been committed in the means of Manner of living of the natives. Procuring provisi

This infatiable thirst of gold, which neither tended to subsistence, safety, nor policy, was the only motive for establishing new settlements, some of which have been kept up, while several have decayed, and others have been formed in their stead. The fate of them all has corresponded with the discovery, progress, or declension, of the mines to which they were subordinate.

Fewer errors have been committed in the means of: 1. To fublime, etc. 2. To the barbarous and bloody manners of the conquerors. They were induced to expect so much independence as a land infinitely more remote from the mother-country.

Cuzco attracted the conquerors in multitudes. They found this capital built on a ground that was very irregular, and divided into as many quarters as there were provinces in the empire. Each of the inhabitants might follow the uffages of his native country; but every body was obliged to conform to the worship established by the founder of the monarchy. There was no edifice that had any grandeur, elegance, or convenience; because the people were ignorant of the first elements of architecture. The magnificence of what they called the palace of the foreign, of the princes of the blood, and of the great men of his empire, consisted in the profusion of the metals that were lavished in decorating them. The temple of the Sun was distinguished above all other edifices; its walls were incrusted or feathered with gold and silver, ornamented with divers figures, and loaded with the idols of all the nations whom the Incas had enlightened and subdued.

As it was not a solicitude for their own preservation which occupied the Spaniards at first, they had no sooner pillaged the immense riches which had been amassed at Cuzco for four centuries, than they went in great numbers in 1534, under the order of Sebastian de Benalcazar, to undertake the destruction of Quito. The other towns and boroughs of the empire were overrun with the same spirit of rapine; and the citizens and the temples were plundered in all parts.

Those of the conquerors, who did not take up their residence in the settlements which they found already formed, built towns on the sea-coasts, where before there were none: for the fertility of the soil had not permitted the Peruvians to multiply much there, and they had not been induced to remove thither from the extremity of their country, because they failed very little. Patia, Truxillo, Callao, Pica, and Arica, were the roads which the Spaniards deemed most convenient for the communication they intended to establish among themselves and with the mother-country. The different positions of these new cities determined the degree of their prosperity.

Those which were afterwards built in the inland parts of the country were not erected in regions which presented a fertile soil, copious harvests, excellent pastures, a mild and salubrious climate, and all the conveniences of life. These places, which had hitherto been so well cultivated by a numerous and flourishing population, were now totally disregarded. Very soon they exhibited only a deplorable picture of a horrid desert; and this wildness must have been more melancholy and hideous than the dreary aspect of the earth before the origin of societies. The traveller, who was led by accident or curiosity into these desolate plains, could not forbear abhorring the barbarous and bloody authors of such devastations, while he reflected that it was not owing even to the cruel illusions of glory, but to the stupid and abject desire of gold, that they had sacrificed so much more real treasure, and to numerous populations.

This is a considerable step; but there still remained much more to be done. After the invasions in which they groaned did not allow them to exercise their former industry, they contented themselves with the coarse clothes of Europe, for which they were made to pay an exorbitant price. When the gold and silver which had escaped the rapacity of the conquerors were exhausted, they thought of re-establishing their national manufactures. These were some time after prohibited, on account of the deficiency which they occasioned in the exports of the mother-country. The impossibility which the Peruvians found of purchasing foreign fluffs and paying their taxes, occasioned permission to be given at the end of ten years for their re-establishment. They have not been discontinued since that time; and have been brought to so great a degree of perfection as was possible they could be under a continual tyranny.

With the wool of the vicuna, a species of wild pasture, they make, at Cuzco and in its territory, flocks, handkerchiefs, and fcars. These manufactures would have been multiplied, if the frightful destruc

64 Manufactures, &c.

Thee wool, mixed with that of the sheep imported thither from Europe, which have E e z been exceedingly regenerated,
The manufactures subservient to luxury are established at Arequipa, Cuzco, and Lima. In these three towns is made a prodigious number of gold toys and plate, for the use of private persons, and also for the churches. All these manufactures are but coarsely wrought, and mixed with a great deal of copper. We seldom discover more taffetas in their gold and silver laces and embroideries which their manufactures also produce. This is not altogether the case in regard to their lace, which, when mixed with that of Europe, looks very beautiful. This last manufacture is commonly in the hands of the nuns, who employ in it the Peruvian girls, and the young Meflees of the towns, who for the most part before marriage pass some years in the convent.

Other hands are employed in painting and gilding leather for rooms, in making with wood and ivory pieces of inlaid work and sculpture, and in drawing figures on the marble that is found at Cuzco, or on linen imported from Europe. These different works, which are almost all manufactured at Cuzco, serve for ornaments for houses, palaces, and temples: the drawing of them is not bad, but the colours are neither exact nor permanent. If the Indians, who invent nothing, but are excellent imitators, had able masters and excellent models, they would at least make good copies. At the close of the last century, some works of a Peruvian painter, named Michael de St Jacques, were brought to Rome; and the connoisseurs discovered marks of genius in them.

Though the Peruvians were unacquainted with coin, they knew the use of gold and silver; for they employed them in different kinds of ornaments. Independent of what the torrents and accident procured them of these metals, some mines had been opened of little depth. The Spaniards have not transmuted to us of the manner in which these rich productions were drawn from the bosom of the earth. Their pride, which has deprived us of so much useful knowledge, undoubtedly made them think, that, in the inventions of a people whom they called barbarous, there was nothing worthy to be recorded.

The difference as to the manner in which the Peruvians worked their mines, did not extend to the miners themselves. The conquerors opened them on all sides. At first the gold mines tempted the avarice of the greater number. Fatal experience discouraged those whom passion had not blinded. They clearly saw, that, for some enormous fortunes nailed in this manner, great numbers, who had only moderate fortunes, were totally ruined. These mines sunk into such discredit, that, in order to prevent them from being abandoned, the government was obliged to take the 20th part of their produce, instead of the fifth which it at first received.

The mines of silver were more common, more equal, and richer. They even produced silver of a singular species, rarely found elsewhere. Towards the sea-coast, great lumps of this metal are found in the rocks, and on the mountains. Several of them gave false hopes. Such, in particular, was that of Ucuntuya, discovered in 1713. This was only an incrustation of almost malleable silver, which at first yielded several millions, but was soon exhausted.

Others which were deeper have been alike deserted. Their produce, though equal to what it originally was, was not sufficient to support the expense of working them, which augmented every day. The mines of Quivito, Cuzco, and Arequipa, have experienced that revolution which awaits many of the rest.

There are greater numbers of very rich mines which the waters have invaded. The disposition of the ground, which from the summit of the Cordilleras goes continually shelving to the South Sea, must necessarily render these events more common at Peru than in other places. This inconvenience, which with greater care and skill might often have been prevented or diminished, has been in some instances remedied.

Joseph Salcedo, about the year 1660, had discovered, not far from the town of Puna, the mine of Laycanota. It was so rich, that they often cut the silver with a chisel. Prosperity had so elevated the mind of the proprietor, that he permitted all the Spaniards who came to seek their fortune in this part of the New World, to work some days on their own account, without weighting or taking any account of the presents he made them. This generosity drew around him an infinite number of people, whose avidity made them quarrel with each other, and the love of money made them take up arms and fall upon one another; and their benefactor, who had neglected no expedient to prevent and extinguish their fiaguary contentions, was hang’d as being the author of them. Whilst he was in prison, the water got possession of his mine. Superfluity soon made it imagined that this was a punishment for the horrid act they had perpetrated against him. This idea of divine vengeance was revered for a long time; but at last, in 1740, Diego de Bina associated with other opulent people to avert the springs which had deluged so much treasure. The labours which this difficult undertaking required, were not finished till 1754. The mine yields as much now as it did at first. But mines still richer than this have been discovered. Such, for example, is that of Potosi, which was found in the same country where the Indians worked that of Porco.

An Indian, named Hualpa, in 1545, pursuing some deer, in order to climb certain steep rocks and hold off a bull, the roots of which loosened from the earth, and brought to view an ingot of silver. The Indian had recourse to it for his own use; and never failed to return to his treasure every time that his wants or his desires solicited him to it. The change that had happened in his fortune was remarked by one of his countrymen, and he discovered to him the secret. The two friends could not keep their counsel and enjoy their good fortune. They quarrelled; on which the indi­creeft confidential discovered the whole to his master, Villaricell, a Spaniard who was settled in the neigh­bourhood. Upon this the mine became known, and was worked; and a great number of them were found in its vicinity, the principal of which are in the northern part of the mountain, and their depth is from north to south. The most intelligent people of Peru have observed,
observed, that this is in general the direction of the richest mines.

The fame of what was passing at Potosi soon spread abroad; and there was quickly built at the foot of the mountain a town, confiding of 60,000 Indians and 10,000 Spaniards. The fertility of the soil did not prevent its being immediately peopled. Corn, fruit, flocks, American fluffs, European luxuries, arrived there from every quarter. Industry, which every where follows the current of money, could not search for it with fo much success as at its source. It evidently appeared that in 1738 these mines produced annually near 978,000 (sterling, without reckoning the silver which was not registered, and what had been carried off by fraud. From that time the produce has been so much diminished, that no more than one-eighth part of the coin which was formerly struck is now made.

At the mines of Potosi, and all the mines of South America, the Spaniards, in purifying their gold and silver, use mercury, with which they are supplied from Guanca Velica. The common opinion is, that this mine was discovered in 1564. The trade of mercury was then still free; it became an exclusive trade in 1571. At this period all the mines of mercury were shut; and that of Guanca Velica alone was worked, the property of which the king reserved to himself. It is not found to diminish. This mine is dug in a prodigiously large mountain, 60 leagues from Lima. In its profound abysses are seen streets, squares, and a chapel, where the mysteries of religion on all festivals are celebrated. Multitudes of flambeaux are continually kept to enlighten it.

Private people at their own expense work the mine of Guanca Velica. They are obliged to deliver to government at a stipulated price, all the mercury they extract from it. As soon as they have procured the quantity which the demands of one year require, the work is suspended. Part of the mercury is sold on the spot, and the rest is sent to the royal magazines throughout all Peru; from whence it is delivered out at the same price it is sold for in Mexico. This arrangement, which has occasioned many of the mines to drop, and prevented others from being opened, is inexcusable in the Spanish system. The court of Madrid, in this respect, merits the fame reproaches as a ministry in other countries would incur, that would be blind enough to lay a duty on the implements of agriculture.

The mine of Guanca Velica generally affects those who work in it with convulsions; this and the other mines, which are not less unhealthy, are all worked by the Peruvians. The unfortunate victims of an insupportable avarice are crowded all together and plunged into those abysses, the greatest part of which are deep, and all excessively cold. Tyranny has invented this refinement of cruelty, to render it impossible for any thing to escape its ruthless vigilance. If there are any wretches who long survive such barbarity, it is the use of cocoa that preserves them.

In the Cordilleras, near the city of Paz, is a mountain of remarkable height, called Illimani, which doubtless contains immense riches; for a crag of it being some years ago covered by a flusk of lightning, and falling on a neighbouring mountain, such a quantity of gold was found in the fragments; that for some time that metal was sold at Paz for eight pieces of eight per ounce; but its summit being perpetually covered with ice and snow, no mine has been opened in the mountain.

The city of La Paz is of a middling size, and from its situation among the breaches of the Cordilleras, the ground on which it stands is unequal, and it is also surrounded by mountains. When the river Titicaca is increased, either by the rains, or the melting of the snow on the mountains, it current forces along large masses of rocks with some grains of gold, which are found after the flood has subsided. Hence some idea may be formed of the riches inclosed in the bowels of these mountains; a remarkable proof of which appeared in the year 1730, when an Indian, washing his feet in the river, discovered a large lump of gold, that the marquis de Castile Fuerte gave twelve thousand pieces of eight for it, and sent it as a present to the king of Spain.

Balban of Peru. See Myroxilon.

PERUGIA, a town of Italy, in the pope's territories, and capital of Perugino. It is an ancient, handomé, populous, and large city, with a strong citadel, an university and a bishop's fee. The churches, and many other buildings as well public as private, are very handomé. It is seated on a hill, in E. Long. 12° 30', N. Lat. 43° 6'.

PERUGINO, a province of Italy, in the territory of the church, bounded on the west by Tuscany, on the south by Orvietano, on the east by the duchies of Spoletto and Urdino, and on the north by the county of Citta Cassellana. It is one of the smallest provinces in the territory of the church. The air is very pure, and the soil fertile in corn and good wine; besides, the lake Perugia supplies them with plenty of fish. The capital town is Perugia. The lake is eight miles from the city, and is almost round, being about five miles in diameter; in it there are three islands. This province is about 25 miles in length, and near as much in breadth.

PERUVIAN BARK. See Cinchona, and Peruvia Bark.

PERUVIAN BARK. See Perusa.

PERUVIAN, a general name given to that vast peninsula, extending itself from the isthmus of Darien to Cape Horn, in the form of a triangle, of which the Terre Magellania and the Cape form the vertex. It includes the whole of South America, although, as is well known, all the countries included within these limits do not acknowledge the dominion of the crown of Spain. See Terza Firm.

PESCARO, a town of Italy, in the territory of the pope, and duchy of Urbino, with a bishop's fee. It is a large place, whose streets are paved with bricks. The castle is very well fortified, the harbour excellent, and the cathedral church magnificent. The environs are remarkable for producing good figs, of which they send large quantities to Venice. It is seated on an eminence at the mouth of the river Fogha, on the Gulph of Venice. E. Long. 13° 0', N. Lat. 43° 56'.

PESSARA, a very strong town in the kingdom of Naples, and in the Hither Abruzzo; seated at the mouth of a river of the same name, which falls into
PETAGUEL, a territory of South America, in Brazil, bounded on the north by Del; on the east by the sea; on the south by the captainship of Rio Grande; and on the west by Tupys. It contains mines of silver.

PETAL, in botany, one of the coloured leaves which compose the flower.

PETALISM, a mode of deciding on the guilt of citizens similar to the Athenian OSTRACISM. It was introduced in Syracuse about the year before Christ 460, in order to prevent the tyranny of the richer citizens, who had often about that time aimed at the diadem. To prevent, therefore, the evils daily arising from thence, and to bring down the aspiring minds of the wealthy citizens, the Syracusans were forced to make a law not unlike that of the Athenian otracism; for as at Athens every citizen was to write on a leaf the name of the person whom they conceived to be the most likely, on account of his wealth and adherents, to aspire to the crown; so at Syracuse they used to write on a leaf the names of such as they apprehended powerful enough to usurp the sovereignty. When the leaves were counted, he who had the most suffrages against him was, without any further inquiry, banished for five years. This new-contrived method of impairing the elates, and weakening the interest of the overgrown citizens, was called petalism, from the Greek word petalon, which signifies "a leaf." This law was attended with many evil consequences; for those who were most capable of governing the commonwealth were driven out, and the administration of public affairs committed to the meanest of the people; nay, many of the chief citizens, who were able to render their country great service, fearing to fall under penalties of this law, withdrew from the city, and lived private in the country, not concerning themselves with public affairs: whence all the employments being filled with men of no merit or experience, the republic was on the brink of ruin, and ready to fall into a state of anarchy and confusion. The law therefore of petalism, upon more mature deliberation, was repealed soon after it had been first enacted, and the reins of government were again put into the hands of men who knew how to manage them.

PETARD, in the art of war. See GUNNERY, n° 36, and Plate CCXXIV.

PETAL (Denis), or Dionysius Petauius, a French Jesuit of great erudition, born at Orleans in 1583. His father was a man of literature, and observing strong parts and an excellent genius for letters in his son, he took every means in his power to improve them. He used to tell his son, that he ought to qualify himself so, as to be able to attack and confound "the giant of the Allophylæ;" meaning that most eminent scholar Joseph Scaliger, whose abilities and learning were allowed to have done great honour and much service to the reformed. Young Petavius seems to have entered readily into his father's views; for he studied most intensively, and afterwards水准 much of his erudition against Scaliger. He joined the study of the mathematics to that of the latter letters, and afterwards applied himself to a course of philosophy which he began in the college of Orleans, and finished at Paris. He afterwards maintained theses in Greek, which was as familiar to him as Latin; and the Latin, it is said, he understood better than he did his own native language. When he was pretty well advanced, he had free access to the king's library, which he often visited on account of the Latin and Greek manuscripts. Among other advantages which accompanied his literary pursuits, was the friendship of Isaac Casaubon, whom Henry IV. called to Paris in 1600. It was at Casaubon's instigation, that Petavius, though then but very young, undertook an edition of The Works of Syenestus. In this edition he corrected the Greek from the manuscripts, translated that part which yet remained to be translated into Latin, and wrote notes upon the whole. He was but 19 years of age when he was made professor of philosophy in the university of Bourges; and he spent the two following years in studying the ancient philosophers and mathematicians. In 1604, when Morel, professor of Greek at Paris, published The Works of Chryfotom, some part of Petavius's labours on Syenestus were added to them: from the title of which we learn, that he then took the name of Petus, which he afterwards changed into Petavius. His own edition of The Works of Syenestus did not appear till 1612.

He entered into the society of the Jesuits in 1605, and did great credit to it by his vast and profound erudition. He became a zealous advocate for the church of Rome; and there was no way of serving it more agreeable to him than that of criticizing and abusing its adversaries. He was most bitter against Scaliger; nor did he even spare his friend Casaubon whenever he came in his way.—Petavius excelled particularly in the dark science of chronology; the learned world in general being obliged to him for some exact and nice disquisitions on this subject. His chief work, which is in great repute to this day, he intitled, Rationarum Temporum. It is an abridgment of universal history, from the earliest times to 1632, in chronological order, with references to proper authorities. It was improved and several additions made to it, by Perizonius, and others after his death. This eminent father, after a very laborious life, died at Paris in the end of the

Petcheli

Peters.

... greedily devour, notwithstanding filth and all the inconveniences resulting from low, damp, and crowded lodgings, where all the individuals of the same family are, as it were, heaped one upon another, the plague never makes its appearance: in Petcheli; and the people are seldom attacked by any of those epidemical distempers which are so common in Europe. daily. Providences of every kind may be kept at Peking a long while, without being subject to corruption. Rains are there fresh even in May, apples and pears till midsummer; wild boars, fads, deer, redbucks, rabbits, hare, pheasants, ducks, geese, and all kinds of game brought from Tartary to Peking after the commencement of winter, fish of every species, transported from the rivers of Leutong—will keep without the assistance of salt, in their state of congelation, for two or three months, although they are exposed every day in the markets, carried from the markets to private houses, and from private houses brought back to the markets until they are all sold, which does not happen before the end of March. It is certain, that these facts announce an antiseptic quality in the air, which must undoubtedly proceed from the great quantity of nitre contained in it.

And daily, the earth which forms the soil of Petcheli abounds no less with nitre; whole fields may be seen in the neighborhood of Peking which are covered with it. Every morning at sunrife the country in certain canons appears as white as if sprinkled by a gentle fall of snow. If a quantity of this substance be swept together, a great deal of kien, nitre, and salt, may be extracted from it. The chineses pretend, that this salt may be substituted for common salt; however this may be, it is certain, that, in the extremity of the province towards Suin-hoa-fon, poor people and the greater part of the peasants make use of no other. With regard to the kien procured from the earth, they use it for washing linen, as we do soap. Although the land of Petcheli is replete with nitrous particles, it does not, however, form dry deposits; it is cultivated with care, and becomes fruitful by incessant labour. The earth is frozen in winter to the depth of two or three feet, and does not become soft before the end of March. This may sufficiently explain why the fruit kills plants in the neighborhood of Peking, which Mr. Linnaeus raised in Sweden, although it is 20 degrees farther north than the capital of the Chinesse empire.

PETECHIA, in medicine, a name given to those spots, whether red or of any other colour, which appear in the malignant fevers.

PETELIA. See STRONGOLI.

PETER (St), the apostle, born at Bethsaida, was son of John, Jona, or Joanna, and brother of St Andrew (John i. 42, 43). His first name was Simon or Simeon: but when our Saviour called him to the apostleship, he changed his name into Cephas, that is, Peter. He was a married man; and had his house, his mother-in-law, and his wife, at Capernaum, upon the lake of Genesareth (Mark i. 29, Mat. viii. 14, Luke iv. 38.) St Andrew, having been first called by Jesus Christ, met his brother Simon, and told him (John i. 41.) we have found the Messiah, and then brought him to Jesus. Jesus beholding him, said to him, thou art Simon son of Jona; henceforth thou shalt be called Cephas, that is, stone or rock. After having passed one day with our Saviour, they returned to their ordinary occupation, which was fishing. Yet it is thought they were present with him at the marriage of Cana in Galilee. This happened in the 30th year of the vulgar Christian era.

Towards the end of the same year, Jesus Christ being on the shore of the lake of Genezareth, saw Peter and Andrew busy about their fishery, and washing their nets (Luke v. 1, 2, 3.) He entered into their boat, and bid Peter throw out his nets into the sea, in order to fill. Peter obeyed him, though he had already filled the whole night without catching anything. They took so many fishes at this draught, that their own vessels, and that of James and John sons of Zebedee, were filled with them. Then Peter threw himself at the feet of Jesus, and said to him, Depart from me, Lord, for I am a sinner. Then Jesus said to them, Follow me, and I will make you fishers of men. He said the same thing to James and John; and immediately they quitted their boats and nets, and followed our Saviour.

Some time after, Jesus coming to Capernaum entered into the house of St Peter, where his mother-in-law lay sick of a fever. He immediately healed her, and the began to minister to him (Luke iv. 38, and Mat. viii. 14.) A little while before the ascent of the passover of the following year, being the 32d of the vulgar era, after Jesus returned into Galilee, he made choice of twelve apostles, among which St Peter has always the first place (Mat. x. 2. Luke vi. 13.) One night that Jesus Christ walked upon the waters of the lake of Genezareth, St Peter asked him leave to come and meet him (Mat. xiv. 28, 29.) Jesus gave him leave; but he seeing a great wave coming, was afraid, and therefore began to sink. Then Jesus held him up, and said, O man of little faith why wouldest thou fear? Afterwards landing on the other side of the lake, and the multitude that he had fed the day before beyond the lake being come to him at Capernaum, he spoke to them of his body and of his blood which he was to give to his disciples to eat and drink. This fo offended the multitude, that fever 1 of them quitted him thereupon. He therefore asked his apostles if they also would leave him; to which Peter replied, To whom shall we go, Lord? for thou hast the words of eternal life (John vi. 53, 54, &c.) One day, as our Saviour was near Cafarea Philippi, he asked his apostles whom the world took him for? they answered, that some said he was John the Baptist; others, Elias; and others Jeremiah, or one of the prophets. But whom do ye say I am? says Jesus Christ. Simon Peter answered, Thou art Christ, the son of the living God. Jesus then said unto Peter, Blessed art thou, Simon Barjona; for flesh and blood hath not revealed it unto thee, but my Father which is in heaven (Mat. xvi. 13, 14, &c.) And I say unto thee, that, as thou art Peter, so upon this rock will I build my church, and the gates of hell shall not prevail against it; and I will give unto thee the keys of the kingdom of heaven, and whatsoever thou shalt bind on earth shall be bound in heaven, and whatsoever thou shalt loose upon earth shall be loosed in heaven. About six eight days after this, our Saviour taking Peter, James, and John, up
PET [ 225 ]

up a high mountain, apart from the other disciples, showed them a glimpse of his glory, and was transfigured before them (Mat. xvii. 1, 2, &c. and Luke ix. 28.) Whereupon Peter, seeing Moses and Elias, together with Jesus, cried out to them in an ecstasy, Lord, it is good for us to be here! if you please, we will make three tents; one for you, one for Moses, and one for Elias.

Jesus, returning thence to Capernaum, showed that gathered the tribute money came to Peter, and said, Does not your matter pay tribute? Whereupon Jesus ordered Peter to throw his line into the sea, and that he should find wherewith to pay the toll for them two in the mouth of the first fish he should take. Peter obeyed; and finding a piece of money in the mouth of the fish, he gave it to the tribute-gatherers, as he was directed. One day, as Jesus was discourse concerning the forgiveness of injuries (Mat. xix. 13-15), St Peter asked him how often they must forgive, and whether it was sufficient to pardon an offender seven times? Jesus told him, I say, you must pardon not only as far as seven times, but even seventy times seven. Upon another occasion (Mat. xix. 27, 28.), as our Saviour was speaking of the danger of riches, Peter said to him, Lord, we have left all to follow you. Jesus answered him, Tell you in truth, that you who have left all things to follow me shall receive an hundred fold even in this world, and in the other eternal life; and at the last day when the son of man shall come to judge the world, you shall sit upon twelve thrones to judge the twelve tribes of Israel.

On the Thursday before our Saviour's passion, Peter showed him the fig-tree he had cursed the evening before, which was now dried up and withered (Mark xi. 21-23); and the day following, as they sat upon the mountain of Olives, he, with the other apostles, asked Jesus when the temple was to be destroyed (Mat. xxiv. 1, 2, &c. Mark xiii. 1, 2, &c. Luke xiv.) On Thursday he was sent with St John to prepare all things for the passover; and at evening, when Jesus was come into the city with his apostles, and being set down at table, began to speak of him that should betray him, Peter made signs to John to ask him who this should be (John xiii. 24). After supper, the disciples entered into a dispute which should be the greatest among them: whereupon Jesus Christ, laying aside his garments bestowed himself to wash their feet, to give them an example of humility in his own person. St Peter at first made some difficulty, and would not suffer his master to wash his feet: but Jesus telling him, that if he did not wash his feet, he could have no part in him; St Peter replied, Lord, wash not only my feet, but my hands and head also (John xiii. 6-10).

Some time after, Jesus said to him (Luke xxii. 31, 32, &c.), Peter, Satan has desired to lift you as a man's head; but I have prayed for you, that your faith may not fail: and when you are converted, confirm your brethren. By this he warned St Peter of his fall, that was just at hand, and of his renouncing him; from which, by the affliction of God, he was afterwards to recover. St Peter then asked him, where he was going? and said, he was ready to follow him everywhere, not only to prison, but to death itself. But Christ declared to him, that he would be far from following him to death that he would abjure him three times that very night before the cock should crow, or before break of day. When supper was ended, he went to the garden of olives, where, taking Peter, James, and John, he went with them apart, that they might be witnesses of his agony. Peter, though before he had flowed to much resolution, yet fell asleep with the rest; which occasioned Jesus to say to him, Do you sleep, Simon? Could not you watch with me one hour? (Mark iv. 37. Mat. xxvi. 40, &c.)

Judas being come with the soldiers to seize Jesus, Peter drew his sword, and cut off the right ear of one called Malchus, who was servant to the high priest: but Jesus bid him put up his sword into the scabbard; and told him, that all those that fought with the sword should perish by the sword; and at the same time healed Malchus's ear (John xviii. 10, &c.). Peter followed Jesus afar off, as far as the house of Caiphas, and was let in by means of another disciple who was known in the family. The soldiers and servants that had brought Jesus, having lighted a fire in the middle of the hall, Peter mingled among them to warm himself; when a maid servant, having looked earnestly upon him, said, Surely this man was with Jesus of Nazareth. But Peter made answer, I know not what you say, for I do not so much as know the man. Presently after he went out into the porch, when immediately the cock crew. A little while after another maid said to those that were present, This man was with Jesus of Nazareth. But Peter denied it with an oath. About an hour after one of the company affirmed that Peter was a disciple of Jesus. Others insisted upon the same thing; and said, that surely he was one of them, for his very speech betrayed him to be a Galilean. Lastly, one of them, being a kinsman of Malchus whose ear Peter had cut off, affirmed the same thing; and asked him, Did not I see you with him in the garden? Peter again denied it with an oath, protesting that he did not know the man. And at the same time the cock crowed the second time. Then Jesus, being in the same hall, and not far from Peter, looked upon him; and Peter then remembering what Jesus had said to him, that before cock-crow he should deny him thrice, went out of Caiphas's house, and wept bitterly (Mat xxvi. 73, 75. Mark xiv. 34, 72.).

Very probably he remained in secret, and in tears, all the time of our Saviour's passion, that is, all Friday and Saturday following; but on Sunday morning, Jesus being risen, and Mary having been at the tomb, and not finding the body of Jesus, she came in haste into the city, to tell Peter and John that they had taken away their master, and that she could not find where they had put him. Peter and John made haste thither, and John coming first, did not go into the sepulchre. Peter then coming up to him, presently flopped down, and faw the linen clothes wherein the body had been wrapped. He went then into the sepulchre, and John with him; after which they returned to Jerusalem, not knowing what had come to pass. But soon after Jesus appeared to the holy women who had come first to the sepulchre, and bid them give his apostles notice of his resurrection. And the same day Ff
Some days after St Peter being returned into Galilee as Jesus had commanded him, and going to fish in the sea of Galilee, or in the lake of Gennefaath, with some other of the apostles, Jesus appeared to them on the shore, and bid them throw out their nets on the right side of the vessel. They threw them out, and took such a multitude of fishes that they could not draw up their nets again. Then St John said to Peter, It is the Lord, Peter immediately girded himself, for he was naked, and swimming to shore he came to Jesus: then drawing their nets to shore, Jesus dined with them. After dinner, Jesus said to Peter, Simon, son of Jonas, do you love me more than these? He answered, Yea, Lord, you know that I love you. Jesus said to him, Then feed my lambs. He put the same question to him again; and Peter making the same answer, our Lord said to him again, Feed my sheep. This he repeated a third time; at which St Peter was troubled, and said, You know, Lord, that I love you. Jesus replied to him, If you love me, follow me. I tell you for a truth, that when you were young, you girded yourself and went where you pleased; but now you are old, another shall gird you, and lead you where you would not go.” This he said to let him know what death he was to die. At the same time, Peter seeing St John the Evangelist, said to our Saviour, Lord, what must become of him? Jesus answered, If I will that he tarry till I come, what does that concern you; Do you follow me.” Thus he refused to declare in what manner St John should end his life.

After that Jesus Christ had ascended into heaven, and that the apostles had been witness of his ascension they returned to Jerusalem, to wait there for the Holy Ghost, whom our Saviour had promised to send them; and being assembled together in a house, they continued there in prayer, and in the union of charity, till the time that the Holy Ghost descended upon them, in the form of tongues of fire. During this interval, St Peter propounded to the apostles, and to the rest of the assembly to fill up the place that the traitor Judas had left vacant in the apostleship. The proposal was agreed to by all; and two persons were propounded, Joseph Barsabas and Matthias: upon this last the lot fell; and from that time he was admitted one of the apostles. The tenth day after the ascension of our Saviour, being the day of Pentecost, the Holy Ghost having descended upon the apostles, and upon all the faithful that were assembled with them, and having replenished them with supernatural gifts, and especially with the gift of tongues, all those who were witnesses of this miracle expressed their admiration at it; and there being upon that day in Jerusalem a great many Jews from several provinces of the earth, they could not comprehend by what means these men, who were Galileans, should speak the languages of all these pagan nations (Acts ii. 1, 2, &c.). Some of them said, that the apostles were full of new wine. But St Peter standing up, told them, that what they heard and saw was not the effect of drunkenness, but was the completion of the promise that the Holy Ghost had made by the prophet Joel (ii. 28.), to send his spirit upon all flesh, and to give the spirit of prophecy to young and old, to men and women. He afterwards spake to them of Jesus Christ, and told them that he was the true Messiah, that he was risen from the dead as the scripture had foretold he should; declaring that himself and the other apostles were witnesses of his resurrection; of his ascension into heaven, and of the filling of the Holy Ghost, the visible effects of which they saw with their own eyes in the gifts of languages wherewith they had been replenished.

Then those that heard him were touched with compassion, and asked the apostles, Brethren, what shall we do? Peter answered them, Repent and be baptized, and you shall receive the Holy Ghost. Then he instructed them, baptized them, and that very day three thousand persons were added to the church (Acts iii. 1, 2, &c.). Some days after, St Peter and John, going to the temple at the hour of prayers, met at a gate of the temple a man who had been lame from his birth, so that he was carried about. This man seeing Peter and John, asked alms of them: upon which Peter said to him, Silver or gold I have not; but such as I have I give thee; in the name of Jesus of Nazareth, rise up and walk. Presently the man got up, and went into the temple along with them; lifting up his voice and glorifying God. He held St Peter, telling the people that assembled all that happened unto him. Then Peter, taking this occasion, told the people, that it was not by his own power that he had performed the miracle they so much wondered at, but that it was by the power of Jesus Christ that this man was healed. He then laid before them the great crime they had committed, in putting Jesus Christ to death, who was the Saviour of the world, and of the Messiah; and after he had shown them by all the prophecies that Christ was to die thus, he exhorted them to repentance, and to make a proper use of the death of Christ.

He was thus speaking to the people, when the priests and Sadducees coming upon them, laid hold on Peter and John, and put them in prison, until the day following, it being now late (Acts iv. 1, 2, &c.) But the number of those that were converted this day at the second preaching of St Peter was about five thousand. The day following, the rulers, magistrates, and chief priests being assembled on this occasion, ordered the apostles to be brought before them: and then asked them, by whose authority they performed the miracle of healing the lame man? St Peter answered, that it was in the name of Jesus of Nazareth, whom they had crucified, and whom God raised again from the dead. The assembly were surprised at the boldness of the apostles upon this occasion: but came to a resolution to dismay them, charging them at the same time to teach no more in the name of Jesus; and threatening them if they should persist in disobedience to their orders. The two apostles returned to their brethren, and related to them all that had passed; which having heard, the brethren raised their voices to heaven, begging God to give them strength and courage to declare his word with perfect liberty; and having finished their prayers, the place shook where they were assembled, and they were again filled with the Holy Ghost.

At this time many of the faithful fold their estates, and brought the money to the apostles (id. v. 1, 2, &c.) Of this number was a man called Ananias, with his
PET [ 227 ]

By a private agreement between themselves, Sapphira, who had concealed a part of the money for which they had sold their land, and brought the rest, to St Peter, it was the whole sum. Ananias came first; and St Peter said to him, Ananias, how came Satan to seduce you, and to prevail with you to lie to the Holy Ghost, by concealing part of the price of your land? It is not men that you thought to impose on, but God. Immediately Ananias fell down dead, and carried him out and buried him. About three hours after his wife Sapphira came in, and St Peter said to her almost the same things he had before said to her husband, and immediately the fell down also, and gave up the ghost. This affured a great awe into the whole church, and amongst all those that heard of it. (See Acts v.)

The number of believers considerably increased every day; so that they even brought out the sick into the streets, and laid them where Peter was to pass, that at least his shadow might cover some of them, by which means they were healed of their distempers. Then the high-priest and his associates, that is, the Pharisees, caused the apostles to be apprehended and put into prison. But an angel brought them forth, and bid them go into the temple, and there boldly declare all the words of life which God had taught them. This they performed; upon which the princes and priests caused them to be brought before them; and having demanded why they had disobeyed their orders, in continuing to speak in the name of Jesus Christ, Peter and the apostles answered, that it was more necessary to obey God than man. This answer provoked them very much, and they were going to condemn them to death, when Gamaliel prevailed with them to change their resolution, by representing to them, that if this matter proceeded from God, every one of them, by which means they were healed of their distempers. Then the faithful of these provinces. From thence he went to Rome, in the 42d year of the Christian era; and it is thought that at his leaving Antioch he there fixed St Ignatius in his place. Eusebius thinks, that the chief occasion of his going to Rome was to oppose Simon Magnus, who by his deceits had perverted a great number of persons. However, the presence of St Peter, and the true miracles that he opposed to the tricks
of Simon, ruined, or much diminished, the reputation of this impostor.

St Peter, leaving Rome, came to Jerusalem at the passover, in the 44th year of the Christian era, when Herod Agrippa began to persecute the church. That prince put St James the Greater, brother of John, to the sword (Acts xii. 1, &c.) and perceiving that his death was agreeable to the Jews, he moreover caused Peter to be apprehended and put in prison, with a design of executing him publicly after the passover. But the very night that Herod thought of putting him to death, as Peter, loaded with chains, was asleep between two soldiers, the angel of the Lord awakened him, broke of his chains, opened the prison door and brought him out the length of a street. Then the angel leaving him, he came to the house of Mary the mother of John, where many of the faithful were assembled at prayers; and having knocked at the door, a damsel named Rhoda came to open it; but when the heard Peter's voice, instead of opening the door, she ran in a transport of joy to acquaint the family that Peter was at the door. Tho' that heard she could not believe it, and said, it was his angel, and not himself: but continuing to knock, and being let in, he informed them of what had happened to him.

He then left Jerusalem; but we are not told what became of him till the time of the council held at Jerusalem in the year 51. It is thought that before this time he made his second journey to Rome, from whence he wrote his first epistle.

St Peter was obliged to leave Rome in the year 51 by order of the emperor Claudius, who had banished all Jews from thence because of the tumults they continually raised there, excited by one Chrestus, as Suetonius says, meaning probably by this name Jesus Christ. The apostle then returned to Judea, where he held the council of Jerusalem; in which, after a strict examination of the matter proposed to Peter and the apostles, he spoke to them with much wisdom, saying (Acts xx. 7, 8, &c.), that God having given his Holy Ghost and the gift of faith to the Gentiles as well as to the Jews, they ought not to impose the yoke of the legal observances on the new converts, which (as he says) neither we nor our fathers have been able to bear. But we believe, that it is through the grace of Jesus Christ that both we and they shall be saved. St James the Less, bishop of Jerusalem, seconded this opinion of St Peter; and the council came to this conclusion, that no new obligation should be imposed on the Gentiles, but only that they should be required to abstain from fornication, from the use of blood, and from meats offered to idols. The resolution of this council was written to the faithful of Antioch, because it was there this question was first flourished.

Some time after, St Peter coming to Antioch (Gal. ii. 11, &c.), he eat and drank with the Gentiles, without regarding that distinction of meats enjoined by the law. But after that, when some of the faithful of Jerusalem came to Antioch, being converted Jews, St Peter, out of fear to offend them, separated himself from the converted Gentiles, and would no longer eat with them as before. St Paul, fearing that what St Peter did might be interpreted as if he had a desire to oblige the Gentiles to judaize, and to submit themselves to the yoke of the law, and so to revoke and annul what he himself had determined in the council of Jerusalem, he withstood Peter to his face, and openly expostulated with him, telling him, he was much in the wrong to endeavour to oblige the Gentiles, at least tacitly by his own manner of acting, to live as the Jews do; and St Peter received this reprehension with silence and humility.

The particulars of St Peter's life are little known from the 51st year of the vulgar era, in which the council of Jerusalem was held, till his last journey to Rome, which was some time before his death. Then being acquainted by revelation that the time of his death was not far off (2 Pet. i. 14.), he had a mind to write to the faithful that had been converted by him, to put them in mind of the truths he had before taught them. He sent them therefore his second epistle.

St Peter and St Paul came to Rome about the same time, in the year of Christ 65, where they performed many miracles, and made many converts. Simon Magus by his tricks continued here to deceive the people, pretending himself to be the Messiah, and attempting to ascend into heaven: for having caused himself to be carried up into the air by his demons, in a fiery chariot, St Peter and St Paul betook themselves to their prayers; and then the impostor, being for­ taken by his demons, fell down upon the ground, which fell some time afterwards occasioned his death.

See Simon Magus.

Soon after this, St Peter was taken up and thrown into prison, where it is said he continued for nine months; at last he was crucified at Rome in the Via Oliva; with his head downwards, as he himself had desired of his executioners. This he did out of a sense of humility, for fear it should be thought, as St Am­ brose says, that he affected the glory of Jesus Christ, and the more to augment the pain of his execution.

It is said, that the body of St Peter was at first buried in the catacombs, two miles from Rome, from whence it was afterwards transported to the Vatican, where it has lain ever since. His festival is celebrated on the 29th of June. St Peter died in the 66th year of the vulgar era, after having been bishop of Rome for about 24 or 25 years. His age might be about 74 or 75 years. It is generally agreed, that St Linus was his successor. The following is the portraiture that Nicephorus gives us of Peter, which he has probably taken from the ancient pictures that were preferred of this apostle. He was not fat, but pretty tall and upright, having a countenance. The hair of his head was thick, frizzled, and not long. His eyes were black, and blood-shot; his eye-brows protruberant and lofty; his nose something long, and rather flat than sharp.

The two epistles of St Peter are addressed to those Jewish converts who were scattered throughout Pontus, Galatia, &c., not only upon the persecution raised at Jerusalem, but upon former dispersions of the Jews, into those places on several other occasions. The first epistle is principally designed to comfort and confirm them under those fiery trials and manifold temptations they were then subject to, and to direct and in­ struct them how to behave in the several states and relations both of the civil and the Christian life, that
they might not be engaged in those rebellions against Cæsar and his officers, then somented among the Jews; and that they might stop the mouths of those who spoke against them as evil doers. In the second epistle, he prosecutes the same subject, to prevent their apostacy from the faith, on account of any perfections they were liable to. He likewise guards them against the corrupt principles of the gnostics, and those who scoffed at the promulg of Christ's coming, as it would never be verified.

St Peter's style, says a modern author, expresses the noble vehemence and fervour of his spirit, the full knowledge he had of Christiannity, and the strong assurance he had of the truth and certainty of his doctrine: and he writes with the authority of the first man in the college of the apostles. He writes with that quickness and rapidity of style, with that noble neglect of some of the formal consequences and niceties of grammar, still preferring its true reason, and natural analogy (which are always marks of a sublime genius), that you can scarce perceive the pauses of his discourse and disjunction of his periods. The great Joseph Scaliger calls St Peter's first epistle majestic; and we hope he was more judicious than to exclude the second, though he did not name it.

A noble majesty, and becoming freedom, is what distinguishes St Peter; a devout and judicious person cannot read him without solemn attention and awful concern. The conflagration of this lower world, and future judgment of angels and men, in the third chapter of the second, is described in such strong and terrible terms, such awful circumstances, that in the description we see the planetary heavens and this our earth wrapped up with devouring flames, hear the groans of an expiring world, and the cruelties of nature tumbling into universal ruin.

The authority of this second epistle of St Peter was for some time doubted of, as Origen, EuthUS, St Jerome, and others have observed. What made the ancients call it in question, is the difference of its style from the first. The third chapter, which describes the catastrophe of the visible world, made Grotius think this epistle was written after the taking of Jerusalem; because that was not to happen till after the destruction of that city; upon which he conjectures, that Simeon bishop of Jerusalem is the author of this epistle, and that the inscription which carries St Peter's name is corrupted. But the best critics admit this epistle to be the genuine work of St Peter, who discovers himself, where he says that he was present at our Lord's transfiguration; and where he tells the Jews, this was the second letter he had written to them. The reader may see this question fully discussed, and the authority of this epistle established beyond all doubt, by the learned Dr Sherlock, in his Dissertation on the authority of the Second Epistle of St Peter.

St Peter has not been the author of several books; such were his Acts, his Gospel, his Revelation, his work about preaching, and another about judgment. There is extant a large history of St Peter, called the Recognitions, attributed to St Clement.

Peter of Blois, a learned man of the 12th century, was born about the year 1120, at the city of Blois in France, from whence he derived his name. His parents being opulent gave him a learned education. In his youth, when he studied in the university of Paris, he was excessively fond of poetry; and when he was a little further advanced in life, he became no less fond of rhetoric, to the study of which he applied with the greatest ardour. From Paris he removed to Bononia in Italy, to acquire the civil and canon law; in the knowledge of both which he very much excelled. He appears from his writings to have cultivated medicine, and several branches of the mathematics, with no little care and success. The study of theology was the chief delight and business of his life, in which he spent the greatest part of his time, and made the greatest progress. But unfortunately it was that scholastic theology, which confuted in vain attempts to prove and explain the many absurd opinions which then prevailed in the church, by the subtleties of Aristotelian logic. In attempting to explain in this manner the most absurd of all opinions that ever existed amongst mankind, he was said to be the first person who employed the famous word transferred classification, which was soon after adopted by the church of Rome, and hath ever since made so great a noise, though others contend that it was used in the fourth and fifth centuries. Being appointed preceptor to William II. king of Sicily in 1167, he obtained the custody of the privy seal; and, next to the archbishop of Palermo, the prime minister, had the greatest influence in all affairs. But his power was not of long duration; for the archbishop being banished in 1168, our author soon after left the court of Sicily, and returned into France. He was not long, however, without a royal patron, being invited into England by Henry II. who employed him as his private secretary, made him archdeacon of Bath, and gave him some other benefits. When he had spent a few years at court, he conceived a disgust at that way of life (of which he hath drawn a very unpleasing picture in one of his letters), and retired into the family of Richard archbishop of Canterbury, who had made him his chancellor about the year 1176. In this station he continued to the death of the archbishop in 1183, enjoying the highest degree of favour with that prelate. Our author remained in the same station in the family of archbishop Baldwin, who succeeded Richard, acting both as his secretary and chancellor. He was also sent by that prelate on an embassy to Rome in 1187, to plead his cause before Pope Urban III. in the famous controversy between him and the monks of Canterbury about the church of Hackington. After the departure of his friend and patron Baldwin for the Holy Land in 1190, our author was involved in various troubles in his old age, the causes of which are not distinctly known; and died about the end of the 13th century. He appears from his works, which may be justly reckoned among the most valuable monuments of the age in which he flourished, to have been a man of sound judgment, and sincere piety, as well as of a lively inventive genius and uncommon erudition. His printed works consist of 134 letters, which he collected together at the desire of Henry II.; of 65 sermons, delivered on various occasions; and of 17 tracts on different subjects.
Peter, afterwards emperor, of Russia, founder of the Russian empire; for though the country was well known, and of great antiquity, yet it had no extent of power, of political influence, or of general commerce, in Europe, till his time. He was born in 1672; and was proclaimed czar when but ten years of age, in exclusion of John his elder brother, who, being of a fickle constitution, was at the same time very weak in his understanding. The princes Sophia, his half-sister, made an insurrection in favour of John: and to put an end to the civil war, it was at last agreed that the two brothers should jointly share the imperial dignity, Peter had been very ill brought up, not only through the general defects of the Russian education, but like-wis through the arts of the princes Sophia, who surrounded him with every thing that might sully his natural desire of knowledge, deprave his mind, and enervate it with pleasure. Notwithstanding this, his inclination for military exercise discovered itself in his tenderest years. He formed a company of 50 men, commanded by foreign officers, clothed and exercised after the German manner. He entered himself into the lowest part, that of a drummer; and never rose otherwise than as a soldier of fortune. Herein his design was to teach his nobility, that merit, not birth was the only title to military employments. He re-inforced his company with several others, till at last he had got together a considerable body of soldiers. As he then had no war on his hands, he exercised them in all sorts of mock-engagements, and by this means fecured to himself a body of well-disciplined troops. The fight of a Dutch vessel, which he had met with on a lake belonging to one of his pleasure-houses, made such an impression on his mind, that he conceived the almo impracticable design of forming a navy. His first care was to get some Hollander to build some small vessels at Moscou; and he paid two successive sums on board English or Dutch ships, which set out from Archangel, that he might instruct himself in every branch of naval affairs (a). In 1696 czar John died, and Peter was now sole master of the empire. In 1698 he sent an embassy to Holland; and went in群岛 in the retinue, and visited England as well as Holland in order to inform himself fully in the art of ship-building. At Amsterdam he worked in the yard as a private ship-carpenter, under the name of Peter Michaelof; but he has been often heard to say, that if he had never gone to England, he had still remained ignorant of that art. In 1700 he had got together a body of standing forces, consisting of 50,000 foot; and now the vast project he had formed displayed itself in all its parts. He opened his dominions, which till then had been shut up, first having sent the chief nobility of his empire into foreign countries to improve themselves in knowledge and learning. He invited into Russia all the foreigners he could meet with, who were capable of instructing his subjects in any manner, and offered them great encouragement to settle in his dominions. This raised many discontent; and the despotic authority he exerted on that occasion was fiercely powerful enough to suppress them. In 1700, being strengthened by the alliance of Augustus king of Poland, he made war on Charles XII. king of Sweden. His first ill success did not deter him; for he used to say, I know that my armies must be overcome for a great while; but even this will at last teach them to conquer. He afterwards gained considerable advantages; and founded Peterburg in 1703. In 1709 he gained a complete victory over the Swedes at Pultowa. In 1712 he was inclosed by the Turks on the banks of the Pruth; and seemed inevitably lost, had not the czarina Catharine bribed the grand vizir, and the czar's prudence completed his deliverance. In 1716 he made a tour through Germany and Holland, and visited the royal academy of sciences at Paris. It would be endless to enumerate all the various establishments for which the Russians are obliged to him. He formed an army according to the manner of the politest and most experienced nations: he fitted out fleets in all the four seas which border upon Russia; he caused many strong fortresses to be raised after the best plans; and made convenient harbours: he introduced arts and sciences into his dominions, and freed religion from many superfluous abuses: he made laws, built cities, cut canals, &c.; was generous in rewarding, impartial in punishing; faithful, laborious, and humble; yet was not free from a certain roughness of temper natural to his nation. He had indeed cured himself of excess in drinking; but he has been branded with several other vices, particularly cruelty. He published the unfortunate history of his son Prince Alexis (b); towards whom some blame his severity, while others think

(a) The following circumstance, it is said, in some measure determined Peter to attempt these reformations which he afterwards accomplished. Great events have been sometimes the effect of little causes: and it is at least possible that without the occurrence we are going to relate, Russia might still have been in a state of barbarism. A young Genevefe, called Le Fort, about 1695, went to Moscou with the Danish ambassador. The czar Peter, who was then 19 years old, fell into company with this Genevefe, who had soon learnt the Russian tongue, and spoke almost all the tongues of Europe. Le Fort ingratiated himself with the prince, entered into his service, and soon afterwards into his familiarity. He made him comprehend that there was a different manner of living and reigning from what he had unhappily obtained throughout his vall and miserable empire. A prince must be born with an uncommon greatness of soul to be then readily to a stranger, and to be able to divest himself of the prejudices of a theocracies and of his country. The czar was sensible that neither himself nor his people were yet to be reckoned among men; and that he had an empire to form, but could have no asistance at home. From that time he took a resolution to leave his dominions; and set out, like another Prometheus, to borrow celestial fire for animating his countrymen.

(b) Alexis, like his father, is said to have married a slave, and, like him, quitied Moscovy secretly, but had not the same success in his undertakings; and the being but a bad imitator of his father, coil him his life. He became an example of the most terrible severity that ever was given from the tribunal of the throne: but, what is
Peter.

think it no more then was necessary. He perfectly knew the honours due to persons of merit; and not only heaped honours upon them during their life, but gave them marks of esteem even after their death. He died of the iranthropy in 1725, and left the world with the magnanimity of a hero and the piety of a Christian.

Peter was tall of stature, and of a bold and majestic aspect, though sometimes disfigured by convulsions, which altered his features. This deformity was ascribed to poison, given him, as it is said, by his sister Sophia; but it was indeed no other than wine and brandy, which he often drank to excess, relying too much on the strength of his constitution. He converted with persons in all stations, from the mechanic to the general of an army; and his conversation was neither like that of a barbarian who makes no distinction between men, nor of a popular prince who seeks to please all the world, but that of a person who aims at instruction. He loved women as much as the king of Sweden, his rival, dreaded them, and all were equally agreeable to him as well in bed as at board; he valued himself on drinking large draughts, rather than sipping delicious wines. We are told that kings and legislators should never suffer themselves to be transported by passion; but never was any man more passionate than Peter the Great, nor more merciful. In a king this is more than an infirmity for which we make amends by confiding it; but it was generally remarked of Peter, and he himself said to a magistrate of Holland, at his second voyage, "I have reformed my nation, and have not been able to reform myself." It is true, the cruelties with which he is reproached were not novelties at the court of Moscow, any more than at that of Morocco; it was not uncommon to see a czar, with his own royal hand inflict 100 lashes of a bull’s pizzle on the naked shoulders of a prime officer of the crown, or of a lady of the palace, for failing in their duty, by getting drunk; or to try the goodness of his fabric, by trying off the head of a criminal. Peter had himself performed some of those ceremonies of his country; Le

is much to the honour of the empress Catherine, she had no hand in the misfortunes of that prince, who was born of another woman, and loved nothing that his father loved. Catherine was not in the leaf suspected of acting the cruel stepmother. The great crime of the unfortunate Alexis was his being too much a Russian, and his disapproving every thing that was grand and immortal, and projected by his father for the glory of the nation. One day, hearing some Moscovites lamenting the inexpressible fatigue they were to undergo in the building of Peterburg, he said, “Take courage, this city will not stand long.” When he was called to attend his father in a journey of 600, or 700 leagues, which the czar often made, he feigned sickness. He took violent purges for a dilatement which he had not; and such quantities of medicines, with excessive drinking of brandy, impaired his health and his wits. At first he had an inclination to learning, was acquainted with geometry and history, and had learnt the German tongue: but he hated war, and would never learn it; for which he was most reproached by his father. They had married him in 1711 to the princess of Wolfenbuttle, sister of the empress; comfort to Charles VI. This marriage was unfortunate; the princess was often abandoned for a debauch in brandy, and for Afrofina, a Finland wench, of a large nature, well made, and very agreeable. It is reported that the princess died of chagrin, if it be possible for chagrin to prove mortal; and that afterwards the czarowitz secretly espoused Afrofina in 1713, when the empress Catherine had just brought him a brother, at which he had no reason to be uneasy.

The misunderstandings between the father and the son became every day more serious; till at length the father, about the year 1716, threatened the prince to disfigure him; and the prince told him that he intended to go into a monastery.

The czar, in 1717, renewed his journeys, as well with a view to politics as curiosity. He came at last into France. If the son had entertained an inclination to revolt, if he had actually had a party formed in his favour, now was the time to declare himself; but instead of remaining in Russia, making himself popular, and encouraging his dependents, he took a journey in his turn, having with much difficulty Fleaped together some thousands of ducats, which he had secretly borrowed. He threw himself under the protection of the emperor Charles VI, brother of his deceased wife. They kept him for some time incognito at Venice, from whence he passed to Naples, where he resided almost a year, while neither his father nor any person in Russia knew the place of his retreat.

While the son kept himself thus concealed, the father was at Paris, where he was received with all the respect paid him in other places, but with a gallantry nowhere to be found but in France. If he went to visit a manufactory, and one piece of work attracted his sight more than another, he was presented with it the next day. He went to dine at the Duke d'Antin's at Petitbourg, where the first thing he saw was his own picture, at full length, in the same habit that he wore. When he was at the royal mint of medals, they struck all kinds before him, and presented him with; at last they struck one which they let drop on purpose at his feet, and left him to take it up. He there saw himself perfectly engraved with these words, Peter the Great. The reverve was a Fame, and round her in letters Vibe acquisit eundo; an allusion no less than flattering to a prince who really acquired new merit by travelling.

After he had seen this country, where every thing disposes men to gentleness and indulgence, he returned to his own, and returned his severity. He had engaged his son to return from Naples to Peterburg, from whence that young prince was conducted to Moscow before the czar his father; who began with depriving him of his succession to the throne, by making him sign a solemn act of renunciation at the end of January 1718, in consideration of which act the father promised the son to spare his life.
It was not altogether improbable that such an act would have been some time or other annulled. The czar, therefore, in order to give it more force, forgetting that he was a father, and only remembering that he was the founder of an empire, which his son might overturn, and involve in its ancient barbarity, ordered a public process to be drawn up against that unfortunate prince, for some concealment, with which he was charged, in the confection that they had exacted of him.

An assembly was held of the bishops, inferior ecclesiastics, and professors; who found in the Old Testament that those who curst their father or their mother should be put to death; that David indeed had pardoned Absalom who rebelled against him, but that Absalom was never pardoned by God. Such was their opinion, without drawing any conclusion; but it was in effect signing a warrant for his death. Alexis had not in fact curst his father, either had he ever revoluted like Absalom; he had never lain publickly with the king's concubines, but he had left the kingdom without his father's permission, and had written letters to his friends, in which he only signified that he hoped they would one day be mindful of him in Russia. But whatever might be his cafe, of 124 lay judges, who were appointed to sit on him, there was not one that judged his offences less than capital; and those who could not write, made others sign for them. It is reported in Europe that the czar had got translated from Spanish into Russian the criminal process against Don Carlos, that unfortunate prince whom his father Philip II. had confined in a prifon, where the heir of that great monarchy ended his days. But there was nothing like a process carried on against Don Carlos, nor was it ever known whether that prince died a natural or a violent death.

Peter, the most despotick of princes, wanted not an example. Certain it is that the prince died the day after the sentence, and that the czar had at Moscow one of the bleft apothecary shops in Europe. It is probable, however, that the prince Alexis, the heir of the most extensive empire in the world, being condemned unanimously by his father's subjecks, which were one day to be his own, might die of the sudden shock and change given to the body at the apprehension of so strange and difmal a sentence. The father went to fee his fon in his last agonies; and it is said he flied tears, I infernus utcunque feren et fata nepotes. These tears however, did not prevent the wheels from being covered with the broken limbs of his fon's friends. He beheaded his own brother-in-law Count Lapuchin, brother to his wife Ottokofla Lapuchin whom he had divorced, and uncle to prince Alexis. The prince's confecfors had also his head cut off. If Moscovy has been civilized, he has, it must be confessed, paid dear for her politeness.

The remainder of the czar's life was nothing but a series of grand projects, labour, and exploits, that seemed to efface the memory, of his excessive severities, which were perhaps necessary. He made frequent speeches to his court and to his council. In one he told them that he had sacrificed his fon to the welfare of his dominions.
was transferred to the care of his brother Peter.

The czar, satisfied of their sincerity, ordered great search to be made for her, with the offer of a considerable reward to the perfid who should discover what became of her, but to no purpose: the parents and relations, apprehending she was no more, went into mourning for her.

Above a year after she was discovered by an accident. A colonel who had come from the army to see his friends, going a hunting into that wood, and following his game through the morass, he came to the hut, and looking into it saw a pretty young woman in a mean dress. After inquiring of her who she was, and how she came to live in so solitary a place, he found out that at last she was honestly whole disappearance had made so great a noise in the utmost confusion, and with the most ferventéré, she prayed him on her knees that he would not betray her; to which he replied, that he thought her danger was now past, as the czar was then otherwise engaged, and that she might with safety discover herself, at least to her parents, with whom he would consult how matters should be managed. The lady agreed to this proposal; and he set out immediately, and overjoyed her parents with the happy discovery: the issue of their deliberations was to consult Madame Catherine (as she was then called) in what manner the affair should be opened to the czar. The colonel went also upon this busines, and was advised by Madame to come next morning and she would introduce him to his majesty, when he might make the discovery and claim the promised reward. He went according to appointment; and being introduced, told the accident by which he had discovered the lady, and represented his misfortune to the queen; she was tenderly moved on the occasion of his having suffered by being so long shut up in such a dismal place, from the delicacy of her sex. The czar showed a great deal of concern that she should have been the cause of all her sufferings, declaring that he would endeavour to make her amends. Here Madame Catherine suggested, that she thought the best amends his majesty could make, was to give her a handsome fortune and the colonel for a husband, who had the best right, having caught her in pursuit of his game. The czar, agreeing perfectly with Madame Catherine's sentiments, ordered one of his favourites to go with the colonel, and bring the young lady home; where the arrived to the inexpressible joy of her family and relations, who had all been in mourning for her. The marriage was under the direction and at the expense of the czar, who himself gave the bride to the bridegroom, saying, that he presented him with one of the most virtuous of women; and accompanied his declaration with very valuable presents, besides settling on her and her heirs three thousand rubles a-year. This lady lived highly esteemed by the czar, and every one who knew her. Besides the concurring reports of other people, I had the story from her own mouth.

On the whole, that Peter I. was a great man, few

Vol. XIV.
Peter was well made, and of the middle size. His countenance had not the appearance of an idiot, nor was there anything particular in his form, except that two of the fingers of his left hand were united by a web up to the middle joint. He had a natural ear for music, and was so delighted with it, that if he heard any musical instrument played upon him, he would immediately dance and caper about till he was almost quite exhausted with fatigue: and though he could never be taught the difficult utterance of any word, yet he could easily learn to hum a tune. All those idle tales which have been published to the world about his climbing up trees like a squirrel, running upon all fours like a wild bea
t, &c. are entirely without foundation; for he was so exceedingly timid and gentle in his nature, that he would suffer himself to be seized by a child. There have been also many false stories propagated of his incontinence; but, from the minute inquiries among those who constantly lived with him, it does not appear that he ever discovered any natural passion for women, though he was subject to the other passions of human nature, such as anger, joy, &c. Upon the approach of bad weather he always appeared ill and uneasy. At particular feasons of the year he showed a strange fondness for stealing away into the woods, where he would feed eagerly upon leaves, beechnut, acorns, and the green bark of trees, which proves evidently that he had cultivated in that manner for a considerable length of time before he was first taken. His keeper therefore at such seasons generally kept a look after him, and sometimes even confined him, because if he ever rambled to any distance from his home he could not find his way back again; and once in particular, having gone beyond his knowledge, he wandered as far as Norfolk, where he was taken up, and being carried before a magistrate, was committed to the house of correction in Norwich, and punished as a sturdy and obdurate vagrant, who would not (for indeed he could not) give any account of himself: but Mr. Fenn, having advertised him in the public papers, he was released from his confinement and brought back to his usual place of abode.

Notwithstanding the extraordinary and savage state in which Peter was first found, greatly excited the attention and curiosity of the public; but, after all that has been said of him, he was certainly nothing more than a common idiot without the appearance of one. But as men of some eminence in the literary world have in their works published strange opinions and ill-founded conjectures about him, which may seem to stamp a credit upon what they have advanced; that perversity may not through their authority be hereafter misled upon the subject, this short and true account of Peter is recorded in the parish-register by one who constantly resided above 30 years in his neighbourhood, and had daily opportunities of seeing and observing him."

Perhaps it may not be disagreeable to our readers if we present them with Lord Monboddo's account of this extraordinary creature (A). "It was in the beginning of June 1782 (says his Lordship) that I saw him in a farm-house called Broadway, within about a mile of Berkhamsted, kept there upon a pension which the king pays. He is but low of stature, not exceeding five feet three inches; and although hemult now be about 70 years of age, has a fresh healthy look. He wears his beard; his face is not at all ugly or disagreeable; and he has a look that may be called feminine and sagacious for a savage. About 20 years ago he was in life tolerable, and to be missing for several days; and once, I was told, he wandered as far as Norfolk; but of late he has been quite tame, and either keeps in the house or saunters about the farm. He has been the 13 last years where he lives at present; and before that he was 12 years with another farmer, whom I saw and conversed with. This farmer told me, that he had been put to school somewhere in Hertfordshire, but had only learned to articulate his own name Peter, and the name of King George, both which I heard him pronounce very distinctly. But the woman of the house where he now is (for the man happened not to be at home) told me, that he understood every thing that was said to him concerning the common affairs of life; and I saw that he readily understood several things that the said to him while I was present. Among other things, she desired him to sing Nancy Dawson; which he did, and another tune which she named. He never was mischievous, but had always that gentleness of nature which I hold to be characteristic of our nature, at least till we became carnivorous, and hunters or warriors. He feeds at present as the farmer and his wife do; but, as I was told by an old woman (one Mrs. Collop, living at a village in the neighbourhood called Hempstead, who remembered to have seen him when he first came to Hertfordshire, which he computed to be 55 years before the time I saw her), he then fed very much upon leaves, and particularly upon the leaves of cabbages, which he eat raw. He was then, as the thought, about 15 years of age, walked upright, but could climb trees like a squirrel. At present he not only eats flesh, but has also got the taste of beer, and even of spirits, of which he inclines to drink more than he can get. And the old farmer abovementioned, with whom he lived 12 years before he came to this last farmer, told me, that he had acquired that taste before he came to him, which is about 25 years ago. He has also become very fond of fire, but has not yet acquired a liking for money; for though he takes it, he does not keep it, but gives it to his landlord or landlady, which I suppose is a lesson that they have taught him.

(A) This eccentric writer, in support of his hypothesis, that man in a state of nature is a mere animal, without clothes, houses, the use of fire, or even speech, adduces the orang-outang, or man in the woods, and this Peter the wild man and others, as examples. He denies the want of the organs of speech as an objection, and infers they only want the artificial use of them.

PET

him. He retains so much of his natural instinct, that he has a fore-feeling of bad weather, growling and howling, and showing great disorder, before it comes.

"These are the particulars concerning him which I observed myself, or could learn by information from the neighbourhood." From all these facts put together his lordship makes the following observations:

"1st. Whatever doubts there may be concerning the humanity of the orang-outang, it was never made a question but that Peter was a man.

"2dly. That he was, as the Dean [Swift] says, of a father and mother like one of us. This, as I have said, was the case of two savages found in the dismal swamps in Virginia, of the one found in the island of Diego Garcia, and of him that was discovered by M. le Roy in the Pyrenees, and in general of all the savages that have been found in Europe within these last 300 years; for I do not believe, that for these 2000 years past there has been a race of such savages in Europe.

"3dly. I think there can be no reason to doubt of what was written from Hanover, and published in the newspapers, that he was found afoot all fours, as well as other solitary savages that have been found in Europe. It is true that others have been found erect; which was the case of the two found in the dismal swamp of Virginia, like wife of the man of the Pyrenees, and of him in the island of Diego Garcia: but these I suppose were not exposed till they had learned to walk upright; whereas Peter appears to have been abandoned by his parents before he had learned that lesson, but walked as we know children do at first.

"4thly. I think it is evident that he is not an idiot, not only from his appearance, as I have described it, and from his actions, but from all the accounts that we have of him, both those printed and those attain'd by per sons yet living; for as to the printed accounts, there is not the least information of that kind in any of them, except one, viz. Wye's letter, No 8, wherein is said, that some imputed his not learning to speak to want of understanding; which I should think showed a want of understanding in those who thought so, when it is considered that at this time he had not been a year out of the woods, and I suppose but a month or two under the care of Dr Arbuthnot, who had taken the charge of his education. The Dean indeed tells us, that he suspected he was a pretender, and no genuine wild man, but not a word of his being an idiot. And as to the per sons living, not one with whom I have conversed appeared to have the least suspicion of that kind; though it is natural that men who were not philosophers, and knew nothing of the progress of man from the mere animal to the intellectual creature, nor of the improvement of our understanding by social intercourse and the arts of life, but believed that man when he came to a certain age has from nature all the faculties which we see him exert, and particularly the faculty of speech, should think him an idiot, and wanting even the capacity of acquiring understanding. I knew an officer of dragoons, a man of very good sense, who was quartered where Peter then lived for some months, and saw him almost every day, and who assured me that he was not an idiot, but showed common understanding, which was all that could be expected from one no better educated than he.

"5thly. Lastly, those who have considered what I have said (a) of the difficulty of articulation, will not be surprised that a man who had lived a savage for the first 14 or 15 years of his life, should have made so little progress in that art. I cannot, however, have the least doubt, that if he had been under the care of Mr Braidwood of Edinburgh, he would have learned to speak, though with much more difficulty than a man who had been brought up tame among people who had the use of speech, and who consequently must know the advantage of it. And I can have as little doubt that Mr Braidwood could have taught the orang-outang in Sir Aliston Lever's collection, who learned to articulate a few words, so as to speak plainly enough."

St Peter's Le Port, a market-town of England, in the south-east part of Guernsey, in Hampshire, in the British channel, consisting of only one long and narrow street. The mouth of the harbour is well fit with rocks, and is on each side defended by a castle, one called the old castle, and the other castle corner. The governor of the island generally resides here, who has the command of the garrison in this and all the other castles. The harbour has a good road, from whence ships may fall with any wind, and from the road pass under the guns of the castle to the pier, close up to the town. The pier is a noble work, formed of valet stones, joined together with great art and regularity; it is not only a security to the ships, but, being contiguous to the town, is hallowed paved at the top with large smooth flag-stones, guarded with parapets, and being of a great length and breadth, forms a pleasant walk, affording a fine prospect of the sea and the neighbouring islands. Cormorant-castle, which commands both the town and the harbour, stands on a rock, separated from the land by an arm of the sea, not less than 600 yards wide, and not fordable but at low water in great spring tides.

St Peter's Island, in the lake of Bienne in Switzerland, remarkable for being one of the retreats of Rouffiez; whence it has also got the name of Rouffiez's Island. It lies towards the south side of the lake, and produces a great variety of shrubs and trees, particularly large oaks, beech, and Spanish chestnut. The southern shore slopes gradually to the lake, and is covered with herbage; the remaining borders are steep and rocky; their summits in a few places thinly covered with shrubs; in others their perpendicular sides are clothed to the water's edge with hanging woods. The views from the different parts of the island are beau-

(a) Lord Monboddo, far from thinking speech or articulation natural to man, rather wonders how he can by any teaching or imitation attain to the ready performance of such various and complicated operations. Add to this, when the organs are completely formed to one language, how hard it is to make them answer another.
beautiful and diversified; that to the north being the most extensive and pleasing. It commands the prospect of the lake, which is of an oval form; its cultivated borders, interspersed with villages and cailleys, with the towns of Nidan and Biene standing upon the farther extremity. Agreeable walks are carried through the woods, and terminate in a circular pavilion placed in the centre of the island. Before the bridge, is navigable dancing in the circular pavilion. How

There is a town in Scotland, in the county of Aberdeen, lies about 30 miles north-east of that city. It stands on the most easterly point in Scotland, and from thence due west that kingdom is broadest.

Peterhead is the nearest land to the northern continent of Europe, and lies within 300 miles of the Cape, which is called the Name of Norway. Through this channel the grand body of the herrings pass in their annual migrations from Shetland and the north seas to the more southern latitudes, attended with the all-devouring cod and ling; on which account Peterhead, or as it is sometimes called, Buchanens, hath always been the second port of the Dutch in the Shetland islands. Tradition says that some hundred years ago the Dutch offered Lord Mareschal, then the proprietor of the coast, to cover a small island called Inch-Keith with silver for the property of it to carry on their fisheries, which for obvious reasons could not be accepted. Be that as it may, the Dutch still frequent the coast in July and August, and sometimes 100 sail are seen within the sight of land, busily employed in the herring and white fisheries. The natives, to whom this fishery properly belongs, have lately made some attempts towards the white fishery, of which they are expert and vend chiefly at the London market 4000 barrels of delicate small cod and ling annually. They also fit out some vessels for the Hebridean fishery off Barrahead for the Barcelona market and they claim the merit of having taught the islanders how to take and cure the large fish which abound on their coasts. They have often gained the highest premiums allowed by government for curing white fishes.

Few harbours in Great Britain are of more importance to navigation than this of Peterhead, as in case of violent storms from the easterly points, large vessels embayed betwixt this and the mouth of the Forth have not a port that they can safely take at every time of the tide, that of Aberdeen excepted. If therefore they cannot make their way to sea in the teeth of a strong easterly wind, or dare this headland that they may gain the Murray firth, they must inevitably come
Peterhead, on shore. This harbour lies on a spacious bar, where vessels of any burden may ride in all other winds, and is therefore the general rendezvous of the shipping which frequent the northern seas, where they call anchor on clean ground, and ride safely till the storms have abated. Though nature hath done so much for the benefit of navigation, something is left for the exercise of human art. The harbour can at present contain in perfect safety 40 or 50 sail of vessels drawing 12 feet water, and is capable of being extended so as to admit a greater number of ships drawing 20 feet; by which means not only casual merchantmen but small ships of war with their convoys, would find this a most defensible refuge when pursued by superior force. The harbour is defended by a good battery. A considerable trade is carried on from this place directly to the Baltic for deals, iron, hemp, tar, and other articles. There is also a manufacture of fishing thread, which employs many young girls. A mineral well in the summer-months gives great gouty to the place; its saline virtues have long, and we believe very justly, been celebrated. The waters of this spring are powerfully diuretic, and are thought to be efficacious in removing complaints in the bowels. There are here many elegant houses for the accommodation of strangers. There is also a ball room, under which there are two salt-water baths. These baths are much frequented in nervous disorders; their effect in strengthening the constitution is often surprising. Owing to the open panfluinated situation, the air of this place is peculiarly pure and healthful; even the saggings from the sea are thought to be medicinal: the town is therefore much enlivened by the concourse of company who frequent it on these accounts. Upon the whole, the town is neat and well built, the houses are handsome, and the streets tolerably spacious and very clean; and it has every appearance of a thriving, plentiful, and happy place.

PETERHOFF, in Russia, is situated about 50 miles from Petersburg, and is distinguished for its palace and gardens. The palace was begun by Peter I. and finished by Elizabeth. As it is placed upon an eminence, it commands a most superb view of the island, Peterbourg, the intervening gulf, and the opposite coast of Carelia. The palace is most magnificently furnished, and the saloon of apartments is truly princely. The presence-chamber is richly ornamented with portraits of the sovereigns of the house of Romanoff, who have reigned in Russia since 1613.

"The gardens of Peterhof (says an intelligent traveller) have been celebrated for their taste and elegance; and from the number of jet d’eaux, fountains, basins, cascades, parterres, &c., they have been compared to those of Versailles: and indeed in one respect they are far superior; for the water-works of the Latter only play upon particular occasions, while those of Peterhof are perennial. These gardens, which at the time of their formation were greatly admired in this country, though not congenial to the taste of the emperors, are far from falling in their present state; as during summer her majesty principly resides at Tsarsko-Setl, where the grounds are disposed in a more modern and pleasing manner." A vast number of live dolphins and gilded statues are scattered through them; but the most remarkable figure are those of two gladiators placed in a basin of water. These are represented, not with the sword and buckler, the ancient implements of war, but with a brace of pistols. These they point to each other in a threatening posture, while the water gushes impetuously from the barrel. In that part of the garden which lies between the palace and the gulf, close to the water, is a building which was the favourite retreat of Peter I. It is presented, together with its furniture, entirely in its original state with a kind of religious veneration. Its plainness shows the frugal simplicity in which this monarch was accustomed to live. In the same celebrated gardens there is a remarkable building called the mountain for fedges, and often by travellers the flying mountain. "It stands (says Mr. Cox) in the middle of an oblong area, inclosed by an open colonnade, with a flat roof, which is raised for the convenience of holding spectators. The circumference of this colonnade is at least half a mile. In the middle of the area stands the flying mountain, stretching nearly from one end to the other. It is a wooden building, supported upon pillars, representing an uneven surface of ground, or a mountain composed of three principal rocks, gradually diminishing in height, with an intermediate space to resemble valleys; from top to bottom is a floored way, in which three parallel grooves are formed. It is thus used; a small carriage containing a person being placed in the centre grove upon the highest point, goes with great rapidity down one hill; the velocity which it acquires in its descent carries it up a second; and it continues to move in a similar manner until it arrives at the bottom of the area, where it rolls for a considerable way on the level surface, and stops before it attains the boundary: it is then placed in one of the side grooves, and drawn up by means of a cord fixed to a windlass. To a person unacquainted with the mechanism, this amusement would appear tremendous; but as the grooves always keep the carriage in its right direction, there is not the least danger of being overturned. At the top of the mountain there is a handsome apartment in which the court and principal nobility there is also a room for many thunderspectators within the colonnade and upon its roof. Near the flying mountain is a spacious amphitheatre, in which tournaments are usually exhibited.

PETERS (Father), a Jesuit, was confessor and counsellor to James II. king of England. This prince dethroned him in 1688, because he was considered as the author of those troubles in which the kingdom was then involved. "He was (says Bishop Burnet) the most violent of the king’s advisers, and the person most listened to. Though he had the honour of being nobly defended, he was a man of extensive erudition, and was eminent only for his bigotry and forwardness." Though Burnet is not always to be believed, yet certain it is, from the testimony of other historians, that Father Peters was by no means a person properly qualified to direct King James in the critical situation in which he then found himself.

PETERSBURG (St.), a city of the province of Ingria in Russia, and capital of the whole empire. It is situated in N. Lat. 59°, 26', 25, and E. Long. 25°, 25', from the first meridian of Greenwich. It was founded in the year 1703 by Czar Peter the Great, whose

ambit-
The spot he pitched upon was a low, fenney, uncultivated island, formed by the branches of the river Neva, before they fall into the gulf of Finland. In the summer this island was covered with mud; and in winter became a frozen pool, rendered almost inaccessible by dreary winter. The spot became a frozen pool, rendered almost inaccessible by dreary winter. The spot upon which Peter, the conqueror assembled in Ingria above 300,000 men, Russians, Tartars, Cossacks, Livonians, and others, even from the most distant parts of his empire, and laid the foundation of the citadel and fortifications, which were finished in four months, almost in defiance of nature. He was obliged to open ways through forests, drain bogs, raise dykes, and lay caissons, before he could pretend to found the new city. To workmen were all provided with necessary tools and implements, such as spades, pick-axes, shovels, planks, and wheel-barrows; they were even obliged to fetch the earth from a great distance in the skirts of their garments, or in little bags made of old mats and rags sewed together. They had neither huts nor houses to shelter them from the severity of the weather; the country, which had been desolated by war, could not accommodate such a multitude with provisions; and the supplies by the lake Ladoga were often retarded by contrary winds. In consequence of these hardships, above 100,000 men are said to have perished; nevertheless the work proceeded with incredible vigour and expedition; while Peter, for the security of his workmen, formed a great camp, in such a manner, that his infantry continued in Finland, and his cavalry were quartered in Ingria. Some Swedish cruisers being delayed in the neighbourhood, the Czar posted a body of troops in the Isle of Rutzari, by whom the Swedes were repulsed, and the work met with no farther interruption. The buildings of the city kept pace with the fortresses, which is the centre of the town, surrounded on all sides by the Neva; and in little more than a year, above 30,000 houses were erected. At present there may be about double that number in Petersburg, though many of them are paltry and inconvenient. In order to people this city, Peter invited other merchants, artificers, mechanics, and lemen, from all the different countries of Europe: he demolished the town of Neuchantz, and brought hither not only the materials of the houses, but the inhabitants themselves. A thousand families were drawn from Moscow; he obliged his nobility to quit their palaces and their villas in and about Moscow, and take up their residence at Petersburg, in a much more cold and comfortable climate. Finally, resolving to remove hither the trade of Archangel, he issued an ordnance, imposing that all such merchandise as had been conveyed to Archangel, in order to be sold to foreigners, should now be sent to Petersburg, where they should pay no more than the usual duties. These endeavours and regulations have rendered this one of the greatest and most flourishing cities in Europe. The Russian boyars and nobility have built magnificent palaces, and are now reconciled to their situation. At first many houses were built of timber; but these being subject to sudden conflagrations in spite of all the precautions that could be taken, the Czar, in the year 1714, issued an order, that all new houses should be walled with brick and covered with tiles. The fort is an irregular hexagon, with opposite bastions. This, together with all the rest of the fortifications, was in the beginning formed of earth only; but in the sequel they were faced with strong walls, and provided with cæsates, which are bomb-proof. In the curtain of the fort, on the right hand side, is a noble dispensary, well supplied with excellent medicines, and enriched with a great number of porcelain vases from China and Japan. From one of the gates of the fort a drawbridge is thrown over an arm of the river, in which the Czar's galleys and other small vessels are sheltered in the winter. The most remarkable building within the fort is the cathedral, built by the direction of an Italian architect. Petersburg is partly built on little islands, some of which are connected by bridges; and partly on the continent. In the highest part, on the bank of the Neva, the Czar fixed his habitation, or ordinary residence, built of freestone, and situated so as to command a prospect of the greater part of the city. Here likewise is a royal foundery; together with the superb houses of many noblemen. The marshy ground on which the city is built, being found extremely slippery, dirty, and incommodious, the Czar ordered every inhabitant to pave a certain space before his own door. In the year 1716, Peter taking a fancy to the island Wafilk-Olterno, which he had given as a present to prince Menzikoff, refused the grant and ordered the city to be extended into this quarter. He even obliged the boyars, or nobles, to build stone-houses on this spot, though they were already in possession of others on the side of Ingria: accordingly this is now the most magnificent part of the city. On the other side of a branch of the Neva stands the Czar's country or summer palace, provided with a fine garden and orangery. On the bank of the same river is the laboda, or suburbs, in which the Germans generally choose their habitation. Petersburg is very much subject to dangerous inundations. In the year 1715, all the battlements and drawbridges were either overwhelmed or carried away. The breadth, depth and rapidity of the Neva, have rendered it extremely difficult, if not impracticable, to join the islands and the continent by bridges. Besides, Peter was averse to this expedient for another reason; resolved to accustom his subjects to navigation, he not only rejected the project of a bridge, but also ordered that no boat should pass between the islands and continent, except by the help of oars only. In consequence of this strange regulation, many lives were lost; but at length he gained his point; and by habituating his flagni Moucovites to the dangers of the sea, in a little time produced a breed of hardy sailors. The adjacent country is so barren, that the town must be supplied with provisions from a great distance; consequently they are extremely dear. Here are woods in plenty, consisting of pine, fir, alder, birch, poplar, and elm; but the oak and the beech are generally brought from Casan. In winter the weather is extremely cold, and hot in the summer. In June the length of the night does not exceed three hours, during which the natives...
improvements, which the passing century has given Peterburg birth to, but in the annals of history; and Russia would again, in all probability, relapse into her original barbarism.

The erection of such a city as Peterburg in so short a time is truly wonderful. Mr. Coxe says his mind was filled with astonishment, when he reflected that so late as the beginning of this century the ground on which it stands was one vast morass, occupied by a very few fishermen's huts. The present divisions of the town, some of which we have already mentioned, are called, 1. The Admiralty quarter; 2. The Valfill O-firo or Island; 3. The Fortress; 4. The Island of St Peterburg; and, 5. The various suburbs of Livonia, of Moscows, of Alexander Nevski, and Wilburgh.

The present Empress has done so much for this city, that the may not improperly be called her second hundred. It is, nevertheless, still an infant place, and, as Mr. Wraxall observes, "only an immense outline, which will require future emperors, and almost future ages, to complete."

"The streets in general, says a late traveller, are Coxe's broad and spacious; and three of the principal ones, Travels, which meet in a point at the Admiralty, and reach to the extremities of the suburbs, are at least two miles in length. Most of them are paved; but a few are still covered to remain floored with planks. Several parts of the metropolis, particularly in the Valfill O-firo, wooden houses and habitations, fearfully superior to common cottages, are blended with the public buildings; but this motley mixture is far less common than at Moscow, where alone can be formed any idea of an ancient Russian city. The brick houses are ornamented with a white stucco, which has led several travellers to say that they are built with stone; whereas, unless I am greatly mistaken, there are only two stone structures in all Peterburg. The one is a palace, building by the empress upon the banks of the Neva, called the marble palace; its vast marble columns, with marble statues and ornaments; the other is the church of St Isaac, constructed with the same materials, but not yet finished.

"The mansions of the nobility are many of them vast piles of buildings, but are not in general upon so large and magnificent a scale as several I observed at Moscow; they are furnished with great cellof, and in the same elegant style as at Paris or London. They are situated chiefly on the south side of the Neva, either in the Admiralty quarter, or in the suburbs of Livonia and Moscow, which are the finest parts of the city."

See Nева.

"Peterburgh, although it is more compact than the other Russian cities, and has the houses in many streets contiguous to each other, yet still bears a resemblance to the towns of this country, and is built in a very fragrancing manner. By an order lately issued from government, the city has been inclosed within a rampart, the circumference whereof is 21 versts, or 14 English miles."

The same accurate observer calculates the number of inhabitants at Peterburg, and makes the medium number 130,000.

We have already said that Peterburg is very liable to inundation. An inundation of a very alarming nature took place when Mr. Coxe was there in Sep-
The inundation of 1777 was accompanied, or instantaneously succeeded, by a south-westerly wind in that sea and the gulf of Finland. All these circumstances concurred at the inundation of 1777; it happened two days before the autumnal equinox, four before the full moon, two after her setting through the perigeeum, and by a storm at south-west, which was preceded by strong south-west winds in the northern ocean, and strong north winds at the mouth of the Baltic."

See *Notices et Remarques sur les débordements de la Neva à St Peterbourg*, accompagnées d'une carte représentant la crue et la diminution des eaux, &c. in Nov. Acad. Pet. for 1777, P. II. p. 47, to which excellent treatise we would refer the curious reader for farther information.

All our readers have unquestionably heard of the equerrian statue of Peter I. in bronze. We shall give an account of that extraordinary monument in Mr Coxe's own words. "It is (of br) of a colossal size, and is the work of M. de Falconet, the celebrated French flautry, caft at the expense of Catharine II., in honour of her great predecessor, whom she reveres and admires. It represents that monarch in the attitude of mounting a precipice, the summit of which he has nearly attained. He appears crowned with laurel, in a loose Asiatic veil, and sitting on a housing of bear-skin: his right hand is stretched out as in the act of giving benediction to his people; and his left holds the reins. The design is masterly, and the attitude is bold and spirited. If there be any defect in the figure, it consists in the flat position of the right hand; and for this reason, the view of the left side is the most striking, where the whole appearance is graceful and animated. The horse is rearing upon its hind legs; and its tail, which is full and flowing, slightly touches a bronze serpent, artfully contrived to afford in supporting the vaft weight of the statue in due equilibrium. The artist has, in this noble effay of his genius, represented Peter as the legislator of his country, without any allusion to conquest and bloodshed; wisely preferring his civil qualities to his military exploits. The contrail between the composed tranquility of Peter (though perhaps not absolutely characteristic) and the fire of the horse, eager to press forward, is very striking. The simplicity of the inscription corresponds to the sublimity of the design, and is far preferable to a pompous detail of exalted virtues, which the voice of flattery applies to every sovereign without distinction. It is elegantly finished in brass characters, on one side in Latin, and on the oppofite in Russian.*

The statue, when I was at Peterourg, was not erected, but fixed under a large wooden shed near the Neva, within a few yards of its enormous pedestal. When Falconet had conceived the design of his statue, the base of which was to be formed by a huge rock, he carefully examined the environs of Peterbourgh, if, among the detached pieces of granite which are scattered about these parts, one could be found of magnitude correspondent to the dimensions of the equerrian figure. After a confiderable research, he discovered a stupendous mass half buried in the midst of the morass. The expanse and difficulty of transporting it were no obstacles to Catharine II. By her order the
Petersburg, the morass was immediately drained, a road was cut through a forest, and carried over the marshy ground; and the flume, which after it had been somewhat reduced weighed at least 1500 tons, was removed to Petersburg. This more than Roman work was, in less than six months from the time of its first discovery, accomplished by a windlass, and by means of large friction-balls alternately placed and removed in grooves fixed on each side of the road. In this manner it was drawn, with forty men seated upon its top, about four miles to the banks of the Neva; there it was embarked in a vessel constructed on purpose to receive it, and thus conveyed by the same distance by water to the spot where it now stands. When landed at Petersburg, it was 42 feet long at the base, 39 at the top, 21 thick, and 17 high; a bulk greatly surpassing in weight the most boasted monuments of Roman grandeur, which, according to the fond admirers of antiquity, would have baffled the skill of modern mechanics, and were alone sufficient to render conspicuous the reign of the most degenerate emperors. "The pedestal, however, though half of prodigious magnitude, is far from retaining its original dimensions, as, in order to form a proper station for the statue, and to represent an aspect, the summit whereof the horse is endeavouring to attain, its bulk has been necessarily diminished. But I could not observe, without regret, that the artist has been deficient to improve upon nature; and in order to produce a resemblance of an abrupt broken precipice, has been too lavish of the chisel. Near it was a model in platter, to the shape of which the workmen were fashioning the pedestal. It appeared to me, that in this model the art was too conspicuous; and that the effect would have been far more sublime, if the flume had been left as much as possible in its rude state, a vail unwieldy stupendous mass. And indeed, unless I am greatly mistaken, the pedestal, when finished according to this plan, will have scarcely breadth sufficient to afford a proper base for a statue of such colossal size."

"The statue was erected on the pedestal on the 27th of August 1782. The ceremony was performed with great solemnity, and was accompanied with a solemn inauguration. At the same time the empress issued a proclamation, in which, among other instances of her clemency, she pardons all criminals under sentence of death; all deserters, who would return on duty, having no boards, which are of great use to protect the glands of the throat, generally tie handkerchiefs under their chins, and cover their ears with small cases of flannel."

Petersburg, in America, is a sea-port town in Virginia, 25 miles southward of Richmond, seated on the south side of the Appamatox river, about 15 miles above its junction with James River, and contained nearly 300 houses in 1787, in two divisions; one is upon a clay, cold soil, and is very dirty; the other upon a plain of sand or loam. There is no regularity, and very little elegance in Petersburg. It is merely a place of business. The Free Masons have a hall tolerably elegant; and the seat of the Bowling family is pleasant and well built. It is very unhealthy. About 2200 hogheads of tobacco are imported here annually. Like Richmond, Williamsburg, Alexandria, and Norfolk, it is a corporation; and what is singular, Petersburg city comprehends part of three counties. The celebrated Indian queen, Pocahontas, from whom descended the Randolph and Bowling families, formerly resided at this place.

PETERSFIELD, is a handsome town in Hampshire in England, and sends two members to parliament. It is seated in W. Long. 1° 5' N. Lat. 51° 5'.

PETERWARADIN, a fortified town in Scania, and one of the strongest frontier places the house of Austria has against the Turks, seated on the Danube between the Drave and the Save. E. Long. 20° 0'. N. Lat. 45° 20'.

PETIOLE, in botany, the slender flanks that support the leaves of a plant.

PETIT, or PETIT, a French word signifying little or small.

PETITE GUERRE, denotes the operations of detached parties and the war of polks. See War, Part III.

PETIT SERGEANT. See SERGEANT.

PETIT TRESOR. See TREASURE.

PETIT (John), a doctor of the Sorbonne, very early gained to himself a character by his knowledge, and those eloquent orations which he pronounced before the university of Paris. He was employed in the famous embassy which was sent from France to Rome, for the purpose of healing the schism in 1407; but he soon lost all the honour which he had acquired. John Sans
Sans Peur, duke of Burgundy, having treacherously contrived to affranchise Louis of France, duke of Orleans, only brother to Charles VI. John Petit, entirely devoted to the views of the murderer, maintained in a public disputation, at Paris, the 8th of March 1408, that the murder was lawful. He had the effrontery to asert, that it is allowable to employ fraud, treason, and every other method, however base, in order to get rid of a tyrant; and that no oath ought to be kept with him." He dared to add further, that "the man who should commit such an action, not only deferred to be exempted from punishment, but to receive a reward." This singular doctrine was loudly exclaimed against; but the duke of Burgundy’s powerful influence sheltered Petit for some time. Some eminent writers, however, of that period, with Germain at their head, denounced the doctrine to John de Montigu, bishop of Paris, who condemned it as heretical, the 3rd of November 1414. It was likewise condemned by the council of Constance the year following at the instigation of Germain; but no notice was taken of either of Petit’s name or his writings. In fine, the king, on the 16th of September 1416, ordered the parliament of Paris to pronounce a severe decree against this dangerous performance; and it was also cenured by the university. But the duke of Burgundy, in 1418, had interest enough to compel the grand vicars of the bishop of Paris, who then lay sick at St Omer’s, to retract the sentence which that prelate had passed in 1414. Petit died three years before, i.e. in 1411, at Heidelberg; and his apology in favour of the duke of Burgundy, with all the particulars of that infamous translation, may be seen in the fifth volume of the last edition of Germain’s works.

Father Pinchon, of the order of St Francis, and author of the Dictionary of Heresies, in 1410, has endeavoured to vindicate his order from a charge brought by some writers who have called Petit a Cordelier or Franciscan friar. "He proves very clearly (says Abbé Prevot) that he was a secular priest; and adds, that upon the same evidence, Father Mercier, a Cordelier, had a warm dispute in 1717 with M. Dupin, who had given this title to Petit in his Collection of Censures. He represented to him (says he), before a meeting of the Faculty, the falsity of such a claim, and the injury which he offered to the order of St Francis. Dupin, convinced of his error, candidly owned that he was led into it by following some infidel writers, and promised to retract it in the new edition of the Censures, which was published in 1720. M. Fleury, who had committed the same mistake, promised also to make amendments for it by a solemn reparation; but dying before he had an opportunity of doing that piece of justice to the Cordeliers, the continuator of his Ecclesiastical History, who had not such opportunities of information, fell into the same fault."

Petit (John Lewis), an eminent surgeon, born at Paris in 1674. He had so early an inclination to surgery, that Mr Littre, a celebrated anatomist, being in his Father’s house, he regularly attended that gentleman’s lectures, from his being seven years of age. He was received master in surgery in the year 1700; and acquired such reputation in the practice of that art, that in 1726 the king of Poland sent for him to his court, and in 1734 the king of Spain prevailed on him to go into that kingdom. He restored the health of those princes; and they endeavoured to detain him by offering him great advantages, but he chose rather to return to France. He was received into the academy of sciences in 1715; became director of the royal academy of surgery; made several important discoveries; and invented new instruments for the improvement of surgery. He died at Paris in 1750. He wrote an excellent Treatise on the Difficulties of the Bones, the best edition of which is that of 1731; and many learned Disquisitions in the Memoirs of the Academy of Sciences, and in the first volume of the Memoirs of Surgery.

PETITIO PRINCIPII, in logic, the taking a thing for true, and drawing conclusions from it as such, when it is really false; or at least wants to be proved before any inferences can be drawn from it.

PETITION, a supplication made by an inferior to a superior, and especially to one having jurisdiction. It is used for that remedy which the subject hath to help a wrong done by the king, who hath a prerogative not to be sued by writ: In which case it is either general, that the king do him right; whereupon follows a general endorsement upon the same, Let right be done the party: Or it is special, when the conclusion and indorsement are special, for this or that to be done, &c.

By statute, the soliciting, labouring, or procuring the putting the hands or content of above twenty persons to any petition to the king or either house of parliament, for alterations in church or state, unless by assent of three or more justices of the peace of the county, or a majority of the grand jury in the affizes or sessions &c. and repairing it to the king or parliament to deliver such petition with above the number of ten persons, is subject to a fine of 100l. and three months imprisonment, being proved by two witnesses within six months, in the court of B. R. or at the affizes, &c. And if what is required by this statute be observed, care must be taken that petitions to the king contain nothing which may be interpreted to reflect on the administration; for, if they do, it may come under the denomination of a libel: and it is remarkable, that the petition of the city of London for the sitting of a parliament was deemed libellous, because it suggested that the king’s disolving a late parliament was an obstruction of justice; also the petition of the seven bishops, sent to the tower by James II. was called a libel, &c. To subscribe a petition to the king, to fright him into a change of his measures, intimating that if it be denied many thousands of his subjects will be discontents, &c. is included among the contents against the king’s person and government, tending to weaken the same, and is punishable by fine and imprisonment.
PET

Petitot was born at Geneva in 1609. He studied the art with such application, that he arrived at a degree of perfection that may almost be accounted miraculous. He was wonderfully patient in finishing his works, though he had the address to conceal his labour; however, he only painted the heads and hands of the figures; the hair, grounds, and drapery being executed by Border his brother-in-law. These two artists had the credit of associating and labouring together for fifty years, without the least misunderstanding happening between them. It is attested by an ingenious French writer, that Petitot and Border derived the knowledge of the most curious and durable colours proper for enamelling, from Sir Theodore Mayerne at London, who recommended Petitot to Charles I. He had the honour to paint the portraits of that monarch and the whole royal family, and continued in England until Charles’s unhappy end: he then went to Paris, where he was highly favoured by Louis XIV. and acquired an ample fortune. Being a Protestant, the revocation of the edict of Nantes obliged him to retire to Geneva; but settling soon after at Veray in the canton of Berne, he passed the remainder of his life in peace and affluence. He died in 1691; and had 17 children: of whom one took to painting, and settled at London, where he gained good reputation; but was much inferior to his father.

Petitot may be called the inventor of painting portraits in enamel. Though his friend Border made several attempts before him, and Sir Theodore Mayerne had facilitated the means of employing the most beautiful colours; yet Petitot completed the works, which under his hand acquired a softness and liveliness of colouring that will never change, and will ever render his works valuable. He made use of gold and silver plates, and seldom enamelled on copper. When he had the address to conceal his labour; however, he soon railed to 40. It was his custom to take a painter with him, who painted the picture in oil; after which Petitot sketched out his work, which he always finished after the life. When he painted the king of France, he took those pictures for his copies that most resembled him; and the king afterwards gave him a sitting or two to finish his work.

PETIVERIA, in botany: A genus of the tetragyna order, belonging to the hexandria clafs of plants; and in the natural method ranking under the Holoracete.

PETRA (Cæsar, Lucian), a town of Greece, on the coast of Illyricum, near Dyrrhachium, and not far from the mouth of the river Panyas. Another PETRA, (Livy) ; a town of the river Medea, a district of Thrace, lying towards Macedonia; but in what part of Macedonia he does not say.

PETRA (Ptolemy). PETRAS, (Silius Italicus), PETRINA (Italicus); in both which last art is understood; an inland town of Sicily, towards the south-west of Ennygium, now Petra Phasis (Cheruisus).

PETRA (Teckiel (2 Kings xiv.), a town of the Amalekites; near the Advenius Scorpionis (Judges i.) and the valley of Salt in the south of Judæa; afterwards in the possession of the Edomites, after the destroying the Amalekites.

PETRA ruin or Rekui, so called from Rekam, king of the Midianites, this by the Israelites (Num. xxxi.) Formerly called Arcas, now Petra, the capital of Arabia Petra (Josephus). Petreum places it in Long. 66, 45, from the Fortunate Island, and Lat. 30. 20. It declines therefore 80 miles to the south of Jerusalem; and 156 miles, more or less, from its meridian to the calf. Josephus says, that the mountain on which Aaron died stood near Petra; which Strabo calls the capital of the Nabataeans; at the distance of three or four days journey from Jericho. This Petra seems to be the Sela of Isaiah xvi. 1. and xlii. 11. the Hebrew name of Petra “a rock.” Though some imagine Petra to be no older than the time of the Macedonians.

PETRARCH (Francis), a celebrated Italian poet, was born at Arezzo in 1304, and was the son of Petrarco di Parenzo. He studied grammar, rhetoric, and philosophy, for four years at Carpentras; from whence he went to Montpellier, where he studied the law under John Andreas and Cino of Pilota, and probably from the latter received a taste for Italian poetry. As Petrarch only studied the law out of complaisance to his father, who on his wishing him at Bologna had thrown into the fire all the Latin poets and orators except Virgil and Cicero; he, at 22 years of age, hearing that his father and mother were dead of the plague at Avignon, returned to that city to settle his domestic affairs, and purchased a country-house in a very solitary but agreeable situation, called Vauculs; where he first knew the beautiful Laura, with whom he fell in love, and whom he has immortalized in his poems. He at length travelled into France, the Netherlands, and Germany; and at his return to Avignon entered into the service of Pope John XXII., who employed him in several important affairs. Petrarch was in hopes of being raised to some considerable post; but being disappointed, he applied himself entirely to poetry; in which he met with such applause, that in one and the same day he received letters from Rome and the chancellor of the university of Paris, by which they invited him to receive the poetic crown. By the advice of his friends, he preferred Rome to Paris, and received that crown from the senate and people on the 8th of April 1341. "The ceremony of his coronation (says Gibbon) was performed in the Capitol by his friend and patron the supreme magistrate of the republic. Twelve patrician youths were arrayed in scarlet; fix representatives of the most illustrious families, in green robes, with garlands of flowers, accompanied the procession; in the midst of the princes and nobles, the senator, count of Anguillara, a kinman of the Colonna, affirmed his throne; and at the voice of an herald Petrarch aetate. After discharging on a text of Virgil, and thrice repeating his vows for the prosperity of Rome, he knelt before the throne, and received from the senates a laurel crown, with a more precious declaration, 'This is the reward of merit.' The people shouted, "Long life to the Capitol and the poet!” A fanet in praise of Rome was accepted as the effusion of genius and gratitude; and after the whole procession had visited the Vatican, the prelatic wreath was suspended before the shrine of St. Peter. In the act or diploma which was presented to Petrarch, the title
Petrarch

Petrarch, the title and prerogatives of poet-laureate are revived in the Capitol after the lapse 1300 years; and he receives the perpetual privilege of wearing, as his choice, a crown of laurel, ivy, or myrtle; of assuming the poetic habit; and of teaching, disputing, interpreting, and composing, in all places whatever, and on all subjects of literature. The grant was ratified by the authority of the senate and people; and the character of citizen was the recompense of his affection for the Roman name. They did him honour, but they did him justice. In the familiar society of Serafino Dobson, in 2 volumes folio. His life has been written by several authors. Amongst these there was one by Mrs Susanna Dobson, in 2 volumes 8vo, collected and abridged from the French. In this work we have the following elegant and just character of Petrarch.

"Few characters, perhaps, have in a stronger light the advantage of well-regulated dispositions than that of Petrarch, from the contrast we behold in one particular of his life, and the extreme misery he suffered from the indulgence of an affection, which, though noble and delightful when justly placed, becomes a reproach and a torment to its possessor when once directed to an improper object. For, let us not deceive ourselves or others; though (from the character of Laura) they are acquitted of all guilt in their personal intercourse, yet as she was a married woman, it is not possible, on the principles of religion and morality, to clear them from that just censure which is due to every delusion of the mind from those laws which are the foundation of order and peace in civil society, and which are flamped with the sacred mark of divine authority."

In this particular of his character, therefore, it is finely hoped that Petrarch will serve as a warning to those unhappy minds, who, partaking of the same feelings under the like circumstances, but not yet suffering his misery, may be led by the contemplation of it, by a generous regard to the honour of human nature, and by a view to the approbation of that all-seeming Judge who penetrates the most secret recesses of the heart, to check every unhappy inclination in its birth, and destroy, while yet in their power the feds of those passions which may otherwise destroy them.

"As to the cavils or cenures of those who, incapable of tenderness themselves, can neither enjoy the view of it when presented in its most perfect form, nor pity its sufferings when, as in this work, they appear unhappily indulged beyond the bounds of judgment and tranquility; to such minds I make no address, well convinced, that no callous heart can enjoy, neither will it ever be in danger of being misled by the example of Petrarch in this tender but unfortunate circumstance of his character."

To susceptible and feeling minds alone Petrarch will be ever dear. Such, while they regret his failings, and consider them as warnings to themselves will love his virtues; and touched by the growing piety and heart-feel contrition which often impressed his soul, will ardently desire to partake with him in those pathetic and sublime reflections which are produced in grateful and affectionate hearts, on reviewing their own lives, and contemplating the works of God.

"Petrarch had received from nature a very dangerous present. His figure was so distinguished as to attract universal admiration. He appears, in his portraits, with large and manly features, eyes full of fire, a blooming complexion, and a countenance that bespoke all the genius and fancy which shone forth in his works. In the flower of his youth, the beauty of his person was so very striking, that wherever he appeared, he was the object of attention. He possessed an understanding active and penetrating, a brilliant wit, and a fine imagination. His heart was candid and benevolent, susceptible of the most lively affections, and inspired with the noblest sentiments of liberty."

"But his failings must not be concealed. His temper was, on some occasions, violent, and his passions headstrong and unruly. A warmth of conflagration hurried him into irregularities, which were followed with repentance and remorse.—No essential vice, however, could be cast on his manners, till after the 25th year of his age. The fear of God, the thoughts of death, the love of virtue, and these principles of religion which were inculcated by his mother, preserved him from the surrounding temptations of his earlier life."

A resemblance has been traced, in several infancies, between this admired poet and our late famous Yorick.—Both, we know, had great wit and genius, and no less imprudence than eccentricity; both were canonics, or prebendaries, the Italian of Padua, &c. and the Englishman of York; they both ran over France, without any business there. If the bishop of Lombe's patronized and corresponded with the one, a prelate of the English church now deceased, defired Dr Gilpin in a letter, to forward the other. In their attachments to Laura and Eliza, both married women, these two prebendaries were equally warm and equally innocent. And even after death, a most remarkable circumstance has attended them both; some persons, prelom....we are told, stole Petrarch's bones, in order to sell them; and, in like manner, Yorick's body, it is confidently affirmed, was also stolen, and his skull has been exhibited at Oxford.

PETRE,
PETRE, of SALTPETRE, in chemistry. See CHEMISTRY, § 724, &c.

PETREA, in botany: A genus of the angiospermae order, belonging to the didynamia class of plants; and in the natural method of arranging under the order Pericarya. The calyx is quincuncipartite, very large, and coloured; the corolla rotundaceous; the capsule bicollare, and situated in the bottom of the calyx; and the seeds solitary. There is only one species, a native of New Spain. It rises to the height of 15 or 16 feet, with a woody stalk covered with grey bark, sending out several long branches. These have a white bark than the stem, and are garnished with leaves at each joint, which, on the lower part of the branches, are placed by three round them; but, higher up, they are rough, and have a rough surface. The flowers are produced at the ends of the branches, in loose bunches nine or ten inches long, each flower standing on a slender flower-stalk about an inch long: the emplacement of the flower is composed of five narrow obtuse leaves about an inch long, which are of a fine blue colour, and much more conspicuous than the petals, which are white, and not more than half the length of the emplacement. The plant is propagated by seeds procured from the places where they are natives, and of which very few are good; for though Dr Houfton, the discoverer of the plant, sent parcels of seeds to several persons in England, only two plants were produced from the whole. The seeds must be sown in a good hot-bed, and when the plants come up, they should all be planted in a separate small pot filled with light loamy earth, and plunged into a hot-bed of tanners' bark, where they should afterwards constantly remain.

PETRELA, in ornithology. See PROCÉLLARIA.

PETRIDIA, in natural history, a genus of scrupula, of a plain uniform texture; of so great variety of colours, and emulating the external form of pebbles.

PETRIFICATION, in phytology, denotes the conversion of wood, bones, and other substances, principally animal or vegetable, into stone. These bodies are more or less altered from their original state, according to the different substances they have lain buried among in the earth; some of them having suffered very little change, and others being so highly impregnated with crystaline, sparly, pyritic, or other extraneous matter, as to appear mere masses of stone or lumps of the matter of the common pyrites; but they are generally of the external dimensions, and retain more or less of the internal figure, of the bodies into the pores of which this matter has made its way. The animal substances thus found petrified are chiefly shells; the teeth, bony palates, and bones of fish, the bones of land animals, &c. These are found variously altered, by the infusion of limy and mineral matter into their pores; and the substance of some or them is now wholly gone, there being only flaky, sparry, or other mineral matter remaining in the shape and form.

Reflecting the manner in which petrification is accomplished, we know but little. It has been thought by many philosophers, that this was one of the rare processes of nature; and accordingly such places as afforded a view of it, have been looked upon as great curiosities. However, it is now discovered, that petrification is exceedingly common; and that every kind of water carries in it some earthly particles, which being precipitated from it, become stone of a greater or lesser degree of hardness; and this quality is mostly remarkable in those waters which are much impregnated with selenitic matter. Of late, it has also been found, vide Phil. Trans. p. 35. by some observations on a petrification in East Lothian in Scotland, that iron contributes greatly to the process: and this it may do by its precipitation of any aluminous earth which happens to be disolved in the water by means of an acid; for iron has the property of precipitating this earth, though it cannot precipitate the calcareous kind. The calcareous kinds of earth, however, by being soluble in water without any acid, must contribute very much to the process of petrification, as they are capable of a great degree of hardness; by means only of being joined with fixed air, on which depends the solidity of our common cement or mortar used in building houses.

The name petrification belongs only, as we have seen, to bodies of vegetable or animal origin; and in order to determine their class and genus, or even species, it is necessary that their texture, their primitive form, and in some measure their organization, be fully discernible. Thus we ought not to place the foamy kernels, moulded in the cavity of some shell, or rather organized body, in the rank of petrification properly so called.

Petrifications of the vegetable kingdom are almost all either gravelly or siliceous; and are found in gullies, trenches, &c. Those which strike fire with a shell are principally found in sandy situations; those which effervesce in acids are generally of animal origin, and are found in the horizontal beds of calcareous earth, and sometimes in beds of clay or gravel; in which case the nature of the petrification is different. As to the substances which are found in gypsum, they seldom undergo any alteration, either with respect to figure or composition, and they are very rare.

Organized bodies, in a state of petrification, generally acquire a degree of solidity of which they were not possessed before they were buried in the earth, and some of them are often fully as hard as the stones or matrices in which they are enclosed. When the stones are broken, the fragments of petrifications are easily found, and easily distinguished. There are some organized bodies, however so changed by petrification, as to render it impossible to discover their origin. That there is a matter more or less agitated, and adapted for penetrating bodies, which crumbles and separates their parts, draws them along with it, and disperses them here and there in the fluid which surrounds them, is a fact of which nobody seems to entertain any doubt. Indeed we see almost every substance, whether solid or liquid, infensibly change, diminish in bulk, and at last, in the lapse of time, vanish altogether.

A petrified substance, strictly speaking, is nothing more than the skeleton, or perhaps image, of a body which has once had life, either animal or vegetable, combined with some mineral. Thus petrified wood is not in that state wood alone. One part of the compound or mass of wood having been destroyed by local causes, has been compensated by earthy and sandy substances diluted and extremely minute, which the
The waters surrounding them had deposited while they themselves evaporated. These earthy substancess, being then moulded in the skeleton, will be more or less indurated, and will appear to have its figure, its structure, its size, in a word the same general characters, the same specific attributes, and the same individual differences. Further, in petrified wood, no veigite of ligneous matter appears to exist. We know that common wood is a body in which the volume of solid parts is greatly exceeded by that of the pores. When wood is buried in certain places, lapidific fluids, extremely divided and sometimes coloured, infinate themselves into its pores and fill them up. These fluids are afterwards moulded and condensed. The solid part of the wood is decomposed and reduced into powder, which is expelled without the malis by aqueous filtrations. In this manner, the places which were formerly occupied by the wood are now left empty in the form of pores. This operation of nature produces no apparent difference either of the size or of the shape; but it occasions both at the surface and in the inside, a change of sublance, in the ligneous texture is inverted; that is to say, that which was pore in the natural wood, becomes solid in that which is petrified; and that which was solid or full in the first state, becomes porous in the second. In this way, says M. Mufard, petrified wood is much less extended in pores than solid parts, and at the same time forms a body much more denfe and heavy than the firft. As the pores communicate from the circumference to the centre, the petrifaction ought to begin at the centre, and end with the circumference of the organic body subjected to the action of the lapidific fluids. Such is the origin of petrifications. They are organized bodies which have undergone changes at the bottom of the sea or the surface of the earth, and which have been buried by various accidents at different depths under ground.

In order to understand properly the detail of the formation of petrified bodies, it is necessary to be well acquainted with all their constituent parts. Let us take wood for an example. Wood is partly solid and partly porous. The solid parts consist of a sublance, hard, ligneous, and compact, which forms the support of the vegetable; the porous parts consist of vessels or interfaces which run vertically and horizontally across the ligneous fibres, and which serve for conducting air, lymph, and other fluids. Among these vessels the trachie which rise in spiral forms, and which contain only air, are easily distinguished. The cylindric vessels, some of which contain lymph, and others the ficac propius, are full only during the life of the vegetable. After its death they become vacant by the evaporation and abfence of the fluids with which they were formerly filled. All these vessels whether ascending or descending, unite with one another, and form great cavities in the wood and in the bark. According to Malpigii and Duhamel, the ligneous fibres are themselves tubular, and afford a passage to certain liqours; in short, the wood and bark are intersected with utriculi of different sizes and figures. The augmentation of the trunk in thickness, according to Malpigii, is accomplished by the annual addition of a new exterior covering of fibres and of trachie. Others think that a concentric layer of sapwood is every year hardened, while a new one is forming from the bark. But it is on all sides agreed that the concentric layers of wood are distinct from one another, because at the point of contact between any two of them, the new vessels, as well as new fibres, are more apparent and perceptible than they are in any other place. Having made these preliminary remarks on the structure of vegetables, we shall now proceed to give an abridged account of the manner in which M. Mongez explains their petrifcation.

In proportion to the tendereness and bad quality of wood, it imbibes the greater quantity of water; therefore this sort will unquestionably petrify more easily than that which is hard. It is thought that all the petrified wood so often found in Hungary has been originally soft, such as firs or poplars. Suppose a piece of wood buried in the earth; if it be very dry, it will suck up the moisture which surrounds it like a sponge. This moisture, by penetrating it, will dilate all the parts of which it is composed. The trachie, or air-vessels will be filled first, and then the lymphatic vessels and those which contain the ficac propius, as they are likewise empty. The water which forms this moisture keeps in dissolution a greater or a less quantity of earth; and this earth, detached, and carried along in its course, is reduced to such an attenuated state, that it escapes our eyes and keeps itself suspended, whether by the medium of fixed air or by the motion of the water. Such is the lapidific fluid. Upon evaporation, or the departure of the menhirum, this earth, sand or metal, again appears in the form of precipitate or sediment in the cavities of the vessels, which by degrees are filled with it. This earth is there moulded with exactness; there is a little larger, and consequently makes the vessels adhere to one another; the lateral fiction of the surrounding fibres, the obstruction of the moulds, and the hardening of the moulded earth, become general; and there confits nothing but an earthy sublance which prevents the sinking of the neighbouring parts. If the deposit is formed of a matter in general pretty pure, it preserves a whiter and clearer colour than the rest of the wood; and as the concentric layers are only perceptible and distinct in the wood, because the vessels are there more apparent on account of their size, the little earthy cylinders, in the state of petrified wood, must be there a little larger, and consequently must represent exactly the turnings and separations of these layers. At the place of the utriculi, globules are observed, of which the figures are various as the moulds wherein they are formed. The annelomodes of the proper and lymphatic vessels, form besides points of support or reunion for this earthy sublance.

With regard to holes formed by worms in any bits of wood, before they had been buried in the earth, the lapidific fluid, in penetrating these great cavities, deposits there as easily the earthy sediment, which is exactly moulded in them. These vermiform cylinders, are somewhat less in bulk than the holes in which they are found, which is owing to the retreat of the more refined earth and to its drying up.

Let any one represent to himself this collection of little cylinders, vertical, horizontal, inclined in different directions, the fony masses of utriculi and of annelomodes,
tomofes, and he will have an idea of the flony substance which forms the ground work of petrifaction. Hitherto not a single ligneous part is destroyed; they are all existing, but surrounded on every side with earthly deposits; and that body which, during life, was composed of solid and of empty parts, is now entirely solid: its destruction and decomposition do not take place till after the formation of these little deposits. In proportion as the water abandons them, it penetrates the ligneous substance, and destroys it by an insensible fermentation. The woody fibres being decomposed, form in their turn voids and interstices, and there remains in the whole piece nothing but little flony cylinders. But in proportion as these woody fibres disappear the surrounding moisture, loaded with earth in the state of dissolution, does not fail to penetrate the piece of wood, and to remain in its new cavities. The new deposit assumes exactly the form of decomposed fibres; it envelopes in its turn the little cylinders which were formed in their cavities, and ends by incorporating with them. We may suppose here, that in proportion as it decomposes, there is a reaction of the ligneous part against the lapidific fluid: from this reaction a colour arises which stains more or less the new deposit; and this colour will make it easily distinguishable from that which has been laid in the inside of the vessels. In all petrified wood this shade is generally perceptible.

We have then, says M. Mongez, four distinct epochs in the processes by which nature converts a piece of wood into flone; or, to speak more truly, by which she substitutes a flony deposit in its place: 1. Perfect vegetable wood, that is to say, wood composed of solid and of empty parts, of ligneous fibres, and of vessels. 2. Wood having its vessels obstructed and choked up by an earthly deposit, while its solid parts remain unaltered. 3. The solid parts attacked and decomposed, forming new cavities between the flony cylinders, which remain in the same state, and which support the whole mass. 4. These new cavities filled with new deposits, which incorporate with the cylinders, and compose nothing else but one general earthy mass representing exactly the piece of wood.

Among the petrifactions of vegetables called dendrites, are found parts of shrubs, ferns, roots, portions of the trunk, some fruits, &c. We must not, however, confound the impressions of mosses, ferns, and leaves, nor incrustations, with petrifactions.

Among the petrifactions of animals, we find shells, crustaceous animals, polyparii, some worms, the bony parts of fishes, and of amphibia, fow or no real insects, rarely birds and quadrupeds, together with the bony portions of the human body. The cornas amonis are petrified serpents; and with regard to figured and accidental bodies, there are fylla nature.

In order, says M. Bertrand, in his Dictionnaire des Fossilites, that a body should become petrified, it is necessary that it be, 1. Capable of preservation under ground: 2. That it be sheltered from the air and running water (the ruins of Herculaneum prove that bodies which have no connection with free air, preserve themselves untouched and entire). 3. That it be secured from corrosive exhalations. 4. That it be in a place where there are vapours or liquids, loaded either with metallic or flony particles in a state of dissolution, and which, without destroying the body, penetrate it, impregnate it, and unite with it in proportion as its parts are dissipated by evaporation.

It is a question of great importance among naturalists, to know the time which Nature employs in petrifying bodies of an ordinary size.—It was the wish of the late emperor, Duke of Lorraine, that some means should be taken for determining this question. M. le Chevalier de Baillu, director of the cabinet of natural history of his imperial majesty, and some other naturalists, had several years ago, the idea of making a research which might throw some light upon it. His imperial majesty being informed by the unanimous observations of modern historians and geographers, that certain pillars which are actually seen in the Danube in Gervia, near Belgrade, are remains of the bridge which Trajan constructed over that river, presumed that these pillars having been preferred for so many ages belonged to be petrified, and that they would furnish some information with regard to the time which Nature employs in changing wood into flone. The emperor thinking this hope well founded, and wishing to satisfy his curiosity, ordered his ambidator at the court of Constantinople to ask permission to take up from the Danube one of the pillars of Trajan's bridge. The petition was granted, and one of the pillars was accordingly taken up; from which it appeared that the petrifaction had only advanced three fourths of an inch in the space of 1500 years. There are, however, certain waters in which this transformation is more readily accomplished.—Petrifications appear to be formed more slowly in earths that are porous and in a slight degree moister than water itself.

When the foundations of the city of Quebec in Canada were dug up, a petrified sawage was found among the left boulders which they proceeded. Although there was no idea of the time at which that man had been buried under the ruins, it is however, true, that his quiver and arrows were still well preserved. In digging a lead mine in Derbyshire in 1744, a human skeleton was found among flag's horns. It is impossible to say how many ages this carcass had lain there. In 1695 the entire skeleton of an elephant was dug up near Tonna in Thuringia. Some time before this epoch the petrified skeleton of a crocodile was found in the mines of that country. We might cite another fact equally curious which happened at the beginning of the last century. John Munte, curate of Sigarp in Scania, and several of his parishioners, willing to procure turf from a drained marshy soil, found, some feet below ground, an entire cart with the skeletons of the horses and carter. It is presumed that there had formerly been a lake in that place, and that the carters attempting to pass over on the ice, had by that means probably perished. In fine, wood partly fossil and partly coaly has been found at a great depth, in the clay of which tile was made for the Abbey of Fontenay. It is but very lately that fossil wood was discovered at the depth of 75 feet in a well between Iff and Vauvres near Paris. This wood was in sand between a bed of clay and pyrites, and water was found four feet lower than the pyrites. M. de Lamont, inspector general of the mines, says (Journal de Physique, Mai 1736), that in the lead mine at Pontpéan near Rennes, is a figure, perhaps the only one of its kind. In that figure, feashells,
petrifactions. They are found 240 feet deep. This beech was laid horizontally in the direction of the fissure. Its bark was converted into pyrites, the sap-wood into jet, and the centre into coal.

A great many pieces of petrified wood are found in different countries of France and Savoy. In Cobourg in Saxony, and in the mountains of Mindana, trees of a considerable thickness have been taken from the earth which were entirely changed into a very fine agate, as also their branches and their roots. In sawing them, the annual circles of their growth have been distinguished. Pieces have been taken up, on which it was difficultly seen that they had been gnawed by worms; others bear visible marks of the animals themselves could not have made. The different species of petrifactions, according to Cronstedt, are,

I. Terra Larvatus; extraneous bodies changed into a limy sub stance or calcareous changes. These are, 1. Loosé or friable. 2. Indurated. The former are of a limy or chalky nature, neither do they decay in the air.

2. Thofe found in flate or clay are compreffed and flattened. The different species of petrifactions, according to Cronstedt, are,

I. Terra Larvatus; extraneous bodies changed into a limy sub stance or calcareous changes. These are, 1. Loosé or friable. 2. Indurated. The former are of a limy or chalky nature, neither do they decay in the air.

3. Thofe found in flate or clay are compreffed and flattened. The different species of petrifactions, according to Cronstedt, are,

I. Terra Larvatus; extraneous bodies changed into a limy sub stance or calcareous changes. These are, 1. Loosé or friable. 2. Indurated. The former are of a limy or chalky nature, neither do they decay in the air. The latter kind is the ofreocolla; which is said to be found in the collection of Peru.

II. Larva Argillacea; where the bodies appear to be changed into clay. Thefe are found either loose and friable, or indurated. Of the former kind is a piece of porcelain clay met with in a certain collection, with all the marks of the root of the tree upon it. Of the latter kind is the oitecolla; which is said to be the roots of the poplar- tree changed, and not to confift of any calcareous sub stance. A fort of fossil ivory, with all the properties of clay, is said likewise to be found in some places.

III. Larva Infinita; where the sub stances are impregnated with great quantities of salts. Human bodies have been twice found impregnated with vitriol of iron in the mine of Falun, in the province of Dalarne in Sweden. One of them was kept for several years in a glass cabinet, but at last began to moulder and fall to pieces. Turf and roots of trees are likewise found in water strongly impregnated with vitriol. They do not flame, but look like a coal in a long fire; neither do they decay in the air.

IV. Bodies penetrated by mineral inflammable sub stances. 1. By pit-coal, such as wood; whence some have imagined coal to have been originally produced from wood. Some of the substances are fully saturated with the coal-y matter; others not. Among the former Cronstedt reckons jet; among the latter the substance called mumiavegetabilis, which is of a loose texture resembling amber, and may be used as such. 2. Thofe penetrated by asphaltum, or rock-oil. The only example of these given by our author is a kind of turf in the province of Skone in Sweden. The Egyptian mummiies, he observes, cannot have any place among this species, as they are impregnated artificially with asphaltum, in a manner similar to what happens naturally with the wood and coal-y matter in the last species. 3. Thofe impregnated with sulphur which has dissolved iron, or with pyrites. Human bodies, bivalve and univalve shells and insects, have been all found in this state; and the latter are found in the alum flate at Andrarum, in the province of Skone in Sweden.

V. Larva Metalifer; where the bodies are impregnated with metals. These are, 1. Covered with native silver; which is found on the surface of shells
The Peppermint Tree.

Plate CCCLXXXVIII.
In England. 2. Where the metal is mineralised with copper and sulphur. Of this kind is the fabulifer or grey silver ore, in the shape of ears of corn, and supposed to be vegetables found in argillaceous slate at Frankenberg and Tabitteren in Hesse. 3. Larvæ capriformis, where the bodies are impregnated with copper. To this species principally belong the Turquois or Turkey stones, improperly so called; being ivory and bones of the elephant or other animals impregnated with copper. See Turchois. At Simore in Languedoc there are bones of animals dug up, which, during calcination, assume a blue colour; but according to Cordier it is not probable that these owe their colour to copper. 3. With mineralised copper. Of these our author gives two examples. One is where the copper is mineralised with sulphur and iron, forming a yellow marcasitical ore. With this some shells are impregnated which lie upon a bed of leadstone in Norway. Other petrifications of this kind are found in the form of fish in different parts of Germany. The other kind is where the copper is impregnated with sulphur and silver. Of this kind is the grey silver ore like ears of corn, found in the slate quarries at Hesse. 4. Larvæ ferriferæ, with iron in form of a cals, which has attached the place or shape of extraneous bodies. These are either loose or indurated. Of the latter kind are some roots of trees found at the lake Langelma in Finland. The indurated kinds are exemplified in some wood found at Orbifian in Bohemia. 5. Where the iron is mineralised, as in the pyriticous larve, already described.

VII. Where the bodies are tending to decomposition, or in a way of destruction. Among these, our author enumerates Mould and Turf, which see; also Cement, Mortar, Rock, Sand, Selinite, Stone, and Water. See likewise the article Fossil, Plates CC and CCI, and Mountain.

We shall add the following description of a very curious animal petrifaction. The Abbé de Sauvages, celebrated for his refined taste and knowledge in natural history, in a tour through Languedoc, between Alais and Uzes, met with a narrow vein of no more than two toises wide, which crosses the road, and is bordered on one side by a grey dirty soil, and on the other by a dry sandy earth, each of a vast expanse, and on a level with a narrow vein which separates them. In this narrow vein only are contained petrified shells, cemented together by a whitish marl. They are in prodigious plenty; among which there is one species which the Abbé does not remember to have known to have been any where described, and may probably be a new acquisition to natural history.

This shell has the shape of a horn, somewhat incurved towards the base. (See figure 9. Plate CCCLXXXVIII.) It seems composed of several cups, let into each other, which are sometimes found separate. They have all deep channels, which extend, as in many other shells, from the base to the aperture; the projecting ribs which form these channels are mostly worn away, being rarely found entire. Sometimes several are grouped together; and a proof that they are not a fortuitous assemblage caused by the petrifaction, they are fixed together through their whole length, in such fort, that their base and aperture are regularly turned the same way. The Abbé should have referred this to the genus which Linnaeus and the Marquis d'Argenville named Centilia, had they not been let into each other. He found some of them whose aperture or hollow was not stopped up by the petrifaction, and seemed as cones adapted to another (fig ii.), forming a row of narrow cells, separated by a very thin partition; this row occupied not more than one half of the cavity of the shell.

Our article has already extended to such a length as to preclude any further additions; we cannot, however, finish it without observing, that fossil bones, are very common in Dalmatia. They are of various kinds, and in their nature, apparently very extraordinary; but we have found no tolerable account or probable conjecture of their origin. Vitaliano Donati of Padua, in his Saggio sopra la naturale dell' Adriatico, was the first who took notice of them; and Fortis, in his travels into Dalmatia, has given a copious account of them. They are most common in the islands of Corfu and Olera. See Fortis's Travels into Dalmatia, page 440—460, and our article Vitaliano.

PETRIFIED CITY. The story of a petrified city is well known all over Africa, and has been believed by many considerable persons even in Europe. Louis XIV. was so fully persuaded of its reality, that he ordered his ambassador to procure the body of a man petrified from it at any price. Dr Shaw's account of this affair it as follows: "About 40 years ago (now more than 70), when M. le Maire was the French consul at Tripoli, he made great inquiries, by order of the French court, into the truth of the report concerning a petrified city at Ras Sem; and amongst other very curious accounts relating to this place, he told me a remarkable circumstance, to the great discredit, and even constutation, of all that had been so positively advanced with regard to the petrified bodies of men, children, and other animals.

Some of the Janizaries, who in collecting tribute traverse the district of Ras Sem, promised him that as an adult person would be too cumbersome, they would undertake, for a certain number of dollars, to bring him from thence the body of a little child. After a great many pretended difficulties, delays, and disappointments, they produced at last a little child, petrified, which they had found, as he learned afterwards, among the ruins of Leptis; and, to conceal the deceit, they broke off the quiver, and some other of the distinguishing characteristics of that deity. However, he paid them for it according to promise, 1000 dollars, which is about 150l. sterling, as a reward for their faithful service and hazardous undertaking; having run the risk, as they pretended, of being stung if they should have been discovered in thus delivering up to an infidel one of those unfortunate Mohtemans, as they take them originally to have been.

But notwithstanding this cheat and impostion had made the consul defist from searching after the petrified bodies of men and other animals; yet there was one matter of fact, as he told me, which still very strongly embarrased him, and even strongly engaged him in favour of the current report and tradition. This was some little loaves of bread, which he called a Tom, which had been brought to him from that place. His reasoning, indeed, thereupon, provided the pretended matter of fact had been clear and evident, was just and satisfactory.
P E T [ 250 ]

PETRIFIED
City.

satisfactory: for where we find loaves of bread, there, as he urged, some persons must have been employed in making them, as well as others for whom they were prepared. One of these loaves, he had, among other petrifications, very fortunately brought with him to Cairo, where I saw it, and found it to be an escultura of the difcoid kind, of the same fashion with one I had lately found and brought with me from the defects of Marah. We may therefore reasonably conclude, that there is nothing to be found at Ras Sem, unless it be the trunks of trees, echinites, and such petrifications as have been discovered at other places.

M. le Maire, inquirys, which we find were supported by the premise and performance of great rewards, have brought nothing further to light. He could never learn that any traces of walls, or buildings, or animals, or utensils, were ever to be seen within the verge of these pretended petrifications. The like account I had from a Sicilian renegado, who was the janizary that attended me whilst I was in Egypt; and as in his earlier years he had been a foldier of Tripoli, he assured me that he had been several times at Ras Sem. This I had confirmed again in my return from the Levant by the interpreter of the British factory at Tunis, who was likewise a Sicilian renegado; and being the libertus or freedman of the Bath of Tripoli, was preferred by him to be the bey or viceroy of the province of Darna, where Ras Sem was immediately under his jurisdiction. His account was likewise the same: neither had he ever seen, in his frequent journeys over this district, any other petrification than what are above-mentioned. So that the petrified city, with its walls, caleis, freets, shops, cattle, inhabitants, and utensils, were all of them at first the mere inventions of the Arabs, and afterwards propagated by such persons, who, like the Tripoli ambassador, and his friend above-mentioned, were credulous enough to believe them.

However, there is one remarkable circumstance relating to Ras Sem that deserves well to be recorded. When the winds have blown away the billows of sand which frequently cover and conceal these petrifications, they discover, in some of the lower and more depHessed places of this district, several little pools of water, which is usually of fo ponderous a nature, that, upon drinking it, it passes through the body like quicksilver. This perhaps may be that petrifying fluid which has all along contributed to the conversion of the palm-trees and the echinites into stones; for the formation not only of these, but of petrifications of all kinds, may be entirely owing to their having first of all lodged in a bed of loam, clay, sand, or some other proper nidus or matrix and afterward gradually been acted upon and pervaded by such a petrifying fluid as we may suppose this to be.

To this account it may not be amis to subjoin the memorial of Caffem Aga, the Tripoli ambassador at the court of Britain. The city, he says, is situated two days journey south from Ounguela, and 17 days journey from Tripoli by carava; and he writes: "As one of my friends (says the ambassador) desired me to give him in writing an account of what I know touching the petrified city, I told him what I had heard from different persons, and particularly from the mouth of one of credit who had been on the spot that is to say, that it was a very spacious city, of a round form, having great and small streets there in furnished with shops, with a vast cattle magnificently built; that he has seen there several forts of trees, the most part olives and palms, all of stone, and of a blue or rather lead colour: that he saw also figures of men in a posture of exercising their different employments, some holding in their hands staffs, others bread, every one doing something, even women suckling their children, and in the embraces of their husbands, all of stone; that he went into the cattle by three different gates, though there were many more where he saw a man lying upon a bed of stone: that there were guards at the gates with pikes and javelins in their hands; in short, that he saw in this wonderfully city many forts of animals, as camels, oxen, horses, asses, sheep, and birds, all of stone, and the colour above mentioned."

We have subjoined this account, because it shows in striking colours the amazing credulity of mankind, and the avidity with which they swallow the marvellous, and the difficulty of discovering the truth respecting places or things at a distance from us.

PETROBRUSSIANS, a religious sect, which had its rise in France and the Netherlands about the year 1150. The name is derived from Peter Bruys, a Provençal, who made the most laudable attempt to reform the abuses and remove the superstitious that disgraced the beautiful simplicity of the gospel. His followers were numerous; and for 20 years his labour in the ministry was exemplary and unremitting. He was, however, burnt in the year 1190 by an enraged populace set on by the clergy.

The chief of Bruys' followers was a monk named Henry; from whom the Petrobrussians are also called Henricians. Peter the Venerable, abbot of Cluny, has an express treatise against the Petrobrussians; in the preface to which he reduces their opinions to five heads. 1. They denied that child:en before the age of reason can be justified by baptism, in regard it is our own faith that saves by baptism. 2. They held that no churches should be built, but that those that already are should be pulled down; an inn being as proper for prayers as a temple, and a stable as an altar. 3. That the cross ought to be pulled down and burnt, because we ought to abhor the instruments of our Saviour's passion. 4. That the real body and blood of Christ are not exhibited in the eucharist, but merely represented by their figures and symbols. 5. That sacrifices, alms, prayers, &c. do not avail the dead.

F. Langlois objects Manichæism to the Petrobrussians; and says, they maintained two gods, the one good, the other evil: but this we rather ascribe an effect of his zeal for the catholic cause, which determined him to blacken the adversaries thereof than any real sentiment of the Petrobrussians.

PETROJOANNITIES, were followers of Peter John or Peter Joannis, i.e. Peter the son of John, who flourished in the 15th century. His doctrine was not known till after his death, when his body was taken out of his grave and burnt. His opinions were, that he alone had the knowledge of the true fene, wherein the apostles preached the gospel; that the reasonable soul is not the form of man; that there is no grace infused by
PET

by baptism: and that Jesus Christ was pierced with a lance on the cross before he expired.

PETROLEUM *, or Rock oil; a thick oily substance exuding out of the earth, and collected on the surface of the well: in many parts of the world. It is found on some in Italy, and in a deserted mine in the province of Dalame in Sweden. In this last place it collects itself in small hollows of limestone, like resin into wood of the pine-tree. It is found trickling from the rocks, or issuing from the earth, in many parts of the duchy of Modena, and in various parts of France, Switzerland, Germany, and Scotland as well as in Asia. It is also found not only on the surface of wells as already mentioned, but mixed with earth and sand, from whence it may be separated by infusion of water. It is of a pungent and acid taste, and smells like the oil of amber, but more agreeable. It is very light and very pellucid; but though equally bright and clear under all circumstances, it is liable to a very great variety in its colour. It is naturally almost colourless, and in its appearance greatly resembles the most pure oil of turpentine: this is called white petroleum, though it has no more colour than water. It is sometimes tinged of a brownish, reddish, yellowish, or faint greenish colour; but its most frequent colour is a mixture of the reddish and blackish, in such a degree that it looks black when viewed behind the light, but purple when placed between the eye and a candle or window. It is rendered thinner by distillation with water, and leaves a refrinous residuum; when diffused with a volatile alkali, the latter acquires the properties of fucinated ammoniac, and contains the acid of amber. It is the most frequent of all the liquid bitumens, and is perhaps the most valuable of them all in medicine. It is to be chosen the purest, lightest, and most pellucid that can be had, such as is the most penetrating smell and is most inflammable. Monet informs us that some kinds of it are of the density of mint oil. It is insoluble in spirit of wine; which though it be the great dissolvent of sulphur, has no effect upon petroleum, not even with ever so long a digestion. It will not take fire with the deephegated acid spirits; as oil of cloves and other of the vegetable essentail oils do; and in distillation, either by balneum mariae or in sand, it will neither yield phlegm nor acid spirit; but the oil itself rises in its own form, leaving in the retort only a little matter, thick as honey, and of a brownish colour.

The finer kinds resemble naphtha. Kirwan is of opinion that naphtha is converted into petroleum by a process similar to what takes place in essentail oils when exposed to the atmosphere; in which case the oil absorbs not only the pure, but also the phlogisticated, part of the atmosphere, in consequence of which several alterations take place in them.

Mr Bouldoc made several experiments with the white petroleum of Modena: an account of which he gave to the Paris academy.

PET

It easily took fire (A) on being brought near a candle. Petroleum and that without immediately touching the flame; and when heated in any vessel it will attract the flame of a candle, though placed at a great height above the vessel; and the vapour it sends up taking fire, the flame will be communicated to the vessel of heated liquor, and the whole will be consumed. It burns in the water; and when mixed with any liquor it swims on the surface of it, even of the highest rectified spirit of wine, which is five heavier than pure petroleum. It readily mixes with all the essentail oils of vegetables, as oil of lavender, turpentine, and the rest, and seems very much of their nature; nor is this very strange, since the alliance between these bodies is probably nearer than is imagined, as the essentail oils of vegetables may have been originally mineral ones, and drawn up out of the earth into the vessels of the plants.

The distinguishing characteristic of the petroleum is its thickness, resembling inquistipated oil; when pure it is lighter than spirit of wine; but though ever so well rectified, it becomes in time thick and black as before. Petroleum, when shaken, yields a few bubbles; but they sooner subside than in almost any other liquor, and the liquor refumes its clear state again almost immediately. This seems owing to the air in this fluid being very equally distributed to all its parts, and the liquor being composed of particles very evenly and nicely arranged. This extensibility of the oil is also amazing. A drop of it will spread over several feet of water, and in this condition it gives a great variety of colours; that is, the several parts of which this thin film is composed act as so many prisms. The most severe frost never congeals petroleum into ice; and paper wetted with it becomes transparent as when wetted with oil; but it does not continue so, the paper becoming opaque again in a few minutes as the oil dries away.

There are three varieties of it according to Mongez.

1. The yellow, found at Modena in Italy: very light and volatile. 2. The red, or yellowish red: some of which is collected at Gabian in Languedoc and in Alface. 3. The heavy, black, or brown kind, which is the most common, and met with in England, France, Germany, and some other countries. It generally runs out either from chinks or gaps of rocks, or is mixed with the earth, and gushes out of it; or it swims on the water of some fountains, as already mentioned. According to Dr Lippert, a kind of rofin is produced by mixing petroleum with smoking nitrous acid. The taste of this substance is very bitter, but the smell resembles that of musk. The vitriolic acid, according to the same author, produces a rofin still more bitter, but without any aromatic smell. Cronsted enumerates the following species.

1. Molva, or Barbadoes tar, a thick substance resembling soft pitch. It is found in several parts of Europe and Asia; particularly Sweden, Germany, and Switzerland: on the coast of the Dead Sea in

112

Palestine.

(a) Alonso Barba, in his book of metals, gives a very melancholy influence of the power of petroleum of taking fire at a distance. He tells us, that a certain well yielding petroleum on the surface of its water, being to be repaired, the workman took down into the well with him a lantern and a candle in it; there were some holes in the lantern, through which the petroleum at a considerable distance sucked out the flame of the candle, and, taking fire, burned up with the noise of a cannon, and tore the man to pieces.
PET

PET

Petroleum. Paleflme; in Peru, in the chinks of rocks, and in frata of gypsum and limestone, or floating upon water. It is found also in America, and at Coalbrookdale in England. Kirwan tells us, that petroleum exposed for a long time to the air forms this substance. It is of a vitrile consellation; and of a brown, black, or reddish black colour. Sometimes it is inodorous, but generally of a more or less disagreeable smell, particularly when burned. It melts easily, and burns with much smoke and foot, leaving either ashes or a flag according to the heterogeneous matter it contains. It contains a portion of the acid of amber. It gives a bitter salt with mineral alkali, more difficult of solution than common salt, and which, when treated with charcoal, does not yield any sulphur.

II. Elastic Petrel; a very singular kind of fossil met with in some parts of England. This in colour and consellation, exactly resembles the Caoutchouc, or elastic, gum-refin, commonly called Indian rubber, found in South America, and used for rubbing out the traces of black lead pencils from paper. It is of a dark brown colour, almost black; and in some pieces has a yellowish brown call like the same gum refin. It can scarce be distinguished from the caoutchouc with regard to its elastic property, excepting that the cohesion of its parts is not so great. It burns with a smoky flame, and melts likewise in a thick oily fluid: but emits a disagreeable smell like the Fossil Pitch or Barbadoes tar. On the whole (says M. Petroleum

Magellan, this fossil seems to confirm the opinion of those mineralogists who believe that thee oily combustibles derive their origin from the vegetable kingdom. It seems worth trying whether pieces of asphaltum, buried in damp beds of sappy rubbish or other kinds of earth, would take the same elastic consellation. This substance was found in the year 1795 near Caflerton in Derbyshire, but in very small quantities. Some of the specimens were of a cylindrical form, like bits of small branches or flakes of vegetables: tho' much more flexible, being perfectly elastic.

III. Hardened rock-oil, or fossil pitch, an inflammable substance dug out of the ground in many parts of the world, and known by the names of petroleum induratum, pix montana, indempex, bergbary, &c. There are two species. 1. The asphaltum (a), or pure fossil pitch, found on the shores of the Dead Sea and of the Red Sea; also in Sweden, Germany, and France; See Asphaltum. It is a smooth, hard, brittle, inodorous substance, of a black or brown colour when looked at; but on holding it up between the eye and the light, appears of a deep red. It swins in water; breaks with a smooth and shining surface; melts easily; and, when pure, burns without leaving any ashes; but, if impure, leaves ashes, or a flag. M. Monet affirms that it contains sulphur, or at least the vitriolic acid. It is lightly and partially acted upon by spirit-of-wine and

(a) This species is found in great quantity in a bituminous lake or plain in the island of Trinidad, of which Mr Anderson gives the following copious account in the 75th volume of the Philosophical Transactions.

A most remarkable production of nature in the island of Trinidad, is a bituminous lake, or rather plain, known by the name of Tar Lake; by the French called La Bras, from the resemblance to, and answering the intention of, ship-pitch. It lies in the leeward side of the island, about half-way from the Bocas to the south end, where the mangrove swamps are interrupted by the land-banks and hills; and on a point of land which extends into the sea about two miles, exactly opposite to the high mountains of Pana, on the north side of the gulf.

This cape, or headland, is about 50 feet above the level of the sea, and is the greatest elevation of land on this side of the island. From the sea it appears a mass of black vitrified rocks; but, on a close examination, it is found a composition of bituminous sferis, vitrified sand, and earth, cemented together: in some parts beds of cinders only are found. In approaching this cape, there is a strong sulphurous smell, sometimes disagreeable. This smell is prevalent in many parts of the ground to the distance of eight or ten miles from it.

This point of land is about two miles broad, and on the east and west sides, from the distance of about half a mile from the sea, falls with a gentle declivity to it, and is joined to the main land on the South by the continuation of the mangrove swamps; so that the bituminous plain is on the highest part of it, and only separated from the sea by a margin of land which surrounds it, and prevents a distant prospect of it. Its situation is similar to a savannah, and like them, it is not seen till treading upon its verge. Its colour and even surface present at first the aspect of a lake of water; but it is possible it got the appellation of Lake when seen in the hot and dry weather, at which time its surface to the depth of an inch is liquid; and then from its cohesive quality it cannot be walked upon.

It is of a circular form, about three miles in circumference. At my first approach it appeared a plain, as smooth as glass, excepting some small clumps of shrubs and dwarf trees that had taken possession of some spots of it; but when I had proceeded some yards on it, I found it divided into areoles of different sizes and shapes: the chains or divisions anastomosed through every part of it; the surface of the areole perfectly horizontal and smooth; the margins undulated, each undulation enlarged to the bottom till they join the opposite. On the surface the margin or first undulation is distant from the opposite from four to six feet, and the same depth before they coalesce; but where the angles of the areole oppose, the chains or ramifications are wider and deeper. When I was at it, all these chains were full of water, the whole forming one true horizontal plane, which rendered my investigation of it difficult and tedious, being necessitated to plunge into the water a great depth in passing from one areole to another. The true form that can be formed of its surface will be from the areole and their ramifications on the back of a turtle. Its more common consistence and appearance is that of pit-coal, the colour rather greyer. It breaks into small fragments of
a cellular appearance, and glossy, with a number of minute and shining particles interspersed through its substance; it is very friable, and, when liquid, is of a jet black colour. Some parts of the surface are covered with a thin and brittle scoria, a little elevated.

As to its depth, I can form no idea of it; for in no part could I find a substratum of any other substance, in some parts I found calcined earth mixed with it.

Although I smelt sulphur very strong on puffing over many parts of it, I could discover no appearance of it, or any rent or crack through which the substance falls into the receiver, which is left in the retort after distillation, or upon the charcoal if burnt in the open fire. It coheres like a flag, and is of the colour of black-lead; but in a strong heat this earth is soon volatilized, so that its nature is not yet well known. During the distillation a liquid substance falls into the receiver, which is found to be of the same nature with rock-soil. The substance itself is found in Sweden and several other countries.

The piasphaltum is of a mean confidence between the asphaltum and the common petroleum. Mongez says that it is the same with the bitumen collected from a well named De la Pege, near Clermont Ferrand in France.

The people of mount Ciaro, in Italy, have some years since found out a much easier way of finding petroleum than that which they formerly had been used to. This mountain abounds with a sort of greyish salt, which lies in large horizontal beds, mingled with strata of clay, and large quantities of a spar of that kind called...
called by the Germans *sicken,* which is the common
fort, that ferments with acids, and readily dissolves in
them, and calcines in a small fire. They pierce these
plates in a perpendicular direction till they find water;
and the petroleum which had been intermixed among
the cracks of these plates is then washed out by the wa-
ter, and brought from all the neighbouring places to
the hole or well in which they have dug, on the surface
of the water of which it swims after eight or ten days.
When there is enough of it got together, they lade it
from the top of the water with brute basons; and it
is then easily separated from what little water is taken
up with it. These wells or holes continue to furnish
the oil in different quantities for a considerable time;
and when they will yield no more, they pierce the plates
in some other place.

It is never used in Britain as a medicine; but the
French give it internally in hysterical complaints, and
to their children for worms: some also give it from 10 to
15 drops in wine for suppurations of the menses. This,
however, is rather the practice of the common people
than of the faculty.

PETROMYZON, the Lamprey, a genus of fishes
belonging to the class of amphibian nates. It has fe-
ven *piracula* at the side of the neck, no gills, a filula
on the top of the head, and no breast or belly fins.
There are three species, distinguished by peculiarities
in their back fins.

1. The marinus, or sea-lamprey, is sometimes found so
large as to weigh four or five pounds. It greatly
resembles the eel in shape; but its body is larger, and
its snout longer, narrower, and sharper, at the termi-
nation. The opening of the throat is very wide; each
jaw is furnished with a single row of very small teeth;
in the middle of the palate are situated one or two
other teeth, which are longer, stouter, and moveable
towards the inside of the throat; the inferior part of
the palate presents moreover a row of very small teeth,
which reaches to the bottom of the throat, where we
find four long notched bones; two short situ1ous pro-
cedles are observable at the extremity of the snout, and
there are two others thicker but still shorter above the
eyes. Willoughby supposes that the latter are the or-
gans of hearing, and the former the organ of smell.

His opinion with regard to the auditory faculty of
this fish is founded on what we read in ancient au-
thors, that the fishermen attracted the lampreys by
whistling, and that Cnepis had tamed one of them to
such a degree that it knew his voice and obeyed his call.

The eyes of the lamprey are small, and covered
with a transparent light blue membrane; the pupil is
bordered with a circle of a colour resembling gold;
neart the gills, which are four in number, there is a
round hole on both sides, through which it discharges
the water. The lamprey has no fins on its belly or
breast; on the back we observe a fin, which begins
pretty near the head, extends to the tail which it turns
round, and is afterwards continued to the anus: this
fin is covered by the skin of the body, to which it ad-
heres but loosely; the skin is smooth, of a red blackish
colour, and flecked with yellow; the lamprey ad-
vances in the water with winding motions like those of
a serpent, which is common to it, with all the anguilo-
form fishes.

The lamprey lives on flesh. During the cold it lies
concealed in the crevices of sea-rocks, and consequently
is fished for only at certain seasons. It lives in a flat
of hostility with the poulpe, a kind of sea-polyapus,
which hunts the combat as long as it can; but when it
finds the impossibility of escape, it endeavours to
surround the lamprey with its long arms. The latter
flips away, and the poulpe becomes its prey. The
lobster, we are told, avenges the poulpe, and destroys
the lamprey in his turn. See Cancer.

Rondelet says, that the fishermen consider the bite
of the lamprey as venomous and dangerous, and never
touch it while alive but with pincers. They beat it
on the jaws with a flick, and cut off its head. The
fame naturalist observes, that its aitches are a cure for
its bite and for the king's evil. When any one has

part of it has had its origin from a very different cause to that of
volcanoes; but they have certainly laid the
foundation of it, as is evident from the high ridge of mountains which surronds its windward side to protect
it from the depredations of the ocean, and it is aiy only barrier against that overpowering element, and may properly
be called the skeleton of the island.

"From every examination I have made, I find the whole island formed of an argillaceous earth, either in
its primitive flate or under its different metamorphoses. The bafes of the mountains are composed of *schiuss,
argillaeus and tatum lithomarqu,* but the plains or lowlands remaining nearly in the same moif state as at its
formation. The component particles have not experienced the vicissitudes of nature so much as the more elevated
parts, consequently retain more of their primitive forms and properties. As argillaceous earth is formed from
the sediment of the ocean, from the situation of Trinidad to the continent its formation is easily accounted for,
granting at first the formation of the ridge of mountains that bound its windward side, and the high mountains
on the continent that nearly join it; for the great influx of currents into the gulf of Paria from the coasts of
Brazil and Andalania must bring a vast quantity of light earthy particles from the mouth of the numerous
large rivers which traverse these parts of the continent; but the currents being repelled by these ridges of
mountains, eddies and smooth water will be produced where they meet and oppose; and therefore the earthy
particles would settle, and form banks of mud, and by fresh accumulations added, would form dry land:
and from these causes it is evident such a tract of country as Trinidad must be formed. But these
causes still exist, and the effect from them is evident; for the island is daily growing on the leeward side, as
may be seen from the mud beds that extend a great way into the gulf, and there constantly increase. But from
the great influx from the ocean at the south end of the island, and its egress to the Atlantic again, through
the Boca, a channel must ever exist between the continent and Trinidad." See Trinidad.
been bit by a lamprey, the most effectual method is to cut out the part affected. Lampreys are very detestable in having themselves: when taken with a hook, they cut the line with their teeth; and when they perceive themselves caught in a net, they attempt to pass through the meshes. They fish for lampreys only on the pebbly edges of sea-rocks; some of these pebbles are drawn together to make a pit as far as the water-edge, or perhaps a little blood is thrown in, and the lamprey is immediately observed to put forth its head between two rocks. As soon as the hook, which is baited with crab or some other flesh, is presented to it, it swallows it greedily, and drags it into its hole. There is then occasion for great dexterity to pull it out suddenly; for if it is allowed time to attach itself by the tail, the jaw would be torn away before the great bone of this fish could be taken. This shows that its strength refides in the end of its tail; the reason of which is, that the great bone of this fish is reversed, so that the bones, which in all other fishes are bent towards the tail, are here turned in a contrary direction, and ascend towards the head. After the lamprey is taken out of the water, it is not killed without a great deal of trouble: the best way is to cut the end of its tail, or perhaps to crush it with repeated blows on the spine, in order to prevent it from leaping. This shows that in the lamprey animal life extends to the end of the spinal marrow.

M. de Querhoen removes our fears concerning the supposed poison of the lamprey. This species of fish, he tells us, abounds on the coasts of Africa and at the Antilles islands; it is found likewise on the coast of Brazil, at Surinam, and in the East-Indies. When taken with a hook, we must have the precaution to kill it before we take it off, otherwise it darts upon the fisher and wounds him severely. Its wounds, however, are not venomous, M. de Querhoen having found several sailors who were bit by it, but experienced no disagreeable consequences. Lampreys are likewise found in great abundance at Aseaflion Island, but particularly in the seas of Italy: their flesh when dried is excellent; and boiling gives to the vertebrae the colour of gridelin.

The flesh of the lamprey is white, fat, soft, and tender; it is pretty agreeable to the taste, and almost as nourishing as that of the eel; those of a large size are greatly superior to the small ones. We know that the most wealthy of the Romans kept them in fish ponds at a great expense. Vellius Poillon, the friend of Augustus, who is distinguished in history for his savage gluttony, on supposition that lampreys fed on human flesh, were more delicate, ordered his slaves when accouched of the slightest faults to be thrown into his fish ponds. We are no less surprized, in reading the ancient authors, to perceive the extraordinary attachment which the celebrated orators Hortensius and Cæsarius, men in other respects so grave and sensible, had to this animal. One of them shed tears at the loss of a lamprey; the other improved upon this puerility, and wore mourning at the death of his favourite. It is remarkable, that this fish, which is proper to the sea, and never comes into the rivers, can live and fatten in fresh water. For the advancement of natural history, it was to be wished, that some person who lives near the sea shore would make observations, in order to discover whether the lamprey is viviparous; its scales are so imperceptible, that they have been overlooked by most ichthyologists.

Mr. Pennant is of opinion, that the ancients were acquainted with this fish; at least, he says, it is certain, that which Dr. Arbuthnot and other learned men render the word lamprey, is a species unknown in our seas, being the murmura of Ovid, Pliny, and others, for which we wish an English name. This fish, the leptos (our baffe), and the myxus, (a species of mullet), formed that pride of Roman banquets the tripalum, so called, according to Arbuthnot, from their being served up in a machine with three bottoms. The words lampetra and petromyon are but of modern date, invented from the nature of the fish; the first a lambendo petrae, the other from petros and nymie, because they are suppose to lick or suck the rocks.

2. The fluvitatis, or seifer lamprey, sometimes grows to the length of 10 inches. The mouth is formed like that of the preceding. On the upper part is a large bifurcated tooth; on each side are three rows of very minute ones; on the lower part are seven teeth; the exterior of which on one side is the largest. The irides are yellow. As in all the other species, between the eyes on the top of the head is a small orifice, of great use to clear its mouth of the water that remains on adhering to the bones; for through that orifice it ejects the water in the same manner as the catfish. On the lower part of the back is a narrow fin, beneath that rides another, which at the beginning is high and angular, then grows narrow; surrounds the tail, and ends near the anus. The colour of the back is brown or duncky, and sometimes mixed with blue; the whole under side silvery. These are found in the Thames, Severn, and Dee; are potted with the larger kind; and are by some preferred to it, as being milder tasted. Vast quantities are taken about Mortlake, and sold to the Dutch for bait for their cod-fishery. Above 430,000 have been sold in a season at 40s. per 1000; and of late, about 100,000 have been sent to Harwich for the same purpose. It is said that the Dutch have the secret of preserving them till the turbot fishery.

3. The bronchialis or lampern, is sometimes found on the length of eight inches, and about the thickness of a swan’s quill; but they are generally much smaller. The body is marked with numbers of transverse lines, that pass cross the sides from the back to the bottom of the belly, which is divided from the mouth to the anus by a straight line. The back fin is not angular like that of the former, but of an equal breadth. The tail is lancedolate, and short at the end. They are frequent in the rivers near Oxford, particularly the Isis; but not peculiar to that county, being found in others of the English rivers, where, instead of concealing themselves under the bones, they lodge themselves in the mud, and never are observed to adhere to any thing like other Lampreys.

PETRONIUS was a renowned Roman senator. When governor of Egypt, he permitted Herod, king of the Jews, to purchase in Alexandria any quantity of corn which he should judge necessary for the supply of his subjects, who were afflicted with a severe famine. When Tiberius died, Caius Caligula, who succeeded him, took from Vitellius the government of Syria, and gave it
The French critics, who had attacked its authenticity, were silent from the moment it was deposited in the Petronius, royal library. It is now generally attributed to Petronius, and found in every subsequent edition of the works of that refined voluptuary. The public did not form the same favourable opinion of some other fragments, which were extricated from a manuscript found at Belgrade in 1688, and printed at Paris by Nodier in 1694, though they are ascribed by the editor Charpentier, and several other learned men, to Petronius; yet, on account of the Gallicisms and other barbarous expressions with which they abound, they have generally been considered as unworthy of that author. His genuine works are, 1, A Poem on the civil war between Cæsar and Pompey, translated into prose by Abbé de Marolles, and into French verse by President Bouhier, 1737, in 4to. Petronius, full of fire and enthusiasm, delighted with Lucan’s flowery language, opposed Pharailus to Pharailus; but his work though evidently superior to the other in form respect, is by no means in the true style of epic poetry. 2. A Poem on the Education of the Roman Youth. 3. Two treatises; one upon the Corruption of Eloquence, and the other upon the Causes of the Decay of Arts and Sciences. 4. A poem on the Vanity of Dreams. 5. The Shipwreck of Lucan. 6. Reflections on the Inconstancy of Human Life. And, 7. Trimalchio’s Banquet. To this last performance morality is not much indebted. It is a description of the pleasures of a corrupt court; and the painter is rather an ingenuous courtier than a perfôn whose aim is to reform abuses. The best editions of Petronius are those published at Venice, 1499, in 4to; at Amsterdam, 1669, in 8vo, cum notis variorium; ibid. with Boschius’s notes, 1677, in 4to; and 1700, 2 vols in 4to. The edition of variorium was reprinted in 1745, in 2 vols 4to, with the learned Peter Burman’s commentaries.—Petronius died in the year 65 or 66.

Petronius (Maximus) was born in the year 395 of an illustrious family, being at first a senator and confid of Rome. He put on the imperial purple in 455, after having effected the assassination of Valentinian III. In order to establish himself upon the throne, he married Eudoxia the widow of that unfortunate prince, as she was ignorant of his villany, he conferred on her a transport of love, that the strong desire he had of being her husband, had made him commit this atrocious crime. Whereupon Eudoxia privately applied to Genserid, king of the Vandals, who coming into Italy with a very powerful army, entered Rome, where the usurper then was. The unhappy wretch endeavoured to make his escape, but the soldiers and people enraged at his cowardice, fell upon him, and overwhelmed him with a shower of stones. His body was dragged through the streets of the city for three days; and after treating it with every mark of disgrace, they threw it into the Tiber the 12th of June the same year, 455. He reigned only 77 days. He had some good qualities. He loved and cultivated the sciences. He was prudent in his councils, circumcised in his actions, equitable in his judgments; a facetious companion, and steady friend. He had the good fortune to win the affection of every body, while he remained a private character; but as a prince, he was so much the more detestable, in that, after he had obtained the throne by villany, he kept possession of it only by violence.
The crown was fearfully on his head before it appeared to him an infupportable burden. "Happy Democles exclaimed he in his despair, thou art a king during a single entertainment!"

PETROSA ossa, in anatomy, a name given to the fourth and fifth bones of the cranium, called also ossa temporum and ossa squamosa; the substance whereof, as their first and last names express, is squamos and very hard.

PETROSELINUM (aphium petroselimum, Lin.) Parley. This plant is commonly cultivated for culinary purposes. The seeds have an aromatic flavour, and are occasionally used as carminatives, &c. The root of parley is one of the five aperient roots, and with this intention is sometimes made an ingredient in apozems and diet-drinks; if liberally used, it is apt to occasion flatulencies; and this, we have no one corresponding in our language. The parts, which the Greeks call by the name of this root is somewhat sweetish, with an effect tooccasion occasionally used as carminatives, &c. The same year he became a member of the college of physicians in Ireland; where he continued till 1659, and acquired a great fortune. After the restoration, he was introduced to King Charles II., who knighted him in 1661. In 1662, he published "A Treatise of taxes and contributions." Next year he was greatly applauded in Ireland for his invention of a double bottomed ship. He died at London of a gangrene in his leg, in 1697, and was created a baronet.

PETTERIA, in the ancient music, a term to which we have no one corresponding in our language.

The melodioe, or the art of arranging sounds in succession so as to make melody, is divided into three parts, which the Greeks call syllogi, mixtia, and cheires; the Latins fupplea, mixtia, and u/ia. The art of expressing the several passions intended to be raised. Thus it shows what sounds are to be used, and what not; how often they are severally to be repeated; with which to begin, and with which to end; whether with a grave sound to rise, or an acute one to fall, &c. The pettia constitutes the manners of the muse; chooses this or that passion, or that motion of the soul, to be awakened; and determines whether it be proper to excite it on this or that occasion. The pettia, therefore, is in music much what the manners are in poetry.

It is not easy to discover whence the denomination should have been taken by the Greeks, unleas from πετητις, their game of chiefs; the musical pettia being a sort of combination and arrangement of sounds, as chiefs is of pieces called περτος, calculi, or "chiefs-men."

PETTY (Sir William), son of Anthony Petty, a clothier, was born at Rumsey, a little haven-town in Hampshire, in 1623; and while a boy took great delight in spending his time among the artificers there, who taught him all work as well as twelve years of age. Then he went to the grammar-school there; at 15 he was master of the Latin, Greek, and French tongues, and of arithmetic and those parts of practical geometry and astronomy usual to navigation. Soon after he went to Caen in Normandy, and Paris, where he studied anatomy, and read Vesalius with Mr. Hobbes. Upon his return to England, he was preferred in the king's navy. In 1643, when the war between the king and parliament grew hot, he went into the Netherlands and France for three years; and having vigorously prosecuted his studies, especially in physis, at Utrecht, Leyden, Amsterdam, and Paris, he returned home to Rumsby. In 1647, he obtained a patent to teach the art of double writing for seventeen years. In 1648, he published at London "Advice to Mr Samuel, Hartlib, for the advancement of some particular parts of learning." At this time he adhered to the prevailing party of the kingdom; and went to Oxford where he taught anatomy and chemistry, and was created a doctor of physis. 1659, he was made professor of anatomy there; and soon after a member of the college of physicians in London. The same year he became physician to the army in Ireland; where he continued till 1659, and acquired a great fortune. After the restoration, he was introduced to King Charles II., who knighted him in 1661. In 1662, he published "A Treatise of taxes and contributions." Next year he was greatly applauded in Ireland for his invention of a double bottomed ship. He died at London of a gangrene in his leg, occasioned by the swelling of the gout, in 1657. The character of his genius is sufficiently seen in his writings, which were much more numerous than those we have mentioned above. Amongst these I find, he wrote the history of his own life, which unquestionably contained a full account of his political and religious principles, as may be conjectured from what he has left us upon those subjects in his will. In that he has these remarkable words: "As for legacies to the poor, I am at a stand; and for beggars by trade and election I give them nothing; as for impotents by the hand of God, the public ought to maintain them; as for those who can get no work, the magistrates should cause them to be employed; which may be well done in Ireland, where are fifteen acres of improveable land for every head: as for prisoners for crimes by the king, or for debt by their profecutors, those who compassionately the sufferings of any object, let them relieve themselves by relieving such sufferers; that is, give them alms (a), &c. I am contented, that I have affioted all my poor relations, and put many into a way of getting their own bread, and have laboured in public works and inventions, and have fought out real objects of charity; and do hereby enjoin all who partake of my estate, from time to time to do the same at their peril. Nevertheless, to answer custom, and to take the sure side, I give twenty pounds to the most wanting of the parish wherein I died." As for religion, he says, "I die in the profession of that faith, and in the practice of such worship, as I find established by the laws of my country; not being able to believe what I myself please, nor to worship God better than by doing as I would be done unto, and observing the laws of my country, and expressing my love and honour to Almighty God, by such signs and tokens as are understood to be such by the people with whom I live." He died possessed of a very large fortune, as appears by his will; where he makes his real estate about

(a) In the town of Rumsby there is a house which was given by him for the maintenance of a charity school the rent of which is still applied to that use.
This should seem to be possessed of some medicinal virtues, but they have never been ascertained with any precision. The expressed juice was used by the ancients in leprous disorders.

PEUTEMAN (Peter) was born at Rotterdam in 1650, and was a good painter of inanimate objects; but the most memorable particular relative to this artist was that incident which occasioned his death.

He was requested to paint an emblematical picture of mortality, representing human skulls and bones fur. Painters adorned with rich gems and musical instruments, to express the vanity of this world's pleasures, amusements, or possessions; and that he might imitate nature with the greater exactness, he went into an anatomy room, where several skeletons hung by wires from the ceiling, and bones, skulls, &c. lay scattered about; and immediately prepared to make his designs.

While he was thus employed, either by fatigue, or by intense study, insensibly he fell asleep; but was suddenly roused by a shock of an earthquake, which happened at that instant, on the 18th of September 1692. The moment he awoke, he observed the skeletons move about as they were shaken in different directions, and the loose skulls roll from one side of the room to the other; and being totally ignorant of the cause, he was struck with such a horror, that he threw himself down stairs, and tumbled into the street half dead. His friends took all possible pains to efface the impression made on his mind by that unlucky event, and acquainted him with the real cause of the agitation of the skeletons; yet the transfixion still affected his spirits in such a manner, that it brought on a disorder, which in a very short time ended his days. His general subjects were either allegorical or emblematical allusions to the shortness and misery of the human life.

PETWORTH, sea crow, or more crow, in ornithology. See Larus.

PEWTER, a facitious metal used in making domestic utensils, as plates, dials, &c.—The ball of the metal is tin; which is converted into pewter by mixing at the rate of an hundred weight of tin with 15 pounds of lead and six pounds of brass.—Besides this composition, which makes the common pewter, there are other kinds, compounded of tin, regulus of antimony, bismuth, and copper, in several proportions.

PEYRERE (Isaac la), was born at Bourdeaux, of protestant parents. He entered into the service of the Prince of Conde, who was much pleased with the singularity of his genius. From the perusal of St Paul's writings he took into his head to aver, that Adam was not the first of the human race; and, in order to prove this extravagant opinion, he published in 1655 a book, which was printed in Holland in 40 and in 12mo, with this title, Pradamitice, five exercitatio super verbiis 12, 13, 14, cap. 15, Epistola Pauli ad Romanos. This work was burnt at Paris, and the author imprisoned at Brussels, through the influence of the archbishop of Malines's grand vicar. The Prince of Conde having obtained his liberty, he travelled to Rome in 1666, and there gave to Pope Alexander VII. a solemn renunciation both of Calvinism and Pradantism. His concession was not thought to be sincere, at least with regard to this last hereby. His desire to be the head of a new sect is evident; and his book discovers his ambition.
PEY

amblion; for he there pays many compliments to the Jews, and invites them to attend his lectures. Upon his return to Paris, notwithstanding the earnest solicitations of his holiness to remain at Rome, he went again into the Prince of Conde's service in the quality of librarian. Some time after he retired to the seminary des Vcris, where he died the 30th of January 1676, at the age of 82, after the sacraments of the church had been administered to him. Father Simon says, that when he was importuned in his last moments to retract the opinion which he had formed respecting the Preadamites, his answer was, *Hi quacunque ignarant, blasphemenat.* His having no fixed sentiments of religion is supposed to proceed more from a peculiar turn of mind than a corruption of the heart; for good nature, simplicity of manners, and humanity, seem to have formed his character. “He was,” says Niceron, a man of a very equal temper, and most agreeable conversation. He was a little too fond, however, of indulging his wit, which sometimes bordered on raillery; but he took care never to hurt or wound the feelings of his neighbor. As to his learning, it was extremely limited. He knew nothing either of Greek or Hebrew; and yet he ventured to give a new interpretation of several passages of the sacred volume. He piqued himself on his knowledge of the Latin; but excepting a few poets which he had read, he was by no means an adept in that language. His style is very unequal; sometimes too swelling and pompous, at other times low and groveling.” Before the works already mentioned, he has left behind him, I. A treatise as singular as it is scarce, intitled, *Du rappel des Juifs,* 1643, in 8vo. The recall of the Israelites, in the opinion of this writer, will be not only of a spiritual nature, but they will be reintegrated in the temporal blessings which they enjoyed before their rejection. They will again take possession of the holy land, which will resume its former fertility. God will then raise up to them a king more just, and more victorious, than any of their former sovereigns had been. Now, though all this is doublets to be understood spiritually of Jesus Christ, yet our author is of opinion, that it ought also to be understood of a temporal prince, who shall arise for the purpose of effecting the temporal deliverance of the Jews; and that this prince shall be no other than the king of France, for the following reasons, which, it is believed, will carry conviction to few minds: 1. Because the two titles of *Maij Christian,* and of *Elder Son of the Church,* are ascribed to him by way of excellence. 2. Because it is presumable, if the kings of France possest the virtue of curing the evil or scourful, which can only affright the bodies of the Jews; that they will likewise have the power of curing their obdurate incredulity and the other inveterate diseases of their souls. 3. Because the kings of France have for their arms a *fleur de luce*; and because the beauty of the church is in scripture compared to the beauty of lilies. 4. Because it is probable that France will be the country whither the Jews shall first be invited to come and embrace the Christian faith, and whither they shall retreat from the persecution of the nations that have dominion over them; for France is a land of freedom; it admits of no slavery, and whoever touches it is free. Peyrere, after explaining his strange system, proposes a method of converting the Jews to Christianity; a method, says Niceron, which will not be acceptable to many. He proposes to reduce the whole of religion to a bare faith or belief in Jesus Christ; taking it for granted, without any shadow of proof, that it is as difficult to comprehend the articles of our faith, as to observe the ceremonies of Moses.—From this scheme (says he) there would result a double advantage to the church; the reunion of the Jews, and of all those Christians who are separated from the body of the church.” Peyrere, when he wrote this book, was a Calvinist; but his Calvinism too nearly resembled the Deism of our age. He confessed himself that his reason for quitting the Preadamites was on account of their being the first and principal opposers of his book concerning the Preadamites. 11. A curious and entertaining account of Greenland, printed in 8vo, 1647. When he was asked, on an occasion of this work, why there were so many witches in the north; he replied, “It is because part of the property of these pretended conjurers, when condemned to suffer death, is declared to belong to their judges.” 11. An equally interesting account of Iceland, 1663, 8vo. IV. A letter to Philotimus, 1678, in 8vo, in which he explains the reasons of his recantation. &c. We find in Moreri the following epitaph of him, written by a poet of his own times.

*Le bon homme partit, & n'en choisit pas une.*

PEYRONIUS (Frances de la) for a long time practised surgery at Paris with such distinguished eclat, that he obtained for himself the appointment of first surgeon to Louis XV. He improved this favourable situation with his majesty, and procured to his protection those honours which had the effect to quicken its progress, and those enlargements which contributed to extend its benefits. The royal College of Surgery at Paris was founded by his means in 1731, was enlightened by his knowledge, and encouraged by his munificence. At his death which happened at Versailles the 24th of April, 1747, he bequeathed to the society of surgeons in Paris two thirds of his effects, his estate of Marigny, which was sold to the king for 200,000 livres, and his library. This useful citizen also left to the society of surgeons at Montpellier two houses situated in that town, with 100,000 livres, for the purpose of erecting there a chirurgical amphitheatre. He appointed the same society universal legatee for the third of his effects; and all these legacies contain clauses whose sole object is to promote the public good, the perfection and improvement of surgery; for which he always solicited the protection of the court. At the time of the famous dispute between the physicians and surgeons, he entertained the Chancellor d'Aguesseau to build up a brazen wall between the two bodies. “I will do so, replied the minifter, but on what side of the wall shall we place the sick?” Peyronius afterwards behaved with more moderation.—He was a philo­opher without any ostentation; but his philosophy was tempered by a long acquaintance with the world and with the court. The acuteness and delicacy of his
PEZAY (N. Masson, marquis of), born at Paris, very early applied himself to the study of letters, and afterwards went into the army. He was made a captain of dragons; and had the honour of giving some lemons to the ill-fated Louis XVI. Being appointed inspector-general of some coasting vessels, he repaired to the maritime towns, and executed his commission with more care and attention than was to have been expected from a votary of the muses. But as, at the same time, he showed too much haughtiness, a complaint was brought against him to the court, and he was banished to his country seat, where he died soon after, in the beginning of 1778. He was an intimate friend and companion of Dora. The story about it is

PEZENAS, a place in France about 24 miles from Montpellier. The soil about it is family. The rock is limestone. The fields are open, and produce corn, wine, and oil. There are to be seen at this place the extensive ruins of a castle, which formerly belonged to the Montmorency family. This strong fortress was blown out of the rock on which it stands, and appears to have been complicated and full of art. The walls are lofty, and above 8 feet in thickness. The rock, which is perpendicular, is a mass of shells, such as turban, oysters, cockles, with a calcareous cement. From hence the circumjacent plain decked with luxuriant verdure, and shut in by rugged mountains, affords a most delightful prospect. E. Long: 3: 35; N. L. 43: 18.

PEZIZA, cup mushrom, in botany; a genus of the natural order of fungi, belonging to the cryptogama class of plants. The fungus capsumulata and felle; Linnium enumerates 8 species.

PEZRON (Paul), a very learned and ingenious Frenchman, born at Hennemont in Brittany in 1639, and admitted into the order of Citeaux in 1660. He was a great antiquarian, and was indefatigable in tracing the origin of the language of the Goths; the result of which was, that he was led to oppose a system of the world's being much more ancient than modern chronologers have supposed. This he communicated to the public in a treatise printed at Paris in 1687, intitled, The antiquity of Time, restored and defended against the Jews and modern chronologers. This book of Pezron's was extremely admired for the ingenuity and learning in it; yet caus'd no small alarm among the religious, against whom he neverthelessedefended his opinions. He went through several promotions, the last of which was to the abbey of Charmoy, to which he was nominated by the king; and died in 1706.

PHAÇA, in botany: A genus of the decandria order, belonging to the diadelphus class of plants; and in the natural method ranking under the 32d order, Papilionaceae. The legumens is semibifoliar.

PHEA, a famous fow which infected the neighbourhood of Cromyion. Theseus destroyed it as he was travelling from Trezene to Athens to make himself known to his father. Some imagine that the boar of Calydon sprang from this fow. According to some authors, Phoea was a woman who prostituted herself to strangers, whom she murdered, and afterwards plundered.

PHEACIA, one of the names of the island Corcyra, (Homer, Stephanus). Phaeaces the people, (Ovid), noted for their insolence and luxury; hence Horace ues Phæaces for a person indolent and fleek; and hence arose their insolence and pride, (Aristotle). The island was famous for producing large quantities of the finest flavoured apples, (Ovid, Juvenal, Propertius).

PHÆDON, a disciple of Socrates, who had been feized by pirates in his youth; and the philopher, who seemed to discover something uncommon and promising in his countenance, bought his liberty for a sum of money, and ever after esteemed him, Phædon, after Socrates's death, returned to Elis his native country, where he founded a fect of philosophers who composed what was called the Elue school. The name of Phædon is affixed to one of Plato's dialogues.

PHÆDRA (tab. hif.) was a daughter of Minos and Pasiphae; she married Theseus, by whom she was the mother of Acamas and Demophoon. They had already lived for some time in conjugal felicity when Venus, who hated all the descendants of Apollo, because he had discovered her amours with Mars, inspired Phædra with the strongest passion for Hippolythus the son of Theseus, by the Amazon Hippolyte. This passion the long attempted to stifle, but in vain; and therefore, in the absence of Theseus, she address'd Hippolythus with all the impiance of despoding love. He rejected her with horror and disdain. She, however, incend'd by the reception she had met, resolved to punish his coldness and refufl; and at the return of Theseus she accused Hippolythus of attempts upon her virtue. He listened to her accusation; and without hearing Hippolythus's defence, he banished him from his kingdom, and implored Neptune, who had promised to grant three of his requets, to punifh him in an exemplary manner. As Hippolythus fled from Athens, his horsef were suddenly terrified by a sea monster, which Neptune had sent on the shore; and he was thus dragged through precipices and over rocks, trampled under the feet of his horsef, and crush'd under the wheels of his chariot. When his tragical end was known at Athens, Phædra confessed her crime, and hung her-
Phædrus, an ancient Latin writer, who composed five books of fables, in fable verse. He was a Thracian; and was born, as there is reason to conclude, some years before Julius Cæsar made himself master of the Roman empire. How he came into the service of Augustus is not known; but his being called Augustus' freedman in the title of the book, shows, in very pure and elegant language: and it is remarkable that they remained buried in libraries altogether unknown to the public, until they were discovered and published by Peter Pithou, or Pithous, a learned French gentleman, toward the close of the 16th century.

Phædrus (Thomas) was a professor of eloquence at Rome, early in the 16th century. He was canon of Lateran, and keeper of the library in the Vatican. He owed his rise to the acting of Seneca's Phælytus, in which he performed the part of Phœbus. Erasmus, who tells this, says he had it from Cardinal Raphael Georgianus, in whose court-yard, before the palace, that tragedy was acted. The cause of its death was very remarkable; for as he was riding through the city on a mule, he met a cart drawn by wild oxen, and was thrown by its mule, who took fright at them. Though corpulent, the cart fortunately passed over him without doing him any hurt, as he fell in the space between the wheels; but fright and the fall together spoiled the whole mass of his blood so much, that he contracted a distemper, of which, after languishing some time, he died under the age of 95. If he had lived, he would most probably have become an author; and perhaps, adds Bayle, have confirmed what has been observed of him, that his tongue was better than his pen. The observation was made by Erasmus, who tells us, that he knew and loved him; and owns that he was called the Cicero of his time. Janus Paraphæus, his colleague, was much grieved at his death, and gave the titles of several works, which were almost ready for public view.

Phænomeneon, in philosophy, denotes any remarkable appearance, whether in the heavens or earth, and whether discovered by observation or experiment.

Phaeton, in fabulous history, was the son of the Sun, or Phœbus and Clymene, one of the Oceanides. He was son of Cephalus and Aurora, according to Theocritus and Pausanias; or of Tithonus and Aurora, according to Apollodorus. He is, however, more generally acknowledged to be the son of Phœbus and Clymene. He was naturally of a lively disposition, and a handsome figure. Venus became enamoured of him, and enthrall’d him with the care of one of her temples. This distinguishing favour of the goddess rendered him vain and aspiring; and when Epaphus, the son of Io, had told him, to check his pride, that he was not the son of Phœbus, Phaeton resolved to know his true origin, and at the instigation of his mother, he visited the palace of the Sun. He begged Phœbus, that if he really was his father he would give him incontestable proofs of his paternal tenderness, and convince the world of his legitimacy. Phœbus received him with great tenderness, and swore by Styx to grant whatever he requested as a proof of his acknowledging him for his son. The youth boldly asked the direction of the chariot of the Sun for one day. His father, grieved and surprised at this demand, used all his arguments to dissuade him from the rash attempt; but all was in vain: and being by his oath reduced to submit to his obstinacy, enthrall’d him with the reins, after he had directed him how to use them. The young adventurer was however soon sensible of his madness. He was unable to guide the fiery steeds; and loosing the reins, Jupiter, to prevent his confounding the heavens and earth, struck him with a thunderbolt, and hurled him from his seat into the river Eridanus or Po. His sisters Phaethus, Lamia, and Phæbe, lamenting his loss upon its banks, were changed by the gods into black poplar trees; and Cyamus king of Liguria, also grieving at his fate, was transformed into a swan.

The poets say, that while Phaeton was driving the chariot of his father, the blood of the Ethiopians was dried up; and their skin became black; a colour which is still preferred among the greatest part of the inhabitants of the torrid zone. The territories of Libya were also, they tell us, parched up, on account of their too great vicinity to the Sun; and ever since, Africa, unable to recover her original verdure and fruitfulness, has exhibited a sandy country and uncultivated wastes. According to those who explain this poetical fable, Phaeton was a Ligurian prince, who studied astronomy, and in whose age the neighbourhood of the Po was, visited with uncommon heats.

Phaeton, in ornithology, a genus of birds belonging to the order of anseres; the characters of which are: The bill is sharp, straight, and pointed; the nostrils are oblong, and the hinder toe is turned forward. There are two species, viz.

1. The demererus, or red-footed penguin, has a thick, arched, red bill; the head, hind-part of the neck, and the back of a dusky purplish hue, and breast and belly white; brown wings, with the tips of the feathers white; instead of a tail, a few black bristles; and red legs. It is found on Pinguin isle, near the Cape of Good Hope, is common all over the South Seas, and is about the size of a goose.

2. The eheerus, or tropic bird, is about the size of a partridge, and has very long wings. The bill is red, with an angle under the lower mandible. The eyes are encompassed with black, which ends in a point towards...
towards the back of the head. Three or four of the larger quill-feathers, towards their ends are black, tipped with white; all the rest of the bird is white, except the back, which is variegated with curved lines of black. The legs and feet are of a vermilion red. The toes are webbed. The tail consists of two long straight narrow feathers, almost of equal breadth from their quills to their points. See Plate CCCXXXIX.

The name tropic bird (says Latham), given to this genus arises from its being chiefly found within the tropic circles; but we are not to conclude, that they never stray voluntarily, or are driven beyond them; for we have met with a few instances to prove the contrary (a). It is, however, so generally found within the tropical limits, that the sight of this bird alone is sufficient to inform the mariner of a very near approach to if not his entrance therein. It has also been thought to portend the contiguity of land (b); but this has often proved fallacious, as it is not unfrequently found at very great distances therefrom. The flight of this bird is often to a prodigious height; but at other times it is seen, along with the frigate pelican, booby, and other birds attending the flying fishes at their rise from the water, driven from the native element into the air by their watery enemies, the shark (c), porpoise albacore bonito, and dolphin, which pursue them behind and prey upon them. These birds are sometimes observed to rest on the surface of the water, and have been now and then seen in calm weather upon the backs of the drowzy tortoises, supinely floating in the sea, so that they have been easily taken by the long boat manned. On shore they will perch on trees; and are said to breed in the woods, on the ground beneath them. They have been met with in plenty on the islands of St Helena, Ascension, Mauritius, New Holland, and various places in the South Seas; but in no place so numerous as at Palmerston Island, where these birds, as well as the frigates, were in such plenty that the trees were absolutely loaded with them, and so tame that they suffered themselves to be taken of the boughs with the hand. At Otaheite, and in the Friendly isles, the natives give them the names of baingoo and toolaite.

As the tropic bird flies the long tail feathers every year, the inhabitants of such isles as they frequent, collect and make use of them by way of ornament in various manners; they are worn in the caps of the Sandwich islanders, being in great plenty at Tahborn, as also in various parts of their dress; but in none more conspicuous than in the mourning garment of Otaheite, in which island numbers are picked up in the mountainous parts, where it also breeds. The flesh cannot be called good, but was found sufficiently acceptable to those who had long been confined to salt provisions, and in which circumstance the sailors did not despise it.”

There is a variety of this bird called by Latham the subite tropic bird. It is less than the one we have already described, and is found in as many places as it. The plumage of this bird is in general of a silvery white. The yellow tropic bird is a further variety of the same species, the plumage being of a yellowish white. These differences, Mr Latham thinks, arise merely from age, if they are not the distinguishing mark of sex.

3. The black-billed tropic bird is smaller than any of the former. The bill is black; the plumage on the upper part of the body and wings is striated, partly black and partly white; before the eye there is a large crescent of black, behind it is a streak of the same colour; the forehead and all the under parts of the body are of a pure white colour; the quills and tail are marked as the upper parts, but the ends of the first are white, and most of the feathers of the tail are marked with dusky black at the tips; the sides over the thighs are striated with black and white; the legs are black.

One of these was found at Turtle and Palmerston islands, in the South Seas, and is in the possession of Sir Joseph Banks.

4. The red-tailed tropic bird is in length about two feet ten inches, of which the two tail-feathers alone measure one foot nine inches. The bill is red; the plumage white, tinged of an elegant pale rose-colour; the crescent over the eyes is somewhat abrupt in the middle; the ends of the scapulars are marked with black. This bird is distinguished from others by two middle long tail feathers, which are of a beautiful deep red colour, except the shafts and base, which are black; the sides over the thighs are dusky; and the legs are black.

“This species (says Latham) is met with frequently as large as the others, but does not seem to be so far spread. Our navigators met with them in various places, though they were seldom seen by them on shore except in the breeding season, which is in September and October. They are found in great numbers in the island of Mauritius, where they make the nest in hollows in the ground under the trees; the eggs are two in number, of a yellowish white marked with rufous spots.

(a) “Dr Forster observes that they are never seen beyond 28 degrees of latitude; but others talk of their spreading far beyond it. In lat. 32° 45'. Ell. Narr. ii. p. 64.—33° 10'. N. Coast's Tav. Voy. iii. p. 178.—38° 34'. S. Park. Voy. p. 132.—38° 29'. Haukef. Voy. iii. p. 77. This is mentioned as not being common; but Kalm says he met with these in 40 degrees north. See Trav. i. p. 22.—And a friend of mine assured me, that he saw one in latitude 47° north; but at the same time observed, that it was the first instance he had ever known of such a circumstance."

(b) "Ulua's Voy. ii. p. 301. He observes, that they seldom are met with above eight or ten leagues from land.

(c) "Squallus conductor, delphinus phocens, scomber thynnus, scomber pelamis, delphinus eorephina. See Phil. Trans. vol. iv. viii. p. 800. It is there observed, that the flying fish is able to fly 60 or more yards at one stretch, and repeat it a second or even a third time, only the slightest momentary touch of the surface that can be conceived intervening; and it is common in these flights for them to fly against ships, or fall on the deck."
spots. The same author gives an account of the introduction of paradise grackles into the island of Bourbon, from whence they spread into that of Mauritius; at first intended for the very useful purpose of destroying the locusts and grasshoppers, which swarmed there to a great degree; the result of their profligate incease, and the unlooked for conseqences of it, he has likewise mentioned. These birds, we are told, are great enemies to the tropic birds, ocular demonstration of which was had by M. de Querhoent; for, being seated beneath a tree in which were perched a number of the grackles, he observed a tropic bird come to its hole, in order to go to the nest; but the grackles attacked the bird all at once, and obliged it to fly off; it then returned with its comfort in company, but without effect, as they were both driven away, as the single one had been before; when the grackles returned to their tree, and the spectator left them in that situation.

"This species of tropic bird has been met with in several places of the south seas; very common at Palmerston and Turtle islands; at Hervey’s island in the greatest plenty, and of which considerable numbers were killed for provisions: and here also they make the nefts in the same manner as at Mauritius. The name it is known by at Otahite and the Friendly Isles is towage and tato. See DIONEDE and PINOIN.

PHAGÉDÉNA, in medicine, denotes a corroding ulcer.

PHAGÉDÉNIC MÉDICINES, those used to eat off proud or fungous flesh; such as are all the eaufties. PHAGÉDÉNIE WATER, in chemistry, denotes a water made from quicklime and sublimate; and is very efficacious in the cure of phagédénic ulcers. To prepare this water, put two pounds of fresh quicklime in a large earthen pan, and pour upon it about ten pounds of rain-water; let them stand together for two days, stirring them frequently; at last leave the lime to settle well, then pour off the water by inclination, filter it, and put it up in a glass bottle, adding to it an ounce of corrosive sublimate in powder; which from white becomes yellow, and sinks to the bottom of the vessel. The water being setted, is fit for use in the cleaning of wounds and ulcers, and to eat off superfluous flesh, and especially in gangrenes; in which case it may be added to it a third or fourth part of spirit of wine.

PHALÉNA, the Moth, in zoology, a genus of insects belonging to the order of lepidoptera. The feelers are cetaceous, and taper gradually towards the points; the wings are often bent backwards.

Barbut divides this genus into eight families, and we are told that there are no less than 460 species. The names of the several families are given by Barbut as follows: 1. The attack, whose wings incline downwards and are spread open: they have pedicinate antennae without a tongue, or pedicinate antennae with a spiral tongue, or cetaceous antennae with a spiral tongue. 2. The bombyces, whose wings cover the body in a position nearly horizontal, and which have pedicinate antennae. They are either elingues, which want the tongue, or have it fo short as not to be manifestly spiral; their wings are either reversed or deflected; or spirelingues, which have a spiral tongue; and are either leaves with smooth backs, or criffate dorfo with a kind of crest or tuft of hair on the back. 3. The noctua, whose wings are incumbent as in the bombyces, from which they differ chiefly in the formation of the antennae, which are cetaceous. The noctua are either elingues, wanting tongues, or spirelingues having spiral tongues. 4. The geometru, whose wings when at rest are extended horizontally; the antennae in one subdivision of this section are pedicinate, in another cetaceous; the under wing in each of these divisions are either angulated, or round with entire edges. 5. The tortrices. The wings are exceedingly obtuse, their exterior margin is curve, and declines towards the sides of the body. They have short palpi. 6. The pyralides. The inner margins of the wings in this section are laid one over the other: the wings themselves decline a little towards the sides of the body, and in shape resemble a delta; they have considerable palpi of different forms. 7. The tinece. The wings are wrapped up or folded round the body, so as to give the insect a cylindrical form; the forehead is stretched out or advanced forwards. 8. The alucites. The wings of this division are split, or divided into branches almost to their base.

The caterpillars of this genus vary much as to size, and considerably as to their shape and number of feet. It is remarkable, that caterpillars of almost every species of this genus are found with 10, 12, 14, and 16 feet. The last are the most common and the largest; those of 10 and 12 feet are called geometri. "Amongst the geometru caterpillars (says Barbut) there are some very singular, whether for their colour, or the tubercula which they bear, or lastly for the difference of their attitudes. Many resemble small branches or bits of dry wood; and that resemblance may be a means of saving many of those insects from the voraciousness of birds, who do not so easily discern them. Other caterpillars are very hairy, while several are quite smooth; the latter have a cleaner look, whereas the hairy ones have something hideous, and may even be hurtful when touched.

"All the caterpillars of phaléna, after having several times cast their flough, spin their cod, in which they are transformed to chrysalids. The texture of the cod, the finenes of the thread of which it is composed, and the different matters joined to the threads, are infinitely various.

"The chrysalids of phaléna are generally oblong, not angular as those of butterflies, nor so soon transformed to perfect insects. They remain a much longer time within the cod, the greatest part not coming forth till the ensuing year. Some I have met with that remained in that state during two or three years successively. Heat or cold contribute greatly to forward or put back their final metamorphosis; a fact which may be ascertained by procuring them a certain degree of moderate heat, by which means one may see phaléna brought forth upon one's mantel-piece in the depth of winter.

The Phaléna or perfect insects spring from those cods, are generally more clumsy and heavy than butterflies; their colours are likewise more brown, dim, and obscure, though there are some phaléna whose colours are very lively and brilliant. Several of them,
The caterpillar feeds upon the roots of burdock, hops, &c. changes into a chrysalis in May, appears in the winged state in June, frequenting low marshy grounds where hops grow.

**Phalaena noctua promina spirinquis, No. 4.** The thorax, head, antennae, feet, and upper wings, are of a brown colour, more or less dark, sometimes so deep as to be nearly black, but often a bluish cast. The upper wings are moreover somewhat clouded, and have two black spots, one on the middle, the other towards the outward angle of the lower part of the wing. The under ones are of a beautiful orange colour, with a broad black band near the lower edge of the wing, of which it follows the direction. The caterpillar is smooth; to be found on several plants, but particularly upon the thalphi and some other cruciferous plants. It keeps in concealment during the day, and only feeds by night. Its metamorphosis is performed underground, and some varieties of colour are observable amongst these caterpillars: some being green, others brown; which latter yield males, the former females.

**Phalaena tetricia prafinana.** The superior wings of this species are of a fine green colour, having two diagonal yellow bars on each, the body and inferior wings are whitish, shaded with yellowish green. The caterpillar is a pale yellowish green, ornamented with small brown specks or spots, the tail being forked and tipped with orange red colour; feeds on the oak, changes to a chrysalis in September, and assumes the fly-state about May, frequenting woods.

**Phalangium, in zoology, a genus of insects belonging to the order of aptera.** They have eight feet, two eyes on the top of the head placed very near each other, and other two on the sides of the head; the feelers resemble legs, and the belly is round. There are nine species.

Mr. Barbut only describes one species, viz. the phalangium opillus of Linneus. His description is as follows: "Its body is roundish, of a dusky brown on the back, with a deeper spot of a rhomboidal figure near the middle of it. The belly is whitish; the legs are extremely long and slender. On the back part of the head there flanks a little eminence, which has on it a kind of double crest, formed as it were of a number of minute spines; the eyes are small and black, and are two in number. It is commonly called the *shepherd spider.*"

"This species of spider multiplies singularly. They are great spinners. In autumn the fluffly is quite covered with the threads of these spiders, by means of which they travel with ease, and ensnare their prey. However, those threads are thought rather to be the produce of a species of tick called *autumnal cocoon.*" A small degree of attention discovers an amazing multitude of those ticks almost imperceptible, and that is their work. The threads, when united appear of a beautiful white, wave about in the air, and are known in the country by the name of virgins' threads. Some naturalists think that those threads, floating in the air, serve the insect as a net to waft it through the air, and as a net to entrap insects on the wing; for remnants of prey, say they, are discoverable in them. As to those parcels in which nothing is seen, they are only essays rejected by those travelling insects. The analogy between the phalangium and the crab, and the facility with
Phaeton or Tripe Bird.

Persepolis.
PHALANGOSIS, in surgery, is a tumor and relaxation of the eye lids, often so great as to deform the eye, and render it impossible to perceive vision. Sometimes the eye lids when in this state subside or sink down, occasioned perhaps either by a puffiness of the muscles which inflame and elevates the eye lids, or else from a relaxation of the cutis above, from various causes. Sometimes an acrimonious or aqueous tumour is formed on the eye lids, so as almost entirely to exclude vision; but this last case should be distinguished from the other, and may be easily remedied by the use of internal and topical medicines, such as purges and diuretics given inwardly, and a compress dipped in warm spirit of wine and lime-water. But in the paralytic or relaxed case, the use of cordial and nervous medicines must be proposed internally; and outwardly, balsam of Peru and Hungary water are to be employed. If these fail, the remaining method of cure is to extirpate a sufficient quantity of the relaxed cutis, and then, after healing up the wound, the remainder will be sufficiently shortened.

PHALANX, in Grecian antiquity, a square battalion of soldiers, with their shields joined and pikes crossing each other; so that it was next to impossible to break it.

The Macedonian phalanx is suppos'd by some to have had this advantage, in valour and strength, over the Roman legion. Its number was 8000 men. But the word phalanx is used for a party of 28, and several other numbers; and even sometimes for the whole body of foot. See Legion.

Phalanx is applied, by anatomists, to the three rows of small bones which form the fingers. In natural history it is a term which Dr Woodward and some other writers of fossils have used to express an arrangement of the columns of that fort of fossil corolloloe body found frequently in Wales, and called lithifolution. In the great variety of specimens we find of this, some have the whole phalanx of columns craked through, and others only a few of the external ones; but these cracks never remain empty, but are found filled up with a white spar, as the smaller cracks of stone usually are. This is not wonderful, as there is much spar in the composition of this fossil; and it is easily washed out of the general mass to fill up these cracks, and is then always found pure, and therefore of its natural colour, white.

The lithifolution, or general crangement of these phalanges of columns, is commonly found immersed in a grey shone, and found on the tops of the rocky cliffs about Milford in Wales. It is usually cretaceous, though somewhat inclining in some specimens, but never lies horizontal. It seems to have been all white at first, but to have been since gradually tintured with the matter of the stone in which it lies. The single columns, which form each phalanx, are usually round or cylindric, though sometimes flattened and bent; some of them are also naturally of an angular figure; these, however, are not regular in the number of their angles, some consisting of three sides, some of five, and some of seven; some are hexagonal also, but these are scarce. They are from five or six to sixteen inches in length; and the largest are near half an inch over, the least about a quarter of an inch; the greater number are very equal to one another in size; but the sides of the columns being unequal, the same column measures of a different thickness when measured different ways; the phalanges or congeries of these are sometimes of a foot or more in diameter.

The columns are often burst, as if they had been affected by external injuries; and it is evident that they were not formed before several other of the extraneous fossils; for there are found a bivalve shells of sea-fishes and entrochi immersed and bedded in the bodies of the columns. It appears plainly from hence, that when these bodies were washed out of the sea, and tossed about in the waters which then covered the tops of these cliffs, this elegant fossil, together with the fomy bed in which it is contained, were so soft, that those other bodies found entrance into their very substance, and they were formed as it were upon them. This fossil takes an elegant polish, and makes in that flate a very beautiful appearance, being of the hardnes of the common white marl, and carrying the elegant structure visible in the smallest lineaments.

PHALARIS, a remarkable tyrant, born at Crete, where his ambitious dispositions occasioned his banishment: he took refuge in Agrigentum, a free city of Sicily, and there obtained the supreme power by stratagem. The circumstance which has chiefly contributed to preserve his name in history is his cruelty; in one act of which he gave, however, an example of first justice. It is thus related: Perillus, a brass-founder at Athens, knowing the cruel disposition of Phalaris, contrived a new species of punishment for him to inflict on his subjects. He cast a brazen bull, bigger than the life, with an opening in the side to admit the victims; who being shut up in the body, a fire was kindled under it, to roast them to death; and the throat was cut off, that their dying groans resembled the roaring of a bull. The artific brought it to the tyrant, expelling a great reward. Phalaris admired the invention and workmanship, but ordered the inventor to be put into it to make the first trial. In allusion to which, Ovid says,

Quam neci artifiae arte perire sua.

The end of this detestable tyrant is differently related; but it is very generally believed, with Cicero, that he fell by the hands of the Agrigentines; and, as some suppute, at the instigation of Pythagoras. Ovid tells us, that his tongue was cut out; and that he was then put into the bull to perish by the flame burning fire by which means he had murdered so many before. Others say that he was stoned to death; and all agree that his end was violent. He reigned, Eusebus says, 28 years; others say 16. After all, there is great uncertainty both as to his life, death, and history. Many of the circumstances related of him, as they are collected by Mr Boyle, depend upon the authenticity of those epistles which go under the name of the tyrant; and which have been judiciously questioned, and with great probability rejected, as the spurious production of some modern sophist. See Bentley, p. 177, col. 2.
Phalaris, or Canary-grass, in botany; a genus of the trigynia order, belonging to the triandra class of plants. The calyx is bivalved, carinated, and equal in length, containing the corolla. There are ten species, of which the most remarkable are the canariensis, or manured Canary-grasses; and the arundinacea, or reed Canary-grasses. These are both natives of Britain. The first grows by the road-sides; and is frequently cultivated for the sake of the seeds, which are found to be the best food for the Canary and other small birds. The second grows on the banks of rivers. It is used for thatching ricks or cottages, and endures much longer than rye. In Scandinavia they mow it twice a-year, and their cattle eat it. There is a variety of this cultivated in our gardens with beautifully rippled leaves. The stripes are generally green and white; but sometimes they have a purplish cast. This is commonly called painted lady-grass, or ladies truffles.

Phaleræ, among the ancient Romans, were military rewards bestowed for some signal act of bravery. Authors do not agree whether the Phaleræ were a suit of rich trappings for a horse, or golden chains something like the torques, but so formed as to hang down to the breast and display a greater profusion of ornament. The late opinion appears to have the greater prevalence, but perhaps both are true.

Phaleræus (Nepos), a village and port of Athens; this last neither large nor commodious, for which reason Themistocles put the Athenians on building the Piræus; both joined to Athens by long walls. The Phaleræ lay nearer the city (Pausanias). Demetrius Phaleræus, the celebrated scholar of Theophrastus, was of this place; to whom the Athenians erected above three statues; which were afterwards destroyed by his enemies, on his flight to Ptolemæus king of Egypt (Strabo). Here Demosthenes was wont to declaim, to accustom his voice to surmount the noise and roaring of the sea; a just and lively emblem of popular assemblies.

Phaleucian Vers, in ancient poetry, a kind of verse consisting of five feet; the first of which is a sponde, the second a dactyl, and the three last trochees.

Phallus, the morel, in botany; a genus of fungi, belonging to the cryptogamia class of plants. The fungus is reticulated above and smooth below. There are two species.

1. The eculentus, or eculent morel, is a native of Britain; growing in woods, groves, meadows, pastures, &c. The substance, when recent, is wax-like and friable; the colour a whitish yellow, turning brownish in decay; the height of the whole fungus, about four or five inches. The stalk is thick and clumsy, somewhat tuberous at the base, and hollow in the middle. The pileus is either round or conical; at a medium about the size of an egg, often much larger; hollow within; its base united to the stalk; and its surface cellular, or latticed with irregular fissures. The magnified seeds are oval. It is much esteemed at table both recent and dried, being commonly used as an ingredient to heighten the flavour of ragouts. We are informed by Gleditch, that morels are observed to grow in the woods of Germany in the greatest plenty in those places where charcoal has been made. Hence the good women who collect them to sell, receiving a hint how to encourage their growth, have been accustomed to make fires in certain places of the woods, with heath, broom, cannabis, and other materials, in order to obtain a more plentiful crop. This strange method of cultivating morels being however sometimes attended with dreadful consequences, large woods having been set on fire and destroyed by it, the magistrates thought fit to interpose his authority, and the practice is now interdicted.

2. The impudicus, flinking morel, or flinkhorn, is also a native of Britain, and found in woods and on banks. It arises from the earth under a veil or volva, shaped exactly like a hen's egg, and of the same colour, having a long fibrous radicle at its base. This egg like volva is composed of two coats or membranes, the space between which is full of a thick, viscid, transparent matter, which, when dry, glues the coats together, and foames like varnish. In the next stage of growth, the volva suddenly bursts into several rared permanent segments, from the centre of which arises an erect, white, cellular, hollow stalk, about five or six inches high and one thick, of a wax-like friable substance, and most fetid cadaverous smell, conical at each end, the base invested in a white, concave, membranaceous turbinate cup, and the summit capped with a hollow, c-nical pileus, an inch long, having a reticulated cellular surface, its base detached from the stalk, and its summit umbilicated, the umbilicus sometimes perforated and sometimes closed. The under side of this pileus is covered with a clear, viscid, gelatinous matter, similar to that found between the membranes of the volva; and under this viscid matter, concealed in reticulated receptacles, are found the seeds, which when magnified appear spherical. As soon as the volva bursts, the plant begins to diffuse its intolerable odours, which are so powerful and widely expanded, that the fungus may be readily discovered by the scent only, before it appears to the sight. At this time, the viscid matter between the coats of the volva grows turbid and fuculent; and when the plant attains its full maturity, the clear viscid substance in the pileus becomes gradually discoloured, putrid, and extremely fetid, and soon afterwards turns blackish, and, together with the seeds and internal part of the pileus itself, melts away. The fetid smell then begins to remit, the fungus fades, and continues for a short time sapless and coriaceous, and at last becomes the food of worms. The cadaverous scent of this fungus g'eatly allures the flies; which, lighting upon the pileus, are entrapped in the viscid matter and perish. We are informed by Gleditch, that the vulgar people in Thuringia call the unopened volva by the ridiculous name of ghafls and demon's egg; and that they collect and dry them either in the smoke or open air, and when reduced to powder, use them in a galls of spirits as an aphrodisiac.

Phallus, among the Egyptians, was the emblem of fecundity. It was very fervently worshipped by women, especially by those who were barren. This custom was introduced among the Greeks, and fêtivals in honour of it were called phallos. See Mythologies, n° 38, &c. Among the Hindoos a similar emblem called lingam is used, and for similar purposes, See Hindoos, n° 4.

Phalti, or Phaltiel, son of Laish. He married...
Pharamond, after Saul had taken her from David; but David afterwards took her away from Phalti.

Some interpreters are of opinion Phalti did not meddle with Michael all the time he continued in his house, for fear that both of them should incur the penalty of death, to be inflicted on adulterers (Levit. x. 10), because Michael had not been legally divorced; but these reasons are frivolous. Saul looked upon David as a rebel to his king, and an outlaw, whose goods and wives belonged to him, and which he could absolutely dispose of. He would not have given Michael to Phalti, nor would he have received her, if he had not thought he might use her as his wife. If Michael had no children by Phalti, by whom then were those children that the scripture says she had, since it is known she had none by David? See 2 Sam. xxvi. 6, and vi. 23.

Phanatics, or Fanatics, a visionary; one who fancies he sees spirits, spirits, apparitions, or other imaginary objects, even when awake; and takes them to be real. See Phantasy and Fanatic.

Such are phrenetics, necromancers, hypochondriacs, lycanthropes, &c. See Phrenetic, Hypochondriac, Lycanthrope.

Hence the word is also applied to enthusiasts, pretenders to revelations, new lights, prophets, &c. See Enthusiast, and Second Sight.

Phantasia, was the daughter of Nicharchus of Memphis in Egypt. It has been supposed she wrote a poem on the Trojan war, and another on the return of Ulysses to Ithaca, from which compositions Homer copied the greatest part of his Iliad and Odyssey, when he visited Memphis, where they were deposited.

Phantasm, a term sometimes used in a synonymous sense with idea, or notion retained in the mind, of an external object.

Phantasy, or Fancy, the Imagination; the second of the powers or faculties of soul, by which the species of objects received by the external organs of sense are retained, recalled, further examined, and either compounded or divided. See Imagination; and Metaphysics, Part I. Chap. ii.

Others define the phantasy to be that internal sense or power, whereby the ideas of absent things are formed, and represented to the mind as if they were present. In melancholics and madmen this faculty is very strong, representing many extravagant and monstrous things, and framing its images as lively as those of sensation; whence the visions and deceptions these persons are liable to.

Phanuel, of the tribe of Asher, the father of a holy widow and prophetess called Anna, who was in the temple when our Saviour was presented there by his parents (Luke ii. 50, 37, 38.)

Phaon, a young man of Mytilene, in the island of Lesbos, received from Venus, as fable reports, an abafter vase filled with an essence which had the virtue of conferring beauty. He had no sooner anointed his body with it, than he became the most beautiful of men. The ladies of Mytilene fell desperately in love with him; and the celebrated Sappho threw herself down a precipice because he would not encourage her passion. He is said to have been killed by a husband who surprised him with his wife. We have in Ovid a letter from Sappho to Phaon, which Mr Pope has translated into English verse.

Phara (anc. geog.), a village between Egypt and Arabia Petraea; or, according to Ptolemy, at a prominence situated between the Sinus Hieropolitis and Elaniticus of the Red Sea; where Ishmael is said to have dwelt. In Heb. brew it is Paran, and in most interpreters Pharan, Septuagint and Vulgate. Pharan, the people (Ptolemy.) Paran or Pharan, the name of the wilderness in its neighbourhood, adjoining to Kadesh.

Pharæ (anc. geog.) a town of Achaea in Peloponnesus, on the river Pirus, 70 stadia from the sea, and to the south of Patre 150 stadia. Another, of Crete (Pliny.) a colony from the Phare of Melitenia, (Stephanus.) A third Phare, or Phara (Strabo, Ptolemy.) Phare, s. Polybius.) a town of Melitenia, on the river Nedo (Strabo); on the north side of the Sinus Melitenius, and to the north west of Abaca. Anciently read Pharis in Homer (Paghinius, Statius), though now read Phare. Phare is the name of the people.

Pharamond is the name which is given by the generality of historians to the first king of France. He is said to have reigned at Treves, and over a part of France, about the year 420; and to have been succeeded by his son Clodion: but the account which is given of these two princes is very uncertain. It is probable Pharamond was properly no more than a general of an army, the head of a military society of Franks, who were masters of their perkins and their fortunes. Gregory of Tours seems to have been of this opinion. "It is not generally known (says he) who was the first king of the French. Sulpius Severus, who mentions several things respecting that nation, takes no notice of its first monarch; he only says that it had generals." Be that as it may, the institution of the famous Salique law (so named from the Salians, the most illustrious of the Franks) is generally attributed to Pharamond. "This law fixed the punishment of crimes, and various points of police. There is no just ground for believing that it expressly settled the right of succession to the crown: it only says, that, with relation to the Salic land, women have no share of heritage, without restricting it to the royal family in particular; for all those were generally called Salic lands which were held by right of conquest; and it is easy to conceive that a nation of foldiers, whose general was their king, would not submit to be governed by a woman. A long custom, supported by the principles of the nation, came in time to be the established law of the kingdom." (See M. Abbe du Bån, Elém. de Pologne de France, tom. 1.)

Pharaoh, a common name of the kings of Egypt. Josephus says, that all the kings of Egypt, from Memnon the founder of Memphis, who lived several ages before Abraham, have always had the name of Pharaoh, down to the times of Solomon, for more than 3300 years. He adds, that in the Egyptian language the word Pharaoh signifies a king; and that those princes did not assume this name but when they ascended the throne, at which time they quitted also their former name. From hence it comes to pass, L 12 says.
What Josephus adds concerning queen Nicaule, or Nicotris, who entertained the patriarch Jacob and his family in Egypt, and gave them the land of Gochen for their habitation. See Joseph and Jacob.

The second Pharaoh spoke of by the Scripture is he that reigned when Joseph arrived there. This prince or his successor had the mysterious dream of the fat and lean king, and the seven full and barren ears of corn, which Joseph explained so well to his satisfaction, that he made him governor of his house and of all Egypt, referring only to himself the name of a king. This is the same Pharaoh that sent for and entertained the patriarch Jacob and his family in Egypt, and gave them the land of Gochen for their habitation. See Joseph and Jacob.

The third Pharaoh known in holy writ is he that persecuted the Israelites. Moses tells us that he was a new king, and had no knowledge of Joseph (Exod. i. 8.). This prince, observing that the Israelites were become very numerous and powerful, resolved to deprive them by hardship and labour; and set cruel and pitiful taskmasters over them. But the more he oppressed them, the fatter they multiplied; insomuch that he gave orders to the Egyptian midwives, who assisted the Hebrew women in their labour, to put all the male children to death, and to save alive the females only. But this command was not strictly executed. The midwives feared the Lord, and preferred alive not only the female children, but the males also.

Pharaoh, seeing this project did not succeed to his wishes, published a decree (Exod. i. 22.) that all the male children born of Hebrew women should be thrown into the Nile, and that only the females should be spared. This order was rigorously executed; yet by the providence of God Moses was preferred, and even brought up in Pharaoh's own court, by his own daughter, who by chance had found the child, as he was exposed upon the Nile.

Moses being grown up, and having killed an Egyptian who had abused an Hebrew, was obliged to fly from Egypt to avoid that death that Pharaoh had threatened him with.

Several years after, being about 80 years old, he returned again by an order from God, and performed mighty miracles before Pharaoh. See Moses. There is a good deal of probability that this Pharaoh before whom Moses appeared, and in whose sight he smote Egypt with so many plagues, was a different person from him who would have had hands on him after he had slain the Egyptian. This same Pharaoh having at last been compelled to fend away the Hebrews, and to suffer them to go out of Egypt, soon repented of the leave he had given, and pursued them at the head of his army with his chariots. But he was drowned in the Red Sea, wherein he had rashly entered in the eagerness of his pursuit. Some historians pretend to give us the name of this Pharaoh; some, as Appian, call him Amosis or Amanis; Eusebius calls him Chenchis; Usher calls him Amenophis; but we may assure ourselves that there can be nothing certain in all this.

The fifth Pharaoh known to us is he that gave protection to Hadad son of the king of Edom, who gave him to wife the sister of his own queen, enriched him with lands, and brought up his son Genuah in his own court. Hadad returned to Edom after the death of David.

The sixth Pharaoh is he that gave his daughter in marriage to Solomon king of the Hebrews (1 Kings iii. 1.) and having taken Gezzar, he set it on fire, drove the Canaanites out of it, and gave it for a present to Solomon, in lieu of a dowry for his daughter, whom he had married to this prince (1 Kings iv. 16.) Before the death of Solomon, a rebellious subject of Solomon, and offered him a refuge in opposition to the king his master. The fame Shishak declared war against Rehoobam the son and successor of Solomon, besieged and took
Pharaoh is probably the name whom Herodotus names the year before he took him. Herodotus sent an army of rats, which knawed the furnaces of Chaldea. Herodotus pronounced ~x.x. The principal rules of which are: the banker keeps, when the card of the ponte is drawn, or the ponte wins, and the gain of the banker is the number of the cards remaining in the stock. De Moivre has calculated a table exhibiting this gain or loss for any particular circumstance of the play; and he observes, that at this play the least disadvantage of the ponte, under the same circumstances of cards remaining in the stock, is when the card of the ponte is, but twice in it, the next greater when three times, the next when once, and the greatest when four times. He has also demonstrated, that the whole gain per cent. of the banker, upon all the money that is ventured at this game, is 21. 195. 10d. See De Moivre's Doctrine of Chances, p. 77; &c. p. 105, &c.

Pharisees, a famous sect of the Jews, who distinguished themselves by their zeal for the traditions of the elders, which they derived from the fountain with the written word itself; pretending that both were delivered to Moses from Mount Sinai, and were therefore both of equal authority. From their rigorous observance of these traditions, they looked upon themselves as more holy than other men; and therefore separated themselves from those whom they thought sinners or profane, so as not to eat or drink with them; and hence, from the Hebrew word pharisi, which signifies "to separate," they had the name of Pharisees or S. paral. This sect was one of the most ancient and most considerate among the Jews; but its original is not very well known (a): however, it was in great repute in the

(a) The Jesuit Serrarius places their first rise about the time of Edras; because it was then that the Jews first began to have interpreters of their traditions. Maldonat, on the other hand, will not have this sect to have arisen among the Jews till a little before the time of Christ. Others, perhaps with more probability, refer the origin of the Pharisees to the time of the Maccabees. Dr Lightfoot thinks, that Pharisaism arose gradually, from a period which he does not assign, to the maturity of a sect. It is certain, from the account given by Josephus, that in the time of John Hyrcanus, the high priest and prince of the Ammonian line, about 188 years before Christ, the sect was not only formed, but made a considerable figure; and that it had advanced to a high degree of popularity and power about 80 years before Christ. Jof. Ant. lib. xiii. cap. 10. § 5, 6. cap. 15. § 5. & cap. 16. § 1. According to Balfage, Hist. of the Jews, book ii. cap. 9. § 2. one Arilobulus, an Alexandrian Jew, and a Peripatetic philosopher, who
The extraordinary pretences of the Pharisees to righteousness drew after them the common people, who held them in the highest esteem and veneration. Our Saviour frequently however, charges them with hypocrisy, and making the law of God of no particular mention. In the gospel; but they had a Saviour and Luke according to John, this more than a tradition which this Pharisees had many pagan notions of other traditions which these are propagators of it as a Pharisee, very shrewdly supposed to teach it as a Pharisee, very shrewdly supposed the Pharisees were both men; but others maintain that a man in the next world to represent the females, performed this office. They performed sacriiice, and wore figs about their necks called unction, 258, which when taken inwardly, were supposed to cause blindness, madness, love, others infected by touch; such was the garment sent by Meade to Creusa, prepared ficundam artem; and others operated upon persons at a distance. PHAROSA foteria were employed as antidotes against these malicious compositions: Thus the herb moly preferred Ulytles from the magical influence of Circe. The laurel, the rhamnus, the Ste-bane, the Jasper-flone, were used for similar purposes. See Potter's Grec. Ant.

PHARMACI, were two persons who were employed in the purification or purification of cities. Some say they were both men; but others maintain that a man to represent the males, and a woman to represent the females, performed this office. They performed sacrifice, and wore figs about their necks called unction, those of the man were blackish, and those of the woman white. Figs were an emblem of fertility, which they doubtless prayed for on their solemn occasions.

PHARMA COCHEMIA, means that part of the chemical art which treats of the preparation of medicines. It is so named by way of distinction from that chemistry which is wholly employed about the transmutation of metals by means of the philosopher's stone; this being called philosophical chemia.

PHARMACOLOGY, is a treatise of medicines, or the art of preparing them, judging of them, &c.

PHARMACOPEIA (from σαμακατανοον remedy, and are ut to male), means a dispensatory, or a treatise describing the preparations of the several kinds of medicines, with their uses, manner of application, &c.

We have various pharmacopoeias, as those of Bauderon, Quercetan, Zwiefel, Charas, Bates, Salmon; Lemery

who flourished about 125 years before Christ, and wrote some allegorical commentaries on the scripture, was the author of those traditions by an adherence to which the Pharisees were principally distinguished from other sects.
PHARMACY (A), is the art of preparing, preserving, and compounding substances, for the purposes of medicine. This art has been commonly divided into two branches, Galenical and Chemical pharmacy. But for this division there is no foundation in nature; and accordingly proceeds in one pharmacopoeia referred to the head of Chemical, are in another referred to the head of Galenical. There can be no doubt, that even the most simple pharmaceutical preparations are to a certain extent chemical. Hence this division, founded on prejudice, and supported merely by a veneration for antiquity, is now banished from pharmacy. But for this division there is no foundation in principles, as are also the operations, which remain to be discussed here only in so far as they are made subservient to the medicinal art, distinct from that which is purely chemical. The objects of pharmacy, however, are much more limited than those of chemistry; the latter comprehending, in the utmost latitude of the word, almost every substance in nature; while pharmacy regards only such bodies in the vegetable, animal, and mineral kingdoms, as, by their effects on the human frame, tend to preserve health, or to relieve it when lost.

**PART I. ELEMENTS OF PHARMACY.**

**CHAP. I. A general View of the Properties and Relations of Medicinal Substances.**

**Sect. I. Vegetables.**

Vegetables are organized bodies, furnished with a variety of vessels for reception, transmixture, and perforation of different fluids. Analogous to animals, they are produced from seeds and eggs, and are endowed with functions, by which the aliment they imbibe is changed into new forms, into solids and fluids, peculiar to particular plants, and to different parts of the same plant.

The analogy between the vegetable and animal kingdoms will appear still more striking, when we consider that the former exhibit, though in a less degree, all the phenomena of sensibility and motion. The plant of vegetables, like that of most animals, is of a mixed nature; and is composed of the necessary union of water, heat, and light, and left necessarily of air and earth: the office of these two last elements seems to be that of filtres, or vehicles for conveying the other principles in proper form.

From varieties in the state and proportion of these several agents, a very multiplied diversity takes place in the external form, quantity, and quality, of one and the same vegetable: hence the difference of plants from the soil, climate, season, and other similar circumstances. The influence of heat and light, mace, heat, and light, or what is probably the same thing, the absorption of the inflammable principle, is perhaps the most important article in the aliment of vegetables. This principle, whether derived from the solar rays, from putrid matters employed in manure, or from the putrefaction of the wild growth, affiliated by calcareous earths and other septs, is found at all times to modify, in a peculiar manner, the form, the quantity, and even the sensible and inherent properties, of vegetables. It is of importance however to remark, that the foundness and specific principles of vegetables are not invariably the more complete in proportion to the vigour of their growth; high health, which is always a dangerous state in the constitution of animals, is often the

---

(A) For this article we are indebted to the liberality of Mr Creech bookseller in Edinburgh, who, with his well known zeal for the cultivation of science, and, regardless of the advantage to be expected from his copyright, has permitted us to infert into this work the third and much improved edition of the Edinburgh New Dispensatory.
PHARMACY.

Elements.

means of perverting or destroying the economy of vegetable life. Thus the finer aromatics, which naturally inhabit the dry and sandy soils, when transplanted into a moist and rich one, or in other words, when placed in a soil abounding with the fimiler of inflammable principle, grow with rapidity and vigour, and have their bulk considerably increased; but lose very much of their fragrance, as if their active principles were exhausted by the luxuriance of their growth.

Plants are also found to differ considerably in the different periods of their growth. Thus, some herbs in their infancy abound molt with odoriferous matter; others again yield little or nothing from each other. Thus the bitter herb wormwood, when placed in inflammable principle, grow with rapidity and vigour, principles were exhausted by the common grain, orange, are remarkably different, yet to a more advanced age. Many fruits, in their immature state, contain an aulteric acid juice, which by maturation is changed into a sweet one: others, as the orange, are first warm and aromatic, and afterwards by degrees become filled with a strong acid. The common grain, and sandy other seeds, when beginning to vegetate, are in taste remarkably sweet; yet the kernels of certain fruits prove, at the same period, extremely acid. The roots of some of our indigenous plants, whole juice is, during the summer, thin and watery, if wounded early in the spring, yield rich balsamic juices, which, exposed to a gentle warmth, Soon concrete into solid gummy-refins, superior to many of those brought from abroad. In open exposures, dry soils, and fair warm seasons; aromatic plants become stronger and more fragrant, while those of an opposite nature become weaker. To these particulars, therefore, due regard ought to be had in collecting plants for medicinal uses.

It may be proper to observe also, that the different parts of one plant are often very different in quality from each other. Thus the bitter herb wormwood rises from an aromatic root; and the narcotic poppy-head includes seeds which have no narcotic power. These differences, though very obvious in the common culinary plants, do not seem to have been sufficiently observed or attended to, in those plants that have been admitted as articles of the materia medica.

Without any obvious dependence on the circumstances abovementioned, vegetables are, like animals, also obnoxious to disaases and death; which, whether occasioned by intense cold, by insects, lightning, or other causes, always maintain a striking analogy to the affections of animals. The principal difference between animals and vegetables is, that the several parts of vegetables do not constitute such a mutually depending system as those of the more perfect animals; Hence it is, that a very considerable part of a plant may be disfigured or dead, while the rest enjoys perfect good health and vigour. Though the physiology of vegetables is hitherto insufficient for forming any complete doctrines of the causes and cure of their several diseases; yet, in many cases, it might be useful to attend to the formation of a pathology of the vegetable kingdom; in the late even of our prent knowledge, it is of importance in the study of pharmacy to be aware that such diseases really exist, and are capable of changing or destroying the active principles of many of our most valuable herbs. In the plants more evidently festive, the diseases exhibit a very close analogy to many of those of animals; several of the remote causes are such as are known to obstruct perpiration, to induce general debility, or otherwise disorder the animal economy. The diseases also are evidently marked by a diminution of their sensitive and moving principle; and perhaps, in consequence of this diminution, their folids, sap, and other fluids, shrivel and decay, and the whole plant assumes new forms, and is impregnated with inert, or fraught with noxious principles. Analogous also to animals, the plant when deprived of the living principle, runs into all those changes common to what is called inanition mutat. We shall now proceed to examine the changes to which vegetables are subject.

I. Productions from Vegetables by Fermentation.

Fermentation is a spontaneous motion excited in fermentable dead vegetables and animals, which is peculiar to those organic substances in conformance of the principle of vegetable or animal life. See Fermentation.

The circumstances favouring fermentation are in general, a certain degree of fluidity, a certain degree of heat, and the contact of the air.

There are, however, several substances, themselves not susceptible of fermentation, which nevertheless may be brought into that state by the admixture of those that are; as by adding to them, along with a proper quantity of water, a portion of the yeat or head thrown up to the surface of fermenting liquors. Without this expedient many vegetables would run immediately into the acetic, and some of them into the putrefactive fermentations. It is also found, that though acetic and putrefactive fermenters are unable to stop the vinous fermentation, they are however capable of afflicting the liquor to their own nature in a more perfect form: and hence it is, that in the manufactures of wine, rum, and vinegar, it is found useful to keep the vessels well seasoned with the liquor intended to be prepared. Three different kinds of fermentations have been generally distinguished by chemists. The vinous, which furnishes alcohol, or what is commonly called spirit; the acetic, which affords vinegar; and the putrefactive, which yields volatile alkalii. Being generally constant in succession to each other, the whole process will be best understood by considering each of them apart. All vegetable substances are not capable of the vinous fermentation; the conditions necessary to its production are, a saccharo-mucilaginous matter; a fluidity some what viscous, the proper degree of which is best learned from experience; a heat from 40 to 96 of Fahrenheit's thermometer; a considerable mass of matter; and the action of the external air.

The phenomena exhibited in the vinous fermentation are, a brisk tumultuary motion, the liquor loses its transparency and homogeneous appearance, its bulk and heat are considerably increased, the solid parts are buoyed up to the top, and a great quantity of a permanently elastic fluid is diffused. This fluid or gas being heavier than atmospheric air, floats in separate masses near the surface of the liquor; and is easily distinguishable from common air by extinguishing flame and animal life, precipitating lime from limewater, crystallizing and rendering mild the cough.
Elements.  
13 Carbonic acid.

Wines, various kinds of.

Fermented or vinous liquors are prepared from a great variety of substances: the saccharine substances, or those rendered so by a beginning and inebriating liquor, called wine or vinous liquor.

Wines, various kinds of.

fermentation.

The product of the vinous fermentation.  

Of the product of the vinous fermentation.  

The product of all these fermented vegetables is, as we have just now mentioned, the pungent and intoxicating liquor called wine. It is proper, however, in pharmacy, to inquire into the different principles which enter its composition. As the wine furnished by grapes is the most valuable and generally known, we shall take it as an example: grape-wine, then, is composed of a large quantity of water, of alcohol, of tartar, and of a colouring matter. It is proper, however, that we should lay down the proofs of such a combination, in wine, and explain the methods by which it may be decomposed and separated into the constituent parts abovementioned.

For this purpose, recourse is generally had to the Vol. XIV.
phenomena takes place, yet the wine still suffers a slow and imperceptible degree of fermentation. We are not then to consider the liquor as being in a quiescent state, but as constantly approaching to the next stage, viz. the acetous fermentation, which we are now to consider. This kind of inoffensive fermentation, or what we may call the intermediate change, seems to be necessary to the perfection of the wine. Its degree, however, is to be regulated under certain limitations: when too much checked, as by cold, thunder, or such like causes, the wine becomes vivid: when too much encouraged by heat, contact of air, &c. it approaches too far to the acetous change: but in order that the vinous stage proceed fully to the acetous fermentation, several circumstances are required: and these are in general the same that were before necessary to the vinous stage. These conditions are, a temperate degree of heat, a quantity of unfermented mucilage, an acid matter, such as tartric, and the free access of external air: When thus situated, the liquor soon passes into the acetous fermentation; but during this stage the phenomena are not so remarkable as in the vinous; the motion of air is now less considerable, a gross undigested matter separates at the bottom, the liquor loses its vinous taste and flavour, becomes sour, and on distillation affords no inflammable spirit. It is now the acetic acid or vinegar; and when separated by distillation from the undigested lees, may be preferred a considerable length of time without undergoing the putrid change: to this laft, however, it always approaches in the same manner as the vinous constantly verges to the acetous fermentation; and this will much more readily happen if the acid be allowed to remain with the undigested matter above-mentioned. When thus situated, the vinegar quickly loses its transparency, assumes a blackish colour, loses its fumes and agreeable odour, has an offensive taste and smell, and, when distilled at a certain period of the process, yields volatile alkali.

The liquor is now arrived to the last stage, viz.

3. The Putrefactive Fermentation.

From the preceding phenomena, it is obvious, that the same substance which is capable of the vinous and acetous, is also capable of the putrefactive fermentation. It is perhaps impossible to induce the first without a mixture of the second; or the second without a mixture of the third. Hence every wine is a little acid; and there are few vinegars without some disposition towards putrefaction, or without volatile alkali, neutralized by the acid which predominates. Notwithstanding this seeming continuance of one and the same process, the putrefaction of vegetables has its particular phenomena. The vegetable matter, if in a fluid state, becomes turbid, and deposit a large quantity of fecculent matter; a considerable number of air-bubbles are raised to the top; but their motion is not so brisk in the putrefactive as in the vinous, or even the acetous fermentation: neither the bulk nor heat of the liquor seems to be increased; but an acid pungent vapour is perceived by the smell, and which, by chemical trials, is found to be the volatile alkali; by degrees this pungent odour is changed into one less pungent, but much more nauseous. If the same train of phenomena have taken place in a vegetable consisting of parts somewhat solid, its cohesion is broke down into a soft pulpy mass; this mass, on drying, entirely loses its odour, leaving a black cherry-like residuum, containing nothing but earthy and saline substan-

It is proper to observe, that though the circumstances favourable the putrefactive are the same with those requisite to the vinous and acetous fermentations, yet these several conditions are not so indispensable to the former as to the latter stages. All vegetables have more or less tendency to putrefaction, and a great number of them are capable of the acetous fermentation; but the proportion of those capable of the vinous is not considerable; and these last will run into the putrid in circumstances in which they cannot undergo the vinous or the acetous fermentations. Thus flour made into a soft paste will become sour; but it must be perfectly dissolved in water to make it fit for the vinous stage; whereas merely dampness is sufficient to make it pass to the putrid fermentation: besides the condition of fluidity, a less degree of heat, and a more limited access of air, are sufficient for producing the putrefactive fermentation.

It is therefore probable, that all vegetables, in whatever state they may be, are liable to a kind of putrefaction; in some the change is slow and gradual, but never fails at length to break down the texture and cohesion of the moist solid.

We formerly observed, that the vapours separated during the vinous fermentation were fixed air or aerial acid; and it is indeed true, that in the incipient stage of this fermentation a quantity of gas is still evolved, and along with it a quantity of alkali air: in the advanced stage, however, we find these vapours of a different nature; they now tarnish silver, and render combinations of lead with the vegetable acids black. When produced in large quantity, and much confined, as happens in flacks of hay put up wet, they burst into actual flame, consuming the hay to ashes: on other occasions, the escape of these vapours discovers itself by an emission of light, as in the luminous appearance of rotten wood when placed in the dark. From the above phenomena it is evident, that these vapours abound with the principle of inflammability; and their odour probably depends on this principle loosely combined with the water, or some other parts of the volatile matter. This gas, is therefore different from that separated during the vinous fermentation; it is the phlogisticated, and sometimes the inflammable air of Dr Priestley, or the hydrogen of Lavoisier. See table of chemical nomenclature, &c. Chemistry, page 158.

We have thus, for the sake of clearness, and in order to comprehend the whole of the subject, traced the phenomena of fermentation through its different stages: it is proper, however, to observe, that though every vegetable that has suffered the vinous will proceed to the acetous and putrefactive fermentations, yet the second stage is not necessarily preceded by the first, nor the third by the second; or in other words, the acetous fermentation is not necessarily confined to those substances which have undergone the vinous, nor the putrefactive to those which have undergone the acetous fermentation. Thus it is, that gums dissolved in water pass to the acetous
Part I.  

PHAR...  

...maceutical without undergoing the vinous fermentation; and glutinous matter seems to run into putrefaction without flowing any previous accidence: and farther, these changes frequently happen although the matter be under those conditions which are favourable to the preceding stages.

From the foregoing sketch, the importance of this subject in the study of Pharmacy will be obvious at first sight: it cannot, however, afford us any useful information on the native principles of vegetables; but it presents to us new products, the importance of which is well known in chemistry, in medicine, and in arts. The necessity of being well acquainted with the several facts (for of theory we know none satisfactory), will appear in the pharmaceutical history and preparation of many of our most valuable drugs. We are next to consider a set of no less complicated operations, viz.

II. Productions from vegetables by Fire.

In order to analyse, or rather to decompose, vegetables by the naked fire, any given quantity of dry vegetable matter is put into a retort of glass or earthen. Having filled the vessel about one half or two thirds, we place it in a reverberatory furnace, adapting it to a proper receiver. To collect the elatic fluids, which, if confined, would burst the vessels (and which, too, it is proper to preserve, as being real products of the analysis), we use a perforated receiver with a crooked tube, the extremity of which is received into a vessel full of water, or of mercury, and inverted in a bag containing the same fluid: by this contrivance, the liquid matters are collected in the receiver, and in the aeriform fluids pass into the inverted vessel. If the vegetable is capable of yielding any saline matter in a concrete state, we interpose between the retort and the receiver another vessel, upon whose sides the salt sublimes. These things being properly adjusted, we apply at first a gentle heat, and increase it gradually, that we may observe the different products in proper order. At first an inipid watery liquor passes over, which is chiefly composed of the water of vegetation; on the heat being a little farther increased, this watery liquor, or phlegm, becomes charged with an oily matter, having the odour of the vegetable, if it possessed any in its entire state; along with this oil we also obtain an acid resembling vinegar, and which communicates to the oil somewhat of a faponaceous nature; on the heat being carried still farther, we procure more acid, with an oil of a dark colour, and the colour gradually deepens as the distillation advances. The oil now ceases to retain the peculiar odour of the vegetable; and being scorched by the heat, sends forth a strong disagreeable smell like tar; it is then called empyramatic oil. About this time also some elatic vapours rush into the inverted vessel; these generally consist of inflammable or fixed airs, and very often of a mixture of both; the volatile part now also sublimes, if the vegetable was of a nature to furnish it. By the time the matter in the retort has acquired a dull red colour, nothing further will arise; we then stop; and allowing the vessel to cool, we find a mass of charcoal, retaining more or less the form and appearance of the vegetable before its decomposition.

We have thus described, in the order of their succession, the several products obtained from the general nature of vegetables when analyzed in close vessels and in a naked fire.

It is, however, to be understood, that the proportion of these principles turns out very various; the more sucentuous yield more water, and the more fixed afford a greater quantity of the other principles. Independently also of this difference, the nature of the products themselves are found to differ in different vegetables: thus in the cruciform plants, and in the eminently and farraceous seeds, the saline matter which comes over with the water and oil is found to be alkaline; sometimes it is ammoniacal, from the combination of the acid with the volatile alkali passing over at the end of the proces; it is also probable, that the acids of vegetables are not all of the same nature, though they exhibit the same external marks. When volatile alkali is obtained, it is always found in the first distillation, it is produced, however, from a few vegetables only; it is formed in a concrete form, being generally dissolved in the phlegm; and as it ordinarily makes its appearance about the end of the process, it is probable that its formation is owing to some peculiar combination of the oil and fixed alkali. The plants containing much oily combustible matter seem to be those which more peculiarly yield inflammable alkali, while the mucilages appear to be as peculiarly fitted for affording the fixed air or aerial acid. The chemical properties of charcoal seem to be always the same from whatever vegetable it has been produced: on a minute examination (which however, is not the business of pharmacy), it is found to consist of fixed air, the principle of inflammability, a small quantity of earth, saline matter, and a little water. The whole of the analysis then amounts to air, water, earth, and the principle of inflammability; for by repeated distillations the oil is resolved into water, the principle of inflammability, and a little earth; the saline matter also is a product arising from a combination of the earthy matter with water or the principle of inflammability, in some shape or other, or perhaps with both. That these combinations take place, has at least been the opinion of the chemists. We formerly said that charcoal was partly composed of saline matter; it therefore remains that we should next decompose the charcoal, in order to obtain or separate the articles next to be mentioned.

The fixed Salts of Vegetables.

When vegetable charcoal has been burnt, there remains a quantity of ashes or cinders of a blackish grey or white colour: these, when boiled or inhaled in water, communicate to it a pungent saline taste; the salt thus held in solution may, by evaporation, be reduced to a concrete state: this saline matter, however, is generally found to be mixed with ferruginous earthy and other impurities, and likewise with a number of neutral salts of different kinds. In this mixed condition it is the

Potash of burnt charcoal.

This salt, or rather compound of different kinds, is procured by burning large quantities of wood of any kind; and this process is called in reaction; the pre-dominating salt, however, is alkaline; and as the neutra...
The fixed vegetable Alkali.

Alkalis in general are distinguished by a pungent taste, the very reverse of that of forwards; by their destroying the acidity of every four liquor; and by their changing the blue and red colours of vegetables to a green, they attract more or less the moisture of the air, and some of them deliquesce. The fixed alkali, which we shall at present consider more particularly, are fusible by a gentle heat; by a greater degree of heat they are dissipated; their affinity, therefore, is only relative to the other kind of alkali, viz. the volatile: they dissolve and form glass with earths: and, lastly, when joined with acids to the point of saturation, they form what are called Neutral Salts.

These characters will afford some necessary and preliminary knowledge of these substances in general; and we shall afterwards find that they are sufficient to distinguish them from all other saline bodies: it is necessary, however, to examine them more minutely, for our analysis has not yet reached so far as to present them in their simplest state. Previous to the discoveries of Dr Black, the vegetable fixed alkali (which we at present speak of particularly), when separated from the foreign matters with which it is mixed in the ashes, was confidered to be in its purest state: we shall afterwards find that it is only a compound body, and is really a neutral salt, compounded of pure alkali, and fixed air or the aerial acid. We presume, then, that the particular history of its chemical and medicinal properties will be better understood when we come to those processes by which it is brought to its most pure and simple state: See Chemistry. We shall only therefore observe for the present, that fixed vegetable alkali, not only in its purest state, but also when neutralized by aerial acid, seems always to be one and the same thing, from whatever vegetable it has been produced. Thoso of some sea-plants must, however, be excepted: the saline matter obtained from these last is, like the former, in a mixed and impure state; it differs, however, from potash, in containing an alkali of somewhat different properties. The cinder of sea-plants containing this alkali is called Soda.

Soda, then, as we have just now hinted, is produced by the incineration of the kalk and other sea-plants: And from this impure and mixed mass of cinder, is obtained the marine, mineral, or muriatic alkali, or natron, as it is now denominated by the London College. This alkali has acquired these names, because it is the base of the common marine or sea-salt; it differs from the vegetable alkali in being more easily crystallizable; when dried, it does not like the former attract humidity sufficient to form a liquid; it is somewhat less pungent to the taste, and, according to Bergman, has less attraction for acids than the vegetable alkali.

It is, however, to be observed, that this alkali, when deprived of fixed air, that is to say, when brought to its purest state, can scarcely, if at all, be distinguished from the vegetable alkali; and indeed the true distinction can only be formed from their combinations, each of them affording with the same acid very different neutral salts. It belonged to this place to mention some of the characters of alkalis in general, and also some of those marks by which the vegetable and mineral alkalis are distinguished from each other: but for a more particular history of their chemical and medicinal properties, we refer to an account of the pharmaceutical preparations. As the volatile alkali is rarely produced from vegetables, but is generally obtained from animal matter, we shall consider that kind of alkali when we come to analyze the animal kingdom.

Of Vegetable Earth.

After all the saline matter contained in the ashes of vegetable vegetables has been washed off by the processes before mentioned, there yet remains one infipid earthy-like powder, generally of a whitish colour, infoluble in water, and from which some iron may be attracted by the magnet. It is said to have formed alum with the vitriolic acid; a kind of felenite has also been obtained, but somewhat different from that produced by the union of the same acid with calcareous earth; this residuum of burnt vegetables differs also from calcareous earth, in not being susceptible of becoming quicklime by calculation. It has been found that this residuum, instead of an earth, is a calcareous phosphoric salt, similar to that obtained from the bones of animals.

We have thus finished our analysis of vegetables by the naked fire; and have only to observe, that, like the analysis by fermentation, it can afford us no useful information on the native principles of the vegetable itself.

When chemistry began first to be formed into a rational science, and to examine the component parts and internal constitution of bodies, it was imagined, that this resolution of vegetables by fire, discovering to us all their active principles, unclogged and unmixed with each other, would afford the surest means of judging of their medicinal powers. But on prosecuting these experiments, it was soon found that they were insufficient for that end: that the analyses of poisonous and efficacions plants agreed often as nearly as the analyses of one plant; that by the action of a burning heat, two principles of vegetables are not barely separated, but altered, transformed, and combined into new forms; in which it was impossible to know in what form they existed, and with what qualities they were endowed, before these changes and transformations happened. If, for example, 32 ounces of a certain vegetable substance are found to yield ten ounces and a half of acid liquor, above one ounce and five drams of oil, and three drams and a half of fixed alkaline salt: what idea can this analysis give of the medicinal qualities of gum Arabic?

III. Substances naturally contained in vegetables, and separable by Art without Alteration of their native Qualities.

It has been supposed, that there is one general fluid or blood which is common to all vegetables, and from which the fluids peculiar to particular plants and their parts are prepared by a kind of secretion: To this supposed...
Part I.

PHARMACY.

Elements. 28

Vegetable fluids botanists have given the name of Sap. This opinion is rendered plausible from the analogy in many other respects between vegetable and animal substances: and indeed if we consider the water of vegetation as this general fluid, the opinion is perhaps not very far from the truth; but the notion has been carried much farther than supposing it to be mere water; and the opinion of naturalists on this subject does not seem to be well supported by experience. It is difficult to extract this Sap without any mixture of their constituent parts. But in a few vegetables, from which it diffils by wounding their bark, we find this suppossed general blood possessing properties not a little various: Thus the juice effused from a wounded birch is consideribly different from that poured out from an incision in the vine.

Vegetables, like animals, contain an oil in two different states. That is, in several vegetables a certain quantity of oil is superabundant to their constitution, is often lodged in distinct reservoirs, and does not enter into the composition of their other principles: in most vegetables, again, another quantity of oil is combined, and makes a constituent part of their principles. Of this last we formerly spoke in our analysis of vegetables by fire; and it is the former we mean to consider, under the three following heads.

Gross oils abound chiefly in kernels of fruits, and in certain seeds; from which they are commonly extracted by expression, and are hence distinguished by the name of expressed oils. They are contained also in all the parts of all vegetables that have been examined, and may be forced out by vehemence of fire; but here their qualities are much altered in the process by which they are extracted or discovered, as we have seen under the foregoing head.

These oils, in their common state, are not dissolvable either in vinous spirits or in water: though by means of certain intermedia they may be united both with the one and the other. Thus a skilful interposition of sugar renders them miscible with water into what are called loachs and oily draughts; by the intervention of gum or mucilage they unite with water into a milky fluid: by alkaline salts they are changed into a soap, which is miscible both with water and spiritsious liquors, and is perfectly dissolved by the latter into an uniform transparent fluid. The addition of any acid to the foapy solution absorbs the alkaline salt; and the oil, which of course separates, is found to have undergone this remarkable change, that it now dissolves without any intermedium in pure spirit of wine.

Expressed oils exposed to the cold lose their fluidity greatly: some of them, in a small degree of cold, congeal into a consistant mass. Kept for some time in a warm air, they become thin and highly rancid: their soft, lubricating, and relaxing quality is changed into a sharp acrimonious one: and in this state, instead of allaying, they occasion irritation; instead of obtunding corrosive humours, they corrode and inflame. These oils are liable to the fame noxious alteration while contained in the original subject: hence arises the rancidity which the oily seeds and kernels, as almonds and those called the cold seeds, are so liable to extract in keeping. Nevertheless, on triturating these seeds or kernels with water, the oil, by the intervention of the other matter of the subject, unites with the water, into an emulsion or milky liquor, which, instead of growing rancid, turns four on standing.

It appears then that some kind of fermentation goes on in the progress of oils in the rancid state; and it would seem from some experiments by Mr Macquar, that an acid is evolved, which renders them more soluble in spirit of wine than before.

In the heat of boiling water, and even in a degree of heat much exceeding this as the heat of boiling water does that of the human body, these oils suffer little: distillation of their parts. In a greater heat they emit a pungent vapour, seemingly of the acid kind: and when suffered to grow cold again, they are found to have acquired a greater degree of consistence than they had before, together with an acrid taint. In a heat approaching to ignition, in close vessels, the greatest part of the oil arises in an empyrean state, a black coal remaining behind.

2. Gross sebaceous matter.

From the kernels of some fruits, as that of the choicest colate nut, we obtain, instead of a fluid oil, a substance of seaceous butyrous consistence; and from others, as the Juan sementes, a solid matter as firm as tallow. These concretes are most commodiously extracted by boiling the substance in water: the sebaceous matter, liquefied by the heat, separates and rises to the surface, and resumes its proper consistence as the liquor cools.

The substances of this class have the same general properties with expressed oils, but are left disposed to become rancid in keeping than most of the common fluid oils. It is suppos'd by the chemists, that their thick consistence is owing to a larger admixture of an acid principle: for, in their resolution by fire, they yield a vapour more fсолifacible than the fluid oils; and fluid oils, by the admixture of concentrated acids, are reduced to a thick or solid mass.

3. Essentia1 Oils.

Essential oils are obtained only from those vegetables, or parts of vegetables, that are considerably odorous. They are the direct principle in which the whence of certain matters consists; and from which the name of essences or essential oils.

Essential oils are secreted fluids; and are often lodged in one part of the plant, while the rest are entirely void of them. Sometimes they are found in separate spaces or receptacles; and are there visible by the naked eye: thus, in the rind of lemons, oranges, citrons, and many others, there are placed everywhere small pellucid vehicles, which, by press ing the peel near to the flame of a candle, squirt out a quantity of essential oil, forming a stream of lambent flame: hence, too, an oleofascharum may be made, by rubbing the exterior surface of these peels with a piece of lump sugar, which at once tears open these vehicles, and absorbs their contained oil.

Essential oils unite with rectified spirit of wine, and compose with it one homogeneous transparent fluid; though some of them require for this purpose a much larger
larger proportion of the spirit than others. The difference of their solubility perhaps depends on the quantity of disengaged acid; that being found by Mr. Macquer not only to promote the solution of essential oils, but even of those of the unintoxic kind. Water also, though it does not dissolve their whole substance, may be made to imbibe some portion of their more subtle matter, so as to become considerably impregnated with their flavour; by the admixture of sugar, gum, the yolk of an egg, or alkaline salts, they are made totally dissoluble in water. Digested with volatile alkali, they undergo various changes of colour, and some of the less odorous acquire considerable degrees of fragrance, while fixed alkali universally impairs their odour.

The specific gravity of most of these oils is less than that of water: some of them, however, are so heavy as to sink in water; but these varieties shall be noticed when we come to their preparation.

In the heat of boiling water, these oils totally exhale; and on this principle they are commonly esteemed with their flavour; by the admixture of sugar, gum, the yolk of an egg, or alkaline salts, they are made totally dissoluble in water. Digested with volatile alkali, they undergo various changes of colour, and some of the less odorous acquire considerable degrees of fragrance, while fixed alkali universally impairs their odour.

The specific gravity of most of these oils is less than that of water: some of them, however, are so heavy as to sink in water; but these varieties shall be noticed when we come to their preparation.

In the heat of boiling water, these oils totally exhale; and on this principle they are commonly extracted from subjects that contain them; for no other fluid, which naturally exists in vegetables, is exhalable by that degree of heat, excepting the aqueous moisture, from which the greatest part of the oil is easily separated. Some of these oils arise with a much less heat, a heat little greater than that in which water begins visibly to evaporate. In their resolution by a burning heat, they differ little from expressed oils.

Essential oils, exposed for some time to a warm air, suffer an alteration very different from that which the expressed undergo. Instead of growing thin, rancid, and acrimonious, they gradually become thick, and at length harden into a solid brittle concrete; with a remarkable diminution of their volatility, fragrancy, pungency, and warm stimulating quality. In this state, they are found to consist of two kinds of matter; a fluid oil, volatile in the heat of boiling water, and nearly of the same quality with the original oil; and of a grofer substance which remains behind, not exhalable without a burning heat, or such as changes its natural and resolves it into an acid, an empyreumatic oil, and a black coal.

The admixture of a concentrated acid instantly produces, in essential oils, a change nearly similar to that which time effects. In making these kinds of mixtures, the operator ought to be on his guard; for when a strong acid, particularly that of nitre, is poured hastily into an essential oil, a great heat and ebullition ensue, and often an explosion happens, or the mixture bursts into flame. The union of expressed oils with acids is accompanied with much less conflict.

Concrete essential oil.

Some vegetables, as roes and decampine root, instead of a fluid essential oil yield a substance possessing the same general properties, but of a thick or febaceous consistence. This substance appears to be of as great volatility and facility of parts as the fluid oils: it equally exhales in the heat of boiling water, and concretes upon the surface of the collected vapour. The total exhalation of this matter, and its concreting again into its original conffitut flat, without any separation of it into a fluid and a solid part, distinguishes it from essential oils that have been thickened or indurated by age or by acids.

5. Camphor.

Camphor is a solid concrete, obtained chiefly from Camphor, the woody parts of certain Indian trees. See Camphor, distinguitishing characters of.

Or spiritus rectior, is the name given to the odorous principle of vegetables. These bodies differ greatly from one another in the quantity, strength, and volatility of the odorous principle which they contain. It is generally found united with volatile oils; but in its indurated form, it is soluble in alcohol and water as well as in thefe. The flighted degree of heat is sufficient to disengage the aroma of plants. To obtain it, the plant must be distilled in a balneum mariae, and its vapours received into a cold capital, which may condense and afterwards conduct them in a fluid state into the receiver. The product is pure odoriferous water, and is known by the name of essential or distilled water. This liquor is to be considered as a solution of the aroma or odorous principle in water. When aromatic water is heated, it loses its smell in consequence of the odorous principle being more volatile than the fluid in which it was dissolved. This principle is also diffipated by exposure to the air. Many facts would induce us to believe, that the principle of smell is one of the elementary principles of volatile oils; but we are as yet almost completely ignorant of its chemical nature, properties, and combinations.

6. Aroma.

Or spiritus rectior, is the name given to the odorous principle of vegetables. These bodies differ greatly from one another in the quantity, strength, and volatility of the odorous principle which they contain. It is generally found united with volatile oils; but in its indurated form, it is soluble in alcohol and water as well as in thefe. The flighted degree of heat is sufficient to disengage the aroma of plants. To obtain it, the plant must be distilled in a balneum mariae, and its vapours received into a cold capital, which may condense and afterwards conduct them in a fluid state into the receiver. The product is pure odoriferous water, and is known by the name of essential or distilled water. This liquor is to be considered as a solution of the aroma or odorous principle in water. When aromatic water is heated, it loses its smell in consequence of the odorous principle being more volatile than the fluid in which it was dissolved. This principle is also diffipated by exposure to the air. Many facts would induce us to believe, that the principle of smell is one of the elementary principles of volatile oils; but we are as yet almost completely ignorant of its chemical nature, properties, and combinations.

7. Resin.

Essential oils, indurated by age or acids, are called resins. When the indurated mass has been exposed to heat, the heat of boiling water, till its more subtle part, or the pure essential oil that remained in it, has exhaled, the gross matter left behind is likewise called resin. We find,

(5) It may likewise be procured from most of the volatile oils, by volatilizing the oil in a temperature a few degrees below that which is sufficient to elevate the camphor.
Part I. 

PHARMCACY.

Elements. — find, in many vegetables, resins analogous both to one and the other of the five concretes; forms containing a sufficient oil, separable by the heat of boiling water; others containing nothing that is capable of dissolving in that heat.

Resins in general dissolve in rectified spirit of wine, though some of them much less easily than others: it is chiefly by means of this solvent that they are extracted from the subjects in which they are contained. They dissolve also in oils both expressed and essential, and may be united with watery liquors by means of the same intermediary which render the fluid oils miscible with water. In a heat less that of boiling water, they melt into an oily fluid; and in this state they may be incorporated one with another. In their resolution by fire, in close vessels, they yield a manifelled acid, and a large quantity of empyreumatic oil.

8. Gum.

Gum differs from the foregoing substances in being unflammable; for though it may be burnt to a coal, and thence to ashes, it never yields any flame. It differs also from gum, in the proportion of the principles into which it is resolved by fire; the quantity of empyreumatic oil being far less, and that of an acid far greater. In the heat of boiling water, it suffers no dilatation; nor does it liquefy like resins; but continues unchanged, till the heat be so far increased as to fcorch or turn it to a coal.

By a little quantity of water, it is softened into a viscid adhesive mass, called mucilage: by a larger quantity it is dissolved into a fluid, which proves more or less glutinous according to the proportion of gum. It does not dissolve in vinous spirits, or in any kind of oil; nevertheless, when softened with water into a mucilage, it is easily miscible both with the fluid oils and with resins; which by this means becomes soluble in watery liquors along with the gum, and are thus excellently fitted for medicinal purposes.

This elegant method of uniting oils with aqueous liquors, which has been kept a secret in few hands, and by which we had been known to Dr. Grew: "I take (says he) the oil of aniseed, and pouring it upon a body, I sf order it, that it was thereby turned into a perfect milk-white balsam or butter; by which means the oil became mingeable with any vinous or watery liquor, easily and instantaneously dissolving therein in the form of a milk. And note, this is done without the leas alteration of the smell, taste, nature, or operation of the said oil. By somewhat the same means any other inflammable oil may be transformed into a milk-white butter, and in like manner be mingled with water or any other liquor: which is of various use in medicine, and what I find oftentimes very convenient and advantageous to be done." (Grew of Mixtures, chap. v. &c. p. 6.) This inquiry has lately been further prosecuted in the first volume of the Medical Observations published by a society of physicians in London; where various experiments are related, for rendering oils, both essential and expressible, and different unctuous and resinous bodies, soluble in water by the mediation of gum. Mucilages have also been used for suspending crude mercury, and some other ponderous and insoluble substances: the mercury is by this means not a little divided; but it is found that the particles are very apt to run together or subside, if a pretty constant agitation be not kept up.

As oily and resinous substances are thus united to water by the means of gum, so gums may in like manner be united to spirit of wine by the intervention of resins and essential oils; though the spirit does not take up far so much of the gum as water does of the oil or resin.

Acid liquors, though they thicken pure oils, or render them confettent, do not impede the diffusion of gum, or of oils blended with gum. Alkaline salts, on the contrary, both fixed and volatile, though they render pure oils insoluble in water, prevent the solution of gum, and of mixtures of gum and oil. If any pure gum be dissolved in water, the addition of any alkali will occasion the gum to separate, and fall to the bottom in a confluent form; if any oily or resinous body was previously blended with the gum, this also separates, and either sinks to the bottom, or rises to the top, according to its gravity.

By gum-refin is understood a mixture of gum and resin. Many vegetables contain mixtures of this kind, in which the component parts are so intimately united, that the compound, in a pharmaceutical view, may be considered as a distinct kind of principle; the whole mass dissolving almost equally in aqueous and in spirituous liquors; and the solutions being not turbid or milky, like those of the groffer mixtures of gum and resin, but perfectly transparent. Such is the affrangent matter of bitternroot, and the bitter matter of gentian. It were to be wished that we had some particular name for this kind of matter; as the term gum-refin is appropriated to the grossest mixtures, in which the gummy and resinous parts are but loosely joined, and easily separable from each other.

We shall afterwards find that it will be convenient to imitate this natural combination by art. As the effects of medicines very generally depend on their solubility in the stomach, it is often necessary to bring their more inoffensive parts, such as resinous and oily matters, into the state of gum-refin: this is done, as we have mentioned in the former article, by the mediation of mucilage. By this management these matters become much more soluble in the stomach; and the liquor thus prepared is called an emulsion, from its whitish colour, resembling that of milk.

10. Saline Matter.

Of the saline juices of vegetables there are different kinds, which have hitherto been but little examined: the sweet and the acid ones are the most plentiful and the best known.

There have lately, however, been discovered a consideraflible variety of salts in different vegetables. The salts in very mild fixed alkali, which was formerly considered as a redal, product of the fire, has been obtained from almost all plants by macerating them in acids; the vegetable alkali is the most common, but the mineral is also found in the marine plants. Besides the fixed alkali, several other salts have been detected in different vegetables; such as vitriolated tartar, common salt, Glaber's salt, nitre, ferruginous salt, and selenite. From 

sone
Pharmacy.

11. Farina or flour.

This substance partakes of the nature of gum, but has more taste, is more fermentable, and much more nutritive. It abounds in very many vegetables, and is generally deposited in certain parts, seemingly for the purpose of its being more advantageously accommodated to their nourishment and growth. Several of the bulbous and other roots, such as those of potatoes, briony, those from which cassia is extracted, salsify, and many others, contain a great quantity of white juce resembling and really possessing the properties of farina. The plants of the leguminous tribe, such as peas and beans, are found also to abound with this matter. But the largest quantity of farina resides in grains, which are therefore called farinaeum. Of this kind are wheat, rye, barley, oats, rice, and other similar plants.

At first sight farina appears to be one homogeneous farina of subfance: it is, however, found to be a compound of what are three different and separable parts. To illustrate this, we shall take as an example the farina of wheat, being the vegetable which affords it in greatest quantity, and in its most perfect state. To separate these different parts we form a paste with any quantity of flour and cold water; we suspend this paste in a bag of muffin or such-like cloth; we next let fall on it a stream of cold water from some height, and the bag may now and then be very gently squeezed; the water in its descent carries down with it a very fine white powder, which is received along with the water in a vessel placed below the bag; the process must be continued till no more of this white powder comes off, which is known by the water that passes through the bag ceasing to be of a milky colour. The process being now finished, the farina is found to be separated into three different substances: the glutinous or vegeto-animal part remains in the bag; the amylo or farina is deposited from the water which has been received in the vessel placed below the bag; and, lastly, a mucous matter is held dissolved in the same water from which the farina has been deposited; this mucous part may be brought to the confidence of honey, by evaporating the water in which it is kept in solution.

These several parts are found also to differ remarkably in their sensible and chemical properties. The vegeto-animal part is of a whitish grey colour, is a tenacious, ductile, and elastic matter, partly possessing the texture of animal membranes. Distilled in a retort, it yields, like all animal matters, a true volatile alkali; and its coal affords no fixed alkali. It is not only indoluble, but even indiffuible, in water; both which appear from its remaining in the bag after long-continued lotions. Like gums, it is insoluble in alcohol, in oils, or ether; but it is also indoluble in water, and yields on distillation products very different from those afforded by gums: it is therefore of an animal nature, and approaches perhaps nearer to the coagulable lymph of animals than to any other substance.

The fixed alkali, by means of heat, dissolves the gluten vegeto-animal; but when it is precipitated from this solution by means of acids, it is found to have lost its elasicity. The mineral acids, and especially the nitric,
Part I. PHARMACY.

NITROUS, are also capable of dissolving the vegeto-animai part of the farina.

The starch, amyllum, or the amylaceous matter, makes the principal part of the farina. As we before noticed, it is that fine powder deposited from the water which has pervaded the entire farina: it is of a greyish white colour, but can be rendered much whiter by making it undergo a certain degree of fermentation. Starch is insoluble in cold water; but in hot water it forms a transparent glue: hence the necessity of employing cold water in separating it from the vegeto-animai part. Diluted in a retort, it yields an acid phlegm; and its coal affords, like other vegetables, a fixed alkaline salt. As starch forms the greatest part of the farina, it is probably the principal nutritive constituent in bread.

The mucous or rather the mucoso-saccharine matter, is only in a very small quantity in bread. This substance on distillation is found to exhibit the phenomenon of sugar. The use of this matter seems to be that of producing the vinous fermentation: and we may observe for once, for all that the preparation of good bread probably depends on a proper proportion of the three different parts above described; viz. that the vinous fermentation is promoted by the mucoso-saccharine part, the acetic by the starch, and the putrid by the gluten vegeto-animai. From different states or degrees of these several stages of fermentation the qualities of good bread are probably derived.

The colouring matter of vegetables seems to be of an intermediate nature between the gummy and resinous parts. It is in many plants equally well extracted by water, and by rectified spirit: it is also, however, procurable in the form of a lake, not at all soluble in either of these menstrua. It would seem that the colouring matter, strictly so called, has hitherto eluded the researches of chemists. It is only the bals or nids, in which the real colouring matter is embodied, that chemistry has as yet reached; and on the chemical properties of this bals colours are capable of being extracted by different menstrua, and of being variously accommodated to the purposes of dyeing. The substance from which the colours of vegetables are immediately derived, is without doubt a very subtle body. Since plants are known to lose their colour when excluded from the light of the sun, there is reason to think that the immediately colouring substance is primarily derived from the matter of the sun, somewhat elaborated by vegetable life.

Many of these dyes are evolved or variously modified by chemical operations. Thus a colouring matter is somewhat deposited in the form of a fascula during the putrefaction of the vegetable; in others it is evolved or changed by alum, by acids, or by alkali. We may also observe, that any part of the vegetable may be the balse of the colouring matter. This appears from the solubility of the different dyes in their proper menstrua; and in these solutions we have not been able to separate the real colouring matter from the balse in which it is inviolated. After all, then, we must conclude, that a full investigation of this subject more properly belongs to the sublimer parts of Chem.

MISTRY, than to the business in which we are at present engaged.

The colouring drugs are considered in their proper places.

In finishing our history of the vegetable kingdom, it only remains that we should offer some

General Observations on the foregoing Principles.

1. Essential oils, as already observed, are obtainable only from a few vegetables: but gross oil, resin, gums, and fufpicious matter, appear to be common, in greater or less proportion, to all; some abounding more or less with one and others with another.

2. The several principles are in many cases intimately combined; so as to be extracted together from the subjed, or by these solvents, in which some of them separately could not be dissolved. Hence water infusions and spidrous tinctures of a plant, contain respectively more of these than those of which water or spirit is the proper solvent.

3. After a plant has been sufficiently infused in water, that spirit extracts from the residuum may be considered as confitling wholly of such matter as directly belongs to the action of spirit. And, on the contrary when spirit is applied first, all that water extracts afterwards may be considered as confitling only of that matter of which water is the direct solvent.

4. If a vegetable substance, containing all the principles we have enumerated, be boiled in water, the essential oil, whether fluid or concrete, and the camphor, and volatile essential oil, will gradually exhaile with the steam of the water, and may be collected by receiving the steam in proper vessels placed beyond the action of the heat. The other principles not being volatile in this degree of heat, remain behind: the gross oil and sebaceous matter float on the top: the gummy and saline substance, and a part of the resin, are dissolved by the water, and may be obtained in a solid form by draining the liquor, and exposing it to a gentle heat till the water has exhaled. The rest of the resin, still retained by the subject, may be extracted by spirit of wine, and separated in its proper form by exhalation of the spirit. On these foundations most of the substances contained in vegetables may be extracted, and obtained in a pure state, however they may be compounded together in the subject.

5. Sometimes one or more of the principles is found naturally disengaged from the others, lying in distinct receptacles within the subject, or extraneous and accumulated on the surface. Thus, in the dried roots of angelica, cut longitudinally, the microscope discovers veins of resin. In the flower cups of hypericum, and the leaves of the orange-tree, transparent points are distinguished by the naked eye: which, at first view, seem to be holes, but on a closer consideration are found to be little vesicles filled with essential oil. In the bark of the fir, pine, larch, and some other trees, the oily receptacles are extremely numerous, and so copiously supplied with the oily and resinous fluid, that they frequently burst, especially in the warm climates, and discharge their contents in great quantities. The acacia tree in Egypt, and the plum and cherry among our selves, yield almost pure gummy exudations. From
a species of sfa is secreted the saline sweet substance manna; and the only kind of sugar with which the ancients were acquainted, appears to have been a natural exudation from the cane.

6. The foregoing principles are, as far as is known, all that naturally exist in vegetables; and all that art can extract from them, without such operations as change their nature, and destroy their original qualities. In one or more of these principles, the colour, smell, taste, and medicinal virtues, of the subject, are almost always found concentrated.

7. In some vegetables the whole medicinal activity resides in one principle. Thus, in sweet almonds, the only medicinal principle is a gross oil; in horde-radish root, an essential oil; in jalap root, a resin; in marshmallow root, a gum; in the leaves of forrel, a saline acid substance.

8. Others have one kind of virtue residing in one principle, and another in another. Thus Peruvian bark has an astringent resin and a bitter gum; wormwood a strong flavoured essential oil and a bitter gum resin.

9. The gross impid oils and febacious matters, the simple infipid gums, and the sweet and acid saline substances, seem to agree both in their medicinal qualities and in their pharmacutic properties.

10. But essential oils, resins, and gum-resins, differ much in different subjects. As essential oils are universally the principle of odour in vegetables, it is obvious that they must differ in this respect as much as the subjects from which they are obtained. Resins frequently partake of the oil, and consequently of the differences depending on it; with this further diversity, that the gross resinous part often contains other powers than those which reside in oils. Thus from wormwood a resin may be prepared, containing not only the strong smell and flavour but likewise the whole bitterness of the herb; from which last quality the oil is entirely free. The bitter, astringent, purgative, and emetic virtue of vegetables, reside generally in different sorts of resinous matter, either pure or blended with gummy and saline parts; of which kind of combinations there are many so intimate, that the component parts can scarcely be separated from each other, the whole compound diffusing almost equally in aqueous and spirituous menstrua.

11. There are some substances also, which, from their being totally soluble in water, and not in spirit, may be esteemed to be mere gums; but which, nevertheless, possess virtues never to be found in the simple gums. Such are the astringent gum called acacia, and the purgative gum extracted from aloes.

12. It is supposed that vegetables contain certain subtile principles different in different plants, of too great tenuity to be collected in their pure state, and of which oils, gums, and resins, are only the matrices or vehicles. This inquiry is foreign to the purposes of pharmacy, which is concerned only about grosser and more sensible objects. When we obtain from an odoriferous plant an essential oil, containing in a small compass the whole fragrance of a large quantity of the subject, our intentions are equally answered, whether the substance of the oil be the direct odorous matter, or whether it has diffused through it a fragrant principle more subtile than itself. And when this oil in long keeping loses its odour, and becomes a resin, it is equal in regard to the present considerations, whether the effect happens from the evaporation of a subtile principle, or from a change produced in the substance of the oil itself.

Sect. II. Animals.

From the history we have already given of the vegetable kingdom, our details on animal substances may in many particulars be considerably abridged. All animals are fed on vegetables, either directly or by the intervention of other animals. No part of their substance is derived from any other source except water. The small quantity of salt used by man and some other animals, is only necessary as a seasoning or stimulant to the stomach. As the animal then is derived from the vegetable matter, we accordingly find that the former is capable of being resolved into the same principles as those of the latter. Thus, by repeated distillations, we obtain from animal substances, water, oil, air, an easily destructible salt, and charcoal. These secondary principles are by farther processes at length resolvable into the same proximate principles which we found in vegetables, viz. water, oil, air, earth, and the principle of inflammability. But though the principles of vegetable and animal substances are fundamentally the same, yet these principles are combined in a very different manner. It is exceedingly rare that animal substances are capable of the vinous or acetous fermentations; and the putrefactive, into which they run remarkably fast, is also different in some particulars from the putrefaction of vegetables; the escape of the phlogiston in the form of light is more evident, and the smell is much more offensive, in the putrefaction of animal than of vegetable substances. The putrefaction of urine is indeed accompanied with a peculiar fetor, by no means so intolerable as that of other animal substances: this we suppose to be owing to the pungency derived from the volatile alkali, and also to the urine containing less inflammable matter than the blood and many other fluids. When analyzed by a destructive heat, animals afford products very different from those of vegetables: the empyreumatic oil has a particular and much more fetid odour; and the volatile salt, instead of being an acid, as it is in most vegetables, is found in animals to be a volatile alkali. Chemists have spoken of an acid procurable from animal substances, and indeed certain parts of animal bodies are found to yield a salt of this kind; but it by no means holds with animal substances in general; and though the proofs to the contrary were even conclusive, it is confidcucely in so small a quantity as not to deserve any particular regard. In some animals, however, an acid exsits, uncombined and ready formed in their bodies. This is particularly manifest in some insects, especially ants, from which an acid resembling the acetous has been procured by boiling them in water. The solid parts of animal bodies, as the muscles, tendons, cartilages, and even the bones, when boiled with water, give a gelatinous matter or glue resembling the vegetable gums, but much more adhesive. We must, however, except the horned parts and the hair, which seem to be little soluble either in water or in the liquors of the stomach. The acids, the alkalis, and quicklime, are also found to be powerful solvents of animal matters. It is from the solid parts
parts, that the greatest quantity of volatile alkali is obtained; it arises along with a very fluid empyreumatic oil, from which it is in some measure separated by exposed rectifications. This oil is mostly in a fluid, and partly in a concrete state; and from its having been extensively prepared in the greatest quantity from the horns of the hart, it has been called \textit{fat} or spirit of hartborn. Volatile alkali is, however, procurable from all animals, and from almost every part of animal bodies except fat. Though we are sometimes able to procure fixed alkali from an animal cinder, yet it is probable that this oil did not make any part of the living animal, but rather proceeded from the introduction of some fatty matter, incapable of being assimilated by the functions of the living creature.

In speaking of the fluid parts of animals, we should first examine the general fluid, or blood, from whence the reft are secreted. The blood, which at first sight appears to be an homogeneus fluid, is composed of several parts, easily separable from each other, and which the microscope can even perceive in its uncoagulated state. On allowing it to stand at rest, and to be exposed to the air, it separates into what are called the 	extit{crassamentum}, and the 	extit{ferum}. The crassamentum, or crust, chiefly consists of the red globules, joined together by another substance, called the coagulable lymph: the chemical properties of these globules are not as yet understood; but they seem to contain the greatest quantity of the iron found in the blood. The ferum is a yellow subfividic liquor, having little sensible falt or smell: at a heat of 160 of Fahrenheit, it is converted into a jelly. This coagulation of the ferum is also owing to its containing a matter of the same nature with that in the crassamentum, viz. the coagulable lymph: whatever then coagulates animal blood, produces that effect on this concrescent part. Several causes, and many different subfiances, are capable of effecting this coagulation; such as contact of air, heat, alcohol, mineral acids, and their combinations with earths, as alum, and some of the metallic farts. The more perfect neutral farts are found to prevent the coagulation, such as common falt and nitre.

Of the fluids secreted from the blood, there are a great variety in men and other animals. The excrementitious and redundant fluids are those which afford in general the greatest quantity of volatile alkali and empyreumatic oil: there are also some of the secreted fluids, which, on a chemical analysis, yield products in some degree peculiar to themselves. Of this kind is the urine, which is found to contain in the greatest abundance the noted falt formed from the pholphoric acid and volatile alkali. The fat, too, has been found to differ from the other animal matters, in yielding by distillation a strong acid, but no volatile alkali. There is also much variety in the quantity and state of the combination of the falt and other matters in different secreted fluids. But for a fuller investigation of this and other parts of the subject, we refer to \textit{Anatomy, Chemistry, and Physiology}; with which it is more immediately connected than with the elements of \textit{Pharmacy}.

Animal oils and fats, like the gross oils of vegetables, are not of themselves soluble either in water or vinous spirits: but they may be united with water by the intervention of gum or mucilage. Melt of them may be changed into soap, by fixed alkaline farts; and be thus rendered miscible with spirit as well as water.

The odorinous matter of some odoriferous animal substances, as must, civet, castore, is, like effalent oils, soluble in spirit of wine, and volatile in the heat of boiling water. Carthusian relates, that from castore an animal essentail oil has been obtained in a very small quantity, but of an exceedingly fragrant diffusive smell.

The vesicating matter of carthamides, and those parts of sundry animal substances in which their peculiar tallow resides, are dissolved by rectified spirit, and seem to have some analogy with retins and gummy retins.

The gelatinous principle of animals, like the gum of vegetables, dissolves in water, but not in spirit or in oils: like gums also, it renders oils and fats miscible with water into a milky liquor.

Some insects, particularly the ant, are found to contain an acid juice, which approaches nearly to the nature of vegetable acids.

There are, however, sundry animal juices, which differ greatly, even in these general kinds of properties, from the corresponding ones of vegetables. Thus animal serum, which appears analogous to vegetable gummy juices, has this remarkable difference, that though it mingles uniformly with cold or warm water, yet on considerably heating the mixture, the animal-matter separates from the watery fluid, and concretes into a solid mass. Some physicians have been apprehensive, that the heat of the body, in certain difeases, might rise to such a degree, as to produce this dangerous or mortal concretion of the fermo humours: but the heat requisite for this effect is greater than the human body appears capable of sustaining, being nearly about the middle point between the greatest human heat commonly observed and that of boiling water.

The soft and fluid part of animals are strongly disposed to run into putrefaction; they putrify much sooner than vegetable matters; and when corrupted, prove more offensive.

This process takes place, in some degree, in the bodies of living animals, as often as the juices stagnate, or are prevented, by an obftruction of the natural emanations, from throwing off their more volatile and corruptible parts.

During putrefaction, a quantity of air is generated; all the humours become gradually thinner, and the fibrous parts more lax and tender. Hence the tympany, which succeeds the corruption of any of the viscera, or the imprudent suppression of dyenteries by alriment; and the weakness and laxity of the vessels observable in seuries, &c.

The crassamentum of human blood changes by putrefaction into a dark livid-coloured liquor; a few drops of which ting the serum with a tawny hue, like the ichor of fores and dyenteric fluids, as also the white of the eye, the saliva, the serum of blood drawn from a vein, and the liquor that oozes from a blister in deep seuries and the advanced state of malignant fevers.

The patrid crassamentum changes a large quantity of recent urine to a flame-coloured water, so common in fevers and in the seury. This mixture, after standing an hour or two, gathers a cloud resembling what is seen in the crude water of acute distempers, with some
The putrefaction of animal substances is prevented or retarded by most saline matters, even by the fixed and volatile alkaline salts, which have generally been supposed to produce a contrary effect. Of all the salts that have been made trial of, sea-salt seems to resist putrefaction the least; in small quantities it even accelerates the process. The vegetable bitters, as chamomile flowers, are much stronger antiseptics, not only preventing flesh long uncorrupted, but likewise somewhat correcting it when putrid: the mineral acids have this last effect in a more remarkable degree. Vinous spirits, aromatic and warm substances, and the acid plants, falsely called alkali-plant, as scurvy-grass and horse-radish, are found also to resist putrefaction. Sugar and camphor are found to be powerfully antiseptic. Fixed air, or the aerial acid, is likewise thought to resist putrefaction; but above all the vapours of nitrous acid, in the form of air (the nitrous air of Dr. Priestley), is found to be the most effectual in preserving animal bodies from corruption. The lift of the septic, or of those substances that promote putrefaction, is very short; and such a property has only been discovered in calcareous earths and magnesia, and a very few salts, whose bases are of these earths.

It is observable, that notwithstanding the strong tendency of animal matters to putrefaction, yet broths made from them, with the admixture of vegetables, instead of putrefying turn sour. Sir John Pringle has found, that when animal flesh in sub stance is beaten up with bread or other farinaceous vegetables, and a proper quantity of water, into the consistence of a pap, this mixture likewise, kept in a heat equal to that of the human body, grows in a little time sour; while the vegetable matters, without the flesh, suffer no such change.

It was observed in the preceding section, that some few vegetables, in the resolution of them by fire, discover some agreement in the matter with bodies of the animal kingdom; yielding a volatile alkaline salt in considerable quantity, with little or nothing of the acid or fixed alkali, which the generality of vegetables afford. In animal sub stances also, there are some exceptions to the general analysis: from animal fats, as we before observed, instead of a volatile alkali, an acid liquor is obtained; and their empyreumatic oil wants the peculiar offensiveness of the other animal oils.
Part 1.

Of this kind are,

1. The mineral calcareous earth: distinguished by its being convertible in a strong fire, without addition, into an acrimonious calx called quicklime. This earth occurs in a variety of forms in the mineral kingdom: the fine soft chalk, the coarser limestone, the hard marbles; the transparent spar, the earthy matter contained in waters, and which separating from them incrusts the sides of the caverns, or hangs in icicles from the top, receiving from its different appearances different appellations. How strongly foredo some of these bodies have been recommended for particular medicinal purposes, they are fundamentally no other than different forms of this calcareous earth: simple pulverization depriving them of the superficial characters by which they were distinguished in the mafs. Most of them generally contain a greater or less admixture of some of the indissoluble kinds of earth; which, however, affects their medicinal qualities no otherwise than by the addition which it makes to their bulk. Chalk appears to be one of the purer sorts; and is therefore in general preferred. They all burn into a strong quicklime: in this state a part of them dissolves in water, which thus becomes impregnated with the astringent and lithotrityptic powers that have been erroneously ascribed to some of the earths in their natural state.

During the calcination of calcareous earths, a large quantity of elastic vapour is discharged: the absence of this fluid is the cause of the causticity of quicklime, and of its solubility in water in the form of lime-water. For a more full inquiry into this subject, see Fixed Air, &c.

2. The animal calcareous earth: burning into quicklime like the mineral. Of this kind are oyster-shells and all the marine shells that have been examined; though with some variation in the strength of the quicklime produced from them.

3. The earth of bones and horns: not at all burning into quicklime. This kind of earth is more difficult of solution in acids than either of the preceding. It is accompanied in the subjefts with a quantity of gelatinous matter, which may be separated by long boiling in water, and more perfectly by burning in the open air. The earth may be extracted also from the bone or horn, though difficulty, by means of acids; whereas vegetables and the soft parts of animals yield their pure earth by burning only.

2d. Earth soluble with ease in the vitriolic as well as other acids, and yielding, in all other combinations therewith, saline concretes soluble in water.

1. Magnesia alba: compoing with the vitriolic acid a bitter purgative salt. This earth has not yet been found naturally in a pure state. It is obtained from the purging mineral waters and their salts; from the bitter liquor which remains after the crystallization of sea-salt from sea-water; and from the fluid which remains uncrystallized in the purest fraction of some sorts of rough nitre. The ashes of vegetables appear to be nearly the same kind of earth.

2. Aluminous earth: compoing with the vitriolic acid a very astringent salt. This earth also has not been found naturally pure. It is obtained from alum; which is no other than a combination of it with the vitriolic acid; it may likewise be extracted, by strong boiling in that acid, from clays and boles.

3d. Earths which by digglng in acids, either in the cold or in a moderate warmth, are not at all dissolved.

1. Argillaceous earth: becoming hard, or acquiring an additional hardnifs, in the fire. Of this kind of earth there are several varieties, differing in some particular properties: as the purer clays, which when moistened with water form a very vitious mafs, diffusibly through a larger quantity of the fluid, and slowly subdubing from it; bricks, less vitious, more readily miscible with water, and more readily subdubing; and coks, which have little or nothing of the virtiofity of the two foregoing, and are commonly impregnated with a yellow or red ferruginous calx.

2. Crystalline earth: naturally hard so as to strike sparks with steel; becoming friable in a strong fire. Of this kind are clints, crysfals, &c. which appear to confi, of one and the same earth, differing in the purity, hardnefs, and transparency of the mafs.

3. Gypseous earth: reducible by a gentle heat into a soft powder, which unites with water into a snafs, somewhat vitious and tenacious while moist, but quickly drying and becoming hard. A greater heat deprives the powder of this property, without occafioning any other alteration. Such are the transparent felenites; the fibrous fomy maffes improperly called English talc; and the granulated gypfa or playfer of Paris fones. Though these bodies, however, have been commonly thought to be mere earths, of a distinct kind from the refl, they appear, both from analytical and fynthetical experiments, to be no other than combinations of the mineral calcareous earth with vitriolic acid.

4. Talty earth: scarcely alterable in a vehement fire. The maffes of this earth are generally of a fibrous or leafy texture; more or less pellucid, bright or glittering, smooth and unctuous to the touch; too flexible and elastic to be easily pulverized; soft so as to be cut with a knife. In these respects some of the gypseous earths nearly resemble them, but the difference is readily discovered by fire; a weak heat reducing the gypseous to powder, while the strongest makes no other alteration in the talty, than somewhat diminishing their flexibility, brightnefs, and unctuoity.

III. Metals.

Of metals, the next division of mineral bodies, the Metals, most obvious characters are, their peculiar bright perfed and imperfect opaqueness, and great weight; the lightest of them is fix, and the heaviest upwards of 91 times heavier than an equal bulk of water.

To understand the writers in chemistry, it is proper to be informed, that metals are subdivided into the perfect, the imperfect, and the femimetal.

Those possesed of dulthility and malleability, and which are not sensibly altered by very violent degrees of heat, are called perfect metals: Of these there are three; gold, silver, and platina. It is, however, probable, that the mark of their indefluxibility by fire is only relative: and indeed modern chemists have been able, by a very intense degree of heat, to bring gold into the state of a calx, or something very nearly resembling it.
Those metallic substances which possess the distinctive properties of the perfect metals, but in a less degree, are called the imperfect metals: These are, copper, iron, tin, lead.

Lately, those bodies having the metallic characters in the most imperfect state, that is to say, those which have no ductility and the least figurative in the fire, are distinguished by the name of semi-metals: These are, regulus of antimony, bismuth, zinc, regulus of cobalt, nickel, and regulus of arsenic; which latter might be rather considered as the boundary between the metallic and the saline bodies.

Mercury has been generally ranked in a class by itself.

All metallic bodies, when heated in close vessels, melt or fuse. This fusion takes place at different degrees of heat in different metals; and it does not appear that this process produces any change in the metals, provided it be conducted in close vessels. Metals, exposed to the combined action of air and fire, are converted into an earth like substance called calx; by this process, which we call calcination, the metal suffers remarkable changes. From the diffusive marks we have before given of the metallic bodies, it will be obvious, that the perfect metals are most fluidly, the imperfect more quickly, and the semi-metals most easily and soonest, affected in this operation. This earth-like powder, or calx, is found to possess no metallic aspect, but is considerably heavier than the metal before its calculation: it has no longer any affinity with metallic bodies, nor even with the metal from which it has been produced.

Besides this method of calcining metals by air and fire, they may likewise be brought into the state of a calx, by dissolving them in acids, from which they may be afterwards freed by evaporating the acid, or by adding to the solution an alkaline salt. Metals are also sometimes dephlogisticated by detonation with nitre. This change in their obvious properties is generally accompanied with a remarkable alteration in their medicinal virtues: thus quicksilver, which taken into the body in its crude state and undivided, seems inactive; proves, when calcined by fire, even in small doses, a strong emetic and cathartic, and in smaller ones, a powerful alternative in chronic disorders; while regulus of antimony, on the contrary, is changed by the same treatment, from a high degree of virulence to a state of inactivity.

Caleces of mercury and arsenic exhale in a heat below ignition: those of lead and bismuth, in a red or low white heat, run into a transparent glass; the others are not at all vitreifiable, or not without extreme vehemence of fire. Both the caleces and glaeses recover their metallic form and qualities again by the skilful addition of any kind of inflammable substance that does not contain a mineral acid. This recovery of the metallic caleces into the metallic form is called reduction. During this process, an elastic aerial fluid escapes, which is found to be pure air.

Is the conversion of metals into caleces owing to the discharge of phlogition, or to the absorption of pure air? And is the reduction effected by the absorption of phlogition, either furnished by inflammable bodies or precipitated in consequence of the discharge of pure air? On these questions there is much dispute among modern chemists: We thought it only necessary to state them here, as a full inquiry into the subject is by no means the province of pharmacy. We, however, think it prudent to retain the doctrine of Stahl: and we do this the more readily, because it has been followed in our article Chemistry, and because it is abundantly clear in its illustration of the pharmaceutical processes. We do not mean, however, to reject any modern discovery which may serve to illustrate our subjects.

All metallic bodies dissolve in acids; some only in particular acids, as silver and lead in the nitrous: some only in compositions of acids, as gold in a mixture of the nitrous and marine: and others, as iron and zinc, in all acids. Some likewise dissolve in alkaline liquors, as copper: and others, as lead, in express oils. Fused with a composition of sulphur and fixed alkaline salt, they are all except zinc, made soluble in water.

All metallic substances, dissolved in saline liquors, have powerful effects in the human body, though many of them appear in their pure state to be inactive; their activity is generally in proportion to the quantity of acid combined with them: Thus lead, which in its crude form has no sensible effect, when united with a small portion of vegetable acid into ceruss, discovers a low degree of the pyritic and malignant quality, which it so strongly exerts when blended with a larger quantity of the same acid into what was called succarum Saturni, but now more properly sal plumbo, or plumbum acetaum: and thus mercury, with a certain quantity of the marine acid, forms the violent corrosive sublimate, which by diminishing the proportion of acid becomes the mild medicine called mercurius dulcis.

IV. Acids.

The facts of this order are very numerous; but as we are at present treating of Minerals, it is only therefore the mineral or fusil acids we mean to speak of in various places.

These are distinguished by the names of the concretes from which they have been principally extracted; the vitriolic from vitriol, the nitrous from nitre or sulphur; and the marine or muriatic from common sea-salt. The form they are generally in, is that of a watery fluid: They have all a remarkable attraction for water: They imbibe the humidity of the air with rapidity and the generation of heat. Although heat be produced by their union with water, yet when mixed with ice in a certain manner, they generate a prodigious degree of cold. Acids change the purple and blue colours of vegetables to a red: they infect fermentation; and lastly, they impregnate that peculiar sensation on the tongue called Fourmets, and which their name imports. But it is to be observed, that they are all highly corrosive, in much as not to be safely touched, unless largely diluted with water, or united with such substances as obtund or supress their acuity. Mixed hastily with vineous spirits, they raise a violent ebullition and heat accompanied with a copious discharge of noxious fumes: a part of the acid unites
The nitrous acid unites intimately with the vinous spirit into a new compound, void of acidity, called dulcitel spirit. It is observable, that the marine acid is much less disposed to this union with spirit of wine than either of the other two; nevertheless, many of the compound salts resulting from the combination of earthy and metallic bodies with this acid, are soluble in that spirit, while those with the other acids are not. All these acids effervesc strongly with alkaline fixed and volatile, and form with them neutral salts; that is, such as discover no marks either of an acid or alkaline quality.

The nitrous and marine acids are obtained in the form of a thin liquor; the acid part being blended with a large proportion of water, without which it would be diffused into an incendible vapour: the vitriolic stands in need of so much less water for its condensation as to assume commonly an oily consistence (whence it is called oil of vitriol), and in some circumstances even a solid one. Alkaline salts, and the soluble earths and metals, absorb from the acid liquors only the pure acid part, so that the water may now be evaporated by heat, and the compound salt left in a dry form.

From the coalition of the different acids with the three different alkalis, and with the several soluble earths and metallic bodies, result a variety of saline compounds; the principal of which shall be particularized in the sequel of this article.

The vitriolic acid, in its concentrated liquid state, is much more ponderous than the other two; it emits no visible vapour in the heat of the atmosphere, but imbibes moisture which increases its weight: the nitrous and marine emit copious corrosive fumes, the nitrous yellowish red, and the marine white ones. If bottles containing the three acids be flopped with cork, the cork is found in a little time tinged black with the vitriolic, corroded into a yellow substance by the nitrous, and into a whitish one by the marine.

It is above laid down as a character of one of the classes of earths, that the vitriolic acid precipitates them when they are previously diffused in any other acid: it is obvious, that on the same principle this particular acid may be distinguished from all others. This character serves not only for the acid in its pure state, but likewise for all its combinations that are soluble in water. If a solution of any compound salt, whose acid is the vitriolic, be added to a solution of chalk in any other acid, the vitriolic acid will part from the substance with which it was before combined, and join itself to the chalk, forming therewith a compound; which, being no longer soluble in the liquor, renders the whole milky for a time, and then gradually subsides.

This acid may be distinguished also, in compound salts, by another criterion not less strongly marked: If any salt containing it be mixed with powdered charcoal, and the mixture exposed in a close vessel to a moderately strong fire, the acid will unite with the directly inflammable part of the charcoal, and compose therewith a genuine sulphur. Common brimstone is no other than a combination of the vitriolic acid with a small proportion of inflammable matter. With any kind of inflammable matter which is not volatile in close vessels, as the coal of vegetables, of animals, or of bitumens, this acid composes always the same identical sulphur.

The nitrous acid also, with whatever kind of body it be combined, is both distinguished and extricated by means of any inflammable substance being brought to a state of ignition with it. If the subject be mixed with a little powdered charcoal and made red hot, a deflagration or fulmination ensues, that is, a bright flame with a hissing noise; and the inflammable matter and the acid being thus consumed or diffused together, there remains only the substance which was before combined with the acid, and the small quantity of ashes afforded by the coal.

These properties of the nitrous acid desfigrating with inflammable substances, and of the vitriolic forming sulphur with them, serve not only as criteria of the respective acids in the various forms and disguises, but likewise for discovering inflammable matter in bodies, when its quantity is too small to be sensible on other trials.

All these acids will be more particularly examined when we come to treat of each of them apart. There are, however, a few other mineral acids which are of importance to be known: these are, aqua regia; acid of borax; sparry acid; and, lastly, fixed air, which has of late been called aerial acid, or acid of chalk.

Aqua regia has been generally prepared by a mixture of certain proportions of the nitrous and muriatic acids. It is of little avail in pharmacy whether we consider it as a distinct acid, or only as a modification of the muriatic. It has been found, that the muriatic acid when diffused with manganese (a peculiar volatile substance, showing a remarkable attraction to phlogiston), suffers a change which renders it capable of diffusing gold and platinum. Whether this change be produced by the acid acquiring a redundancy of pure air, or by its being deprived of phlogiston, it is not our business to decide. This experiment, however, renders it probable, that the nitrous acid in the common aqua regia is only sublimate of accomplishing the same change in the muriatic acid which is produced by diffusing that acid with manganese.

As aqua regia has been only used in the nicer operations in chemistry, and in the art of etching, we think it unnecessary to say more of it in this place.

The acid of borax, or fediae fall of Homberg, may be extracted from borax, a neutral salt, whole base is mineral alkali. It has also been found native in the waters of several lakes in Tuscany. It is a light, crystallized, concrete salt; its taste is febile; it is difficultly soluble in water; but the solution changes blue vegetable colours to a red. With vitriform earths it fuses into a white glass; it unites with the other alkalies, with magnesia, and with quicklime. The salts resulting from these combinations are very imperfectly known. The salt has been called fediae, from its supposed virtues as an anodyne and refrigerant remedy; but modern physicians have very little faith in this once celebrated drug.

The sparry acid is so called from its being extracted from a foill called sparry flour, or nitrous flour. It is not yet determined whether it be a distinct acid; and as it has not yet been employed for any purpose in pharmacy, we think it would be improper to attempt any farther account of it here.

Besides
Besides the acids abovementioned, there have also been discovered acids seemingly of a particular nature, in amber, in arsenic, and in black-lead: but as these have not hitherto been applied to any use in pharmacy, they cannot properly have a place in this article.

We now come to the left, but perhaps the most generally diffused, acid in nature: this is the aerial acid, or fixed air.

Fixed Air.

In our pharmaceutical history of this body, we shall only make use of the two names fixed air and aerial acid; being those most generally used, and which in our opinion are most applicable to our own subject. Fixed air is a permanently elastic fluid, being only fixed when in a state of combination with calcareous earth or other substances from which it may be extricated. It has received many different names, according to the substances from which it is diffused, and to the different opinions concerning its nature; it is called the atmosphere of Helmot, the fixed air of Dr Black, the acid of chalk, calcareous gas, mephitic gas, mephitic acids, and aerial acid, of many modern chemists. In accommodating our account of it to the purposes of pharmacy, it is most convenient to consider it as an acid. The aerial acid may be extricated by heat, or by other acids, from all calcareous earths; that is, from all those earths which by calcination are converted into quicklime; such as chalk, marble, limestone, sea-shells, &c. It is likewise extracted from mild, fixed, and volatile alkalies, and from magnesia alba. Thus, if the vitriolic, or almost any other acid, be added to a quantity of calcareous earth or mild alkali, a brief evaporation immediately ensues; the fixed air, or aerial acid, is discharged in bubbles; and the other acid takes its place. If this process be conducted with an apparatus to be afterwards described, the aerial acid, now separated from the calcareous earth, may be received and preserved in close vessels. When this diffused gas is difengaged, viz. that of a permanently elastic fluid, fixed air is also separated in great quantity during the vinous fermentation of vegetable matters. When a calcareous earth is deprived of this acid by heat, it is converted into the calcic substance quicklime. When alkali, fixed or volatile, are deprived by any means of their aerial acid, they are rendered much more caustic, incapable of crystallization, or of effervescing with other acids. They are also in this deteriorated state much more powerful in dissolving other bodies. By recomposing this acid with quicklime, calcined magnesia, or alkali, any of which had been deprived of it, these substances again assume their former weight and properties. These bodies, then, when combined with aerial acid, are called mild; as mild calcareous earth, mild alkali, &c. and when deprived of this acid they are called caustic; as caustic calcareous earth, caustic alkali, &c. But as magnesia is not rendered caustic by calcination, there would perhaps be less danger in calling them aerated and deteriorated. The aerial acid is more diffused to unite with calcic calcareous earth (quicklime) than with any other substance; next to that, its attraction is for fixed alkali, then for magnesia, and lastly for volatile alkali. We shall afterwards find that these relative powers of the different substances to unite with this acid, lay the foundation of many important processes in pharmacy.

When we pour a small quantity of the aerial acid into lime-water, the liquor instantly assumes a white colour, and the lime gradually precipitates, leaving the water clear and tasteless: the lime in this experiment has absorbed the acid, and has therefore become mild or aerated earth. The aerial acid is capable of being absorbed by water, and the water thus impregnated precipitates lime in lime-water; but if a certain larger quantity of this impregnated water be added, the lime is redissolved, and the liquor recovers its transparency. Water impregnated with aerial acid is capable of dissolving iron; and in this way are formed native and artificial chalybeate waters. Zinc is also soluble in the same liquor. This acid is easily expelled from the water by removing the pressure of the atmosphere, by boiling, and even by time alone, if the vessel be not kept close shut. Fixed air extinguishes flame, vegetable and animal life; and ought therefore to be cautiously managed: like other acids it changes the blue colours of vegetables to a red, and communicates an acidulous taste to the water impregnated with it. The attraction of the aerial acid, even to quicklime, is but feeble; as we know of no other acids whatever that are not able to disengage it.

From these several facts it will appear obvious, that mild or aerated alkalies, whether fixed or volatile, are really neutral salts, compounded of the aerial acid and pure alkali: like other acids, it unites with these bodies, diminishes their causticity, and effects their crystallization. In speaking, therefore, of pure alkali, we ought to confine ourselves to those in the calceic or deaerated state; or, in other words, to those which are deprived of their fixed air or aerial acid, with which they formed a compound salt. Many other properties of this acid might be mentioned, but we have now noticed all those which we thought were concerned in the business of pharmacy. We shall have occasion to recur to the subject when we come to the preparation of several compound drugs.

Let us next take a view of what passes in the combinations of acids with different substances.

If a fixed alkaline salt be united with a vegetable acid, as vinegar, and formed into a neutral salt, on adding to this compound some marine acid, the acetous acid will be disengaged, so as to exhale totally in a moderate heat, leaving the marine in possession of the alkali; the addition of the nitrous acid will in like manner dispossess the marine, which now unites in its proper white fumes, though without such an addition it could not be extricated from the alkali by any degree of heat: on the addition of the vitriolic acid, the nitrous gives way in its turn, exhaling in red fumes, and leaving only the vitriolic acid and the alkali united together.

Again, if any metallic body be dissolved in an acid, the addition of any earthy body that is dissoluble in that acid will precipitate the metal: a volatile alkaline salt will in like manner precipitate the earth; and a fixed alkali will dislodge the volatile; which left being readily exhaled by heat, the remaining salt will be the same as if the acid and fixed alkali had been joined together at first, without the intervention of any of the other bodies.
The power in bodies on which these various transpositions and combinations depend, is called by the chemists affinity or elective attraction; a term, like the Newtonian attraction, designed to express not the cause, but the effect. When an acid spontaneously quits a metal to unite with an alkali, they say it has a greater affinity or attraction to the alkali than to the metal: and when, on the contrary, they say it has a greater affinity to fixed alkali than to the volatile, they mean only that it will unite with the fixed in preference to the volatile; and that if previously united with a volatile alkali, it will forfake this for a fixed one.

The doctrine of the affinities of bodies is of a very extensive use in chemical pharmacy: many of the official processes, as we shall see hereafter, are founded on it; several of the preparations turn out very different from what would be expected by a person unacquainted with these properties of bodies; and several of them, if, from an error in the process, or other causes, they prove unfit for the use intended, may be rendered applicable to other purposes, by such transpositions of their component parts as are pointed out by the knowledge of their affinities.

We shall therefore subjoin a table of the principal affinities observed in pharmaceutical operations, formed from that of the famous Bergman. See other tables for more general purposes in the article Chemistry.

The table is to be thus understood. The substances printed in capitals, on the top of each series, has the greatest affinity with that immediately under it, a less affinity with the next, and so on to the end of the series: that is, if any of the remote bodies has been combined with the top one, the addition of any of the intermediate bodies will disunite them; the intermediate body uniting with the uppermost body of the series, and throwing out the remote one. Thus, in the first series of the affinities of the vitriolic acid, a fixed alkali being placed between the acid and iron, it is to be concluded, that wherever vitriolic acid and iron are mixed together, the addition of any fixed alkaline salt will unite with the acid, and occasion the iron to be separated. Where several substances are expressed in one series, it is to be understood, that any of those bodies which are nearer to the uppermost, will in like manner disengage from it any of those which are more remote.

## By Fire

The most simple furnace in the common stove, otherwise called the furnace for open fire. This is usually made of an iron hoop, five or six inches deep; with a grate or some iron bars across the bottom for supporting the fuel. It either stands upon feet, so as to be movable from place to place; or is fixed in brickwork. In this last case, a cavity is left under the grate, for receiving the ashes that drop through it; and an aperture or door, in the forepart of this ash-pit, serves both for allowing the ashes to be occasionally raked out, and for admitting air to pass up through the fuel. This furnace is designed for such operations as require only a moderate heat; as infusion, decoction, and the evaporation of liquid.

A deeper hoop or body, cylindrical, parallelopipedal, widening upwards, elliptical, or of other figures; formed of, or lined with, such materials as are capable of sustaining a strong fire; with a grate and ash-pit beneath, as in the preceding; and communicating at the top with a perpendicular pipe, or chimney; makes a wind furnace.

The greater the perpendicular height of the chimney, the heat of the greater will be the draught of air through the furnace, and the more intensively will the fire burn; provided the width of the chimney is sufficient to allow a free passage to all the air that the furnace can receive through the grate; for which purpose, the area of the aperture of the chimney should be nearly equal to the area of the interstices of the grate.

Hence, where the chimney consists of moveable pipes, made to fit upon each other at the ends, so that the length can be occasionally increased or diminished, the vehemence of the fire will be increased or diminished in the same proportion.

In furnaces whose chimney is fixed, the same advantage may be procured on another principle. As the intensity of the fire depends wholly upon the quantity of air successively passing through and animating the burning fuel, it is obvious, that the most vehement fire may be suppressed or restrained at pleasure, by closing more or less either the ash-pit door by which the air is admitted, or the chimney by which it passes off; and that the fire may be more or less raised again, by more or less opening these passages. A moveable plate, or regulator, in any convenient part of the chimney, affords commodious means of varying the width of the passage, and consequently of regulating the heat. This is most conveniently accomplished by keeping the ash-pit door entirely shut, and regulating the heat by a range of holes in a damping plate; each hole is provided with a proper pin, whereby we may shut it at pleasure. These holes may be made to bear a certain proportion to each other; the smallest being considered as one, the next to it in size must have twice the opening, to the next that double of the second, &c.; and so on to the number of seven or eight; and by combining these holes variously together, we can admit any quantity of air from 1 to 128; as 1 2 4 8 16 32 64 128. See Furnace, p. 507.

There are two general kinds of these wind-furnaces; one, with the chimney on the top, over the middle of the furnace; the other with the chimney on one side, and the mouth clear.
In the first, either the upper part of the furnace is contracted to fuch an aperture, that the chimney may fit upon it; or it is covered with an arched dome, or with a flat plate, having a like aperture in the middle. As in this disposition of the chimney, the inside of the furnace cannot be come at from above, a door is made in the side, a little above the grate, for supplying the fuel, inspecting the matter in the fire, &c.

For performing futfins in this furnace, the crucible, or melting vessel, is placed immediately among the fuel, with a flip of brick, or some other like support, between it and the grate, to keep the cold air, which enters underneath, from striking on its bottom.

When designed as a reverberatory, that is for distillation in long-necked coated glass retorts, two iron bars are placed acrofs, above the fire, for supporting the vessel, whose neck comes out at an aperture made for that purpose in the fide. This aperture should be made in the fide opposite to the door abovementioned; or at least so remote from it, that the receiver, fitted out with fide made to fit the distilling veffel without the furnace, may not lie in the operator's way when he wants to fill the fire or throw in fresh fuel.

The other kind of wind-furnace communicates, by an aperture in its back part near the top, either with an upright pipe of its own, or with the chimney of the room; in which fmall, all other passages into the chimney must be clofed. Here the mouth of the furnace serves for a door, which may be occasionally covered with a plate or tile. Of this kind is the furnace most commonly used for fufion in a crucible.

This fmall contrivance, by leaving the mouth of the furnace clear, affords the convenience of letting into it a boiling or evaporating pan, a copper still, an iron pot, for distilling hartthorn, an iron fand-pot, or other like vessels, of fuch a fize that they may be supported on the furnace by their rims. The mouth being thus occupied by the vefsels, a door must be made in the fide for supplying and ftrirring the fuel.

When a furnace of this kind is designed only for a fand-bath, it is most commodious to have the fand placed on a long iron plate, furnifhed with a ledge of freestone or brick work at each fide. The mouth of the furnace is to be clofely covered by one end of this plate; and the canal by which the furnace communicates with its chimney, is to be lengthened and carried along under the plate, the plate forming the upper fide of the canal. In this kind of fand-bath, digifitions, &c. requiring different degrees of heat, may be carried on at once; for the heat decreases gradually from the end over the furnace to the other.

When large vefefls, as stills and iron pots for distilling hartthorn and aquafortis, are fixed in furnaces, a confiderable part of the bottom of the vessel is commonly made to refi upon folid brick-work.

The large still, whose bottom is narrow in proportion to its height, and whose weight, when charged with liquor, requires great part of it to be thus supported, excels but a small surface to the action of the fire underneath. To make up for this disadvantage, the heat, which rises at the further end of a long narrow grate, is conveyed all round the fides of the veffel by a fpiral canal, which communicates at top with a common chimney.

The pots for distilling hartthorn and aquafortis in the larger way, have part of their great weight borne up by three strong pins or trụnsions at equal difiances round the pot towards the middle reaching into a brick-work: so that let support being neceflary underneath, a greater surface of the wide bottom lies expoed to the immediate action of the fire.

If a furnace, communicating with its chimney by a lateral canal, as in the fand-furnace abovementioned, be carried to a conliderable height above the part where this canal enters it, and if it be filled with fuel to the top, and closely covered, the fuel will burn no higher than up to the upper fide of the canal through which the air paffes off; and in proportion as this lower part of the fuel continues, it will be supplied by that above, which falls down in its place. Hence in this furnace, called an athme, a conftant heat may be kept up for a conliderable length of time without attendance.

The tower of the athenm, or that part which receives the fuel, is commonly made to widen a little downwards, that the coals may fall the more freely; but not so much as that the parf on fire at bottom may be too strongly preffed. A small aperture is made opposite to the canal or fume, or a number of openings according to the fize of the furnace and the degree of heat required, for supplying the air, which is more conveniently admitted in this manner than through the grate, as the interfeices of the grate are in time choked up by the ashes.

This furnace is designed only for heating bodies exterior to it. Its canal or flue, as in the fand-furnace already decribed, paffes under a fand-bath or water-bath; at the farther end of which it rises perpendicularly to fuch a height, as may occafion a fufficient draught of air through the fire.

The flue may be fo wide as to correspond to the whole height of the fire-place. A regifter or fiding plate, placed between the flue and the furnace, enable us to increafe or diminish this height, and consequently the quantity of fire, at pleafure. If the space beneath the flue be inclofed to the ground, the heat in this cavity will be confiderable enough to be applicable to fome useful purpofes.

With regard to the materials of furnaces, the fixed of the ma­
ones are built of bricks, cemented together by some tertials of
which furnaces are made.

good loam or clay. Any kind of loam or clayey com­
position that is of a proper degree of tenacity, which
when made into a paffe with water and well-worked,
does not flick to the fingers, and which, when thoroughly
ried, neither cracks nor melts in a vehement fire, is
fit for us. The purer and more tenacious clays require
to have their tenacity leffened by an admixture of fand,
or rather of the fame kind of clay burnt and grofsly
powdered.

Smaller portable furnaces are made of frong iron or
copper plates, lined, to the thicknefs of an inch or
more, with the fame kind of clayey composition which
for this ufe may be beaten with fome horfe-dung, chopp­
d straw, or cut hair or tow.

Very commodious portable furnaces, for a bufinefs
of moderate extent, may be formed of the larger kind
of common black-lead melting-pots, by cutting a door
at the bottom of the pot for the afh-pit, another above
this for the fire-place, and introducing a circular iron
grate of fuch a fize as may refi between the two doors.
For a more particular account of the method of preparing furnaces, see Furnace.

Baths.

Where a strong degree of heat is requisite, as in the fusion of metals, &c. the vessel containing the subject matter is placed among the burning fuel, or immediately over it: this is called operating in a naked fire. Where a smaller heat is sufficient, and the vessel employed is either of glafs, or of the more tender kinds of earthen ware, the sand-bath or water-bath is used to defend the vessel from the immediate action of the fire, and to render the heat less fluctuating.

Both these baths have their peculiar advantages and inconveniences. In water, the heat is equal through every part of the fluid: whereas in sand it varies in different parts of one perpendicular line, decreasing from the bottom to the top. Water cannot be made to receive, or to retain among the vessels immersed in it, almost a certain degree of heat, viz. that which is sufficient to make it boil; and hence it secures effectually against any danger of an excess of heat in those operations wherein the product would be injured by a heat greater than that of boiling water: but this advantage renders it useless for processes which require a greater heat, and for which sand or other solid intermedii are necessarily employed. There is this convenience also in the sand-bath, that the heat may be readily diminished or increased about any particular vessel, by raising it higher out of the sand or sinking it deeper; that different vessels may be employed to different degrees of heat from one fire; and that it keeps the vessels steady. The sand made choice of should be a large coarse grained kind, separated from the finer parts by washing, and from little stones by the sieve.

Coating of Glasses, Lutes.

Some processes require to be performed with glass vessels in a naked fire. For these purposes, vessels made of the thinnest glass should be chosen; for these bear the fire without cracking, much better than those which are thicker, and in appearance stronger.

All glasses, or other vessels that are apt to crack in the fire, must be cautiously sealed, that is, heated by flow degrees: and when the process is finished, they should be as soon cooled, unless where the vessel is to be broken to get out the preparation, as in some sublimations; in this case it is more advisable to expose the hot glasses suddenly to the cold air, which will soon occasion it to crack, than to endanger throwing down the sublimated matter by a long time.

As a defence from the violence of the fire, and to prevent the contact of cold air on supplying fresh fuel, &c. the glasses is to be coated over, to the thickness of about half-a-crown, with Windsor loam, softened with water into a proper consistence, and beaten up with horse-dung, or with the other clayey compositions abovementioned.

These compositions serve also as a lute, for securing the junctures of the vessels in the distillation of the volatile spirits and spirits of animals; for the distillation of acid spirits, the matter may be mixed with a solution of fixed alkaline salts instead of water. For most other purposes, a piece of wet bladder, or pale of flour and water, or of linseed meal (that is, the cake left after the expression of oil of linseed), are sufficient lutes.

Sometimes clay and chalk are mixed up into a paste, and spread upon slips of paper; and sometimes gum-arabic is used instead of the clay, and mixed up in the same manner.

Wet bladders contract so strongly by drying, that they are often obliged, even where the common lutes are employed, to leave or make an opening which may be occasionally stopped by a plug: by this means we give passage to a part of these vapours, which prevents the bursting of the vessels and facilitates the condensation of the reft. If we wish to collect incondensible vapours, we receive them into a jar inverted under a basin of water, or quicksilver, as is usually done in the analysis of vegetables by fire.

Besides these, there are also required some other kinds of lutes for joining vessels together in operations requiring a strong heat, and for lining furnaces; for which see Chemistry, n. 604, 605.

Vessels.

In this place, we shall only give the operator a few general cautions with regard to the matter of the vessels designed for containing the subject; and refer their description, to the account of the operations in which they are employed. See likewise Chemistry, n. 557, &c.

Metalline vessels possess the advantage of being able to bear sudden alterations of heat and cold, and of being very strong, so as to be capable of containing elastic flames; but, except those made of gold or silver, they are readily corroded by acids, even by the mild solutions of the vegetable kingdom. Copper vessels are corroded also by alkaline liquors, and by some neutral ones, as solutions of sal ammoniac. It is observable, that vegetable acids do not act upon this metal by boiling, so much as by standing in the cold; for even lemon juice may be boiled in a clean copper vessel, without receiving from it any taint or ill quality; whereas, in the cold, it soon dissolves so much as to contract a pungent taint. The tin, with which copper vessels are usually lined, gives likewise a sensible impregnation to acid juices; and this impregnation also is probably not innocent, more especially as a quantity of lead is commonly mixed with the tin. From the want of transparency in these vessels, we are also deprived of the advantage of seeing the different changes during the operation. The earthen vessels possess none of the desirable qualities for chemical operations, except that of sustaining very violent degrees of heat, without being melted or otherwise changed. These vessels are less liable to external cracks, from sudden applications of heat and cold, when they are made with a certain proportion of sand, than with pure clay. Black lead, too, mixed with the clay, makes the vessels sustain violent degrees and sudden alterations of heat surprizingly well: crude clay, reduced to a kind of sand by violent heat, and then mixed with raw clay, is also found to furnish vessels excellently fitted for those operations.
PHARMACY.

Part I. Elements.

The medical or Troy pound is less than the Avoirdupois, but the ounce and the dram greater. The Troy pound contains 5760 grains; the Avoirdupois 7000 grains. The Troy ounce contains 480 grains; the Avoirdupois only 437. The Troy dram is 60; the Avoirdupois dram somewhat more than 27. Eleven drams Avoirdupois are nearly equal to five drams Troy; 12 ounces Avoirdupois to nearly 11 ounces Troy; and 19 pounds Avoirdupois are equal to somewhat more than 23 pounds Troy.

These differences in our weights have occasioned great confusion in the practice of pharmacy. As the druggists and grocers fell by the Avoirdupois weight, the apothecaries have not in general kept a weight adjusted to the Troy pound greater than two drams, using Avoirdupois ounces. By this means it is apparent, that in all compositions, where the ingredients are prescribed, some by pounds and others by ounces, they are taken in a wrong proportion to each other; and the same happens where any are directed in letter denominations than the ounce, as these subdivisions used by the apothecaries are made to a different ounce.

Measures.

The measures employed in pharmacy are the common wine measures.

A gallon contains eight pints (librae.)
The pint contains sixteen ounces.
The ounce contains eight drams.

Though the pint is called by Latin writers libra or pound, there is not any known liquor of which a pint measures answers to that weight. A pint of the weight redistilled spirit of wine exceeds a pound by above half an ounce; a pint of water exceeds it by upwards of three ounces; and a point of oil of vitriol weighs more than two pounds and a quarter.

The Edinburgh College, sensible of the many errors from the promiscuous use of weights and measures, and of their different kinds, have in the last edition of their Pharmacopæa entirely rejected measures, and employ the Troy weight in directing the quantity of either of solid or fluid substances. They have, however, taken all possible care that the proportion of the simples and strength of the compounds should neither be increased nor diminished by this alteration. This change in the Edinburgh Pharmacopæa must be very particularly adverted to. And it is, we think to be regretted, that the London College have not in the last edition of their Pharmacopæa followed the same plan.

A table of the weights of certain measures of different fluids may on many occasions be useful, both for the weights affiling the operator in regulating their proportions in certain cases, and showing the comparative gravities of the fluids themselves. We here insert such a table, not only for a pint, an ounce, and a dram measure, of those liquids whose gravity has been determined by experiments that can be relied on. The wine gallon contains 231 cubic inches; whereas the pint contains 28 1/3, the ounce 1 3/8, and the dram 1/48 of a cubic inch.
### PHARMACY.

#### Chap. III. Of the Pharmaceutical Operations.

**Part I. Solution.**

**SECT. I. Solution.**

Solution is an intimate conniuncture of solid bodies with fluids into one seemingly homogeneous liquor of solution, both in the humid and dry way.

Objections have been made, and perhaps with propriety, to these terms; as it is supposed that the two bodies uniting in solution act reciprocally on each other: there is, however, no danger from the words themselves, if we do not derive them from a mistaken theory. Solution cannot take place, unless one of the bodies, at least, be in a fluid state; and this fluidity is effected either by water or fire: hence solution is said to be performed in the humid or the dry way. Thus, for instance, if any quantity of brimstone be dissolved in a solution of fixed alkali, the brimstone is said to be dissolved in the humid way: but if the brimstone be dissolved by melting it in a pan with the dry alkali, the solution is said to be done in the dry way. The hepar sulphur is the same in both. Another kind of solution resembling that by the dry way, is, however, to be carefully distinguished from it: if, for instance, a piece of Glauber's salt is put into a pan over the fire, the salt very soon assumes a liquid state; but on continuing the heat, it loses its fluidity, and becomes a white powder: this powder is the salt freed from its water, and it is found to be very refractory. This liquidity depended on the water of crystallization being enabled by the heat to keep the salt in solution, and the salt ceased to be fluid as soon as its crystallizing water was evaporated. This kind of solution, then, differs not from the first, or humid way.

If one of the two bodies to be united is transparent, the solution, if complete, is a transparent compound: this is the case in solutions of alkalis and calcareous earths in acids. But if the solution be opaque and milky, as is the case with soap and water, it is then considered as incomplete.

The principal menstrua used in pharmacy are, water, tinctures, oils, acid and alkaline liquors.

Water is the menstrum of all salts, of vegetable gums, and of animal gellies. Of salts, it dissolves only a determinate quantity, though of one kind of salt more than another; and being thus *saturated*, leaves any additional quantity of the same salt untouched.

Experiments have been made for determining the quantities of water which different salts require for the dissolution. Mr. Eller has given a large part in the Memoirs of the Royal Academy of Sciences of Berlin for the year 1750, from which the following table has been taken.

Eight ounces by weight of distilled water dissolved.

Though great care appears to have been taken in making their experiments, it is not to be expected that the proportions of the several salts, soluble in a certain quantity of water, will always be found exactly the same with these above set down. Salts differ in their solubility according to the degree of their purity, perfection, and dryness: the vitriols, and the artificial compound salts in general, differ remarkably in this respect, according as they are more or less impregnated with the acid ingredient. Thus vitriolated tartar, perfectly neutralized, is extremely difficult of solution: the matter which remains in making Glau-ber's spirit of nitre is no other than a vitriolated tartar; and it dissolves so difficultly, that the operator is obliged to break the retort in order to get it out; but on adding more of the vitriolic acid, it dissolves with ease. Hence many have been tempted to use an over-proportion of acid in this preparation: and we frequently find in the shops, under the name of vitriolated tartar, this acid soluble salt. The degree of heat occasions also a remarkable difference in the quantity of salt taken up: in very cold weather, 8 ounces of water will dissolve only about one ounce of nitre; whereas in warm weather, the same quantity will take up three ounces or more. To these circumstances are probably owing, in part, the remarkable differences in the proportionable solubilities of salts, as determined by different authors. It is observable that common salt is less affected in its solubility by a variation of heat than any other; water in a temperate state dissolving nearly as much of it as very hot water: and accordingly this is the salt in which the different experiments agree the best. In the experiments of Hoffmann, Neumann, and Pett, the proportion of this salt, on a reduction of the numbers comes on exactly the same, viz. three ounces of the salt to eight of water; Dr Brownrigg makes the quantity of salt a little more; Dr Grew, a dram and a furlong more; and Eller, as appears in the above table, four drams more: so that in the trials of six different persons, made probably in different circumstances, the greatest difference is only one fifth of the whole quantity of salt; whereas in some other salts there are differences of twice or thrice the quantity of the salt. In the experiments from which the table is drawn, the water was of the temperature of between 40 and 42 degrees of Fahrenheit's thermometer, or above freezing by about one-sixth of the interval between freezing and the human heat.

Some salts omitted by Eller are here subjoined; the first is taken from Dr Grew, and the other four from Neumann.

Though water takes up only a certain quantity of one kind of salt, yet when saturated with one, it will still dissolve some portion of another; and when it can bear no more of either of these, it will still take up a third, without letting go any of the former. The principal experiments of this kind which have been made relative to pharmaceutical subjects, are exhibited in the following table; or which the two first articles are from Grew, and the others from Eller.

In regard to the other clas of bodies for which water is a menstruum, viz. those of the gummy gelatious kind, there is no determinate point of saturation: the water unites readily with any proportions of them, forming with different quantities liquors of different consistence. This fluid takes up likewise, when affil- ed by trituratation, the vegetable gummy refrains, as amno- nium and myrrh; the solutions of which, though imperfect, that is, not transparent, but turbid and of a milky hue, are nevertheless applicable to valuable purposes in medicine. It mingles with vinous spirits, with acid and alkaline liquors, not with oils, but imbibes some of the more soluble parts of essentitial oils, so as to become impregnated with their smell and taste.

Rectified spirit of wine, or rather alcohol, is the men- struum of the essentitial oils and refrains of vegetables; of spirit of the pure distilled oils, and several of the colouring and medicinal parts of animals; of some mineral bituminous and mineral substances, as of ambergris; and of soaps, though it of the essence does not act upon the expressed oil and fixed alkaline fential salts, of which soap is composed: whence, if soap contains any superfluous quantity of either the oil or salt, of vegetable tables, it may by means of this menstruum be excellently purified. It dissolves, by the affinity of heat, volatile alkaline salts; and more readily the neutral ones, composed either of fixed alkali and the acetous acid, as the sul diuretus, or of the volatile alkali and the nitrous acid, as also the salt of amber, &c. It mingles with water and with acids; not with alkaline lixivia.

Oils dissolve vegetable refrains and balsams, wax, ani- mal fats, mineral bituminus, sulphur, and certain metallic refrains, particularly lead. The expressed oils are, for most of those bodies, more powerful menstru- a than those obtained by distillation; as the former are more capable of sustaining, without injury, a strong heat, which is in most cases necessary to enable them to act. It is said, that one ounce of sulphur will dissolve in seven ounces of expressed oil, particularly linseed.
All acids dissolve alkaline salts, alkaline earths, and metallic substances. The different acids differ greatly in their action upon these salt; one dissolving only some particular metals; and another, others.

The vegetable acids dissolve a considerable quantity of zinc, iron, copper, lead, and tin; and extract so much from the metallic part of antimony, as to become powerfully emetic; they dissolve lead more readily, if the metal be previously calcined by fire, than in its metallic state.

The marine acid dissolves zinc, iron, and copper; and though it scarcely acts on any other metallic substance in the common way of making solutions, it may nevertheless be artfully combined with them all except gold. The corrosive sublimate, and antimonial cauffe of the elets, are combinations of it with mercury and the metallic part of antimony, effected by applying the acid, in the form of fume, to the subjects, at the same time also strongly heated.

The nitrous acid is the common menstruum of all metallic substances, except gold and the metallic part of antimony; of which two, the proper solvent is a mixture of the nitrous and marine acids, called aqua regia.

The vitriolic acid diluted with water, easily dissolves zinc and iron. In its concentrated state, and diffused by a boiling heat, it may be made to corrode, or imperfectly dissolve, most of the other metals.

The aerial acid dissolves iron, zinc, and calcareous earth: and those solutions must be conducted without heat.

Alkaline liquor inevitable dissolves oils, resineous substances, and sulphur. Their power is greatly promoted by the addition of quicklime; infinrures of which occur in the preparation of soap, and in the common cauffe. Thus acuited, they reduce the flesh, bones, and other solid parts of animals, into a gelatinous matter. This increased acrimony in alkaline fluids is owing to the abstraction of their fixed air; that acid having a greater attraction for quicklime than for alkalies.

Solutions made in water and in spirit of wine possess the virtues of the body dissolved; while oils generally sheath its activity, and acids and alkalis vary its quality. Hence watery and spirituous liquors are the proper menstrua of the native vegetables and animal matters.

Most of the foregoing solutions are easily eflfect, by pouring the menstruum on the body to be dissolved, and inyang them to stand together for some time exposed to a suitable warmth. A strong heat is generally requisite to enable oils and alkaline liquors to perform their office; nor will acids act en fome metallic bodies without its assistance. The action of watery and spirituous menstrua is likewise expedited by a moderate heat; though the quantity which they afterwards keep dissolved is not, as some suppose, by this means increased; all that heat occasioneth the heat, take up, more than they would do in a longer time in the cold, will, when the heat ceases, subside again. This at least is most commonly the case, though there may be some infinures of the contrary.

The action of acids on the bodies which they dissolve is generally accompanied with heat, effervescence, and a copious discharge of fumes. The fumes which arise during the solution of some metals in the vitriolic acid, prove inflammable: hence in the preparation of the artificial viorfols of iron and zinc, the operator ought to be careful, especially where the solution is made in a narrow mouthed vessel, left by the imprudent approach of a candle the exhalating vapour be set on fire. This vapour is the inflammable air of Dr. Priestley and other modern chemists.

There is another species of solution, in which the moisture of the air is the menstruum. Fixed alkaline salts, and those of the neutral kind, composed of alkaline earths and the vegetable acids, or of soluble earths and any acid, except the vitriolic, and some metallic salts, on being exposed for some time to a moist air, gradually attract its humidity, and at length become liquid. Some substances, not dissoluble by the application of water in its larger form, as the butter of antimony, are easily liquified by this flow action of the aerial moisture. This process is called dissolution.

**Sect. II. Extraction.**

The liquors which dissolve certain substances in their pure state, serve likewise to extract them from admixtures of other matter. Thus ardent spirit, the menstruum of essential oils and resins, takes up the virtues of the resins and oily vegetables, as water does the body of the mucilaginous and fatty; the inactive earthly parts remaining untouched by both. Water extracts likewise from many plants, substances which by themselves it has little effect upon; even essential oils being, as we have formerly observed, rendered insoluble in that fluid by the admixture of gummy and fatty matter, of which all vegetables participate, in a greater or less degree. Thus many of the aromatic plants, and most of the bitters and astringents, yield their virtues to this menstruum.

Extraction is performed, by macerating or steeping the subject in its appropriated menstruum in the cold; or digerating or circulating them in a moderate warmth; or infusing the plant in the boiling liquor, and suffering them to stand in a covered vessel till grown cold; or actually boiling them together for some time. If the vegetable matter be itself succulent and watery, it is sometimes only necessary to express the juice, and evaporate it to the proper consistence.

The term digestion is sometimes used for maceration; and in this case the process is directed to be performed without heat: where this circumstance is not expressed, digestion always implies the use of heat. Circulation differs from digestion only in this, that the steam, into which a part of the liquor is resolved by the heat, is, by means of a proper disposition of the vessels, condensed and conveyed back again upon the subject. Digestion is usually performed in a matrafs (or bolt head), Florence flask, or the like; either of which may be conveyed into a circulatory vessel, by inverting another into the mouth, and securing the juncture with a piece of waxed bladder. A single matrafs, if its neck be very long and narrow, will answer the purpose as effectually; the vapour cooling and condensing before it can rise to the top; in a vessel of this kind, even spirit of wine, one of the most volatile liquors we know, may be boiled without any considerable loss: the use of the
Decantation, colature, and filtration, are applicable to most of the medicated liquors that stand in need of purification. Distillation and clarification very rarely have place; since these, along with the impurities of the liquor, frequently separate its medicinal parts. Thus, if the decoction of poppy heads, for makingassic, be formally distilled or clarified, the medicine will lose almost all that the poppies communicated; and instead of a mild opiate, turns out little other than a plain syrup of sugar.

It may be proper to observe, that the common sorts of filtering paper are apt to communicate a disagreeable flavour: and hence in filtering fine bitters or other liquids, whole gratefulness is of primary consequence, the part which passes through first ought to be kept apart for inferior purposes.

Sect. IV. Crystallization.

Water, affixed by heat, dissolves a larger proportion of most tinctuous substances than it can retain when grown pure, and cold; hence, on the abatement of the heat, a part of the salt separates from the menstruum, and concretes by crystallization at the sides and bottom of the vessel. The concretions, unless too hastily formed by the sudden cooling of the liquor, or disturbed in their coalescence by agitation, or other similar causes, prove transparent and of regular figures, resembling in appearance the natural spring-crystals.

Salt, dissolved in a large quantity of water, may in like manner be recovered from it in their crystalline form, by boiling down the solution, till so much of the fluid has exhaled as that the remainder will be too little to keep the salt dissolved when grown perfectly cold. It is customary to continue the evaporation till the salt shows a disposition to concrete even from the hot water, by forming a pellicle on that part which is least hot, viz. on the surface. If large, beautiful, and perfectly figured crystals are required, this point is somewhat too late for if the salt thus begins to coalesce whilst considerably hot, on being removed into a cold place its particles will run too hastily and irregularly together; the pellicle at the same time falling down through the liquor, proves a farther disturbance to the regularity of the crystallization.

In order to perform this process in perfection, the evaporation must be gentle, and continued no longer than till some drops of the liquor, let fall on a cold glass plate, discover crystalline filaments. When this mark of sufficient exhalation appears, the vessel is to be immediately removed from the fire into a less warm but not cold place, and covered with a cloth to prevent the access of cold air, and consequently the formation of a pellicle.

The fixed alkalies, especially the mineral, when fully saturated with fixed air or the aerial acid, assume a crystalline form; but these crystals, are not so perfect as when the same alkalies are united with the other acids; the volatile alkalies cannot crystallize, because they escape before the menstruum exhalates.

Some even of the other neutral salts, particularly those of which certain metallic bodies are the bases, are so strongly retaing by the aqueous fluid, as not to exhibit any appearance of crystallization, unless some...
other solvents be added, with which the water has a greater affinity. The table of Affinity shows that spirit of wine is such a substance; by the prudent addition of which, these kinds of salt separate freely from the menstruum, and form large and beautiful crystals scarcely obtainable by any other means.

The operator must be careful not to add too much of the spirit; lest, instead of a gradual and regular crystallization, the baths of the salt be hasty precipitated in a powdery form. One-twentieth part of the weight of the liquor will in most cases be a sufficient, and in some too large a quantity.

Different sorts require different quantities of water to keep them dissolved: and hence, if a mixture of two or more be dissolved in this fluid, they will begin to separate and crystallize at different periods of the evaporation. Upon this foundation, salts are freed not only from such impurities as water is not capable of dissolving and carrying through the pores of a filter, but likewise from admixtures of each other; that which requires most water to dissolve shooting first into crystals.

It is proper to remark, that a salt, when crystallizing, still retains and combines with a certain portion of water: this water is not essential to the salt as a salt, but is essential to a salt as being crystallized; it is therefore called by the chemists the water of crystallization. The quantity of this water varies in different sorts: In some of them, as in Glauber’s salt, alum, and copperas, it makes up about one half of their weight; in others, as in nitre, common salt, and especially sulfur, it is in very small quantity. As salts unite to the water of their crystallization by their attraction for water alone, we accordingly find that this water is perfectly pure, and contains, in complete crystals, no substance foreign to the salt. Salts not only differ in the quantity of water necessary to their solution, but some of them are also soluble with equal facility in cold as in hot water. Sometimes then we employ evaporation; sometimes cooling; and at other times both these expedients are used alternately, to separate different sorts dissolved in the same liquor. It is obvious, then, that those which are nearly or equally soluble in cold as in boiling water, can only be crystallized by evaporation; those again, which are much more soluble in boiling than in cold water, are to be separated by cooling. Of the first of these is common or marine salt; of the latter is nitre or saltpetre. It remains, then, that we should know how to separate these two sorts, when both of them happen to be dissolved in the same water; this method consists in alternate evaporation and cooling. If in such a solution a pellicle appears in the boiling liquor before crystals can be formed in the cooling, we then conclude that the common salt predominates: in this case we evacuate the water, and separate the common salt as fast as it is formed, till the liquor on cooling shows crystals of nitre: we then allow the nitre to crystallize by cooling. After all the nitre which had been dissolved by the heat alone has now separated by cooling, we resume the evaporation, and separate the common salt till the cooling liquor again shows crystals of nitre. We thus repeat the same series of operations, by which means these two sorts may be alternately crystallized: the one by evaporation, the other by cooling, till they are perfectly separated from each other. If in the beginning of the operation the liquor had, upon trial, given crystals of nitre by cooling, before any pellicle appeared on its surface when boiling, this would have indicated that the nitre was predominant in the solution; the nitre in this case would have been crystallized, first by cooling, till the quantity of nitre exceeding that of the common salt having been separated, the common salt would next have crystallized in its turn by evaporation. The example we have now given may be applied to other salts, or to a number of salts which may happen to be dissolved in the same liquor. For though there are few so completely soluble in cold water as common salt, and few so scantily as nitre; yet there are scarcely two sorts which either precisely show the same solubility or the same appearance of their crystals. It is obvious, too, that by crystallization we discover the peculiar predominant salt in any solution of mixed saline matter; but as one salt always takes down a small portion of another, it is necessary to redissolve the first products, and repeat the crystallization, in order to render the separation complete.

We see, then, that though the crystal appearance and form does not alter the salt itself, yet that this proceeds affords an elegant method of discovering compound solutions of salts, of judging of their purity, and lastly of separating different sorts very completely from each other. Crystallization, then, is one of the most important agents in pharmacy, and ought to be well understood. We shall attempt to explain the particular management in crystallizing particular sorts, when we come to treat of each of them separately.

SECT. V. PRECIPITATION.

By this operation bodies are recovered from their Nature of solutions by means of the addition of some other substance, with which either the menstruum or the body dissolved have a greater affinity than they have with each other.

Precipitation, therefore, is of two kinds: one, where the substance superadded unites with the menstruum, and occasions that before dissolved to be thrown down; the other, in which it unites with the diffolved body, and falls along with it to the bottom. Of the first, we have an example in the precipitation of sulphur from alkaline lixiviae by the means of acids; of the second, in the precipitation of mercury from aquafortis by fea­­salt, or its acid.

The subjects of this operation, as well those which are capable of being precipitated as those which precipitate them, will readily appear from inspection of the Table of Affinity. See Chemistry, page 438. The manner of performing it is so simple, as not to stand in need of any particular directions; no more being required than to add the precipitant by degrees as long as it continues to occasion any precipitation. When the whole of the powder has fallen, it is to be well adulterated, that is, washed in several fresh parcels of water, and afterwards dried for use.

Where metals are employed as precipitants, as in the purification of martial vitriol from copper by the addition of fresh iron, they ought to be perfectly clean and free from any rusty or greatly matter; otherwise they will not readily, if at all, dissolve, and consequent­
PHARMACY. 

EVAPORATION, the third method of recovering solid bodies from their solutions, is effected by the means of heat; which evaporating the fluid part, that is forcing it off in steam, the matter which was dissolved therein is left behind in its solid form.

The general rules for evaporation are, to place the matter in a flat, shallow, wide vessel, so that a large surface of the liquor may be presented to the air; for it is only from the surface that evaporation takes place.

The degree of heat ought to be proportioned to the volatility of the substance to be evaporated, and to the degree of the fixity of the matter to be left: thus, the less fixed the matter to be left is, and the more strongly it adheres to the volatile parts, the less the degree of heat ought to be; and in such cases, too, a forcible current of air is sometimes scarcely admittable: on the contrary, when the matter to be evaporated is not very volatile, and when the matter to be left is very fixed, and does not adhere strongly to the volatile part, the evaporation may be urged by a strong heat, aided by a current of air directed upon the surface of the liquor.

This process is applicable to the solutions of all these substances which are less volatile than the menirrum, or which will not exhalbe by the heat requisite for the evaporation of the fluid; as the solutions of fixed alkaline salts; of the gumy, gelatinous, and other inodorous parts of vegetables and animals in water; and of many refinuous and odorous substances in spirit of wine.

Water extracts the virtues of sundry fragrant aromatic herbs, almost as perfectly as rectifed spirit of wine; but the aqueous infusions are far from being equally suited to this process with those made in spirit, water carrying off the whole odour and flavour of the subject which that lighter liquor leaves entire behind it. Thus a watery infusion of mint loefs in evaporation the smell, taste, and virtues, of the herb; whilst a tincture drawn with pure spirit yields on the same treatmen a thick balsamic liquor, or solid gummy refins, extremely rich in the peculiar qualities of the mint. 

In evaporating these kinds of liquors, particular care must be had, towards the end of the process, that the heat be very gentle; otherwise the matter as it grows thick will burn to the vessel, and contrate a disagreeable smell and taste: this burnt flavour is called empyreuma. The liquor ought to be kept stirring during the evaporation; otherwise a part of the matter concretes on the surface exposed to the air, and forms a pellicle which impedes the farther evaporation.

Sect. VII. Distillation.

Is the foregoing operation fluids are rarely dried by heat into steam, or vapour, which is suffered to exhale in the air, but which it is the business of distillation to collect and preserve. For this purpose the steam is received in proper vessels, luted to that in which the subject is contained, and being there cooled, condenses into a fluid form again.

There are two kinds of distillation: by the one, the more subtle and volatile parts of liquors are elevated from the groffer; by the other, liquids incorporated with solid bodies, are forced out from them with vehemence by fire.

To the fist belong the distillation of the pure inflammable spirit from vinous liquors; and of such of the active parts of vegetables as are capable of being extracted by boiling water or spirit, and at the same time of ariling along with their stem.

As boiling water extracts or disolves the essential oils of vegetables, while blended with the other principles of the subject, without saturation, but imbibes only a determinate, and that a small proportion of them, in their pure state; as these oils are the only substances contained in common vegetables, which prove totally volatile in that degree of heat; and as it is in them that the virtues of aromatics, and the peculiar odour and flavour of all plants, reside; — it is evident, that water may be impregnated by distillation, with the more valuable parts of many vegetables: that this impregnation is limited, the oil arising in this process pure from those parts of the plant which before rendered it soluble in water without limitation; hence the greatest part of the oil separates from the distilled aqueous liquor, and, according to its greater or less gravity, either sinks to the bottom, or floats on the surface; that consequentluy infusious and distilled waters are very different from each other: that the first may be rendered stronger by pouring the liquor on fresh parcels of the subject; but that the latter cannot be in like manner improved by coloting or redistilling them from fresh ingredients.

As the oils of many vegetables do not freely distil with a less heat than that in which water boils; as rectifed spirit of wine is not susceptible of this degree of heat; and as this menirrum totally disolves these oils in their pure state; it follows, that spirit elevates far less from most vegetables than water; but that nevertheless the distilled spirit, by keeping all that it does elevate perfectly dissolved, may, in some cases, prove as strong of the subject as the distilled water. The more gentle the heat, and the flower the distillation goes on, the volatile parts are the more perfectly separated in their native state.
It may be observed, that as the parts which are preferred in evaporation cannot arise in distillation, the liquor remaining after the distillation, properly depurated and infuscated, will yield the same extracts as those prepared from the tincture or decoction of the subjedt made on purpose for that use; the one of these operations collectively only the volatile parts, and the other the more fixed; so that where one subjedt contains medicinal parts of both kinds, they may thus be obtained distinct, without one being injured by the process which collects the other.

The subjedts of the second kind of distillation are, the gross oils of vegetables and animals, the mineral acid spirits, and the metallic fluid quicksilver; which as they require a much stronger degree of heat to elevate than the foregoing liquors can fullain, so they likewise condense without arising so far from the action of the fire. The distillation of these is performed in low glass vesfels, called, from their neck being bent to one fide, revere. To to the further end of the neck a receiver is luted, which, standing without the furnace, the vapours flow condense in it, without the use of a refrigeratory: nevertheless, to promote this effect, some are accustomed, especially in warm weather, to cool the receiver, by occasionally applying wet clothes to it, or keeping it partly immersed in a fessel of cold water.

The vapours of some subfances are fo fliggili, or strongly retained by a fixed matter, as fearce to arise even over the low neck of the revere. These are most commodiously distilled in straight-necked earthen vesfels called longnecks, laid on their fides, so that the vapour passes off laterally with little or no accent: a receiver is luted to the end of the neck without the furnace. In this manner, the acid spirit of vitriol is disflied. The matter which remains in the revere or longneck, after the distillation, is vulgarly called caput-mortuum.

In these distillations, a quantity of elafic air is frequently generated: which, unless an exit be allowed, blows off or burfts the receiver. The danger of this may in good measure be prevented, by slowly rafing the fire; but more effectually by leaving a small hole in the luting, to be occasionally opened or flot with a wooden plug; or inferting at the junclure an upright pipe of fuch a height, that the fream of the diftilling liquor may not be able to rise to the top: but it is flill better done by fetting to the apparatus other vesfels, by which their vapours may be condended. For the purpofe of diftilling, and the apparatus made uf of, fee Distillation; and Chemistry, p. 574.

SEC. VIII. Sublimation.

As all fluids are volatile by heat, and confequently capable of being separated, in many cafes, from fixed matters, hy the foregoing process; fo various folid bodies are subjected to a similar treatment. Fluids are laid to diftil, and folida to fublime; though sometimes both are obtained in one and the fame operation. If the fubliming matter concrctes into a mass, it is commonly called a fublimate; if into a powdery form, flourer.

The principal subjedts of this operation are, volatile alkaline fads; neutral fads, compofed of volatile alkalies and acid-, as falt ammoniac; the falt of amber, and flowers of benzoin; mercurial preparations; and fulphur. Bodies of themfelves not volatile, are frequently made to fublime, by the mixture of volatile ones: this iron is carried up by falt ammoniac in the preparation of the fers martials, or ferum ammoniacalis.

The fumes of solid bodies in clofe vesfels rise but little way, and adhere to that part of the vesfels where they concrete. Hence a receiver or condenser is left necessary here than in the preceding operation; a single vesfels, as a matrafs, or tall pliafd, or the like, being frequently fufficient.

SEC. IX. Expiration.

The fublime is chiefly made uf of, for forcing out the On the ex- juices of succulent herbs and fruits, and the imipid oils of the nucous feeds and kernels. The harder fruits, as quinces, require to be previoufly well beat or ground; but herbs are to be only moderately bruised. The fublime is then included in a hair bag, and preffed between wooden plates, in the common fcrew-preff, as long as any juice runs from it.

The expiration of oils is performed nearly in the fame manner as that of juices: only here, iron-plates are substituted for the wooden ones there made uf of. The subjedt is well pounded, and included in a frong canvas bag, between which and the plates of the preff a hair cloath is interposed.

The imipid oils of all the nucous feeds are obtained, uninjured, by this operation, if performed without the use of heat which though it greatly promotes the extraction of the oil, at the fame time imprifes an ungrateful flavour, and increafes its propensity to grow rancid.

The oils exprefled from aromatic subfances generally carry with them a portion, of their effential oil; hence the small and flavour of the expreffed oils of nutmegs and mace. They are very rarely found impreffed with any of the other qualities of the subjedt; oil of muftard feed, for inffance, is as soft and void of acrimony as that of the almonds, the pungency of the muftard remaining entire in the cake left after the expiration.

SEC. X. Exsiccation.

There are two general methods of exsiccating or Two me- drying moist bodies; in the one, their humid parts are kinds of ex- exhibited by heat; in the other, they are imbied or adhrea by heat; and in the other, they are imbied or adsorbed by subfances whose soft and fpongy texture adapts them to that use. Bodies intimately combined do not, with, or diffolved in a fluid, as recent vegetables and their juices, require the first; fuch as are only superficially mixed, as when earthly or indiffoluble powders are ground with water, are commodiously separated from it by the second.

Vegetables and their parts are ufually exsiccated by the natural warmth of the air; the affiduity of a gentle artificial heat may, nevertheless, in general, be not only safely, but advantageously, had recourse to. By a moderate fire, even the more tender flowers may be dried, in a little time, without any considerable loss either of their odous or lively colour; which would both be greatly injured or destroyed by a more forcible exsiccation in the air. Some plants, indeed, particularly
The comminution of the harder minerals, as calamine, crysal, flint, &c., is greatly facilitated by exclusion; that is, by heating them red-hot, and quenching them in water: by repeating this process a few times, most of the hard stones become easily pulverizable. This process, however, is not to be applied to any of the alkaline or calcareous stones; lest, instead of an infipid powder, we produce an acrimonious calx or lime.

Some metals, as tin, though strongly cohering in their natural state, prove extremely brittle when heated, insomuch as to be easily divided into small particles by dexterous agitation. Hence the official method of pulverizing tin, by melting it, and at the instant of its beginning to return into a state of fluidity, briskly shaking it in a wooden box. The comminution of metals, in this manner, is termed by the metallurgists granulation.

On a similar principle, certain salts, as nitre, may be reduced into powder in large quantity, by dissolving them in boiling water, setting the solution over a moderate fire, and keeping the salt constantly stirring during its evaporation, so as to prevent its particles, disjointed by the fluid, from reuniting together into larger masses.

Powders are reduced to a great degree of fineness by triturating, or rubbing them, for a length of time, in a mortar. Such as are not diissolvable in water, or injured by the admixture of that fluid, are moistened with it into the consistence of a paste, and levigated or ground on a flat smooth marble or iron plate; or where a large quantity is to be prepared at a time, in mills made for that use.

Comminution, though one of the most simple operations of pharmacy, has, in many cases, very considerable effect. The refrinous purgatives, when finely triturated, are more easily soluble in the animal fluids, and consequently prove more cathartic, and less irritating, than in their grocer state. Crude antimony, which, when reduced to a tolerably fine powder, discovers a little medicinal virtue, if levigated to a great degree of subtility proves, a powerful medicine in many chronic disorders.

By comminution, the heaviest bodies may be made to float in the lightest fluids (c), for a longer or shorter time, according to their greater or less degree of tenacity. Hence we are furnished with an excellent criterion of the fineness of certain powders, and a method of separating the more subtile parts from the grosser, distinguished by the name of elutrition or washing over.

(c) Some attribute this effect to a diminution of the specific gravity of the body; and at the same time, suppose the peculiar virtues of certain medicines, particularly mercury, to be in great measure owing to their gravity. If these hypotheses were just, it should follow, that the mercurial preparations, by being finely comminuted, would lose proportionably of their efficacy; and so indeed mercurius dulcis, for instance, has been supposed to do. But experience shows, that this is far from being the case; and that comminution by no means lessens but rather increases its power: when reduced to a great degree of subtility, it passes readily into the habit, and operates, according to its quantity, as an alterative or a dialogue; while in a grofer form, it is apt to irritate the flomach and bowels, and run off by the intestines, without being conveyed into the blood.

**PHARMACY.**

Sect. XII. Fusion.

Fusion is the reduction of solid bodies into a flake of fluidity by fire. Almost all natural substances, the pure earths and the solid parts of animals and vegetable excepted, melt in proper degrees of fire; some in a very gentle heat, while others require its utmost violence.

Turpentine, and other soft resinous substances, liquefy in a gentle warmth; wax, pitch, sulphur, and the mineral bitumens, require a heat too great for the hand to support: fixed alkaline salts, common salts, nitre, require a red or almost white heat to melt them; and glass, a full white heat.

Among metallic substancess, tin, bismuth, and lead, flow long before ignition: antimony likewise melts before it is visibly red-hot; but not before the vessel is considerabily hot; the regulus of antimony demands a much stronger fire. Zinc begins to melt in a red heat; gold and silver require a low white heat; copper a bright white heat; and iron an extreme white heat.

One body, rendered fluid by heat, becomes sometimes a menstruum for another, not fusible of itself in the same degree of fire. Thus red-hot silver melts on being thrown into melted lead less hot than itself; and thus if steel, heated to whiteness, be taken out of the furnace, and applied to a roll of sulphur, the sulphur instantly liquefying, occasions the steel to melt with it; hence the chalcopyrite or sulphure of the thorns. This concrete, nevertheless, remarkably impedes the fusion of some other metals, as lead; which when united with a certain quantity of sulphur is scarce to be perfectly melted by a very strong fire. Hence the method, described in its place, of purifying zinc; a metal upon which sulphur has no effect from the lead so frequently mixed with it.

Sulphur is the only unmetallic substance which mixes in fusion with metals. Earthy, saline, and other like matters, even the calces and glases prepared from metals themselves, float distinct upon the surface, and form what is called scoria or dross. Where the quantity of this is large in proportion to the metal, it is most commodiously separated by pouring the whole into a conical mould; the pure metal or regulus, though small in quantity, occupies a considerable height in the lower narrow part of the cone; and when congealed, may be easily freed from the scorie by a hammer. The mould should be previously greased, or rather smoked, to make the metal come freely out; and thoroughly dried and heated, to prevent the explosion which sometimes happens from the sudden contact of melted metals with moist bodies.

Sect. XIII. Calcination.

Calcination, or reducing bodies by means of fire from a coherent to a powdery state, and changing their quality.

By calcination is understood the reduction of solid bodies, by the means of fire, from a coherent to a powder, accompanied with a change of their quality; in which last respect this process differs from combustion.

To this head belong the burning of vegetable and animal matters, otherwise called fussion, incineration, or congestration; and the change of metals into a powder, which in the fire either does not melt or vitrifies, that is, runs into glases.

The metals which melt before ignition, are calcined by keeping them in fusion for some time. The free admission of air is effectually necessary to the success of this operation; and hence, when the surface of the metal appears covered with calx, this must be taken off or raked to one side, otherwise the remainder excluded from the air will not undergo the change intended. If any coal, or other inflammable matter which does not contain a mineral acid, be suffered to fall into the vessel, the effect expected from this operation will not be produced, and part of what is already calcined will be revived or reduced; that is, it will return into its metallic form again.

Those metals which require a strong fire for fusion, calcine with a much less heat than is sufficient to make them flow. Hence the burning or scorification of such iron or copper vessels as are long exposed to a considerable fire without defence from the air. Gold and silver are not calcinable by any degree of fire.

In calcination, the metals visibly emit fumes; nevertheless the weight of the calx proves greater than that of the metal employed. The antimonial regulus gains about one-twelfth part of its weight; zinc sometimes one-tenth; tin above one-sixth; and lead in its conversion into minium often one fourth.

The calcination of metallic bodies, gold, silver, and mercury excepted, is greatly promoted by nitre. This salt exposed to the fire in conjunction with any inflammable substancess, extricates their inflammable matter, and burns with it into flame, accompanied with a hissing noise. This process is usually termed decommission or detonation.

All the metallic calces and scorie are revived into their metallic state by fusion with any vegetable or animal inflammable matter. They are all more difficult of fusion than the respective metals themselves; and scarcely any of them, those of lead and bismuth excepted, can be made to melt at all, without some addition, in the strongest fire that can be produced in the common furnaces. The additions called fluxes employed for promoting the fusion, consist chiefly of fixed alkaline salts. A mixture of alkaline salt with inflammable matter, as powdered charcoal, is called a reducing flux, as contributing at the same time to bring the calx into fusion, and to revive it into metal. Such a mixture is commonly prepared from one part of nirre and two parts of tartar, by grinding them well together, setting the powders on fire with a bit of coal or a red hot iron, then covering the vessel, and suffering them to deaggregate or burn till they are changed into a black alkaline coally mafs. This is the common reducing flux of the chemists, and is called from its colour the black flux. Metallic calces of scorie, mingled with twice their weight of this compound, and exposed to a proper fire in a close covered crucible, melt and resume their metallic form; but though they receive an increase of weight in the calcination, the revived metal is always found to weigh considerably less than the quantity from which the calx was made.

For a more particular account of all these processes, and an explanation of the principles on which they depend, see Chemistry, and the articles themselves as they occur in the order of the alphabet.

Part
CHAP. I. The more Simple Preparations.

The preparation of some substances not soluble in water. L.

Pour these substances first in a mortar; then, pouring on a little water, levigate them on a hard and polished, but not calcareous, stone, that they may be made as fine as possible. Dry this powder on blotting-paper laid on chalk, and let it in a warm place, or at least a dry place, for some days.

In this manner are to be prepared, Amber, Antimony, Calamine, Chalk, Coral, Oyster-shells, first cleaned from their impurities, Tuttty. Crab claws, first broken into small pieces, must be washed with boiling water before they be levigated.

Verdegris must be prepared in the same manner.

Where large quantities of the foregoing powders are to be prepared, it is customary instead of the stone and mallet, to employ hand-mills made for this purpose, consisting of two stones; the uppermost of which turns horizontally on the lower, and has an aperture in the middle, for supplying fresh matter, or of returning that which has already passed, till it be reduced to a proper degree of fineness.

For the levigation of hard bodies, particular care should be taken, whatever kind of instruments be used, that they may be of sufficient hardness, otherwise they will be abraded by the powders. The hematomas, a hard iron one, is most conveniently levigated between two iron planes; for if the common levigating stones be used, the preparation, when finished will contain almost as much foreign matter from the instrument as the hematomas.

It has been customary to moisten several powders in levigation, with rose, balm, and other diffiluted waters: these, nevertheless, have no advantage above common water, since in the subseuent excitation they must necessarily exhale, leaving the medicine pollenated of no other virtue than what might be equally expected from it when prepared with the cheaper element.

Some few substances, indeed, are more advantageously levigated with spirit of wine than with water. Thus bezoar has the green colour usually expected in this costly preparation considerably improved thereby. A little spirit may be added to the other animal substances, if the weather be very hot, and large quantities of them be prepared at once, to prevent their running into patresfaction; an accident which in those circumstances sometimes happens when they are levigated with water only. Crab-eyes, which abound with animal gelatinous matter, are particularly liable to this inconvenience.

The caution given above for reducing antimony, calamine, and turtty, to the greatest subtility possible, demands particular attention. The tenderest of the parts to which the two last are usually applied, requires them to be perfectly free from any admixture of gross irritating particles. The first, when not thoroughly comminuted, might not only, by its sharp needle-like spicula, wound the stomatch, but likewise answers little valuable purpose as a medicine, proving either an useless load upon the viscerâ, or at best palping off without any other sensible effect than an increase of the grofer evacuations; while, if reduced to a great degree of fineness, it turns out a medicine of considerable efficacy.

The most successful method of obtaining these powders of the requisite tenacity, is, to wash off the finer parts by means of water, and continue levigating the remainder till the whole become fine enough to remain for some time suspended in the fluid; this process is received in the Edinburgh pharmacopoeia, and there directed in the preparation of the following article.

Prepared antimony. E.

Let the antimony be first pounded in an iron mortar, and then levigated on a porphyry with a little water. After this, put it into a large vessel, and pour a quantity of water on it. Let the vessel be repeatedly shaken, that the finer part of the powder may be diffused through the water; the liquor is then to be poured off, and set by till the powder settles. The gross part, which the water would not take up, is to be further levigated, and treated in the same manner.

By this method, which is that commonly practised in the preparation of colours for the painter, powders may be obtained of any required degree of tenacity; and without the least mixture of the gross parts, which are always found to remain in them after long continued levigation; all the coarser matter settles at first, and the finer powder continues suspended in the water longer and longer, in proportion to the degree of its fineness. The same process may likewise be advantageously applied to other hard pulverizable bodies of the mineral kingdom, or artificial preparations of them; provided they be not soluble in, or specifically lighter than water. The animal and absorbent powders, crab-claws, crab-eyes, oyster-shells, egg-shells, chalk, pearl, coral, and bezoar, are not well adapted to this treatment; nor indeed do they require it. These substances are readily soluble in acid juices without much comminution: if no acid be contained in the first passage, they are apt to concret, with the mucous matter; usually lodged there, into hard indissoluble masses; the greater degree of fineness they are reduced to, the more they are disposed to form such concretions, and become liable to obstruct the orifices of the small vessels.
Prepared calamine.  E.

Calamine previously calcined for the use of those who make bracts, is to be treated in the same manner as antimony.

Prepared chalk.

Chalk first triturated, and then frequently washed with water, till it imports to it neither taste nor colour, is to be treated in the same manner as antimony.

As calamine is intended for external application, and often to parts very irritated, too much pains cannot be bestowed on reducing it to a fine powder; and the frequent washing of the chalk may have the effect of freeing it from some foreign matters: But with regard to this substance, the after part of the process, if not improper, is, in our opinion at least unnecessary: and this observation may also be made with regard to the oculi, or more properly lapilli, cancrorum, which is not improper, is, in our opinion at least unnecessary: for the process requires to be very cautiously conducted, to prevent the fat from burning or turning black.

The preparation of hog’s lard and mutton fat.  L.

Cut them into pieces, and melt them over a slow fire; then separate them from the membranes by strain­ing.

These articles had formerly a place also among the preparations of the Edinburgh college: But now they introduce them only into their list of the materia medica; as the apothecary will in general find it more for his interest to purchase them thus prepared, than to prepare them for himself: for the process requires to be very cautiously conducted, to prevent the fat from burning or turning black.

The purification of gum ammoniacum.  L.

If gum ammoniac do not seem to be pure, boil it in water till it become soft; then squeeze it through a canvas bag, by means of a press. Let it remain at rest till the resinous part subsides; then evaporate the water; and toward the end of the evaporation re­move the resinous part, mixing it with the gummy.

In the same manner are purified asafoetida and such like gum refins.

You may also purify any gum which melts easily, such as Galbanum, by putting it in an ox bladder, and holding it in boiling water till it be so soft that it can be separated from its impurities by pressing through a coarse linen cloth.

In straining all the gums, care should be taken that the heat be neither great nor long continued; otherwise a considerable portion of the more active volatile matter will be lost; an inconvenience which cannot by any care be wholly avoided. Hence the purer tears, unstrained, are in general to be preferred, for internal use, to the strained gums.

As an additional reason for this preference, we may add, that some of the gum-refins, purified in the common way, by solution in water, expression and evaporation, are not so easily soluble in aqueous menstrua after as before such depuration. On these accounts this process is entirely omitted by the Edinburgh college; and in every case where a gummy resinous substance, before it be taken, is to be dissolved in water, it may be as effectually freed from impurities at the time of solution as by this process. And when it is to be employed in a solid state, care should be taken that the pure parts alone be selected.

The burning of hart­horn.  L.

Burn pieces of hart­horn till they become perfectly white; then reduce them to a very fine powder.

The pieces of horn generally employed in this operation are those left after distillation.

In the burning of hart­horn, a strong fire and the free admixture of air are necessary. The potter’s furnace was formerly directed for the sake of convenience; but any common furnace or stove will do. If some lighted charcoal be spread on the bottom of the grate, and above this the pieces of the horn are laid, they will be burnt to whiteness, still retaining their original form.

Burnt hart­horn is not now considered as a pure earth, having been found to be a compound of calcareous earth and phosphoric acid. It is the weakest of the animal absorbents, and is difficultly soluble in acids; but whether it be of equal or superior use in diarrhoas to more powerful absorbents, must be left to observation.

The drying of herbs and flowers.

Let these, spread out lightly, be dried by a gentle heat.  L.

Herbs and flowers must be dried by a gentle heat, from a stove or common fire. They must be taken in such quantities at a time, that the process will be speedily finished; for by this means their medical powers are best preserved. The most certain test of this is the perfect preservation of the natural colour: but the leaves of cicuta, and of other plants containing a volatile matter, must be immediately pounded, after being dried, and afterwards kept in a phial with a ground stopper. E.

The directions given by the London college are here left explicit, and perhaps less proper, than those of the Edinburgh college: for there can be no doubt of the propriety of drying these substances hastily, by the aid of artificial heat, rather than by the heat of the sun.

In the application of artificial heat, the only caution requisite is to avoid burning; and of this a sufficient test is afforded by the preservation of colour. And the direction given with regard to cicuta may perhaps with advantage be followed with most of the other flowers and herbs, afterwards to be exhibited in powder.

The purifying of honey.  L.

Melt the honey by the heat of a water bath, and remove the scum.

The intention of this process is to purify the honey from wax, or other droppy matters that have been united with it by the violence of the press in its separation from the combs, and from meal and such-like substances, which are sometimes fraudulently mixed with it. When the honey is rendered liquid and thin by the heat, these lighter matters rise freely to the surface.

This preparation is not so necessary for honey that is to be used as an article of diet, as for that which is employed
employed in the preparation of oxymels: hence the Edinburgh college, who have rejected all the oxymels, have omitted this process.

The preparation of millipedes. L. E.

The millipedes are to be inclosed in a thin canvas cloth, and suspended over hot proof spirit in a close vessel, till they be killed by the steam, and rendered friable.

This is a convenient way of rendering millipedes pulv-ervisible, without endangering any loss of such virtues as they may posses.

The directions given by both colleges are precisely the same, and delivered in almost the same words.

The extracting of pulps. L. E.

Unripe pulpy fruits, and ripe ones if they be dry are to be boiled in a small quantity of water until they become soft: then press out the pulp through a strong hair-sieve, and afterwards boil it down to the confinence of honey in an earthen vessel, over a gentle fire; taking care to keep the matter continually stirring, to prevent its burning.

The pulp of calia fistularis is in like manner to be boiled out from the bruised pod, and reduced afterwards to a proper consistence, by evaporating the water.

The pulps of fruits that are both ripe and fresh, are to be pressed out through the sieve, without any previous boiling.

In the extraction of pulps, the direction of both colleges so nearly agree, that it is unnecessary to give a separate translation of each. We may only observe, that the London college, instead of softening the fruits by boiling them in a small quantity of water, direct them to be put in a moist place. This direction, though proper in some cases, is not generally the most suitable.

The drying of squills. L. E.

Let the squill, cleared from its outer skin, be cut transversely into thin slices, and dried with a very gentle fire. When properly managed, the squill is friable and retains its bitterness and acrimony.

By this method the squill dries much sooner than when its several coats are only separated, as has been usually directed; the internal part is here laid bare, but, in each of the entire coats, it is covered with a thin skin, which impedes the exhalation of the moisture. The root loaves in this process four-fifths of its original weight; the parts which exhale appear to be merely watery; six grains of the dry root being equivalent to half a dram of the fresh; a circumstance to be particularly regarded in the exhibition of this medicine. In the preceding editions of our pharmacopoeia, a particular caution was given, not to use an iron knife for cutting squills, but one of wood, ivory, or bone; the reason of this caution is said to be, not so much that the squill would receive any ill qualities from the iron; as, that its acrid juice, adhering to the knife, might render a wound received by it extremely painful, or even dangerous; but as no danger is to be apprehended from such an accident, the direction appears unnecessary. Dried squills furnish us with a medicin, sometimes advantageously employed as an emetic, often as an expectorant, but still more frequently as a powerful diuretic.

The burning of a sponge.

Beat the sponge, after cutting it in pieces; and, when separated from its gritty matter, burn it in a close iron vessel, until it becomes black and friable; afterwards rub it to a very fine powder. L.

Put the sponge, cut into small pieces, and well freed from adhering earthy matters, into a close earthen vessel. Place it on the fire, and let it be stirred frequently till it become black and friable; then reduce it to a powder in a glass or marble mortar.

This medicine has been in use for a considerable time, and employed against scrofulous disorders and cutaneous futilities, in doses of a scruple and upwards. Its virtues seem to depend on a volatile salt just formed, and combined with its own oil. If the sponge be distilled with a strong heat, it yields a large proportion of that salt in its proper form. The salt is in this preparation so far extricated, that if the burnt sponge be ground in a brass mortar, it corrodes the metal so as to contract a disagreeable taint, and sometimes an emetic quality.

Bees, earthworms, and other animal substances, have by some been prepared in the same manner, and recommended in different diseases: but as these substances fall much short of sponge in the quantity of volatile salt producible from them by fire, they are probably inferior also in medicinal efficacy. Of all the animal matters that have been tried, raw silk is the only one which exceeds or equals sponge, in the produce of salt.

A good deal of address is requisite for managing this process in perfection. The sponge should be cut small, and beaten for some time in a mortar, that all the flaky matters may be got out, which compared with the weight of the sponge when prepared, will sometimes amount to a considerable quantity. The burning should be discontinued as soon as the matter is become thoroughly black. If the quantity put into the vessel at once be large, the outside will be sufficiently burnt before the inside be affected; and the volatile salt of the former will in part escape, before that in the latter is begun to be formed. The best method of avoiding this inconvenience seems to be, to keep the sponge continually stirring, in such a machine as is used for the roasting of coffee.

And from this circumstance the iron vessel directed by the London college is preferable to the earthen one directed by that of Edinburgh. But the pounding in a glass or marble mortar, directed by the latter, is a necessary caution which the former college have omitted.

The purifying of storax. L.

Dissolve the storax in rectified spirit of wine, and strain the solution; afterwards reduce it to a proper thickness with a gentle heat.

Storax was formerly directed to be purified by means of water; hence it was styled storaxis collatio: but the method now adopted is much preferable, for the active parts
parts of the florum totally dissolve in spirit of wine, the
impurities alone being left. And as these active parts
do not rise in distillation, the spirit may be again re-
covered by distillation.

**Purified filings of iron.** E.

**104**

Apply a magnet to a sieve placed on filings of iron, so
that the filings may be attracted upwards through the
sieve.

*Raft of iron, commonly called savings of iron, pre-
pared.* E.

**105**

Set purified filings of iron in a moist place, that they
may turn to rust, which is to be ground into an im-
palpable powder.

The cleaning of iron filings by means of a magnet
is very tedious, and does not answer so well as might be
expected; for if they are rusty, they will not be at-
ttracted by it, or not sufficiently: nor will they by this
means be entirely freed from brass, copper, or other
metallic substances which may adhere to them. It
appears from the experiments of Henckel, that if iron
be mixed with foven with even its own weight of any
of the other metals, regardless of antimony alone excepted,
the compound will be vigorously attracted by the loadstone.
The rust of iron is to be procured at a moderate rate from the dealers in iron, free from any
impurities except such as may be washed off by wa-
ter.

The rust of iron is by some preferred as a medicine
to the calces or croci made by a strong fire. Hoff-
man relates, that he has frequently given it with re-
markable success in oblitinate chlorotic cafes accompa-
nied with excessive headaches and other violent symp-
toms; and that he usually joined with it pimipinella,
ard root, and salt of tartar, with a little cinnamon
and rufty, where others would otherwise undergo. There are,
however, fundry vegetables whose virtues are impaired
by this treatment. Mucilaginous substances by long
lying with fugar, become less glutinous; and alin-
rents become feebly fober on the palate. Many of
the fragrant flowers are of fo tender and delicate a
texture, as almost entirely to losf their peculiar quali-
ties by being beaten or bruited.

In general, it is obvious, that in this form, on account
of the large admixture of fugar, substances of con-
derable activity can alone be taken to advantage as
medicines. And, indeed, conserves are at prefent con-
fidered chiefly as auxiliaries to medicines of greater
cfficacy, or as intermedia for joining them together.
They are very convenient for reducing into bolufes or
pills, the more ponderous powders of iron, and
alnent. The cleanfing of iron filings by means of a magnet
is very tedious, and does not answer so well as might
be expected; for if they are rusty, they will not be at-
ttracted by it, or not sufficiently: nor will they by this
means be entirely freed from brass, copper, or other
metallic substances which may adhere to them. It
appears from the experiments of Henckel, that if iron
be mixed with foven with even its own weight of any
of the other metals, regardless of antimony alone excepted,
the compound will be vigorously attracted by the loadstone.
The rust of iron is to be procured at a moderate rate from the dealers in iron, free from any
impurities except such as may be washed off by wa-

the fragrant flowers are of fo tender and delicate a
texture, as almost entirely to losf their peculiar quali-
ties by being beaten or bruited.

Pluck the leaves from the falks, the unblown petals
from the cups, taking off the heels. Take off the
outer rind of the oranges by a grater; then beat
each of them with a wooden pestle in a marble mor-
tar, first by themfelves, afterwards with three times
their weight of double refined fugar, until they be
mixed.

Conserves of the freft leaves of mint;
red rofe not blown;
the outer rind of Seville oranges rasped off by
a grater. E.

These are directed to be prepared with triple their
weight of fugar in the fame manner as the conserves
of the London college. The fugar should be pound-
ed by itfelf, and passed through a sieve before it be
mixed with the vegetable mafs; for without this it

cannot be properly incorporated. Rose buds, and some other vegetables, are prepared for mixing with sugar by a small wooden mill contrived for that purpose.

In the same manner conserves may be prepared from many other vegetables. But besides the conserves for which general directions are given, there are others, for which, either on account of the particular mode of preparation, or of the proportion, our pharmacopoeias have thought it necessary to give particular directions. But before taking notice of these, it is necessary to mention the medical properties of the conserves above enumerated.

Conservé of the leaves of wood-sorrel. L.

This is a very elegant and grateful conserve; in tafte it is lightly acidulous, with a peculiar flavour, which some compare to that of green-tea. It is taken occasionally for quenching thirst, and cooling the mouth and fauces, in diarrhœas, where the heat of the body is much increased.

Conservé of the tops of sea wormwood. L.

The conserve of wormwood has been celebrated in dropples; Matthiolus relates, that several persons were cured by it of that distemper without the assistance of any other medicine. Where the disorder indeed proceeds from a simple laxity or flaccidity of the solids, the continued use of this medicine may be of some service; as it appears to be an elegant mild corroborant. It is directed to be given in the dose of half an ounce about three hours before meals.

Conservé of the buds of red rosin. L. E.

This is a very agreeable and useful conserve. A dram or two dissolved in warm milk are frequently given as a light astringent, in weakness of the stomach, and likewise in coughs and phthisical complaints. In the German aphorisms, examples are related of very dangerous phthises cured by the continued use of this medicine: in one of these cases, twenty pounds of the conserve were taken in the space of a month; and in another, upwards of thirty. Riverius mentions several other instances of this kind. There is, however, much room for fallacy in such observations; as phthises has not at all times been accurately distinguished from obliterative catarrhs, and some other affections; the astringent property of the sugar may perhaps have some share in the effect.

Conservé of the yellow rind of Seville orange peel. L. E.

This conserve is a very elegant one, containing all the virtues of the peel in a form sufficiently agreeable, both with regard to the dose and the convenience of taking. It is a pLEasant warm stomachic; and with this intention is frequently used.

Conservé of the leaves of spearmint. E.

The conserve of mint retains the taste and virtues of the herb. It is given in weakness of the stomach and retching to vomit; and frequently does service in some cases of this kind, where the warmer and more active preparations of mint would be less proper.

Conservé of arum.

Take of the fresh root of arum bruised, half a pound; double refined sugar, a pound and a half. Beat them together in a mortar.

The root of arum, in its recent state, is a substance of great-activity; but this activity is almost entirely lost on drying. Hence the compound powder which had formerly a place in our pharmacopoeias is now rejected. And as neither water nor spirit extract its activity, this conserve is perhaps the best form in which it can be preferred in our shops. It may be given to adults in doses of a dram.

Conservé of hips. L.

Take of pulp of ripe hips one pound; double refined sugar, powdered, twenty ounces. Mix them into a conserve.

The conserve of hips is of some esteem as a soft cooling refringent; three or four drams or more are given at a time, in bilious fluxes, sharpness of urine, and hot indispositions of the stomach: A good deal of care is requisite on the part of the apothecary in making this conserve: the pulp is apt to carry with it some of the prickly fibres, with which the inside of the fruit is lined; if these be retained in the conserve, they will irritate the stomach, so as to occasion vomiting.

Conservé of floes. L. E.

Put the floes in water upon the fire that they may soften, taken care that they be not broken; then, the sloes being taken out of the water, press out the pulp, and mix it with three times its weight of double refined sugar into a conserve.

This preparation is a gentle astringent, and may be given as such in the dose of two or three drams. The degree of its astringency will vary according to the maturity of the sloes, and the length of time for which the conserve has been kept.

Conservé of squills.

Take of fresh squills, one ounce; double-refined sugar, five ounces. Beat them together in a mortar into a conserve.

This conserve is directed to be prepared in a small quantity, to guard against its varying in strength. It may be given to adults from half a dram to two or three. But the conserve of squills is a more uncertain and less agreeable mode of exhibiting this article, than the powder of the dried root, particularly when made into pills, or given in the form of bolus with any other conserve.

Conservé of chervil. S. E.

Take of fresh leaves of chervil, double-refined sugar, each equal parts. Beat them together into a conserve.

Chervil has by some been extolled as an useful diuretic; and this is perhaps one of the most pleasant forms under which it can be exhibited.

Conservé of millepeds. B. rum.

Take of live millepeds, one pound; double refined sugar, two pounds and an half. Beat them together into a conserve.

If the millepeds possess those virtues which some have alleged, this is perhaps one of the best forms under
der which they can be exhibited. And by children, to whom they are frequently preferred, it may be easily taken, when other forms cannot be introduced.

**Pharmacuate of Roses.** Brune.

To each pound of the conserve of roses add two drams of the diluted vitriolic acid.

This may be in some cases an useful means of increasing somewhat the subliming of the conserve of roses: But for the purposes for which the vitriolic acid is in general employed, the quantity that can thus be introduced is too inconsiderable to be of much service.

**CHAP. III. Of Juices,**

Juices are obtained from the succulent parts of plants, by including them, after being properly cut, bruised, &c. in a hair bag, and pressing them, between wooden cheeks, in the common screw-press, as long as any liquor exudes.

The harder fruits require to be previously well beaten or ground; but herbes are to be only moderately bruised, for if there are over bruised, a large quantity of the herbaceous matter will be forced out along with the juice. Hemp or woods-bags are apt to communicate a disagreeable flavour; the threads of these likewise swell in proportion as they imbibe moisture, so as in great measure to prevent the free percolation of the juice.

The fluids thus extracted from succulent fruits, both of the acid and sweet kind, from most of the acid herbs, as fuvvy grafs and water-cresses, from the acid herbs, as scrofula and wood-ferrel, from the aperient lacteal plants, as dandelion and hawkweed, and from sundry other vegetables, contain great part of the peculiar tate and virtues of the respective subjects. The juices, on the other hand, extracted from most of the aromatic herbs as thistle of mint and the fragrant Turkey balm, commonly called bain of Gilhead, have scarcely anything of the flavour of the plants, and seem to differ little from decoctions of them made in water boiled till the volatile odorous parts has been distilled. Many of the odoriferous flowers, as the lily, violet, hyacinth, not only impart nothing of their fragrance to their juice, but have it totally destroyed by the previous bruising. From want of sufficient attention to these particulars, practitioners have been frequently deceived in the effects of preparations of this class; juice of mint has been often preferred as a stimulicate, tho' it wants those qualities by which mint itself and its other preparations operate.

The juices, thus forcibly prejus from plants, differ from those which flow spontaneously, or from incisions; these last consisting chiefly of such fluids as are not diffused through the whole substance of the vegetable subject, but elaborated in distinct vessels, or secreted into particular receptacles. From poppy heads, slightly wounded, there issues a thick milky liquor, which dries by a moderate warmth into opium; whilst the juice obtained from them by preasure is of a dark-green colour, and far weaker virtue.

Juices newly expressed are generally thick, viscid, and very impure: By colature, a quantity of gross matter is separated, the juice becomes thinner, limpid, and better fitted for medicinal purposes, though as yet not entirely pure; on standing, it becomes again turbid, and apt to run into a fermentative or putrefactive state. Clarification with whites of eggs renders the compound juices more perfectly fine; but there are few that will bear this treatment without a manifest injury to their flavour, taste, and virtue.

The most effectual method of purifying and preserving these liquors, is to let the strained juices stand in a cool place till they have deposited their greater feces, and then gently pass them several times through a fine strainer till perfectly clear; when about a fourth part of their weight of good spirit of wine may be added, and the whole suffered to stand as before; a fresh sediment will now be deposited, from which the liquor is to be poured off, strained again, and put into small bottles which have been washed with spirit and dried. A little oil is to be poured on the surface, so as very nearly to fill the bottles, and the mouths closed with leather, paper, or lopped with straw, as the flasks in which Florence wine is brought to us. This process of time arises from all vegetable liquors, to escape; which air would otherwise endanger the burfting of the bottles; or, being imbibed air, render their contents rapid and foul. The bottles are to be kept on the bottom of a good cellar or vault, placed up to the necks in sand. By this method some juices may be preferred for a year or two; and others for a much longer time.

It has already been observed, that there are great difference in juices, in regard to their being accompanied in the expression with the virtues of the subjects. There are equal differences in regard to their preferring those virtues, and this independently of the volatility of the active matter, or its disposition to exsahle. Even the volatile virtue of fuvvy-grafs may by the above method be preferred almost entire in its juice for a considerable time: while the active parts of the juice of the wild cucumber quickly separate and settle to the bottom, leaving the fluid part inert. Juices of arum root, iris root, bryony root, and sundry other vegetables, throw off in like manner their medicinal parts to the bottom.

**Compound juice of Fuvvy-grafts.**

Take of the juice of garden fuvvy-grafts two pints; brooklime and water-cresses, of each one pint; Seville oranges, twenty ounces by measure. Mix them, and, after the feeces have subfided, pour off the liquor, or strain it. L.

Take of juice of garden fuvvy-grafts, water-cresses, both expressed from the fresh herbs, Seville oranges, of each two pounds; spirituous nutmeg-water, half a pound. Mix them and let them stand till the feeces have subfided, then pour off the clear liquor. E.

By this formula the Edinburgh college have rejected the brooklime and the fugar of their former editions. The fugar was certainly a very improper addition; for though it may preserve dry vegetable matters, yet when added to juices largely impregnated with watery and mucilaginous matter, it would no doubt furnish that very principle most favourable to the production of the vinous fermentation. For the compound horis radfth water they have substituted the spirituous water of nutmegs: Besides, that, this water has the same property,
Take of juice of ripe elder-berries, five pounds: purée it, with the fugar, one pound. Evaporate with a gentle heat, till it become to the confidence of pretty thick honey.

This preparation, made with or without fugar, keeps well, and proves a medicine of considerable importance as an aperient, generally promoting the natural excretions by flush, urine, or sweat. The dose is from a dram or two to an ounce or more. A spoonful, diluted with water, is usually taken in common colds at bed-time.

Infusiated juice of wolfsbane. E.

Brine the fresh leaves of aconitum; and including them in a hemp bag, strongly comprize them in a pref, so that they may give out their juice; let the juice be evaporated in open vessels in a water bath, to the confidence of pretty thick honey: An empyreuma is to be avoided by constantly ftriting the mixture towards the end of the process.

After the matter has become cold, let it be put up in glazed earthen vessels, and moistened with rectified spirit of wine.

In the same manner are prepared infusiated juices of belladonna or deadly nightshade, and hyocynamus or hembane.

In these infusiated juices, the active parts of the plant are obtained in a concentrated state, and in a condition which admits of preperation for a considerable length of time. They furnifh, therefore, a convenient form for exhibiting these articles which, in the prafice of medicine, are perhaps more frequently used in the state of infusiated juice than any other.

This is particularly the cafe with the hyocynamus, which may often be advantageously employed when opium is indicated, but disagrees with the patient.

But aconite and belladonna in general, with greater advantage, be exhibited under the form of powder made from the dried leaves.

"It is very remarkable that the London college have given no place to these articles. We cannot however help thinking, that their pharmaopeia would be enriched by introducing not only the articles themselves, but likewise these preparations, especially as they are not unfrequently prescribed by British practitioners.

Infusiated juice of hemlock. E.

Having expressed the juice of the leaves and stalks of hemlock when flowering, in the fame manner as directed for that of the aconitum, evaporate it to the confidence of pretty thin honey; when it is cooled, add of the powder of the dried leaves of the plant as much as to make it into a mass fit for forming pills. Care, however, is to be taken, that the evaporation proceed only to such length, that as much of the powder can be mixed with the infusiated juice as shall make up about a fifth part of the whole mass.

A preparation similar to this was published in Vienna by Dr Stoerk, who recommends it as an efficacious resolvent in many obilinate disorders, where the common remedies avail nothing. He observes, that small doses should always be begun with, as two grains, made into a pill twice a day; and that by gradually increasing
increasing the dose, it may be given to two, three, or even four drams a-day, and continued in such quantities for several weeks: that it may be used in safety in infancy, old age, and pregnancy: that it neither accelerates nor disturbs the circulation; neither heats, nor cools, nor affects the animal functions: that it increases the secretions, and renders the mouth moist; seldom purges; very rarely vomits; sometimes augments perspiration; often produces a copious discharge of viscid urine; but in many patients does not increase any of the sensible evacuations: that it removes obstructions and their consequences; relieves rheumatic pains, though of long continuance; cures febrile symptoms, both internal and external; and cures dropies and consumptions proceeding from sthenities: that it often dissolves catarrhs, or stops their progress, and has sometimes removed the gutta percha: that inverte cutaneous eruptions, scald heads, malignant ulcers, cancers, the malignant flor albus indicate any of its having caused any ill effects. A few persons will find relief; that he met with some persons who could not bear its effects; and that consequently there must be some latent difference in the habit, the diagnostic signs of which are at present unknown: that though it is by no means infallible any more than other medicines, yet the great number of deplorable cases that have been happily cured by it, is sufficient to recommend it to further trials. The efficacy of this medicine is confirmed by many eminent practitioners abroad; though the trials hitherto made of it in this country have not been attended with much success. Somewhat, perhaps, may depend on the time of the plant's being gathered, and the manner of the preparation of the extract.

Dr Storck himself takes notice of some mistakes committed in this respect: some have left the herb in a heap for several days, whence it is gathered, and they have become thick and mucilaginous; others have taken a very large quantity of the juice, and boiled it down in copper vessels with a great heat; by which means a strong fetor was diffused to a considerable distance, and the most efficacious parts dispersed: others, with officious care, have clarified the juice, and thus obtained a black tenacious extract, retaining but a small degree of the specific smell of the plant. The extract duly prepared, according to the above prescription, is of a greenish brown colour, and a very disagreeable smell, like that of mice. But though there be reason to believe that much of the extract used here had been ill prepared, we can by no means admit that its general inefficacy was owing to this cause: for though there are not many instances of its discovering any valuable medicinal powers, there are several of its having activity enough, even in small doses, to produce alarming symptoms.

Modern practice, however, seems to hold a middle place; being neither influenced by the extravagant encomiums of Dr Storck, nor frightened by the wary suspicions of Dr Lewis. The infused juice of the hemlock is accordingly given with freedom in a great variety of complaints, without our experiencing the wonderful effects ascribed to it by the former, or the baneful consequences dreaded by the latter. Like other preparations of this valuable herb, it is no doubt a very useful addition to our pharmacopoeia; nor does its use seem to be more hazardous than that of opium and some other narcotics.

The London college direct the infused juice of cicuta to be prepared in the same manner as that of the elder-berry, and without the addition of any of the powder. This is the most pure extract; and the powder may easily be occasionally added. They direct the cicuta to be collected as soon as the flowers appear: and at that time the leaves are most fully impregnated with their active powers.

Infused juice of black currants. L.
Infused juice of lemons. L.

These two the London college also direct to be prepared in the same manner with the elder-berry juice. And under this form the agreeable and useful acid of these vegetables, in a concentrated state, may be preserved for a considerable length of time.

**Observations on Extracts with Water.**

These extracts are prepared by boiling the subject in water, and evaporating the strained decoction to a thick consistence.

This process affords us some of the more active parts of the plants, free from the useless indissoluble earthy matter, which makes the largest share of their bulk. There is a great difference in vegetable substances, with regard to their fitness for this operation; some yielding to it all its virtues, and others scarce any. Those parts in which the sweet glutinous, emollient, cooling, bitter, astringent virtues reside, are for the most part totally extracted by the boiling water, and remain almost entire on evaporating it; whilst those which contain the peculiar odour, flavour, and aromatic quality, are either not extracted at all, or exhaled along with the menstrual. Thus gentian root, which is almost imeagably bitter, yields an extract possessing in a small volume the whole taint and virtues of the root.—Wormwood, which has a degree of warmth and strong flavour joined to the bitter, loses the first in the evaporation, and gives an extract not greatly different from the foregoing: the aromatic quality of cinnamon is dissipated by this treatment, its astringency remaining; while an extract made from the flowers of lavender and rosemary discovers nothing either of the taint, smell, or virtues of the flowers.

**General Rules for making Extracts with Water.**

1. It is indifferent, with regard to the medicine, whether the subject be used fresh or dry; since nothing that can be preferred in this process will be lost by drying. With regard to the facility of extraction, there is a very considerable difference; vegetables in general giving out their virtues more readily when moderately dried than when fresh.

2. Very
Part II.

PHARMACY.

Preparations and Compositions.

2. Very compact dry substances should be reduced into exceeding small parts, previous to the affusion of the menstruum.

3. The quantity of water ought to be no greater than is necessary for extracting the virtues of the subject. A difference herein will sometimes occasion a variation in the quality of the product; the larger the quantity of the liquor, the longer time will be requisite for evaporating it, and consequentially the more volatile parts of the subject will be dilipated. A long-continued heat likewise makes a confiderable alteration in the matter which is not volatile. Sweet substances, by long boiling with water, become nauseous; and the draffie purgatives lose their virulence, though without any remarkable separation of their parts.

4. The decoctions are to be depurated by colature; and afterwards suffered to stand for a day or two, when a confiderable quantity of sediment is usually found at the bottom. If the liquor poured off clear be boiled down a little, and afterwards suffered to cool again, it will depurate a fresh sediment, from which it may be decanted before you proceed to finish the evaporation. The decoctions of very refulnous substances do not require this treatment, and are rather injured by it; the refin subsiding along with the inactive dregs.

5. The evaporation is most conveniently performed in broad shallow vessels; the larger the surface of the liquor, the sooner will the aqueous parts exhale: This effect may likewise be promoted by agitation.

6. When the matter begins to grow thick, great care is necessary to prevent its burning. This accident almost unavoidable if the quantity be large, and the fire applied as usual under the evaporating pan, may be effectually provided against, by carrying on the infillation after the common manner, no farther than to the confluence of a syrup, when the matter is to be poured into shallow tin or earthen pans, and placed in an oven with its door open, moderately heated; which acting uniformly on every part of the liquid, will tend to reduce it to any degree of confidence required. This may likewise be more securely done, by setting the evaporating vessel in boiling water, but the evaporation is in this way very tedious.

Observations on Extracts with Rectified Spirit.

Rectified spirit of wine dissolves the essential oils and refins of vegetables, and does not readily carry off the oil in its exhalation; the heat suficient to exhale pure spirit being much less than that in which water evaporates to any considerable degree, or most essential oils distil. Hence a refulnous or spiritious extract of wormwood, contrary to that made with water contains the warmth and flavour, as well as bitterness, of the herb; one made from cinnamon possesses its aromatic virtue, as well as its astringency; and one from lavender and rosemary flowers, retains great part of their flavour and virtues; the volatile parts, which are carried off by water in its evaporation, being left behind by the spirit.

The spirit employed for this purpose should be perfectly free from any ill flavour, which would be communicated in part to the preparation; and from any admixture of phlegm or water, which would not only vary its dissolving power, but likewise evaporating towards the end of the infillation would promote the dilipation of the volatile parts of the subject. Hence also, the subject itself ought always to be dry; these substances which lose their virtue by drying, lose it equally on being submitted to this treatment with the pure spirit.

The infillation should be performed from the beginning, in the gentle heat of a water bath. It is not needful to suffer the spirit to evaporate in the air; great part of it may be recovered by collecting the vapour in common distilling vessels. If the diffilled spirit be found to have brought over any flavour from the subject, it may be advantageously referred for the same purposes again.

It is observable, that though rectified spirit be the proper menstruum of the pure volatile oils, and of the grosser refuluous matter of vegetables, and water of the mucilaginous and saline; yet these principles are, in almost all plants, so intimately combined together, that whichever of these liquors is applied at first, it will take up a portion of what is directly soluble only in the other. Hence sundry vegetables, extremely refuluous, and whose virtues consist chiefly in their resin, afford nevertheless very useful extracts with water, though not equal to those which may be obtained by a prudent application of spirit. Hence also the extracts made from most vegetables by pure spirit, are not mere refins; a part of the gummy matter, if the subject contained any such, is taken up along with the refin; an admixture of great advantage to it in a medicinal view. The spiritious extracts of several vegetable substances, as mint leaves, rhubarb, saffron, dissolve in water as well as in spirit.

Pure refins are prepared by mixing, with spiritious tincture of very refuluous vegetables, a quantity of water. The refin, incapable of remaining dissolved in the watery liquor, separates and falls to the bottom; leaving in the menstruum such other principles of the plant as the spirit might have extracted at first along with it.

Observations on Extracts with Spirit and Water.

There are sundry vegetables, particularly those of a refuluous nature, which are treated to better advantage with a mixture of water and spirit, than with either of them singly. The virtues of refuluous woods, barks, and roots, may indeed be in great part extracted by long boiling in fresh portions of water; but at the same time they suffer a considerable injury from the continued heat necessary for the extraction, and for the subsequent evaporation of so large a quantity of the fluid. Rectified spirit of wine is not liable to this inconvenience; but the extracts obtained by it from the substances here intended, being almost purely refuluous, are less adapted to general use than those in which the refin is divided by an admixture of the gummy matter, of which water is the direct menstruum.

There are two ways of obtaining these compounds or gummy-refuluous extracts: one, by using proof spirit, that is, a mixture of about equal parts of spirit and water, for the menstruum; the other, by digelling the subject first in pure spirit and then in water, and afterwards uniting into one mass the parts with:

R 2
the two menstrua have separately extracted. In some cases, where a sufficiency of gummy matter is wanting in the subject, it may be artificially supplied, by infusing the spirituous tincture to the consistence of a balsam, then thoroughly mixing with it a thick solution of any simple gum, as mucilage of gum-arabic, and drying the compound with a gentle heat. By this method are obtained elegant gummy refins, extemporaneously miscible with water into milky liquors.

Observations on extracts by long digestion.

It has been observed, that the virtues of vegetable decoctions are altered by long boiling. Decoctions or infusions of draffic vegetables, by long continued boiling or digestion, lose more and more of their virulence; and at the same time deposit more and more of a gross sediment, resulting probably from the decomposition of their active parts. On this foundation it has been attempted to obtain safe and mild preparations from fiindry virulent drugs; and some of the chemists have strongly recommended the process, though without specifying, or giving any intimation of the continuance of boiling requisite for producing the mildness in different subjects. M. Beaumé in his *Elements de pharmacie*, lately published, has given a particular account of an extract of opium prepared on this principle; of which extract, as it is alleged to be very useful in practice, it may not be improper to give a short description: And this we shall accordingly subjoin to our account of the opium purificatum of the London college.

Observations on particular extracts.

Extract of chamomile. broom tops, gentian, liquorice, black hellebore, rue, fparin. L.

Boil the article in distilled water, press out the decoction, strain it, and set it apart that the feces may subside: then boil it again in a wafer-bath saturated with sea-salt to a consistence proper for making pills.

The same kind of bath is to be used in the preparation of all the extracts, that the evaporation may be properly performed.

Extract of gentian. E.

Take of gentian root as much as you please. Having cut and bruised it, pour upon it four times its quantity of water. Boil to the consummation of one half of the liquor; and from the tincture, strain. Evaporate the decoction to the consistence of thick honey in vessels exposed to the vapour of hot water.

In preparing this and every other extract, it is necessary to keep up a constant flirring towards the end of the process, in order to prevent an empyreuma, and that the extract may be of an uniform consistence, and free of clots.

In the same manner are prepared,

Extract of the roots of black hellebore; leaves of the pulsatilla nigricans; leaves of rue; leaves of white poppies; imperfectly ripe seeds of hemlock.

All the above extracts contain the virtues of the vegetable in a state of tolerable perfection.

The extract of chamomile loses in its formation the specific flavour of the plant; but it is said to furnish a bitter remarkably antityptic, and to be given with advantage in different stomach ailments to the extent of a scruple or two, either by itself, or in conjunction with other remedies. The extract of broom tops is chiefly employed in hydropic cases; and when taken to the quantity of about a dram, is said to operate as a powerful diuretic.

The mode of preparing these extracts directed by the London and Edinburgh colleges is not essentially different: but some advantage will arise from employing the distilled water directed by the former; and the directions given by the latter with regard to the quantity of water to be used, and the degree of boiling to be employed before expression, are not without some use.

The extract is the only preparation of the pulsatilla nigricans, and it seems sufficiently well suited to be brought into this form. The extract of the white poppy-heads is not perhaps superior in any respect to opium; but to those who may think otherwise, it is convenient to preserve them in this form for preparing the syrup occasionally. The seeds of hemlock have by some been thought stronger, or at least that they produce giddiness sooner, than the leaves; but this extract has not hitherto come into general use.

Compound extract of coloquinida. L.

Take of pith of coloquinida, cut small, six drams; bocotone aloea, powdered, an ounce and a half; scammony, powdered, half an ounce; smaller cardamom seeds, husked and powdered, one dram; proof-spirit, one pint. Digest the coloquinida in the spirit, with a gentle heat, during four days. To the expressed tincture add the aloea and scammony; when these are dissolved, distill off the spirit, so that what remains may be of a consistence proper for making pills, adding the seeds towards the end of the process.

This composition answers very effectually as a cathartic, so as to be relied on in cases where the patient's life depends on that effect taking place; the dose is from fifteen grains to half a dram. The proof-spirit is a very proper menstruum for the purgative materials; disolving nearly the whole substance of the aloea and scammony, except the impurities; and extracting from the colocynth, not only the irritating resin, but great part of the gummy matter. In the former pharmacopoeias three spices were employed in this composition, cinnamon, mace, and cloves; the cardamom seeds, now introduced, are preferable on account of their aromatic matter being of a less volatile nature; though a considerable part of the flavour, even of these, is distilled during the evaporation of the phlegmatic part of the proof-spirit.

*Elaterium*. L.

Slit ripe wild cucumbers, and pass the juice, very lightly
Part II.

PHARMACY.

Extract of Peruvian bark. L.

Take of Peruvian bark, coarsely powdered, one pound; distilled water, 12 pints. Boil it for one or two hours, and pour off the liquor, which, while hot, will be red and pellicul; but, as it grows cold, will become yellow and turbid. The same quantity of water being again poured on, boil the bark as before, and repeat this boiling until the liquor, being cold, remains clear. Then reduce all these liquors, mixed together and strained, to a proper thickness, by evaporation.

This extract must be prepared under two forms: one, steep, and fit for making pills; the other hard, that it may be reducible to a powder.

Extract of Peruvian bark with the resin. L.

Take of Peruvian bark, reduced to coarse powder, one pound; rectified spirit of wine, four pints. Digest it for four days, and pour off the tincture; boil the residuum in 10 pints of distilled water to two; then strain the tincture and decoction separately, evaporating the water from the decoction, and distilling off the spirit from the tincture, until each begins to be thickened. Lastly, mix the resinous with the aqueous extract, and make the mass fit for forming into pills.

Extract of Peruvian bark. E.

The Edinburgh college, who have not given a place to any pure watery extract of the bark, direct their extract of this medicine to be prepared in the same manner as their extract of jalap, that is, almost precisely in the same manner as the extract with resin of the London college. It is, however, we think with propriety, that the London college have given a place to both extracts; for neither is without its use.

Peruvian bark is a refined drug; the resin melts out by the heat, but is not perfectly dissolved by the water; hence, in cooling, it separates, renders the liquor turbid, and in part falls to the bottom, as appears manifestly upon examining the sediment by spirit of wine. This extract might be made to better advantage by the assistance of spirit of wine, after the same manner as that of jalap; and this method the Edinburgh college have directed. But all the spirits which can be expected to be employed for this process among us, are accompanied with some degree of bad flavour; this adheres most strongly to the phlegmatic part of the spirit, which evaporating last, must communicate this ill flavour to the extract; a circumstance of very great consequence, as this medicine is designed for those whose stomachs are too weak to bear a due quantity of bark in fululence. Ten or twelve grains of the hard extract are reckoned equivalent to about half a dram of the bark itself.

In the Peruvian bark, however, we may readily distinguish two different kinds of taints, an arcingent and a bitter one; the former seems to reside principally in the resinous matter, and the latter chiefly in the gum. The watery extract is moderately strong in point of bitterness, but of the arcingency it has only a small degree. The pure resin, on the other hand, is strong in arcingency, and weak in bitterness. Both qualities.
P H A R M A C Y.

Preparations and Compositions.

are united in the extract with the resin; which appears to be the best preparation of this kind that can be obtained from this valuable drug.

Extract of cascara. L.

This extract, which is now for the first time introduced into the Pharmacopoeia of the London college, and which has not yet obtained a place in that of Edinburgh, is directed to be prepared by spirit and water in the same manner as the extract of bark with the resin. It potshes, in a concentrated state, the active constituent parts of the cascara, and has accordingly been already received into several of the best foreign pharmacopoeias. In some of these, as the Pharmacopoeia Suecica, it is a mere watery extract: but in others, as the Pharmacopoeia Rossica, the aid both of spirits and water are conjoined; and this we consider as the best preparation.

Extract of jalap. L.

Take of jalap root one pound; rectified spirit of wine, four pounds. Digest four days, and pour out the tincture. Boil the remaining magma in ten pounds of water to two pounds; then strain the decoction, and evaporate it to the consistence of pretty thin honey. Draw off the spirit from the tincture by distillation till what remains becomes thick. Then mix the liquors thus impregnated; and keeping them constantly diverted, evaporate to a proper consistence.

This extract is of useful purgative; by some thought preferable to the crude root, as being of more uniform strength, and as the dose, by the rejection of the woody parts, is rendered smaller: the mean dose is 12 grains. If the spirituous tincture were impregnated by itself, it would afford a resinous mass, which, unless thoroughly divided by proper admixtures, occasions violent griping, and yet does not prove sufficiently cathartic: the watery decoctions yield an extract which operates very weakly: both joined together, as in this preparation, compose an effectual and safe purge. This method of making extracts might be advantageously applied to several other resinous substances, as the dry woods, roots, bark, &c. A small quantity of spirit takes up the resin; and much less water than would otherwise be necessary, extracts all the other soluble parts.

In a former edition of the Edinburgh Pharmacopoeia, little fixed alkaline salt was ordered to be added to the water in which the jalap is boiled after the action of spirit: on a supposition that this would enable the water to extract more from the root than it would by itself. But, so far as the quantity of the alkaline salt could go, it had the opposite effect, impeding the action of the water. The resinous parts of the jalap are dissolved by the spirit; and little other than the gummy matter remains for water to extract. Now, if pure gum arabic be put into water along with any alkaline salt, the salt will render the water incapable of dissolving the gum; if the gum be dissolved, the addition of any alkaline salt will precipitate it.

Extract of fenna. L.

Take of fenna, one pound; distilled water, one gallon. Boil the fenna in the distilled water, adding after its decoction a little rectified spirit of wine. Evaporate the strained liquor to a proper thickness.

This extract had no place in our former pharmacopoeias, but may be considered as an useful addition.

The resinous parts of fenna are in so small a proportion to the gummy, that they are readily boiled out together. The spirit may be added when the decoction is reduced to one half or three pints. This extract is given as a gentle purgative from 10 grains to a scruple; or, in less quantity, as an affiant to the milder laxatives.

Purified opium. L.

Take of opium, cut into small pieces, one pound; proof spirit of wine, 12 pints. Digest the opium with a gentle heat, stirring now and then till it be dissolved, and filter through paper. Dilute the tincture so prepared, to a proper thickness.

Purified opium must be kept in two forms; one soft, proper for forming into pills; the other hard, which may be reduced into powder.

Opium was formerly purified by means of water; and in this state it had the name in our pharmacopoeia of extractum thebaicum. But proof spirit has been found, by experiments, to be the best menstruum for opium, having dissolved three-fourths of dried opium, which was much more than was taken up either by rectified spirit or water. Hence we thus reduced more entirely the constituents of opium free from any adhering impurities: but it has been imagined that some particular advantages arise from the parts which are extracted by water, especially after long digestion; and accordingly the following extract of opium has been recommended by Mr Beaumé.

Extract of opium prepared by long digestion.

Let five pounds of good opium, cut in pieces, be boil-ed about half an hour, in 12 or 15 quarts of water: strain the decoction, and boil the remainder once or twice in fresh water, that so much of the opium as is dissoluble in water may be got out. Evaporate the strained decoction to about six quarts; which being put into a tin censer, placed in a sand-bath, keep up such a fire as may make the liquor nearly boil, for three months together if the fire is continued day and night, and for six months if it is intermitted in the night; filling up the vessel with water in proportion to the evaporation, and scraping the bottom with a wooden spatula from time to time, to get off the sediment which begins to precipitate after some days digestion. The sediment needs not to be taken out till the boiling is finished; at which time the liquor is to be strained when cold, and evaporated to an extract of a due consistence for being formed into pills.

The author observes, that by keeping the liquor strongly boiling, the tedious process may be considerably expedited, and the six months digestion reduced.
P H A R M A C Y.

Preparations and Compositions.

to four months; that in the beginning of the digestion, a thick, viscous, oily matter rises to the top, and forms a tenacious skin as the liquor cools; this is supposed to be analogous to crystals. As the liquid cools: that the quantity of resins matter precipitated during the digestion, he obtained a dram of the liquor being then further evaporated in a water-bath to a proper consistence. In this extract, we have one of the Strongest vegetable bitters in its most concentrated state: and though, it is not perhaps to be considered as superior to the extract of gentian, yet it furnishes a good variety, and is a more agreeable form for exhibiting the wormwood than that of strong tincture.

Extract of wormwood. Succ.

This is directed to be prepared from the roots of the dandelion, collected early in the spring, or late in the autumn, in the same manner as the extractum abedfthinii. And as far as the dandelion really possesses a resolvent, aperient, or diuretic power, it furnishes a convenient form for obtaining these effects from it. But as the dandelion is well known to abound with a milky juice, it is probable that the activity of the medicine would be increased from employing spirit also in the extraction of its medical virtues.

Water extract of aloes. Succ.

Take of hepatic aloes one pound ; cold spring-water, four pounds; juice of citrons, one pound. Macerate them in a glass vessel for one or two days, shaking the vessel from time to time. When the resinous and succulent parts have subsided, pour off the liquor: and to the residuum add fresh water, till by this treatment it obtains a little impregnation. Let the strained liquors be then evaporated in a warm bath to the consistence of honey.

Although aloes are perhaps upon the whole a better medicine, in their crude state, where the gummy and resinous matters are united, than in those preparations where either is retained separately, yet the gummy extract which is thus obtained is at least less disagreeable having little smell or taste, while at the same time, it is a very powerful purgative: hence it may be usefully employed at least, on some occasions.

Gummy extract of myrrh. Brun.

Take of myrrh, half a pound; spring water, four pounds. Let the myrrh be dissolved by gentle digestion and repeated agitation of the vessel for four or five days: let the water simmer above the myrrh be then poured off, strained, and evaporated to the consistence of an extract.

This
This watery extract of myrrh may be useful in some cases, as being much deprived of the heating qualities which it has in its crude state; and if it furnishes us in phthisis pulmonary with that useful remedy which some imagine, it may probably be most advantageously exhibited under this form.

Refined liquorice. Dán.

Take all your quantity of Spanish liquorice, cut it into small fragments, disolve it in tepid water, and strain the solution. Let the liquor be poured off from the feculent part after it has subsided, and infused by a gentle heat.

The extract of liquorice already mentioned, when it is prepared with due skill and attention, is unquestionably an article superior to this; but it is very rarely met with in the shops of our druggists or apothecaries as prepared by themselves. In its place they very commonly employ either the extract brought from Spain, or that prepared by the makers of liquorice at home; both of which very commonly abound with impurities. It has even been said, that a portion of sand is not infrequently mixed with it to increase the weight; but whether the impurities arose from this cause, or from the slovenly mode of preparing it, considerable advantage must arise from freeing it from all these before it is employed for any purpose in medicine. And in modern practice it is frequently used, not only in troches and pills, but also for suspending powders in waters; such as the powder of Peruvian bark: and the powder of bark, when thus suspended, is in general taken more readily by children than in any other form. Hence considerable advantage must arise from a proper and easy mode of purifying it, which the above process affords. We are of opinion, therefore, that although a place be with propriety given to the extract of liquorice prepared by the apothecaries themselves, refined liquorice ought also to be introduced into our pharmacopoeias; and it would be very convenient to keep it in the shops in a soft condition fit for making pills, as it would not only answer that purpose but admit of a ready solution in water when requisite. To this convenience, indeed an objection occurs, from its being apt to grow mouldy; but this may be effectually prevented by the addition of a small proportion of spirit.

Besides the extracts which we have here selected from the foreign pharmacopoeias, many others also still retain a place in several of these; such, for example, as the extradum crinice, acenfie, bronia, cardui, centaurii, cocklebread, croi, &c. Several of these had formerly a place in our pharmacopoeias, but are now with propriety rejected; because, where these substances are to be employed, they may with much more advantage be exhibited under other forms. And, indeed, although under the form of extract we have a condensation of some active principles, yet by the action of fire others are very apt to be lost. Hence, where any article can be conveniently exhibited in substance, that form is in general preferable; and recourse should be had to extracts only with a view to some particular intention. Our colleges therefore have with propriety diminished the number of them; and even those which they have adopted are but seldom to be had recourse to in preference to other forms. In the formation of many of these extracts, retained by the foreign colleges, the most valuable principles are either entirely digested or destroyed by the fire. We think, however, that advantage may sometimes be obtained from adopting these which are here selected.

The chapter on extracts and refining in the London pharmacopoeia is concluded with the two following general directions:

1. All the extracts, during the time of infpissation must be gently agitated.
2. On all the softer watery extracts, a small quantity of spirit of wine must be sprinkled.

CHAP. V. Expressed Oils.

Expressed oils are obtained chiefly from certain feeds and kernels of fruits, by thoroughly pounding them in a stone mortar, or where the quantities are large, grinding them in mills, and then including them in a canvas bag, which is wrapped in a hair-cloth, and strongly pressed between iron plates. The canvas, if employed alone, would be squeezed to close the plates of the press as to prevent the oil from running down; by the interposition of the hair-cloth a free passage is allowed it.

Sundry machines have been contrived both for grinding the subject and pressling out the oil, in the way of business. To facilitate the expression, it is usual to warm either the plates of the press, or the subject itself after the grinding, by keeping it flitting in a proper vessel over the fire; the oil, liquefied by the heat separates more freely and more plentifully. When the oil is designed for medicinal purposes, this practice is not to be allowed; for heat, especially if its degree be sufficient to be of any considerable advantage for promoting the separation, renders the oil less soft and palatable, impresses a disagreeable flavour, and increases its disposition to grow rancid: hence the colleges both of London and Edinburgh expressly require the operation to be performed without heat.

Nor are the oils to be kept in a warm place after their expression. Exposed for a few days to heat no greater than that of the human body, they lose their emollient quality, and become highly rancid and acrimonious. Too much care cannot be taken for preventing any tendency to this acid irritating state in medicines, so often used for abating immoderate irritation.

So much are these oils disposed to this injurious alteration, that they frequently contradict an acrimony and rancidity while contained in the original subjects. Hence great care is requisite in the choice of the uncoarse feeds and kernels, which are often met with very rancid; almonds are particularly liable to inconveniences of this kind.

Expressed oils are prepared for mechanic uses from sundry different subjects, as nuts, poppy-seed, hemp-seed, rape-seed, and others. Those directed for medicinal purposes in the London and Edinburgh pharmacopoeias are the following:

Oil of almonds. L. E.

Pound fresh almonds, either sweet or bitter, in a mortar, then press out the oil in a cold press.
In the same manner is to be expressed oil of linseed and oil of mustard-seed.

The oil of almonds is prepared from the sweet and bitter almonds indifferently, the oils obtained from both sorts being exactly the same. Nor are the differences of the other oils very considerable, the distinguishing qualities of the subjects not residing in the oils that are thus obtained by expression. The oil of linseed acquires indeed some peculiarities from containing a portion of vegetable mucilage; but the oil of mustard-seed is as soft, insipid, and void of pungency, as that of sweet almonds, the pungency of the mustard remaining entire in the cake left after the expression. The several oils differ in some of their properties from each other; but in medicinal qualities they appear to be all nearly alike, and agree in one common emollient virtue. They soften and relax the solids, and obtund acrimonious humours; and thus become serviceable internally in pains, inflammations, heat of urine, heart-fails, tickling coughs, &c. in gleeters, for lubricating the integuments, and promoting the ejection of indurated fces; and in external applications, for tension and rigidity of particular parts. Their common dose is half an ounce; in some cases they are given to the quantity of three or four ounces. The most commodious forms for their exhibition we shall see hereafter in the chapter of Emulsions.

Cafier oil. L.

This oil is directed by the London college to be prepared in the same manner as that of almonds, the seeds or nuts being taken from the hulks before putting them into the mortar. Palm Chrifti, or caltor oil, (See Oleum Palma Chrifi, and Ricinus), is a gentle and useful purgative: it generally produces its effects without griping, and may be given with safety where acid purgatives are improper. With adults, from half an ounce to an ounce is generally requisite for a dose. This article, however, is very seldom prepared by our apothecaries, being in general imported under the form of oil from the West Indies: hence the Edinburgh college have not mentioned it among their preparations, but merely given it a place in their list of the materia medica. But when our apothecaries prepare it for themselves, they are more certain of obtaining a pure oil, and one too obtained without the aid of heat, which is often employed, and gives a much inferior oil. It is therefore with propriety that the London college have given directions for the preparation of it by the apothecary himself. But even the London college have not thought it necessary to give directions for the preparation of the expressed oils, which, as well as the oleum ricini, are also introduced into the list of the materia medica by the Edinburgh college.

Expressed oil of bay berries.

These also are principally considered as possessing only an emollient virtue; but as far as they have been supposed to exert any peculiar qualities, these we have

Vol. XIV.
oils almost pure, and nearly similar to those which are obtained from them by distillation. The essential oils, in which the fragrance and aromatic warmth of the fruits reside, are contained in numerous little vesicles, which may be distinguished by the naked eye, spread, all over the surface of the peel. If the rind be cut in slices, and the slices separately doubled or bent in different parts, and squeezed between the fingers, the vesicles burst at the bending, and discharge the oil in a number of fine slender jets. A glass plate being set upright in a glass or porcelain vessel, and the slices squeezed against the plates, the little jets unite into drops upon the plate, and trickle down into the vessel beneath. But though this process affords the true native oil in the same state wherein it existed in the subject, unaltered by fire or other agents, it is not practicable to advantage unless where the fruit is very plentiful, as only a small part of the oil it contains can thus be extracted or collected.

The oil is more perfectly separated by rubbing the rind upon a lump of sugar. The sugar, by the inequality of its surface, produces the effect of a rasp in tearing open the oily vesicles, and in proportion as the vesicles are opened the sugar imbibles the oil. When the outward part of the lump is sufficiently moistened, it is scraped off, and the operation continued on the fresh surface. The oil thus combined with the sugar is fit for most of the uses to which it is applied in a fluid state. Indeed the pure essential oils obtained by distillation are often purposely mixed with sugar to render their use the more commodious.

**Essential oils.**

Essential oils are obtained only from odoriferous substances; but not equally from all of this class, nor in quantity proportional to their degree of odour. Some, which, if we were to reason from analogy, should seem very well fitted for this process, yield extremely little oil, and others none at all. Roses and camomile flowers, whose strong and lasting smell promises abundance, are found upon experiment to contain but a small quantity; the violet and jasmine flower, which perfume the air with their odour, lose their smell upon the gentlest cohesion, and do not afford the least perceptible mark of oil on being distilled unless immense quantities are submitted to the operation at once; while faviol, whose disagreeable scent extends to no great distance, gives out the largest proportion of oil of almost any vegetable known.

Nor are the same plants equally fit for this operation when produced in different soils or seasons, or at different times of their growth. Some yield more oil if gathered when the flowers begin to fall off than at any other time. Of this we have examples in lavender and rue; others, as fage, afford the largest quantity when young, before they have sent forth any flowers; and others, as thyme, when the flowers have just appeared. All fragrant herbs yield a larger proportion of oil when produced in dry soils and warm summers than in opposite circumstances. On the other hand, some of the disagreeable strongly-scented ones, as wormwood, are said to contain most in rainy seasons and when growing in moist rich grounds.

Several of the chemists have been of opinion, that herbs and flowers, moderately dried, yield a greater quantity of essential oil than if they were distilled when fresh. It is supposed, that the oil being already blended in fresh plants, with a watery fluid, great part of it remains diffused through the water after the distillation, divided into particles too minute to unite and be collected; whereas in drying, the oily parts, on the exhalation of the moisture which kept them divided and dispersed, run together into globules, which have little disposition to mingle with watery fluids, and easily separate from the water employed in the distillation.

This theory, however, does not appear to be quite satisfactory; for though the oil is collected in the subject into distinct globules, it does not rise in that form, but is resolved into vapour, and blended and coagitated by the heat with the vapour of the water; and if the oil in a dry plant is less disposed to unite with aqueous fluids than in a fresh one, the dry ought to yield a weaker infusion than the fresh; the contrary of which is generally found to obtain. As the oil of the dry plant is most perfectly extracted and kept diffused by the water before the distillation, it is difficult to conceive any reason why it should have a greater tendency to separate from the water afterwards.

The opinion of dry plants yielding most oil seems to have arisen from an observation of Hoffman, who has probably been misunderstood: "A pound (he says) of dry spike flowers yields an ounce of oil, but if they were distilled fresh they would scarcely yield above half an ounce; and the cafe is the same in balm, fage, &c. The reason is, that in drying the watery humidity exhales; and as from two pounds of a fresh plant we do not obtain above one pound of dry, and little of the fubtile oil evaporates in the drying, it follows, that more oil ought to be afforded by the dry than by the fresh." The meaning of which seems to be no more than this, that if two pounds of a fresh plant are by drying reduced to one without any loss of the oil, then the one pound dry ought to be equivalent to the two fresh. A late writer quotes an experiment of Neumann, which appears to be misunderstood in the same manner; for Neumann, in the place referred to, says only that dry wormwood is found to yield much more oil than an equal weight of the fresh plant. Trials are yet wanting in which fresh and dry plants have been brought to a fair comparison, by dividing a quantity of the subject into two equal weights, and distilling one while fresh, and the other after it has been carefully and moderately dried.

But whatever may be the effect of moderate excitation, it is certain, that if the drying be long continued, the produce of oil will be diminished, its colour altered, and its smell impaired.

With regard to the proportion of water to be employed, if whole plants moderately dried are used, or the havings of wood, as much of either may be put into the vessel as, lightly prefled, will occupy half its cavity: and as much water may be added as will fill two thirds of it. The water and ingredients altogether should never take up more than three-fourths of the full; there should be liquor enough to prevent any danger of an empyreuma, but not so much as to be too apt to boil over into the receiver.
The maceration should be continued so long that the water may fully penetrate the parts of the subject. To promote this effect, woods should be thinly shaved across the grain or fawn, roots cut transversely into thin slices, barks reduced into coarse powder, and seeds slightly bruised. Very compact and tenacious substances require the maceration to be continued a week or two, or longer; for those of softer and looser structure, two or three days are sufficient; while some tender herbs and flowers not only stand in no need of maceration, but are even injured by it.

Whether the addition of sea-salt, which some have recommended, be of any real service, is much to be doubted. The ufs generally assigned to it are, to penetrate and unlock the texture of the subject; more effectually than simple water could do, and to prevent the fermentation or putrefaction which the matter is apt to run into during the length of time for which the maceration is often continued. But sea-salt seems rather to harden and condense, than to soften and resolve, both vegetable and animal substances; and if it prevents putrefaction, it must, on very strict account, be injurious rather than of service. The resolution here aimed at approaches near to a beginning putrefaction; and saline substances, by retarding this, prolong the maceration far beyond the time that would otherwise be necessary. It is in the power of the operator, when he perceives the process coming near this pitch, to put a stop to it at pleasure, by proceeding immediately to distillation. By this means the whole affair will be finished in a very little time, with at least equal advantage in every other respect provided the manual operations of pounding,揉ing, and the like, which are equally necessary in either case, be minutely complied with.

Bodies of a very viscous and compact texture were directed, in the Edinburgh pharmacopoeia, to be fermented for some days with a little yeast. Half their quantity of water is sufficient for performing the fermentation; as much more as is necessary is to be added afterwards before the distillation. This process undoubtedly promotes the resolution of the subject, and the extraction of the oil. It rarely happens, however, that affinities of this kind are perfect. Particular care must be had not to continue the fermentation too long; or to give a bad flavour to the oil by an ill-chozen ferment, or using too large a quantity of any.

Some chemists pretend, that by the addition of salts and acid spirits they have been enabled to gain more oil from certain vegetable matters than could possibly be got from them without such assistance. Experiments made on purpose to settle this point seem to prove the contrary: this at least is constantly found to be true, that where there is any reason to think the produce greater than usual, the quality of the oil is proportionally injured. The quantity of true essential oil in vegetables can by no means be increased, and what is really contained in them may be easily separated without any addition of this kind. All that saline matters can do in this respect is to make the water susceptible of a greater degree of heat than it can sustain by itself, and thus enable it to carry up a gross undigested matter not volatile enough to rise with pure water; this gross matter, mingling with the pure oil, increases the quantity, but at the same time must necessarily debase its quality. And indeed, when the pure water alone is used, the oil which comes over during the end of the operation is remarkably less fragrant, and of a thicker consistence, than that which rises at the beginning; distilled a second time, with a gentle heat, it leaves a large quantity of gross almost iniquitous refrinous matter behind.

The choice of proper instruments is of great consequence for the performance of this process to advantage. There are some oils which pass freely over the swan neck of the head of the common still; others, less volatile, cannot easily be made to rise so high. For obtaining these last, we should recommend a large low head, having a rim or hollow canal round it. In this canal the oil is detained on its first ascent, and thence conveyed at once to the receiver, the advantages of which are sufficiently obvious.

With regard to the fire, the operator ought to be expeditious in raising it at first; and to keep it up, during the whole process, of such a degree that the oil may freely distil; otherwise the oil will be exposed to an unnecessary heat; a circumstance which ought as much as possible to be avoided. Fire communicates to all these oils a disagreeable impregnation, as is evident from their being much less grateful when newly distilled, than after they have stood for some time in a cool place; the longer the heat is continued, the more alteration it must produce in them.

The greater number of oils require for their distillation the heat of water strongly boiling; but there are many also which rise with a heat considerably less; such as those of lemon and citron-peel, of the flowers of lavender and rosemary, and of almost all the more odoriferous kinds of flowers. We have already observed, that these flowers have their fragrance much injured, or even destroyed, by beating or bruising them; is impaired also by the immersion in water in the present process, and the more so in proportion to the continuance of the immersion and the heat: hence oils, distilled in the common manner, prove much less agreeable in smell than the subjécts themselves. For the distillation of substances of this kind another method has been contrived; instead of being immersed in water, they are exposed only to its vapour. A proper quantity of water being put into the bottom of the still, the odoriferus herbs or flowers are laid lightly in a basket, of such a size that it may enter into the still, and rest against its sides, just above the water. The head being then fixed on, and the water made to boil, the steam, percolating through the subjéct, imbibes the oil, without impairing its fragrance and carries it over to the receiver. Oils thus obtained preserve the odour of the subjéct in an exquisite degree, and have nothing of the disagreeable scent perceptible in those distilled by boiling them in water in the common manner.

It may be proper to observe, that those oils which rise with a less heat than that of boiling water, are generally called, by the chemical and pharmaceutical writers, light oils; and those which require the heat of water strongly boiling, are called ponderous. We have avoided these expressions, as they might be thought to relate to the comparative gravities of the oils; with which the volatility or fixedness have no connexion. Olive oil is lighter than most of the essential
Essential oils; but the heat requisite to make it distil, exceeds that in which the heaviest essential oil distils, considerably more than the heat of boiling water exceeds that of ice.

The water employed in the distillation of essential oils always imbibes some portion of the oil; as is evident from the smell, taste, and colour, which it acquires. It cannot, however, retain above a certain quantity; and therefore, such as has been already used and consequently saturated with oil, may be advantageously employed, instead of common water, in a second, third, or any future distillation of the same subject.

Some late chemical writers recommend, not the water which comes over, but that which remains in the still, to be used a second time. This can be of no service; as confining only of such parts of the vegetable as are incapable of arising in distillation, and which, therefore only to impede the action of the water as a menstruum, and to endanger an empyreuma.

After the distillation of one oil particular care should be taken to cleanse the worm before it be employed in the distillation of a different plant. Some oils, those of wormwood and aniseeds for instance, adhere to it so tenaciously, as not to be melted out by heat, or washed off by water; the best way of clearing the worm from these, is to run a little spirit of wine through it.

Essential oils, after they are distilled, should be suffered to stand for some days, in vials loosely covered with paper, till they have lost their disagreeable fiery odour, and become limpid; then put them up in small bottles, which are to be kept quite full, closely stopt, in a cool place: with these cautions, they will retain their virtues in perfection for many years.

When carefully kept, they in time gradually lose their flavour, and become gross and thick. Some endeavours to recover them after they have undergone this change, by grinding them with about three times their weight of common salt, then adding a large proportion of water, and distilling them afresh; the purer part flies thin and limpid, possessing a great degree of the pristine smell and taste of the oil, though inferior in both respects to the original oil. This rectification, as it is called, succeeds equally without the salt; the oils, when thus altered, are nearly in the same flat with the turpentine, and other thickened oily juices, which readily yield their purer oil in distillation with water alone.

When essential oils have entirely lost their smell, some recommend adding them in the distillation of a fresh quantity of the oil of the same plant; by which means they are said to fatiate themselves anew with the odorous matter, and become entirely renovated. This practice, however, ought doubtless to be disapproved, as being no other than a specious sophilication; for it can do no more than divide, between the old and the new, the active matter which belongs to the new alone.

Essential oils medically considered, agree in the general qualities of pungency and heat; in particular virtues, they differ as much as the subject from which they are obtained, the oil being the direct principle in which the virtues, or at least a considerable part of the virtues, of the several subjects reside. Thus the carminative virtue of the warm seeds, the diuretic of juniper-berries, the emmenagogue of fiesmus, the nervine of rosemary, the stomachic of mint, the antiscorbutic of seavy grafts, the cordial of aromatics, &c. are suppos'd to be concentrated in their oil.

There is another remarkable difference in essential oils, the foundation of which is less obvious, viz. the degree of their pungency and heat. These are by no means in proportion, as might be expected, to those of the subject they were drawn from. The oil of cinnamon, for instance, is very pungent and fiery; in its undiluted state it is almost caustic; whereas cloves, a spice which in substance is far more pungent than the other, yields an oil which is far less so. This difference seems to depend partly on the quantity of oil afforded, cinnamon yielding much less than cloves, and consequently having its active matter concentrated into a smaller volume; partly on a difference in the nature of the active parts themselves; for though essential oils contain always the specific odour and flavour of their subjects, whether grateful or ungrateful, they do not always contain the whole pungency; this resides frequently in a more fixed refrinous matter, and does not rise with the oil. After the distillation of cloves, pepper, and some other spices, a part of their pungency is found to remain behind; a simple tincture of them in rectified spirit of wine is even more pungent than their pure essential oils.

The more grateful oils are frequently used for reconciling to the stomach medicines of themselves difficult. It has been customary to employ them as correctors for the refrinous purgatives; an use which they do not seem to be well adapted to. All the service they can here be of, is to make the refin fit more easily at first on the stomach; far from abating the irritating quality on which the virulence of its operation depends, their pungent oils superadd a fresh stimulus.

Essential oils are never given alone, on account of their extreme heat and pungency; which in fome is so great, that a single drop let fall upon the tongue produces a gangrenous effchar. They are readily inhibited by pure dry sugar, and in this form may be conveniently exhibited. Ground with eight or ten times their weight of sugar, they become soluble in aqueous liquors, and thus may be diluted to any alligned degree. Mucilages also render them miscible with water into an uniform milky liquor. They dissolve like wine in spirit of wine; the more fragrant in an equal weight, and almost all of them in less than four times their own quantity; these solutions may be either taken on sugar, or mixed with syrups, or the like; on mixing them with water, the liquor grows milky, and the oil separates.

The more pungent oils are employed externally against paralytic complaints, numbness, pains, and aches, cold tumors, and in other cases where particular parts require to be heated or stimulated. The tooth-ach is sometimes relieved by a drop of these almost caustic oils, received on cotton, and cautiously introduced into the hollow-tooth.
P H A R M A C Y.

Part II. Preparations and Compositions.

Essential oil of aniseed. L. E.

This oil poizes the taste and smell of the aniseeds in perfection. It is one of the mildest of the distilled oils; 15 or 20 drops may be taken at a time without danger, though common practice rarely goes so far as half this number. Its smell is extremely durable and diffusive; milk drawn from the breast after taking it, is found impregnated with its odour; and possibly this may be, in part, the foundation of the pectoral virtues usually ascribed to it; in flatulences and colics, it is said by some to be less effectual than the seeds themselves.

It is remarkable of this oil, that it congeals, even when the air is not sensibly cold, into a butyrous confluence: and hence, in the distillation of it, the operator ought not to be over-solicitous in keeping the water in the refrigeratory too cool: it behoves him rather to let it grow somewhat hot, particularly towards the end of the process; otherwise the oil congealing may, if it happen, as to endanger blowing off the head of the still, or at least a considerable quantity of oil will remain in it.

Essential oil of caraway seeds. L.

The flavour of this exactly resembles that of the caraway itself. It is a very hot and pungent oil: a single drop is a moderate dose, and five or six is a very large one. It is not unfrequently used as a carminative; and suppos'd by some to be peculiarly serviceable for promoting urine, to which it communicates some degree of its smell.

Essential oil of lavender flowers. L. E.

This oil, when in perfection, is very limpid, of a pleasant yellowish colour, extremely fragrant; poising in an eminent degree the peculiar smell generally admired in the flowers. It is a medicine of great use, both externally and internally, in paralytic and lethargic complaints, rheumatic pains, and debilities of the nervous system. The dose is from one drop to five or six.

Lavender flowers yield the most fragrant oil, and consideribly the largest quantity of it, when they are ready to fall off spontaneously, and the leaves begin to flow themselves: the seeds give out extremely little the flowers may be separated from the root of the plant, by drying it a little, and then gently beating it: they should be immediately committed to distillation, and the procès conducted with a well-regulated gentle heat; too great heat would not only change the colour of the oil, but likewise make a disagreeable alteration in its smell.

Essential oil of the leaves of peppermint. L. E.

This poises the smell, taste, and virtues of the peppermint in perfection; the colour is a pale greenish yellow. It is a medicine of great pungency and subtility; and diffuses, almost as soon as taken, a glowing warmth through the whole system. In colics, accompanied with great coldness, and in some hysterical complaints, it is of excellent service. A drop or two are in general a sufficient dose.

Essential oil of the leaves of common mint. L. E.

This oil smells and tastes strongly of the mint, but is in both respects somewhat less agreeable than the herb itself. It is an useful stomacical medicine; and not unfrequently exhibited in want of appetite, weakness of stomach, retching to vomit, and other like disorders, when not accompanied with heat or inflammation: two or three drops, or more are given for a dose. It is likewise employed externally for the same purposes; and is an useful ingredient in the stomacical plaster of the fluxes.

Essential oil of the leaves of origanum. L.

This oil has a very pungent acrimonious taste, and a penetrating smell. It has been chiefly employed externally as an erthine and for easing pains of the teeth.
**PHARMACY.**

**Essential oil of the leaves of pennyroyal.** L.

This oil, in smell and taste, resembles the original plant; the virtues of which it likewise possesses. It is given in hyberic doses, from one to four or five drops.

**Essential oil of rosemary.** L. E.

The oil of rosemary is drawn from the plant in flower. When in perfection, it is very light and thin, pale, and almost colourless; of great fragrancy, though not quite so agreeable as the rosemary itself. It is recommended, in the dose of a few drops, in nervous and hyberic complaints. Boerhaave holds it in great esteem against epilepsies and suppressions of the ureter purgatives occasioned by weakneds and inactivity.

**Essential oil of juniper-berrics.** L. E.

This oil is a very warm and pungent one; of a strong flavour, not unlike that of the berries. In the dose of a drop or two, it proves a serviceable carminative and stomachic; in one of six, eight, or more, a stimulating, detergent, diuretic, and emmenagogue; it seems to have somewhat of the nature of the turpentine, or their distilled oil; like which it communicates a violent smell to the urine.

The oil of these berries refides partly in vessels spread through the substance of the fruit, and partly in little cells contained in the seeds: when the berry is dry, and the oil hardened into a resinous substance, it becomes visible, on breaking the seeds, in form of little transparent drops. In order therefore to obtain this oil to advantage, we ought previous to the distillation, to bruise the berry thoroughly, so as to break the seeds, and entirely lay open the oily receptacles.

**Essential oil of saffron.** L. E.

This is the most ponderous of all the known essential oils, but rises in distillation with sufficient ease: it appears limpid as water, has a moderately pungent taste, a very fragrant smell, exactly resembling that of the saffron. It stands greatly commended as a digestive, and for purifying the blood and juices; it is likewise supposed to be of service in humoral athmas and coughs. The dose is from one drop to eight or ten; though Geoffroy goes as far as twenty.

The decoction remaining after the distillation of the oil, affords by infipidation an useful extract, of a mild, bitterish, subastringent taste. Hoffman says, he has given it with great benefit, in dosis of a scruple, as a corroborative in cachectic cases, in the decline of intermitting fevers, and for abating hypochondriacal pains.

**Essential oil of savin leaves.** L. E.

Savin is one of the plants which, in former editions of the Edinburgh pharmacopoeia, were directed to be lightly fermented before the distillation: this, however, is not very necessary; for savin yields, without fermentation, and even without any such maceration, a very large quantity of oil. The oil of savin is a celebrated ureteric and emmenagogue: in cold phlegmatic habits, it is undoubtedly a medicine of great service, though not capable of performing what it has been often represented to do. The dose is, two or three drops, or more.

**Essential oil of Jamaica pepper.** E.

This is a very elegant oil, and may be used as a succedaneum to those of some of the dearer spices. It is of a fine pale colour; in flavour more agreeable than the oil of cloves, and not far short of that of nutmegs. It sinks in water, like the oils of some of the eastern spices.

**Oil of tall turpentine.** L.

Take of common turpentine five pounds; water four pints. Distil the turpentine with the water from a alembic of copper. After the distillation of the oil, what remains is yellow resin.

**Rectified oil of turpentine.** L.

Take of oil of turpentine one pound; water four pints. Distil.

The process here proposed for rectifying this oil, is not only tedious but accompanied with danger. For unless the luting be very close, some of the vapour will be apt to get through; and if this catch fire, it will infallibly burst the vessels. This rectified oil, which in many pharmacopoeias is styled zoilium, does not considerably differ in specific gravity, smell, taste, or medical qualities, from the former.

The spirit of turpentine, as this essential oil, has been styled, is not unfrequently taken internally as a diuretic and sudorific. And in these ways it has sometimes a considerable effect when taken even to the extent of a few drops only. It has, however been given in much larger doses, especially when mixed with honey. Recourse has principally been had to such doses in cases of chronic rheumatism, particularly in those modifications of it which are styled sciatica and lumbago. But they have not been often successful, and sometimes they have had the effect of inducing bloody urine.

**Animal oil.**

Take of oil of thornthorn one pound. Distil three times.

**Rectified oil of horns, or animal oil.** E.

Take of empyreumatic oil, newly distilled from the horns of animals, as much as you will. Distil with a gentle heat, in a mattras furnished with a head, as long as a thin colourless oil comes over, which is to be freed of alkaline salt and spirit by means of water.
of water. That this oil may remain limpid and good, it ought to be put up in small phials, completely filled and inverted, having previously put into each phial a few drops of water, that on inverting it the water may interpose itself between the oil and the mouth of the phial.

The quantity of oil employed in this process should be considerable: for it leaves so much black matter behind in the several distillations, that it is reduced at last to a small portion of its original quantity. It is said, that the product is rendered more limpid by mixing the oil with quicklime into a soft paste; the lime keeping down more of the gross matter than would remain without such an addition. The quicklime may here also perhaps act by extracting fixed air; to the absorption of which we are disposed to refer in some measure the spoiling of the oil on exposure to the atmosphere.

The oil was first introduced by Dippelius, whose name it has since generally borne.

Animal oils thus rectified, are thin and limpid, of a subtile, penetrating, not disagreeable smell and taste. They are strongly recommended as anodynes and antispasmodics, in doses from 15 to 20 drops. Hoffman reports, that they procure a calm and sweet sleep which continue often for 20 hours, without being followed by any languour or debility, but rather leaving the patient more alert and cheerful than before; that they procure likewise a gentle sweat, without increasing the heat of the blood: that given to 20 drops or more on an empty stomack, six hours before the accession of an intermittent fever, they frequently remove the disorder; and that they are likewise a very gentle remedy in inveterate and chronical epilepsies and in convulsive motions, especially if given before the usual time of the attack, and preceded by proper evacuations.

The empyreumatic oils of vegetables, rectified in the same manner by repeated distillations, suffer a like change with the animal losing their dark colour and offensive smell, and becoming limpid, penetrating, and agreeable: in this state they are fupposed, like the animal oil, to be anodyne, antispasmodic, and diaphoretic or sudorific. It is observable, that all the empyreumatic oils diffuse in spirit of wine, and that the oftener they are rectified or redistilled, they diffuse the more readily; a circumstance in which they differ remarkably from essential oils, which, by repeated distillations, become more and more difficult of solution.

How far these preparations really possess the virtues that have been ascribed to them, has not yet been sufficiently determined by experience; the tediousness and trouble of the rectification having prevented their coming into general use, or being often made. They are liable also to a more material inconvenience, in regard to their medicinal use, precariousness in their quality; for how perfectly ever they be rectified, they gradually lose in keeping the qualities they had received from that process, and return more and more towards their original fetid state.

Oil of salt of amber. E.

Take equal parts of amber reduced to a powder and of pure sand. Mix them and put them into a glass retort, of which the mixture may fill on half: then adapt a large receiver, and distil in a sand furnace, with a fire gradually increased. At first a spirit will come over, with some yellow oil; then more yellow oil, along with a little salt; and on raising the heat, more of the salt, with a reddish and black coloured oil. When the distillation is finished, empty the liquor out of the receiver; and having collected together the salt which adheres to the fides, dry it by gentle preheur between the folds of blotting paper; then purify it by solution in warm water and by crystallization.

Rectified oil of amber.

Distil the oil in a glass retort with six times its quantity of water till two thirds of the water have passed into the receiver; then separate the rectified oil from the water, and keep it for use in close flate vessels. E.

Take of oil of amber one pound. Distil three times L.

The London college introduce their directions for the preparation of the salt and oleum succini at an after part of their work, under the head of fates. Here we may only observe, that they direct it to be prepared from the amber alone, without the intervention of sand. But this makes no essentia difference in the article when prepared.

The Edinburgh college have rejected what was formerly called the spirit, as being nothing else than the watery parts, fraught with the inert impurities of the bitumen and a very small portion of the salt. In the distillation of amber, the fire must for some time be continued gentle, scarce exceeding the degree at which water boils, till the aqueous phlegm and thin oil have arisen; after which it is to be slowly increased. If the fire were urged hastily, the amber would swell up, and rise in its whole substance into the receiver, without undergoing the required decomposition or separation of its parts. When sand or similar intermedias are mixed with it, it is less subject to this rarefaction, and the fire may be raised somewhat more expeditiously; though this little advantage is perhaps more than counterbalanced by the room which the sand takes up in the retort.

Our chemists generally leave the receiver unluted, that it may be occasionally removed as the salt rises and concretes in the neck of the retort; from whence it is every now and then scraped out to prevent the oil from carrying it down into the receiver. When a gros thick oil begins to arise, and no more salt appears, the distillation is ftopt, though it might perhaps be continued longer to advantage.

Mr Pott informs us (in a curious dissertation on the salt of amber, published in the ninth volume of the Memoirs of the Academy of Sciences of Berlin), that the Prussian workmen, who prepare large quantities of this salt for exportation, from cuttings and small pieces of amber, perform the distillation without any intermediate, and in an open fire: that sweeping out the salt from the neck of the retort being found too troublesome, they suffer the oil to carry it down into the receiver, and afterwards separate it by means of bibulous paper, which imbibles the oil, and leaves the salt dry; which paper is afterwards squeezed and distilled; that they continue the distillation till all that can be forced...
forced over has arisen, taking care only to catch the last thick oil in a separate receiver; and that from this they extract a considerable quantity of salt, by shaking it in a strong vessel with three or four fresh portions of hot water, and evaporating and crystallizing the filtered waters.

The spirit of amber, so called, is no more than a solution of a small proportion of the salt in phlegm or water; and therefore is very properly employed for dissolving the salt in order to its crystallization.

The salt, freed from as much of the oil as spongy paper will imbibe, retains so much as to appear of a dark brown colour. Mr Pott says, the method he has found to succeed best, and with least loss, is to dissolve the salt in hot water, and put into the paper, through which the solution is to be filtered, a little cotton slightly moistened with oil of amber: this, he says, detains a good deal of the oil of the salt, and the solution passes through the more pure. The liquor being evaporated with a very gentle heat, of about twenty times its own weight; of boiling purified by a reflux-bath, and then to shoot, the first crystals prove transparent, with a slight yellowish tinge; but those which follow, are brown, oily, and bitter, and are therefore to be further separated in the same manner. The whole quantity of crystals amounts to about one thirtieth of the weight of the crude amber employed. By sublimation from this salt, as directed in former editions of the Edinburgh pharmacopoeia, the salt is thought to be more perfectly and more expeditiously purified: Mr Pott objects to sublimation, that a part of the salt is decomposed by it, a coaly matter being left behind, even though the salt was previously purified by crystallization; it may be presumed, however, that this coal proceeds rather from the burning of some remnants of the oily matter, than from the decomposition of any part of the true salt.

Pure salt of amber has a penetrating, subastringent, acrid, taste. It dissolves both in water and in rectified spirit; though not readily in either, and scarcely at all in the latter without the assistance of heat; of cold water in summer, it requires for its solution about twenty times its own weight; of boiling water only about twice its weight. Exposed in a glass vessel, to a heat little greater than that of boiling water, it first melts, then rises in a white fume, and concretes again in the upper part of the glass into fine white flakes, leaving, unleas it was perfectly pure, a little coaly matter behind. It effervesces with alkalis both fixed and volatile, and forms with them neutral compounds much resembling those compouded of the same alkalis and vegetable acids. Mixed with acid liquors, it makes no sensible commotion. Ground with fixed alkali salts it does not exhale any unionous odour. By these characters, it is conceived this salt may be readily distinguished from all the other matters that have been mixed with or vended for it. With regard to its virtue, it is accounted aperient, diuretic, and, on account of its retaining some portion of the oil, antihysteric: Boerhaave gives it the character of diureticum et antihystericum princeps. Its great price, however, has prevented its coming much into use; and perhaps its real virtues are not equal to the opinion generally entertained of them.

The rectified oil has a strong bituminous smell, and a pungent acid taste. Given in a dose of ten or twelve drops, it heats, stimulates, and promotes the fluid secretions: It is chiefly celebrated in hysterical disorders, and in deficiencies of the uterine purgations. Sometimes it is used externally, in liniments for weak or paralytic limbs and rheumatic pains. This oil differs from all those of the vegetable kingdom, and agrees with the mineral petroleum, in not being soluble either in its rectified or unrectified state, by spirit of wine, fixed alkaline licitria, or volatile alkaline spirits; the oil, after long digestion or agitation, separating as freely as common oil does from water.

Oil of wine. L.

Take alcohol, vitriolic acid, of each one pint. Mix them by degrees, and distil; taking care that no black form passes into the receiver. Separate the oily part of the distilled liquor from the volatile vitriolic acid. To the oily part add as much water of pure kali as is sufficient to take away the phosphoric smell: then dilute the ether with a gentle heat. The oil of wine remains in the retort, swimming on the watery liquor, from which it is to be separated.

Some caution is requisite in mixing the two liquors, that the consequent heat and ebullition, which would not only dissipate a part of the mixture, but hazard the breaking of the vessel and the hurt of the operator, may be avoided. The securest way is to add the vitriolic acid to the spirit of wine by a little at a time, waiting till the first addition be incorporated before another quantity be put in. By this, the ensuing heat is inconsiderable, and the mixture is effected without inconvenience.

Essential oil of wormwood. Roff.

Let the fresh leaves of wormwood slightly dried be macerated with a sufficient quantity of water, and then subject to distillation; and let the oil which comes over be separated from the water which accompanies it.

This is one of the more ungrateful oils: it smells strongly of the wormwood, and contains its particular nauseous taste, but has little or nothing of its bitterness, this remaining entire in the decoction left after the distillation: its colour, when drawn from the fresh herb is dark green; from the dry, a brownish yellow. This oil is recommended by Hoffman as a mild anodyne in phasmoid contractions; for this purpose, he directs a dram of it to be dissolved in an ounce of rectified spirit of wine, and seven or eight drops of the mixture taken for a dose in any convenient vehicle. Boerhaave greatly commends, in tertian fevers, a medicated liquor composed of about seven grains of this oil ground first with a dram of sugar, then with two draughts of the fluid of wormwood, and afterwards dissolved in fix ounces of the distilled water of the same plant: two hours before the fit is expected, the patient is to bathe his feet and legs in warm water, and then to drink two ounces of the liquor every quarter of an hour till the two hours are expired: by this means, he says, all cases of this kind are generally cured with ease and safety; provided there be no feverishness or dampness.

The oil of wormwood is employed chiefly as a vermifuge; and for this purpose is sometimes applied both externally to the belly, and taken
PHAR

MACY.

Preparations and Compositions.

Part II.

taken internally; it is most conveniently exhibited in
the form of pills, into which it may be reduced by
mixing it with crumb of bread.

In the same manner with the oil of wormwood, the
following oils, mentioned on the authority of the
pharmacopoeia Rossica, are also directed to be prepa-
red.

Essential oil of orange flowers. Ross.

Essence of lemons.

Of these essential oils, as existing in a separate state
in the growing vegetable, we have already offered
some observations. They are obtained in a very pure
state by distillation. They are now rejected from our
pharmacopoeias, being employed rather as perfumes
than as medicines. This is particularly the case with
the essence of lemons, which is a pleasant oil, of a fine
smell, very nearly as agreeable as that of the fresh peel;
it is one of the lightest and most volatile essential oils
we have, perfectly limpid, and almost colourless. It
is taken in doses of two or three drops, as a cordial, in
weakness of the stomach, &c; though more frequently
for external application; but the essential oil is meant
to be used internally.

It is a very pungent oil, of a strong not ungrateful
smell, resembling that of the flowers: its colour is yel-
low, with a cast of greenish or brown. It is sometimes
given in the dose of a few drops, as a carminative, in
hysterical disorders, and likewise as a vermifuge; it may
be conveniently made into pills with crumb of bread.

Oil of cinnamon. Ross.

This valuable oil is extremely hot and pungent, of a
most agreeable flavour, like that of the cinnamon it-
self. In cold langui[es, and debilities of the ner-
vous system, it is one of the most immediate cordials
and restoratives. The dose is one, two, or three drops;
which must always be carefully diluted by the medita-
tion of sugar, &c: for so great is the pungency of this
oil, that a single drop let fall upon the tongue, undi-
luted, produces as Boerhaave observes, a gangrenous
either. In the distillation of this oil, a smart fire is
required; and the low head, with a channel round it,
recommended for the distillation of the less volatile
oils, is particularly necessary for this, which is one of
the least volatile, and which is afforded by the spice
in exceeding small quantity. The distilled water retains
no small portion of the oil; but this oil being very
pungent, great part of it sublimes from the water,
on standing for two or three weeks in a cool place.

Essential oil of fennel seeds. Ross.

The oil obtained from sweet fennel seeds is much
more elegant and agreeable than that of the common
fennel. It is one of the mildest of these preparations;
it is nearly of the same degree of warmth with that
of aniseeds; to which it is likewise similar in flavour,
though far more grateful. It is given from two or
three drops to ten or twelve, as a carminative, in cold
indispositions of the stomach; and in some kinds of
coughs for promoting expectoration.

Essential oil of rhodium. Ross.

This oil is extremely odoriferous, and principally
employed as a perfume in scenting pomatums, and the
like. Custom; as not yet received any preparation of
this elegant aromatic wood into internal use among
us.

Essential oil of mace. Ross.

The essential oil of mace is moderately pungent,
very volatile, and of a strong aromatic smell, like that
of the spice itself. It is thin and limpid, of a pale
yellowish colour, with a portion of thicker and dark-
er coloured oil at the bottom. This oil, taken inter-
ally to the extent of a few drops, is celebrated in
vomiting, flegelitis, and colic pains; and in the same
complaints it has also been advised to be applied exter-
ally to the umbilical region. It is however, but rare-
ly to be met with in the shops.

Essential oil of marjoram. Ross.

This oil is very hot and penetrating, in flavour not
near so agreeable as the marjoram itself: when in per-
fection, it is of a pale yellow colour; by long keeping,
Essential oil of nutmegs. Ross.

The essential oil of nutmegs possesses the flavour and aromatic virtues of the spice in an eminent degree. It is similar in quality to the oil of mace, but somewhat less grateful.

Essential oil of rue. Ross.

The oil of rue has a very acid taste, and a penetrating smell, resembling that of the herb, but rather more unpleasant. It is sometimes made use of in hysterical disorders and as an anthelmintic; and also in epilepsy proceeding from a relaxed state of the nerves. Rue yields its oil very sparingly. The largest quantity is obtained from it when the flowers are ready to fall off, and the seeds begin to show themselves; suitable maceration, previous to the distillation, is here extremely necessary.

Essential oil of sassafras. Ross.

Savory yields on distillation a small quantity of essential oil, of great subtilty and volatility; and it is unquestionably an active article, but among us it is not employed in medicine.

Essential oil of tansy. Ross.

Tansy yields on distillation an oil of a greenish colour inclining to yellow. It smells strongly of the herb, and possesses at least its aromatic property in a concentrated state.

Oil of wax. Dan.

Melt yellow bees wax with twice its quantity of sand, and distil it in a retort placed in a sand-furnace. At first an acid liquor rises, and afterwards a thick oil, which sticks in the neck of the retort, unless it be heated by applying live coal. This may be rectified into a thin oil, by distilling it several times, without addition, in a sand-heat.

Boerhaave directs the wax, cut in pieces, to be put into the retort first, so as to fill one half of it; when as much sand may be poured thereon as will fill the remaining half. This is a nearer, and much less troublesome way, than melting the wax, and mixing it with the sand before they are put into the retort. The author above-mentioned highly commends this oil against roughnefs and chaps of the skin, and other like purposes: the college of Strasburgh speak also of it being given internally, and say it is a powerful diuretic (ingent diureticum) in doses from two to four or more drops: but its disagreeable smell has prevented its coming into use among us.

The number of essential oils which have now a place in the London and Edinburgh pharmacopoeias, and likewise in the foreign ones of modern date, is much less considerable than formerly; and perhaps those still retained afford a sufficient variety of the more active and useful oils. Most of the oils mentioned above particularly those which have a place in the London and Edinburgh pharmacopoeias, are prepared by our chymists in Britain, and are easily procurable in a tolerable degree of perfection; but the oils from the more pure and expensive spices, though still introduced among the preparations in the foreign pharmacopoias, are, when employed amongst us, usually imported from abroad.

These are frequently so much adulterated, that it is not an easy matter to meet with such as are fit for use. Nor are these adulterations easily discoverable. The grozer abusers, indeed, may be readily detected: thus, if the oil be mixed with spirit of wine, it will turn milky on the addition of water; if with expressed oils, rectified spirit will dissolve the essential, and leave the other behind; if with oil of turpentine, on dipping a piece of paper in the mixture, and drying it with a gentle heat, the turpentine will be betrayed by its smell. But the more subtle artists have contrived other methods of sophification, which elude all trials of this kind.

Some have looked upon the specific gravity of oils as a certain criterion of their genuineness: and accordingly we have given a table of the gravity of several. This, however, is not to be absolutely depended on: for the genuine oils, obtained from the same subjects, often differ in gravity as much as those drawn from different ones. Cinnamon and cloves, whose oils usually sink in water, yield, if slowly and warily distilled, an oil of great fragrancy, which is nevertheless specifically lighter than the aqueous fluid employed in the distillation of it, while, on the other hand, the last runnings of some of the lighter oils prove sometimes to ponderous as to sink in water.

As all essential oils agree in the general properties of solubility in spirit of wine, indissolubility in water, miscibility with water by the intervention of certain intermediaries, solubility in the heat of boiling water, &c., it is plain that they may be variously mixed with each other, or the dearer sophificated with the cheaper, without any possibility of discovering the abuse by any trials of this kind. And indeed it would not be of much advantage to the purveyor, if he had infallible criteria of the genuineness of every individual oil. It is of as much importance that they be good as that they be genuine; for genuine oils, from inattentive distillation and long careless keeping, are often weaker both in smell and taste than the common sophificated ones.

The smell and taste seem to be the only certain test of which the nature of the thing will admit. If a bark should have in every respect the appearance of good cinnamon, and should be proved indisputably to be the genuine bark of the cinnamon-tree; yet if it want the cinnamon flavour, or has it but in a low degree, we reject it; and the case is the same with the oil. It is only from use and habit, or comparisons with specimens of known quality, that we can judge of the goodness either of the drugs themselves or of their oils. Most of the essential oils, indeed, are too hot and pungent to be tasted with safety; and the smell of the subject is so much concentrated in them, that a small variation in this respect is not easily distinguished; but we can readily dilute them to any assignable degree. A drop of the oil may be diffolved in spirit of wine, or received on a bit of sugar, and diffolved by that intermedium in water. The quantity of liquor which it thus impregnates with its flavour, or the degree of flavour
flavour which it communicates to a certain determinate quantity, will be the measure of the degree of goodness of the oil.

We shall here subjoin the result of some experiments, showing the quantity of essential oil obtained from different vegetables, reduced into the form of a table. The first column contains the names of the respective vegetable substances; the second, the quantity of each which was submitted to the distillation; and the third, the quantity of oil obtained. In every other part of this article, where pound weights are mentioned, the Troy pound of 12 ounces is meant: but these experiments having been all made by a pound of 16 ounces, it was thought expedient to set down the matter of the oil in the original weights; especially as the several materials, in the large quantity commonly required for the distillation of oils, are purchased by weights of the same kind. But to remove any ambiguity which might arise from hence, and to enable the reader to judge more readily of the product, a reduction of the weights is given in the next column; which shows the number of parts of each of the subjects from which one part of oil was obtained. To each article is affixed the author's name from whom the experiment was taken. The different distillations of one subject, several of which are inserted in the table, show how variable the product of oil is, and that the exotic spices, as well as our indigenous plants, do not always yield the same proportion of this active principle; though it must be observed, also, that part of the differences may probably arise from the operation itself having been more or less carefully performed.

| DILUTED OR WEAK VITRIOL ACID. |

196 Take of vitriolic acid, one ounce by weight; distilled water, 8 ounces by weight. Mix them by degrees.

Weak vitriolic acid, common called weak spirit of vitriol. E.

Take of vitriolic acid, one part; water, seven parts. Mix them in the former editions of our pharmacopoeias, directions were given for the preparation of the vitriolic acid by the apothecary himself, under the heads of spirit and oil of vitriol, spirit or oil of sulphur by the bell, &c.: but as it is now found that all these modes are expensive, and that this acid may be furnished at a cheaper rate from the trading chemists preparing it on a large scale, it is with propriety that both colleges have now rejected it from the preparations, and introduced it only into the list of the materia medica.

When, however, it is of the degree of concentration there required, it can be employed for very few purposes in medicine. The most simple form in which it can be advantageously employed internally, is that in which it is merely diluted with water; and it is highly proper that there should be some fixed standard in which the acid in this state should be kept. It is, however, much to be regretted, that the London and Edinburgh colleges have not adopted the same standard in respect to strength: for in the one, the strong acid constitutes an eighth; and in the other, only a ninth of the mixture. The former proportion, which is that of the Edinburgh college, we are inclined to prefer, as it gives exactly a dram of acid to the ounce; but the dilution by means of distilled water, which is directed by the London, is preferable to spring-water: which, even in its purest state, is rarely free from impregnations in part affecting the acid.

The acid of vitriol is the most ponderous of all the liquors we are acquainted with, and the most powerful of the acids. If any other acid be united with a fixed alkaline salt or earth, on the addition of the vitriolic, such acid will be dislodged, and arise on applying a moderate heat, leaving the vitriolic in possession of the alkali; though without this addition it would not yield to the most vehement fire. Mixed with water, it instantly creates great heat, insomuch that glass vessels are apt to crack from the mixture, unless it be very slowly performed: exposed to the air, it imbues moisture, and looses a remarkable increase of weight. In medicine, it is employed chiefly as subservient to other preparations: it is also frequently mixed with juleps and the like, in such quantity as will be sufficient to give the liquor an agreeable tartness, and its pleasant taste is a cooling antiseptic, a restringent, and a stomachic.

It is particularly useful for allaying inordinate actions of the stomach, when under the form of finguistus or vomiting. For its medical properties, see Acids and Vitriol.

**Nitrous acid.**

Take of purified nitre, by weight, 60 ounces; vitriolic acid, by weight, 29 ounces. Mix and distil. The specific gravity of this is to the weight of distilled water as 1550 to 1000.

Nitrous acid commonly called Glauber's spirit of nitre. E.

Take of purest nitre, bruised, two pounds; vitriolic acid, one pound. Having put the nitre into a glass retort, pour on it the spirit; then distil in a sand-heat, gradually increasing the fire, till the sand-pot becomes of a dull red colour.

Hence the vitriolic acid expels the nitrous, in red corosive vapours, which begin to issue immediately on mixture; and which the operator ought cautiously to avoid. A pound of acid of vitriol is sufficient to expel all the acid from about two pounds of nitre, not from more: some direct equal parts of the two. The spirit, in either case, is of equal the same; the difference, in this respect, affecting only the residuum. If two parts of nitre be taken to one of volatile acid, the remaining alkaline basis of the nitre is completely saturated with the vitriolic acid; and the result is a neutral salt, the same with vitriolated tartar, as we shall
shall fee hereafter. If more nitre be used, a part of the nitre in substance will remain blended with this neutral salt; if less nitre, it cannot afford alkali enough to saturate the vitriolic acid, and the residuum will not be a neutral salt, but a very acid one. In this latter case there is one convenience; the acid salt being readily soluble in water, so as to be got out without breaking the retort, which the others are not.

**Diluted or weak nitrous acid.** L.

Take of nitrous acid, distilled water, each one pound. Mix them.

**Weak nitrous acid.** E.

Take of nitrous acid, water, equal weights. Mix them, taking care to avoid the noxious vapours.

In the old editions both of the London and Edinburgh pharmacopoeas, directions were given for the preparation of aquafortis simplex and duplex; but these were no more than different forms of preparing an impure nitrous acid, unfit for medical purposes. They are therefore, with propriety, superceded by the more simple formulæ of nitrous acid and diluted or weak nitrous acid, mentioned above. In making the diluted acid, distilled water is preferable to common water.

The vapour separated during the mixing of nitrous acid and water, is the permanently elastic fluid called nitrous acid air, which is deleterious to animal life.

The acid of nitre is next in strength to the vitriolic, and dillodes all others from alkaline salts or earths. It differs from all the other acids in dissolving with inflammable matters: it's a solution of any inflammable substance, as burnthorn, &c. in this acid, be let to evaporate, as soon as the matter approaches to dryness, a violent detonation ensues. The chief use of this acid is as a menstruum for certain minerals, and as the basis of some particular preparations to be mentioned hereafter. It has been given likewise, diluted with any convenient vehicle, as a diuretic, from 10 to 50 drops.

**Muriatic acid.** L.

Take of dry sea-salt, 10 pounds; vitriolic acid, six pounds; water, five punds. Add the vitriolic acid first mixed with the water by degrees, to the salt; then distil.

The specific gravity of this acid is to distilled water as 1170 to 1000.

**Muriatic acid, commonly called spirit of sea-salt.** E.

Take of sea-salt, two pounds; vitriolic acid, water, each one pound. Let the salt be first put into a pot, and brought to a red heat, that the oily impurities may be conformed; then put it into the retort. Next mix the acid with the water, and when the mixture has cooled, pour it upon the salt. Lastly, distil in a sand heat with a middling heat, as long as any acid comes over.

The marine, or muriatic acid, arises, not in red fumes like the nitrous, but in white ones. The addition of water is more necessary here than in the foregoing processes; the marine vapours being so volatile, as scarcely to condense without some adventitious humidity. The acid of vitriol is most conveniently mixed with the water in an earthen or flint-ware vessel; for unless the mixture be made exceedingly slow, it grows so hot as to endanger breaking a glass one.

The spirit of sea-salt is the weakest of the mineral acids, but stronger, than any of the vegetable; it requires a greater fire to distil it than that of nitre, yet it is more readily diffipated by the action of the air. It is used chiefly as a menstruum for the making of other preparations; sometimes, likewise, it is given, properly diluted, as an antiphlogistic, aperient, and diuretic, from 10 to 60 or 70 drops.

**Diluted vinegar.**

Take of vinegar five pints. Dilute with a gentle fire, in glass vessels, so long as the drops fall free from exposure.

Let eight pounds of vinegar be distilled in glass vessels with a gentle heat. Let the two first pounds that come over be thrown away as containing too much water; let four pounds next following be reserved as the distilled vinegar. What remains is a still stronger acid, but too much acted on by the heat.

This process may be performed either in a common still with its head, or in a retort. The better kinds of wine-vinegar should be used; those prepared from malt liquors, however fine and clear they may seem to be, contain a large quantity of a viscid substanee, as appears from the slimmeries and ropyness to which they are very much subject; this not only hinders the acid parts from rising freely, but likewise is apt to make the vinegar boil over into the recipient, and at the same time disposes it to receive a disagreeable impression from the fire. And indeed, with the best kind of vinegar, if the distillation be carried on to any great length, it is extremely difficult to avoid an empyreuma.

The best method of preventing this inconvenience is, if a retort be used, to place the sand but a little way up its sides, and when somewhat more than half the liquor is come over, to pour on the remainder a quantity of fresh vinegar equal to the liquor drawn off. This may be repeated three or four times; the vinegar supplied at each time being previously heated. The addition, of cold liquor would not only prolong the operation, but also endanger the breaking of the retort. If the common still be employed, it should likewise be occasionally supplied with fresh vinegar in proportion as the spirit runs off; and this continued until the process can be conveniently carried no farther: the distilled spirit must be rectified by a second distillation in a retort or glass alembic; for although the head and receiver be of glass or flint ware, the acidi will contract a metallic taint from the pewter worm.

The residuum of this process is commonly thrown away as useless, although if skillfully managed, it might be made to turn to good account; the molten acid parts of the vinegar still remaining in it. Mixed with about three times its weight of fire-dry sand, and committed to distillation in a retort, with a well-regulated fire, it yields an exceeding strong acid spirit, together with an empyreumatic oil, which taints the spirit with a disagreeable odour. This acid is nevertheless, without any rectification, better for some purposes (as a little...
Part II. PHARMA CY.

Preparations and Compositions.

The spirit of vinegar is a purer and stronger acid than vinegar itself, with which it agrees in other respects. (See Vinegar). Their principal difference from the mineral acid consists in their being milder, less stimulating, less disposed to affect the kidneys and promote the urinary excrescences, or to corurate the animal juices. The matter left after the distillation in glass vessels, though not used in medicine, would doubtless prove a serviceable dentergent sapnaceous acid; and in this light sunds recommended by Boerhaave.

Concentrated vinegar. Sucr.

201 Let white wine vinegar be frozen in a wooden vessel in cold winter weather; and let the fluid separated from the ice be preferred for use. It may be considered as sufficiently strong, if one dram of it be capable of saturating a scruple of the fixed vegetable alkali.

This is a very easy mode for obtaining the acid of vinegar in a concentrated state, and freed from a considerable portion of its water. But at the same time we do not thus obtain the acid either so much concentrated, or in so pure a state as by the following process.

Acetous acid. L.

202 Take of verdigris, in coarse powder, two pounds. Dry it perfectly by means of a water-bath saturated with sea-salt; then distil it in a sand-bath, and after that distil the liquor. Its specific gravity is to that of diluted water as 1050 to 1000.

By this process, it may be readily concluded that we obtain the acetous acid in its most concentrated state, and with the least admixture of water. And after the re-distillation, it may also be supposed that it will be free from all mixture of the copper. But the internal use of it has been objected to by some, on the supposition that it may fill retain a portion of the metal; and hitherto it has, we believe, been but little employed.

Crystallized acid of tartar. Sucr.

203 Take of prepared chalk, frequently washed with warm water, two pounds; spring water, 32 pounds. After flight boiling, by degrees add of cream of tartar 7 pounds, or as much as is sufficient for saturation. Removing the vessel from the fire, let it stand for half an hour, then cautiously pour off the clear liquor into a glass vessel. Wash the residuum or tartaraceous felenites by pouring water on it three or four times. To this residuum afterwards add of weak vitriolic acid 16 pounds, let it be digested for a day, frequently stirring it with a wooden spatula. After this pour the acid liquor into a glass vessel; but with the residuum mix 16 pounds of spring water; strain it through paper, and again pour water on the residuum till it become infused. Let the acid liquors mixed together in a glass vessel be boiled to the confinence of a thin syrup; which being strained, must be set apart for the formation of crystals. Let the crystals collected after repeated distillations be dried on paper, and afterwards kept in a dry place.

If before crystallization a little of the impregnated acid liquor be diluted with four times its quantity of pure water, and a few drops of vinegar of litharge be put into it, a white sediment will immediately be deposited. If a few drops of the diluted nitrous acid be then added, the mixture will become limpid, if the tartaraceous liquor be pure and entirely free from the vitriolic acid; but if it be not, it will become white. This fault, however, may be corrected, if the acid of tartar be diluted with fix pounds of water and a few ounces of the tartaraceous felenites be added to it. After this it may be digested, strained, and crystallized.

By this process, the acid of tartar may be obtained in a pure solid form. It would, however, be perhaps an improvement of the process, if quicklime were employed in place of chalk. For Dr Black has found that quicklime absorbs the whole of the tartaraceous acid, and then the supernatant liquor contains only the alkaline part of the tartar; whereas, when chalk is employed, it contains a solution of soluble tartar, the chalk taking up only the superabundant acid. By this method then a greater quantity of tartaraceous acid might be obtained from the sediment. The tartaraceous acid has not hitherto been much employed in its pure state. But besides being useful for some purposes in medicine, for which the cream of tartar is at present in use, and where that superfaturated neutral may be less proper, there is also reason to suppose, that from the employment of the pure acid, we should arrive at more certainty in the preparation of the antimonial tartarizatum, on tartar emetic, than by employing the cream of tartar, the proportion of acid in which varies very much from different circumstances. The pure acid of tartar might also probably be employed with advantage for bringing other metallic substances to a stable state.

Distilled acid of tar tar. Sucr.

204 Let pounded crude tartar be put into a tubulated earthen or iron retort till it fills about two-thirds of it, and let distillation be performed by gradually increasing the heat. Into the recipient, which should be very large, an acid liquor will pass over together with the oil; which being separated from the oil, must again be distilled from a glass retort. If the residuum contained in the earthen or iron retort be diluted with water, strained through paper, and boiled to dryness, it gives what is called the alkali of tartar. If this do not appear white, it may be made so by burning, solution, straining, and evaporation.

This is another mode of obtaining both the acid and alkali of tartar in a pretty pure state; and, as well as the former, it is not unworthy of being adopted into our pharmacopoeias.

Aerated water. Roff.

205 Let spring water be saturated with the fixed air, or aerial acid, arising from a solution of chalk in vitriolic acid, or in any similar acid. Water may also be impregnated by the fixed air rising from fermenting liquors.

The aerial acid, on which we have already occasion to
to make some observations, besides the great influence which it has as affecting different saline bodies into whose composition it enters, is also frequently employed in medicine, with a view to its action on the human body. The late ingenious Dr. Dobson, in his Commentary on Fixed Air, has pointed out many purposes for which it may be usefully employed, and several different forms under which it may be used. But there is no form under which it is at present more frequently had recourse to than that of aerated or mephitic water, as it has often been called. And although not preparative on Fixed Air, has pointed out properties of a well known and sufficiently simple apparatus, contrived by that ingenious philosopher Dr. Nootz. Such a machine ought, we think, to be kept in every shop for the more ready preparation of this fluid. Water properly impregnated with the aerial acid has an agreeable acidulous taste. It is often employed with great advantage in the way of common presence, and by calculous patients. But besides this, it furnishes an excellent vehicle for the exhibition of many other medicines.

Besides the simple aerated water, the Pharmacopoeia Rosica contains also an aqua aérea fixi martialis, or ferruginous aerated water. This is prepared by suspending iron wires in that water till the water be fully saturated with the metal. And in consequence of this acid, simple water becomes a menstruum both for different metallic and earthy substances. But water in this state may be considered rather as fitted for those purposes for which chalybeates are in use, than as a preparation of the aerial acid.

Still oil of amber. L.

Take of amber two pounds. Distil in a sand heat, gradually augmented; an acid liquor, oil, and salt impregnated with oil, will ascend.

On this article we have already offered some observations under the head of Effential Oils. The directions here given by the London college differ chiefly from those of the Edinburgh college formerly mentioned, in no sand being employed: But when care is taken that the sand be pure, it can give no improper impregnation to the medicine, and may prevent some inconveniences in the distillation, particularly that of the amber rising in sub stance into the receiver.

Purified salt of amber. L.

Take of salt of amber half a pound; distilled water, one pint. Boil the salt in the distilled water, and let aside the solution to crystallize.

Salt of amber, when perfectly pure, is white, of an acid taste, and not un grateful. It requires, for its solution, of cold water, in summer, about twenty times its weight; and of boiling water about twice its weight; it is scarcely soluble in redistilled spirit without the assistance of heat.

PHARMACY.

It is given as a cooling diuretic in doses of a few grains, and also in hysterical compositions.

Flowers of benzoin.

Take of benzoin, in powder, one pound. Put it into an earthen pot, placed in sand; and, with a flow fire, sublime the flowers into a paper cone fitted to the pot.

If the flowers be of a yellow colour, mix them with white clay, and sublime them a second time. L.

Put any quantity of powdered benzoin into an earthen pot, to which, after fitting it with a large conical paper cap, apply a gentle heat that the flowers may sublime. If the flowers be impregnated with oil, let them be purified by solution in warm water and crystallization. E.

Benzoin, exposed in a retort to a gentle fire, melts, and sends up into the neck white, fuming crystalline flowers, which are followed by an oily substance. These flowers, which are at present considered as a peculiar acid, are by some termed acidum benzoeicum. On raising the heat a little (a recipient being applied to the neck of the retort), a thin yellow oil comes over, intermixed with an acid liquor, and afterwards a thick butyrous substance: this last, liquified in boiling water, gives out to it a considerable quantity of fatty matter (separable by filtration and proper evaporation), which appears in all respects similar to the flowers.

It appears, therefore, that the whole quantity of flowers which benzoin is capable of yielding, cannot be obtained by the above processes, since a considerable portion arises after the time of their being discontinued. The greatest part of the flowers arise with a less degree of heat than what is necessary to elevate the oil; but if the operation be hastily conducted, or if the fire be not exceedingly gentle, the oil will arise along with the flowers, and render them foul. Hence in the way of trade, it is extremely difficult to prepare them of the requisite whiteness and purity; the heat which becomes necessary, when large quantities of the benzoin are employed, being too great as to force over some of the oil along with them.

In order, therefore, to obtain these flowers in perfection, only a small quantity of benzoin should be put into the vessel at a time; and that this may not be any impediment to the requisite dispatch, a number of shallow, flat bottomed, earthen dishes may be employed, each fitted with another vessel inverted over it, or a paper cone. With these you may fill a sand furnace; having fresh dishes charged in readiness to replace those in the furnace, as soon as the process shall appear finished in them: the residuum of the benzoin should be scraped out of each of the vessels before a fresh parcel be put in.

These flowers, when made in perfection, have an agreeable taint and fragrant smell. They totally dissolve in spirit of wine; and likewise by the assistance of heat, in water; but separate again from the latter upon the liquor's growing cold, floating into saline fatty, which unite together into irregular masses. By the mediation of sugar they remain suspended in cold water, and thus form an elegant balsamic syrup. Some have held them in great esteem as pectoral and

fudorific
Take of tartar, what quantity you please. Roll it up in a piece of moist bulbus paper, or put it into a crucible, and surrounding it with live coals, burn it to a coal; next, having beat this coal, calcine it in an open crucible with a moderate heat, taking care that it do not melt, and continue the calcination till the coal becomes of a white, or at least of an ash, colour. Then dissolve it in warm water; strain the liquor through a cloth, and evaporate it in a clean iron vessel; diligently stirring it towards the end of the process with an iron spatula, to prevent it from sticking to the bottom of the vessel. A very white salt will remain, which is to be left a little longer on the fire, till the bottom of the vessel becomes almost red. Lastly, when the salt is grown cold, let it be put up in glass vessels well that.

Native tartar is a saline substance, compounded of an acid, of a fixed alkali, and of oily visous, and colouring matter. The purpose of the above process is, to free it from every other matter but the fixed alkali. From the mistaken notion that tartar was essentially an acid mixed only with impurities, it has been generally supposed that the effect of this operation was the conversion of an acid into an alkali by means of heat. But since Mr Scheele has discovered that the proper matter of tartar, freed from the oily and colouring parts is really a salt compounded of an acid, which is predisminant, and a fixed alkali, we have no farther need of such an obscure theory. The acid of the tartar by this process is dissipated by means of the heat; and the oily, visous, and colouring matters, are partly dissipated, and partly brought to the state of inflammable earthy matter, easily separable by the future dissimulation from the alkali, wherewith they were loosely combined. But by the last of these processes, something farther is carried on than the separation of the more palpable foreign matters. By allowing the salt, freed from the water of the lixivium, to remain on the fire till the bottom of the vessel become almost red, any oily matter that may still be present seems to be decomposed by the united action of the heat and fixed alkali, forming with a part of the latter, by their reciprocal action, a volatile alkali salt, which is forthwith discharged in elastic vapours. Besides the complete discharge of the above principles, the remaining fixed alkali also suffers a considerable loss of its fixed air, or aerial acid; with which, when fully saturated, it forms the imperfect neutral salt, denominated by Dr Black mild fixed alkali: on this account it is somewhat caustic, considerablv deliquecant, and in proportion to its poofeering these properties more or less, it more or less nearly approaches to the state of pure alkali. It is not, however,

ever, so essentially deprived of fixed air as to be sufficiently caustic for a number of purposes. Where causticity is not required, the salt thus purified is abundantly fit for most pharmaceutical purposes; but as native tartar generally contains small portions of neutral salts besides the foreign matters already noticed, it is necessary if we wish to have a very pure alkali for nice operations, to employ crystallization and other means, besides the process here directed.

The white and red sorts of tartar are equally fit for the purpose of making fixed salt; the only difference is, that the white affords a somewhat larger quantity than the other; from 16 ounces of this sort, upwards of four ounces of fixed alkaline salt may be obtained. The use of the paper is to prevent the smaller pieces of the tartar from dropping down into the ash-hole, through the interstices of the coals, upon first injecting it into the furnace.

The calcination of the salt (if the tartar was sufficiently burnt at first) does not increase its strength so much as is supposed; nor is the greenish or blue colour any certain mark either of its strength, or of its having been, as was formerly supposed, long exposed to a vehement fire: for if the crucible be perfectly clean, close covered, and has stood the fire without cracking, the salt will turn white, though kept melted and reverberated ever so long; while, on the other hand, a slight crack happening in the crucible, or a spark of coal falling in, will in a few minutes give the salt the colour admired. The colour in reality is a mark rather of its containing some inflammable matter than of its strength.

The vegetable alkali prepared from tartar has now no place in the London pharmacopœia, or at least it is included under the following article.

Prepared kali. L.

Take of pot-ash, two pounds; boiling distilled water, three pints. Dissolve and filter through paper; evaporate the liquor till a pellicle appears on the surface; then set it aside for a night, that the neutral-salts may crystallize; after which pour out the liquor, and boil away the whole of the water, constantly stirring, lest any salt should adhere to the pot. In like manner is purified impure kali from the ashes of any kind of vegetable. The same salt may be prepared from tartar burnt till it becomes of an ash-colour.

Fixed vegetable alkaline salt purified. E.

Let the fixed alkaline salt, called in English pearl-ash, be put into a crucible, and brought to a somewhat red heat, that the oily impurities, if there be any, may be consumed; then having beat and agitated it with an equal weight of water, let them be well mixed. After the feces have fubided, pour the ley into a very clean iron pot, and boil to dryness, diligently stirring the salt towards the end of the process, to prevent its sticking to the vessel. This salt, if it hath been rightly purified, though it be very dry, if rubbed with an equal weight of water, may be dissolved into a liquor void of colour or smell.

The potash used in commerce is an alkali mixed with a considerable quantity of remaining charcoal; U u sulphur,
sulphur, vitriolated tartar, and oily matter. In the large manufactures, the alkaline part is indeed confi-
doubtedly freed from impurities by mixing the weed-
ishes with water, evaporating the clear ley, and burn-
ing the residuum in an oven; but besides that this pro-
cess is insufficient for the complete separation of the
impurities, it also superadds a quantity of fliny mat-
ter, giving to the alkali the pearl appearance (whence
its name), and rendering it altogether unfit for phar-
macetical purposes. By the processes here directed,
the alkali is effectively freed from all these hetro-
geous matters, excepting perhaps a small proportion
of vitriolated tartar, or other neutral salts, which may
generally be neglected. As in the process no af-
ter calcination is directed, it is probable that the fix-
ced alkali thus prepared will not prove so caustic, that
to be, is not to be considerably deprived of fixed air,
as in the process directed for preparing the salt of tar-
tar. It is, however sufficiently pure for most purp-
oposes; and we consider the above processes as the most
convenient and cheap method of obtaining the vege-
table fixed alkali in its mild state.

The purified vegetable alkali has been known in our
pharmaceuticals under the different names of salt of
warm wood, salt of tartar, &c. But all these being now
known to be really the same, the terms, as leading to
error, have been with justice expunged; and it has been
a defideratum to discover some short name equally ap-
licable to the whole. The term employed by the
Edinburgh college is too long, being rather a descrip-
tion than a name; but to that employed by the Lon-
don college, Kali, objections have also been made.
And it must be allowed, that besides the inconvenience
which arises from its being an indeclinable word, the
foillf alkali is equally intitled to the same appellation.
Besides this, as a considerable portion of the foiff
alkali is prepared from burning a vegetable growing on
the sea coasts, which has the name of kali, the Kali
phosphatium of Linne, some apparent contradiction and
ambiguity may therefore arise. And the London col-
lege would perhaps have done better, if they had
adopted the term Potash; a name which has been ap-
propriated to this salt by some of the most eminent mo-
 dern chemists.

The purified potash is frequently employed in me-
dicine in conjunction with other articles, particularly
for the formation of saline neutral draughts and mix-
tures: But it is used also by itself in doses from three
or four grains to 15 or 20; and it frequently ope-
rates as a powerful diuretic, particularly when aided by
proper dilution. See Pearl-Ash and Pot-Ash.

Water of kali. L.

Take of kali, one pound, fet it by in a moist place
until it be dissolved, and then strain it.

This article had a place in former editions of our
pharmaceuticals under the titles of lay of tartar or oil
of tartar per dilution, &c. It is now considered as a
merely watery solution of the mild vegetable alkali,
formed by its attracting moisture from the air; and therefore it is with propriety styled the
water of kali.

The solutions of fixed alkaline salts, made by ex-
posing them to a moist air, are generally considered
as being purer than those made by applying water
directly; for though the salt be repeatedly dissolved
in water, filtered, and extirpated; yet, on being li-
quified by the humidity of the air, it will still de-
posite a portion of earthy matter: but it must be ob-
erved, that the extirpated salt leaves always an earthy
matter on being dissolved in water, as well as on be-
ing deliquated in the air. Whether it leaves more in
the one way than in the other, is not determined with
precision. The deliquated lixivium is said to contain
nearly one part of alkaline salt to three of an aque-
ous fluid. It is indifferent, in regard to the lixivium
itself, whether the white ashes of tartar, or the salts
extracted from them, be used; but as the ashes leave
a much greater quantity of earth, the separation of the
ley proves more troublesome.

The water of kali of the present edition of the Lon-
don pharmacopoeia, may then be considered as an im-
provement of the lixivium tatar of their former edi-
tion. But the Edinburgh college, considering this fo-
lution as being in no respect different from that made
by pure water, have entirely rejected this preparation
from their pharmacopoeia, and probably with justice.

Water of pure kali. L.

Take of kali, four pounds; quicklime, six pounds;
diluted water four gallons. Put four pints of water
to the lime, and let them stand together for an hour;
after which, add the kali and the rest of the water;
them boil for a quarter of an hour: sufter the liquor to cool, and strain. A pint of this
liquor ought to weigh 16 ounces. If the liquor effervesces with any acid, add more lime.

A preparation similar to this had a place in the
former edition of the London pharmacopoeia, un-
der the title of soap-ley. Quicklime, by depriving
the mild alkali of its aerial acid, renders it caustic;
hence this ley is much more acrimonious, and ade-
pt more powerfully as a menstruum of oils, fats, &c.

The soap ley should be used fresh from the kettle;
by long keeping, even in close vessels, it loses its strength; such should be made choice of as is thoroughly burnt or calcined,
which may be known by its comparative lightness.

All the instruments employed in this proceed
should be either of wood, earthen ware, or glass; the
common metallic ones would be corroded by the ley,
sO as either to discolor or communicate disagreeable
qualities to it. If it should be needful to filter or strain
the liquor, care must be taken that the filter or strainer
be of vegetable matter: woollen, silk, and that
sort of filtering paper which is made of animal sub-
stances, are quickly corroded and disioded by it.

The liquior is most conveniently weighed in a nar-
row-necked glass bottle, of such a size, that the mea-
sure of a wine pint way arise some height into its neck;
the place to which it reaches being marked with a
diamond. A pint of the common leys of our soap-
makers weighs more than 16 ounces: it has been
found that their soap-ley will be reduced to the stan-
dard here proposed, by mixing it with something
less than an equal measure of water.

Although this liquor is indeed pure alkali dissolved
in water, yet we are inclined to give the preference
Part II.  

PHARMACY.

Preparations and Compotions.

To the name employed by the Edinburgh college, as well as to the modes of preparing it, directed in the following formula.

**Caustic ley.** E.

214 Take of fresh burnt quicklime, eight ounces; purified fixed vegetable alkaline salt, six ounces. Throw the quicklime, with 28 ounces of warm water, into an iron or earthen vessel. The ebullition, and extinction of the lime being perfectly finished, instantly add the alkaline salt, and having thoroughly mixed them, let the vessel till it cool. Stir the cooled matter, and pour out the whole into a glass funnel, whose throat must be filled up with a piece of clean rag. Let the upper mouth of the funnel be covered, while the tube of it is inserted into a glass vessel, so that the ley may gradually drop through the rag into that vessel. When it first gives over dropping, pour into the funnel some ounces of water; but cautiously, and in such a manner, that the water shall swim above the matter. The ley will again begin to drop, and the affusion of water is to be repeated in the same manner, until three pounds have dropped, which takes up the space of two or three days; then agitating the inferior and interior parts of the ley together, mix them, and put up the liquor in a well flat vessel.

If the ley be rightly prepared, it will be void of colour or smell: nor will it raise an effervescence with acids except perhaps a very slight one. Colour and odour denote the salt not sufficiently calcined; and effervescence, that the quicklime has not been good.

The reasons and propriety of the different steps in the above process will be best understood by studying the theory on which it is founded. The principle of mildness in all alkaline salts, whether fixed or volatile, vegetable or fossil, is very evidently fixed air, or the aerial acid: But as quicklime has a greater attraction for fixed air than any of these salts, so if this substance be presented to any of them, they are thereby deprived of their fixed air, and forthwith become caustic. This is what precisely happens in the above process. The propriety of closely shutting the vessels through almost every step of the operation, is sufficiently obvious; viz. to prevent the absorption of fixed air from the atmosphere, which might defeat our intentions. When only a piece of cloth is put into the throat of the funnel, the operation is much more tedious, because the pores of the cloth are soon blocked up with the wet powdery matter. To prevent this, it may be convenient to place above the cloth a piece of fine Fly's wirework; but as metallic matters are apt to be corroded, the method used by Dr. Black is the most eligible. The doctor first drops a rugged stone into the tube of the funnel, in a certain place of which it forms itself a firm bed, while the inequalities on its surface afford interstices of sufficient size for the passage of the filtering liquor. On the upper surface of this stone he puts a thin layer of lint or clean tow; immediately above this, but not in contact with it, he drops a stone similar to the former and of a size proportioned to the swell in the upper part of the tube of the funnel. The interstices between this second stone and the funnel are filled up with flint of a less dimension, and the graduation uniformly continued till pretty small flint is employed. Finally, this is covered with a layer of earthen hand and small flint to sustain the weight of the matter, and to prevent its being invad in the minute interstices of the flask. The throat of the funnel being thus built up, the flinty fabric is to be freed of clay and other adhering impurities, by making clean water pass through it till the water seems clear and transparent from the extremity of the funnel. It is obvious, that in this contrivance, the author has, as usual copied nature in the means he employs to deprive watery matters in the bowels of the earth; and it might be usefully applied for the filtration of various other fluids.

It is a very necessary caution to pour the water gently into the funnel; for if it be thrown in a forcible stream, a quantity of the powdery matter will be washed down, and render all our previous labour useless. That part of the ley holding the greatest quantity of salt in solution will no doubt be heaviest, and will consequently sink lowest in the vessel: the agitation of the ley is therefore necessary, in order to procure a solution of uniform strength through all its parts. If the salt has been previously freed of oily and other inflammable matters, this ley will be colourless and void of smell. If the quicklime has been so effectually deprived of its own fixed air, as to be able to absorb the whole of that in the alkali, the ley will make no effervescence with acids, being now deprived of fixed air, to the discharge of which by acids this appearance is to be ascribed in the mild or aerated alkalis.

The caustic ley is therefore to be considered as a solution of pure alkali in water. See the article Fixed Air.

It may be proper to observe, for the sake of understanding the whole of the theory of the above process, that while the alkali has become caustic, from being deprived of fixed air by the quicklime, the lime has in its turn become mild and insoluble in water from having received the fixed air of the alkali.

The caustic ley, under various pompous names, has been much used as a lithontriptic; but its fame is now beginning to decline. In acridities in the stomach, attended with much flatulence and laxity, the caustic ley is better adapted than mild alkalis; as in its union with the acid matter it does not separate air. When covered with mucilaginous matters, it may be safely taken into the stomach: and by stimulating, it coincides with the other intentions of cure; by some dyspeptic patients it has been employed with advantage.

**Pure kali.** L.

Take of water of pure kali, one gallon. Evaporate it to dryness; after which let the salt melt on the fire, and pour it out.

*The strongest common caustic.* E.

Take of caustic ley, what quantity you please. Evaporate it in a very clean iron vessel on a gentle fire, till,
PHARMACY.

The effect of the above processes is simply to discharge the water of the solutio, whereby the cauticinity of the alkali is more concentrated in any given quantity. These preparations are strong and funded caulitics. The cautic prepared in this way has an inconvenience of being apt to liquify too much on the part to which it is applied, so that it is not easily confined within the limits in which it is intended to operate; and indeed the suddenness of its action depends on this disposition to liquify.

Lime with pure kali. L.

Take of quicklime, five pounds and four ounces; water of pure kali, 16 pounds by weight. Boil away the water of pure kali to a fourth part; then sprinkle in the lime, reduced to powder by the af-fusion of water. Keep it in a vessel close floped.

The milder common cautic. E.

Take of cautic ley, what quantity you please. Evaporate in an iron vessel till one third remains; then mix with it as much new flaked quicklime as will bring it to the consistencie of pretty solid pap, which is to be kept in a vessel closely sloped.

These preparations, do not essentially differ from each other, while the chief difference between the present formula, and that which is adopted in the London Pharmacopoeia, is in the name. It was then styled the strongest common cautic.

Here the addition of lime in substance renders the preparation left apt to liquify than the foregoing, and consequently it is more easily confined within the intended limits, but proportionally flower in its operation. The design of keeping or of flaking the lime is, that its acrimony may be somewhat abated.

Exposed long to the air, these preparations gradually renew their power of effervescence, and lose proportionally the additional activity which the quicklime had produced in them.

Prepared natron. L.

Take of barilla, powdered, two pounds; distilled water, one gallon. Boil the barilla in four pints of water for half an hour, and strain. Boil that part which remains after draining with the ret of the water, and strain. Evaporate the mixed liquors to two jints, and let them by for eight days; strain this liquor again; and, after due boiling, let it aside to crystallize. Dissolve the crysials in distilled water; strain the solution, boil, and set it aside to crystallize.

The name of natron, here used by the London college for the fixed soflalkali, has, as well as their name for the vegetable alkali, been objected to. And though they are here supported by the authority of the ancients, yet perhaps they would have done better in following the best modern chemists by employing the term salt of soda. This article differs in name only from the following.

Fixed soflalkali salt purified. E.

Take of ashes of Spanish kali, commonly called soda or barilla, as much as you please. Bruise them; then boil in water till all the salt be dissolved. Strain this through paper, and evaporate in an iron vessel, so that after the liquor has cooled the salt may con­crete into crysials.

By the above processes, the soflalkali is obtained sufficiently pure, being much more disposed to crys­tallize than the vegetable alkali; the admixture of this last, objected to by Dr. Lewis, is hereby in a great measure prevented.

It is with great propriety, that in this, as well as many other processes, the London college directs the use of distilled water, as being free from every impreg­nation.

The natron, or soflalkali, is found lying on the ground in the island of Tenerife, and some other count­ries. The native productions, of this alkali seem to have been better known to the ancients than to late naturalists; and it is, with good reason, supposed to be the nitre of the Bible. How far the native natron may supersede artificial means to procure it from mixed bod­ies, we have not been able to learn with certainty.

The soflalkali is not only a constituent of different neutrals, but is also sometimes employed as a medicine by itself. And in its purified state it has been by some reckoned useful in affections of the scrofulous kind. See NATRUM.

Prepared ammoniac. L.

Take of sal ammoniac, powdered one pound; prepared chalk, two pounds. Mix and sublame.

Water of ammoniac. L.

Take of sal ammoniac, one pound; pot-ash, one pound and a half; water, four pints. Draw off two pints by distillation, with a low fire.

Volatile alkali from sal ammoniac, commonly called vola­tilis sal ammoniacus.

Take of ammoniac, one pound; chalk, very pure and dry, two pounds; mix them well, and sublimate from a retort into a refrigerated receiver.

Spirit of Sal ammoniacus. E.

Take sal ammoniac, purified vegetable fixed alkali, of each sixteen ounces; water, two pounds. Having mixed the salts, and put them into a glass retort, pour in the water; then distil dryness with a sand-bath, gradually raising the heat.

These articles, which in the last edition of the London Pharmacopoeia were styled the volatile salt and spirit of sal ammoniacus, were then directed to be prepared in the same manner.

Sal ammoniacus is a neutral salt, composed of volatile alkali and marine acid. In these processes the acid is absorbed by the fixed alkali or chalk; and the volatile alkali is of course set at liberty.

The volatile alkali is, however, in its mild state, being
being combined with the fixed air, or discharged from the fixed alkali or chalk on their uniting with the mutriastic acid.

The fixed alkali begins to act on the salt ammoniac, and extricates a pungent urinous odour as soon as they are mixed. Hence it is most convenient not to mix them till put into the distilling vessel. The two salts may be dissolved separately in water, the solutions poured into a retort, and a receiver immediately fixed on. An equal weight of the fixed salt is fully, perhaps more than sufficient to extract all the volatile.

Chalk does not begin to act on the salt ammoniac till a considerable heat be applied. Hence they may be without inconvenience, and indeed ought to be thoroughly mixed together before they are put into the retort. The surface of the mixture may be covered with a little more powdered chalk, to prevent such particles of the salt ammoniac as may happen to lie uppermost from subliming unchanged. Though the fire must here be much greater than when fixed alkaline salt is used, it must not be strong, nor suddenly raised; for if it be, a part of the chalk (though of itself not capable of being elevated by any degree of heat) will be carried up along with the volatile salt. M. du Hamel experienced the justness of this observation. He relates in the Memoirs of the French Academy of Sciences for the year 1735, that he frequently found his volatile salt, when a very strong fire was used in the sublimation, amount to more, sometimes by a half, than the weight of the crude salt ammoniac employed; and although not three fourths of this concrete are pure volatile salt, yet the fixed earthy matter, when once volatilized by the alkali, rose along with it again on the gentle sublimation, dissolved with it in water, and exhaled with it in the air.

When all the salt has sublimed, and the receiver grown cool, it may be taken off, and luted to another retort charged with fresh materials. This process may be repeated till the recipient appears lined with volatile salt to a considerable thickness of the vessel must then be broken in order to get out the salt.

The volatile salt and spirit of salt ammoniac are the purest of all the medicines of this kind. They are somewhat more acrimonious than those produced directly from animal substances, which always contain a portion of the oil of the subject, and receive from thence some degree of a pungent quality. These salt may be reduced to the same degree of purity by combining them with acids into ammoniacal salts, and afterwards recovering the volatile alkali from these compounds by the processes above directed.

The matter which remains in the retort after the distillation of the spirit, and sublimation of the volatile salt ammoniac, is found to confine of marine acid united with the fixed alkali or chalk employed. When fixed alkaline salt has been used as the intermediate, the residuum, or caput mortuum as it is called, yields, on solution and crystallization, a salt exactly similar to the spirit of sea-salt coagulated afterwards described; and hence we may judge of the extraordinary virtues formerly attributed to this salt under the names of sal antiphisfericium, antiphosphoricium, fœbrisfæcum, digestfæcum Sylvia, &c.

The caput mortum of the volatile salt, where chalk is employed as an intermediate, exposed to a moist air, runs into a pungent liquor, which proves nearly the same with a solution of salt made directly in the marine acid. It is called by some oleum creat, oil of chalk. If calcined shells, or other animal limes, be mingled with salt ammoniac, a mass will be obtained, which likewise deliquesces in the air, and forms a liquor of the same kind.

**Water of pure ammonia.**

Take of salt ammoniac, one pound; quicklime, two pounds; water one gallon. Add to the lime two pints of the water. Let them stand together an hour; then add the salt ammoniac and the other fix pints of water, boiling, and immediately cover the vessel. Pour out the liquor when cold, and distil off with a slow fire one pint.

**Caustic volatile alkali, commonly called spirit of salt ammoniac with quicklime.**

Take of quicklime, fresh burnt, two pounds; water, one pound. Having put the water into an iron or fire-ware vessel, add the quicklime previously heated, cover the vessel for 24 hours; when the lime has fallen into a fine powder, put it into the retort; then add 16 ounces of salt ammoniac, diluted with four times its weight of water; and, shutting the mouth of the retort, mix them together by agitation. Lastly, distil it into a refrigerated receiver, with a very gentle heat, so that the operator can easily bear the heat of the retort applied to his hands. Twenty ounces of liquor are to be drawn off. In this distillation the vessels are to be so luted as thoroughly to exclude the vapours, which are very penetrating. After the distillation, however, they are to be opened, and the alkali poured out before the retort hath altogether cooled.

The theory of this process is precisely the same with that directed for the preparation of caustic ley. The effect of the quicklime on the salt ammoniac is very different from that of the chalk and fixed alkali in the foregoing process. Immediately on mixture a very penetrating vapour exhaled; and in distillation the whole of the volatile salt arises in a liquid form, no part of it appearing in a concrete state, how gently forever the liquor be re-distilled. This spirit is far more pungent than the other both in smell and taste; and, like fixed alkalis rendered caustic by the same intermedium, it raises no effervescence on mixture with acids. The whole of the phenomena are to be ascribed to the absorption of fixed air from the alkali by means of the quicklime; and from being thus deprived of the aerial acid the volatile alkali is brought to a caustic state.

This spirit is held to be too acrimonious for internal use, and has therefore been chiefly employed for smelting to in fainings, &c. though when properly diluted it may be given inwardly with safety. It is a powerful menstruum for some vegetable substances, as Peruvian barks, from which the other spirits extract little. It is also most convenient for the purpose of rendering oil miscible with water, as in the preparation of what is called in extemporaneous practice the oily mixture.

Some have mixed a quantity of this with the official spirits both of salt ammoniac and of hartshorn; which thus become more pungent, so as to bear an addition.
addition a considerable quantity of water, without any danger of the discovery from the taste or smell. This abuse would be prevented, if what has been formerly laid down as a mark of the strength of these spirits, some of the volatile salt remaining undissolved in them, were attended to. It may be detected by adding to a little of the suspected spirit about one-fourth its quantity or more of rectified spirit of wine; which, if the volatile spirit be genuine, will precipitate a part of its volatile salt, but occasions no visible separation or change in the caustic spirit, or in those which are sophificated with it.

Others have substitutted for the spirit of sal ammoniac a solution of crude sal ammoniac and fixed alkaline salt mixed together.

This mixture deposits a saline matter on the addition of spirit of wine, like the genuine spirit; from which, however, it may be distinguished, by the salt which is thus separated not being a volatile alkaline, but a fixed neutral salt. The abuse may be more readily detected by a drop or two of solution of silver in aquafortis, which will produce no change in the appearance of the true spirit, but will render the counterfeit turbid and milky.

The volatile liquor, salt, and oil of hartshorn. L.

Take of hartshorn, ten pounds. Distill with a fire gradually increased. A volatile liquor, salt, and oil, will ascend. The oil and salt being separated, distill the liquor three times. To the salt add an equal weight of prepared chalk, and sublimate thrice, or till it become white.

The same volatile liquors, salt and oil, may be obtained from any parts (except the fat) of all kinds of animals.

The volatile alkali obtained from hartshorn, whether in a solid or fluid state, is precisely the same with that obtained from sal ammoniac. And as that proceeds is the easiest, the Edinburgh college have entirely rejected the present. While, however, the names of spirit and salt of hartshorn are still in daily use, ammonia, or the volatile alkali, is still prepared from bones and other animal substances by several very extensive traders.

The dealers have very large pots for the distillation of hartshorn, with earthen heads almost like those of the common still; for receivers, they use a couple of oil jars, the mouths of which are luted together; the pipe that comes from the head enters the lowermost jar through a hole made on purpose in its bottom. When a large quantity of the subject is to be distilled, it is customary to continue the operation for several days successively; only unloosening the head occasionally to put in fresh materials.

When only a small quantity of spirit or salt is wanted, a common iron pot, such as is usually fixed in tand furnaces, may be employed, an iron head being fitted to it. The receiver ought to be large, and a glass, or rather tin adoptor, inserted between it and the pipe of the head.

The distilling vessel being charged with pieces of the horn, a moderate fire is applied, which is slowly increased, and raised at length almost to the utmost degree. As first a watery liquor arises, the quantity of which will be smaller or greater according as the horns were more or less dry; this is succeeded by the salt and oil; the salt at first dissolves as it comes over in the phlegm, and thus forms what is called spirit. Preparations.

When the phlegm is saturated, the remainder of the volatile alkali, is a solid form to the fides of the recipient. If it be required to have the whole of the salt solid and undissolved, the phlegm should be removed as soon as the salt begins to arise, which may be known by the appearance of white fumes; and that this may be done the more commodiously, the receiver should be left unloosed till this first part of the process be finished. The white vapours which now arise sometimes come with such vehemence as to throw off or burst the receiver. To prevent this accident, it is convenient to have a small hole in the luting, which may be occasionally stopped with a wooden peg, or opened, as the operator shall find proper. After the salt has all arisen, a thick dark-coloured oil comes over. The process is now to be discontinued; and the vessels, when grown cold, unloosed.

All the liquid matters being poured out of the receiver, the salt which remains adhering to its sides is to be washed out with a little water and added to the reil. It is convenient to let the whole stand for a few hours, that the oil may the better disengage itself from the liquor, so as to be first separated by a funnel, and afterwards perfectly by filtration through wet paper. The salt and spirit are then to be farther purified as above directed.

The spirit of hartshorn met with in the shops is extremely precarious in point of strength; the quantity of salt contained in it (on which its efficacy depends) varying according as the distillation in rectifying it is continued for a longer or shorter time. If after the volatile salt has arisen, so much of the phlegm or watery part be driven over as is just sufficient to dissolve it, the spirit will be fully saturated, and as strong as t can be made. If the process be not at this instant stopped, the phlegm, continuing to arise, must render the spirit continually weaker and weaker. The distillation therefore ought to be discontinued at this period, or rather while some of the salt still remains undissolved; the spirit will thus prove always equal, and the buyers be furnished with a certain criterion of its strength. Very few have taken any notice of the abovementioned inconvenience of these kinds of spirits; and the remedy is first hinted at in the Pharmacopoeia Reformata. The purity of the spirit is easily determined from its clearness and grateful odour.

Volatile alkaline salts, and their solutions called spirits, agree in many respects with fixed alkalis, and their solutions or leys; as in changing the colour of blue flowers to a green; effervescing, when in their cold state, with and neutralizing acids: liquefying the animal juices; and corroding the fleshly parts, so as, when applied to the skin, and prevented from exhaling by a proper covering, to act as caustics; dissolving oils and sulphur, though less readily than the fixed alkalis, on account probably of their not being able to bear any considerable heat, by which their activity might be promoted. Their principal difference from the other alkalis seems to consist in their volatility. They exhale or emit pungent vapours in the coldest state of the atmosphere; and by their stimulating smell they prove serviceable in langours and faintings. Taken internally, they discover a greater colliquating effect as well as stimulating power: the blood drawn from a vein
vein after their use has been continued for some time, is said to be remarkably more fluid than before; they are likewise more disposed to operate by perpiration, and to act on the nervous system. They are particularly useful in lethargic cases; in hysterical and hypochondriacal disorders; and in the languid, headachy, inflations of the stomach, flatulent colics, and other symptoms which attend them. They are generally found more serviceable to aged persons, and in phlegmatic habits, than in the opposite circumstances. In some fevers, particularly those of the low kind, accompanied with a cough, hoarseness, and a redundancy of phlegm, they are of great utility, raising the vital force, and exciting a salutary diaphoretic; but in putrid fevers, scurvy, and wherever the man of blood is thin and acrimonious, their use is ambiguous. As they are more powerful than the fixed in liquefying tenacious humour, so they prove more hurtful where the fluids are already in a colliquated state. In vernal intermitents, particularly those of the low kind, they are often the most efficacious remedy. Dr. Biflet observes, in his Essay on the Medical Constitution of Great Britain, that though many cafes occur which will yield to no other medicine than the bark, yet he has met with many which were only improved from time to time by the bark, but were completely cured by alkaline spirits. He tells us, that these spirits will often carry off vernal intermitents without any previous evacuation: but that they are generally more effectual if a purge be premised; and in plethoric or inflammatory cafes, or where the fever peritonea remittent, venefication is necessary.

These salts are most commodiously taken in a liquid form, largely diluted: or in that of a bolus, which should be made up only as it is wanted. The dose is from a grain or two to ten or twelve. Ten drops of a well made spirit, or saturated solution, are reckoned to contain about a grain of the salt. In intermitents, 15 or 20 drops of the spirit are given in a tea-cupful of cold spring water, and repeated five or six times in each intermission.

The volatile salts and spirits prepared from different animal substances, have been found to be capable of producing different effects on the human body, and to receive specific virtues from the subject. The salt of vipers has been esteemed particularly serviceable in disorders occasioned by the bite of that animal; and a falt drawn from the human skull, in diseases of the head. But modern practice acknowledges no such different effects from these preparations; and chemical experiments have shown their identity. There is indeed when not sufficiently purified, a very perceptible difference in the smell, taste, degree of pungency, and volatility of these salts; and in this state their medicinal virtues vary considerable enough to deserve notice; but this difference they have in common, according as they are more or less loaded with oil, not as they are produced from this or that animal substance. At first distilled, they may be looked on as a kind of volatile soap, in which the oil is the prevailing principle; in this state they have much less of the proper alkaline acrimony and pungency than when they have undergone repeated distillations, and such other operations as divest the oil from the salt; for by those means they lose their saponaceous quality, and acquiring greater degrees of acrimony, become medicines of a different class. These preparations therefore do not differ so much from each other, as they do from themselves in different states of purity.

To which may be added, that when we consider them as loaded with oil, the virtues of a distilled animal oil itself are likewise to be brought into the account. These oils, as first distilled, are highly fetid and offensive, of an extremely heating quality, and of such activity, that, according to Hoffman's account, half a drop dissolved in a dram of spirit of wine is sufficient to raise a copious sweat. By repeated rectifications, they lose their offensiveness, and at the same time become mild in their medicinal operation. The rectified oils may be given to the quantity of twenty or thirty drops, and are said to be anodyne and antiphlogistic, to procure a calm sleep and gentle sweat, without heating or agitating the body, as has been observed in treating of the animal oil. It is obvious, therefore, that the salts and spirits must differ, not only according to the quantity of oil they contain, but according to the quality of the oil itself in its different states.

The volatile salt and spirits, as first distilled, are of a brown colour, and a very offensive smell; by repeated rectification, as directed in the processes above set down, they lose great part of the oil on which these qualities depend, the salt becomes white, the spirit limpid as water, and of a grateful odour; and this is the mark of sufficient rectification.

It has been objected to the repeated rectification of these preparations, that, by separating the oil, it renders them similar to the pure salt and spirit of ammoniac, which are procurable at an easier rate. But the intention is not to purify them wholly from the oil, but to separate the graver part, and to sublimate the rest, so as to bring it towards the same state as when the oil is rectified by itself. The rectification of spirit of hart-thorn has been repeated twenty times successively, and found still to participate of oil, but of an oil very different from what it was in the first distillation.

The rectified oils, in long-keeping, become again fetid. The salt and spirits also, however carefully rectified, suffer in length of time the same change; re-uniting their original brown colour and ill smell; a proof that the rectification is far from having divested them of oil. Any intentions however, which they are thus capable of answering, may be as effectually accomplished by a mixture of the volatile alkali with the animal oil, in its rectified state, to any extent that may be thought necessary.

**Phlrazilated kali.**

Take of the salt which remains after the distillation of the nitrous acid, two pounds. Distilled water, two gallons. Burn out the superfluous acid with a strong fire in an open vessel: then boil it a little while in the water; strain and let the liquor aside to crystallize.

The salt thus formed is the same with the vitriolated tartar of the last edition of the London pharmacopoeia; but it is now prepared in a cheaper and easier manner, at least for those who distill the nitrous acid. In both ways a neutral is formed, confiding of the fixed vegetable.
table alkali, united to the vitriolic acid. But a similar
compound may also be obtained by the following
process of the Edinburgh pharmacopoeia.

Vitriolated fixed vegetable alkali, commonly called vitri-
olated tartar. E.

Take of vitriolic acid, diluted with six times its
weight of water, as much as you please. Put it into a ca-
cious glass vessel, and gradually drop it into, of
purified fixed vegetable alkali, diluted with six times its
weight of water, as much as is sufficient thoro-
guously to neutralize the acid. The effervescence
being finished, strain the liquor through paper;
and after proper evaporation, let it abide to crys-
tallize.

The operator ought to take care that the vapour
separated during the effervescence shall not be applied
to his nostrils; as fixed air, when applied to the olfac-
tory nerves, is highly deleterious to life.

This is an elegant and one of the least troublesome
ways of preparing this salt. The Edinburgh college,
in their former editions, ordered the acid liquid to be
dropped into the alkali; by the converse procedure
now received, it is obviously more easy to secure a
again a redundance of acidity; and for the greater
certainty in this point it may be expedient, as in the
foregoing process, to drop in a little more of the alka-
line ley than the cessation of the effervescence seems to
require.

In a former edition of the same pharmacopoeia, the
acid was directed to be diluted only with its equal
weight of water, and the alkali with that quantity of
water which is capable of imbiping from the atmo-
sphere. By that imperfection there was not water
enough to keep the vitriolated tartar dissol'ved; on
which account, as fast as the alkali was neutralized
by the acid, a great part fell to the bottom in a
powdery form. In order to obtain perfect and well
formed crystals, the liquor should not be set in the
cold, but continued in moderate heat, such as the
hand can fearfully bear, that the water may slowly eva-
porate.

It is remarkable, that although the vitriolic acid
and fixed alkaline salt do each readily unite with wa-
ter, and strongly attract moisture, even from the air,
yet the neutral resulting from the combination of these
two, vitriolated tartar, is one of the salts most diffi-
cult of solution, very little of it being taken up by cold
water.

Vitriolated tartar, in small doses, as a frupule or half
a dram, is an useful aperient; in large ones, as four or
drines, a mild cathartic, which does not pass so
harmfully as the bitter cathartic salt or salt of Glauber, and
seems to extend its action further. The whole sale deal-
ers in medicines have commonly substitued for it an
article otherwise almost ufeles in their shops, the re-
fuldium of Glauber's spirit of niter. This may be
looked on as a venal fraud, if the spirit has been pre-
pared as formerly directed, and the residuum dissolved
and crystallized: but it is a very dangerous one if the
vitriolic acid has been used in an over proportion, and
the caput mortuum employed without crystallization;
the salt in this case, instead of a mild neutral one, of
a moderately bitter taste, proving highly acid. The
 purchaser ought therefore to infall on the salt being in
a crystalline form. The crystals when perfect are ob-
long, with fix flat sides, and terminated at each end
by a fix- sided pyramid; some appear composed of two
pyramids joined together by the bases; and many, in
the most perfect crystallizations we have seen, are very
irregular. They decrepitate in the fire, somewhat like
those of sea-salt, for which they have sometimes been
miftaken.

Salt of many virtues. E.

Take nitre in powder, flowers of sulphur, of each
equal parts. Mix them well together, and inject the
mixture by little and little at a time into a red-
hot crucible; the deflagration being over, let the
salt cool, after which it is to be put up in a glass
vefel well shut. The salt may be purified by dis-
folving it in warm water, filtering the solution, and
exhaling it to dryness, or by crystallization.

This is another method of uniting the vitriolic acid
with the common vegetable fixed alkali. Both the
nitre and the sulphur are decomposed in the opera-
tion: the acid of the nitre, and the inflammable prin-
ciple of the sulphur, detene together, and are disfi-
pated; while the acid of the sulphur, (which, as we
have already seen, is no other than the vitriolic acid)
remains combined with the alkaline basis of the nitre.
The shops accordingly have substituted the foregoing
preparation for the sad pocheylest.

Vitriolated natron. L.

Take of the salt which remains after the distillation of
the muriatic acid, two pounds; distilled water,
two pints and an half. Burn out the superfluous
acid with a strong fire in an open vessel; then boil
it for a little in the water; strain the solution, and
set it by to crystallize.

Vitriolated fods, commonly called cathartic salt of
Glauber. E.

Dissolve in warm water the mass which remains after
the distillation of spirit of sea-salt: filter the solution,
and crystallize the salt.

The directions given for the preparation of this falls,
long known by the name of fal mirabile Glaubers, are
nearly the same in the pharmacopoeias of both colleges;
but those of the London college are to be preferred, as
being most accurate and explicit.

In a former edition of the Edinburgh pharma-
copoeia, it was ordered, that if the crystals (obtained as
above) proved too sharp, they should again be dissolved
in water, and the filtered liquor evaporated to such a
pitch only as may dispose the salt to crystallize. But
there is no great danger of the crystals proving too
sharp, even when the spirit of salt is made with the
largest proportion of oil of vitriol directed under that
proces. The liquor which remains after the crys-

tallization is indeed very acid; and with regard to this
preparation, it is convenient it should be f; for oth-
erwise the crystals will be very small, and likewise in a
small quantity. Where a sufficient proportion of oil
of vitriol has not been employed in the distillation of the
spirit, it is necessary to add some to the liquor, in
order to promote crystallization of the salt.

The title of cathartic falls, which this salt has often
had, exp refles its medical virtues. Taken from half
an ounce to an ounce, or more, it proves a mild and useful purgative; and in smaller doses, largely diluted, a serviceable aperient and diuretic. The flaps frequently substitute for it the bitter cathartic salt, which is nearly of the same quality, but somewhat more unpleasant, and, as is said, less mild in operation. They are very easily diluting by each other, by the effect of alkaline salts upon solutions of them. The solutions of Glauber's salt suffer no visible change from this addition, its own basis being a true fixed alkali; but the solution of the bitter cathartic salt grows instantly white and turbid; its basis, which is an earth, being extruded copiously by the alkaline salt.

Purified nitre. L.

Take of nitre two pounds; distilled water, four pints. Boil the nitre in the water till it be dissolved; strain the solution, and let it abide to crystallize. Common nitre contains usually a considerable portion of a feeble salt, which in this process is separated, the feeble salt remaining dissolved after the greatest part of the nitre has crystallized. The crystals which float after the first evaporation are large, regular, and pure: but when the remaining liquor is further evaporated, and this repeated a second or third time, the crystals prove at length small, imperfect, and tipt with little cubical crystals of feeble salt.

When rough nitre, in the state wherein it is first extracted from the earths impregnated with it, is treated in this manner, there remains at last a liquor called mother-liquor, which will no longer afford any crystals. This appears to participate of the nitrous and carbonic acids, and to contain an earthy matter dissolved by these acids. On adding alkaline lixivium, the earth is precipitated; and when thoroughly washed with water, proves infipid. If the liquor be evaporated to dryness, a bitterish saline matter is left; which being strongly calcined in a crucible, part with the acids, and becomes, as in the other case, infipid.

This earth has been celebrated as an excellent purgative, in the dose of a dram or two; and in smaller doses, as an alterative in hypochondriacal and other disorders. This medicine was for some time kept a great secret, under the name of magnesia alba, nitrous pumice, Count Pomat's powder, il poire albo Romano, puder de Scentiti, &c. till Lannehi made it public in his notes on the Metalllographia Vaticana. It has been supposed, that this earth is no other than a portion of the lime commonly added in the elixir of the nitre at the European nitre works: but though the specimens of magnesia examined by Neumann, and some of that which has lately been brought hither from abroad, gave plain marks of a calcareous nature; yet the true magnesia must be an earth of a different kind, calcareous earths being rather astringent than purgative. The earthy basis of the bitter cathartic salt is found to have the properties ascribed to the true magnesia of nitre, and appears to be the very same species of earth: from that salt therefore this medicine is now prepared, as will be seen hereafter. The magnesia alba differs from calcareous earths, in having a less powerful attraction for fixed air, and in not becoming caustic by calculation.

Acetated kali. L.

Take of kali one pound; boil it with a slow fire in four or five times its quantity of distilled vinegar; the effervescence ceasing, let there be added at different times more distilled vinegar, until the last vinegar being nearly evaporated, the addition of fresh will excite no effervescence, which will happen when about twenty pounds of distilled vinegar are consumed: afterwards let it be dried slowly. An impure salt will be left, which melts for a little while with a flow fire; then let it be distilled in water, and filtered through paper. If the fusion has been rightly performed, the strained liquid will be colourless; if otherwise, of a brown colour. Lastly, evaporate this liquor, with a fire, in a very shallow glass vessel; frequently stirring the mass, that the salt may be more completely dried, which should be kept in a vessel close stopped. The salt ought to be very white, and diffusive wholly, both in water and spirit of wine, without leaving any feces. If the salt although white, should deposite any feces in spirit of wine, that solution in the spirit should be filtered through paper, and the salt again dried.

Acetated fixed vegetable alkali, commonly called regenerat-ed tartar. E.

Take of salt of tartar one pound; boil it with a very gentle heat in a four or five times its quantity of distilled vinegar; and more distilled vinegar at different times, till on the water part of the former quantity being nearly dissipated by evaporation, the new addition of vinegar ceases to raise any effervescence. This happens when about twenty pounds by weight of distilled vinegar has been consumed. The impure salt remaining after the evaporation, is to be liquefied with a gentle heat for a short time, and it is proper that it should only be for a short time; then desolve it in water, and strain through paper. If the liquefaction has been properly performed, the strained liquor will be limpid, but if otherwise, of a brown colour. Evaporate this liquor with a very gentle heat in a shallow glass vessel, occasionally stirring the salt as it becomes dry, that its moisture may sooner be dissipated. Then put it up into a vessel very closely stopped, to prevent it from liquefying in the air.

This salt had formerly the name of diuretic salt in the London pharmacopoeia; but that which they now employ, or in preference to it, the name of continena acetata, gives a clearer idea of its nature.

The purification of this salt is not a little troublesome. The operator must be particularly careful, in melting it, not to use a great heat, or to keep it long liquefied; a little should be occasionally taken out, and put into water; and as soon as it begins to part freely with its black colour, the whole is to be removed from the fire. In the last drying, the heat must not be so great as to melt it; otherwise it will not prove totally soluble. If the solution in spirit of wine be exsiccated, and the remaining salt liquefied with a very gentle fire, it gains the leafy appearance which has procured it the name terra foliata.

X x
In the fourth volume of the Memoirs of the correspondents of the French Academy, lately published, Mr Cadet has given a method of making the salt white at the first evaporation, without the trouble of any farther purification. He observes that the brown colour depends on the oily matter of the vinegar being burnt by the heat commonly employed in the evaporation: and his improvement consists in diminishing the heat at the time that this burning is liable to happen. The process he recommends is as follows:

Dissolve a pound of salt of tartar in a sufficient quantity of cold water; filter the solution, and add by degrees as much distilled vinegar as will sature it, or a little more. Set the liquor to evaporate in a stone-ware vessel in a gentle heat, not so strong as to make it boil. When a pellicle appears on the surface, the rest of the process must be finished in a water-bath. The liquor acquires by degrees an oily confluence, and a pretty deep brown colour; but the pellicle or scum on the top looks whitish, and when taken off and cooled, appears a congeries of little brilliant silver-like plates. The matter is to be kept continually stirring, till it be wholly changed into this white flaky matter; the complete drying of which is most conveniently effected in a warm oven.

We shall not take upon us to determine whether the pure or impure salt is preferable as a medicine; observing only, that the latter is more of a papyraceous nature, the former more acid, though somewhat more agreeable to the stomach. Mr Cadet reckons the salt prepared in his method superior both to the brown and white sorts made in the common way, as possetting both the oily quality of the one and the agreeableness of the other, and as being always uniform or of the same power; whereas the others are liable to vary considerably, according to the degree of heat employed in the evaporation. They are all medicines of great efficacy, and may be so dosed and managed as to prove either mildly cathartic, or powerfully diuretic; few of the saline deobstruents comes up to them in virtue. The dose is from half a scruple to a dram or two. A bare mixture, however, of alkaline salt and vinegar, with excitation, is not perhaps much inferior as a medicine to the more elaborate salt.

Two drams of the alkali, saturated with vinegar, have been known to occasion ten or twelve fiools in hydroptic females, and a plentiful discharge of urine, without any inconvenience.

Tartarized salt. L.

Take of kali one pound; crystals of tartar, three pounds; distilled water, boiling, one gallon. To the salt, dissolved in water, throw in gradually the crystals of tartar, powdered; filter the liquor, when cold, through paper; and, after due evaporation, set it apart to crystallize.

Tartarized vegetable fixed alkali, commonly called soluble tartar. E.

Take of purified fixed vegetable alkaline salt one pound; water, 15 pounds. To the salt dissolved in the boiling water gradually add crystals of tartar in fine powder, as long as the addition thereof raises any effervescence, which almost ceases before three times the weight of the alkaline salt hath been injected; then strain the cooled liquor through paper, and after due evaporation let it abide to crystallize.

Common white tartar is perhaps preferable for this operation to the crystals usually met with. Its impurities can here be no objection; since it will be sufficiently depurated by the subsequent filtration.

The preparation of this medicine by either of the above methods is very easy; though some chemicalists have rendered it sufficiently troublesome, by a nicety which is not at all wanted. They insist upon hitting the very exact point of saturation between the alkaline salt and the acid of the tartar; and caution the operator to be extremely careful, when he comes near this mark, left by imprudently adding too large a portion of either, he renders the salt too acid or too alkaline. If the liquor be suffered to cool a little before it be committed to the filter, and then properly exhausted and crystallized, no error of this kind can happen, though the saturation should not be very exactly hit: for since crystals of tartar are very difficultly soluble even in boiling water, and when dissolved therein concreta again upon the liquor's growing cold, if any more of them has been employed than is taken up by the alkali, this superfusious quantity will be left upon the filter; and, on the other hand, when too much of the alkali has been used, it will remain uncryllalized. The crystallization of this salt indeed cannot be effected without a good deal of trouble: it is therefore most convenient to let the acid salt prevail at first; to separate the superfusious quantity, by suffering the liquor to cool a little before filtration; and then proceed to the total evaporation of the aqueous fluid, which will leave behind it the neutral salt required. The most proper vessel for this purpose is a stone-ware one; iron discolors the salt.

This is an excellent aperient saline liquor. Taken warm in bed, it proves commonly a powerful diaphoretic or sudorific; and as it operates without heat, it has place in febrile and inflammatory disorders, where medicines of the warm kind, if they fail of procuring sweat, aggravate the dilatation. Its action may likewise be determined to the kidneys, by walking about in a cool air. The common dose is half an ounce, either by itself, or along with other medicines adapted to the intention. Its strength is not a little precarious, depending much on that of the vinegar: an inconvenience which cannot easily be obviated, for the saline matter is not reducible to the form of a concrete salt.
Soluble tartar, in doses of a scruple, half a dram, or a dram, is a mild cooling aperient; two or three drams commonly loosen the belly; and an ounce proves pretty strongly purgative. It has been particularly recommended as a purgative for maniacal and melancholic patients. Malouin says, it is equal in purgative virtue to the cathartic salt of Glauber. It is an useful addition to the purgative of the refining kind, as it promotes their operation, and at the same time tends to correct their griping quality. But it must never be given in conjunction with any acid; for all acids decompose it, absorbing its alkaline salt, and precipitating the tartar. On this account it is improper to join it to tamarinds, or such like acid fruits; which is too often done in the extemporaneous practice of those physicians who are fond of mixing different cathartics together.

**Tartarized natron. L.**

Take of natron, 20 ounces; crys\(\text{t}a\)ls of tartar, powdered, 2 pounds; distilled water, 8 drams. Dissolve the natron in the water, and gradually add the crys\(\text{t}a\)ls of tartar: filter the liquor through paper: evaporate and set it aside to crystallize.

**Tartarized sod., commonly called Rochel salt. E.**

The Rochel salt may be prepared from purified fossil alkaline salt and crys\(\text{t}a\)ls of tartar, in the same manner as directed for the soluble tartar. This is a species of soluble tartar, made with the salt of kali or f\(\text{d}\)a, which is the same with the mineral alkali, or baits of sea salt. It crystallizes far more easily than the preceding preparation, and does not, like it, grow moist in the air. It is also considerably less purgative, but is equally decomposed by acids. It appears to be a very elegant salt, and begins now to come into esteem in this country, as it has long been in France.

**Purification of alum. L.**

Take of alum, one pound; chalk one dram by weight; distilled water, one pint. Boil them a little, strain, and let the liquor aside to crystallize.

We have already offered some observations on alum (see Alu\(\text{m}\)); and in general we may say that it comes from the alum works in England in a state of such purity as to be fit for every purpose in medicine; accordingly we do not observe that the purification of alum has a place in any other pharmacopoeias: but by the present process it will be freed, not only from different impurities, but also from superabundant acid.

**Burnt alum. L. E.**

Take of alum, half a pound. Burn it in a earthen vessel so long as it bubbles.

This, with strict propriety, ought rather perhaps to be called dried alum than burnt alum: for the only effect of the burning here directed is to expel the water. In this state it is so acid as to be frequently employed as an elixiratic; and it is with this intention chiefly that it has a place in our pharmacopoeias: but it has sometimes also been taken internally, particularly in cases of cholic.

**Salt or sugar of milk. Suc.**

Take of the whey of milk, prepared by runnet, any quantity; let it be boiled over a moderate fire to the confluence of a syrup; then put it in a cold place, that crys\(\text{t}a\)ls may be formed. Let the fluid which remains be again managed in the same manner, and let the crys\(\text{t}a\)ls formed be washed with cold water.

It has been by some imagined, that the superiority of one milk over another depends on its containing a larger proportion of this saline or succharine part; and particularly that upon this the reputed virtues of afs milk depend. Hence this preparation has been greatly celebrated as disorders of the breast, but it is far from an\(\text{f}i\)ng what has been expected from it. It has little sweetness, and is difficult of solution in water. A saline substance, much better deferving the name of sugar, may be obtained by evaporating new milk, particularly that of the afs, to dryness,digesting the dry matter in water till the water has extracted its soluble parts, and then infusing the filtered liquor. This preparation is of great sweetness, though neither white nor crystalline; nor is it perhaps in the pure crystallizable parts of milk that its medicinal virtues reside; and so little reliance is put on it as a medicine, that it has no place in the London or Edinburgh pharmacopoeias; although it long has stood, and still stands, in the foreign ones.

**Salt of forrel. Suc.**

Take any quantity of the express'd juice of the leaves of wood forrel; let it boil gently, that the succulent matter may be separated; then strain it till it be clear, and after this boil it on a moderate fire to the confluence of a syrup. Put it into long-necked glass vessels, and place it in a cold situation that it may crystallize. Let these crys\(\text{t}a\)ls be dissolved in water, and againformed into purer ones.

To make the forrel yield its juice readily, it should be cut to pieces, and well bruised in a small mortar, before it be committed to the press. The magma which remains in the bag still retaining no inconsiderable quantity of saline matter, may be advantageously boiled in water, and the decoction added to the express'd juice. The whole may be afterwards depurated together, either by the method above directed, or by running the liquor several times through a linen cloth.

In some cases the addition of a considerable portion of water is necessary, that the juice, thus diluted may part the more freely with its fecularities; on the separation of which the success of the process much depends.

The evaporation should be performed either in shallow glass basins, or in such earthen ones as are of a compact close texture; such are those usually called stone ware. The common earthen vessels are subject to have their glazing corroded, and are so extremely porous, as readily to imbibe and retain a good quantity of the liquor; metallic vessels are particularly apt to be corroded by these acid kinds of juices.

These juices are so vi\(\text{v}\)id, and abound so much with heterogeneous matter, of a quite different nature from any thing saline, that a pellicle, or pure saline incrustation upon the surface, is in vain expected. Boerhaave, therefore, and the more expert writers in pharmaceutical chemistry, with great judgment directed the evaporation of the superfluous moisture to be continued...
until the matter has acquired the consistence of cream. If it be now suffered to stand for an hour or two in a warm place, it will, notwithstanding the former de- purations, deposite a fresh sediment, from which it should be warily decanted before it be put into the vege-

tal in which it is designed to be crystallized.

Some recommend an unglazed earthen vessel as preferable for this purpose to a glass one; the smoothness of the latter being supposed to hinder the salt from sticking thereto; while the juice easily infiltrating itsel{ into the pores of the former, has a great advantage of shooting its fatty fpecula to the sides. Others

slightly inculcate the sides and bottom of whatever vessel they employ with a certain mineral salt, which greatly dilutes the juice to crystallize, to which of itsel{ it is very averse; but this addition is, with regard to its medical virtue, quite different from the falt here intended.

The liquor which remains after the crystallization may be depurated by a gentle colature, and after due infipillation fett to shoot again; when a farther produce of crystals will be obtained.

The proceeds for obtaining this falt is very tedious; and the quantity of falt which the juices afford is extremely small: hence they are hardly ever made or exported in the fshops. They may be somewhat fooner separated from the mucilage and other feculencies, by clarification with whites of eggs, and by adding very pure white clay.

In the manner above described, falts may also be obtained from other acid, auflere, and bitter plant, which contain but a small quantity of oil.

The virtues of the effential falts have not been sufficiently determined from experience. This much, however, is certain, that they do not, as has been supposed, possess the virtues of the fubjects entire, excepting only the acids and fweets. The others seem to be almost all of them nearly similar, whatever plant they were obtained from. In watery extracts of worm-

wood, carduus, cannoline, and many other vegetables, kept for some time in a fett flate, there may be ob-

erved fine fatty effulences on the surface, which have all nearly the fame taste, somewhat of the nitrous kind. They are fuppofed by fome to be in reality no more than an impure fpecies of volatile nitre (that is, a falt compos'd of the nitrous acid and volatile alkali): those which were examined by the chemists of the French academy defigilated in the fire, and being tri-

turated with fixed alkali, exhaled an urinous odour; plain marks of their containing those two ingredients.

Acid falt of borax. Succ.

Take of borax an ounce and a half; warm spring-

water, one pound. Mix them in a glafs veftel, that the borax may be disfolved; then pour into it three

drums of the concentrated acid of vitriol; evaporate the liquor till a pellicle appears upon it; after this let it remain at reft till the crystals be formed. Let them be washed with cold water, and kept for use.

This falt, which has long been known by the title of the fuddative falt of Homberg, is not unfrequently formed by fublimation: but the proceeds by crystallization here direcled is lefs troublesome, though the falt proves generally less white, and is apt likewise to re-

tain a part of Glauber's falt, especiall if the evapo-

ration be long protracted.

The falt of borax to the taste appears to be a neutral; but when it is examined by alkalis, it shows the properties of an acid, effervescing, uniting, and crysfalizing with them, and it destroys their alkaline quality. It diibolves both in water and spirit of wine, although not very readily in either.

The virtues attributed to it may in some degree be inferred from the name of fudative, by which it was long distinguished. It has been supposed to be a mild antifeptic, to diminish febrile heat, to prevent or remove delirium, and to allay, at least for fome time, spafmodical affections, particularly those which are the attendants of hypochondria and hysteric. It may be given in doses from two to twenty grains.

Purified falt ammoniac. Succ.

Difolve falt ammoniac in fpring water; strain the li-

quor through paper; evaporate it to dryness in a glafs veftel by means of a moderate fire.

The falt ammoniac imported from the Mediterranean often contains fuch impurities as to render the above proceeds neceffary; but that which is prepared in Britifh from foot and sea-falt, is in general brought to market in a flate of very great purity. Hence this proceeds is now altogether omitted both in the London

and Edinburgh Pharmacopoeias. It furnifhes, however, when neceffary, an easy and effective mode of obtaining a pure ammonia muriata.

CHAP. VIII. Magnesia.

White magnesia.

Take of bitter purging falt, kali, each two pounds; disfolved water, boiling, 20 pints. Disolve the bit-

ter falt and the kali separately in 10 pints of water, and fifter through paper; then mix them. Boil the liquor a little while, and strain it while hot through linen, upon which will remain the white magnesia: then wash away, by repeated affufions of disfolved water, the vitriolated kali. I.

Take of bitter purging falt, and purified fixed vegetable alkali, equal weights. Disolve them separately in double their quantity of warm water, and let the liquor be strained or otherwise freed from the feces; then mix them, and infantly add eight times their quantity of warm water. Let the liquor boil a little, thirring it very well at the fame time; then let it reft till the heat be somewhat diminished; af-

ter which strain it through a cloth: the magnesia will remain upon the cloth, and it is to be washed with pure water till it be altogether void of faltine faltls. E.

The feries here directed by the London and Ed-

inburgh colleges are nearly the fame; but the former feem to have improved fomewhat on the latter, both in simplifying the proceeds, and in the employment of disfolved water.

The bitter cathartic falt, or Ephym falt, is a com-

bination of the vitriolic acid and magnesia. In this pro-

cess, then, a double elecive attraction takes place: the vitriolic
Part II.

PHARMACY.

Magnesia is the same species of earth with that obtained from the mother-leaf of nitre, which was for several years a celebrated secret in the hands of some particular persons abroad. Hoffman, who describes the preparations of the nitrous magnesia, gives it the character of an useful antacid, a safe and inoffensive laxative in doses of a dram or two, and a diaphoretic and diuretic when given in smaller doses of 15 or 20 grains. Since his time, it has had a considerable place in the practice of foreign physicians; and is now in great esteem among us, particularly in heart-burns, and for preventing or removing the many disorders which children are so frequently thrown into from a redundance of acid humours in the first paffages; it is preferred, on account of its laxative quality, to the common aborments, which, unless gentle purgatives be occasionally given to carry them off, are apt to lodge in the body, and occasion a coffiveness very detrimental to infants.

Magnesia alba, when prepared in perfection, is a white and very soluble earth, perfectly void of smell or taste, of the class of those which dissolve in acids. It diffolves freely even in the vitriolic acid; which, in the common way of making solutions, take up only an incon siderable portion of other earths. Combined with this acid, it forms the bitter purgative or Epsom salt, very easily soluable in water: while the common aborments form with the same acid almost infipid con cretes, very difficult of solution. Solutions of magnesia in all acids are bitter and purgative, while those of the other earths are more or less dull and astringent. A large dose of magnesia, if the stomach contain no acid to dissolve it, does not purge or produce any fermentable effect; a moderate one, if an acid be lodged there, or if acid liquors be taken after it, procures several stools; whereas the common aborments, in the same circumstances, instead of loosing, bind the belly. It is obvious, therefore, that magnesia is specifically different from the other earths, and that it is applicable to several useful purposes in medicine.

Magnesia was formerly made with the mother-water of nitre evaporated to dryness, or precipitated by a fixed alkalii. It has gone under different names, as the white Powder of the Count of Palma, powder of ferniate, psychris, laxative powder, &c. It seems to have got the character of a substance to distinguish it from the dark coloured mineral called sile magnesia or mangane: a substance possessing very different proprieties. We have not heard that pure native magnesia has been found in its uncombined state. A combination of it with sulphur has been discovered to cover a stratum of coal at Littry in Lower Normandy. It has also been found in certain serpentine earths in Saxony, and in marly and alun earths.

Calced magnesia.

Take of white magnesia, four ounces. Expose it to a strong heat for two hours; and, when cold, set it by. Keep it in a vessel closely stoped. L.

Let magnesia, put into a crucible, be continued in a red heat for two hours; then put it up in clofe glass vessels. E.

By this process the magnesia is freed of fixed air; which, according to Dr Black's experiments, 

1/4
PHARMACY.

Part II.

Preparations and Compilations.

Tinctures about \( \frac{3}{4} \) ths of its weight. A kind of opaque foggy vapour is observed to escape during the calcination, which is nothing else than a quantity of fine particles of magnesia buoyed off along with a stream of the difengaged air. About the end of the operation, the magnesia exhibits a kind of luminous or phosphorescent property; and this may be considered as a pretty exact criterion of its being deprived of air.

Calcined magnesia is equally mild as when satured with fixed air; and this circumstance is sufficient to establish a difference between it and calcareous earths, all of which are converted by calcination into caustic quicklime.

The calcined magnesia is used for the same general purposes as the magnesia combined with fixed air. In certain affections of the stomach, accompanied with much flatulence, the calcined magnesia is found preferable, not only as containing more of the real earth of magnesia in a given quantity, but as being also deprived of its air. It neutralizes the acid of the flomach without that extirpation of air which is often troublesome consequence in employing the aerated magnesia in these complaints. It is proper to observe, that magnesia, whether combined with or deprived of fixed air, is similar to the mild calcareous earths in promoting and increasing putrefaction. The fame has even been observed with respect to the Epson and some other salts which have this earth for their base.

CHAP. IX. Preparations of Sulphur.

Washed flowers of Sulphur.

Take of flowers of sulphur, one pound; distilled water, four pints. Boil the flowers of sulphur a little while in the distilled water; then pour off this water, and wash off the acid with cold water; lastly, dry the flowers.

In the former editions of our pharmacopoeias directions were given for the preparation of the flowers of sulphur themselves; but as a large apparatus is necessary for doing it with any advantage, it is now scarcely ever attempted by the apothecaries. When the flowers are properly prepared, no change is made on the qualities of the sulphur. Its impurities only are separated; and at the same time it is reduced to a finer powder than it can easily be brought to by any other means. But as the flowers of sulphur are generally sublimed in very capacious rooms, which contain a large quantity of air, or in vessels not perfectly close, some of those that strike at first are apt to take fire, and thus are changed into a volatile acid vapour, which mingling with the flowers that sublimate afterwards, comminutes to them a considerable degree of acidity. In this case the sublimation here directed is for the general use of the medicine absolutely necessary; for the flowers thus tainted with acid sometimes occasion gripes, and may in other respects be productive of effects different from those of pure sulphur. There are, however, some particular combinations to which they are supposed to be better adapted when unwashed, such as their union with mercury into calathia mineral; and accordingly for that preparation the unwashed flowers are directed by the London college.

Sulphurated kali. L.

Take of flowers of sulphur, one ounce; kali, five ounces. Mix the salt with the melted sulphur, by frequently stirring, until they unite into an uniform mass.

This preparation, in the former editions of our pharmacopoeias, had the name of hepar sulphur or liver of sulphur.

It is much more convenient to melt the sulphur first by itself, and add the salt of tartar by degrees, as here directed, than to grind them together, and afterwards endeavour to melt them, as ordered in former editions; for in this last case the mixture will prove insufficiently thin to be properly united by stirring; and the sulphur either takes fire or sublimes in flowers, which probably has been the reason why so large a proportion of it has been commonly directed. Even in the present method a considerable part of the sulphur will be diffipated; and if it were not, the hepar would not be of its due quality: for one part of sulphur requires two of the alkaline salt to render it perfectly soluble in water, which this preparation ought to be.

The hepar sulphurhas a fetid smell and a nauseous taste. Solutions of it in water, made with sugar into a fyrup, have been recommended in coughs and other diffidays of the breath. Our pharmacopoeias, nevertheless, have delievred rejected this fyrup, as common practice has aimed it done the balsams. Solutions of the hepar in water have also been recommended in herpetic and other cutaneous affections. Some physicians have even employed this solution, in a large quantity, as a bath for the cure of psores; and in cases of tinea capitis it has often been used by was of the hepar.

The hepar, digested in refrig'd spirit of wine, imparts a rich gold colour, a warm, somewhat aromatic taste, and a peculiar, not ungrateful smell. A tincture of this kind is kept in the shops under the name of another mineral. The hepar sulphurhas been by some strongly recommended to prevent the effects of mineral poison.

Sulphurated oil and sulphurated petroleum.

Take of flowers of sulphur, four ounces; olive oil, sixteen ounces. Boil the flowers of brimstone with the oil, in a pot lightly covered, until they be united. In the same manner is made sulphurated petroleum.

These articles are analogous to what had formerly a place in our pharmacopoeias under the titles of balsamum sulphuris simplex, crassum, et Barbadum iuf. And besides there a place was also given to the balsamum sulphuris o-fideum, tercbentinum, &c. While these articles, however, are now banished from our pharmacopoeias, even those retained are left in the same name, as formerly.

These preparations are more conveniently and safely made in a tall glass body, with the mouth at least an inch in diameter, than in the circulatory or clofe vefels in which they have commonly been directed to be prepared: for when the sulphur and oil begin to act vehemently upon each other, they not only rarify into a large volume, but likewise throw out impetuously great quantities of an elastic vapour; which, if the vefels be clofed, or the orifices not sufficient to allow it
it a free exit, will infallibly burst them. Hoffman relates a very remarkable history of the effects of an accident of this kind. In the vessel above recommended the procès may be completed, without danger, in four or five hours, by duly managing the fire, which should be very gentle for some time, and afterwards increased so as to make the oil just bubble or boil; in which state it should be kept till all the sulphur appears to be taken up.

Effential oils, employed as menstrua for sulphur, undergo a great alteration from the degree of heat necessary for enabling them to diffuse the sulphur; and hence the balsams have not nearly so much of their flavour as might be expected. It should therefore seem more eligible to add a proper quantity of the effential oils to the simple balsam: these readily incorporate by a gentle warmth, if the vessel be now and then shaken. We may thus compose a balsam more elegant than those made in the manner formerly recommended, and which retains so much of the flavour of the oil as is in some measure sufficient to cover the taste of the sulphur, and render it supportable.

The balsams of sulphur have been strongly recommended in coughs, consumption, and other disorders of the breath and lungs; but the reputation which they have had in these cases does not appear to have been built on any fair trial or experience of their virtues. They are manifestly hot, acrimonious, and irritating; and therefore should be used with the utmost caution. They have frequently been found to injure the appetite, offend the stomach and vitreous, parch the body, and occasion thirst and febrile heats. The dose of the simple balsam is from ten to forty drops: those of effential oils are not given in above half these quantities. Externally, they are employed for cleansing and healing foul running ulcers. Boerhaave conjectures that their use in these cases gave occasion to the virtues attributed to them when taken internally.

Precipitated sulphur. L.

Take of sulphurated kali, fix ounces; distilled water one pound and a half; vitriolic acid, diluted, as much as is sufficient. Boil the sulphurated kali in the distilled water until it be diffolved. Filter the liquor through paper, to which add the vitriolic acid. With the precipitated powder by often pouring on water till it becomes fluid.

This preparation is not so white as that of the last pharmacopoeia, which was made with quicklime; and which in some pharmacopoeias had the name of milk of sulphur.

Pure milk of sulphur is not different in quality from pure sulphur itself; to which it is preferred in unguents, &c., only on account of its colour. The whiteness does not proceed from the sulphur having lost any of its parts in the operation, or from any new matter superadded: for if common sulphur be ground with alkaline salts, and set to sublime, it rises of a white like colour, the whole quantity of the alkali remaining unchanged; and if the milk be melted with a gentle fire, it returns into yellow sulphur again.

It may be observed, that the name lae sulphuris, or milk of sulphur, applied among us to the precipitate, is by the French writers confined to the white liquor before the precipitate has fallen from it.

**Precipitated sulphur. L.**

Take of sulphurated kali, six ounces; distilled water one pound and a half; vitriolic acid, diluted, as much as is sufficient. Boil the sulphurated kali in the distilled water until it be diffused. Filter the liquor through paper, to which add the vitriolic acid. With the precipitated powder by often pouring on water till it becomes fluid.

This preparation is not so white as that of the last pharmacopoeia, which was made with quicklime; and which in some pharmacopoeias had the name of milk of sulphur.

Pure milk of sulphur is not different in quality from pure sulphur itself; to which it is preferred in unguents, &c., only on account of its colour. The whiteness does not proceed from the sulphur having lost any of its parts in the operation, or from any new matter superadded: for if common sulphur be ground with alkaline salts, and set to sublime, it rises of a white like colour, the whole quantity of the alkali remaining unchanged; and if the milk be melted with a gentle fire, it returns into yellow sulphur again.

It may be observed, that the name lae sulphuris, or milk of sulphur, applied among us to the precipitate, is by the French writers confined to the white liquor before the precipitate has fallen from it.
If similar delicate effects have been observed, that when diaphoretic powder is taken by such operations as do not destroy or calcine the metal, the remaining snifs becomes proportionally more active.

The sulphur of antimony may be expelled by deflagration with nitre: the larger the quantity of nitre, to a certain point, the more of the sulphur will be dissipated, and the preparation will be the more active.

If the quantity of nitre be more than sufficient to consume the sulphur, the rest of it, deflagrating with the inflammable principle of the regulus itself, renders it again mild.

The sulphur of antimony is likewise absorbed in fusion by certain metals and alkaline fables. The last, when united with sulphur, prove a menstrum for all the metals (zinc excepted), and hence, if the fusion be long continued, the regulus is taken up, and rendered soluble in water.

From these particulars with respect to antimony, it may naturally be concluded, that it not only furnishes us with an useful and active medicine, but that it may also be exhibited for medical purposes under a great variety of different forms, and that the effects of these will be considerably diversified. And this has in reality been the case. For further information respecting antimony, and its uses in medicine, we refer our readers to the articles Antimony; Materia Medica, p. 653, &c.; and Chemistry-Index. But although there is perhaps no preparation there mentioned, which is not fitted to serve some useful purpose; yet the colleges of London and Edinburgh have now reduced the number of preparations in their pharmacopoeias to a few only. And it is highly probable, that from the proper employment of them, every useful purpose to be answered by antimony may be accomplished.

Calculated antimony. L.

Take of antimony, powdered, eight ounces; nitre, powdered, two pounds. Mix them, and cast the mixture by degrees into a red hot crucible. Burn the white matter about half an hour; and, when cold, powder it; after which wash it with distilled water.

In the last edition of the London Pharmacopoeia, this preparation had the name of calx of antimony; and it may be considered as at least very nearly approaching to some other antimonials of the old pharmacopoeias, particularly to the nitrated diaphoretic antimony, washed ditto, and filiated nitre; none of which are now received as separate formulas of the Edinburgh Pharmacopoeia, and indeed even the calx of antimony itself, as last as thus prepared, has now no place in that pharmacopoeia.

The calx of antimony, when freed by washing from the saline matter, is extremely mild, if not altogether inactive. Hoffman, Lemeroy, and others, affirme us, that they have never experienced from it any such effects as its usual title imports: Boerhave declares, that it is a mere metallic earth, entirely delusive of all medicinal virtue: and the committee of the London college admit that it has no sensible operation. The common dose is from five grains to a dram; though Wilton relates, that he has known it given by half ounces, and repeated two or three times a day, for several days together.

Some report that this calx, by keeping for a length of time, contracts an emetic quality: From whence it has been concluded, that the powers of the regulus part are not entirely destroyed; that the preparation has the virtues of other antimonials which are given as alternatives; that is, in small doses as not to stimulate the prime vices; and that therefore diaphoretic antimony, or calculated antimony, as it is now more properly styled, is certainly among the mildest preparations of that mineral, and may be used for children, and similar delicate constitution where the stomach and intestines are easily affected. The observations, however, from which these conclusions are drawn, do not appear to be well founded: Ludovici relates, that after keeping the powder for four years, it proved as mild as at first: and the Strasburgh Pharmacopoeia, with good reason, suspects, that where the calx has proved emetic, it had either been given in such cases as would of themselves have been attended with this symptom (for the great alexipharmic virtues attributed to it have occurred to it to be exhibited even in the more dangerous malignant fevers, and other disorders which are frequently accompanied with vomiting); or that it had not been sufficiently calcined, or perfectly freed from such part of the regulus as might remain uncalcined. The uncalcined part being grooser than the true calx, the separation is effected by often washing with water, in the same manner as directed for expasting earthly powders from the groser parts.

It has been observed, that when diaphoretic antimony is prepared with nitre abundantly with three parts, of which all the common nitre contains some portion, the medicine has proved violently emetic. This effect is not owing to any particular quality, of the false, but to its quantity, by which the proportion of the nitre to the antimony is rendered less.

The nitrum filiatum, as it was called, produced by the deflagration of the sulphur of the antimony with the nitre in the same manner as the ful polycrebri, from which it differs no otherwise than in retaining some portion of the antimonial calx.

Notwithstanding the doubts entertained by some respecting the activity of the antimonium calxantium, yet the London college have in our opinion done right in retaining it. For while it is on all hands allowed that it is the mildest of our antimonials, there are some accurate observers who consider it by no means indifferent. Thus Dr. Heale tells us, that he has been in the habit of employing it in upwards of 40 years, and is much deceived, if when genuine, it be not productive of good effects.

Nitrated calx of antimony. E.

Take of antimony calculated for making the galls of antimony, and nitre, equal weights. Having mixed, and put them into a crucible, let them be heated, so that the matter shall be of a red colour for an hour; then let it be taken out of the crucible, and, after beating it, wash it repeatedly with warm water till it be infipid.

Although this preparation agrees nearly in name with
the preceding, and has been considered as being nearly
a complete calx of antimony, yet there can be no
doubt that it is a medicine of a much more active
nature than the former; and in place of being one
of the mildest of the antimonials, it often operates
with great violence when given in doses of a few
grains only.

But as the effects of every preparation of antimony,
not already conjoined with an acid, must depend on
the quantity and condition of the acid in the fomach,
so the ablution of the base of the nitre in this process
gives full power to the acid of the fomach to act as
far as possible on the calx, whereas, when the un-
washed calx is employed, a great quantity of the acid
in the fomach is neutralized by the alkaline base
of the nitre adhering to the calx. The nitrated calx of
antimony is supposed to be nearly the fame with the article
which has been so much celebrated, and has had such
an extensive sale under the title of Dr James's fever-
powder. And it was as an article which might be
employed in the place of James's powder, that the
Edinburgh college introduced this into their pharma-
copoeia. There is, however, reason to believe, that
the preparation of James's powder is somewhat dif-
ferent from that here directed; but their effects, as far
as our observation goes, appear to be very nearly the
fame.

The nitrated calx of antimony has been thought by
some preferable to emetic tartar, where the permanent
effects of a long continued nausea are required, and
where we with our antimonials to pass the pylorus and produce purging. But, like every other preparation
where the reguine part is only rendered active by the
acid in the fomach, the nitrated calx of antimony is in
all cafes of uncertain operation: sometimes proving per-
fectly inert, and at other times very violent in its ef-
efts. The dose is generally 10 or 12 grains, and
this is often given all at once; an inconvenience not
attending the emetic tartar; the quantity and effects
of which we can generally measure with surprising mi-
nutenefs.

There is, however reason to believe, that by means
of James's powder, and the nitrated calx, an artificial
termination of fever is sometimes accomplished, and
that too more frequently than by emetic tartar. This
perhaps may sometimes be the consequence of the vio-
ience with which they operate. At the fame time it
must be admitted, that even the most violent operation
by no means ensuring an immediate recovery, but that
on the contrary it is sometimes manifeftly attended
with bad effects.

Crocus of antimony.

Take of antimony, powdered; nitre, powdered, of
each one pound; tefalt, one ounce. Mix, and
put them by degrees into a red hot crucible, and
melt them with an augmented heat. Pour out the
melted matter; and, when cold, separate it from the
fcoriure. L

Equal parts of antimony and nitre are to be injected
by degrees into a red-hot crucible; when the de-
composition is over, separate the reddish metallic
matter from the whitish cuttle; beat it into a powder,
and add to it by repeated washings with hot
water, till the water comes off impid. E.

Vol. XIV.
the former edition of the London pharmacopoeia, is extremely dangerous, inasmuch that even the life of the operator, though tolerably verified in common pharmacy, may be much endangered for want of due care. Boerhaave relates, that one who from the title he gives him is not to be supposed inexpert in chemical operations, or unacquainted with the danger attending this, was suffocated for want of proper care to prevent the bursting of the retort. The fumes which arise, even upon mixing the antimony with the sublimate, are highly noxious, and sometimes inflame copiously and suddenly, as very difficultly to be avoided. The utmost circumspection therefore is necessary.

The caustic, or butter as it is called, appears to be a solution of the metallic part of the antimony in the marine acid of the sublimate: the sulphur of the antimony and the mercury of the sublimatic remain at the bottom of the retort united into an ethiop. This solution does not succeed with spirit of salt in its liquid state, and cannot be effected, unless (as in the case of making sublimate) either the acid be highly concentrated, and both the ingredients strongly heated; or when the antimony is exposed to the vapours of the acid diffused from the black calx of manganite. By this last process a perfect solution of the regulus of antimony in the muriatic acid is effected. Of this more simple, more safe, and less expensive method of preparing muriated antimony, an account is given by Mr Ruffell in the Transactions of the Royal Society of Edinburgh.

If regulus of antimony were added in the distillation of spirit of sea-salt without water, a solution would also be made.

The method however, now directed by the London college, in which vitriolic acid and sea-salt are employed to give a double elective attraction, is perhaps to be considered as preferable to any of the others. In this they have followed very nearly the directions given in the pharmacopoeia Suecica, which are taken from the process of Mr Scheele.

When the congealed matter that arises into the neck of the retort is liquified, by the moisture of the air, it proves less corrosive than when melted down and rectified by heat; though it seems, in either case, to be sufficiently strong for the purposes of consuming fungous flesh and the callous lips of ulcers. It is remarkable, that though this saline concrete readily and almost entirely dissolves by the humidity of the air, only a small quantity of white powder separating, it nevertheless will not dissolve on putting water to it directly; even when previously liquefied by the air; the addition of water will precipitate the solution. And accordingly, by the addition of water is formed that one celebrated article known by the title of muriatus vitri, or Algeorth's powder. This preparation, though never used by itself, is employed both by the Edinburgh and by London colleges, in the preparation of muriatic antimony; in the formation of emetic tartar, the most useful of all the antimonials. And although chemists are not altogether agreed with regard to the best mode of making the tartarized antimony, yet we shall afterwards have occasion to observe, when treating of that article, that the preparation of it from the muriated antimony, or rather from its precipitate (Algeroth's powder), is perhaps the best mode which has yet been practised. And were it even with no other intention than this; a safe, easy, and cheap method of forming a muriated antimony, may be considered as an important improvement in our pharmacopoeia.

Antimonial powder. L.

Take of antimony, coarsely powdered, harthorn shavings, each two pounds; mix, and put them into a wide red hot iron pot, stirring constantly till the mass acquires a grey colour. Powder the matter when cold, and put it into a coated crucible. Lute to it another crucible inverted, which has a small hole in its bottom: augment the fire by degrees to a red heat, and keep it so for two hours. Lastly, reduce the matter, when cold, to a very fine powder.

In this preparation the metallic part of the antimony in a flake of calx will be united with that part of the harthorn which is indestructible by the action of fire, viz. its absorbent earth. If this powder be properly prepared, it is of a white colour. It is a mild antimonial preparation, and is given as an alternative from three to six grains for a dose. In this quantity, however, it sometimes creates nausea, and even vomits. In larger doses it proves emetic, and operates by stool.

Precipitated sulphur of antimony. L.

Take of antimony, powdered, two pounds; water of pure kali, four pints; distilled water, three pints; mix, and boil them with a slow fire for three hours, constantly stirring, and adding the distilled water as it shall be wanted: strain the hot ley through a double linen cloth, and into the liquor, whilst yet hot, drop by degrees as much diluted vitriolic acid as is sufficient to precipitate the sulphur. Wash off, with warm water, the vitriolated kali.

Golden sulphur of antimony. E.

Boil, in an iron pot, four pounds of caustic ley distilled with three pints of water, and throw in by degrees two pounds of powdered antimony; keeping them continually stirring with an iron spatula for three hours, over a gentle fire, and occasionally supplying more water. The liquor loaded with the sulphur of antimony being then strained through a woolen cloth, drop into it gradually, while it continues hot, so much spirit of nitre, diluted with an equal quantity of water, as shall be sufficient to precipitate the sulphur which is afterwards to be carefully washed with hot water.

The foregoing preparations are not strictly sulphurs; they contain a considerable quantity of the metallic part of the antimony, which is reducible from them by proper fluxes. These medicines must needs be liable to great variation in point of strength; and in this respect they are, perhaps the most precarious, though some have affirmed that they are the most certain, of the antimonial medicines.

They prove emetic when taken on an empty stomach, in a dose of four, five, or six grains; but at present they are scarcely prescribed with this intention; being chiefly used as alterative debubrents, particularly in cutaneous disorders. Their emetic quality is easily blunted, by making them up into pills with re-
Part II.

PHARMACY.

Preparations and Compositions,

Tartarized antimony. L.

Take of crocus of antimony, powdered, one pound and an half; crystals of tartar, two pounds; distilled water two gallons: boil in a glass vessel about a quarter of an hour; filter through paper, and set aside the strained liquor to crystallize.

Emetic tartar. E.

Take of the butter of antimony what quantity you choose; pour it into warm water, in which is much of the purified vegetable fixed alkali has been previously dissolved, that the antimonial powder may be precipitated, which, after being well washed, is to be dried. Then to five pounds of water add of this powder nine drams, of crystals of tartar, beat into a very fine powder, two ounces and a half, boil for a little till the powders be dissolved. Let the strained solution be slowly evaporated in a glass vessel to a pellicle; so that crystals may be formed.

We have here two modes of making the most common, and perhaps we may add the most useful, of all the antimonial preparations, long known in the shops under the name of emetic tartar. These modes differ considerably from each other; but in both, the reguline part of the antimony is united with the acid of the tartar. It is perhaps difficult to say to which mode of preparation the preference is to be given: for on this subject the best chemists are still divided in their opinion. The mode directed by the London college is nearly the same with that in the former editions of their pharmacopoeia, while that now adopted by the Edinburgh college, in which they have nearly followed the Pharmacopoeia Rhetica, is of later date. That in both ways a good emetic tartar may be formed, is very certain: but in our opinion, it is formed of the precipitate from the muriatic acid or the prepuce del Algemeen, as it has been called, is the least chance of its being certain in its operation: and this method comes recommended to us by the authority of Bergman, Schenck, and some other of the best names in chemistry. Bergman states, that the calx be precipitated, by simple water, as being least liable to variation; and this is the direction followed in the Pharmacopoeia Rhetica. But when the calx is precipitated by an alkaline ley, as is directed by the Edinburgh college, it is more certainly freed from the muriatic acid, and will of course be better.

In the latter part of the process, whether precipitate or crocus have been used, the quantity of the antimonial ought always to be some drams more than is absolutely necessary for saturating the acid of tartar, so that no crystals may shoot which are not impregnated with the active metallic part of the antimony. And in order to secure an uniform strength, some attention is necessary in collecting the crystals, as some may contain more metal than others. After they are all separated from the liquor, they ought to be beat together in a glass mortar into a fine powder, that the medicine may be of uniform strength.

Emetic tartar, of all the preparations of antimony, the most certain in its operation.

It will be sufficient, in considering the medicinal effects of antimonials, that we should observe, once for all, that their emetic property depends on two different conditions of the reguline part: the first is where the reguline part is only active, by being rendered fo from meeting with an acid in the stomach: the second is where the reguline part is already joined with an acid, rendering it active. It is obvious, that those preparations, reducible to the first head, must always be of uncertain operation. Such then is the equal uncertainty in the chemical condition and medicinal effects of the croc, the hepata, and the calces; all of which proceed from different steps or degrees of freeing the reguline part from sulphur and phlogiston. It is equally plain, that the preparations coming under the second head must be always constant and certain in their operation. Such a one is emetic tartar, the dose and effects of which we can measure with great exactness.

The title of this medicine expresses its principal operation. It is one of the best of the antimonial emetics, acting more powerfully than the quantity of crocus contained in it would do by itself, though it does not so much muffle the constitution. And indeed antimonials in general, when thus rendered soluble by vegetable acids, are more safe and certain in their effects than the violent preparations of that mineral exhibited by themselves; the former never varying in their action from a difference in the food taken during their use, or other similar circumstances; which occasioning more or less of the others to be dissolved, make them operate with different degrees of force. Thus, crude antimony, where acid food has been liberally taken, has sometimes proved violently emetic; whilst in other circumstances it has had no such effect.

The dose of emetic tartar, when designed to produce the full effect of an emetic, is from two to four grains. It may likewise be advantagiously given in much smaller doses as a nauseating and sedative medicine.

Purified antimony. L.

Take of powdered antimony, four ounces. Calxine in a broad earthen vessel, with a fire gradually raised, till it no longer emits a fulphureous smoke. Put this powder into a crucible, to as to fill two third of it. Aever being fired Y 2 on,
PHARMACY.

Preparations and Compositions.

Glafs of antimony. E.

Strew antimony, beat into a coarse powder like sand, upon a shallow unglazed earthen vessel, and apply a gentle heat underneath, that the antimony may be heated slowly; keeping it at the same time continually stirring to prevent it from running into lumps. White vapours of a fulphureous smell will arise from it. If they cease to exhale with the degree of heat first applied, increase the fire a little, so that vapours may again arise: go on in this manner, till the powder, when brought to a red heat, exhales no more vapours. Melt the calx in a crucible with an intense heat, till it assumes the appearance of melted glafs; then pour it out on a heated brass plate or dish.

The calcination of antimony, in order to procure transparent glafs, succeeds very slowly, unless the operator be not a little circumspect in the management of it. The most convenient vessel is a broad shallow dish, or a smooth flat tile, placed under a chimney. The antimony should be the purer sort, such as is usually found at the apex of the cones; this, grossly powdered, is to be evenly spread over the bottom of the pan, so as not to lie above a quarter of an inch thick on any part. The fire should be at first no greater than is just sufficient to raise a fume from the antimony, which is to be now and then stirred: when the fumes begins to decay, increase the heat, taking care not to raise it so high as to melt the antimony, or run the powder into lumps; after some time the vessel may be made red-hot, and kept in this state until the matter will not, upon being stirred, any longer fuse. If this part of the process be duly conducted, the antimony will appear in an uniform powder, without any lumps, and of a grey colour.

With this powder fill two-thirds of a crucible, which is to be covered with a tile, and placed in a wind-furnace. Gradually increase the fire till the calx be in perfect fusion, when it is to be now and then examined by dipping a clean iron wire into it. If the matter which adheres to the end of the wire appears smooth and equally transparent, the vitrification is completed, and the glafs may be poured out upon a hot smooth stone or copper-plate, and suffered to cool slowly to prevent its cracking and flying in pieces. It is of a transparent yellowish red colour.

The glafs of antimony usually met with in the shops, is said to be prepared with certain additions; which may, perhaps, render it not so fit for the purpose here designed. By the method above directed, it may be easily made of the requisite perfection without any addition.

As antimony may be rendered nearly or altogether inactive by calcination, it might be expected that the calx and glafs of the present process would be likewise inert. But here the calculation is far less perfect than in the other case, where the inflammable principle of the regulus is totally burnt out by deflagration with nitre; there the calx is of perfect whiteness, and a glafs made from that calx (with the addition of any saline flux, for of itself it will not vitrify) has little colour:

but here so much of the inflammable principle is left, that the calx is grey, and the glafs of a high colour.

The calcined antimony is said by Boerhaave to be violently emetic. Experience has shown that the glafs is so insomuch as to be unsafe for internal use. At present it is chiefly employed in forming some other antimonial preparations, particularly the cerated glafs of antimony, the next article to be mentioned; and the wine of antimony, afterwards to be treated of under the head of wines. It is also not unfrequently employed in the formation of emetic tartar; and it was directed for that purpose in the last edition of the Edinburgh pharmacopoeia, being perhaps even superior to the crocus of antimony.

Cerated glafs of antimony. E.

Take of yellow wax, a dram; glafs of antimony, reduced into powder, an ounce. Melt the wax in an iron vessel, and throw into it the powdered glafs: keep the mixture over a gentle fire for half an hour, continually stirring it; then pour it out on paper, and when cold grind it into powder.

The glafs melts in the wax with a very gentle heat: after it has been about twenty minutes on the fire, it begins to change its colour, and in ten more comes near to that of Scotch snuff; which is a mark of its being sufficiently prepared; the quantity set down above loses about one dram of its weight in the process.

This medicine was for some time much esteemed in dysereties: several influences of its good effects in those cases may be seen in the fifth volume of the Edinburgh Essays, from which the above remarks on the preparations are taken. The dose is from two or three grains to twenty, according to the age and strength of the patient. In its operation, it makes some persons sick and vomit; it purges almost everyone; though it has sometimes effected a cure without occasioning any evacuation or sickness. It is now, however, much less used than formerly.

Mr Geoffroy gives two pretty singular preparations of glafs of antimony, which seem to have some affinity with this. One is made by distilling the glafs, very finely levigated, with a solution of mastic made in spirit of wine, for three or four days, now and then shaking the mixture; and at last evaporating the spirit so as to leave the mastic and glafs perfectly mixed. Glafs of antimony thus prepared, is said not to prove emetic, but to act merely as a cathartic, and that not of the violent kind. A preparation like this was first published by Hartman, under the name of Clysta.

The other preparation is made by burning spirit of wine on the glafs three or four times, the powder being every time exquisitely rubbed upon a marble. The dose of this medicine is from ten grains to 20 or 30: it is said to operate mildly both upwards and downwards and sometimes to prove sudorific.

Cerus of antimony. Brun.

Take of regulus of antimony, one part; nitre, three parts. Deflagrate them together; in the manner directed for the calcined antimony.

The result of this process and that formerly directed for the calcined antimony are nearly the same.

It is not necessary to use so much nitre here as when antimony
antimony is employed: for the sulphur which the crude mineral contains, and which requires for its dissipation nearly an equal weight of nitre to the antimony, is here already separated. Two parts of nitre to one of the regulus are sufficient. It is better, however, to have an over, than an under, proportion of nitre, lest some parts of the regulus should escape being sufficiently calcined.

It may be proper to observe, that though crude antimony and the regulus yield the same calces, yet the calces separated in washing the calces are very different. As crude antimony contains common sulphur, the acid of the sulphur unites with the alkaline basis of the nitre, and the result is a neutral salt. As the regulus contains the phlogistic, or inflammable principle, but no sulphur, the nitre is alkalified, and the fire kept up strongly for an hour or more, the salt will prove more caustic than even the potential caustic of the flops. But the causticity of the salt will still be far greater, if, instead of the simple regulus of antimony, the martial regulus be used.

**Kerme Mineral.**

Take of crude antimony, powdered, half a pound; fixed vegetable alkali, two pounds; boiling water, eight pounds. Boil them together in an iron pot for a quarter of an hour, continually stirring the mixture with an iron spatula, and filter as speedily as possible while it is hot. The filtered liquor, set in cool places, will soon deposit a powder, which must be repeatedly washed, first with cold and afterwards with warm water, until it be perfectly inus. This medicine has of late been greatly esteem in France, especially under the names of **Kerme Mineral, pulvis Carthusians, poeder des Chartreux.**

It was originally a preparation of Glauber, and for some time kept a great secret, till at length the French king purchased the preparation from M. de la Ligerie, for a considerable sum, and communicated it to the public in the year 1720. In virtue, it is not different from the sulphurs abovementioned; all of them owe their efficacy to a part of the regulus of the antimony, which the alkaline salt, by the mediation of the sulphur, renders soluble in water.

Chemists are, however, divided in their opinions, with respect to the precise chemical condition of the regulus part in the preparations called *bpota of antimony.* Some have alleged that they contain not a particle of alkaline salt: it is at any rate certain, that the quantity and condition of the regulus part must vary according to the different proportions of the ingredients, the time of the precipitation, the greater or less degree of causticity of the alkali employed, and several other circumstances. At best the whole of them are liable to the same uncertainty in their operation as the calces of antimony.

**Panacea of antimony.**

Take of antimony, six ounces; nitre, two ounces; common salt, an ounce and a half; charcoal, an ounce of white sugar candy, and made up into a mafs with mucilag of Gum Gugganath, may be divided into an hundred small pills; of which one, two or three, taken at a time, are said to work gently by food and vomit. The compact liver-coloured fulphur, which lies immediately above the regulus, operates more fiercely. This pill appears to be nearly of the same nature with the crocus of antimony, and the former with the golden sulphur.

**Chap. XI. Preparations of Silver.**

**Nitrated Silver. L.**

Take of silver, one ounce; diluted nitrous acid, four ounces. Dissolve the silver in the nitrous acid, in a glass vessel, over a sand-heat; then evaporate with an heat gently raised: afterwards melt the residuum in a crucible, that it may be poured into proper forms, carefully avoiding too great a heat.

**Salt of Silver, commonly called Lunar Caustic. E.**

Take of purest silver, beat into plates, and cut in pieces, four ounces; weak nitrous acid, eight ounces; purest water, four ounces. Dissolve the silver in the phial with a gentle heat, and evaporate the solution to dryness. Then put the mafs into a large crucible, and apply the heat, at first gently, but augment it by degrees till the mafs flows like oil; then pour it into iron moulds, previously heated, and greased with tallow. These processes do not differ in any material particular. But the name of *nitrated Silver* is preferable to the more indefinite one of *Salt of Silver.*

Strong spirit of nitre will dissolve somewhat more than half its weight of pure silver; and the weaker of the aquafortis formerly described, proportionally less, according to their quantity of pure nitrous acid. Sometimes this spirit contains a portion of the vitriolic or marine acids; which, however minute, renders it unfit for dissolving this metal, and should therefore be carefully separated before the solution be attempted. The method which the refiners employ for examining the purity of their aquafortis, and purifying it if necessary, is to let fall into it a few drops of a perfect solution of silver already made: if the liquor remain clear, and grow not in the least turbid or whitish, it is fit for use; otherwise they add a small quantity more of the solution, which immediately turns the whole of a milky white colour; the mixture being then suffered to reft for some time, deposits a white sediment; from which it is warily decanted, examined afresh, and,
The silver beat into thin plates, as directed in the secon of the above proceed, needs not be cut in pieces; the solution will go on the more speedily if they latterly turned round into spiral circumvolutions, so as to be conveniently got into the glass, with care that the paral surfaces do not touch each other. By this management, a greater extent of the surface is exposed to the action of the menstruum, than when the plates are cut in pieces and laid above each other. Good aquafortis will dissolve about half its weight of silver; and it is not advisable to use a greater quantity of the menstruum than is sufficient for effecting the solution, for all the surplus must be evaporated in the subsequent fusion.

It is necessary to employ very pure water; for if hard water were used in this process, the nitrous acid would forfeit a part of the silver to join with the calcareous earth of the imperfect nitrous saltpetre; but a part of the silver would be precipitated.

The crucible ought to be large enough to hold five or six times the quantity of the dry matter; for it bubbles and swells up greatly, and is consequently apt to run over. During this time, also, little drops are now and then spat up, whose causticity is increased by their heat, against which the operator ought therefore to be on his guard. The fire must be kept moderate till this ebullition ceases, and till the matter becomes consistent in the heat that made it boil before; then quickly increase the fire till the matter flows thin at the bottom like oil, when it is to be immediately poured into the mould, without waiting till the fumes cease to appear; for when this happens, the preparation proves not only too thick to run freely into the mould, but likewise less corrosive than it is expected to be.

For want of a proper iron mould, one may be formed of tempered tobacco-pipe clay, not too moist, by making in a lamp of it, with a smooth flieck first greased, as many holes as there is occasion for: pour the liquid matter into these cavitities, and when congealed, take it out by breaking the mould. Each piece is to be wiped clean from the grease, and wrapped up in soft dry paper, not only to keep the air from acting on them, but likewise to prevent their corroding or discolouring the fingers in handling.

This preparation is a strong caustic; and is frequently employed as such for consuming warts and other fibrous excrescences, keeping down fungous flesh in wounds or ulcers, and other similar ills. It is rarely applied where a deep cauch is required, as in the laying open of imposthumes and tumours; for the quantity necessary for these purposes, liquefying by the moisture of the skin, spreads beyond the limits, within which it is intended to operate.

The lunar pills.

Dissolve pure silver in aquafortis, as in the foregoing proceed; and after due evaporation, let the liquor aside to crystallize. Let the crystals be again dissolved in common water, and mixed with a solution of equal weight of nitre. Evaporate this mixture to dryness, and continue the exsiccation with a gentle heat, keeping the matter constantly stirring till no more fumes arise.

Here it is necessary to continue the fire till the fumes entirely cease, as more of the acid is required to be dissipated than in the preceding proceed. The preparation is, nevertheless, in taste very sharp, intensely bitter and nauseous: applied to ulcers, it acts as a caustic, but it is much milder than the foregoing. Boerhaave, Boyle, and others, commend it highly in hydropic cases. The former assures us, that two grains of it made into a pill with crumb of bread and a little sugar, and taken on an empty stomach (some warm water, sweetened with honey, being drank immediately after), purge gently without griping, and bring away a large quantity of water, albeit without the patient’s perceiving it; that it kills worms, and cures many inveterate ulcerous disorders. He neverthelefs cautions against using it too freely, or in too large a dose; and observes, that it always proves corrosive and weakening, especially to the stomatch.

**Part II. Preparations and Composition.**

**Ammoniacal iron.**

Take of iron filings, one pound; sal ammoniac, two pounds. Mix, and fablime. What remains at the bottom of the vessel mix by rubbing together with the sablum matter, and again sublime.

**Martial flowers, commonly called Ens Veneris. E.**

Take of colchochar of martial vitriol, washed and well dried; sal ammoniac, equal weights. Having mixed them well, sublime.

Though the mode of preparation directed by the two colleges is here different, yet the preparation is fundamentally the same; and it is perhaps difficult to say which mode of preparation is to be preferred as the easiest and best.

The name of *Ens veneris* has by some been very improperly applied to this preparation, as it contains not a particle of copper. The proper *Ens veneris* is prepared from the blue vitriol; but, as we shall soon see, is often not materially different from the martial flowers.

The succees of this proceed depends principally on the fire being hastily raised, that the sal ammoniac may not sublime before the heat be sufficient to enable it to carry up a sufficient quantity of the iron. Hence glafs vessels are not to proper as earthen or iron ones: for when the former are used, the fire cannot be raised quickly enough, without endangering the breaking of them. The most convenient vessel is an iron pot: to which may be luted an inverted earthen jar, having a small hole in its bottom to suffer the elastic vapours, which arise during the operation, to escape. It is of advantage to thoroughly mix the ingredients together, molten them with a little water, and then gently dry them; and to repeat the pulverization, humecation, and exsiccation, two or three times, or oftener. If this method be followed, the sal ammoniac may be in-creased to two or three times the quantity of the iron, or farther; and a single sublimation will often be sufficient to raise flowers of a very deep orange colour.

This preparation is fuppofed to be highly aperient and
and attenuating; though no otherwise so than the rest of the chalybeates, or at most only by virtue of the saline matter joined to the iron. It has been found of service in hysterical and hypochondriacal cafes, and in diltempers proceeding from a laxity and weakness of the folds, as the rickets. It may be conveniently taken in the form of a bolus, from two or three grains to ten; it is nauseous in a liquid form (unless in spirituous tincture); and occasions pills to swell and crumble, except such as are made of the gums.

**Ruff of iron** L.

Take of iron filings, one pound; expose them to the air, often moistening them with water, until they be corroded into rust; then powder them in an iron mortar, and wash off with distilled water the very fine powder. But the remainder, which cannot by moderate rubbing be reduced into a powder capable of being easily washed off, must be moistened, exposed to the air for a longer time, and again powdered and washed as before. Let the washed powder be dried.

**Rust of iron, commonly called prepared iron fillings.** E.

Set purified filings of iron in a moist place, that they may turn to rust, which is to be ground into an impalpable powder.

The cleansing of iron fillings by means of a magnet is very tedious, and does not answer so well as might be expected: for if they be rusty, they will not be attracted by it, or not sufficiently; nor will they by this means be entirely freed from brass, copper, or other metallic substances which may adhere to them. It appears from the experiments of Henckel, that if iron be mixed by fusion with even its own weight if any of the other metals, regulus of antimony alone excepted, the compound will be vigorously attracted by the lodestone. The rust of iron is to be procured at a moderate rate from the dealers in iron, free from any impurities, except such as may be washed off by water.

The rust of iron is preferable as a medicine to the calces or croci, made by a strong fire. Hoffman relates that he has frequently given it with remarkable success in obdurate chlorate de accommodis with excessive headaches and other violent symptoms; and that he usually joined it with pimpinella, arum root, and falt of tartar, with a little cinnamon and sugar. The dose is from four or five grains to twenty or thirty. Some have gone as far as a dram; but all the preparations of this metal answer best in small doses, which should rather be often repeated than enlarged.

**Tartarised iron.** L.

Take of filings of iron, one pound, powdered crystals of tartar, two pounds. Mix them with distilled water into a thick paste. Expose it to the air in an open earthen vessel for eight days; then grind the matter, dried in a lath of sand, to a very fine powder.

This is an useful preparation of iron in which that metal is chiefly brought to a saline state by means of the cream of tartar. It has now for the first time a place in the London pharmacopeia; but it had before been introduced into some of the foreign ones, particularly the pharmacopoeia Genesewiensis under the title of *mors tartaratus*; and indeed it is almost precisely the same with the *mors fulminating* of the old editions of the Edinburgh pharmacopoeia.

**Vitriolated iron.** L.

Take of filings of iron, vitriolic acid, each eight ounces; distilled water, three pints. Mix them in a glass vessel, and when the effervescence has ceased, place the mixture for some time upon hot sand; then pour off the liquor, draining it through paper: and after due exhalation set it aside to crystallize.

**Vitriol of iron, or salt of steel.** E.

Take of purified filings of iron, six ounces; vitriolic acid, eight ounces; water, two pounds and a half. Mix them; and when the effervescence ceases, let the mixture stand for some time upon warm sand; then strain the liquor through paper, and after due evaporation set it aside to crystallize.

During the dilution of the iron an elastic vapour rises, which on the approach of flame catches fire and explodes, as sometimes to burst the vessel. To this particular therefore the operator ought to have due regard.

This vapour is also noxious to animal life. It is the inflammable air of Dr Priestly.

The chemists are seldom at the trouble of preparing this salt according to the directions above given; but in its lead substitue common green vitriol, purified by solution in water, filtration, and crystallization. The only difference between the two is, that the common vitriol contains somewhat more metal in proportion to the acid; and hence in keeping, its green colour is much sooner debased by a rusty brownish cast. The superfusional quantity of metal may be easily separated by suffuring the solution of the vitriol to stand for some time in a cold place, when a brownish yellow ochery sediment will fall to the bottom; or it may be perfectly dissolved, and kept suspended by a suitable addition of oil of vitriol. If the vitriol be suspended to contain any cuprous matter, which the common English vitriol seldom does, though almost all the foreign vitriols do, the addition of some bright iron wire to the solution will both discover, and effectually separate, that metal: for the acid quits the copper to dissolve a proportionable quantity of the iron; and the copper, in its separation from the acid, adheres to the undissolved iron, and forms a skin of a true copper colour on its surface. Even a vitriol of pure copper may on this principle, be converted into a small vitriol of iron.

But though the vitriolic acid appears in this operation to have so much stronger a disposition to unite with iron than with copper, that it totally rejects the latter when the former is presented to it; the operator may nevertheless give a dangerous impregnation of copper to the purest and most saturated solution of iron in the vitriolic acid, by the use of copper vessels. If the martial solution be boiled in a copper vessel, it never fails to dissolve a part of the copper, distinguishable by its giving a cupreous film to a piece of bright iron immersed in it. By the addition of the iron, the
copper is separated; by boiling it again without iron, more of the copper is dissolved; and this may in like manner be separated by adding more iron.

The salt of steel is one of the most efficacious preparations of this metal; and not unfrequently made use of in caustic and chlorotic cases for exciting the uterine purgations, strengthening the tone of the vessels, and destroying worms. It may be conveniently taken in a liquid form, largely diluted with water: Borehawe directs it to be dissolved in an hundred times its weight of water, and the solution to be taken in the dose of twelve ounces on an empty stomach, walking gently after it. Thus managed, he says, it opens the body, provokes diuresis and expels worms, tingles the excrements black, or forms them into a matter like clay, strengthens the fibres, and thus cures many different distempers. The quantity of vitriol in the above dose of the solution is fifty-seven grains and a half; but in common practice, such large doses of this strong chalybeate are never ventured on. Four or five grains, and in many cases half a grain, are sufficient for the intention in which chalybeate medicines are given. Very dilute solutions, as that of a grain of the salt in a pint of water, may be used as succedanea to the natural chalybeate waters, and will in many cases produce similar effects.

Colocbar of vitriol. E.

Let calcined vitriol be urged with a violent fire till it becomes of a very red colour.

In this preparation, the iron which had been brought to a fine line by means of the acid of vitriol, is again deprived of that acid by the action of fire. It may be cooled, three or four as differing and expels worms from the residuum which remains in the retort, when vitriolic acid is diffused from martial vitriol. The colocbar is very early employed by itself for medical purposes; but it is used in the preparation of some other chalybeates, particularly the medicinal flowers, when prepared according to the method directed by the Edinburgh college.

Martial athips. Gen.

Take of the rust of iron, as much as you please: olive oil, a sufficient quantity to make it into a paste. Let this be diffused in a retort by a strong fire to dryness. Keep the residuum reduced to a fine powder in a clove vessel.

An article under this name had formerly a place in some of the old pharmacopoeias, and is described by Lernery in the Memoirs of the French Academy; but it was formed by a tedious process, continued for several months by the aid of water. Here the process is much shorter, and is supposed to give nearly the same product. Some have recommended it, on the supposition that the iron has here obtained in a very subtle state; but it is not in general supposed to have any advantage over the other more common chalybeates.

Open and asftringent crocus of iron.

These are prepared by mixing iron filings with twice their weight of powdered sulphur, degrading in a red-hot crucible; and in the one case keeping the preparation over the fire till it assumes a red colour: in the other, by reverberating it for a long time in the most extreme degree of heat.

Preparations under these names still retain a place in some of the foreign pharmacopoeias, but they are variously prepared. They may, however, be considered as polishing the same medical powers: and although the preparations mentioned above probably differ from each other in their virtues, yet that difference is not of such a nature as is imported by the titles by which they are usually distinguished. For all the preparations of iron probably act by an astringent quality; and that which is above denominated the asftringent crocus has probably least effect in that way. At one period, these preparations were not unfrequently in use; and they were given in the form of bolus, clefsbury, or pill, from a few grains to a scruple; but among us they are at present so little in use as to have no place in our pharmacopoeias.

Chap. XIII. Preparations of Mercury.

We have already treated of mercury in various parts of our work, as we found occasion, and what we have already discussed is unnecessary to repeat. See MERCURY, CHEMISTRY-Index, MATERIAL MEDICA, p. 553. METALLURGY, and QUICKSILVER. On the whole, it appears evident that there is no article which has been employed for medical purposes in a greater variety of forms. The colleges of London and Edinburgh have admitted into their pharmacopoeias only a few of these; but from the selection they have made, there is reason to believe that every useful purpose for which mercury has been employed may be answered; and these purposes are both numerous and considerable. For it is at least very generally allowed among intelligent practitioners, that there are few articles kept in the shops of our apothecaries which can be considered as so extensively useful.

Mercury or quicksilver, in its crude state, is a ponderous metallic fluid, totally volatile in a strong fire, and calcinable by a weaker one (though very difficultly) into a red powdery substance. It dissolves in the nitrous acid, is corroded by the vitriolic, but not acted on by the marine in its liquid state: it nevertheless may be combined with this last skillfully applied in the form of fume. Quicksilver unites by triturating with earthy, unctuous, retinous, and other similar substances, so as to lose its fluidity: triturated with sulphur, it forms a black mafs, which by sublimation changes into a beautiful red one.

For the general virtues of the mercurial preparations, see some of the articles above referred to, and MEDICINE. Here we shall only observe, that while in certain circumstances they act as stimulants, and even as corrosives, to the parts to which they are applied, under a different management, when introduced into the habit, they seem to forward circulation through even the smallest and most remote vessels of the body; and may be so managed as to promote all the excretions. But while they thus operate as a powerful stimulus to the sanguiferous, and probably also to the lymphatic system, they seem to exert but little influence on the nervous system. By this means they proveeminently serviceable in some inveterate chronic disorders, proceeding from obliterative obstructions of the glands. Crude mercury has

PHARMACY.

Preparations and Compositions.

has no effect this way. Resolved into fume, or divided into minute particles, and prevented from returning by the intervention of other substances, it operates very powerfully, unless the dividing body be ful, hur, which reunites its action. Combined with a small quantity of the mineral acids, it acts effectually, though in general mildly; with a larger it proves violently corrosive.

Purified quicksilver. L.

Take of quicksilver, filings of iron, each four pounds.

Rub them together, and diffil from an iron vessel.

As in the dilution of quicksilver glafs retorts are very liable to be broken, an iron one is here with propriety directed; and by the addition of the filings of iron, matters which might otherwise arise with the quicksilver will be more apt to be detained in the retort. But still this happens so readily, even merely with that degree of heat which is necessary to elevate the mercury, that it is very doubtful whether much advantage be obtained from this process; and accordingly it has now no place in the pharmacopoeia of the Edinburgh college. A

Actuated quicksilver. L.

Take of purified quicksilver, one pound; diluted nitrous acid, two pounds; water of kali, as much as is sufficient. Mix the quicksilver with the acid in a glass vessel, and diffuse it in a sand-bath; then drop in by degrees the water of kali, that the calx of quicksilver may be precipitated; wash this calx with plenty of diffiluted water, and dry it with a gentle heat. These things being done, take of the calx of quicksilver, above described, one pound; acetic acid, as much as is necessary to diffuse the calx. Mix them in a glass vessel; and the solution being completed, strain it through paper; then evaporate it till a pellicle appears; and let it affide to crystallize. Keep their crystalls in a vessel close stoped.

Of all the saline preparations of mercury, it has long been the opinion of the best chemists, that those in which it was brought to a saline form, by means of acetic acid, would be the mildest; and such a preparation was conjectured to be the basis of a celebrated pill, prepared and sold by Mr Keyser. It was, however, found to be a very difficult matter to imitate his pill, or to obtain a combination of mercury with the acetic acid; but not long since, the process for preparing these pills was published by authority at Paris after being purchased by the French king. The process here described though in some particulars much less operose than that of Mr Keyser, yet nearly approaches to it, and furnishes us with the mildest of the saline mercurials.

Calcined quicksilver. L.

Take of purified quicksilver, one pound; expose the quicksilver in a flat-bottomed glass crucible, to an heat of about 600 degrees in a sand-bath, till it becomes a red powder.

This preparation may now be made in a shorter time than by the process formerly directed in the London pharmacopoeia, which in general required several months; for the access of air, without which calcina-

tion cannot be performed, was then very much ex-

cluded. Still, however, the process is a tedious one, and might perhaps be improved. A vessel might be so contrived, as to occasion a continual flux of air over the surface of the mercury.

This preparation is highly esteemed in venereal cases, and supposed to be the most efficacious and certain of all the mercurials. It may be advantageously given in conjunction with opiates: a bolus or pill, containing from half a grain to two grains of this calx, and a quarter or half a grain or more of opium, with the addition of some warm aromatic ingredient, may be taken every night. Thus managed it acts mildly, though powerfully, as an alterative and diaphoretic: given by itself in larger doses, as four or five grains, it proves a rough emetic and cathartic.

Afhl-coloured powder of mercury. E.

Take of quicksilver, weak nitrous acid, equal weights.

Mix them so as to dissolve the quicksilver; dilute the solution with pure water, and a spirit of sal ammoniac as much as is sufficient to separate the mercury perfectly from the acid; then wash the powder in pure water, and dry it.

In this process the mercurial nitre is decomposed; the precipitate, therefore, is a calx of mercury, and the clear liquor a solution of nitrous ammoniac. From the great attraction which the nitrous acid has for phlogiston, or from its ready diffusion to part with pure air, the precipitates of mercury from its solution in this acid are more completely in the state of a calx than those from any other menstruum. There are, however, several niceties to be observed in conducting this process. If we employ too small a proportion of acid, and affil the solution by heat, the solution will contain an excess of calx capable of being separated by the water; and the whole precipitate from such a solution would be of a white colour. If, on the other hand, we employ too large a proportion of acid, the mercury is then so far calcined as to be capable of being dissolved by the volatile alkali; and this might happen in proportion as the quantity should be superabundant to the neutralization of the acid. The use of the water is to dissolve the nitrous ammoniac as fast as it is formed, and thereby prevent it from falling down and mixing with the precipitate. It is necessary to employ the purest water. If such be used, as contains a nitrous selenite, not only a part of the mercury may be precipitated by the base of the selenite, but this last might also be deposited by the preceding addition of the alkali.

The ashl-coloured powder of mercury has of late years been much celebrated for the cure of venereal affections. It was first prepared by Dr Saunders to be made by precipitating the mercury from calomel, as the belt substitute for the tedious and expensive process of the precipitate per f_., and of the grey powder produced by trituration with gum arabic. From the testimony of Dr Home, and several other practitioners, we have no doubt of its being a very valuable preparation of mercury. It may be given in a bolus or wafer, in the quantity of from one fix or seven grains: the dose being gradually increased according to its effects upon the person.
PHARMACY.

Part II.

Preparations and Compositions.

Take of purified quicksilver, three ounces; powdered chalk, five ounces. Rub them together until the globules disappear.

In this preparation, as well as the two former, we have also the mercury in a state of calx; but in place of being brought to that state by the aid of fire or of acids, what may here be considered as calcination is effected by triturate.

This preparation, had no place in the former editions of the London pharmacopoeia. A preparation nearly similar indeed, under the title of mercarius alkalifatus, in which crabs eyes were employed instead of chalk, had a place in the old editions of the Edinburgh pharmacopoeia, but was rejected from the edition of 1744, and has never again been restored. One reason for rejecting it was its being liable to gross abuse in the preparation, by the addition of some intermediate, facilitating the union of mercury with the absorbent earth, but diminishing or altering its power. The present preparation is liable to the same objection. Some, however, are of opinion that when duly prepared, it is an useful alterative. But there can be little doubt, that the absorbent earth, by decoying acid in the alimentary canal, will diminish the activity of the mercurial calx.

Muriated quicksilver. L.

Take of purified quicksilver, vitriolic acid, each two pounds; dried sea-salt, three pounds and an half. Mix the quicksilver with the acid in a glass vesse, and boil in a sand heat until the matter be dried. Mix it, when cold, with the sea-salt, in a glass vesse; then sublime in a glasse cucurbit, with a heat gradually raised. Lastly, let the sublimed matter be separated from the former.

Sublimate corrosive mercury. E.

Take of quicksilver, weak nitrous acid, each four ounces; calcined sea-salt, calcined vitriol, of each five ounces. Difioe the quicksilver in the nitrous acid, and evaporate the solution to a white and thoroughly dry mass; then add the sea-salt and vitriol. Having ground and mixed them well together, put the whole into a phial, one half of which they ought to fill; then sublime in sand, first with a gentle, but afterwards with an increased heat.

The sublimed prepared by either of these methods is the same, they both contain only of mercury and the acid of the sea-salt united together. In the process directed by the Edinburgh college, the materials being mixed and exposed to the fire, first the vitriol parts with its acid, which, dissolving those of the nitre and marine salt, takes their place. The marine acid, resolved into fume and aflisted by the nitrous, dissolves the mercury, now also strongly heated. This acid, though it very difficulty acts on mercury, yet when thus once united with it, is more strongly retained thereby than any other acid. The nitrous spirit, therefore, having nothing to retain it (for its own bases, and that of the sea-salt are both occupied by the vitriolic, and that which the vitriolic forsook to unite with these, is now scarcely combinable with it), arifes; leaving the mercury and marine acid to sublime together when the heat shall be strong enough to elevate Preparations. Some small portion of the marine spirit arises along with the nitrous: and hence this compound acid has been usually employed instead of the compound aquare, to which it is similar, for making the red corrosive.

It appears therefore that the vitriol, and the bases of the nitre and sea-salt, are of no farther use in this process, than as convenient intermediates for facilitating the union of the mercury with the marine acids. They likewise serve to afford a support for the sublimate to rest upon, which thus assumes the form of a placenta or cake.

This processes, however, now adopted by the London college, is a better and more simple one. There the mercury corroded by the vitriolic acid into a white mass, is mixed with about an equal quantity of sea-salt, and let to sublume; the vitriolic acid quits the mercury to unite with the bases of the sea-salt; and the acid of the sea-salt, now let at liberty, unite with the mercury, and sublimes with it into the compound required. The discovery of this method is generally attributed to Boulduc, though it is also given in Knuckel's Laboratorium Chymicum. When the process is conducted in this way, the residual matter is a pure Glauber's salt, and the sublimate is still free of ferruginous matter; a greater or less quantity of which is very generally carried up along with the mercury when vitriol of iron is employed. Boulduc's method has therefore the advantage in this, that the proportion of mercury in a given quantity of sublimate must be less liable to variation.

If the mercury be corroded by the nitrous acid instead of the vitriolic, the event will be the same; that is, equally quitting the mercury, and setting loose the marine; and the sublimate made by this method is the same with the foregoing; but as the quantity of fixed matter is smaller, it more difficulty assumes the form of a cake. It requires indeed some skill in the operator to give it this appearance when either process is followed. When large quantities are made, this form may be easily obtained, by placing the masses no deeper in the sand than the surface of the matter contained in it; and removing a little of the sand from the sides of the glass, as soon as the flowers begin to appear in the neck; when the heat should likewise be somewhat lowered, and not at all raised during the whole process. The sublimation is known to be completed by the edges of the crystalline cake which will form on the surface of the caput mortuum, appearing smooth and even, and a little removed from it.

Our apothecaries rarely, and few even of the chemists, attempt the making of this preparation themselves; greatest part of what is used among us comes from Venice and Holland. This foreign sublimate has been reported to be adulterated with arsenic. Some affirm, that this dangerous fraud may be discovered by the sublimate turning black on being moistened with alkaline ley; which by others is denied. As this point seemed of some importance to be determined, fundry experiments have been made with this view, which proves the inefficiency of alkalis for discovering arsenic. Alkaline leys, poured into a solution of pure arsenic, and into a mixture of the two solutions in different proportions, produced no blackness in any; and though...
though the pure sublimate, and the mixtures of it with
an end, exhibited some differences in these trials, yet
these differences were neither so constant nor so
strongly marked as to be laid down universally for criteria
of the presence or absence of arsenic; different speci-
mens of sublimate, known to be pure, have been found
to differ considerably in this respect; probably from
holding a little more or less mercury in proportion
to the acid, or from their retaining some small
portion of those acids which were employed in the prepa-
ration as intermediate.

Some chemists deny the practicability of this adul-
teration. There is a process common in books of che-
metry, wherein sublimate and arsenic being mixed to-
gether, and set to sublime, do not arise in one mass,
or yield any thing similar to the preparation here
intended: the arsenic absorbs the acid of the sublimate,
and is reduced thereby into a liquid or butyrous con-
fluence; while the mercury thus freed from the
acid diffuses in its fluid form; if the quantity of ar-
senic be insufficient to decompound the whole of
the sublimate, the remainder of the sublimate concretes
diftinct from the arsenical butter. From whence they
conclude, that arsenic and sublimate cannot be united
in the form in which this preparation is brought to
us.

The above experiment is not altogether decisive;
for though arsenic and sulphur do not assume the re-
quired form by the common processes, it is possible they
may by some other management. It will therefore be
proper to point out means for the satisfaction of those
who may be desirous of convincing themselves of the
genuineness of this important preparation. Let some
of the sublimate, powdered in a glass mortar, be well
mixed with twice its weight of black flux, and a little
slagging or filings of iron; put the mixture into a crucible
capable of holding four or five times as much;
give a gradual fire till the ebullition ceases, and then
haftily increase it to a white heat. If no fumes of a gar-
ic smell can be perceived during the process, and if
the particles of iron retain their form without any
of them being melted, they may be sure that the mix-
ture contained no arsenic.

Sublimate is a most violent corrosive, soon corrupting
and destroying all the parts of the body it touches.
A solution of it in water, in the proportion of about
a dram to a quart, is useful for keeping down proud
fever, and cleaning foul ulcers; and a more diluted solution
as a constrictor, and for destroying cutaneous infections.
But a great deal of caution is requisite even in these
external uses of it.

Some have nevertheless ventured to give it inter-
ally, in the dose of one-tenth or one-eighth of a grain,
Boerhaave relates, that if a grain of it be dissolved in
an ounce or more of water, and a dram of this solu-
tion, sweetened with syrup of violets, be taken twice
or three a day, it will prove efficacious in many dis-
tempers though incurable; but he particularly cau-
ses us not to venture upon it, unless the method of
managing it be well known.

Sublimate dissolved in vinous spirit has of late been
given internally in larger does; from a quarter of a
grain to half a grain. This method of using it was
brought into repute by Baron Van Swieten at Vienna,
especially for venereal maladies; and several trials of
it have also been made in this kingdom with success.

Take of corrosive sublimate mercury, fix grains; sal
ammoniac, twelve grains. Dissolve in a pound of dis-
tilled water. If hard water be used for this purpose,
the solution suffers a kind of decomposition from the
nitrous felenite of the water.

The solution of corrosive sublimate in water is very
muchavored by sal ammoniac. There was a practice
some years ago, of mixing up this solution with wheat
flour into the confluence of pills for internal use: and
the quantity of sublimate in each pill was easily ascer-
tainable.

This solution may also be used for washing venereal
and other sores; but in many instances it will be found
too acid for that purpose, and will require to be weak-
ened by the addition of a portion of water.

Take of muriated quicksilver, one pound; purified
quicksilver, nine ounces. Rub them together till
the quicksilver ceases to appear. Put the
solution into a glass mortar, four ounces; pure quicksilver,
three ounces and a half. Mix them well together,
by long triturating in a glass or marble mortar, until
the quicksilver ceases to appear. Put the
solution into an oblong phial, of such a size that only
one-third of it may be filled; and set the phial in
fand, that the mass may sublime. After the sub-
limation, break the glass; and the red powder which
stands in its bottom, with the whitish one that
sticks about the neck, being throwaway, let the
white mercury be sublimed again three or four times,
and reduce it to a very fine powder.

Take of corrosive mercury sublimate reduced to a pow-
der in a glass mortar, four ounces; pure quicksilver,
three ounces and a half. Mix them well together,
by long triturating in a glass or marble mortar until
the quicksilver ceases to appear. Put the powder
into an oblong phial, of such a size that only
one-third of it may be filled; and set the phial in
sand, that the mass may sublime. After the sub-
limation, break the glass; and the red powder which
stands in its bottom, with the whitish one that
sticks about the neck, being throwaway, let the
white mercury be sublimed again three or four times,
and reduce it to a very fine powder.
The trituration of corrosive sublimate with quicksilver is a very noxious operation: for it is almost impossible, by any care, to prevent the lighter particles of the former from rising so as to affect the operator's eyes and mouth. It is nevertheless of the utmost consequence, that the ingredients be perfectly united before the sublimation is begun. It is necessary to pulverize the sublimate before the mercury is added to it: but this may be safely performed with a little caution; especially if during the pulverization the matter be now and then sprinkled with a little spirit of wine: this addition does not at all impede the union of the ingredients, or prejudice the sublimation: it will be convenient not to clore the top of the subliming vessel with a cap of paper at first (as is usually practised), but to defer this till the mixture begins to sublime, that the spirit may escape.

The rationale of this process deserves particular attention; and the more so, as a mistaken theory herein has been productive of several errors with regard to the operation of mercurials in general. It is supposed, that the *dulci fication*, as it is called, of the corrosive mercury is owing to the fucile or sharp points, on which its corrosiveness depends, being broken and worn off by the frequent sublimations. If this opinion were just, the corrosive would become mild, without any addition, barely by repeating the sublimation; but this is contrary to all experience. The abatement of the corrosive quality of the sublimate is entirely owing to the combination of as much fresh mercury as is capable of being united with it; and by whatever means this combination be effected, the preparation will be sufficiently dulced. Triture and digestion promote the union of the two, while sublimation tends rather to disunite them. The prudent operator, therefore, will not be solicitous about separating such mercurial globules as appear distinct after the first sublimation: he will endeavour rather to combine them with the reft, by repeating the trituration and digestion.

The college of Wurtemberg require their sweet mercury to be only twice sublimed, and the Augsflan but once; and Neumann proposes making it directly by a single sublimation from the ingredients of the corrosive sublimate, by only taking the quicksilver in a larger proportion.

Mr Selle of Berlin has lately proposed a method of making sweet mercury, nearly similar to that of Neumann. He directs, that to four ounces of true quicksilver there should be added as much strong vitriolic acid. These are to be mixed over a strong fire till they become a solid hard mass. This mass is to be triturated in a stone mortar with two ounces and half of quicksilver and four ounces and half of dried common salt. And by a single, or at most two, sublimations, he assures an excellent sweet mercury is obtained.
