To ſolder upon ſilver, braſs, or iron: Take ſilver, five pennyweights; braſs, four pennyweights; melt them together for ſoft ſolder, which runs ſooneſt. Take ſilver, five pennyweights; copper, three pennyweights; melt them together for hard ſolder. Beat the ſolder thin, and lay it on the place to be ſoldered, which muſt be firſt fitted and bound together with wire as occaſion requires; then take borax in powder, and temper it like pap, and lay it upon the ſolder, letting it dry; then cover it with live coals, and blow, and it will run immediately; take it preſently out of the fire, and it is done. It is to be obſerved, that if any thing is to be ſoldered in two places, which cannot well be done at one time, you muſt firſt ſolder with the harder ſolder, and then with the ſoft; for if it be firſt done with the ſoft, it will unſolder again before the other is faſtened. Let it be obſerved, that if you would not have your ſolder run about the piece that is to be ſoldered, you muſt rub ſuch places over with chalk—In the ſoldering either of gold, ſilver, copper, or either of the metals above mentioned, there is generally uſed borax in powder, and ſometimes roſin. As to iron, it is ſufficient that it be heated red-hot, and the two extremities thus hammered together, by which means they will become incorporated with each other. For the finer kinds of iron and ſteel inſtruments, however, gold proves an excellent ſolder. This metal will diſſolve twice or thrice its weight of iron in a degree of heat very far leſs than that in which iron itſelf melts; hence if a ſmall plate of gold

gold is wrapped round the parts to be joined, and afterwards melted by a blow-pipe, it strongly unites the pieces together without any injury to the instrument however delicate.

SOLDIER, a military man listed to serve a prince or state in consideration of a certain daily pay.

Soldier-Crab. See Cancer.

Fresh Water Soldier. See Stratiotes.

SOLE, in the manege, a sort of horn under a horse's foot, which is much more tender than the other horn that encompasses the foot, and by reason of its hardness is properly called the *horn* or *hoof*.

Sole, in ichthyology. See Pleuronectes.

SOLEA. See Sandal and Shoe.

SOLECISM, in grammar, a false manner of speaking, contrary to the rules of grammar, either in respect of declension, conjugation, or syntax.—The word is Greek, σολοικισμος, derived from the *Soli*, a people of Attica, who being transplanted to Cilicia, lost the purity of their ancient tongue, and became ridiculous to the Athenians for the improprieties into which they fell.

SOLEMN, something performed with much pomp, ceremony, and expence. Thus we say, solemn feasts, solemn funerals, solemn games, &c.—In law, *solemn* signifies something authentic, or what is clothed in all its formalities.

SOLEN, razor-sheath, or *Knife-handle Shell*; a genus belonging to the class of *vermes*, and order of *testacea*. The animal is an ascidia. The shell is bivalve, oblong, and opening at both sides: the hinge has a tooth shaped like an awl, bent back, often double, not inserted into the opposite shell; the rim at the sides somewhat worn away, and has a horny cartilaginous hinge. There are 23 species. Three of them, viz. the siliqua, vagina, and ensis, are found on the British coasts, and lurk in the sand near the low-water mark in a perpendicular direction. When in want of food they elevate one end a little above the surface, and protrude their bodies far out of the shell. On the approach of danger they dart deep into the sand, sometimes two feet at least. Their place is known by a small dimple on the surface. Sometimes they are dug out with a shovel; at other times they are taken by striking a barbed dart suddenly into them. When the sea is down, these fish usually run deep into the sand; and to bring them up, the common custom is to throw a little salt into the holes, on which the fish raises itself, and in a few minutes appears at the mouth of its hole. When half the shell is discovered, the fisherman has nothing more to do than to take hold of it with his fingers and draw it out: but he must be cautious not to lose the occasion, for the creature does not continue a moment in that state; and if by any means the fisherman has touched it, and let it slip away, it is gone for ever; for it will not be decoyed again out of its hole by salt; so that there is then no way of getting it but by digging under it, and throwing it up with the sand. The fish has two pipes, each composed of four or five rings or portions of a hollow cylinder, of unequal lengths, joined one to another; and the places where they join are marked by a number of fine streaks or rays. Now the reason why the salt makes these creatures come up out of their holes, is, that it gives them violent pain, and even corrodes these pipes. This is somewhat strange, as the creature is nourished by means of salt-water; but it is very evident, that if a little salt be strewed upon these pipes in a fish taken out of its habitation, it will corrode the joinings of the rings, and often make one or more joints drop off: the creature, to avoid this mischief, arises out of its hole, and throws off the salt, and then retires back again. The use of these pipes to the animal is the same with that of many other pipes of a like kind in other shell-fish; they all serve to take in water: they are only a continuation of the outer membrane of the fish, and serve indifferently for taking in and throwing out the water, one receiving, and the other discharging it, and either answering equally well to their purpose. See *Animal Motion*.

This fish was used as food by the ancients; and Athenæus, from Sophron, speaks of it as a great delicacy, and particularly grateful to widows. It is often used as food at present, and is brought up to table fried in eggs.

SOLEURE, a canton of Swisserland, which holds the 11th rank in the Helvetic confederacy, into which it was admitted in the year 1481. It stretches partly through the plain, and partly along the chains of the Jura, and contains about 50,000 inhabitants. It is 35 miles in length from north to south, and 35 in breadth from east to west. The soil for the most part is exceedingly fertile in corn; and the districts within the Jura abound in excellent pastures. The trade both of the town and canton is of little value, although they are very commodiously situated for an extensive commerce. It is divided into 11 bailiwicks, the inhabitants of which are all Roman Catholics except those of the bailiwick of Buckegberg, who profess the reformed religion. The sovereign power resides in the great council, which, comprising the senate or little council of 36, consists of 102 members, chosen by the senate in equal proportions from the 11 tribes or companies into which the ancient burghers are distributed; and, owing to the distinction between the ancient and the new burghers (the former consisting of only 85 families) the government is a complete aristocracy.

Soleure, an ancient and extremely neat town of Swisserland, capital of the canton of the same name. It contains about 4000 inhabitants, and is pleasantly seated on the Aar, which here expands into a noble river. Among the most remarkable objects of curiosity in this town is the new church of St Urs, which was begun in 1762 and finished in 1772. It is a noble edifice of a whitish grey stone, drawn from the neighbouring quarries, which admits a polish, and is a species of rude marble. The lower part of the building is of the Corinthian, the upper of the Composite order. The façade, which consists of a portico, surmounted by an elegant tower, presents itself finely at the extremity of the principal street. It cost at least L. 80,000, a considerable sum for such a small republic, whose revenue scarcely exceeds L. 12,000 a year. Soleure is surrounded by regular stone fortifications, and is 20 miles north north-east of Bern, 27 south south-west of Basle, and 45 west of Zurich. E. Long. 7. 20. N. Lat. 47. 15.

SOLFAING, in music, the naming or pronouncing the several notes of a song by the syllables *ut*, *re*, *mi*, *fa*, *sol*, &c. in learning to sing it.

Of the seven notes in the French scale *ut*, *re*, *mi*, *fa*, *sol*, *la*, *si*, only four are used among us in singing, as

Solfaing, Solfaterra.

mi, fa, sol, la: their office is principally, in singing, that by applying them to every note of the scale, it may not only be pronounced with more ease, but chiefly that by them the tones and semitones of the natural scale may be better marked out and distinguished. This design is obtained by the four syllables *fa, sol, la, mi*. Thus from *fa* to *sol* is a tone, also from *sol* to *la*, and from *la* to *mi*, without distinguishing the greater or less tone; but from *la* to *fa*, also from *mi* to *fa*, is only a semitone. If then these be applied in this order, *fa, sol, la, fa, sol, la, mi, fa*, &c. they express the natural series from C; and if that be repeated to a second or third octave, we see by them how to express all the different orders of tones and semitones in the diatonic scale; and still above *mi* will stand *fa, sol, la*, and below it the same inverted *la, sol, fa*, and one *mi* is always distant from another an octave; which cannot be said of any of the rest, because after *mi* ascending come always *fa, sol, la*, which are repeated invertedly descending.

To conceive the use of this, it is to be remembered, that the first thing in learning to sing, is to make one raise a scale of notes by tones and semitones to an octave, and descend again by the same; and then to rise and fall by greater intervals at a leap, as thirds and fourths, &c. and to do all this by beginning at notes of different pitch. Then those notes are represented by lines and spaces, to which these syllables are applied, and the learners taught to name each line and space thereby, which makes what we call *solfaing*; the use whereof is, that while they are learning to tune the degrees and intervals of sound expressed by notes on a line or space, or learning a song to which no words are applied, they may not only do it the better by means of articulate sounds, but chiefly that by knowing the degrees and intervals expressed by those syllables, they may more readily know the places of the semitones, and the true distance of the notes. See the article SINGING.

SOLFATERRA, a mountain of Italy in the kingdom of Naples, and Terra di Lavoro. This mountain appears evidently to have been a volcano in ancient times; and the soil is yet so hot, that the workmen employed there in making alum need nothing else besides the heat of the ground for evaporating their liquids. Of this mountain we have the following account by Sir William Hamilton. "Near Astruni (another mountain, formerly a volcano likewise) rises the Solfaterra, which not only retains its cone and crater, but much of its former heat. In the plain within the crater, smoke issues from many parts, as also from its sides: here, by means of stones and tiles heaped over the crevices, through which the smoke passes, they collect in an aukward manner what they call *sale armoniaco*; and from the sand of the plain they extract sulphur and alum. This spot, well attended to, might certainly produce a good revenue, whereas I doubt if they have hitherto ever cleared L. 200 a-year by it. The hollow

1

Solfaterra ‖ Solid.

found produced by throwing a heavy stone on the plain of the crater of the Solfaterra, seems to indicate that it is supported by a sort of arched natural vault; and one is induced to think that there is a pool of water beneath this vault (which boils by the heat of a subterraneous fire still deeper), by the very moist steam that issues from the cracks in the plain of the Solfaterra, which, like that of boiling water, runs off a sword or knife, presented to it, in great drops. On the outside, and at the foot of the cone of the Solfaterra, towards the lake of Agnano, water rushes out of the rocks so hot as to raise the quicksilver in Fahrenheit's thermometer to the degree of boiling water (A); a fact of which I was myself an eye-witness. This place, well worthy the observation of the curious, has been taken little notice of; it is called the *Pisciarelli*. The common people of Naples have great faith in the efficacy of this water; and make much use of it in all cutaneous disorders, as well as for another disorder that prevails here. It seems to be impregnated chiefly with sulphur and alum. When you approach your ear to the rocks of the Pisciarelli, from whence this water oozes, you hear a horrid boiling noise, which seems to proceed from the huge cauldron that may be supposed to be under the plain of the Solfaterra. On the other side of the Solfaterra, next the sea, there is a rock which has communicated with the sea, till part of it was cut away to make the road to Puzzole; this was undoubtedly a considerable lava, that ran from the Solfaterra when it was an active volcano. Under this rock of lava, which is more than 70 feet high, there is a stratum of pumice and ashes. This ancient lava is about a quarter of a mile broad; you meet with it abruptly before you come in sight of Puzzole, and it finishes as abruptly within about 100 paces of the town. The ancient name of the Solfaterra was *Forum Vulcani*; a strong proof of its origin from subterraneous fire. The degree of heat that the Solfaterra has preserved for so many ages, seems to have calcined the stones upon its cone and in its crater, as they are very white and crumble easily in the hottest parts. See CHEMISTRY, n° 656.

SOLICITOR, a person employed to take care of and manage suits depending in the courts of law or equity. Solicitors are within the statute to be sworn, and admitted by the judges, before they are allowed to practice in our courts, in like manner as attorneys.

British Solicitor-General

"There is also a great officer of the law, next to the attorney-general, who is styled the king's solicitor-general; who holds his office by patent during the king's pleasure, has the care and concern of managing the king's affairs, and has fees for pleading, besides other fees arising by patents, &c. He attends on the privy-council; and the attorney-general and he were anciently reckoned among the officers of the exchequer; they have their audience, and come within the bar in all other courts."

SOLID, in philosophy, a body whose parts are so firmly

(A) "I have remarked, that after a great fall of rain, the degree of heat in this water is much less; which will account for what Padre Torre says (in his book, intitled *Histoire et Phenomenes du Vesuve*), that when he tried it in company with Monsieur de la Condamine, the degree of heat, upon Reaumur's thermometer, was 68°.

firmly connected together, as not easily to give way or slip from each other; in which sense *solid* stands opposed to *fluid*.

Geometricians define a solid to be the third species of magnitude, or that which has three dimensions, viz. length, breadth, and thickness or depth.

Solids are commonly divided into regular and irregular. The regular solids are those terminated by regular and equal planes, and are only five in number, viz. the tetrahedron, which consists of four equal triangles; the cube or hexahedron, of six equal squares; the octahedron, of eight equal triangles; the dodecahedron, of twelve; and the icosihedron, of twenty equal triangles.

The irregular solids are almost infinite, comprehending all such as do not come under the definition of regular solids; as the sphere, cylinder, cone, parallelogram, prism, parallelopiped, &c.

Solids, in anatomy, are the bones, ligaments, membranes, muscles, nerves, and vessels, &c.

The solid parts of the body, though equally composed of vessels, are different with regard to their consistence; some being hard and others soft. The hard, as the bones and cartilages, give firmness and attitude to the body, and sustain the other parts: the soft parts, either alone or together with the hard, serve to execute the animal functions. See Anatomy.

SOLIDAGO, in botany: A genus of plants belonging to the class of *syngenesia*, and to the order of *polygamia superflua;* and in the natural system ranging under the 49th order, *Compositæ.* The receptacle is naked; the pappus simple; the radii are commonly five; the scales of the calyx are imbricated and curved inward. There are 14 species; sempervirens, canadensis, altissima, lateriflora, bicolor, lanceolata, cœsia, mexicana, flexicaulis, latifolia, virgaurea, minuta, rigida, noveboracensis. Among these there is only one species, which is a native of Britain the *virgaurea*, or golden rod, which grows frequently in rough mountainous pastures and woods. The stems are branched, and vary from six inches to five feet high, but their common height is about a yard. The leaves are a little hard and rough to the touch; the lower ones oval-lanceolate, generally a little serrated and supported on footstalks, those on the stalks are elliptical; the flowers are yellow, and grow in spikes from the alæ of the leaves; the scales of the calyx are lanceolate, of unequal length, and of a pale green colour; the female florets in the rays are from five to eight in number; the hermaphrodite flowers in the disc from ten to twelve. There is a variety of this species called *cambrica* to be found on rocks from six inches to a foot high.

SOLIDITY, that property of matter, or body, by which it excludes all other bodies from the place which itself possesses; and as it would be absurd to suppose that two bodies could possess one and the same place at the same time, it follows, that the softest bodies are equally solid with the hardest. See Metaphysics, n° 44. 173. &c.

Among geometricians, the solidity of a body denotes the quantity or space contained in it, and is called also its solid contents.

The solidity of a cube, prism, cylinder, or parallelopiped, is had by multiplying its basis into its height. The solidity of a pyramid or cone is had by multiplying either the whole base into a third part of the height, or the whole height into a third part of the base.

SOLILOQUY, a reasoning or discourse which a man holds with himself; or, more properly, according to Papias, it is a discourse by way of answer to a question that a man proposes to himself.

Soliloquies are become very common on the modern stage; yet nothing can be more inartificial, or more unnatural, than an actor's making long speeches to himself, to convey his intentions to the audience. Where such discoveries are necessary to be made, the poet should rather take care to give the dramatic persons such confidants as may necessarily share their inmost thoughts; by which means they will be more naturally conveyed to the audience; yet even this is a shift which an accurate poet would not have occasion for. The following lines of the duke of Buckingham concerning the use and abuse of soliloquies deserve attention:

> Soliloquies had need be very few,
> Extremely short, and spoke in passion too.
> Our lovers talking to themselves, for want
> Of others, make the pit their confidant:
> Nor is the matter mended yet, if thus
> They trust a friend, only to tell it us.

SOLIMAN II. emperor of the Turks, surnamed the *Magnificent*, was the only son of Selim I. whom he succeeded in 1520. He was educated in a manner very different from the Ottoman princes in general; for he was instructed in the maxims of politics and the secrets of government. He began his reign by restoring those persons their possessions whom his father had unjustly plundered. He re-established the authority of the tribunals, which was almost annihilated, and bestowed the government of provinces upon none but persons of wealth and probity: "I would have my viceroys (he used to say) resemble those rivers that fertilize the fields through which they pass, not those torrents which sweep every thing before them."

After concluding a truce with Ismael Sophy of Persia, and subduing Gozeli Bey, who had raised a rebellion in Syria, he turned his arms against Europe. Belgrade was taken in 1521, and Rhodes fell into his hands the year following, after an obstinate and enthusiastic defence. In 1526 he defeated and slew the king of Hungary in the famous battle of Mohatz. Three years after he conquered Buda, and immediately laid siege to Vienna itself. But after continuing 20 days before that city, and assaulting it 20 times, he was obliged to retreat with the loss of 80,000 men. Some time after he was defeated by the Persians, and disappointed of his hopes of taking Malta. He succeeded, however, in dispossessing the Genoese of Chio, an island which had belonged to that republic for more than 200 years.

He died at the age of 76, while he was besieging Sigeth, a town in Hungary, on the 30th August 1566.

He was a prince of the strictest probity, a lover of justice, and vigorous in the execution of it; but he tarnished all his glory by the cruelty of his disposition. After the battle of Mohatz he ordered 1500 prisoners, most of them gentlemen, to be ranged in a circle, and beheaded in presence of his whole army.

Soliman thought nothing impoſſible which he commanded: A general having received orders to throw a bridge over the Drave, wrote him, that it was impoſſible. The ſultan ſent him a long band of linen with theſe words written on it: "The emperor Soliman, thy maſter, orders thee to build a bridge over the Drave in ſpite of the difficulties thou mayeſt meet with. He informs thee at the ſame time, that if the bridge be not finiſhed upon his arrival, he will hang thee with the very linen which informs thee of his will."

SOLIPUGA, or SOLIFUGA, in natural hiſtory, the name given by the Romans to a ſmall venomous inſect of the ſpider-kind, called by the Greeks *heliocentros*; both words ſignify an animal which ſtings moſt in the country, and ſeaſons where the ſun is moſt hot. Solinus makes this creature peculiar to Sardinia; but this is contrary to all the accounts given us by the ancients. It is common in Africa and ſome parts of Europe. Almoſt all the hot countries produce this venomous little creature. It lies under the ſand to ſeize other inſects as they go by; and if it meet with any uncovered part of a man, produces a wound which proves very painful: it is ſaid that the bite is abſolutely mortal, but probably this is not true. Solinus writes the word *ſolifuga*, and ſo do many others, erroneouſly deriving the name from the notion that this animal flies from the ſun's rays, and buries itſelf in the ſand.

SOLIS (Antonio de), an ingenious Spaniſh writer, of an ancient and illuſtrious family, born at Placenza in Old Caſtile, in 1610. He was intended for the law; but his inclination toward poetry prevailed, and he cultivated it with great ſucceſs. Philip IV. of Spain made him one of his ſecretaries; and after his death the queen-regent appointed him hiſtoriographer of the Indies, a place of great profit and honour: his Hiſtory of the Conqueſt of Mexico ſhows that ſhe could not have named a fitter perſon. He is better known by this hiſtory at leaſt abroad, than by his poetry and dramatic writings, though in theſe he was alſo diſtinguiſhed. He turned prieſt at 57 years of age, and died in 1686.

SOLITARY, that which is remote from the company or commerce of others of the ſame ſpecies.

SOLITARIES, a domination of nuns of St Peter of Alcantara, inſtituted in 1676, the deſign of which was to imitate the ſevere penitent life of that ſaint. Thus they are to keep a continual ſilence, never to open their mouths to a ſtranger; to employ their time wholly in ſpiritual exerciſes, and leave their temporal concerns to a number of maids, who have a particular ſuperior in a ſeparate part of the monaſtery: they always go bare-footed, without ſandals; gird themſelves with a thick cord, and wear no linen.

SOLO, in the Italian muſic, is frequently uſed in pieces conſiſting of ſeveral parts, to mark thoſe that are to perform alone; as *flauto ſolo, violino ſolo.* It is alſo uſed for ſonatas compoſed for one violin, one German flute, or other inſtrument, and a baſs; thus we ſay, *Corelli's ſolos, Geminiani's ſolos*, &c. When two or three parts play or ſing ſeparately from the grand chorus, they are called a *doi ſoli*, a *tre ſoli*, &c. Solo is ſometimes denoted by *S*.

SOLOMON, the ſon of David king of Iſrael, renowned in Scripture for his wiſdom, riches, and magnificent temple and other buildings. Towards the end of his life he ſullied all his former glory by his apoſtacy from God; for which cauſe vengeance was denounced againſt his houſe and nation. He died about 975 B. C.

SOLOMON'S *Seal*, in botany; a ſpecies of CONVALLARIA.

SOLON, one of the ſeven wiſe men of Greece, was born at Salamis, of Athenian parents, who were deſcended from Codrus. His father leaving little patrimony, he had recourſe to merchandiſe for his ſubſiſtence. He had, however, a greater thirſt after knowledge and fame than after riches, and made his mercantile voyages ſubſervient to the increaſe of his intellectual treaſures. He very early cultivated the art of poetry, and applied himſelf to the ſtudy of moral and civil wiſdom. When the Athenians, tired out with a long and troubleſome war with the Megarenſians, for the recovery of the iſle of Salamis, prohibited any one, under pain of death, to propoſe the renewal of their claim to that iſland, Solon thinking the prohibition diſhonourable to the ſtate, and finding many of the younger citizens deſirous to revive the war, feigned himſelf mad, and took care to have the report of his inſanity ſpread thro' the city. In the mean time he compoſed an elegy adapted to the ſtate of public affairs, which he committed to memory. Every thing being thus prepared, he ſallied forth into the market-place with the kind of cap on his head which was commonly worn by ſick perſons, and aſcending the herald's ſtand, he delivered, to a numerous crowd, his lamentation for the deſertion of Salamis. The verſes were heard with general applauſe; and Piſiſtratus ſeconded his advice, and urged the people to renew the war. The decree was immediately repealed; the claim to Salamis was reſumed; and the conduct of the war was committed to Solon and Piſiſtratus, who, by means of a ſtratagem, defeated the Megarenſians, aud recovered Salamis.

His popularity was extended through Greece in conſequence of a ſucceſsful alliance which he formed among the ſtates in defence of the temple at Delphos againſt the Cirrhæans. When diſſenſions had ariſen at Athens between the rich creditors and their poor debtors, Solon was created archon, with the united powers of ſupreme legiſlator and magiſtrate. He ſoon reſtored harmony between the rich and poor: He cancelled the debts which had proved the occaſion of ſo much oppreſſion; and ordained that in future no creditor ſhould be allowed to ſeize the body of the debtor for his ſecurity: He made a new diſtribution of the people, inſtituted new courts of judicatory, and framed a judicious code of laws, which afterwards became the baſis of the laws of the twelve tables in Rome. Among his criminal laws are many wiſe and excellent regulations; but the code is neceſſarily defective with reſpect to thoſe principles which muſt be derived from the knowledge of the true God, and of pure morality, as the certain foundations of national happineſs. Two of them in particular were very exceptionable; the permiſſion of a voluntary exile to perſons that had been guilty of premiditated murder, and the appointment of a leſs ſevere puniſhment for a rape than for ſeduction. Thoſe who wiſh to ſee accurately ſtated the comparative excellence of the laws of Moſes, of Lycurgus, and Solon, may conſult Prize Diſſertations relative to Natural and Revealed Religion by Teyler's Theological Society, Vol. IX.

The interview which Solon is ſaid to have had with

Crœſus's

Crœsus king of Lydia, the solid remarks of the sage after surveying the monarch's wealth, the recollection of those remarks by Crœsus when doomed to die, and the noble conduct of Cyrus on that occasion, are known to every schoolboy. Solon died in the island of Cyprus, about the 80th year of his age. Statues were erected to his memory both at Athens and Salamis. His thirst after knowledge continued to the last: "I grow old (said he) learning many things." Among the apothegms and precepts which have been ascribed to Solon, are the following: Laws are like cobwebs, that entangle the weak, but are broken through by the strong. He who has learned to obey, will know how to command. In all things let reason be your guide. Diligently contemplate excellent things. In every thing that you do, consider the end.

SOLSTICE, in astronomy, that time when the sun is in one of the solstitial points; that is, when he is at his greatest distance from the equator; thus called because he then appears to stand still, and not to change his distance from the equator for some time; an appearance owing to the obliquity of our sphere, and which those living under the equator are strangers to.

The solstices are two in each year; the æstival or summer solstice, and the hyemal or winter solstice. The summer solstice is when the sun seems to describe the tropic of cancer, which is on June 22. when he makes the longest day: the winter solstice is when the sun enters the first degree, or seems to describe the tropic of capricorn, which is on December 22. when he makes the shortest day. This is to be understood as in our northern hemisphere; for in the southern, the sun's entrance into capricorn makes the summer solstice, and that into cancer the winter solstice. The two points of the ecliptic, wherein the sun's greatest ascent above the equator, and his descent below it, are terminated, are called the *solstitial points;* and a circle, supposed to pass through the poles of the world and these points, is called the *solstitial colure.* The summer solstitial point is in the beginning of the first degree of cancer, and is called the *æstival* or *summer point;* and the winter solstitial point is in the beginning of the first degree of capricorn, and is called the *winter point.* These two points are diametrically opposite to each other.

SOLUTION, in chemistry, denotes an intimate union of solid with fluid bodies, so as to form a transparent liquor. See DISSOLUTION, and *Index* to CHEMISTRY.

Solution of Metals. See *METALS (Solution of).*

SOLVENT, that which dissolves a solid body into a transparent fluid.

SOLWAY MOSS. *See Moving Moss.*

SOMBRERO, the name of an uninhabited island in the West Indies in the form of an hat, whence the name is derived. It is also the name of one of the Nicobar islands in the East Indies.

Wonderful Plant of SOMBRERO, is a strange kind of sensitive plant growing in the East Indies, in sandy bays and in shallow water. It appears like a slender straight stick; but when you attempt to touch it, immediately withdraws itself into the sand. Mr Miller gives an account of it in his description of Sumatra. He says, the Malays call it *lalan lout,* that is, sea grass. He never could observe any tentacula; but, after many unsuccessful attempts, drew out a broken piece about a foot long. It was perfectly straight and uniform, and resembled a worm drawn over a knitting needle. When dry it appears like a coral.

Philosophical Transactions vol. lxviii. p. 178.

SOMERS (John), lord high chancellor of England, was born at Worcester in 1652. He was educated at Oxford, and afterwards entered himself at the Middle-Temple, where he studied the law with great vigour. In 1688 he was one of the council for the seven bishops at their trial, and argued with great learning and eloquence against the dispensing power. In the convention which met by the prince of Orange's summons, January 22. 1689, he represented Worcester; and was one of the managers for the House of Commons, at a conference with the House of Lords upon the word *abdicated.* Soon after the accession of King William and Queen Mary to the throne, he was appointed solicitor-general, and received the honour of knighthood. In 1692 he was made attorney general, and in 1693 advanced to the post of lord keeper of the great seal of England. In 1695 he proposed an expedient to prevent the practice of clipping the coin. In 1697 he was created lord Somers, baron of Avesham, and made lord high chancellor of England. In the beginning of 1700 he was removed from his post of lord chancellor, and the year after was impeached of high crimes and misdemeanors by the House of Commons, of which he was acquitted upon trial by the House of Lords. He then retired to a studious course of life, and was chosen president of the Royal Society. In 1706 he proposed a bill for the regulation of the law; and the same year was one of the principal managers for the union between England and Scotland. In 1708 he was made lord president of the council; from which post he was removed in 1710, upon the change of the ministry. In the latter end of Queen Anne's reign his lordship grew very infirm in his health; which is supposed to be the reason that he held no other post than a seat at the council-table, after the accession of King George I. He died of an apoplectic fit in 1716. Mr Addison has drawn his character very beautifully in the Freeholder.

SOMERSETSHIRE, a county of England, taking its name from Somerton, once the capital, between 50° and 51° 27′ north latitude, and between 1° 25′ and 2° 59′ west longitude. It is bounded on the west by Devonshire, on the south by Dorsetshire, on the north by Bristol Channel or the Severn Sea, on the north-east by a small part of Gloucestershire, and on the east by Wiltshire. It is one of the largest counties in England, extending in length from east to west about 68 miles; in breadth, where broadest, from south to north, about 47; and 240 in circumference. It is divided into 42 hundreds, in which are 3 cities, 32 market towns, 1700 villages, 385 parishes of which 132 are vicarages, containing more than 1,000,000 of acres, and about 300,000 souls. It sends 18 members to Parliament, viz. two for the county, two for Bristol, two for Bath, two for Wells, two for Taunton, two for Bridgewater, two for Ilchester, two for Milbourn-port, and two for Minehead.

The air of this country is very mild and wholesome, especially that of the hilly part. The soil in general is exceeding rich, so that single acres very commonly produce forty or fifty bushels of wheat, and there have been instances of some producing sixty of barley. As there is very fine pasture both for sheep and black cattle, it abounds in both, which are as large as those of

Lincolnshire, and their flesh of a finer grain. In consequence of this abundance of black cattle, great quantities of cheese are made in it, of which that of Cheddar is thought equal to Parmesan. In the hilly parts are found coal, lead, copper, and lapis calaminaris. Wood thrives in it as well as in any county of the kingdom. It abounds also in pease, beans, beer, cyder, fruit, wild-fowl, and salmon; and its mineral waters are celebrated all over the world.

The riches of this county, both natural and acquired, exceed those of any other in the kingdom, Middlesex and Yorkshire excepted. The woollen manufacture in all its branches is carried on to a very great extent; and in some parts of the county great quantities of linen are made. If to these the produce of various other commodities in which it abounds is added, the amount of the whole must undoubtedly be very great. Its foreign trade must also be allowed to be very extensive, when it is considered that it has a large trade for sea coal, and possesses, besides other ports, that of Bristol, a town of the greatest trade in England, next to London.

Besides small streams, it is well watered and supplied with fish by the river Severn, Avon, Parrel, Froome, Ax, Torre, and Tone. Its greatest hills are Mendip, Pouldon, and Quantock, of which the first abounds in coal, lead, &c. The rivers Severn and Parrel breed very fine salmon. The chief town is Bristol.

SOMERTON, an ancient town in Somersetshire, from whence the county derives its name. It is 123 miles from London; it has five streets, containing 251 houses, which are mostly built of the blue stone from the quarries in the neighbourhood. It is governed by constables, and has a hall for petty sessions. The market for corn is considerable, and it has several fairs for cattle. The church has what is not very frequent, an *octangular* tower with six bells. N. Lat. 51. 4. W. Long. 1. 53.

SOMNAMBULI, persons who walk in their sleep. See SLEEPWALKERS.

SOMNER (William), an eminent English antiquary, was born at Canterbury in 1606. His first treatise was The Antiquities of Canterbury, which he dedicated to Archbishop Laud. He then applied himself to the study of the Saxon language; and having made himself master of it, he perceived that the old glossary prefixed to Sir Roger Twisden's edition of the laws of King Henry I. printed in 1644, was faulty in many places; he therefore added to that edition notes and observations valuable for their learning, with a very useful glossary. His Treatise of Gavelkind was finished about 1648, though not published till 1660. Our author was zealously attached to King Charles I. and in 1648 he published a poem on his sufferings and death. His skill in the Saxon tongue led him to inquire into most of the European languages ancient and modern. He assisted Dugdale and Dodsworth in compiling the *Monasticon Anglicanum.* His Saxon Dictionary was printed at Oxford in 1659. He died in 1669.

SON, an appellation given to a male child considered in the relation he bears to his parents. See PARENT and FILIAL *Piety*.

SONATA, in music, a piece or composition, intended to be performed by instruments only; in which sense it stands opposed to *cantata*, or a piece designed for the voice. See CANTATA.

The sonata then, is properly a grand, free, humorous composition, diversified with a great variety of motions and expressions, extraordinary and bold strokes, figures, &c. And all this purely according to the fancy of the composer; who, without confining himself to any general rules of counterpoint, or to any fixed number or measure, gives a loose to his genius, and runs from one mode, measure, &c. to another, as he thinks fit. This species of composition had its rise about the middle of the 17th century; those who have most excelled in it were Bassani and Corelli. We have sonatas of 1, 2, 3, 4, 5, 6, 7, and even 8 parts, but usually they are performed by a single violin, or with two violins, and a thorough bass for the harpsichord; and frequently a more figured bass for the bass viol, &c.

There are a thousand different species of sonatas; but the Italians usually reduce them to two kinds. *Suonate de chiesa*, that is, sonatas proper for church music, which usually begin with a grave solemn motion, suitable to the dignity and sanctity of the place and the service, after which they strike into a brisker, gayer, and richer manner. These are what they more peculiarly call sonatas. *Suonate de camera*, or sonatas for the chamber, are properly serieses of several little pieces, for dancing, only composed to the same tune. They usually begin with a prelude or little sonata, serving as an introduction to all the rest: afterwards come the allemand, pavane, courant, and other serious dances; then jigs, gavots, minuets, chacons, passecailles, and other gayer airs: the whole composed in the same tune or mode.

SONCHUS, SOW-THISTLE, in botany: A genus of plants belonging to the class of *syngenesia*, and to the order of *polygamia æqualis*; and in the natural system ranged under the 49th order, *Compositæ*. The receptacle is naked; the calyx is imbricated, bellying and conical; the down of the seed is simple, sessile, and very soft; the seed is oval and pointed. There are 13 species; the maritimus, palustris, fruticosus, arvensis, oleraceus, tenerrimus, plumieri, alpinus, floridanus, sibiricus, tataricus, tuberosus, and canadensis. Four of these are natives of Britain.—1. *Palustris*, marsh sow thistle. The stem is erect, from six to ten feet high, branched and hairy towards the top: the leaves are firm, broad, half pinnated, serrated, and sharp-pointed; the lower ones sagittate at the base: the flowers are of a deep yellow, large, and dispersed on the tops of the branches: the calyx is rough. It is frequent in marshes, and flowers in July or August.—2. *Arvensis*, corn sow-thistle. The leaves are alternate, runcinate, and heart-shaped at the base; the root creeps under ground; the stem is three or four feet high, and branched at the top. It grows in corn-fields, and flowers in August.—3. *Oleraceus*, common sow-thistle. The stalk is succulent, pistular, and a cubit high or more; the leaves are broad, embracing the stem, generally deeply sinuated, smooth or prickly at the edges; the flowers are of a pale yellow, numerous, in a kind of umbel, and terminal; the calyx is smooth. It is frequent in waste places and cultivated grounds.—4. *Alpinus*, blue-flowered sow-thistle. The stem is erect, purplish, branched, or simple, from three to six feet high: the leaves are large, smooth, and sinuated;

ated; the extreme segment large and triangular: the flowers are blue, and grow on hairy viscid pedicles, in long spikes: the calyx is brown. This species is found in Northumberland.

SONG, in poetry, a little composition, consisting of easy and natural verses, set to a tune in order to be sung. See POETRY, nº 120.

SONG, in music, is applied in general to a single piece of music, whether contrived for the voice or an instrument. See AIR.

Song of Birds, is defined by the honourable Daines Barrington to be a succession of three or more different notes, which are continued without interruption, during the same interval, with a musical bar of four crotchets in an adagio movement, or whilst a pendulum swings four seconds.

It is affirmed, that the notes of birds are no more innate than language in man, and that they depend upon imitation, as far as their organs will enable them to imitate the sounds which they have frequent opportunities of hearing: and their adhering so steadily, even in a wild state, to the same song, is owing to the nestlings attending only to the instruction of the parent bird, whilst they disregard the notes of all others that may perhaps be singing round them.

Birds in a wild state do not commonly sing above 10 weeks in the year, whereas birds that have plenty of food in a cage sing the greatest part of the year: and we may add, that the female of no species of birds ever sings. This is a wise provision of nature, because her song would discover her nest. In the same manner, we may rationally account for her inferiority in plumage. The faculty of singing is confined to the cock birds; and accordingly Mr Hunter, in dissecting birds of several species, found the muscles of the larynx to be stronger in the nightingale than in any other bird of the same size; and in all those instances, where he dissected both cock and hen, the same muscles were stronger in the cock. To the same purpose, it is an observation as ancient as the time of Pliny, that a capon does not crow.

Some have ascribed the singing of the cock-bird in the spring solely to the motive of pleasing his mate during incubation; others, who allow that it is partly for this end, believe it is partly owing also to another cause, viz. the great abundance of plants and insects in the spring, which, as well as seeds, are the proper food of singing birds at that time of the year.

Mr Barrington remarks, that there is no instance of any singing bird which exceeds our blackbird in size; and this, he supposes, may arise from the difficulty of its concealing itself, if it called the attention of its enemies, not only by its bulk, but by the porportionable loudness of its notes. This writer farther observes, that some passages of the song in a few kinds of birds correspond with the intervals of our musical scale, of which the cuckoo is a striking and known instance; but the greater part of their song cannot be reduced to a musical scale; partly, because the rapidity is often so great, and it is also so uncertain when they may stop, that we cannot reduce the passages to form a musical bar in any time whatsoever; partly also, because the pitch of most birds is considerably higher than the most shrill notes of those instruments which have the greatest compass; and principally, because the intervals used by birds are commonly so minute, that we cannot judge of them from the more gross intervals into which we divide our musical octave. This writer apprehends, that all birds sing in the same key; and in order to discover this key, he informs us, that the following notes have been observed in different birds, A, B flat, C, D, F, and G; and therefore E only is wanting to complete the scale: now these intervals, he says, can only be found in the key of F with a sharp third, or that of G with a flat third; and he supposes it to be the latter, because admitting that the first musical notes were learned from birds, those of the cuckoo, which have been most attended to, form a flat third, and most of our compositions are in a flat third, where music is simple, and consists merely of melody. As a farther evidence that birds sing always in the same key, it has been found by attending to a nightingale, as well as a robin which was educated under him, that the notes reducible to our intervals of the octave were always precisely the same.

Most people, who have not attended to the notes of birds, suppose, that every species sing exactly the same notes and passages: but this is by no means true; though it is admitted that there is a general resemblance. Thus the London bird-catchers prefer the song of the Kentish goldfinches, and Essex chaffinches; and some of the nightingale-fanciers prefer a Surry bird to those of Middlesex.

Of all singing birds, the song of the nightingale has been most universally admired: and its superiority (deduced from a caged bird) consists in the following particulars; its tone is much more mellow than that of any other bird, though at the same time, by a proper exertion of its musical powers, it can be very brilliant. Another point of superiority is its continuance of song without a pause, which is sometimes no less than 20 seconds; and when respiration becomes necessary, it takes it with as much judgment as an opera-singer. The skylark in this particular, as well as in compass and variety, is only second to the nightingale. The nightingale also sings (if the expression may be allowed) with superior judgment and taste. Mr Barrington has observed, that his nightingale, which was a very capital bird, began softly like the ancient orators; reserving its breath to swell certain notes, which by these means had a most astonishing effect. This writer adds, that the notes of birds, which are annually imported from Asia, Africa, and America, both singly and in concert, are not to be compared to those of European birds.

The following table, formed by Mr Barrington, agreeably to the idea of M. de Piles in estimating the merits of painters, is designed to exhibit the comparative merit of the British singing birds; in which 20 is supposed to be the point of absolute perfection.

SONNA, a book of Mahometan traditions, which all the orthodox mussulmen are required to believe.

SONNERATIA, in botany; a genus of plants belonging to the class of *icosandria*, and to the order of *monogynia*. The calyx is cut into six segments; the petals are six; the capsule is multilocular and succulent; and the cells contain many seeds. The only species is the *acida*.

SONNET, in poetry, a composition contained in 14 verses, viz. two stanzas or measures of four verses each, and two of three, the eight first verses being all in three rhimes.

SONNITES, among the Mahometans, an appellation given to the orthodox mussulmen or true believers; in opposition to the several heretical sects, particularly the Shiites or followers of Ali.

SOOJU, or SOY. See DOLICHOS.

SOONTABURDAR, in the East Indies; an attendant, who carries a silver bludgeon in his hand about two or three feet long, and runs before the palanquin. He is inferior to the Chubdar; the propriety of an Indian newaury requiring two Soontaburdars for every Chubdar in the train. The Chubdar proclaims the approach of visitors, &c. He generally carries a large silver staff about five feet long in his hands: and among the Nabobs he proclaims their praises aloud as he runs before their palanquins.

SOOT, a volatile matter arising from wood and other fuel along with the smoke; or rather, it is the smoke itself condensed and gathered to the sides of the chimney. Tho' once volatile, however, soot cannot be again resolved into vapour; but, if distilled by a strong fire, yields a volatile alkali and empyreumatic oil, a considerable quantity of fixed matter remaining at the bottom of the distilling vessel. If burnt in an open fire, it flames with a thick smoke, whence other soot is produced. It is used as a material for making sal ammoniac, and as a manure. See CHEMISTRY, n° 796; and AGRICULTURE, n° 20.

Soot-Black. See *Colour-Making*.

SOPHI, or SOFI, a title given to the emperor of Persia; importing as much as wise, sage, or philosopher.

Sophis, Sophism.

The title is by some said to have taken its rise from a young shepherd named *Sophi*, who attained to the crown of Persia in 1370; others derive it from the *sophoi* or sages anciently called *magi*. Vossius gives a different account of the word: sophi in Arabic, he observes, signifies *wool*; and he adds, that it was applied by the Turks out of derision to the kings of Persia ever since Ishmael's time; because, according to their scheme of religion, he is to wear no other covering on his head but an ordinary red woollen stuff; whence the Persians are also called *hezelbaschs*, q. d. *red-heads*. But Bochart assures us, that sophi in the original Persian language, signifies one that is pure in his religion, and who prefers the service of God in all things: and derives it from an order of religious called by the same name. The sophis value themselves on their illustrious extraction. They are descended in a right line from Houssein, second son of Ali, Mahomet's cousin, and Fatima, Mahomet's daughter.

SOPHIS, or *Sofees*, a kind of order of religious among the Mahometans in Persia, answering to what are otherwise called *dervises*, and among the Arabs and Indians *faquirs*. Some will have them called sophis from a kind of coarse camblet which they wear called *souf* from the city Souf in Syria, where it is principally manufactured. The more eminent of those sophis are complimented with the title *schiek*, that is, *reverend*, much as in Romish countries the religious are called *reverend fathers*. Schiek sophi, who laid the foundation of the grandeur of the royal house of Persia, was the founder, or rather the restorer of this order: Ishmael, who conquered Persia, was himself a sophi, and greatly valued himself on his being so. He chose all the guards of his person from among the religious of this order; and would have all the great lords of his court sophis. The king of Persia is still grandmaster of the order; and the lords continue to enter into it, though it be now fallen under some contempt.

SOPHISM, in logic a specious argument having the appearance of truth, but leading to falsehood. Sophisms are reduced by Aristotle into eight classes, an arrangement so just and comprehensive, that it is equally proper in present as in former times. 1. *Ignoratio elenchi* in which the sophist seems to determine the question, while he only does it in appearance. Thus the question, "Whether excess of wine be hurtful?" seems to be determined by proving, that wine revives the spirits and gives a man courage: but the principal point is here kept out of sight; for still it may be hurtful to health, to fortune, and reputation. 2. *Petitio principii*, a begging of the question, or taking for granted that which remains to be proved, as if any one should undertake to prove that the soul is extended through all the parts of the body, because it resides in every member. This is affirming the same thing in different words. 3. Reasoning in a circle; as when the Roman Catholics prove the Scriptures to be the word of God by the authority of the church, and the authority of the church from the Scriptures. 4. *Non causa pro causa*, or the assigning of a false cause to any effect. Thus the supposed principle, that nature abhors a vacuum, was applied to explain the rising of water in a pump before Galileo discovered that it was owing to the pressure of the

atmo-

atmosphere. In this way the vulgar ascribe accidents to divine vengeance, and the heresies and infidelity of modern times are said to be owing to learning. 5. *Fallacia accidentis*, in which the sophist represents what is merely accidental as essential to the nature of the subject. This is nearly allied to the former, and is committed by the Mahometans and Roman Catholics. The Mahometans forbid wine, because it is sometimes the occasion of drunkenness and quarrels; and the Roman Catholics prohibit the reading of the Bible, because it has sometimes promoted heresies. 6. By deducing an universal assertion from what is true only in particular circumstances, and the reverse; thus some men argue, "transcribers have committed many errors in copying the Scriptures, therefore they are not to be depended on." 7. By asserting any thing in a compound sense which is only true in a divided sense; so when the Scriptures assure us, that the worst of sinners may be saved, it does not mean that they shall be saved while they remain sinners, but that if they repent they may be saved. 8. By an abuse of the ambiguity of words. Thus Mr Hume reasons in his Essay on Miracles: "Experience is our only guide in reasoning concerning matters of fact; now we know from experience, that the laws of nature are fixed and invariable. On the other hand, testimony is variable and often false; therefore since our evidence for the reality of miracles rests solely on testimony which is variable, and our evidence for the uniformity of the laws of nature is invariable, miracles are not to be believed." The sophistry of this reasoning depends on the ambiguity of the word *experience*, which in the first proposition signifies the maxims which we form from our own observation and reflection; in the second it is confounded with testimony; for it is by the testimony of others, as well as our own observation, that we learn whether the laws of nature are variable or invariable. The Essay on Miracles may be recommended to those who wish to see more examples of sophistry; as we believe most of the eight species of sophisms which we have mentioned are well illustrated by examples in that essay.

SOPHIST, an appellation assumed in the early periods of Grecian history by those who devoted their time to the study of science. This appellation appearing too arrogant to Pythagoras, he declined it, and wished to be called a *philosopher*; declaring that, though he cold not consider himself as a wise man, he was indeed a lover of wisdom. True wisdom and modesty are generally united. The example of Pythagoras was followed by every man of eminence; while the name *Sophist* was retained only by those who with a pomp of words made a magnificent display of wisdom upon a very slight foundation of knowledge. Those men taught an artificial structure of language, and a false method of reasoning, by which, in argument, the worse might be made to appear the better reason (see SOPHISM). In Athens they were long held in high repute, and supported, not only by contributions from their pupils, but by a regular salary from the state. They were among the bitterest enemies of the illustrious Socrates, because he embraced every opportunity of exposing to contempt and ridicule their vain pretensions to superior knowledge, and the pernicious influence of their doctrines upon the taste and morals of the Athenian youth.

SOPHISTICATION, the mixing of any thing with what is not genuine; a practice too common in the making up of medicines for sale; as also among vintners, distillers, and others, who are accused of sophisticating their wines, spirits, oils, &c. by mixing with them cheaper and coarser materials; and in many cases the cheat is carried on so artfully as to deceive the best judges.

SOPHOCLES, the celebrated Greek tragic poet, the son of Sophilus an Athenian, was born at Colonn, and educated with great attention. Superior vigour and address in the exercises of the palestra, and skill in music, were the great accomplishments of young men in the states of Greece. In these, Sophocles excelled; nor was he less distinguished by the beauty of his person. He was also instructed in the noblest of all sciences, civil policy and religion: from the first of these he derived an unshaken love of his country, which he served in some embassies, and in high military command with Pericles; from the latter he was impressed with a pious reverence for the gods, manifested by the inviolable integrity of his life. But his studies were early devoted to the tragic muse; the spirit of Eschylus lent a fire to his genius, and excited that noble emulation which led him to contend with, and sometimes to bear away the prize from, his great master. He wrote 43 tragedies, of which 7 only have escaped the ravages of time: and having testified his love of his country by refusing to leave it, though invited by many kings; and having enjoyed the uninterrupted esteem and affection of his fellow-citizens, which neither the gallant actions and sublime genius of Eschylus, nor the tender spirit and philosophic virtue of Euripides, could secure to them, he died in the 91st year of his age, about 406 years before Christ. The burial-place of his ancestors was at Decelia, which the Lacedemonians had at that time seized and fortified; but Lysander, the Spartan chief, permitted the Athenians to inter their deceased poet; and they paid him all the honours due to his love of his country, integrity of life, and high poetic excellence. Eschylus had at once seized the highest post of honour in the field of poetry, the true sublime; to that eminence his claim could not be disputed. Sophocles had a noble elevation of mind, but tempered with so fine a taste, and so chastened a judgment, that he never passed the bounds of propriety. Under his conduct the tragic muse appeared with the chaste dignity of some noble matron at a religious solemnity; harmony is in her voice, and grace in all her motions. From him the theatre received some additional embellishments; and the drama the introduction of a third speaker, which made it more active and more interesting: but his distinguished excellence is in the judicious disposition of the fable, and so nice a connection and dependance of the parts on each other, that they all agree to make the event not only probable, but even necessary. This is peculiarly admirable in his "Œdipus King of Thebes;" and in this important point he is far superior to every other dramatic writer.

The ingratitude of the children of Sophocles is well known. They wished to become immediate masters of their father's possessions; and therefore tired of his long life, they accused him before the Areopagus of insanity. The only defence the poet made was to read his tragedy of Œdipus at Colonos, which he had lately finished; and then he asked his judges, whether the author

thor of such a performance could be taxed with insanity? The father upon this was acquitted, and the children returned home covered with shame and confusion. The seven tragedies of Sophocles which still remain, together with the Greek Scholia which accompany them, have been translated into Latin by Johnson, and into English by Dr Franklin and Mr Potter.

SOPHORA, in botany: A genus of plants belonging to the class of *decandria*, and to the order of *monogynia*; and in the natural system arranged under the 32d order, *Papilionaceæ*. The calyx is quinquedentate and gibbous above: the corolla is papilionaceous; the wings being of the same length with the vexillum: the seed is contained in a legumen. There are 16 species; the tetraptera, microphylla, flavescens, alopecuroides, tomentosa, occidentalis, capensis, aurea, japonica, genistoides, australis, tinctoria, alba, lupinoides, biflora, and hirsuta.

SOPORIFIC, or Soporiferous, a medicine that produces sleep. Such are opium, laudanum, the seed of poppies, &c. The word is formed from the Latin *sopor*, "sleep." The Greeks in place of it use the word *hypnotic*.

SORBONNE, or Sorbon, the house or college of the faculty of theology established in the university of Paris. It was founded in 1252 by St Louis, or rather by Robert de Sorbon his confessor and almoner, first canon of Cambray, and afterwards of the church of Paris; who gave his own name to it, which he himself took from the village of Sorbon or Serbon, near Sens, where he was born. The foundation was laid in 1250; queen Blanche, in the absence of her husband, furnished him with a house which had formerly been the palace of Julian the apostate, of which some remains are still seen. Afterwards the king gave him all the houses he had in the same place, in exchange for some others. The college has been since magnificently rebuilt by the cardinal de Richelieu. The design of its institution was for the use of poor students in divinity. There are lodgings in it for 36 doctors, who are said to be of the *society of the Sorbonne*; those admitted into it without being doctors, are said to be of the *hospitality of the Sorbonne*. Six regent doctors formerly held lectures every day for an hour and a half each; three in the morning, and three in the afternoon.

Sorbonne, is also used in general for the whole faculty of theology at Paris; as the assemblies of the whole body are held in the house of the Sorbonne; and the bachelors of the other houses of the faculty, as the house of Navarre, &c. come hither to hold their *sorbonnique*, or act for being admitted doctor in divinity.

SORBUS, service-tree, in botany; a genus of plants belonging to the class of *icosandria*, and to the order of *trigynia*. The calyx is quinquefid; the petals are five; the berry is below the flower, soft and containing three seeds. There are three species; the aucuparia, domestica, and hebrida.

1. The *aucuparia*, mountain-ash, quicken-tree, quickbeam, or roan-tree, rises with a straight upright stem and regular branching head, twenty or thirty feet high or more, covered with a smooth greyish brown bark; pinnated leaves of eight or ten pair of long, narrow, serrated folioles, and an odd one, smooth on both sides; and large umbellate clusters of white flowers at the sides and ends of the branches, succeeded by clusters of fine red berries, ripe in autumn and winter. There is a variety with yellow striped leaves. This species grows wild in many parts of Great Britain in mountainous places, woods, and hedge-rows, often growing to the size of timber; and is admitted into most ornamental plantations, for the beauty of its growth, foliage, flowers, and fruit; the latter, in particular, being produced in numerous red large bunches all over the tree, exhibit a fine appearance in autumn and winter, till devoured by the birds, especially the blackbird and thrush, which are so allured by this fruit as to flock from all parts and feed on it voraciously.—In the island of Jura the juice of the berries is employed as an acid for punch. It is probable that this tree was in high esteem with the Druids; for it is more abundant than any other tree in the neighbourhood of those Druidical circles of stones, so common in North Britain. It is still believed by some persons, that a branch of this tree can defend them from enchantment or witchcraft. Even the cattle are supposed to be preserved by it from danger. The dairy-maid drives them to the summer pastures with a rod of the roan-tree, and drives them home again with the same. In Strathspey, we are told, a hoop is made of the wood of this tree on the 1st of May, and all the sheep and lambs are made to pass through it.

2. The *domestica*, or cultivated service-tree, with eatable fruit, grows with an upright stem, branching 30 or 40 feet high or more, having a brownish bark, and the young shoots in summer covered with a mealy down; pinnated leaves of eight or ten pair of broadish deeply serrated lobes and an odd one, downy underneath, and large umbellate clusters of white flowers at the sides and ends of the branches, succeeded by bunches of large, fleshy, edible red fruit, of various shapes and sizes. This tree is a native of the southern warm parts of Europe, where its fruit is used at table as a desert, and it is cultivated in the north in many gardens, both as a fruit-tree and as an ornament to diversify hardy plantations.

3. The *hebrida*, or mongrel service-tree of Gothland, grows twenty or thirty feet high; it has half-pinnated leaves, very downy underneath; and clusters of white flowers, succeeded by bunches of round reddish berries in autumn.

SORCERY, or Magic: the power which some persons were formerly supposed to possess of commanding the devil and the infernal spirits by skill in charms and invocations, and of soothing them by fumigations. Sorcery is therefore to be distinguished from witchcraft; an art which was supposed to be practised, not by commanding evil spirits, but by compact with the devil. As an instance of the power of bad smells over demons or evil spirits, we may mention the flight of the evil spirit mentioned in Tobit into the remote parts of Egypt, produced, it is said, by the smell of the burnt liver of a fish. Lilly informs us, that one Evans having raised a spirit at the request of Lord Bothwell and Sir Kenelm Digby, and forgetting a fumigation, the spirit, vexed at the disappointment, pulled him without the circle, and carried him from his house in the Minories into a field near Battersea Causeway.

King James, in his *Dæmonologia*, has given a very full account of the art of sorcery. "Two principal things (says he) cannot well in that errand be wanted: holy

Sorcery. holy water (whereby the devill mockes the papists), and some present of a living thing unto him. There are likewise certaine daies and houres that they observe in this purpose. These things being all ready and prepared, circles are made, triangular, quadrangular, round, double, or single, according to the forme of the apparition they crave. When the conjured spirit appeares, which will not be while after many circumstances, long prayers, and much muttering and murmurings of the conjurors, like a papist priest dispatching a hunting masse—how soone, I say, he appeares, if they have missed one jote of all their rites; or if any of their feete once slyd over the circle, through terror of his fearfull apparition, he paies himself at that time, in his owne hand, of that due debt which they ought him, and otherwise would have delaied longer to have paid him: I mean, he carries them with him, body and soule." How the conjurors made triangular or quadrangular circles, his majesty has not informed us, nor does he seem to imagine there was any difficulty in the matter. We are therefore led to suppose, that he learned his mathematics from the same system as Dr Sacheverell, who, in one of his speeches or sermons, made use of the following simile: "They concur like parallel lines, meeting in one common centre."

Another mode of consulting spirits was by the beryl, by means of a speculator or seer; who, to have a complete sight, ought to be a pure virgin, a youth who had not known woman, or at least a person of irreproachable life and purity of manners. The method of such consultation is this: The conjuror having repeated the necessary charms and adjurations, with the litany or invocation peculiar to the spirits or angels he wishes to call (for every one has his particular form), the seer looks into a crystal, or beryl, wherein he will see the answer, represented either by types or figures; and sometimes, though very rarely, will hear the angels or spirits speak articulately. Their pronunciation is, as Lilly says, like the Irish, much in the throat. Lilly describes one of these beryls or crystals. It was, he says, as large as an orange, set in silver, with a cross at the top, and round about engraved the names of the angels Raphael, Gabriel, and Uriel. A delineation of another is engraved in the frontispiece to Aubery's Miscellanies.

These socerers or magicians do not always employ their art to do mischief; but, on the contrary, frequently exert it to cure diseases inflicted by witches; to discover thieves; recover stolen goods; to foretel future events, and the state of absent friends. On this account they are frequently called *white witches*. See Magic, Witchcraft, &c.

Our forefathers were strong believers when they enacted, by statute 33 Hen. VIII. c. 8. all witchcraft and sorcery to be felony without benefit of clergy; and again, by statute 1 Jac. I. c. 12. that all persons invoking any evil spirit, or consulting, covenanting with, entertaining, employing, feeding, or rewarding any evil spirit; or taking up dead bodies from their graves to be used in any witchcraft, sorcery, charm, or inchantment; or killing or otherwise hurting any person by such infernal arts; should be guilty of felony without benefit of clergy, and suffer death. And if any person should attempt by sorcery to discover hidden treasure, or to restore stolen goods, or to provoke unlawful love, or to hurt any man or beast, though the same were not effected, he or she should suffer imprisonment and pillory, for the first offence, and death for the second. These acts continued in force till lately, to the terror of all ancient females in the kingdom; and many poor wretches were sacrificed thereby to the prejudice of their neighbours and their own illusions, not a few having by some means or other confessed the fact at the gallows. But all executions for this dubious crime are now at an end; the legislature having at length followed the wise example of Louis XIV. in France, who thought proper by an edict to restrain the tribunals of justice from receiving informations of witchcraft. And accordingly it is enacted, by statute 9 Geo. II. c. 5. that no prosecution shall for the future be carried on against any person for conjuration, witchcraft sorcery, or inchantment: But the misdemeanor of persons pretending to use witchcraft, tell fortunes, or discover stolen goods, by skill in the occult sciences, is still deservedly punished with a year's imprisonment, and standing four times in the pillory.

Sorex. SOREX, the Shrew, in natural history; a genus of animals belonging to the class of *mammalia*, and order of *feræ*. It has two long fore-teeth in the upper jaw, which are divided into two points; in the lower jaw are two or four fore-teeth, the two middle ones, in the latter-case, being shorter than the others: On each side in both jaws are two or more tusks: The grinders are knobbed. The animals of this genus have in general thick clumsy bodies, and five toes on each of their feet; the head resembles that of the mole, being thick at the fore-head, much elongated, and ending in a conical snout, and having very small eyes; in other circumstances of general figure they resemble the murine tribe of quadrupeds. They burrow in the ground, some species living mostly about the sides of waters; and most of them feeding on worms and insects. There are 16 species; of which the most remarkable are,

1. The *araneus*, or field shrew-mouse, with short rounded ears; eyes small, and almost hid in the fur; nose long and slender, upper part the longest; head and upper part of the body of a brownish red; belly of a dirty white; length from nose to tail, two inches and a half; tail one and a half. Inhabits Europe: lives in old walls and heaps of stones, or holes in the earth; is frequently near hay-ricks, dung-hills, and necessary-houses; lives on corn, insects, and any filth; is often observed rooting in ordure like a hog; from its food, or the places it frequents, has a disagreeable smell; cats will kill, but not eat it: it brings four or five young at a time. The ancients believed it was injurious to cattle; an error now detected. There seems to be an annual mortality of these animals in August, numbers being then found dead in the paths.

2. The *fodiens*, or water-shrew, has a long slender nose; very minute ears; very small eyes, hid in the fur; colour of the head and upper part of the body black; throat, breast, and belly, of a light ash colour; beneath the tail, a triangular dusky spot; much larger, than the last; length, from nose to tail, three inches three quarters; tail, two inches. Inhabits Europe: long since known in England, but lost till May 1768, when it was discovered in the fens near Revesley Abbey,

bey, Lincolnshire; burrows in the banks near the water; is called by the fenmen the *blind-mouse*.

3. The *minutus*, or minute shrew, has a head near as big as the body: very slender nose; broad short naked ears; whiskers reaching to the eyes; eyes small, and capable of being drawn in; hair very fine and shining; grey above, white beneath; no tail; the least of quadrupeds, according to Linnæus. Inhabits Siberia; lives in a nest made of lichens, in some moist place beneath the roots of trees; feeds on seeds, digs, runs swiftly, and has the voice of a bat.

4. The *tucan*, or Mexican shrew, has a sharp nose; small round ears; without sight; two long fore-teeth above and below; thick, fat, and fleshy body; short legs, so that the belly almost touches the ground; long crooked claws; tawny hair; short tail; length, from nose to tail, nine inches. Inhabits Mexico; burrows, and makes such a number of cavities, that travellers can scarce tread with safety; if it gets out of its hole, does not know how to return, but begins to dig another; grows very fat, and is eatable; feeds on roots, kidney-beans, and other seeds. M. de Buffon thinks it a mole; but it seems more properly to belong to the genus of sorex.

SORITES, in logic, a species of reasoning in which a great number of propositions are so linked together, that the predicate of the one becomes continually the subject of the next following, till at last a conclusion is formed by bringing together the subject of the first proposition, and the predicate of the last. Such was that merry argument of Themistocles, to prove that his little son under ten years old governed the whole world. Thus: *My son governs his mother; his mother me; I the Athenians; the Athenians the Greeks; Greece commands Europe; Europe the whole world: therefore my son commands the whole world.* See Logic, n° 96. 97.

SORNING, in Scots law. See Law, N° clxxxvi. 30.

SORREL, in botany, a species of the RUMEX, which grows in pastures and meadows, and is well known. The natives of Lapland boil large quantities of the leaves in water, and mix the juice when cold with the milk of their rein-deers which they esteem an agreeable and wholesome food. The Dutch are said to cultivate this plant for its usefulness in the dyeing of woollen cloths black; and we know that by means of the common broad-leaved sorrel an excellent black colour is, in many places of Scotland, given to woollen stuffs without the aid of copperas. As this mode of dyeing does not in the smallest degree injure the texture of the cloth, which continues to the last soft and silky, without that hardness to the touch which it acquires when dyed black by means of copperas, our readers will probably thank us for the following receipt, with which we have been favoured by a learned physician:

Let the stuff to be dyed be well washed with soap and water, and afterwards completely dried. Then of the common broad-leaved sorrel boil as much as shall make an acid decoction of sufficient quantity to let the stuff to be dyed lie in it open and easy to be stirred. The greater quantity of sorrel that is used, the better will the colour be; and therefore if the pot or cauldron will not hold enough at once, when part has been sufficiently boiled, it must be taken out and wrung, and a fresh quantity be boiled in the same juice or decoction. When the liquor is made sufficiently acid, strain it from the sorrel through a sieve, put the cloth or yarn upon it, and let it boil for two hours, stirring it frequently. If stockings be among the stuff to be dyed, it will be expedient, after they have been an hour in the boiling liquor, to turn them inside out, and at the end of the second hour let the whole be poured into a tub or any other vessel. The pot or cauldron must then be washed, and water put into it, with half a pound of logwood chips for every pound of dry yarn or cloth. The logwood and water should boil slowly for four hours; and then the cloth or yarn being wrung from the sour liquor, and put into the logwood decoction, the whole must be suffered to boil slowly for four hours, stockings, if there be any, being turned inside out at the end of two hours. Of this last decoction there must as of the former be enough to let the cloth lie open and easy to be stirred while boiling. At the end of the four hours the cloth must be taken out, and among the boiling liquor, first removed from the fire, must be poured a Scotch pint or English gallon of stale urine for every pound of dry cloth or other stuff to be dyed. When this compound liquor has been stirred and become cold, the cloth must be put into it and suffered to remain well covered for 12 hours, and then dried in the shade; after which, to divest it of smell or any other impurity, it may be washed in cold water, and dried for use.

Wood-Sorrel, in botany. See Oxalis.

Sorrel-Colour, in the manege, is a reddish colour, generally thought to be a sign of a good horse.

SORRENTO, a sea-port town of the kingdom of Naples, with an archbishop's see. It is seated in a peninsula, on the bay of Naples, at the foot of a mountain of the same name, 17 miles south-east of Naples. It is the birth-place of Torquato Tasso. E. Long. 14. 24. N. Lat. 40. 36.

SORTILEGE (*Sortilegium*), a species of divination performed by means of *sortes* or lots.

The *sortes Prenestinæ*, famous in antiquity, consisted in putting a number of letters, or even whole words, into an urn; and then, after shaking them together, they were thrown on the ground; and whatever sentences could be made out from them, constituted the answer of the oracle. To this method of divination succeeded that which has been called the *sortes Homerianæ* and *sortes Virgilianæ*, a mode of inquiring into futurity, which undoubtedly took its rise from a general custom of the oracular priests of delivering their answers in verse; it subsisted a long time among the Greeks and Romans; and being from them adopted by the Christians, it was not till after a long succession of centuries that it became exploded. Among the Romans it consisted in opening some celebrated poet at random, and among the Christians the Scriptures, and drawing, from the first passage which presented itself to the eye, a prognostic of what would befal one's self or others, or direction for conduct when under any exigency. There is good evidence that this was none of the vulgar errors; the greatest persons, philosophers of the best repute, admitted this superstition. Socrates, when in prison, hearing this line of Homer,

Within three days I Phthia's shore shall see,

immediately

Sortilege. immediately said, within three days I shall be out of the world; gathering it from the double meaning of the word *Phthia*, which in Greek is both the name of a country and signifies corruption or death. This prediction, addressed to Æschinus, was not easily forgotten, as it was verified.

When this superstition passed from Paganism into Christianity, the Christians had two methods of consulting the divine will from the Scriptures; the one, casually, to open the divine writings, and take their direction, as above-mentioned; the other, to go to church with a purpose of receiving, as a declaration of the will of heaven, the words of the Scripture, which were singing at the instant of one's entrance.

This unwarrantable practice of inquiring into futurity prevailed very generally in England till the beginning of the present century; and sometimes the books of Scripture, and sometimes the poems of Virgil, were consulted for oracular responses. One remarkable instance is that of King Charles I. who being at Oxford during the civil wars, went one day to see the public library, where he was showed, among other books, a Virgil nobly printed and exquisitely bound. The lord Falkland, to divert the king, would have his majesty make a trial of his fortune by the *Sortes Virgilianæ*. Whereupon the king opening the book, the period which happened to come up was this:

At bello audacis populi vexatus, et armis,
Finibus extorris, complexu avulsus Iuli,
Auxilium imploret; videatque indigna suorum
Funera; nec, cum se sub leges pacis iniquæ
Tradiderit, regno aut optata luce fruatur;
Sed cadat ante diem, mediaque inhumatus arena.

Æneid. lib. iv.

Yet let a race, untamed and haughty foes,
His peaceful entrance with dire arms oppose;
Oppressed with numbers in the unequal field,
His men discouraged, and himself expelled,
Let men for succour sue from place to place,
Torn from his subjects, and his son's embrace:
First let him see his friends in battle slain,
And their untimely fate lament in vain;
And when at length the cruel war shall cease,
On hard conditions may he buy his peace.
Nor let him then enjoy supreme command,
But fall untimely by some hostile hand,
And lie unburied on the barren sand.

Lord Falkland observing that the king was concerned at this accident, would likewise try his own fortune in the same manner, hoping he might fall upon some passage that would have no relation to his case, and thereby divert the King's thoughts from any impression which the other might have upon him; but the place he stumbled upon was as much suited to his destiny as the other had been to the king's; being the lamentation of Evander for the untimely death of his son Pallas*: for this lords's eldest son, a young man of an amiable character, had been slain in the first battle of Newbury.

* Æneid. lib. xi.

We have ourselves known several whose devotion has not always been regulated by judgment pursue this method of divination; and have generally observed, that the consequence has been despair or presumption. To such we beg leave to recommend one passage in Scripture which will never disappoint them: *Thou shalt not tempt the Lord thy God.*

Soteria || Sound.

SOTERIA, in antiquity, sacrifices offered to the gods for delivering a person from danger; as also poetical pieces composed for the same purpose.

SOUBISE, a town of France, in the department of Lower Charente, and late territory of Saintonge. It is seated on the river Charente, 22 miles south of Rochelle, in W. Long. 1. 2. N. Lat. 45. 57.

SOUGH, among miners, denotes a passage dug under ground, to convey off waters from mines. See MINE.

SOVEREIGN, in matters of government, is applied to the supreme magistrate or magistrates of an independent government or state; because their authority is only bounded by the laws of God and the laws of the state: such are kings, princes, &c. See PREROGATIVE, &c.

SOVEREIGN Power, or *Sovereignty*, is the power of making laws; for wherever that power resides, all others must conform to it, and be directed by it, whatever appearance the outward form and administration of the government may put on. For it is at any time in the option of the legislature to alter that form and administration by a new edict or rule, and to put the execution of the laws into whatever hands it pleases: and all the other powers of the state must obey the legislative power in the execution of their several functions, or else the constitution is at an end. In the British constitution the law ascribes to the king the attribute of sovereignty: but that is to be understood in a qualified sense, *i. e.* as supreme magistrate, not as sole legislator; as the legislative power is vested in the king, lords, and commons, not in any of the three estates alone. Blackst. Comment.

SOU. See SOL.

SOUL, the principle of perception, memory, intelligence, and volition, in man; which, since the earliest era of philosophy, has furnished questions of difficult investigation, and materials of keen and important controversy (see METAPHYSICS, Part III. chap. ii. iii. iv. v.; and RESURRECTION, n° 42—48.) In the fourth volume of the Memoirs of the Literary and Philosophical Society of Manchester, the reader will find a very valuable paper by Dr Ferrier, proving, by evidence apparently complete, that every part of the brain has been injured without affecting the act of thought. An abridgment of that memoir would weaken its reasoning; which, built on matters of fact and experience, appears to us to have shaken the modern theory of the Materialists from its very foundation.

SOUL of Brutes. See BRUTES.

SOUND, in physics, is a term of which it would be preposterous to offer any definition, as it may almost be said to express a simple idea: But when we consider it as a SENSATION, and still more when we consider it as a PERCEPTION, it may not be improper to give a description of it; because this must involve certain relations of external things, and certain trains of events in the material world, which make it a proper object of philosophical discussion. Sound is that primary information which we get of external things by means of the sense of hearing. This, however, does not explain it: for were we in like manner to describe our sense of hearing, we should find ourselves obliged to say, that it is the faculty by which we preceive sound. Languages are not the invention of philosophers; and we must not expect precision, even in the simplest cases. Our methods of expressing the information given us by our different senses are not similar, as a philosopher, cautiously contriving language, would make them. We have no word to express the primary or generic object of our sense of seeing; for we believe, that even the vulgar consider light as the medium, but not the object. This is certainly the case (how justly we do not say) with the philosopher. On the other hand, the words smell, sound, and perhaps taste, are conceived by most persons as expressing the immediate objects of the senses of smelling, hearing, and tasting. Smell and sound are hastily conceived as separate existences, and as mediums of information and of intercourse with the odoriferous and sounding bodies; and it is only the very cautious philosopher who distinguishes between the smell which he feels and the perfume which fills the room. Those of the ancients, therefore, who taught that sounds were beings wafted through the air, and felt by our ears, should not, even at this day, be considered as aukward observers of nature. It has required the long, patient, and sagacious consideration of the most penetrating geniuses, from Zeno the stoic to Sir Isaac Newton, to discover that what we call sound, the *immediate* external object of the sense of hearing, is nothing but a particular agitation of the parts of surrounding bodies, acting by mechanical impulse on our organs; and that it is not any separate being, nor even a specific quality inherent in any particular thing, by which it can affect the organ, as we suppose with respect to a perfume, but merely a mode of existence competent to every atom of matter. And thus the description which we proposed to give of sound must be description of that state of external contiguous matter which is the *cause* of sound. It is not therefore prefatory to any theory or set of doctrines on this subject; but, on the contrary, is the sum or result of them all.

To discover this state of external body by which, without any farther intermedium of substance or of operation, it affects our sensitive faculties, must be considered as a great step in science. It will show us at least one way by which mind and body may be connected. It is supposed that we have attained this knowledge with respect to sound. Our success, therefore, is a very pleasing gratification to the philosophic mind. It is still more important in another view: it has encouraged us to make similar attempts in other cases, and has supplied us with a fact to which an ingenious mind can easily fancy something analogous in many abstruse operations of nature, and thus it enables us to give some sort of explanation of them. Accordingly this use has been most liberally made of the mechanical theory of sound; and there is now scarcely any phenomenon, either of matter or mind, that has not been explained in a manner somewhat similar. But we are sorry to say that these explanations have done no credit to philosophy. They are, for the most part, strongly marked with that precipitate and self-conceited impatience which has always characterised the investigations conducted solely by ingenious fancy. The consequences of this procedure have been no less fatal to the progress of true knowledge in modern times than in the schools of ancient Greece; and the ethereal philosophers of this age, like the followers of Aristotle of old, have filled ponderous volumes with nonsense and error. It is strange, however, that this should be the effect of a great and a successful step in philosophy: But the fault is in the philosophers, not in the science. Nothing can be more certain than the account which Newton has given of the propagation of a certain class of undulations in an elastic fluid. But this procedure of nature cannot be seen with distinctness and precision by any but well-informed mathematicians. They alone can rest with unshaken confidence on the conclusions legitimately deduced from the Newtonian theorems; and even they can insure success only by treading with the most scrupulous caution the steps of this patient philosopher. But few have done this; and we may venture to say, that not one in ten of those who employ the Newtonian doctrines of elastic undulations for the explanation of other phenomena have taken the trouble, or indeed were able, to go through the steps of the fundamental proposion (Prin. II. 50, &c.) But the *general* results are so plain, and admit of such impressive illustration, that they draw the assent of the most careless reader; and all imagine that they understand the explanation, and perceive the whole procedute of nature. Emboldened therefore by this successful step in philosophy, they, without hesitation, *fancy* similar intermediums in other cases; and as air has been found to be a vehicle for sound, they have supposed that something which they call ether, somehow-resembling air, is the vehicle of vision. Others have proceeded farther, and have held that ether, or another something like air, is the vehicle of sensation in general, from the organ to the brain: nay, we have got a great volume called A THEORY OF MAN, where all our sensations, emotions, affections, thoughts, and purposes or volitions, are said to be so many vibrations of another something equally unseen, gratuitous and incompetent; and, to crown all, this exalted doctrine, when logically prosecuted, must terminate in the discovery of those vibrations which pervade all others, and which constitute what we have been accustomed to venerate by the name DEITY. Such *must* be the termination of this philosophy; and a truly philosophical dissertation on the attributes of the Divine Being *can be nothing else* than an accurate description of these vibrations!

This is not a needless and declamatory rhapsody. If the explanation of sound can be legitimately transferred to those other classes of phenomena, these are certain results; and if so, all the discoveries made by Newton are but the glimmerings of the morning, when compared with this meridian splendor. But if, on the other hand, sound logic forbids us to make this transference of explanation, we must continue to believe, for a little while longer, that mind is something different from vibrating matter, and that no kind of oscillations will constitute infinite wisdom.

It is of immense importance therefore to understand thoroughly this doctrine of sound, that we may see clearly and precisely in what it consists, what are the phenomena of sound that are fully explained, what are the data and the assumptions on which the explanations proceed, and what is the *precise mechanical fact* in which it terminates. For this, or a fact perfectly similar, must terminate every explanation which we derive from this by analogy, however perfect the analogy may be. This *previous* knowledge must be completely possessed by every-ry person who pretends to explain other phenomena in a similar manner. Then, and not till then, he is able to say what classes of phenomena will admit of the explanation: and, when all this is done, his explanation is still an *hypothesis*, till he is able to prove, from other indisputable sources, the existence and agency of the same thing analogous to the elastic fluid, from which all is borrowed.

Such considerations would justify us for considering with great attention the nature of sound. But a work like this will not give room for a full discussion; and we must refer our readers to the writers who treat it more at large. Much curious information may be got from the pains-taking authors of the last century; such as Lord Bacon; Kircher; Mersennus; Casserius in his great work *De Voce et Auditu*; Perrault in his *Dissertation du Bruit*, Mussenbroek in his great System of Natural Philosophy, in 3 vols 4to, and in his *Essais de Physique*; and the writings of the celebrated physiologists of the present age. We also refer to what has been said by us in the article Acoustics.

At present therefore we must content ourselves with giving a short history of the speculations of philosophers on this subject, tracing out the steps by which we have arrived at the knowledge which we have of it. We apprehend this to be of great importance; because it shows us what kind of evidence we have for its truth, and the paths which we must shun if we wish to proceed farther: and we trust that the progress which we have made will appear to be so real, and the object to be attained so alluring to a truly philosophical mind, that men of genius will be incited to exert their utmost efforts to pass the present boundaries of our real progress.

In the infancy of philosophy, sound was held to be a separate existence, something which would be, although no hearing animal existed. This was conceived as wafted through the air to our organ of hearing, which it was supposed to affect in a manner resembling that in which our nostrils are affected when they gives us the sensation of smell. It was one of the Platonic species, fitted for exciting the intellectual species, which is the immediate object of the soul's contemplation.

Yet, even in those early years of science, there were some, and, in particular, the celebrated founder of the stoic school, who held that sound, that is, the cause of sound, was only the particular motion of external gross matter, propagated to the ear, and there producing that agitation of the organ by which the soul is immediately affected with the sensation of sound. Zeno, as quoted by Diogenes Laertius*, says, "Hearing is produced by the air which intervenes between the thing sounding and the ear. The air is agitated in a spherical form and moves off in waves, and falls on the ear, in the same manner as the water in a cistern undulates in circles when a stone has been thrown into it." The ancients were not remarkable for precision, either of conception or argument in their discussions, and they were contented with a general and vague view of things. Some followed the Platonic notions, and many the opinion of Zeno, but without any farther attempts to give a distinct conception of the explanation, or to compare it with experiment.

* B. vii. § 158.

But in later times, during the ardent researches in the last century into the phenomena of nature, this became an interesting subject of inquiry. The invention of the air-pump gave the first opportunity of deciding by experiment whether the elastic undulations of air were the causes of sound: and the trial fully established this point; for a bell rung *in vacuo* gave no sound, and one rung in condensed air gave a very loud one. It was therefore received as a doctrine in general physics that air was the vehicle of sound.

The celebrated Galileo, the parent of mathematical philosophy, discovered the nature of that connection between the lengths of musical cords and the notes which they produced, which had been observed by Pythagoras, or learned by him in his travels in the east, and which he made the foundation of a refined and beautiful science, the theory of music. Galileo showed, that the real connection subsisted between the tones and the vibrations of these cords, and that their different degrees of acuteness corresponded to the different frequency of their vibrations. The very elementary and familiar demonstration which he gave of this connection did not satisfy the curious mathematicians of that inquisitive age, and the mechanical theory of musical cords was prosecuted to a great degree of refinement. In the course of this investigation, it appeared that the cord vibrated in a manner precisely similar to a pendulum vibrating in a cycloid. It must therefore agitate the air contiguous to it in the same manner; and thus there is a particular kind of agitation which the air *can* receive and maintain, which is very interesting.

Sir Isaac Newton took up this question as worthy of his notice; and endeavoured to ascertain with mathematical precision the mechanism of this particular class of undulations, and gave us the fundamental theorems concerning the undulations of elastic fluids, which make the 47, &c. propositions of Book II. of his Principles of Natural Philosophy. They have been (perhaps hastily) considered as giving the fundamental doctrines concerning the propagation of sound. They are therefore given in this work in the article Acoustics; and a variety of facts are narrated in the article Pneumatics to show that such undulations *actually obtain* in the air of our atmosphere, and are accompanied by a set of phenomena of sound which precisely tally or correspond to all the mechanical circumstances of these undulations.

In the mean time, the anatomists and physiologists were busily employed in examining the structure of our organs of hearing. Impressed with the validity of this doctrine of aerial undulations being the causes of sound, their researches were always directed with a view to discover those circumstances in the structure of the ear which rendered it an organ susceptible of agitations from this cause; and they discovered many which appeared as contrivances for making it a drum, on which the aerial undulations from without must make very forcible impulses, so as to produce very sonorous undulations in the air contained in it. These therefore they considered as the *immediate* objects of sensation, or the immediate causes of sound.

But some anatomists saw that this would not be a full account of the matter: for after a drum is agitated, it has done all that it can do; it has produced a noise. But a farther process goes on in our ear: There is behind the membrane, which is the head of this drum, a curious mechanism, which communicates the agitations of the membrane (the only thing acted on by the undulating air) to another chamber of most singular construction, where the auditory nerve is greatly expanded. They conceive, therefore, that the organ called the *drum* does not act as a drum, but in some other way. Indeed it seems bad logic to suppose that it acts as a drum merely by producing a noise. This is in no respect different from the noise produced out of the ear; and if it is to be heard as a noise, we must have another ear by which it may be heard, and this ear must be another *such* drum; and this must have another, and so on for ever. It is like the inaccurate notion that vision is the contemplation of the picture on the retina. These anatomists attended therefore to the structure. Here they observed a prodigious unfolding of the auditory nerve of the ear, which is curiously distributed through every part of this cavity, lining its sides, hung across it like a curtain, and sending off fibres in every direction, so as to leave hardly a point of it unoccupied. They thought the machinery contained in the drum peculiarly fitted for producing undulations of the air contained in this labyrinth, and that by these agitations of the air the contiguous fibres of the auditory nerve are impelled, and that thus we get the sensation of sound.

The cavity intervening between the external air and this inner chamber appeared to these anatomists to have no other use than to allow a very free motion to the *stapes* or little piston that is employed to agitate the air in the labyrinth. This piston condenses on a very small surface the impulse which it receives from a much larger surface, strained by the malleus on the entry of the tympanum, on purpose to receive the gentle agitations of the external air in the outer canal. This membranous surface could not be agitated, unless completely detached from every thing round it; therefore all animals which have this mechanism have it in a cavity containing only air. But they held, that nature had even taken precautions to prevent this cavity from acting as a drum, by making it of such an irregular rambling form; for it is by no means a cavity of a symmetrical shape, like a vessel, but rather resembles the rambling holes and blebs which are often seen in a piece of bread; scattered through the substance of the cranium, and communicating with each other by small passages. The whole of these cavernulæ are lined with a softish membrane, which still farther unfits this cavity for producing sound. This reasoning is specious, but not very conclusive. We might even assert, that this anfractuous form, with narrow passages, is well fitted for producing noise. If we place the ear close to the small hole in the side of a military drum, we shall hear the smallest tap of the drumstick like a violent blow. The lining of the cavernulæ is nervous, and may therefore be strongly affected in the numerous naroow passages between the cells.

While these speculations were going on with respect to the ear of the breathing animals, observations were occasionally made on other animals, such as reptiles, serpents, and fishes, which give undoubted indications of hearing; and many very familiar facts were observed or recollected, where sounds are communicated through or by means of solid bodies, or by water: therefore, without inquiring how or by what kind of mechanism it is brought about, it became a very general belief among physiologists, that all fishes, and perhaps all animals hear, and that water in particular is a vehicle of sound. In 1767 or 1768 the writer of this article, at the suggestion of the late professor of astronomy in the university of Glasgow, made an experiment in a lake in that neighbourhood, by striking a large hand-bell under water, and heard it very distinctly and strongly when his head was plunged in the water at the distance of more than 1200 feet. Many experiments are mentioned by Kircher and others on the communication of sound through solid bodies, such as masts, yards, and other long beams of dry fir, with similar results. Dr Monro has published a particular account of very curious experiments on the propagation of sound through water in his Dissertation on the Physiology of Fishes; so that it now appears that air is by no means the only vehicle of sound.

In 1760 Cotunni published his important discovery, that the labyrinth or inmost cavity of the ear in animals is completely filled with water. This, after some contest, has been completely demonstrated (see in particular Meckel Junior *de Labyrinthi Auris Contentis*, Argentor, 1777), and it seems now to be admitted by all.

This being the case, our notions of the immediate cause of sound must undergo a great revolution, and a new research must be made into the way in which the nerve is affected: for it is not enough that we substitute the undulations of water for those of air in the labyrinth. The well informed mechanician will see at once, that the vivacity of the agitations of the nerve will be greatly increased by this substitution; for if water be perfectly elastic through the whole extent of the undulatory agitation which it receives, its effect will be greater in proportion to its specific gravity: and this is confirmed by an experiment very easily made. Immerse a table-bell in water contained in a large thin glass vessel. Strike it with a hammer. The sound will be heard as if the bell had been immediately struck on the sides of the vessel. The filling of the labyrinth of the ear with water is therefore an additional mark of the wisdom of the Great Artist. But this is not enough for informing us concerning the ultimate mechanical event in the process of hearing. The manner in which the nerve is exposed to these undulations must be totally different from what was formerly imagined. The filaments and membranes, which have been described by former anatomists, must have been found by them in a state quite unlike to their situation and condition in the living animal. Accordingly the most eminent anatomists of Europe seem at present in great uncertainty as to the state of the nerve, and are keenly occupied in observations to this purpose. The descriptions given by Monro, Scarpa, Camper, Comparetti, and others, are full of most curious discoveries, which make almost a total change in our notions of this subject, and will, we hope, be productive of most valuable information.

Scarpa has discovered that the solid cavity called the *labyrinth* contains a threefold expansion of the auditory nerve. One part of it, the cochlea, contains it in a fibrillous state, ramified in a most symmetrical manner through the whole of the *zona mollis* of the *lamina spiralis*, where it anastomoses with another production of it diffused over the general lining of that cavity. Another department of the nerve, also in a fibrous state, is spread over the external surface of a membranaceous bag, Sound.

bag, which nearly fills that part of the vestibule into which the semicircular canals open, and also that orifice which receives the impressions of the stapes. This bag sends off tubular membranaceous ducts, which, in like manner, nearly fill these semicircular canals. A third department of the nerve is spread over the external surface of another membranaceous bag, which lies between the one just now mentioned and the cochlea, but having no communication with either, almost completely filling the remainder of the vestibule. Thus the vestibule and canals seem only a case for protecting this sensitive membranaceous vessel, which is almost, but not altogether, in contact with the osseous case, being separated by a delicate and almost fluid cellular substance. The fibrillous expansion of the nerve is not indiscriminately diffused over the surface of these sacculi, but evidently directed to certain foci, where the fibres are constipated. And this is the last appearance of the fibrous state of the nerve; for when the inside of these sacculi is inspected, no fibres appear, but a pulp (judged to be nervous from its similarity to other pulpy productions of the brain (adhering to the membranaceous coat, and not separable from it by gently washing it. It is more abundant, that is, of greater thickness, opposite to the external fibrous foci. No organical structure could be discovered in this pulp, but it probably is organised; for, besides this adhering pulp, the water in the sacculi was observed to be clammy or mucous; so that in all probability the vascular or fibrous state of the nerve is succeeded by an uninterrupted production (perhaps columnar like basalt, though not cohering); and this at last ends in simple dissemination, symmetrical however, where water and nerve are alternate in every direction.

To these observations of Scarpa, Comparetti adds the curious circumstances of another and regular tympanum in the foramen rotundum, the cylindric cavity of which is inclosed at both ends by a fine membrane. The membrane which separates it from the cochlea appears to be in a state of variable tension, being drawn up to an umbo by a cartilaginous speck in its middle, which he thinks adheres to the lamina spiralis, and thus serves to strain the drumhead, as the malleus strains the great membrane known to all.

These are most important observations, and must greatly excite the curiosity of a truly philosophical mind, and deserve the most careful inquiry into their justness. If these are accurate descriptions of the organ, they seem to conduct us farther into the secrets of nature than any thing yet known.

We think that they promise to give us the greatest step yet made in physiology, viz. to show us the last mechanical fact which occurs in the long train interposed between the external body and the incitement of our sensitive system. But there is, as yet, great and essential differences in the description given by those celebrated naturalists. It cannot be otherwise. The containing labyrinth can be laid open to our view in no other way than by destroying it; and its most delicate contents are the first sufferers in the search. They are found in very different situations and conditions by different anatomists, according to their address or their good fortune. Add to this that the natural varieties are very considerable. Faithful descriptions must therefore give very different notions of the ultimate action and reaction between the unorganised matter in the labyrinth and the ultimate expansion of the auditory nerve.

We must therefore wait with patience. Since this Work of ours was begun, the progress which has been made in many parts of natural science has been great and wonderful; and perhaps before it be completed, we may be furnished with such a collection of facts respecting the structure and the contents of the organ of hearing, as might enable us to give a juster theory of sound than is yet to be found in the writings of philosophers. There seems to be no abatement of ardour in the researches of the physiologists; and they will not remain long ignorant of the truth or mistake in the accounts given by Scarpa and Comparetti. Should the result of their inquiries be what we expect, we should be glad of a proper opportunity of laying it before our readers, together with some disquisition on the nature of hearing. A collection of accurate observations on the structure of the ear would give us principles on which to proceed in explaining the various methods of producing external sounds. The nature of *continued sounds* might then be treated of, and would appear, we believe, very different from what it is commonly supposed. Under this head animal voices might be particularly considered, and the elements of human speech properly ascertained. When the production of continued sounds is once shown to be a thing regulated by principle, it may be systematically treated, and this principle may be considered as combined with every mechanical state of body that may be pointed out. This will suggest to us methods of producing sound which have not yet been thought of, and may therefore give us sounds with which we are unacquainted. Such an acquisition is not to be despised nor rejected. The bountiful Author of our being and of all our faculties has made it an object of most enchanting relish to the human mind. The Greeks, the most cultivated people who have ever figured on the stage of life, enjoyed the pleasures of music with rapture. Even the poor negro, after toiling a whole day beneath the tropical sun, will go ten miles in the dark to dance all night to the simple music of the balafoe, and return without sleep to his next day's toil. The penetrating eye of the anatomist has discovered in the human larynx an apparatus evidently contrived for tempering the great movements of the glottis, so as to enable us to produce the intended note with the utmost precision. There is no doubt therefore that the consummate Artist has not thought it unworthy of his attention. We ought therefore to receive with thankfulness this present from our Maker—this *laborum dulce lenimen*; and it is surely worthy the attention of the philosopher to add to this innocent elegance of life. This, however, is not the time to enter upon the subject. From the jarring observations which have yet been made, we could only amuse the curious reader by holding up to his view a specious theory; and we are not so desirous of filling our Work with what is called *original matter*, as to attempt the attainment of that end by substituting fiction for fact and hypothesis for science.

Sound, in geography, denotes in general any strait or inlet of the sea between two headlands. It is given by way of eminence to the strait between Sweden and Denmark,

Denmark, joining the German ocean to the Baltic, being about three miles over. See DENMARK, n° 32. and ELSINORE.

SOUNDING, the operation of trying the depth of the sea, and the nature of the bottom, by means of a plummet sunk from a ship to the bottom.

There are two plummets used for this purpose in navigation; one of which is called the *hand lead*, weighing about 8 or 9 pounds; and the other the *deep sea-lead*, which weighs from 25 to 30 pounds; and both are shaped like the frustum of a cone or pyramid. The former is used in shallow waters, and the latter at a great distance from the shore; particularly on approaching the land after a sea-voyage. Accordingly the lines employed for this purpose are called the *deep-sea lead-line*, and the *hand lead-line*.

The hand lead-line, which is usually 20 fathoms in length, is marked at every two or three fathoms; so that the depth of the water may be ascertained either in the day or night. At the depth of two and three fathoms, there are marks of black leather; at 5 fathoms, there is a white rag; at 7, a red rag; at 10, black leather; at 13, black leather; at 15, a white rag; and at 17, a red ditto.

Sounding with the hand lead, which is called *heaving the lead* by seamen, it generally performed by a man who stands in the main chains to windward. Having the line quite ready to run out without interruption, he holds it nearly at the distance of a fathom from the plummet; and having swung the latter backwards and forwards three of four times, in order to acquire the greater velocity, he swings it round his head, and thence as far forward as is necessary; so that, by the lead's sinking whilst the ship advances, the line may be almost perpendicular when it reaches the bottom. The person sounding then proclaims the depth of the water in a kind of song resembling the cries of hawkers in a city. Thus if the mark of five fathoms is close to the surface of the water, he calls, 'By the mark five!' and as there is no mark at four, six, eight, &c. he estimates those numbers, and calls, 'By the dip four,' &c. If he judges it to be a quarter or an half more than any particular number, he calls, 'And a quarter five! and a half four,' &c. If he conceives the depth to be three quarters more than a particular number, he calls it a quarter less than the next: thus, at four fathoms and three fourths he calls 'A quarter less five!' and so on.

The deep sea-lead is marked with two knots at 20 fathoms, three at 30, four at 40, and so on to the end. It is also marked with a single knot in the middle of each interval, as at 25, 35, 45 fathoms, &c. To use this lead more effectually at sea, or in deep water on the sea-coast, it is usual previously to bring to the ship, in order to retard her course: the lead is then thrown as far as possible from the ship on the line of her drift, so that, as it sinks, the ship drives more perpendicularly over it. The pilot, feeling the lead strike the bottom, readily discovers the depth of the water by the mark on the line nearest its surface. The bottom of the lead being also well rubbed over with tallow, retains the distinguishing marks of the bottom, as shells, ooze, gravel, &c. which naturally adhere to it.

The depth of the water, and the nature of the ground, which is called the *soundings*, are carefully marked in the log-book, as well to determine the distance of the place from the shore, as to correct the observations of former pilots.

SOUP, a strong decoction of flesh or other substances.

Portable or dry soup is a kind of cake formed by boiling the gelatinous parts of animal substances till the watery parts are evaporated. This species of soup is chiefly used at sea, and has been found of great advantage. The following receipt will show how it is prepared.

Chaptal's Chemistry.

Of calves feet take 4; leg of beef 12 lbs.; knuckle of veal 3 lbs.; and leg of mutton 10 lbs. These are to be boiled in a sufficient quantity of water, and the scum taken off as usual; after which the soup is to be separated from the meat by straining and pressure. The meat is then to be boiled a second time in other water; and the two decoctions, being added together, must be left to cool, in order that the fat may be exactly separated. The soup must then be clarified with five or six whites of eggs, and a sufficient quantity of common salt added. The liquor is then strained through flannel, and evaporated on the water-bath to the consistence of a very thick paste; after which it is spread rather thin upon a smooth stone, then cut into cakes, and lastly dried in a stove until it is become brittle: these cakes are kept in well closed bottles. The same process may be used to make a portable soup of the flesh of poultry; and aromatic herbs may be used as a seasoning, if thought proper.

These tablets or cakes may be kept four or five years. When intended to be used, the quantity of half an ounce is put into a large glass of boiling water, which is to be covered, and set upon hot ashes for a quarter of an hour, or until the whole is entirely dissolved. It forms an excellent soup, and requires no addition but a small quantity of salt.

SOUR-CROUTE. See CROUTE.

Sour-Gourd or *African Calabash-tree*. See ADANSONIA.

SOUTH (Dr Robert), an eminent divine, was the son of Mr William South a merchant of London, and was born at Hackney near that city in 1633. He studied at Westminster school, and afterwards in Christ-Church College, Oxford. In 1654, he wrote a copy of Latin verses to congratulate Cromwell upon the peace concluded with the Dutch; and the next year a Latin poem, intitled *Musica Incantans*. In 1660 he was elected public orator of the university; and the next year became domestic chaplain to Edward earl of Clarendon, lord-high-chancellor of England. In 1663 he was installed prebendary of Westminster, admitted to the degree of Doctor of divinity, and had a sinecure bestowed on him in Wales by his patron the earl of Clarendon; after whose retirement into France in 1667 he became chaplain to the duke of York. In 1670 he was installed canon of Christ-Church in Oxford; and in 1676 attended as chaplain to Laurence Hyde, Esq; ambassador extraordinary to the king of Poland. In 1678 he was presented to the rectory of Islip in Oxfordshire; and in 1680 rebuilt the chancel of that church, as he afterwards did the rectory-house belonging to it. After the revolution he took the oath of allegiance to king William and queen Mary, though he excused himself from accepting a great dignity in the Church vacated by the personal refusal of that oath. His health began to de-

South.

cline several years before his death, which happened in 1716. He was interred in Westminster Abbey, where a monument is erected to his memory. He published, 1. Animadversions on Dr Sherlock's Vindication of the Holy and Ever Blessed Trinity. 2. A Defence of his Animadversions. 3. Sermons, 8 vols 8vo. And after his decease were published his *Opera Posthuma Latina*, and his posthumous English works. Dr South was remarkable for his wit, which abounds in all his writings, and particularly in his sermons; but at the same time they equally abound in ill-humour, spleen, and satire. He was remarkable for being a time-server. During the life of Cromwell he was a staunch Presbyterian, and then railed against the Independents: at the Restoration he exerted his pulpit-eloquence against the Presbyterians; and in the reign of Queen Anne, was a warm advocate for Sacheverel.

South, one of the four cardinal points from which the winds blow.

South Sea, or *Pacific Ocean*, is that vast body of water interposed between Asia and America. It does not however, strictly speaking, reach quite to the continent of Asia, excepting to the northward of the peninsula of Malacca: for the water interposed between the eastern coast of Africa and the peninsula just mentioned has the name of the *Indian Ocean*. The South Sea then is bounded on one side by the western coast of America, through its whole extent, from the unknown regions in the north to the straits of Magellan and Terra del Fuego, where it communicates with the southern part of the Atlantic. On the other side, it is bounded by the coast of Asia, from the northern promontory of Tschukotskoi Noss, to the peninsula of Malacca already mentioned. Thence it is bounded to the southward by the northern coast of Borneo, Celebes, Macassar, New Guinea, New Holland, and the other islands in that quarter, which divide it from the Indian Ocean. Then, washing the eastern coast of the great island of New Holland, it communicates with that vast body of water encompassing the whole southern part of the globe, and which has the general name of the *Southern Ocean* all round. Thus does this vast ocean occupy almost the semicircumference of the globe, extending almost from one pole to the other, and about the equatorial parts extending almost 180° in longitude, or 12,500 of our miles.

The northern parts of the Pacific Ocean are entirely destitute of land; not a single island having yet been discovered in it from the latitude of 40° north and upwards, excepting such as are very near the coast either of Asia or America; but in the southern part there are a great number.

Till very lately the South Sea was in a great measure unknown. From the great extent of ice which covers the southern part of the globe, it was imagined that much more land existed there than in the northern regions: but that this could not be justly inferred merely from that circumstance, is plain from what has been advanced under the article America, n° 3—24; and the southern continent, long known by the name of *Terra Australis*, has eluded the search of the most expert navigators sent out from Britain and France by royal authority. See Terra Australis.

South Sea Company. See Company.

Southampton ‖ Sozomenus.

SOUTHAMPTON, a sea-port town of Hampshire in England. It is commodiously seated on an arm of the sea; is a place of good trade, and well inhabited. It is surrounded by walls and several watch-towers, and had a strong castle to defend the harbour, now in ruins. It is a corporation and a county of itself, with the title of an earldom, and sends two members to parliament. W. Long. 1. 26. N. Lat. 50. 55.

SOUTHERN (Thomas), an eminent dramatic writer, was born at Dublin in 1660, and received his education in the university there. He came young to London to study law; but instead of that devoted himself to poetry and the writing of plays. His Persian Prince, or Loyal Brother, was introduced in 1682, when the Tory interest was triumphant in England; and the character of the loyal brother being intended to compliment James duke of York, he rewarded the author when he came to the throne with a commission in the army. On the Revolution taking place, he retired to his studies, and wrote several plays, from which he is supposed to have derived a very handsome subsistence, being the first who raised the advantage of play-writing to a second and third night. The most finished of all his plays is Oroonoko, or the Royal Slave, which is built on a true story related in one of Mrs Behn's novels. Mr Southern died in 1746, in the 86th year of his age; the latter part of which he spent in a peaceful serenity, having, by his commission as a soldier, and the profits of his dramatic works, acquired a handsome fortune; and being an exact economist, he improved what fortune he gained to the best advantage. He enjoyed the longest life of all our poets; and died the richest of them, a very few excepted. His plays are printed in two vols 12mo.

Southern Continent. See America, n° 3—24. and *Terra Australis*.

SOUTHERNWOOD, in botany. See Artemisia.

SOY. See Dolichos.

SOZOMENUS (Hermias), an ecclesiastical historian of the 5th century, was born in Bethelia, a town of Palestine. He was educated for the law, and became a pleader at Constantinople. He wrote an Abridgment of Ecclesiastical History, in two books, from the ascension of our Saviour to the year 323. This compendium is lost; but a continuation of it in nine books, written at greater length, down to the year 440, is still extant. He seems to have copied Socrates, who wrote a history of the same period. The style of Sozomenus is perhaps more elegant; but in other respects he falls far short of that writer, displaying throughout his whole book an amazing credulity and a superstitious attachment to monks and the monastic life. The

Spa. best edition of Sozomenus is that of Robert Stephens in 1544. He has been translated and published by Valesius, and republished with additional notes by Reading at London, 1720, in 3 vols folio.

SPA, a town of Germany, in the circle of Westphalia and bishopric of Liege, famous for its mineral waters, lies in E. Long. 5. 50. N. Lat. 50. 30. about 21 miles south-east from Liege, and 7 south-west from Lomburg. It is situated at one end of a deep valley on the banks of a small rivulet, and is surrounded on all sides by high mountains. The sides of these mountains next to Spa are rude and uncultivated, presenting a rugged appearance as if shattered by the convulsions of earthquakes; but as they are strewed with tall oaks and abundance of shrubs, the country around forms a wild, romantic, and beautiful landscape. The access to the town is very beautiful. The road winds over the mountains till it descends to their bottom, when it runs along a smooth valley for a mile or a mile and a half.

The town consists of four streets in form of a cross, and contains about 400 inhabitants. Spa has no wealth to boast of. It can scarcely furnish the necessaries of life to its own inhabitants during the winter, and almost all the luxuries which are requisite for the great concourse of affluent visitors during the summer are carried from Liege by women. Its only source of wealth is its mineral waters. No sooner does the warm season commence, than crowds of valetudinarians arrive, as well as many other persons who are attracted solely by the love of amusement, and some from less honourable motives. The inhabitants, who spend seven or eight months of the year without seeing the face of a stranger, wait for the return of this period with impatience. The welcome sound of the carriages brings multitudes from the town, either to gratify their curiosity, or to offer their services in the hopes of securing your employment while you remain at Spa. Immediately after your arrival your name and designation is added to the printed list of the annual visitors; for which you pay a stated sum to the bookseller, who has a patent for this purpose from the prince bishop of Liege. This list not only enables one to know at a glance whether any friends or acquaintance are residing there, but also to distinguish persons of rank and fashion from adventurers, who seldom have the effrontery to insert their names.

There are two different ways of accommodating the visitors at Spa with lodging and necessaries. People may either lodge at an hotel, where every thing is furnished them in a splendid and expensive style; or they may take up their residence in private lodgings, from which they may send for provisions to a cook's shop.

Among the people who visit Spa, there are many persons of the first rank and fashion in Europe. Perhaps indeed there is no place in Europe to which so many kings and princes resort; but it is also visited by many self-created nobility, who, under the titles of counts, barons, marquises, and knights, contrive by their address and artifices, to prey upon the rich and unexperienced.

The manners established at Spa are conducive both to health and amusement. Every body rises early in the morning, at six o'clock or before it, when a great many horses stand ready saddled for those who choose to drink the Sauveniere or Geronstere waters at a little distance from Spa. After this healthy exercise a part of the company generally breakfast together at Vauxhall, a magnificent and spacious building. At this place a number of card-tables are opened every forenoon, round which many persons assemble and play for stakes to a very considerable amount. A ball too is generally held once a week at Vauxhall, besides two balls at the assembly rooms near the Pouhon in the middle of the town.

The most remarkable waters at Spa are, 1. The Pouhon, situated in the middle of the town; 2. The Sauveniere, a mile and a half east from it; 3. Groisbeck, near to the Sauveniere; 4. Tonnelet, situated a little to the left of the road which leads to the Sauveniere; 5. Geronstere, two miles south from Spa; 6. Wartroz, near to the Tonnelet; 7. Sarts or Nivefet, in the district of Sarts; 8. Chevron or Bru, in the principality of Slavelot; 9. Couve; 10. Beverse; 11. Sige; 12. Geremont. These four last are near Malmedy.

Dr Brownrigg was the first person who discovered that fixed air, or, as it is now generally called, *carbonic acid gas*, forms a principal ingredient in the composition of the Spa waters, and actually separated a quantity of this elastic fluid, by exposing it to different degrees of heat from 110° to 170° of Fahrenheit. From 20 ounces 7 drams and 14 grains apothecaries weight of the Pouhon water, he obtained 8 ounces 2 drams and 50 grains. Since June 1765, when Dr Brownrigg read a paper on this subject before the Royal Society of London, the waters of Spa have been often analysed, but perhaps by none with more accuracy than by Dr Ash, who published a book on the chemical and medicinal properties of these waters in 1788. We shall present his analysis of the five principal springs in the following table.

Fountains.	Quantity of Water.	Ounce measures of Gas.	Solid contents.	Aerated Lime.	Aerated Magnesia.	Aerated Mineral Alkali.	Aerated Iron.	Selenite.	Aerated Vegetab. Alkali.
	Ounces.		Grains.						
Pouhon	33	35.75	16.25	2,75	9.50	2.25	1.75	—	—
Geronstere	32.75	24.75	5.50	2.50	—	1.75	0.75	0.50	—
Sauveniere	32.50	33.50	3.75	1.50	—	0.75	0.50	—	1.
Groisbeck	32.25	35.50	5.25	1.50	—	1.	0.75	—	2.
Tonnelet	32.	40.75	2.00	0.25	—	0.75	1.	—	—

Spa.

The Pouhon ſpring riſes from the hill to the north of Spa, which conſiſts of argillaceous ſchiſtus and ferrugineous ſlate. The other fountains riſe from the ſurrounding hills to the ſouth-eaſt, ſouth, weſt, and north-weſt of the town; and this ridge of mountains is formed of calcareous earths mixed with ſiliceous ſubſtances. The ſurface of the mountains is covered with woods, interſperſed with large boggy ſwamps filled with mud and water. The Pouhon is conſidered as the principal ſpring at Spa, being impregnated with a greater quantity of iron than any of the reſt, and containing more fixed air than any except the Tonnelet. It is from this ſpring that the Spa water for exportation is bottled; for which the demand is ſo great, that, according to the beſt information which Mr. Thickneſſe could obtain, the quantity exported amounts to 200,000 or 250,000 bottles annually. This exported water is inferior in its virtue to that which is drunk on the ſpot; for the veſſels into which it is collected are injudiciouſly expoſed to the ſun, rain, wind, and duſt, for ſeveral hours before they are corked, by which means a conſiderable part of its volatile ingredients muſt be evaporated; for it has been found by experiment, that by expoſing it to a gentle heat, air-bubbles aſcend in great numbers. It is in its greateſt perfection when collected in cold dry weather; it is then pellucid, colourleſs, and without ſmell, and almoſt as light as diſtilled water. It varies in its heat from 52° or 53° to 67° of Fahrenheit's thermometer.

Thickneſſe's Journey through the Pais Bas.

The Geronſtere is a much weaker chalybeate water than the Pouhon; and as it is exceedingly nauſeous, and taſtes and ſmells like rotten eggs, it certainly contains ſome hepatic gas. This is a circumſtance which Dr Aſh ſeems not to have attended to ſufficiently. The Sauveniere water alſo, when newly taken from the well, ſmells a little of ſulphur. The Groiſbeck contains more alkali, and almoſt as much gas as the Pouhon, and has been celebrated for its good effects in the cauſe of calculous concretions. The Tonnelet contains more gas than any of the reſt. So ſmall is the quantity of any foſſil body held in ſuſpenſion by the aerial acid in it, and ſo volatile is the gas, that it begins to paſs off very rapidly the moment it is taken out of the well, and in a ſhort time is entirely gone. Dr Aſh informs us, that in the neighbourhood of this well, the cellars, on any approaching change of weather, are found to contain much fixed air; and the beſt prognoſtic which they have of rain is the averſion which cats ſhow to be carried into theſe cellars.

The Spa waters are diuretic, and ſometimes purgative. They exhilarate the ſpirits with an influence much more benign than wine or ſpirituous liquors, and they are more cooling, and allay thirſt more effectually than common water. They are found beneficial in caſes of weakneſs and relaxation, either partial or univerſal; in nervous diſorders; in obſtructions of the liver and ſpleen; in caſes where the blood is too thin and putreſcent; in caſes of exceſſive diſcharges proceeding from weakneſs; in the gravel and ſtone; and in moſt caſes where a ſtrengthening remedy is wanted. But they are hurtful in confirmed obſtructions attended with fever, where there is no free outlet to the matter, as in ulcerations of the lungs. They are alſo injurious to bilious and plethoric conſtitutions, when uſed before the body is cooled by proper evacuations.

Space ‖ Spain.

SPACE. See Metaphysics, Part II. Chap. iv.

Space, in geometry, denotes the area of any figure, or that which fills the interval or diſtance between the lines that terminate it.

SPADIX, in botany, anciently ſignified the receptacle of the palms. It is now uſed to expreſs every flower-ſtalk that is protruded out of a ſpatha or ſheath.

The ſpadix of the palms is branched; that of all other plants ſimple. This laſt caſe admits of ſome variety: in calla, dracontium, and pothos, the florets cover it on all ſides; in arum, they are diſpoſed on the lower part only; and in zoſtera on one ſide.

SPAGIRIC art, a name given by authors to that ſpecies of chemiſtry which works on metals, and is employed in the ſearch of the philoſopher's ſtone.

SPAHIS, horſemen in the Ottoman army, chiefly raiſed in Aſia. The great ſtrength of the grand ſeignior's army conſiſts in the janiſaries, who are the foot; and the ſpahis, who are the horſe.

SPAIN, a country of Europe, famous both in ancient and modern hiſtory, ſituated in that large peninſula which forms the ſouth-weſtern part of Europe. It is bounded on the ſouth and eaſt by the Mediterranean ſea and ſtraits of Gibraltar, on the north and weſt by the Bay of Biſcay and Atlantic Ocean, on the ſouth-weſt by Portugal, and on the north-eaſt by the Pyrenees.

1 Different names of Spain.

The moſt ancient name of Spain was *Iberia*, ſuppoſed by ſome to be derived from the *Iberians*, a people inhabiting Mount Caucaſus, a colony of whom ſettled in this country. Others derive it from the Phenician word *Ebra* or *Ibra*, ſignifying a paſſage or limit. By the Romans it was called *Spania* or *Hiſpania*, from the Phenician name *Sphanija*; and this again from *ſhaphan*, a Phenician word ſignifying a rabbit, becauſe the weſtern part of Spain abounded with thoſe animals.

Spain, as well as the reſt of Europe, was probably peopled by the Celtes; but the Spaniſh hiſtorians derive the origin of their nation from Tubal the fifth ſon of Japhet, aſſerting that Spain had been a monarchy for 2226 years before the coming of the Celtes into it. Till the coming of the Carthaginians into Spain, however, nothing certain can be affirmed of the Spaniards; and this happened not long before the commencement of the firſt Punic war. Their ſucceſs in reducing the country, and their final expulſion by the Romans, has already been related under the article Rome and Carthage; we have here, therefore, only, to take notice of the ſtate of Spain under the Roman government, until the Romans were in their turn expelled by the northern barbarians.

2 Conqueſts of the Carthaginians in Spain.

At the time of the Roman conqueſt, Spain, though prodigious quantities of ſilver had been carried out of it by the Carthaginians and Tyrians, was yet a very rich country. In the moſt ancient times, indeed, its riches are ſaid to have exceeded what is related of the moſt wealthy country in America. Ariſtotle aſſures us, that when the Phenicians firſt arrived in Spain, they exchanged their naval commodities for ſuch immenſe quantities of ſilver, that their ſhips could neither contain nor ſuſtain its load, though they uſed it for ballaſt, and made their anchors and other implements of ſilver. When the Carthaginians firſt came to Spain, they found the quantity of ſilver nothing leſſened, ſince the inhabitants at that time made all their utenſils, and even

3 Exceeding great riches of the country

mangers, of that precious metal. In the time of the Romans this amazing plenty was very much diminished; however, their gleanings were by no means despicable, since in the space of nine years they carried off 111,542 pounds of silver, and 4095 of gold, besides an immense quantity of coin and other things of value. The Spaniards were always remarkable for their bravery, and some of Hannibal's best troops were brought from thence. But as the Romans penetrated farther into the country than the Carthaginians had done, they met with nations whose love of liberty was equal to their valour, and whom the whole strength of their empire was scarce able to subdue. Of these the most formidable were the Numatines, Cantabrians, and Asturians.

4
Viriathus opposes the Roman power with success.

In the time of the third Punic war, one Viriathus, a celebrated hunter, and afterwards the captain of a gang of banditti, took upon him the command of some nations who had been in alliance with Carthage, and ventured to oppose the Roman power in that part of Spain called *Lusitania*, now Portugal. The prætor, named *Vetilius*, who commanded in those parts, marched against him with 10,000 men; but was defeated and killed, with the loss of 4000 of his troops. The Romans immediately dispatched another prætor mith 10,000 foot and 1300 horse: but Viriathus having first cut off a detachment of 4000 of them, engaged the rest in a pitched battle; and having entirely defeated them, reduced great part of the country. Another prætor, who was sent with a new army, met with the same fate; so that, after the destruction of Carthage, the Romans thought proper to send a consul named *Quintus Fabius*, who defeated the Lusitanians in several battles, and regained two important places which had long been in the hands of the rebels. After the expiration of Fabius's consulate, Viriathus continued the war with his usual success, till the senate thought proper to send against him the consul Q. Cæcilius Metellus, an officer of great valour and experience.

5
Is reduced to great straits by Metellus.

With him Viriathus did not choose to venture a pitched battle, but contented himself with acting on the defensive; in consequence of which the Romans recovered a great many cities, and the whole of Tarraconian Spain was obliged to submit to their yoke. The other consul, named *Servilianus*, did not meet with the same success; his army was defeated in the field and his camp was nearly taken by Viriathus. Notwithstanding the good fortune of Metellus, however, he could not withstand the intrigues of his countrymen against him, and he was not allowed to finish the war he had begun with so much success. In resentment for this he took all imaginable pains to weaken the army under his command: he disbandoned the flower of his troops, exhausted the magazines, let the elephants die, broke in pieces the arrows which had been provided for the Cretan archers, and threw them into a river. Yet, after all, the army which he gave up to his successor Q. Pompeius, consisting of 30,000 foot and 2000 horse, was sufficient to have crushed Viriathus if the general had known how to use it. But, instead of opposing Viriathus with success, the imprudent consul procured much more formidable enemies.

6
War between the Romans and Numantines.

The Termantines and Numantines, who had hitherto kept themselves independent, offered very advantageous terms of peace and alliance with Rome; but Pompeius insisted upon their delivering up their arms. Upon this, war was immediately commenced. The consul with great confidence invested Numantia; but being repulsed with considerable loss, he sat down before Termantia, where he was attended with still worse success. The very first day, the Termantines killed 700 of his legionaries; took a great convoy which was coming to the Roman camp; and having defeated a considerable body of their horse, pushed them from post to post till they came to the edge of a precipice, where they all tumbled down, and were dashed to pieces. In the mean time Servilian, who had been continued in his command with the title of *proconsul*, managed matters so ill, that Viriathus surrounded him on all sides, and obliged him to sue for peace. The terms offered to the Romans were very moderate; being only that Viriathus should keep the country he at that time possessed, and the Romans remain masters of all the rest. This peace the proconsul was very glad to sign, and afterwards got it signed by the senate and people of Rome.

7
The Romans surrounded on all sides, and forced to conclude a peace with Viriathus.

The next year Q. Pompeius was continued in his command against the Numantines in Farther Spain, while Q. Servilius Cæpio, the new consul, had for his province Hither Spain, where Viriathus had established his new state. Pompeius undertook to reduce Numantia by turning aside the stream of the Durius, now the Douro, by which it was supplied with water; but, in attempting this, such numbers of his men were cut off, that, finding himself unable to contend with the enemy, he was glad to make peace with them on much worse terms than they had offered of their own accord. The peace, however, was ratified at Rome; but in the mean time Cæpio, desirous of showing his prowess against the renowned Viriathus, prevailed upon the Romans to declare war against him without any provocation. As Cæpio commanded an army greatly superior to the Lusitanians, Viriathus thought proper to sue for peace; but finding that Cæpio would be satisfied with nothing less than a surrender at discretion, he resolved to stand his ground. In the mean time, the latter having bribed some of the intimate companions of Viriathus to murder him in his sleep, he by that infamous method put an end to a war which had lasted 14 years, very little to the honour of the republic.

8
Viriathus treacherously murdered.

9
The Romans defeated by the Numantines.

After the death of Viriathus, the Romans with like treachery ordered their new consul Popilius to break the treaty with the Numantines. His infamous conduct met with the reward it deserved; the Numantines sallying out, put the whole Roman army to flight with such slaughter, that they were in no condition to act during the whole campaign. Mancinus, who succeeded Popilius, met with still worse success; his great army, consisting of 30,000 men, was utterly defeated by 4000 Numantines, and 20,000 of them killed in the pursuit. The remaining 10,000, with their general, were pent up by the Numantines in such a manner that they could neither advance nor retreat, and would certainly have been all put to the sword or made prisoners, had not the Numantines, with a generosity which their enemies never possessed, offered to let them depart upon condition that a treaty should be concluded with them upon very moderate terms. This the consul very willingly promised, but found himself unable to perform. On the contrary, the people, not satisfied with declaring his treaty null and void, ordered him to be delivered up to the Numantines. The latter refused to accept him, unless

Plate CCCCLXXIII

Spain.

less he had along with him the 10,000 men whom they had relieved as above related. At last, after the consul had remained a whole day before the city, his successor Furius, thinking this a sufficient recompense to the Numantines for breaking the treaty, ordered him to be received again into the camp. However, Furius did not choose to engage with such a desperate and resolute enemy as the Numantines had showed themselves; and the war with them was discontinued till the year 133 B. C. when Scipio Æmilianus, the destroyer of Carthage, was sent against them. Against this renowned commander the Numantines with all their valour were not able to cope. Scipio, having with the utmost care introduced strict discipline among his troops, and reformed the abuses which his predecessors had suffered in their armies, by degrees brought the Romans to face their enemies, which at his arrival they had absolutely refused to do. Having then ravaged all the country round about the town, it was soon blocked up on all sides, and the inhabitants began to feel the want of provisions. At last they resolved to make one desperate attempt for their liberty, and either to break through their enemies, or perish in the attempt. With this view they marched out in good order by two gates, and fell upon the works of the Romans with the utmost fury. The Romans, unable to stand this desperate shock, were on the point of yielding; but Scipio, hastening to the places attacked, with no fewer than 20,000 men, the unhappy Numantines were at last driven into the city, where they sustained for a little longer the miseries of famine. Finding at last, however, that it was altogether impossible to hold out, it was resolved by the majority to submit to the pleasure of the Roman commander. But this resolution was not universally approved. Many shut themselves up in their houses, and died of hunger, while even those who had agreed to surrender repented their offer, and setting fire to their houses, perished in the flames with their wives and children, so that not a single Numantine was left alive to grace the triumph of the conqueror of Carthage.

9 Scipio Aemilianus sent against them.

10 Miserable end of the people.

After the destruction of Numantia the whole of Spain submitted to the Roman yoke; and nothing remarkable happened till the times of the Cimbri, when a prætorian army was cut off in Spain by the Lusitanians. From this time nothing remarkable occurs in the history of Spain till the civil war between Marius and Sylla. The latter having crushed the Marian faction, as related under the article Rome, proscribed all those that had sided against him whom he could not immediately destroy. Among these was Sertorius, a man of consummate valour and experience in war. He had by Marius been appointed prætor of Spain; and upon the overthrow of Marius, retired to that province. Sylla no sooner heard of his arrival in that country, than he sent thither one Caius Annius with a powerful army to drive him out. As Sertorius had but few troops along with him, he dispatched one Julius Salinator with a body of 6000 men to guard the passes of the Pyrenees, and to prevent Annius from entering the country. But Salinator having been treacherously murdered by assassins hired by Annius for that purpose, he no longer met with any obstacle; and Sertorius was obliged to embark for the coast of Africa with 3000 men, being all he had now remaining. With these he landed in Mauritania; but as his men were straggling carelessly about, great numbers of them were cut off by the Barbarians. This new misfortune obliged Sertorius to re-embark for Spain; but finding the whole coast lined with the troops of Annius, he put to sea again, not knowing what course to steer. In this new voyage he met with a small fleet of Cilician pirates; and having prevailed with them to join him, he made a descent on the coast of Yvica, overpowered the garrison left there by Annius, and gained a considerable booty. On the news of this victory Annius set sail for Yvica, with a considerable squadron, having 5000 land forces on board. Sertorius, not intimidated by the superiority of the enemy, prepared to give them battle. But a violent storm arising, most of the ships were driven on shore and dashed to pieces, Sertorius himself with great difficulty escaping with the small remains of his fleet. For some time he continued in great danger, being prevented from putting to sea by the fury of the waves, and from landing by the enemy; at last, the storm abating, he passed the straits of Gades, now Gibraltar, and landed near the mouth of the river Bætis. Here he met with some seamen newly arrived from the Atlantic or Fortunate Islands; and was so taken with the account which they gave him of those happy regions, that he resolved to retire thither to spend the rest of his life in quiet and happiness. But having communicated this design to the Cilician pirates, they immediately abandoned him, and set sail for Africa, with an intention to assist one of the barbarous kings against his subjects who had rebelled. Upon this Sertorius sailed thither also, but took the opposite side; and having defeated the king named *Ascalis*, obliged him to shut himself up in the city of Tingis, now Tangier, which he closely besieged. But in the mean time Pacianus, who had been sent by Sylla to assist the king, advanced with a considerable army against Sertorius. Upon this the latter, leaving part of his forces before the city, marched with the rest to meet Pacianus, whose army, though greatly superior to his own in number, he entirely defeated; killed the general, and took all his forces prisoners.—The fame of this victory soon reached Spain; and the Lusitanians, being threatened with a new war from Annius, invited Sertorius to head their armies. With this request he very readily complied, and soon became very formidable to the Romans. Titus Didius, governor of that part of Spain called *Bætica*, first entered the lists with him; but he being defeated, Sylla next dispatched Metellus, reckoned one of the best commanders in Rome, to stop the progress of this new enemy. But Metellus, notwithstanding all his experience, knew not how to act against Sertorius, who was continually changing his station, putting his army into new forms, and contriving new stratagems. On his first arrival he sent for L. Domitius, then prætor of Hither Spain, to his assistance; but Sertorius being informed of his march, detached Hirtuleius, or Herculeius, his quæstor, against him, who gave him a total overthrow. Metellus then dispatched Lucius Lollius prætor of Narbonne Gaul against Hirtuleius; but he met with no better success, being utterly defeated, and his lieutenant-general killed.

11 Sertorius supports the Marian faction in Spain.

12 Is driven out, and undergoes many hardships.

13 Lands in Africa and carries on a successful war in that country.

14 Returns to Spain, and defeats the Romans there.

The fame of these victories brought to the camp of Sertorius such a number of illustrious Roman citizens of the Marian faction, that he formed a design of erecting Lusitania into a republic in opposition to that of Rome. Sylla was continually sending fresh supplies to Metellus;

15 Erects Lusitania into a republic.

Metellus; but Sertorius with an handful of men, accuſtomed to range about the mountains, to endure hunger and thirſt, and live expoſed to the inclemencies of the weather, ſo haraſſed the Roman army, that Metellus himſelf began to be quite diſcouraged. At laſt, Sertorius, hearing that Metellus had ſpoken diſreſpectfully of his courage, challenged his antagoniſt to end the war by ſingle combat; but Metellus very prudently declined the combat, as being advanced in years;
16 Obliges Metellus to raiſe the ſiege of Lacobriga.
yet this refuſal brought upon him the contempt of the unthinking multitude, upon which Metellus reſolved to retrieve his reputation by ſome ſignal exploit, and therefore laid ſiege to Lacobriga, a conſiderable city in thoſe parts. This he hoped to reduce in two days, as there was but one well in the place; but Sertorius, having previouſly removed all thoſe who could be of no ſervice during the ſiege, and conveyed 6000 ſkins full of water into the city, Metellus continued a long time before it without making any impreſſion. At laſt, his proviſions being almoſt ſpent, he ſent out Aquinus at the head of 6000 men to procure a new ſupply; but Sertorius falling unexpectedly upon them, cut in pieces or took the whole detachment; the commander himſelf being the only man who eſcaped to carry the news of the diſaſter; upon which Metellus was obliged to raiſe the ſiege with diſgrace.

17 Civilizes the Luſitanians.
And now Sertorius, having gained ſome intervals of eaſe in conſequence of the many advantages he had obtained over the Romans, began to civilize his new ſubjects. Their ſavage and furious manner of fighting he changed for the regular order and diſcipline of a well-formed army; he beſtowed liberally upon them gold and ſilver to adorn their arms, and by converſing familiarly with them, prevailed upon them to lay aſide their own dreſs for the Roman *toga*. He ſent for all the children of the principal people, and placed them in the great city of Oſca, now Hereſca, in the kingdom of Arragon, where he appointed them maſters to inſtruct them in the Roman and Greek learning, that they might, as he pretended, be capable of ſharing with him the government of the republic. Thus he made them really hoſtages for the good behaviour of their parents; however, the latter were greatly pleaſed with the care he took of their children, and all Luſitania were in the higheſt degree attached to their new ſovereign. This attachment he took care to heighten by the power of ſuperſtition; for having procured a young hind of a milk-white colour, he made it ſo tame that it followed him wherever he went; and Sertorius gave out to the ignorant multitude, that this hind was inſpired by Diana, and revealed to him the deſigns of his enemies, of which he always took care to be well informed by the great numbers of ſpies he employed.

While Sertorius was thus employed in eſtabliſhing his authority, the republic of Rome, alarmed at his ſucceſs, reſolved to cruſh him at all events. Sylla was now dead, and all the eminent generals in Rome ſolicited this honourable though dangerous employment.
18 Pompey the Great ſent againſt him.
After much debate a decree was paſſed in favour of Pompey the Great, but without recalling Metellus. In the mean time, the troops of one Perpenna, or Perperna, had, in ſpite of all that their general could do, abandoned him and taken the oath of allegiance to Sertorius. This was a moſt ſignal advantage to Sertorius; for Perperna commanded an army of 33,000 men, and had come into Spain with a deſign to ſettle there as Sertorius had done; but as he was deſcended from one of the firſt families in Rome, he thought it below his dignity to ſerve under any general, however eminent he might be. But the troops of Perperna were of a different opinion; and therefore declaring that they would ſerve none but a general who could defend himſelf, they to a man joined Sertorius; upon which Perperna himſelf, finding he could do no better, conſented to ſerve alſo as a ſubaltern.

On the arrival of Pompey in Spain, ſeveral of the cities which had hitherto continued faithful to Sertorius began to waver; upon which the latter reſolved, by ſome ſignal exploit, to convince them that Pompey could no more ſcreen them from his reſentment than Metellus.
19 Sertorius beſieges Lauron.
With this view he laid ſiege to Lauron, now Lirias, a place of conſiderable ſtrength. Pompey, not doubting but he ſhould be able to raiſe the ſiege, marched quite up to the enemy's lines, and found means to inform the garriſon that thoſe who beſieged them were themſelves beſieged, and would ſoon be obliged to retire with loſs and diſgrace. On hearing this meſſage, "I will teach Sylla's diſciple (ſaid Sertorius), that it is the duty of a general to look behind as well as before him." Having thus ſpoken, he ſent orders to a detachment of 6000 men, who lay concealed among the mountains, to come down and fall upon his rear if he ſhould offer to force the lines. Pompey, ſurpriſed at their ſudden appearance, durſt not ſtir out of his camp; and in
20 Takes and burns it in the ſight of Pompey.
the mean time the beſieged, deſpairing of relief, ſurrendered at diſcretion; upon which Sertorius granted them their lives and liberty, but reduced their city to aſhes.

While Sertorius was thus ſucceſsfully contending with Pompey, his quæſtor Hirtuleius was entirely defeated by Metellus, with the loſs of 20,000 men; upon which Sertorius advanced with the utmoſt expedition to the banks of the Sucro in Tarraconian Spain, with a
21 Defeats Pompey on the banks of the Sucro.
deſign to attack Pompey before he could be joined by Metellus. Pompey, on his part, did not decline the combat; but, fearing that Metellus might ſhare the glory of the victory, advanced with the greateſt expedition. Sertorius put off the battle till towards the evening; Pompey, though he knew that the night would prove diſadvantageous to him, whether vanquiſhed or victorious, becauſe his troops were unacquainted with the country, reſolved to venture an engagement, eſpecially as he feared that Metellus might arrive in the mean time, and rob him of part of the glory of conquering ſo great a commander. Pompey, who commanded his own right wing, ſoon obliged Perperna, who commanded Sertorius's left, to give way. Hereupon Sertorius himſelf taking upon him the command of that wing, brought back the fugitives to the charge, and obliged Pompey to fly in his turn. In his flight he was overtaken by a gigantic African, who had already lifted up his hand to diſcharge a blow at him with his broad ſword; but Pompey prevented him by cutting off his right hand at one blow. As he ſtill continued his flight, he was wounded and thrown from his horſe; ſo that he would certainly have been taken priſoner, had not the Africans who purſued him quarreled about the rich furniture of his horſe. This gave an opportunity to the general to make his eſcape; ſo that at length he reached his camp with much difficulty,

Spain.

ty. But in the mean time Afranius, who commanded the left wing of the Roman army, had entirely defeated the wing which Sertorius had left, and even pursued them so close that he entered the camp along with them. Sertorius, returning suddenly, found the Romans busy in plundering the tents; when, taking advantage of their situation, he drove them out with great slaughter, and retook his camp. Next day he offered battle a second time to Pompey; but Metellus then coming up with all his forces, he thought proper to decline an engagement with both commanders. In a few days, however, Pompey and Metellus agreed to attack the camp of Sertorius. Metellus attacked Perperna, and Pompey fell upon Sertorius. The event was similar to that of the former battle; Metellus defeated Perperna, and Sertorius routed Pompey. Being then informed of Perperna's misfortune, he hastened to his relief; rallied the fugitives, and repulsed Metellus in his turn, wounded him with his lance, and would certainly have killed him, had not the Romans, ashamed to leave their general in distress, hastened to his assistance, and renewed the fight with great fury. At last Sertorius was obliged to quit the field, and retire to the mountains. Pompey and Metellus hastened to besiege him; but while they were forming their camp, Sertorius broke through their lines, and escaped into Lusitania. Here he soon raised such a powerful army, that the Roman generals, with their united forces, did not think proper to venture an engagement with him. They could not, however, resist the perpetual attacks of Sertorius, who now drove them from place to place, till he obliged them to separate, the one went into Gaul, and the other to the foot of the Pyrenees.

22 Pompey defeated a second time.

23 Pompey and Metellus driven out of Spain by Sertorius.

Thus did this celebrated commander triumph over all the power of the Romans; and there is little doubt but he would have continued to make head against all the other generals whom the republic could have sent; had he not been assassinated at an entertainment by the infamous treachery of Perperna, in 73 B. C. after he had made head against the Roman forces for almost ten years. Pompey was no sooner informed of his death, than, without waiting for any new succours, he marched against the traitor, whom he easily defeated and took prisoner; and having caused him to be executed, thus put an end, with very little glory, to a most dangerous war.

24 Sertorius treacherously murdered.

Many of the Spanish nations, however, still continued to bear the Roman yoke with great impatience; and as the civil wars which took place first between Julius Cæsar and Pompey, and afterwards between Octavianus and Antony, diverted the attention of the republic from Spain, by the time that Augustus had become sole master of the Roman empire, they were again in a condition to assert their liberty. The CANTABRIANS and ASTURIANS were the most powerful and valiant nation at that time in Spain; but, after incredible efforts, they were obliged to lay down their arms, or rather were almost exterminated, by Agrippa, as is related under these articles. From this time the Spaniards continued in quiet subjection to the Romans; but on the decline of the empire they were attacked by the northern nations, who put an end to the Roman name in the west. As the inhabitants had by that time entirely lost their ancient valour, the barbarians met with no resistance but from one another. In the reign of the emperor Honorius, the Vandals, Alans, and Suevians, entered this country; and having made themselves masters of it, divided the provinces among themselves. In 444 the Romans made one effort more to recover their power in this part of the world; but being utterly defeated by the Suevians, the latter established a kingdom there which lasted till the year 584, when it was utterly overthrown by the Visigoths under Leovigilde. The Gothic princes continued to reign over a considerable part of Spain till the beginning of the 8th century, when their empire was entirely overthrown by the Saracens. During this period, they had entirely expelled the eastern emperors from what they possessed in Spain, and even made considerable conquests in Barbary; but towards the end of the 7th century the Saracens overran all that part of the world with a rapidity which nothing could resist; and having soon possessed themselves of the Gothic dominions in Barbary, they made a descent upon Spain about the year 711 or 712. The king of the Goths at that time was called *Roderic*, and by his bad conduct had occasioned great disaffection among his subjects. He therefore determined to put all to the issue of a battle, knowing that he could not depend upon the fidelity of his own people if he allowed the enemy time to tamper with them. The two armies met in a plain near Xeres in Andalusia. The Goths began the attack with great fury; but though they fought like men in despair, they were at last defeated with excessive slaughter, and their king himself was supposed to have perished in the battle, being never more heard of.

25 Spain entirely reduced by the Romans.

26 Seized by barbarous nations on the decline of the western empire.

27 The Gothic kingdom overthrown by the Saracens

By this battle the Moors in a short time rendered themselves masters of almost all Spain. The poor remains of the Goths were obliged to retire into the mountainous parts of Asturias, Burgos, and Biscay: the inhabitants of Arragon, Catalonia, and Navarre, though they might have made a considerable stand against the enemy, chose for the most part to retire into France. In 718, however, the power of the Goths began again to revive under Don Pelagio or Pelayo, a prince of the royal blood, who headed those that had retired to the mountains after the fatal battle of Xeres. The place where he first laid the foundation of his government was in the Asturias, in the province of Liebana, about nine leagues in length and four in breadth. This is the most inland part of the country, full of mountains enormously high, and so much fortified by nature, that its inhabitants are capable of resisting almost any number of invaders. Alakor the Saracen governor was no sooner informed of this revival of the Gothic kingdom, than he sent a powerful army, under the command of one Alchaman, to crush Don Pelagio before he had time to establish his power. The king, though his forces were sufficiently numerous (every one of his subjects arrived at man's estate being a soldier), did not think proper to venture a general engagement in the open field; but taking post with part of them himself in a cavern in a very high mountain, he concealed the rest among precipices, giving orders to them to fall upon the enemy as soon as they should perceive him attacked by them. These orders were punctually executed, though indeed Don Pelagio himself had repulsed his enemies, but not without a miracle, as the Spanish historians pretend. The slaughter was dreadful; for the troops who lay in ambuscade joining the

28 The power of the Goths revives under Pelagio.

29 He gives the Saracens a dreadful overthrow.

rest,

reſt, and rolling down huge ſtones from the mountains upon the Moors (the name by which the Saracens were known in Spain), no fewer than 124,000 of theſe unhappy people periſhed in one day. The remainder fled till they were ſtopped by a river, and beginning to coaſt it, part of a mountain ſuddenly fell down, ſtopped up the channel of the river, and either cruſhed or drowned, by the ſudden riſing of the water, almoſt every one of that vaſt army.

30 Another army cut in pieces or taken.

The Moors were not ſo much diſheartened by this diſaſter, but that they made a ſecond attempt againſt Don Pelagio. Their ſucceſs was as bad as ever, the greateſt part of their army being cut in pieces or taken; in conſequence of which, they loſt all the Aſturias, and never dared to enter the liſts with Pelagio afterwards. Indeed, their bad ſucceſs had in a great meaſure taken from them the deſire of conquering a country where little or nothing was to be got; and therefore they rather directed their force againſt France, where they hoped for more plunder. Into this country they poured in prodigious multitudes; but were utterly defeated, in 732, by Charles Martel, with the loſs of 300,000 men, as the hiſtorians of thoſe times pretend.

31 The Saracens utterly defeated by Charles Martel.

Don Pelagio died in 737, and ſoon after his death ſuch inteſtine diviſions broke out among the Moors, as greatly favoured the increaſe of the Chriſtian power. In 745 Don Alonſo the Catholic, ſon-in-law to Pelagio, in conjunction with his brother Froila, paſſed the mountains, and fell upon the northern part of Galicia; and meeting with little reſiſtance, he recovered almoſt the whole of that province in a ſingle campaign. Next year he invaded the plains of Leon and Caſtile; and before the Moors could aſſemble any force to oppoſe him, he reduced Aſtorgas, Leon, Saldagna, Montes de Oca, Amaya, Alava, and all the country at the foot of the mountains. The year following he puſhed his conqueſts as far as the borders of Portugal, and the next campaign ravaged the country as far as Caſtile. Being ſenſible, however, that he was yet unable to defend the flat country which he had conquered, he laid the whole of it waſte, obliged the Chriſtians to retire to the mountains, and carried off all the Moors for ſlaves. Thus ſecured by a deſert frontier, he met with no interruption for ſome years; during which time, as his kingdom advanced in ſtrength, he allowed his ſubjects gradually to occupy part of the flat country, and to rebuild Leon and Aſtorgas, which he had demoliſhed. He died in 757, and was ſucceeded by his ſon Don Froila. In his time Abdelrahman, the khaliff's viceroy in Spain, threw off the yoke, and rendered himſelf independent, fixing the ſeat of his government at Cordova. Thus the inteſtine diviſions among the Moors were compoſed; yet their ſucceſs ſeems to have been little better than before; for, ſoon after, Froila encountered the Moors with ſuch ſucceſs, that 54,000 of them were killed on the ſpot, and their general taken priſoner. Soon after he built the city of Oviedo, which he made the capital of his dominions, in order to be in a better condition to defend the flat country, which he now determined to people.

32 Conqueſts of the Chriſtians.

33 The Saracens in Spain throw off the yoke of the khaliff.

34 Hiſtory of the kingdom of Navarre.

In the year 758 the power of the Saracens received another blow by the riſe of the kingdom of Navarre. This kingdom, we are told, took its origin from an accidental meeting of gentlemen, to the number of 600, at the tomb of an hermit named *John*, who had died among the Pyrenees. At this place, where they had met on account of the ſuppoſed ſanctity of the deceaſed, they took occaſion to converſe on the cruelty of the Moors, the miſeries to which the country was expoſed, and the glory that would reſult from throwing off their yoke; which, they ſuppoſed, might eaſily be done, by reaſon of the ſtrength of their country. On mature deliberation, the project was approved; one Don Garcia Ximenes was appointed king as being of illuſtrious birth, and looked upon as a perſon of great abilities. He recovered Ainſa, one of the principal towns of the country, out of the hands of the infidels, and his ſucceſſor Don Garcia Inigas extended his territories as far as Biſcay; however, the Moors ſtill poſſeſſed Portugal, Murcia, Andaluſia, Valentia, Granada, Tortoſa, with the interior part of the country as far as the mountains of Caſtile and Saragoſſa. Their internal diſſenſions, which revived after the death of Abdelrahman, contributed greatly to reduce the power of the infidels in general. In 778, Charles the Great being invited by ſome diſcontented Mooriſh governors, entered Spain with two great armies; one paſſing through Catalonia, and the other through Navarre, where he puſhed his conqueſts as far as the Ebro. On his return he was attacked and defeated by the Moors; though this did not hinder him from keeping poſſeſſion of all thoſe places he had already reduced. At this time he ſeems to have been maſter of Navarre: however, in 831 count Azner, revolting from Pepin ſon to the emperor Louis, again revived the independency of Navarre; but the ſovereigns did not aſſume the title of kings till the time of Don Garcia, who began to reign in 857.

35 Conqueſts of Charles the Great

In the mean time, the kingdom founded by Don Pelagio, now called the kingdom of *Leon* and *Oviedo*, continued to increaſe rapidly in ſtrength, and many advantages were gained over the Moors, who having two enemies to contend with, loſt ground every day. In 921, however, they gained a great victory over the united forces of Navarre and Leon, by which the whole force of the Chriſtians in Spain muſt have been entirely broken, had not the victors conducted their affairs ſo wretchedly, that they ſuffered themſelves to be almoſt entirely cut in pieces by the remains of the Chriſtian army. In ſhort, the Chriſtians became at length ſo terrible to the Moors, that it is probable they could not long have kept their footing in Spain, had not a great general, named *Mohammed Ebn Amir Almanzor*, appeared, in 979, to ſupport their ſinking cauſe. This man was viſir to the king of Cordova, and being exceedingly provoked againſt the Chriſtians on account of what his countrymen had ſuffered from them, made war with the moſt implacable fury. He took the city of Leon, murdered the inhabitants, and reduced the houſes to aſhes. Barcelona ſhared the ſame fate; Caſtile was reduced to a deſert; Galicia and Portugal ravaged; and he is ſaid to have overcome the Chriſtians in fifty different engagements. At laſt, having taken and demoliſhed the city of Compoſtella, and carried off in triumph the gates of the church of St James, a flux happened to break out among his troops, which the ſuperſtitious Chriſtians ſuppoſed to be a divine judgement on account of his ſacrilege. Taking it for granted, therefore, that the Moors were now entirely deſtitute of all heavenly aid they fell upon them with

36 Exploits of Almanzor a Saracen general.

ſuch fury in the next engagement, that all the valour and conduct of Almanzor could not prevent a defeat.

37
He is defeated, and ſtarves himſelf to death.

Overcome with ſhame and deſpair at this misfortune, he deſired his followers to ſhift for themſelves, while he himſelf retired to Medina Cœli, and put an end to his life by abſtinence in the year 998.

38
Hiſtory of the kingdom of Caſtile.

During this period a new Chriſtian principality appeared in Spain, namely that of Caſtile, which is now divided into the Old and New Caſtile. The Old Caſtile was recovered long before that called the *New.* It was ſeparated from the kingdom of Leon on one ſide by ſome little rivers; on the other, it was bounded by the Aſturias, Biſcay, and the province of Rioja. On the ſouth it had the mountains of Segovia and Avila; thus lying in the middle between the Chriſtian kingdom of Leon and Oviedo, and the Mooriſh kingdom of Cordova. Hence this diſtrict ſoon became an object of contention between the kings of Leon and thoſe of Cordova; and as the former were generally victorious, ſome of the principal Caſtilian nobility retained their independency under the protection of the Chriſtian kings, even when the power of the Moors was at its greateſt height. In 884 we firſt hear of Don Rodriguez aſſuming the title of *count of Caſtile,* though it does not appear that either his territory or title were given him by the king of Leon. Nevertheleſs, this monarch having taken upon him to puniſh ſome of the Caſtilian lords as rebels, the inhabitants made a formal renunciation of their allegiance, and ſet up a new kind of government. The ſupreme power was now veſted in two perſons of quality ſtyled *judges;* however, this method did no long continue to give ſatisfaction, and the ſovereignty was once more veſted in a ſingle perſon. By degrees Caſtile fell entirely under the power of the kings of Leon and Oviedo; and, in 1035, Don Sanchez beſtowed it on his eldeſt ſon Don Ferdinand, with the title of *king;* and thus the territories of Caſtile were firſt firmly united to thoſe of Leon and Oviedo, and the ſovereigns were thenceforth ſtyled *kings of Leon and Caſtile.*

39
Hiſtory of Arragon.

Beſides all theſe, another Chriſtian kingdom was ſet up in Spain about the beginning of the 11th century. This was the kingdom of Arragon. The inhabitants were very brave, and lovers of liberty, ſo that it is probable they had in ſome degree maintained their independency, even when the power of the Moors was greateſt. The hiſtory of Arragon, however, during its infancy, is much leſs known than that of any of the others hitherto mentioned. We are only aſſured,

40
State of Spain in the beginning of the 11th century.

that about the year 1035, Don Sanchez, ſurnamed the *Great,* king of Navarre, erected Arragon into a kingdom in favour of his ſon Don Ramira, and afterwards it became very powerful. At this time, then, we may imagine the continent of Spain divided into two unequal parts by a ſtraight line drawn from eaſt to weſt, from the coaſts of Valentia to a little below the mouth of the Duro. The country north of this belonged to the Chriſtians, who, as yet, had the ſmalleſt and leaſt valuable ſhare, and all the reſt to the Moors. In point of wealth and real power, both by land and ſea, the Moors were greatly ſuperior; but their continual diſſenſions greatly weakened them, and every day facilitated the progreſs of the Chriſtians. Indeed, had either of the parties been united, the other muſt ſoon have yielded; for though the Chriſtians did not make war upon each other conſtantly as the Moors did, their mutual feuds were yet ſufficient to have ruined them, had their adverſaries made the leaſt uſe of the advantages thus afforded them. But among the Moors almoſt every city was a kingdom; and as theſe petty ſovereignties ſupported one another very indifferently, they fell a prey one after another to their enemies. In 1080, the king of Toledo was engaged in a war with the king of Seville, another Mooriſh potentate; which being obſerved by Alphonſo king of Caſtile, he alſo invaded his territories; and in four years made himſelf maſter of the city of Toledo, with all the places of importance in its neighbourhood; from thenceforth making Toledo the capital of his dominions. In a ſhort time the whole province of New Caſtile ſubmitted; and Madrid, the preſent capital of Spain, fell into the hands of the Chriſtians, being at that time but a ſmall place.

41
Toledo and Madrid taken by the Chriſtians.

The Moors were ſo much alarmed at theſe conqueſts, that they not only entered into a general confederacy againſt the Chriſtians, but invited to their aſſiſtance Mahomet Ben Joſeph the ſovereign of Barbary. He accordingly came, attended by an incredible multitude; but was utterly defeated by the Chriſtians in the defiles of the Black Mountain, or Sierra Morena, on the borders of Andaluſia. This victory happened on the 16th of July 1212, and the anniverſary is ſtill celebrated at Toledo. This victory was not improved; the Chriſtian army immediately diſperſed themſelves, while the Moors of Andaluſia were ſtrengthened by the remains of the African army; yet, inſtead of being taught, by their paſt misfortunes, to unite among themſelves, their diſſenſions became worſe than ever, and the conqueſts of the Chriſtians became daily more rapid. In 1236, Don Ferdinand of Caſtile and Leon took the celebrated city of Cordova, the reſidence of the firſt Mooriſh kings; at the ſame time that James I. of Arragon diſpoſſeſſed them of the iſland of Majorca, and drove them out of Valentia. Two years after, Ferdinand made himſelf maſter of Murcia, and took the city of Seville; and in 1303 Ferdinand IV. reduced Gibraltar.

42
A ſignal victory gained over the Moors.

43
England interferes in the Spaniſh affairs.

In the time of Edward III. we find England, for the firſt time, interfering in the affairs of Spain, on the following occaſion. In the year 1284 the kingdom of Navarre had been united to that of France by the marriage of Donna Joanna queen of Navarre with Philip the Fair of France. In 1328, however, the kingdoms were again ſeparated, though the ſovereigns of Navarre were ſtill related to thoſe of France. In 1350, Charles, ſurnamed the *Wicked,* aſcended the throne of Navarre, and married the daughter of John king of France. Notwithſtanding this alliance, and that he himſelf was related to the royal family of France, he ſecretly entered into a negotiation with England againſt the French monarch, and even drew into his ſchemes the dauphin Charles, afterwards ſurnamed *the Wiſe.* The young prince, however, was ſoon after made fully ſenſible of the danger and folly of the connections into which he had entered; and, by way of atonement, promiſed to ſacrifice his aſſociates. Accordingly he invited the king of Navarre, and ſome of the principal nobility of the ſame party, to a feaſt at Rouen, where he betrayed them to his father. The moſt obnoxious were executed, and the king of Navarre was thrown into priſon. In this extremity, the party of the King of Navarre had recourſe to England. The prince of Wales, ſurnamed *the*

44
The king of Navarre impriſoned by John king of France.

Spain. *the Black Prince*, invaded France, defeated king John at Poictiers, and took him prisoner †; which unfortunate event produced the most violent disturbances in that kingdom. The dauphin, now about 19 years of age, naturally assumed the royal power during his father's captivity: but possessed neither experience nor authority sufficient to remedy the prevailing evils. In order to obtain supplies, he assembled the states of the kingdom: but that assembly, instead of supporting his administration, laid hold of the present opportunity to demand limitations of the prince's power, the punishment of past malversations, and the liberty of the king of Navarre. Marcel, provost of the merchants of Paris, and first magistrate of that city, put himself at the head of the unruly populace, and pushed them to commit the most criminal outrages against the royal authority. They detained the dauphin in a kind of captivity, murdered in his presence Robert de Clermont and John de Conflans, mareschals of France; threatened all the other ministers with the like fate; and when Charles, who had been obliged to temporize and dissemble, made his escape from their hands, they levied war against him, and openly rebelled. The other cities of the kingdom, in imitation of the capital, shook off the dauphin's authority, took the government into their own hands, and spread the contagion into every province.

† See France n° 44.

45 Escapes, and heads the French malecontents.

Amidst these disorders, the king of Navarre made his escape from prison, and presented a dangerous leader to the furious malecontents. He revived his pretensions to the crown of France: but in all his operations he acted more like a leader of banditti than one who aspired to be the head of a regular government, and who was engaged by his station to endeavour the re establishment of order in the community. All the French, therefore, who wished to restore peace to their country, turned their eyes towards the dauphin; who, though not remarkable for his military talents, daily gained by his prudence and vigilance the ascendant over his enemies. Marcel, the seditious provost of Paris, was slain in attempting to deliver that city to the king of Navarre. The capital immediately returned to its duty: the most considerable bodies of the mutinous peasants were dispersed or put to sword; some bands of military robbers underwent the same fate; and France began once more to assume the appearance of civil government.

John was succeeded in the throne of France by his son Charles V. a prince educated in the school of adversity, and well qualified, by his prudence and experience, to repair the losses which the kingdom had sustained from the errors of his predecessors. Contrary to the practice of all the great princes of those times, who held nothing in estimation but military courage, he seems to have laid it down as a maxim, never to appear at the head of his armies; and he was the first European monarch that showed the advantage of policy and foresight over a rash and precipitate valour.

Before Charles could think of counterbalancing so great a power as England, it was necessary for him to remedy the many disorders to which his own kingdom was exposed. He accordingly turned his arms against the king of Navarre, the great disturber of France during that age; and he defeated that prince, and reduced him to terms, by the valour and conduct of Bertrand du Guesclin, one of the most accomplished captains of those times, whom Charles had the discernment to choose as the instrument of his victories. He also settled the affairs of Brittany, by acknowledging the title of Mountfort, and receiving homage for his dominions. But much was yet to be done. On the conclusion of the peace of Bretigni, the many military adventurers who had followed the fortunes of Edward, being dispersed into the several provinces, and possessed of strong holds, refused to lay down their arms, or relinquish a course of life to which they were now accustomed, and by which alone they could earn a subsistence. They associated themselves with the banditti, who were already inured to the habits of rapine and violence; and, under the name of *companies* and *companions*, became a terror to all the peaceable inhabitants. Some English and Gascon gentlemen of character were not ashamed to take the command of these ruffians, whose number amounted to near 40,000, and who bore the appearance of regular armies rather than bands of robbers. As Charles was not able by power to redress so enormous a grievance, he was led by necessity, as well as by the turn of his character, to correct it by policy; to discover some method of discharging into foreign countries this dangerous and intestine evil; and an occasion now offered.

46 Is defeated and obliged to submit to the terms prescribed by Char. V. of France.

47 Account of the banditti called companies or companions.

48 Reign of Peter the Cruel, king of Castile.

Alphonso XI. king of Castile, who took the city of Algezira from the Moors, after a famous siege of two years, during which artillery are said first to have been used by the besieged, had been succeeded by his son Peter I. surnamed *the Cruel*; a prince equally perfidious, debauched, and bloody. He began his reign with the murder of his father's mistress Leonora de Gusman: his nobles fell every day the victims of his severity: he put to death his cousin and one of his natural brothers, from groundless jealousy; and he caused his queen Blanche de Bourbon, of the blood of France, to be thrown into prison, and afterwards poisoned, that he might enjoy in quiet the embraces of Mary de Padella, with whom he was violently enamoured.

49 The Companies employed against him.

Henry count of Trastamara, the king's natural brother, alarmed at the fate of his family, and dreading his own, took arms against the tyrant; but having failed in the attempt, he fled to France, where he found the minds of men much inflamed against Peter, on account of the murder of the French princess. He asked permission of Charles to enlist the *campanies* in his service, and to lead them into Castile against his brother. The French king, charmed with the project, employed du Guesclin in negotiating with the leaders of these banditti. The treaty was soon concluded; and du Guesclin having completed his levies, led the army first to Avignon, where the Pope then resided, and demanded, sword in hand, absolution for his ruffian soldiers, who had been excommunicated, and the sum of 200,000 livres for their subsistence. The first was readily promised him; but some difficulty being made with regard to the second, du Guesclin replied, "My fellows, I believe, may make a shift to do without your absolution, but the money is absolutely necessary." His Holiness then extorted from the inhabitants of the city and its neighbourhood the sum of 100,000 livres, and offered it to du Guesclin. "It is not my purpose (cried that generous warrior) to oppress the innocent people. The pope and his cardinals can spare me double the sum from their own pockets. I therefore insist that, this

Spain.

this money be restored to the owners; and if I hear they are defrauded of it, I will myself return from the other side of the Pyrenees, and oblige you to make them restitution." The pope found the necessity of submitting, and paid from his own treasury the sum demanded.

50 He is driven out, but assisted by the Black Prince.

A body of experienced and hardy soldiers, conducted by so able a general, easily prevailed over the king of Castile, whose subjects were ready to join the enemy against their oppressor. Peter fled from his dominions, took shelter in Guienne, and craved the protection of the prince of Wales, whom his father had invested with the sovereignty of the ceded provinces, under the title of the *principality of Aquitaine.* The prince promised his assistance to the dethroned monarch; and having obtained his father's consent, he levied an army, and set out on his enterprise.

The first loss which Henry of Trastamara suffered from the interposition of the prince of Wales, was the recalling of the companies from his service; and so much reverence did they pay to the name of Edward, that great numbers of them immediately withdrew from Spain, and inlisted under his standard. Henry, however, beloved by his new subjects, and supported by the king of Arragon, was able to meet the enemy with an army of 100,000 men, three times the number of those commanded by the Black Prince: yet du Guesclin, and all his experienced officers, advised him to delay a decisive action; so high was their opinion of the valour and conduct of the English hero! But Henry, trusting to his numbers, ventured to give Edward battle on the banks of the Ebro, between Najara and Navarette; where the French and Spaniards were defeated, with the loss of above 20,000 men, and du Guesclin and other officers of distinction taken prisoners. All Castile submitted to the victor; Peter was restored to the throne, and Edward returned to Guienne with his usual glory; having not only overcome the greatest general of his age, but restrained the most blood-thirsty tyrant from executing vengeance on his prisoners.

51 The Spaniards defeated and Peter restored.

This gallant warrior had soon reason to repent of his connections with a man like Peter, lost to all sense of virtue and honour. The ungrateful monster refused the stipulated pay to the English forces. Edward abandoned him: he treated his subjects with the utmost barbarity; their animosity was roused against him; and du Guesclin having obtained his ransom, returned to Castile with the count of Trastamara, and some forces levied anew in France. They were joined by the Spanish malecontents; and having no longer the Black Prince to encounter, they gained a complete victory over Peter in the neighbourhood of Toledo. The tyrant now took refuge in a castle, where he was soon after besieged by the victors and taken prisoner in endeavouring to make his escape. He was conducted to his brother Henry; against whom he is said to have rushed in a transport of rage, disarmed as he was. Henry slew him with his own hand, in resentment of his cruelties; and, though a bastard, was placed on the throne of Castile, which he transmitted to his posterity.

52 Is again driven out, defeated, and put to death.

After the death of Peter the Cruel, nothing remarkable happened in Spain for almost a whole century; but the debaucheries of Henry IV. of Castile roused the resentment of his nobles, and produced a most singular insurrection which led to the aggrandizement of the Spanish monarchy.

Spain.

53 Reign of Henry the Impotent.

This prince, surnamed the *Impotent*, though continually surrounded with women, began his unhappy reign in 1454. He was totally enervated by his pleasures; and every thing in his court conspired to set the Castilians an example of the most abject flattery and most abandoned licentiousness. The queen, a daughter of Portugal, lived as openly with her parasites and her gallants as the king did with his minions and his mistresses. Pleasure was the only object, and effeminacy the only recommendation to favour: the affairs of the state went every day into disorder; till the nobility, with the archbishop of Toledo at their head, combining against the weak and flagitious administration of Henry, arrogated to themselves, as one of the privileges of their order, the right of trying and passing sentence on their sovereign, which they executed in a manner unprecedented in history.

54 He is formally deposed.

All the malecontent nobility were summoned to meet at Avila: a spacious theatre was erected in a plain without the walls of the town: an image, representing the king, was seated on a throne, clad in royal robes, with a crown on its head, a sceptre in its hand, and the sword of justice by its side. The accusation against Henry was read, and the sentence of deposition pronounced, in presence of a numerous assembly. At the close of the first article of the charge, the archbishop of Toledo advanced, and tore the crown from the head of the image; at the close of the second, the Conde de Placentia snatched the sword of justice from its side; at the close of the third, the Conde de Benavente wrested the sceptre from its hand; and at the close of the last, Don Diego Lopez de Stuniga tumbled it headlong from the throne. At the same instant, Don Alphonso, Henry's brother, a boy of about twelve years of age, was proclaimed king of Castile and Leon in his stead.

This extraordinary proceeding was followed by a civil war, which did not cease till some time after the death of the young prince, on whom the nobles had bestowed the kingdom. The archbishop and his party then continued to carry on war in the name of Isabella the king's sister, to whom they gave the title of *Infanta*; and Henry could not extricate himself out of these troubles, nor remain quiet upon his throne till he had signed one of the most humiliating treaties ever extorted from a sovereign; he acknowledged his sister Isabella the only lawful heiress of his kingdom, in prejudice to the rights of his reputed daughter Joan, whom the malecontents affirmed to be the offspring of an adulterous commerce between the queen and Don la Cueva. The grand object of the malecontent party now was the marriage of the princess Isabella, upon which, it was evident, the security of the crown and the happiness of the people must in a great measure depend. The alliance was sought by several princes: the king of Portugal offered her his hand; the king of France demanded her for his brother, and the king of Arragon for his son Ferdinand. The malecontents very wisely preferred the Arragonian prince, and Isabella prudently made the same choice: articles were drawn up; and they were privately married by the archbishop of Toledo.

55 Is obliged to acknowledge his sister Isabella to be heiress to the kingdom.

56 She is married to Ferdinand of Arragon.

Spain.

Henry was enraged at this alliance, which he foresaw would utterly ruin his authority, by furnishing his rebellious subjects with the support of a powerful neighbouring prince. He disinherited his sister, and established the rights of his daughter. A furious civil war desolated the kingdom. The names of Joan and Isabella resounded from every quarter, and were everywhere the summons to arms. But peace was at length brought about. Henry was reconciled to his sister and Ferdinand; though it does not appear that he ever renewed Isabella's right to the succession: for he affirmed in his last moments, that he believed Joan to be his own daughter. The queen swore to the same effect; and Henry left a testamentary deed, transmitting the crown to this princess, who was proclaimed queen of Castile at Placentia. But the superior fortune and superior arms of Ferdinand and Isabella prevailed: the king of Portugal was obliged to abandon his niece and intended bride, after many ineffectual struggles, and several years of war. Joan retired into a convent; and the death of Ferdinand's father, which happened about this time, added the kingdoms of Arragon and Sicily to those of Leon and Castile.

57 Union of the kingdoms of Arragon and Sicily with Leon and Castile.

Ferdinand and Isabella were persons of great prudence, and, as sovereigns, highly worthy of imitation but they do not seem to have merited all the praises bestowed upon them by the Spanish historians. They did not live like man and wife, having all things in common under the direction of the husband; but like two princes in close alliance; they neither loved nor hated each other; were seldom in company together; had each a separate council; and were frequently jealous of one another in the administration. But they were inseparably united in their common interests; always acting upon the same principles, and forwarding the same ends. Their first object was the regulation of their government, which the civil wars had thrown into the greatest disorder. Rapine, outrage, and murder, were become so common, as not only to interrupt commerce, but in a great measure to suspend all intercourse between one place and another. These evils the joint sovereigns suppressed by their wise policy, at the same time that they extended the royal prerogative.

58 Administration of Ferdinand and Isabella.

59 Institution of the Holy Brotherhood.

About the middle of the 13th century, the cities in the kingdom of Arragon, and after their example those in Castile, had formed themselves into an association, distinguished by the name of the *Holy Brotherhood.* They exacted a certain contribution from each of the associate towns; they levied a considerable body of troops, in order to protect travellers and pursue criminals; and they appointed judges, who opened courts in various parts of the kingdom. Whoever was guilty of murder, robbery, or any act that violated the public peace, and was seized by the troops of the Brotherhood, was carried before their judges; who, without paying any regard to the exclusive jurisdiction which the lord of the place might claim, who was generally the author or abettor of the injustice, tried and condemned the criminals. The nobles often murmured against this salutary institution; they complained of it as an encroachment on one of their most valuable privileges, and endeavoured to get it abolished. But Ferdinand and Isabella, sensible of the beneficial effects of the Brotherhood, not only in regard to the police of their kingdom, but in its tendency to abridge, and by degrees annihilate, the territorial jurisdiction of the nobility countenanced the institution upon every occasion, and supported it with the whole force of royal authority; by which means the prompt and impartial administration of justice was restored, and with it tranquillity and order returned.

But at the same time that their Catholic majesties (for such was the title they now bore) were giving vigour to their civil government, and securing their subjects from violence and oppression, an intemperate zeal led them to establish an ecclesiastical tribunal, equally contrary to the natural rights of humanity and the mild spirit of the Gospel. This was the court of inquisition; which decides upon the honour, fortune, and even the life, of the unhappy wretch who happens to fall under the suspicion of heresy, or a contempt of any thing prescribed by the church, without his knowing, or being confronted with his accusers, or permitted either defence or appeal. Six thousand persons were burnt by order of this sanguinary tribunal within four years after the appointment of Torquemada, the first inquisitor-general; and upwards of 100,000 felt its fury. The same furious and blinded zeal which led to the depopulation of Spain, led also to its aggrandizement.

60 And of the Inquisition.

61 Conquest of Granada.

The kingdom of Granada now alone remained of all the Mahometan possessions in Spain. Princes equally zealous and ambitious were naturally disposed to turn their eyes to that fertile territory, and to think of increasing their hereditary dominions, by expelling the enemies of Christianity, and extending its doctrines. Every thing conspired to favour their project: the Moorish kingdom was a prey to civil wars; when Ferdinand, having obtained the bull of Sixtus IV. authorizing a crusade, put himself at the head of his troops, and entered Granada. He continued the war with rapid success: Isabella attended him in several expeditions; and they were both in great danger at the siege of Malaga; an important city, which was defended with great courage, and taken in 1487. Baza was reduced in 1489, after the loss of 20,000 men. Guadix and Almeria were delivered up to them by the Moorish king Alzalgel, who had first dethroned his brother Alboacen, and afterwards been chased from his capital by his nephew Abdali. That prince engaged in the service of Ferdinand and Isabella; who, after reducing every other place of eminence, undertook the siege of Granada. Abdali made a gallant defence; but all communication with the country being cut off, and all hopes of relief at an end, he capitulated, after a siege of eight months, on condition that he should enjoy the revenue of certain places in the fertile mountains of Alpujarros; that the inhabitants should retain the undisturbed possession of their houses, goods, and inheritances; the use of their laws, and the free exercise of their religion. Thus ended the empire of the Arabs in Spain, after it had continued about 800 years. They introduced the arts and sciences into Europe at a time when it was lost in darkness; they possessed many of the luxuries of life, when they were not even known among the neighbouring nations; and they seem to have given birth to that romantic gallantry which so eminently prevailed in the ages of chivalry, and which, blending itself with the veneration of the northern nations for the softer sex, still particularly distinguishes ancient from modern manners.

Spain.

ners. But the Moors, notwithstanding these advantages, and the eulogies bestowed upon them by some writers, appear always to have been destitute of the essential qualities of a polished people, humanity, generosity, and mutual sympathy.

62 Jews expelled from Spain.

The conquest of Granada was followed by the expulsion, or rather the pillage and punishment, of the Jews, who had engrossed all the wealth and commerce of Spain. The inquisition exhausted its rage against these unhappy people, many of whom pretended to embrace Christianity, in order to preserve their property. About the same time their Catholic majesties concluded an alliance with the emperor Maximilian, and a treaty of marriage for their daughter Joan with his son Philip, archduke of Austria and sovereign of the Netherlands. About this time also the contract was concluded with Christopher Columbus for the discovery of new countries; and the counties of Roussillon and Cerdagne were agreed to be restored by Charles VIII. of France, before his expedition into Italy. The discovery of America was soon followed by extensive conquests in that quarter, as is related under the articles MEXICO, PERU, CHILI, &c. which tended to raise the Spanish monarchy above any other in Europe.

63 Discovery of America, &c.

64 Accession of Charles V.

On the death of Isabella, which happened in 1506, Philip archduke of Austria came to Castile in order to take possession of that kingdom as heir to his mother-in-law; but he dying in a short time after, his son Charles V. afterwards emperor of Germany, became heir to the crown of Spain. His father at his death left the king of France governor to the young prince, and Ferdinand at his death left cardinal Ximenes sole regent of Castile, till the arrival of his grandson. This man, whose character is no less singular than illustrious, who united the abilities of a great statesman with the abject devotion of a superstitious monk, and the magnificence of a prime minister with the severity of a mendicant, maintained order and tranquillity in Spain, notwithstanding the discontents of a turbulent and high-spirited nobility. When they disputed his right to the regency, he coolly showed them the testament of Ferdinand, and the ratification of that deed by Charles; but these not satisfying them, and argument proving ineffectual, he led them insensibly towards a balcony, whence they had a view of a large body of troops under arms, and a formidable train of artillery. "Behold (said the cardinal) the powers which I have received from his Catholic majesty: by these I govern Castile; and will govern it, till the King, your master and mine, shall come to take possession of his kingdom." A declaration so bold and determined silenced all opposition; and Ximenes maintained his authority till the arrival of Charles in 1517.

65 Disgrace and death of cardinal Ximenes.

The young king was received with universal acclamations of joy; but Ximenes found little cause to rejoice. He was seized with a violent disorder, supposed to be the effect of poison; and when he recovered, Charles, prejudiced against him by the Spanish grandees and his Flemish courtiers, slighted his advice, and allowed him every day to sink into neglect. The cardinal did not bear this treatment with his usual fortitude of spirit. He expected a more grateful return from a prince to whom he delivered a kingdom more flourishing than it had been in any former age, and authority more extensive and better established than the most illustrious of his ancestors had ever possessed. Conscious of his own integrity and merit, he could not therefore refrain from giving vent, at times, to indignation and complaint. He lamented the fate of his country, and foretold the calamities to which it would be exposed from the insolence, the rapaciousness, and the ignorance of strangers. But in the mean time, he received a letter from the king, dismissing him from his councils, under pretence of easing his age of that burden which he had so long and so ably sustained. This letter proved fatal to the minister; for he expired in a few hours after reading it.

66 Maximilian attempts to get Charles elected emperor.

While Charles was taking possession of the throne of Spain, in consequence of the death of one grandfather, another was endeavouring to obtain for him the imperial crown. With this view Maximilian assembled a diet at Augsburg, were he cultivated the favour of the electors by many acts of beneficence in order to engage them to choose that young prince as his successor. But Maximilian himself never having been crowned by the pope, a ceremony deemed essential in that age, as well as in the preceding, he was considered only as king of the Romans, or emperor elect; and no example occurring in history of any person being chosen successor to a king of the Romans, the Germans, always tenacious of their forms, obstinately refused to confer upon Charles a dignity for which their constitution knew no name.

But though Maximilian could not prevail upon the German electors to choose his grandson of Spain king of the Romans, he had disposed their minds in favour of that prince; and other circumstances, on the death of the emperor, conspired to the exaltation of Charles. The imperial crown had so long continued in the Austrain line, that it began to be considered as hereditary in that family; and Germany, torn by religious disputes, stood in need of a powerful emperor, not only to preserve its own internal tranquillity, but also to protect it against the victorious arms of the Turks, who under Selim I. threatened the liberties of Europe. This fierce and rapid conqueror had already subdued the Mamalukes, and made himself master of Egypt and Syria. The power of Charles appeared necessary to oppose that of Selim. The extensive dominions of the house of Austria, which gave him an interest in the preservation of Germany; the rich sovereignty of the Netherlands and Franche Compte; the entire possession of the great and warlike kingdom of Spain, together with that of Naples and Sicily, all united to hold him up to the first dignity among Christian princes; and the new world seemed only to be called into existence that its treasures might enable him to defend Christendom against the infidels. Such was the language of his partisans.

67 Francis I. aspires to the same dignity.

Francis I. however, no sooner received intelligence of the death of Maximilian, than he declared himself a candidate for the empire; and with no less confidence of success than Charles. He trusted to his superior years and experience; his great reputation in arms; and it was farther urged in his favour, that the impetuosity of the French cavalry added to the firmness of the German infantry, would prove irresistible, and not only be sufficient under a warlike emperor, to set limits to the ambition of Selim, but to break entirely the Ottoman power, and prevent it from ever becoming dangerous again to Germany.

Both claims were plausible. The dominions of Fran-

cis

Spain.

cis were less extensive, but more united than those of Charles. His subjects were numerous, active, brave, lovers of glory, and lovers of their king. These were strong arguments in favour of his power, so necessary at this juncture: but he had no natural interest in the Germanic body; and the electors, hearing so much of military force on each side, became more alarmed for their own privileges than the common safety. They determined to reject both candidates, and offered the imperial crown to Frederic, surnamed the *Wise*, duke of Saxony. But he, undazzled by the splendour of an object courted with so much eagerness by two mighty monarchs, rejected it with a magnanimity no less singular than great.

68 Speech of Frederic duke of Saxony in favour of Charles.

"In times of tranquillity (said Frederic), we wish for an emperor, who has no power to invade our liberties; times of danger demand one who is able to secure our safety. The Turkish armies, led by a warlike and victorious monarch, are now assembling: they are ready to pour in upon Germany with a violence unknown in former ages. New conjunctures call for new expedients. The imperial sceptre must be committed to some hand more powerful than mine or that of any other German prince. We possess neither dominions, nor revenues, nor authority, which enable us to encounter such a formidable enemy. Recourse must be had, in this exigency, to one of the rival monarchs. Each of them can bring into the field forces sufficient for our defence. But as the king of Spain is of German extraction, as he is a member and prince of the empire by the territories which descend to him from his grandfather, and as his dominions stretch along that frontier which lies most exposed to the enemy, his claim, in my opinion, is preferable to that of a stranger to our language, to our blood, and to our country." Charles was elected in consequence of this speech in the year 1520.

69 He is elected in consequence of this speech.

The two candidates had hitherto conducted their rivalship with emulation, but without enmity. They had even mingled in their competition many expressions of friendship and regard. Francis in particular declared with his usual vivacity, that his brother Charles and he were fairly and openly suitors to the same mistress: "The most assiduous and fortunate (added he) will win her; and the other must rest contented." But the preference was no sooner given to his rival, than Francis discovered all the passions natural to disappointed ambition. He could not suppress his chagrin and indignation at being baulked in his favourite pursuit, and rejected, in the face of all Europe, for a youth yet unknown to fame. The spirit of Charles resented such contempt; and from this jealousy, as much as from opposition of interest, arose that emulation between those two great monarchs which involved them in almost perpetual hostilities, and kept their whole age in movement.

70 A mutual hatred takes place between Charles and Francis.

Charles and Francis had many interfering claims in Italy; and the latter thought himself bound in honour to restore the king of Navarre to his dominions, unjustly seized by the crown of Spain. They immediately began to negotiate; and as Henry VIII. of England was the third prince of the age in power and in dignity, his friendship was eagerly courted by each of the rivals. He was the natural guardian of the liberties of Europe. Sensible of the consequence which his situation gave him, and proud of his pre-eminence, Henry knew it to be his interest to keep the balance even between the contending powers, and to restrain both, by not joining entirely with either; but he was seldom able to reduce his ideas to practice. Vanity and resentment were the great springs of all his undertakings; and his neighbours, by touching these, found an easy way to draw him into their measures, and force him upon many rash and inconsiderate enterprises.

71 Both court the friendship of Henry VIII. of England.

All the impolitic steps in Henry's government must not, however, be imputed to himself; many of them were occasioned by the ambition and avarice of his prime minister and favourite cardinal Wolsey. This man, who, by his talents and accomplishments, had risen from one of the lowest conditions in life to the highest employments both in church and state, enjoyed a greater degree of power and dignity than any English subject ever possessed, and governed the haughty, presumptuous, and untractable spirit of Henry, with absolute authority. Francis was equally well acquainted with the character of Henry and of his minister. He had successfully flattered Wolsey's pride by honouring him with particular marks of his confidence, and bestowing upon him the appellation of *Father*, *Tutor*, and *Governor*; and he had obtained the restitution of Tournay, by adding a pension to those respectful titles. He now solicited an interview with the king of England near Calais; in hopes of being able, by familiar conversation, to attach him to his friendship and interest, while he gratified the cardinal's vanity, by affording him an opportunity of displaying his magnificence in the presence of two courts, and of discovering to the two nations his influence over their monarchs. Charles dreaded the effects of this projected interview between two gallant princes, whose hearts were no less susceptible of friendship than their manners were of inspiring it. Finding it impossible, however, to prevent a visit, in which the vanity of all parties was so much concerned, he endeavoured to defeat its purpose, and to pre-occupy the favour of the English monarch, and of his minister, by an act of complaisance still more flattering and more uncommon. Relying wholly upon Henry's generosity for his safety, he landed at Dover, in his way from Spain to the Low Countries. The king of England, who was on his way to France, charmed with such an instance of confidence, hastened to receive his royal guest; and Charles, during his short stay, had the address not only to give Henry favourable impressions of his character and intentions, but to detach Wolsey entirely from the interest of Francis. The tiara had attracted the eye of that ambitious prelate; and as the emperor knew that the papacy was the sole point of elevation, beyond his present greatness, at which he could aspire, he made him an offer of his interest on the first vacancy.

72 An interview projected between Francis and Henry.

73 Charles visits Henry in England.

The day of Charles's departure, Henry went over to Calais with his whole court, in order to meet Francis. Their interview was in an open plain between Guisnes and Ardres; where the two kings and their attendants displayed their magnificence with such emulation and profuse expence, as procured it the name of the *Field of the Cloth of Gold*. Here Henry erected a spacious house of wood and canvas, framed in London, on which, under the figure of an English archer, was the following motto: "He prevails whom I favour;" alluding to his own political situation, as holding in his hands

74 Henry visits Francis in France.

Spain.

hands the balance of power among the potentates of Europe. Feats of chivalry however, parties of gallantry, and such exercises as were in that age reckoned manly or elegant, rather than serious business, occupied the two courts during the time that they continued together, which was 18 days.

After taking leave of this scene of dissipation, the king of England paid a visit to the emperor and Margaret of Savoy at Gravelines, and engaged them to go along with him to Calais; where the artful and politic Charles completed the impression which he had begun to make on Henry and his favourite, and effaced all the friendship to which the frank and generous nature of Francis had given birth. He renewed his assurances of assisting Wolsey in obtaining the papacy; and he put him in present possession of the revenues belonging to the sees of Badajox and Palencia in Spain. He flattered Henry's pride, by convincing him of his own importance, and of the justness of the motto which he had chosen; offering to submit to his sole arbitration any difference that might arise between him and Francis.

75
Charles invested with the imperial crown at Aix-la-Chapelle.

This important point being secured, Charles repaired to Aix-la-Chapelle, where he was solemnly invested with the crown and sceptre of Charlemagne, in presence of a more splendid and numerous assembly than had appeared on any former inauguration. About the same time Solyman the Magnificent, one of the most accomplished, enterprising, and victorious of the Turkish princes, and a constant and formidable rival to the emperor, ascended the Ottoman throne.

The first act of Charles's administration was to appoint a diet of the empire, to be held at Worms, in order to concert with the princes proper measures for checking the progress of "those new and dangerous opinions which threatened to disturb the peace of Germany, and to overturn the religion of their ancestors." The opinions propagated by Luther and his followers were here meant. But all his efforts for that purpose were insufficient, as is related under the articles LUTHER and REFORMATION.

76
War between Francis and Charles.

In 1521, the Spaniards, dissatisfied with the departure of their sovereign, whose election to the empire they foresaw would interfere with the administration of his own kingdom, and incensed at the avarice of the Flemings, to whom the direction of public affairs had been committed since the death of cardinal Ximenes, several grandees, in order to shake off this oppression, entered into an association, to which they gave the name of the *Sancta Juncta*; and the sword was appealed to as the means of redress. This seemed to Francis a favourable juncture for reinstating the family of John d'Albert in the kingdom of Navarre. Charles was at a distance from that part of his dominions, and the troops usually stationed there had been called away to quell the commotions in Spain. A French army, undew Andrew de Foix, speedily conquered Navarre; but that young and inexperienced nobleman, pushed on by military ardour ventured to enter Castile. The Spaniards, though divided among themselves, united against a foreign enemy, routed his forces, took him prisoner, and recovered Navarre in a shorter time than he had spent in subduing it.

Hostilities thus begun in one quarter, between the rival monarchs, soon spread to another. The king of France encouraged the duke of Bouillon to make war against the emperor, and to invade Luxembourg. Charles, after, humbling the duke, attempted to enter France; but was repelled and worsted before Mezieres by the famous chevalier Bayard, distinguished among his cotemporaries by the appellation of *The knight without fear and without reproach*; and who united the talents of a great general to the punctilious honour and romantic gallantry of the heroes of chivalry. Francis broke into the Low Countries, where, by an excess of caution, an error not natural to him, he lost an opportunity of cutting off the whole imperial army; and, what was of still more consequence, he disgusted the constable Bourbon, by giving the command of the van to the duke of Alençon.

During these operations in the field, an unsuccessful congress was held at Calais, under the mediation of Henry VIII. It served only to exasperate the parties which it was intended to reconcile. A league was soon after concluded, by the intrigues of Wolsey, between the pope, Henry, and Charles, against France. Leo had already entered into a separate league with the emperor, and the French were fast losing ground in Italy.

The insolence and exactions of Mareschal de Lautrec, governor of Milan, had totally alienated the affections of the Milanese from France. They resolved to expel the troops of that nation, and put themselves under the government of Francis Sforza, brother to Maximilian their late duke. In this resolution, they were encouraged by the pope, who excommunicated Lautrec, and took into his pay a considerable body of Swiss. The papal army, commanded by Prosper Colonna, an experienced general, was joined by supplies from Germany and Naples: while Lautrec, neglected by his court, and deserted by the Swiss in its pay, was unable to make head against the enemy. The city of Milan was betrayed by the inhabitants to the confederates; Parma and Placentia were united to the ecclesiastical state; and of their conquests in Lombardy, only the town of Cremona, the castle of Milan, and a few inconsiderable forts, remained in the hands of the French.

77
Rapid conquests of Charles.

Leo X. received the accounts of this rapid success with such transports of joy, as are said to have brought on a fever, which occasioned his death. The spirit of the confederacy was broken, and its operations suspended by this accident. The Swiss were recalled; some other mercenaries disbanded for want of pay; and only the Spaniards, and a few Germans in the emperor's service, remained to defend the duchy of Milan. But Lautrec, who with the remnant of his army had taken shelter in the Venetian territories, destitute both of men and money, was unable to improve this favourable opportunity as he wished. All his efforts were rendered ineffectual by the vigilance and ability of Colonna and his associates.

Meantime much discord prevailed in the conclave. Wolsey's name, notwithstanding all the emperor's magnificent promises, was scarcely mentioned there. Julio de Medici, Leo's nephew, thought himself sure of the election; when, by an unexpected turn of fortune, cardinal Adrian of Utrecht, Charles's preceptor, who at that time governed Spain in the emperor's name, was unanimously raised to the papacy, to the astonishment of all Europe and the great disgust of the Italians.

Francis,

78 Francis invades Italy.

Francis, roused by the rising consequence of his rival, resolved to exert himself with fresh vigour, in order to wrest from him his late conquests in Lombardy. Lautrec received a supply of money, and a reinforcement of 10,000 Swiss. With this reinforcement he was enabled once more to act offensively, and even to advance within a few miles of the city of Milan; when money again failing him, and the Swiss growing mutinous, he was obliged to attack the imperialists in their camp at Bicocca, where he was repulsed with great slaughter, having lost his bravest officers and best troops. Such of the Swiss as survived set out immediately for their own country; and Lautrec, despairing of being able to keep the field, retired into France. Genoa, which still remained subject to Francis, and made it easy to execute any scheme for the recovery of Milan, was soon after taken by Colonna: the authority of the emperor and his faction was everywhere established in Italy. The citadel of Cremona was the sole fortress which remained in the hands of the French

The affliction of Francis for such a succession of misfortunes was augmented by the unexpected arrival of an English herald, who in the name of his sovereign declared war against France. The courage of this excellent prince, however, did not forsake him; though his treasury was exhausted by expensive pleasures, no less than by hostile enterprises, he assembled a considerable army, and put his kingdom in a posture of defence for resisting this new enemy, without abandoning any of the schemes which he was forming against the emperor. He was surprised, but not alarmed, at such a denunciation.

79 Charles visits England a second time.

Meanwhile Charles, willing to draw as much advantage as possible from so powerful an ally, paid a second visit to the court of England in his way to Spain, where his presence was become necessary. His success exceeded his most sanguine expectations. He not only gained the entire friendship of Henry, who publicly ratified the treaty of Bruges; but disarmed the resentment of Wolsey, by assuring him of the papacy on Adrian's death; an event seemingly not distant, by reason of his age and infirmities. In consequence of these negotiations an English army invaded France, under the command of the earl of Surrey; who, at the end of the campaign, was obliged to retire, with his forces greatly reduced, without being able to make himself master of one place within the French frontier. Charles was more fortunate in Spain: he soon quelled the tumults which had there arisen in his absence.

While the Christian princes were thus wasting each other's strength, Solyman the Magnificent entered Hungary, and made himself master of Belgrade, reckoned the chief barrier of that kingdom against the Turkish power. Encouraged by this success, he turned his victorious arms against the Island of Rhodes, at that time the seat of the knights of St John of Jerusalem;

80 Rhodes taken by Solyman.

and though every prince in that age acknowledged Rhodes to be the great bulwark of Christendom in the east, so violent was their animosity against each other, that they suffered Solyman without disturbance to carry on his operations against that city and island. Lisle Adam, the grandmaster, made a gallant defence; but, after incredible efforts of courage, patience, and military conduct, during a siege of six months, he was obliged to surrender the place, having obtained an honourable capitulation from the sultan, who admired and respected his heroic qualities (See RHODES and MALTA). Charles and Francis were equally ashamed of having occasioned such a loss to Christendom by their contests; and the emperor, by way of reparation, granted to the knights of St John the small island of Malta, where they fixed their residence, and continued long to retain their ancient spirit, though much diminished in power and splendour.

Adrian VI. though the creature of the emperor, and devoted to his interest, endeavoured to assume the impartiality which became the common father of Christendom, and laboured to reconcile the contending princes, that they might unite in a league against Solyman, whose conquest of Rhodes rendered him more formidable than ever to Europe. The Italian states were no less desirous of peace than the pope: and so much regard was paid by the hostile powers to the exhortations of his holiness, and to a bull which he issued, requiring all Christian princes to consent to a truce for three years, that the imperial, the French, and the English ambassadors at Rome, were empowered to treat of that matter; but while they wasted their time in fruitless negociations, their masters were continuing their preparations for war; and other negociations soon took place. The confederacy against France became more formidable than ever.

81 A powerful confederacy against Francis.

The Venetians, who had hitherto adhered to the French interest, formed engagements with the emperor for securing Francis Sforza in the possession of the duchy of Milan; and the pope, from a persuasion that the ambition of the French monarch was the only obstacle to peace, acceded to the same alliance. The Florentines, the dukes of Ferrara and Mantua, and all the Italian powers, followed this example. Francis was left without a single ally, to resist the efforts of a multitude of enemies, whose armies everywhere threatened, and whose territories encompassed his dominions. The emperor in person menaced France with an invasion on the side of Guienne; the forces of England and the Netherlands hovered over Picardy, and a numerous body of Germans was preparing to ravage Burgundy.

The dread of so many and such powerful adversaries, it was thought, would have obliged Francis to keep wholly on the defensive, or at least have prevented him from entertaining any thoughts of marching into Italy. But before his enemies were able to strike a blow, Francis had assembled a great army, with which he hoped to disconcert all the emperor's schemes, by marching it in person into Italy: and this bold measure, the more formidable because unexpected, could scarcely have failed of the desired effect, had it been immediately carried into execution. But the discovery of a domestic conspiracy, which threatened the destruction of his kingdom, obliged Francis to stop short at Lyons.

82 Francis marches towards Italy, but is obliged to return by a domestic conspiracy.

Charles duke of Bourbon, lord high constable of France, was a prince of the most shining merit: his great talents equally fitted him for the council or the field, while his eminent services to the crown intitled him to its first favour. But unhappily Louisa duchess of Angouleme, the king's mother, had contracted a violent aversion against the house of Bourbon, and had taught her son, over whom she had acquired an absolute ascendant, to view all the constable's actions with a jealous eye. After repeated affronts he retired from court, and

Spain.

and began to liſten to the advances of the emperor's miniſters. Meantime the ducheſs of Bourbon died; and as the conſtable was no leſs amiable than accompliſhed, the ducheſs of Angouleme, ſtill ſuſceptible of the tender paſſions, formed the ſcheme of marrying him. But Bourbon, who might have expected every thing to which an ambitious mind can aſpire, from the doating fondneſs of a woman who governed her ſon and the kingdom, incapable of imitating Louiſa in her ſudden tranſition from hate to love, or of meanly counterfeiting a paſſion for one who had ſo long purſued him with unprovoked malice, rejected the match with diſdain and turned the propoſal into ridicule. At once deſpiſed, and inſulted by the man whom love only could have made her ceaſe to perſecute, Louiſa was filled with all the rage of diſappointed woman; ſhe reſolved to ruin, ſince ſhe could not marry, Bourbon. For this purpoſe ſhe commenced an iniquitous ſuit againſt him; and by the chicanery of chancellor du Prat, the conſtable was ſtripped of his whole family-eſtate. Driven to deſpair by ſo many injuries, he entered into a ſecret correſpondence with the emperor and the king of England; and he propoſed, as ſoon as Francis ſhould have croſſed the Alps, to raiſe an inſurrection among his numerous vaſſals, and introduce foreign enemies into the heart of France.

Happily Francis got intimation of this conſpiracy before he left the kingdom; but not being ſufficiently convinced of the Conſtable's guilt, he ſuffered ſo dangerous a foe to eſcape; and Bourbon entering into the emperor's ſervice, employed all the force of his enterpriſing genius, and his great talents for war, to the prejudice of his prince and his native country.

In conſequence of the diſcovery of this plot, and the eſcape of the powerful conſpirator, Francis relinquiſhed his intention of leading his army in perſon into Italy. He was ignorant how far the infection had ſpread among his ſubjects, and afraid that his abſence might encourage them to make ſome deſperate attempt in favour of a man ſo much beloved. He did not, however, abandon his deſign on the Milaneſe, but ſent forward an army of 30,000 men, under the command of admiral Bonnivet. Colonna, who was entruſted with the defence of that duchy, was in no condition to reſiſt ſuch a force; and the city of Milan, on which the whole territory depends, muſt have fallen into the hands of the French, had not Bonnivet, who poſſeſſed none of the talents of a general, waſted his time in frivolous enterpriſes, till the inhabitants recovered from their conſternation. The imperial army was reinforced; Colonna died; and Lannoy, viceroy of Naples, ſucceeded him in the command: but the chief direction of military operations was committed to Bourbon and the marquis de Peſcara, the greateſt generals of their age. Bonnivet, deſtitute of troops to oppoſe this new army and ſtill more of the talents which could render him a match for its leaders, after various movements and encounters, was reduced to the neceſſity of attempting a retreat into France. He was followed by the imperial generals, and routed at Biagraſſa, where the famous chevalier Bayard was killed.

83 A French army enters Italy.

84 Defeated at Biagraſſa.

The emperor and his allies were leſs ſucceſsful in their attempts upon France. They were baffled in every quarter: and Francis, though ſtripped of his Italian dominions, might ſtill have enjoyed in ſafety the glory of having defended his native kingdom againſt one half of Europe, and have bid defiance to all his enemies; but underſtanding that the king of England, diſcouraged by his former fruitleſs enterpriſes, and diſguſted with the emperor, was making no preparations for any attempt on Picardy, his ancient ardour ſeized him for the conqueſt of Milan, and he determined, notwithſtanding the advanced ſeaſon, to march into Italy.

85 Francis determines to enter Italy in perſon.

The French army no ſooner appeared in Piedmont, than the whole Milaneſe was thrown into conſternation. The capital opened its gates. The forces of the emperor and Sforza retired to Lodi: and had Francis been ſo fortunate as to purſue them, they muſt have abandoned that poſt, and been totally diſperſed; but his evil genius led him to beſiege Pavia, a town of conſiderable ſtrength, well garriſoned, and defended by Antonio de Leyva, one of the braveſt officers in the Spaniſh ſervice; before which place he was defeated and taken priſoner on the twenty-fourth day of February 1524

86 Is defeated and taken priſoner at Pavia.

The captivity of Francis filled all Europe with alarm. Almoſt the whole French army was cut off; Milan was immediately abandoned; and in a few weeks not a Frenchman was left in Italy. The power of the emperor, and ſtill more his ambition, become an object of univerſal terror; and reſolutions were every where taken to ſet bounds to it. Meanwhile Francis, deeply impreſſed with a ſenſe of his misfortune, wrote to his mother Louiſa, whom he had left regent of the kingdom, the following ſhort but expreſſive letter: "All, Madam, is loſt but honour." The ſame courier that carried this letter, carried alſo diſpatches to Charles; who received the news of the ſignal and unexpected ſucceſs which had crowned his arms with the moſt hypocritical moderation. He would not ſuffer any public rejoicings to be made on account of it; and ſaid, he only valued it, as it would prove the occaſion of reſtoring peace to Chriſtendom. Louiſa, however, did not truſt to thoſe appearances; if ſhe could not preſerve what was yet left, ſhe determined at leaſt that nothing ſhould be loſt through her negligence or weakneſs. Inſtead of giving herſelf up to ſuch lamentations as were natural to a woman ſo remarkable for maternal tenderneſs, ſhe diſcovered all the foreſight, and exerted all the activity, of a conſummate politician. She took every poſſible meaſure for putting the kingdom in a poſture of defence, while ſhe employed all her addreſs to appeaſe the reſentment and to gain the friendſhip of England; and a ray of comfort from that quarter ſoon broke in upon the French affairs.

87 Hypocritical conduct of Charles.

Though Henry VIII. had not entered into the war againſt France from any concerted political views, he had always retained ſome imperfect idea of that balance of power which it was neceſſary to maintain between Charles and Francis; and the preſervation of which he boaſted to be his peculiar office. By his alliance with the emperor, he hoped to recover ſome part of thoſe territories on the continent which had belonged to his anceſtors; and therefore willingly contributed to give him the aſcendency above his rival; but having never dreamt of any event ſo deciſive and fatal as the victory at Pavia, which ſeemed not only to have broken, but to have annihilated the power of Francis, he now became ſenſible of his own danger, as well as that of all Europe, from the loſs of a proper counterpoiſe to the power of

Charles

Spain.

88 France assisted by Henry VIII.

Charles. Instead of taking advantage of the distressed condition of France, Henry therefore determined to assist her in her present calamities. Some disgusts also had taken place between him and Charles, and still more between Charles and Wolsey. The elevation of the cardinal of Medici to St Peter's chair, on the death of Adrian, under the name of Clement VII. had made the English minister sensible of the insincerity of the emperor's promises, while it extinguished all his hopes of the papacy; and he resolved on revenge. Charles, too, had so ill supported the appearance of moderation which he assumed, when first informed of his good fortune, that he had already changed his usual style to Henry; and instead of writing to him with his own hand, and subscribing himself "your affectionate son and cousin," he dictated his letters to a secretary, and simply subscribed himself "Charles." Influenced by all these motives, together with the glory of raising a fallen enemy, Henry listened to the flattering submissions of Louisa; entered into a defensive alliance with her as regent of France, and engaged to use his best offices in order to procure the deliverance of her son from a state of captivity.

89 Francis severely used by his conqueror.

Meanwhile Francis was rigorously confined; and severe conditions being proposed to him as the price of his liberty, he drew his dagger, and, pointing it at his breast, cried, "'Twere better that a king should die thus! His hand was with-held: and flattering himself, when he grew cool, that such propositions could not come directly from Charles, he desired that he might be removed to Spain, where the emperor then resided. His request was complied with; but he languished long before he obtained a sight of his conqueror. At last he was favoured with a visit; and the emperor dreading a general combination against him, or that Francis, as he threatened, might, in the obstinacy of his heart, resign his crown to the dauphin, agreed to abate somewhat of his former demands. A treaty was accordingly concluded at Madrid; in consequence of which Francis obtained his liberty. The chief article in this treaty was, that Burgundy should be restored to Charles as the rightful inheritance of his ancestors, and that Francis's two eldest sons should be immediately delivered up as hostages for the performance of the conditions stipulated. The exchange of the captive monarch for his children was made on the borders between France and Spain. The moment that Francis entered his own dominions, he mounted a Turkish horse, and putting it to its speed, waved his hand, and cried aloud several times, "I am yet a king! I am yet a king!"

90 Is at last released.

91 Refuses to execute the conditions of his release.

Francis never meant to execute the treaty of Madrid: he had even left a protest in the hands of notaries before he signed it, that his consent should be considered as an involuntary deed, and be deemed null and void. Accordingly, as soon as he arrived in France, he assembled the states of Burgundy, who protested against the article relative to their province; and Francis coldly replied to the imperial ambassadors, who urged the immediate execution of the treaty, that he would religiously perform the articles relative to himself, but in those affecting the French monarchy, he must be directed by the sense of the nation. He made the highest acknowledgments to the king of England for his friendly interposition, and offered to be entirely guided by his counsels. Charles and his ministers saw that they were over-reached in those very arts of negociation in which they so much excelled, while the Italian states observed with pleasure, that Francis was resolved not to execute a treaty which they considered as dangerous to the liberties of Europe. Clement absolved him from the oath which he had taken at Madrid; and the kings of France and England, the Pope, the Swiss, the Venetians, the Florentines, and the duke of Milan, entered into an alliance, to which they gave the name of the *Holy League*, because his Holiness was at the head of it, in order to oblige the emperor to deliver up Francis's two sons on the payment of a reasonable ransom, and to re-establish Sforza in the quiet possession of the Milanese.

Spain.

In consequence of this league, the confederate army took the field, and Italy once more became the scene of war. But Francis, who it was thought would have infused spirit and vigour into the whole body, had gone through such a scene of distress, that he was become diffident of himself, distrustful of his fortune, and desirous of tranquillity. He flattered himself, that the dread alone of such a confederacy would induce Charles to listen to what was equitable, and therefore neglected to send due reinforcements to his allies in Italy. Meantime the duke of Bourbon, who commanded the Imperialists, had made himself master of the whole Milanese of which the emperor had promised him the investiture; and his troops beginning to mutiny for want of pay, he led them to Rome, and promised to enrich them with the spoils of that city. He was as good as his word; for though he himself was slain in planting a scaling ladder against the walls, his soldiers, rather enraged than discouraged by his death, mounted to the assault with the utmost ardour, animated by the greatness of the prize, and, entering the city sword in hand, plundered it for several days.

92 Rome taken by the imperialists

93 And most cruelly plundered.

Never did Rome in any age suffer so many calamities, not even from the Barbarians, by whom she was often subdued, the Huns, Vandals, or Goths, as now from the subjects of a Christian and Catholic monarch. Whatever was respectable in modesty, or sacred in religion, seemed only the more to provoke the rage of the soldiery. Virgins suffered violation in the arms of their parents, and upon those altars to which they had fled for safety. Venerable prelates, after enduring every indignity and every torture, were thrown into dungeons, and menaced with the most cruel death, in order to make them reveal their secret treasures. Clement himself, who had neglected to make his escape in time, was taken prisoner, and found that the sacredness of his character could neither procure him liberty nor respect. He was confined till he should pay an enormous ransom imposed by the victorious army, and surrender to the emperor all the places of strength belonging to the church.

94 The Pope confined.

95 Shameful hypocrisy of Charles.

Charles received the news of this extraordinary event with equal surprise and pleasure; but in order to conceal his joy from his Spanish subjects, who were filled with horror at the insult offered to the sovereign pontiff, and to lessen the indignation of the rest of Europe, he expressed the most profound sorrow for the success of his arms. He put himself and his court into mourning; stopped the rejoicings for the birth of his son Philip, and ordered prayers to be put up in all the churches of Spain for the recovery of the pope's liberty, which

Spain.

which he could immediately have procured by a letter to his generals.

The concern expressed by Henry and Francis for the calamity of their ally was more sincere. Alarmed at the progress of the imperial arms, they had, even before the taking of Rome, entered into a closer alliance, and agreed to invade the Low Countries with a powerful army; but no sooner did they hear of the Pope's captivity, than they changed, by a new treaty, the scene of the projected war from the Netherlands to Italy, and resolved to take the most vigorous measures for restoring him to liberty. Henry, however, contributed only money. A French army entered Italy, under the command of Marshal Lautrec; Clement obtained his freedom; and war was for a time carried on by the confederates with success; but the death of Lautrec, and the revolt of Andrew Doria, a Genoese admiral in the service of France, entirely changed the face of affairs. The French army was utterly ruined; and Francis, discouraged and almost exhausted by so many unsuccessful enterprises, began to think of peace, and of obtaining the release of his sons by concessions, not by the terror of his arms.

96 A French army enters Italy, but is utterly ruined.

At the same time Charles, notwithstanding the advantages he had gained, had many reasons to wish for an accommodation. Sultan Solyman having over-run Hungary, was ready to break in upon the Austrian territories with the whole force of the East; and the progress of the Reformation in Germany threatened the tranquillity of the empire. In consequence of this situation of affairs, though pride made both parties conceal or dissemble their real sentiments, two ladies were permitted to restore peace to Europe. Margaret of Austria, Charles's aunt, and Louisa, Francis's mother, met in 1529 at Cambray, and settled the terms of accommodation between the French king and the emperor. Francis agreed to pay two millions of crowns as the ransom of his two sons, to resign the sovereignty of Flanders and Artois, and to forego all his Italian claims; and Charles ceased to demand the restitution of Burgundy.

97 Peace concluded at Cambray.

All the steps of this negociation had been communicated to the king of England; and Henry was, on that occasion, so generous to his friend and ally Francis, that he sent him an acquittal of near six hundred thousand crowns, in order to enable him to fulfil his agreement with Charles. But Francis's Italian confederates were less satisfied with the treaty of Cambray. They were almost wholly abandoned to the will of the emperor; and seemed to have no other means of security left but his equity and moderation. Of these, from his past conduct, they had not formed the most advantageous idea. But Charles's present circumstances, more especially in regard to the Turks, obliged him to behave with a generosity inconsistent with his character. The Florentines alone, whom he reduced under the dominion of the family of Medici, had reason to complain of his severity. Sforza obtained the investiture of Milan and his pardon; and every other power experienced the lenity of the conqueror.

98 Charles goes into Germany.

After having received the imperial crown from the hands of the Pope at Bologna, Charles proceeded on his journey to Germany, where his presence was become highly necessary; for although the conduct and valour of his brother Ferdinand, on whom he had conferred the hereditary dominions of the house of Austria, and who had been elected king of Hungary, had obliged Solyman to retire with infamy and loss, his return was to be feared, and the disorders of religion were daily increasing; an account of which, and of the emperor's transactions with the Protestants, is given under the article REFORMATION.

Charles having exerted himself as much as he could against the reformers, undertook his first expedition against the piratical states of Africa. Barbary, or that part of the African continent lying along the coast of the Mediterranean sea, was then nearly in the same condition which it is at present. Morocco, Algiers, and Tunis, were its principal states; and the two last were nests of pirates. Barbarossa, a famous Corsair, had succeeded his brother in the kingdom of Algiers, which he had formerly assisted him to usurp. He regulated with much prudence the interior police of his kingdom, carried on his piracies with great vigour, and extended his conquests on the continent of Africa; but perceiving that the natives submitted to his government with impatience, and fearing that his continual depredations would one day draw upon him a general combination of the Christian powers, he put his dominions under the protection of the grand seignior. Solyman, flattered by such an act of submission, and charmed with the boldness of the man, offered him the command of the Turkish fleet. Proud of this distinction, Barbarossa repaired to Constantinople, and made use of his influence with the sultan to extend his own dominion. Partly by force, partly by treachery, he usurped the kingdom of Tunis; and being now possessed of greater power, he carried on his depredations against the Christian states with more destructive violence than ever.

99 He undertakes an expedition against the state of Barbary.

Daily complaints of the piracies and ravages committed by the galleys of Barbarossa were brought to the emperor by his subjects, both in Spain and Italy; and all Christendom seemed to look up to him, as its greatest and most fortunate prince, for relief from this new and odious species of oppression. At the same time Muley Hascen, the exiled king of Tunis, finding none of the African princes able or willing to support him in recovering his throne, applied to Charles for assistance against the usurper. Equally desirous of delivering his dominions from the dangerous neighbourhood of Barbarossa, of appearing as the protector of an unfortunate prince, and of acquiring the glory annexed in that age to every expedition against the Mahometans, the emperor readily concluded a treaty with Muley Hascen, and set sail for Tunis with a formidable armament. The Goletta, a sea-port town, fortified with 300 pieces of cannon, was taken, together with all Barbarossa's fleet: he was defeated in a pitched battle, and 10,000 Christian slaves, having knocked off their fetters, and made themselves masters of the citadel, Tunis was preparing to surrender. But while Charles was deliberating on the conditions, his troops fearing that they would be deprived of the booty which they had expected, broke suddenly into the town, and pillaged and massacred without distinction. Thirty thousand persons perished by the sword, and 10,000 were made prisoners. The sceptre was restored to Muley Hascen, on condition that he should acknowledge himself a vassal of the crown of Spain, put into the emperor's hands all the fortified sea-ports in the kingdom of Tunis, and

10 Tunis taken, and the inhabitants cruelly massacred.

pay

pay annually 12,000 crowns for the subsistence of the Spanish garrison in the Goletta. These points being settled, and 20,000 Christian slaves freed from bondage either by arms or by treaty, Charles returned to Europe, where his presence was become necessary; while Barbarossa, who had retired to Bona, recovered new strength, and again became the tyrant of the ocean.

101 Francis attempts in vain to revive his pretensions to Italy.

The king of France took advantage of the emperor's absence to revive his pretensions in Italy. The treaty of Cambray had covered up but not extinguished the flames of discord. Francis in particular, who waited only for a favourable opportunity of recovering the territories and reputation which he had lost, continued to negotiate against his rival with different courts. But all his negociations were disconcerted by unforeseen accidents. The death of Clement VII. (whom he had gained by marrying his son the duke of Orleans, afterwards Henry II. to Catharine of Medici, the niece of that pontiff), deprived him of all the support which he hoped to receive from the court of Rome. The king of England, occupied with domestic cares and projects, declined engaging in the affairs of the continent; and the Protestant princes, associated by the league of Smalkalde, to whom Francis had also applied, and who seemed disposed at first to listen to him, filled with indignation and resentment at the cruelty with which some of their reformed brethren had been treated in France, refused to have any connection with the enemy of their religion.

Francis was neither cruel nor bigotted: he was too indolent to concern himself about religious disputes; but his principles becoming suspected, at a time when the emperor was gaining immortal glory by his expedition against the Infidels, he found it necessary to vindicate himself by some extraordinary demonstration of reverence for the established faith. The indiscreet zeal of some Protestant converts furnished him with the occasion. They had affixed to the gates of the Louvre and other public places papers containing indecent reflections on the rites of the Romish church. Six of the persons concerned in this rash action were seized; and the king, pretending to be struck with horror at their blasphemies, appointed a solemn procession, in order to avert the wrath of heaven. The holy sacrament was carried through the city of Paris in great pomp: Francis walked uncovered before it, bearing a torch in his hand; the princes of the blood supported the canopy over it; the nobles walked behind. In presence of this numerous assembly, the king declared, that if one of his hands were infected with heresy, he would cut it off with the other; "and I would sacrifice (added he) even my own children, if found guilty of that crime." As an awful proof of his sincerity, the six unhappy persons who had been seized were publicly burnt, before the procession was finished, and in the most cruel manner. They were fixed upon a machine which descended into the flames, and retired alternately, until they expired.—No wonder that the Protestant princes were incensed at such barbarity!

102 His barbarity to the Protestants

103 Causes an army march towards Italy.

But Francis, though unsupported by any ally, commanded his army to advance towards the frontiers of Italy, under pretence of chastising the duke of Milan for a breach of the law of nations, in putting to death his ambassador. The operations of war, however, soon took a new direction. Instead of marching directly to the Milanese, Francis commenced hostilities against the duke of Savoy, with whom he had cause to be dissatisfied, and on whom he had some claims; and before the end of the campaign, that feeble prince saw himself stripped of all his dominions, except the provinces of Piedmont. To complete his misfortunes, the city of Geneva, the sovereignty of which he claimed, and where the reformed opinions had already got footing, threw off his yoke; and its revolt drew along with it the loss of the adjacent territory. Geneva was then an imperial city, and has ever since remained entirely free.

104 Geneva throws off the yoke of the duke of Savoy.

In this extremity the duke of Savoy saw no resource but in the emperor's protection; and as his misfortunes were chiefly occasioned by his attachment to the imperial interest, he had a title to immediate assistance. But Charles, who was just returned from his African expedition, was not able to lend him the necessary support. His treasury was entirely drained, and he was obliged to disband his army till he could raise new supplies. Mean time the death of Sforza duke of Milan entirely changed the nature of the war, and afforded the emperor full leisure to prepare for action. The French monarch's pretext for taking up arms was at once cut off; but as the duke died without issue, all Francis's rights to the duchy of Milan, which he had yielded only to Sforza and his descendants, returned to him in full force. He instantly renewed his claim to it; and if he had ordered his army immediately to advance, he might have made himself master of it. But he unfortunately wasted his time in fruitless negotiations, while his more politic rival took possession of the duchy as a vacant fief of the empire; and though Charles seemed still to admit the equity of Francis's claim, he delayed granting the investiture under various pretences, and was secretly taking every possible measure to prevent him from regaining footing in Italy.

105 Charles takes possession of Milan.

During the time gained in this manner Charles had recruited his finances, and of course his armies; and finding himself in a condition for war, he at last threw off the mask under which he had so long concealed his designs from the court of France. Entering Rome with great pomp, he pronounced before the pope and cardinals, assembled in full consistory, a violent invective against Francis, by way of reply to his propositions concerning the investiture of Milan. Yet Francis, by an unaccountable fatality, continued to negotiate, as if it had been still possible to terminate their differences in an amicable manner; and Charles, finding him so eager to run into the snare, favoured the deception, and, by seeming to listen to his proposals, gained yet more time for the execution of his ambitious projects.

106 Weakness of Francis.

107 Charles attempts to subvert the French monarchy.

If misfortunes had rendered Francis too diffident, success had made Charles too sanguine. He presumed on nothing less than the subversion of the French monarchy; nay, he considered it as an infallible event. Having chased the forces of his rival out of Piedmont and Savoy, he pushed forward at the head of 50,000 men, contrary to the advice of his most experienced ministers and generals, to invade the southern provinces of France; while other two armies were ordered to enter it, the one on the side of Picardy, the other on the side of Champagne. He thought it impossible that Francis could resist so many unexpected attacks on such different quarters; but he found himself mistaken.

The French monarch fixed upon the most effectual plan

Spain

108 But is disappointed in his designs.

plan for defeating the invasion of a powerful enemy; and he prudently persevered in following it, though contrary to his own natural temper and to the genius of his people. He determined to remain altogether upon the defensive, and to deprive the enemy of subsistence by laying waste the country before them. The execution of this plan was committed to the mareschal Montmorency its author, a man happily fitted for such a trust by the inflexible severity of his disposition. He made choice of a strong camp, under the walls of Avignon, at the confluence of the Rhone and Durance, where he assembled a considerable army; while the king, with another body of troops, encamped at Valence, higher up the Rhone. Marseilles and Arles were the only towns he thought it necessary to defend; and each of these he furnished with a numerous garrison of his best troops. The inhabitants of the other towns were compelled to abandon their habitations: the fortifications of such places as might have afforded shelter to the enemy were thrown down; corn, forage, and provisions of every kind, were carried off or destroyed; the mills and ovens were ruined, and the wells filled up or rendered useless.

This devastation extended from the Alps to Marseilles, and from the sea to the confines of Dauphiny; so that the emperor, when he arrived with the van of his army on the confines of Provence, instead of that rich and populous country which he expected to enter, beheld nothing but one vast and desert solitude. He did not, however, despair of success, though he saw that he would have many difficulties to encounter; and as an encouragement to his officers, he made them liberal promises of lands and honours in France. But all the land which any of them obtained was a grave, and their master lost much honour by this rash and presumptuous enterprize. After unsuccessfully investing Marseilles and Arles, after attempting in vain to draw Montmorency from his camp at Avignon, and not daring to attack it, Charles having spent two inglorious months in Provence, and lost one half of his troops by disease or by famine, was under the necessity of ordering a retreat; and though he was some time in motion before the enemy suspected his intention, it was conducted with so much precipitation and disorder, as to deserve the name of a flight, since the light troops of France turned it into a perfect rout. The invasion of Picardy was not more successful: the imperial forces were obliged to retire without effecting any conquest of impo tance.

Charles had no sooner conducted the shattered remains of his army to the frontiers of Milan, than he set out for Genoa; and unwilling to expose himself to the scorn of the Italians after such a reverse of fortune, he embarked directly for Spain.

109 Violent animosity between him and Francis.

Meanwhile Francis gave himself up to that vain resentment which had formerly disgraced the prosperity of his rival. They had frequently, in the course of their quarrels, given each other the lie, and mutual challenges had been sent; which, though productive of no serious consequences between the parties, had a powerful tendency to encourage the pernicious practice of duelling. Charles, in his invective pronounced at Rome, had publicly accused Francis of perfidy and breach of faith; Francis now exceeded Charles in the indecency of his accusations. The Dauphin dying suddenly, his death was imputed to poison: Montecuculi his cup-bearer was put to the rack; and that unhappy nobleman, in the agonies of torture, accused the emperor's generals Gonzaga and de Leyva, of instigating him to the detestable act. The emperor himself was suspected; nay, this extorted confession, and some obscure hints, were considered as incontestable proofs of his guilt; though it was evident to all mankind, that neither Charles nor his generals could have any inducement to perpetrate such a crime, as Francis was still in the vigour of life himself, and had two sons besides the dauphin, grown up to a good age.

But the incensed monarch's resentment did not stop here. Francis was not satisfied with endeavouring to blacken the character of his rival by an ambiguous testimony which led to the most injurious suspicions, and upon which the most cruel constructions had been put; he was willing to add rebellion to murder. For this purpose he went to the parliament of Paris; where being seated with the usual solemnities, the advocate-general appeared, and accused Charles of Austria (so he affected to call the emperor) of having violated the treaty of Cambray, by which he was freed from the homage due to the crown of France for the counties of Artois and Flanders; adding, that this treaty being now void, he was still to be considered as a vassal of France, and consequently had been guilty of rebellion

110 Charles summoned to appear at Paris.

in taking arms against his sovereign. The charge was sustained, and Charles was summoned to appear before the parliament of Paris at a day fixed. The term expired; and no person appearing in the emperor's name, the parliament gave judgment, and Charles of Austria had forfeited, by rebellion and contumacy, the counties of Flanders and Artois, and declared these fiefs reunited to the crown of France.

Francis, soon after this vain display of his animosity, marched into the Low Countries, as if he had intended to execute the sentence pronounced by his parliament; but a suspension of arms took place, through the interposition of the queens of France and Hungary, before any thing of consequence was effected: and this cessation of hostilities was followed by a truce, concluded at Nice, through the mediation of the reigning pontiff Paul III. of the family of Farnese, a man of a venerable character and pacific disposition.

111 Francis leagues with the Turks.

Each of these rival princes had strong reasons to incline them to peace. The finances of both were exhausted; and the emperor, the most powerful of the two, was deeply impressed with the dread of the Turkish arms, which Francis had drawn upon him by a league with Solyman. In consequence of this league, Barbarossa with a great fleet appeared on the coast of Naples; filled that kingdom with consternation; landed without resistance near Taranto; obliged Castro, a place of some strength, to surrender; plundered the adjacent country; and was taking measures for securing and extending his conquests, when the unexpected arrival of Doria, the famous Genoese admiral, together with the pope's galleys and a squadron of the Venetian fleet, made it prudent for him to retire. The sultan's forces also invaded Hungary, where Mahmet the Turkish general, after gaining several inferior advantages, defeated the Germans in a great battle at Essek on the Drave. Happily for Charles and Europe it was not in Francis's power at this juncture either to join the Turks or assemble

Spain.

semble an army strong enough to penetrate into the Milanese. The emperor, however, was sensible that he could not long resist the efforts of two such powerful confederates, nor expect that the same fortunate circumstances would concur a second time in his favour; he therefore thought it necessary, both for his safety and reputation, to give his consent to a truce: and Francis chose rather to run the risk of disobliging his new ally the sultan, than to draw on his head the indignation, and perhaps the arms, of all Christendom, by obstinately obstructing the re-establishment of tranquillity, and contributing to the agrandizement of the Infidels.

112 A truce concluded.

These considerations inclined the contending monarchs to listen to the arguments of the holy father; but he found it impossible to bring about a final accommodation between them, each inflexibly persisting in asserting his own claims. Nor could he prevail on them to see one another, though both came to the place of rendezvous: so great was the remains of distrust and rancour, or such the difficulty of adjusting the ceremonial! Yet, improbable as it may seem, a few days after signing the truce, the emperor, in his passage to Barcelona, being driven on the coast of Provence, Francis invited him to come ashore; frankly visited him on board his galley, and was received and entertained with the warmest demonstrations of esteem and affection. Charles, with an equal degree of confidence, paid the king next day a visit at Aigues-mortes; where these two hostile rivals and vindictive enemies, who had accused each other of every kind of baseness, conversing together with all the cordiality of brothers, seemed to vie with each other in expressions of respect and friendship.

113 Interview between Francis and Charles.

114 Advantage gained by the pope from this pacification

Besides the glory of having restored tranquillity to Europe, the pope gained a point of much consequence to his family. He obtained for his grandson, Margaret of Austria, the emperor's natural daughter, formerly wife of Alexander de Medici, whom Charles had raised to the supreme power in Florence. Lorenzo de Medici, the kinsman and intimate companion of Alexander, had assassinated him by one of the blackest treasons recorded in history. Under pretence of having secured him an assignation with a lady of the highest rank and great beauty, he drew him into a secret apartment of his house, and there stabbed him as he lay carelessly on a couch, expecting the embrace of the lovely fair, whom he had often solicited in vain. Lorenzo, however, did not reap the fruits of his crime; for though some of his countrymen extolled him as a third Brutus, and endeavoured to seize this occasion for recovering their liberties, the government of Florence passed into the hands of Cosmo II. another kinsman of Alexander. Cosmo was desirous of marrying the widow of his predecessor; but the emperor chose rather to oblige the pope, by bestowing his daughter upon Octavio Farnese, son of the duke of Parma.

115 Charles distressed.

Charles had soon farther cause to be sensible of his obligations to the holy father for bringing about the treaty of Nice. His troops everywhere mutinied for want of pay, and the ability of his generals only could have prevented a total revolt. He had depended, as his chief resource for discharging the arrears due to his soldiers, upon the subsidies which he expected from his Castilian subjects. For this purpose he assembled the Cortes of Castile at Toledo; and having represented to them the great expence of his military operations, he proposed to levy such supplies as the present exigency of affairs demanded, by a general excise on commodities; but the Spaniards, who already felt themselves oppressed by a load of taxes unknown to their ancestors, and who had often complained that their country was drained of its wealth and inhabitants, in order to prosecute quarrels in which they had no interest, determined not to add voluntarily to their own burdens. The nobles, in particular, inveighed with great vehemence against the imposition proposed, as an encroachment on the valuable and distinguishing privilege of their order, that of being exempted from the payment of any tax. After employing arguments and promises in vain, Charles dismissed the assembly with indignation; and from that period neither the nobles nor the prelates have been called to the Cortes, on pretence that such as pay no part of the public taxes should not claim a vote in laying them on. These assemblies have since consisted merely of the procurators or representatives of 18 cities, two from each; in all 36 members, who are absolutely at the devotion of the crown.

116 The Spaniards refuse to assist him with money.

117 Inhabitants of Ghent rebel.

The citizens of Ghent, still more bold, broke out not long after into open rebellion against the emperor's government, on account of a tax which they judged contrary to their ancient privileges, and a decision of the council of Mechlin in favour of the imperial authority. Enraged at an unjust imposition, and rendered desperate on seeing their rights betrayed by that very court which was bound to protect them, they flew to arms, seized several of the emperor's officers, and drove such of the nobility as resided among them out of the city. Sensible, however, of their inability to support what their zeal had prompted them to undertake, and desirous of securing a protector against the formidable forces with which they might expect soon to be attacked, they offered to acknowledge the king of France as their sovereign, to put him into immediate possession of their city, and to assist him in recovering those provinces in the Netherlands which had anciently belonged to his crown. True policy directed Francis to comply with this proposal. The counties of Flanders and Artois were more valuable than the duchy of Milan, for which he had so long contended; and their situation in regard to France made it more easy to conquer or to defend them. But Francis over-rated the Milanese. He had lived in friendship with the emperor ever since their interview at Aigues-mortes, and Charles had promised him the investiture of that duchy. Forgetting, therefore, all his past injuries, and the deceitful promises by which he had been so often duped, the credulous, generous Francis, not only rejected the propositions of the citizens of Ghent, but communicated to the emperor his whole negociation with the malecontents.

118 Extreme credulity of Francis

Judging of Charles's heart by his own, Francis hoped by this seemingly disinterested proceeding to obtain at once the investiture of Milan; and the emperor, well acquainted with the weakness of his rival, flattered him in this apprehension, for his own selfish purposes. His presence being necessary in the Netherlands, he demanded a passage through France. It was immediately granted him; and Charles, to whom every moment was precious, set out, notwithstanding the remonstrances of his council and the fears of his Spanish subjects, with a small

119 He allows Charles to pass thro' his dominions.

small but splendid train of 100 persons. He was met on the frontiers of France by the dauphin and the duke of Orleans, who offered to go into Spain, and remain there as hostages, till he should reach his own dominions; but Charles replied, that the king's honour was sufficient for his safety, and prosecuted his journey without any other security. The king entertained him with the utmost magnificence at Paris, and the two young princes did not take leave of him till he entered the Low Countries; yet he still found means to evade his promise, and Francis continued to believe him sincere.

120
Severity of Charles to the city of Ghent.

The citizens of Ghent, alarmed at the approach of the emperor, who was joined by three armies, sent ambassadors to implore his mercy, and offered to throw open their gates. Charles only condescended to reply, "That he would appear among them as a sovereign and a judge, with the sceptre and the sword." He accordingly entered the place of his nativity on the anniversary of his birth; and instead of that lenity which might have been expected, exhibited an awful example of his severity. Twenty-six of the principal citizens were put to death; a greater number were banished; the city was declared to have forfeited its privileges; a new system of laws and political administration was prescribed; and a large fine was imposed on the inhabitants, in order to defray the expence of erecting a citadel, together with an annual tax for the support of a garrison. They were not only despoiled of their ancient immunities, but made to pay, like conquered people, for the means of perpetuating their own slavery.

121
His base treatment of Francis.

Having thus re-established his authority in the Low Countries, and being now under no necessity of continuing that scene of falsehood and dissimulation with which he had amused the French monarch, Charles began gradually to throw aside the veil under which he had concealed his intentions with respect to the Milanese, and at last peremptorily refused to give up a territory of such value, or voluntarily to make such a liberal addition to the strength of an enemy by diminishing his own power. He even denied that he had ever made any promise which could bind him to an action so foolish, and so contrary to his own interest.

This transaction exposed the king of France to as much scorn as it did the emperor to censure. The credulous simplicity of Francis seemed to merit no other return, after experiencing so often the duplicity and artifices of his rival. He remonstrated, however, and exclaimed as if this had been the first circumstance in which the emperor had deceived him. The insult offered to his understanding affected him even more sensibly than the injury done to his interest; and he discovered such resentment as made it obvious that he would seize on the first opportunity of revenge, and that a new war would soon desolate the European continent.

122
He is obliged to make concessions to the Protestants.

Meanwhile Charles was obliged to turn his attention towards the affairs of Germany. The Protestants having in vain demanded a general council, pressed him earnestly to appoint a conference between a select number of divines of each party, in order to examine the points in dispute. For this purpose a diet was assembled at Ratisbon: and such a conference, notwithstanding the opposition of the pope, was held with great solemnity in the presence of the emperor. But the divines chosen to manage the controversy, though men of learning and moderation, were only able to settle a few speculative opinions, all points relative to worship and jurisdiction serving to inflame the minds of the disputants. Charles, therefore, finding his endeavours to bring about an accommodation ineffectual, and being impatient to close the diet, prevailed on a majority of the members to approve of the following edict of recess; viz. that the articles concerning which the divines had agreed, should be held as points decided; that those about which they had differed, should be referred to the determination of a general council, or if that could not be obtained, to a national synod; and should it prove impracticable also to assemble a synod of Germany, that a general diet of the empire should be called within 18 months, in order to give final judgment on the whole controversy; that, in the mean time, no innovations should be attempted, nor any endeavours employed to gain proselytes.

This diet gave great offence to the pope. The bare mention of allowing a diet, composed chiefly of laymen, to pass judgment in regard to articles of faith, appeared to him no less criminal and profane than the worst of those heresies which the emperor seemed so zealous to suppress. The Protestants also were dissatisfied with it, as it considerably abridged the liberty which they at that time enjoyed. They murmured loudly against it; and Charles, unwilling to leave any seeds of discontent in the empire, granted them a private declaration, exempting them from whatever they thought injurious or oppressive in the recess, and ascertaining to them the full possession of all their former privileges.

The situation of the emperor's affairs at this juncture made these extraordinary concessions necessary. He foresaw a rupture with France to be unavoidable, and he was alarmed at the rapid progress of the Turks in Hungary. A great revolution had happened in that kingdom. John Zapol Scæpus, by the assistance of Solyman, had wrested from the king of the Romans a considerable part of the country. John died, and left an infant son. Ferdinand attempted to take advantage of the minority, in order to repossess himself of the whole kingdom; but his ambition was disappointed by the activity and address of George Martinuzzi, bishop of Waradin, who shared the regency with the queen. Sensible that he was unable to oppose the king of the Romans in the field, Martinuzzi satisfied himself with holding out the fortified towns, all of which he provided with every thing necessary for defence; and at the same time he sent ambassadors to Solyman, beseeching him to extend towards the son that imperial protection which had so generously maintained the father on his throne. Ferdinand used his utmost endeavours to thwart this negociation, and even meanly offered to hold the Hungarian crown on the same ignominious condition by which John had held it, that of paying tribute to the Porte. But the sultan saw such advantages from espousing the interest of the young king, that he instantly marched into Hungary; and the Germans, having formed the siege of Buda, were defeated with great slaughter before that city. Solyman, however, instead of becoming the protector of the infant sovereign whom he had relieved, made use of this success to extend his own dominions: he sent the queen and her son into Transilvania, which province he allotted them, and added Hungary to the Otteman empire.

Happily

Spain.

Happily for the Protestants, Charles received intelligence of this revolution soon after the diet at Ratisbon; and by the concessions which he made them, he obtained such liberal supplies, both of men and money, as left him under little anxiety about the security of Germany. He therefore hastened to join his fleet and army in Italy, in order to carry into execution a great and favourite enterprize which he had concerted against Algiers: though it would certainly have been more consistent with his dignity to have conducted the whole force of the empire against Solyman, the common enemy of Christendom, who was ready to enter his Austrian dominions. But many reasons induced Charles to prefer the African expedition: he wanted strength, or at least money to combat the Turks in so distant a country as Hungary; and the glory which he had formerly acquired in Barbary led him to hope for the like success, while the cries of his Spanish subjects roused him to take vengeance on their ravagers. But the unfortunate event of this expedition has already been related under the article ALGIERS, n° 14—20.

123 Undertakes an unsuccessful expedition against Algiers.

124 War between Francis and Charles.

The loss which the emperor suffered in this calamitous expedition encouraged the king of France to begin hostilities, on which he had been for some time resolved; and an action dishonourable to civil society furnished him with too good a pretext for taking arms. The marquis del Guasto, governor of the Milanese, having got intelligence of the motions and destination of two ambassadors, Rincon and Fergoso, whom Francis had dispatched, the one to the Ottoman Porte, the other to the republic of Venice; knowing how much his master wished to discover the intentions of the French monarch, and of what consequence it was to retard the execution of his measures, he employed some soldiers belonging to the garrison of Pavia to lie in wait for these ambassadors as they sailed down the Po, who murdered them and most of their attendants, and seized their papers. Francis immediately demanded reparation for this barbarous outrage; and as Charles endeavoured to put him off with an evasive answer, he appealed to all the courts of Europe, setting forth the heinousness of the injury, the iniquity of the emperor in disregarding his just request, and the necessity of vengeance. But Charles, who was a more profound negotiator, defeated in a great measure the effects of these representations: he secured the fidelity of the Protestant princes in Germany, by granting them new concessions; and he engaged the king of England to espouse his cause, under pretence of defending Europe against the Infidels; while Francis was only able to form an alliance with the kings of Denmark and Sweden (who for the first time interested themselves in the quarrels of the more potent monarchs of the south), and to renew his treaty with Solyman, which drew on him the indignation of Christendom.

But the activity of Francis supplied all the defects of his negotiation. Five armies were soon ready to take the field, under different generals, and with different destinations. Nor was Charles wanting in his preparations. He and Henry a second time made an ideal division of the kingdom of France. But as the hostilities which followed terminated in nothing decisive, and were distinguished by no remarkable event, except the battle of Cerisoles (gained by count d'Enguien over the imperialists, and in which 10,000 of the emperor's best troops fell), at last Francis and Charles, mutually tired of harassing each other, concluded at Crespy a treaty of peace, in which the king of England was not mentioned; and from being implacable enemies, became once more, to appearance, cordial friends, and even allies by the ties of blood.

125 Peace concluded at Crespy.

The chief articles of this treaty were, that all the conquests which either party had made since the truce of Nice should be restored; that the emperor should give in marriage to the duke of Orleans, either his own eldest daughter, with the Low Countries, or the second daughter of his brother Ferdinand, with the investiture of the Milanese; that Francis should renounce all pretensions to the kingdom of Naples, as well as to the sovereignty of Flanders and Artois, and Charles give up his claim to the duchy of Burgundy; and that both should unite in making war against the Turks.

The emperor was chiefly induced to grant conditions so advantageous to France, by a design of humbling the Protestant princes in Germany. With the papal jurisdiction, he foresaw they would endeavour to throw off the imperial authority; and he determined to make his zeal for the former a pretence for enforcing and extending the latter. However, the death of the duke of Orleans before the consummation of his marriage disentangled the emperor from the most troublesome stipulation in the treaty of Crespy; and the French monarch, being still engaged in hostilities with England, was unable to obtain any reparation for the loss which he suffered by this unforeseen event. These hostilities, like those between Charles and Francis, terminated in nothing decisive. Equally tired of a struggle attended with no glory or advantage to either, the contending princes concluded, at Campe, near Ardies, a treaty of peace; in which it was stipulated, that France should pay the arrears due by former treaties to England. But these arrears did not exceed one-third of the sums expended by Henry on his military operations; and Francis being in no condition to discharge them, Boulogne (a chargeable pledge) was left in the hands of the English as a security for the debt.

126 Charles obliged to conclude a disadvantageous peace with the Turks and Protestants.

In consequence of the emperor's resolution to humble the Protestant princes, he concluded a dishonourable peace with the Porte, stipulating that his brother Ferdinand should pay tribute for that part of Hungary which he still possessed; while the sultan enjoyed the imperial and undisturbed possession of all the rest. At the same time he entered into a league with pope Paul III. for the extirpation of heresy; but in reality with a view to oppress the liberties of Germany. Here, however, his ambition met with a severe check; for though he was successful at first, he was obliged in 1552 to conclude a peace with the Protestants on their own terms; as has been related under the article REFORMATION, n° 26—32.

127 Attempts to recover some of his provinces.

By the peace concluded on this occasion the emperor lost Metz, Toul, and Verdun, which had formed the barrier of the empire on that quarter; and therefore soon after put himself at the head of an army, in order to recover these three bishoprics. In order to conceal the destination of his army, he gave out, that he intended to lead it into Hungary, to second Maurice in his operations against the Infidels; and as that pretext failed him, when he began to advance towards the Rhine, he propagated a report that he was marching

fi ft

Spain.

first to chastise Albert of Brandenburgh, who had refused to be included in the treaty of Passau, and whose cruel exactions in that part of Germany called loudly for redress.

The French, however, were not deceived by these arts. Henry immediately guessed the true object of Charles's armament, and resolved to defend his conquests with vigour. The defence of Metz, against which it was foreseen the whole weight of the war would be turned, was committed to Francis of Lorraine, duke of Guise, who possessed in an eminent degree all the qualities that render men great in military command. He repaired with joy to the dangerous station; and many of the French nobility, and even princes of the blood, eager to distinguish themselves under such a leader, entered Metz as volunteers. The city was of great extent, ill fortified, and the suburbs large. For all these defects the duke endeavoured to provide a remedy. He repaired the old fortifications with all possible expedition, labouring with his own hands; the officers imitated his example; and the soldiers, thus encouraged, cheerfully submitted to the most severe toils; he erected new works, and he levelled the suburbs with the ground. At the same time he filled the magazines with provisions and military stores, compelled all useless persons to leave the place, and laid waste the neighbouring country; yet such were his popular talents, as well as his arts of acquiring an ascendant over the minds of men, that the citizens not only refrained from murmuring, but seconded him with no less ardour than the soldiers in all his operations—in the ruin of their estates, and in the havock of their public and private buildings.

128 Is obliged to raise the siege of Metz.

Meanwhile the emperor continued his march towards Lorraine, at the head of 60,000 men. On his approach Albert of Brandenburgh, whose army did not exceed 20,000, withdrew into that principality, as if he intended to join the French king; and Charles, notwithstanding the advanced season, it being towards the end of October, laid siege to Metz, contrary to the advice of his most experienced officers.

The attention of both the besiegers and the besieged was turned for some time towards the motions of Albert, who still hovered in the neighbourhood, undetermined which side to take, though resolved to sell his service. Charles at last came up to his price, and he joined the imperial army. The emperor now flattered himself that nothing could resist his force; but he found himself deceived. After a siege of almost 60 days, during which he had attempted all that was thought possible for art or valour to effect, and had lost upwards of 30,000 men by the inclemency of the weather, diseases, or the sword of the enemy, he was obliged to abandon the enterprise.

129 Miserable condition of his army.

When the French sallied out to attack the enemy's rear, the imperial camp was filled with the sick and wounded, with the dead and the dying. All the roads by which the army retired were strewed with the same miserable objects; who, having made an effort beyond their strength to escape, and not being able to proceed, were left to perish without assistance. Happily that, and all the kind offices which their friends had not the power to perform, they received from their enemies. The duke of Guise ordered them all to be taken care of, and supplied with every necessary; he appointed physicians to attend, and direct what treatment was proper for the sick and wounded, and what refreshments for the feeble; and such as recovered he sent home, under an escort of soldiers, and with money to bear their charges. By these acts of humanity, less common in that age, the duke of Guise completed that heroic character which he had justly acquired by his brave and successful defence of Metz.

130 His further misfortunes.

The emperor's misfortunes were not confined to Germany. During his residence at Villach, he had been obliged to borrow 200,000 crowns of Cosmo de Medici; and so low was his credit, that he was obliged to put Cosmo in possession of the principality of Piombino as a security for that inconsiderable sum; by which means he lost the footing he had hitherto maintained in Tuscany. Much about the same time he lost Sienna. The citizens, who had long enjoyed a republican government, rose against the Spanish garrison, which they had admitted as a check upon the tyranny of the nobility, but which they found was meant to enslave them; forgetting their domestic animosities, they recalled the exiled nobles; they demolished the citadel, and put themselves under the protection of France.

To these unfortunate events one still more fatal had almost succeeded. The severe administration of the viceroy of Naples had filled that kingdom with murmuring and dissatisfaction. The prince of Salerno, the head of the malecontents, fled to the court of France. The French monarch, after the example of his father, applied to the grand signior; and Solyman, at that time highly incensed against the house of Austria on account of the proceedings in Hungary, sent a powerful fleet into the Mediterranean, under the command of the corsair Dragut, an officer trained up under Barbarossa, and scarce inferior to his master in courage, talents, or in good fortune. Dragut appeared on the coast of Calabria at the time appointed; but not being joined by the French fleet according to concert, he returned to Constantinople, after plundering and burning several places, and filling Naples with consternation.

131 Is successful in the Low Countries.

Highly mortified by so many disasters, Charles retired into the Low Countries, breathing vengeance against France: and here the war was carried on with considerable vigour. Impatient to efface the stain which his military reputation had received before Metz, Charles laid siege to Terouane; and the fortifications being in disrepair, that important place was carried by assault. Heslin also was invested, and carried in the same manner. The king of France was too late in assembling his forces to afford relief to either of these places; and the emperor afterwards cautiously avoided an engagement.

132 But not so in other places.

The imperial arms were less successful in Italy. The viceroy of Naples failed in an attempt to recover Sienna; and the French not only established themselves more firmly in Tuscany, but conquered part of the island of Corsica. Nor did the affairs of the house of Austria go on better in Hungary during the course of this year. Isabella and her son appeared once more in Transylvania, at a time when the people were ready for revolt, in order to revenge the death of Martinuzzi, whose loss they had severely felt. Some noblemen of eminence declared in favour of the young king; and the bashaw of Belgrade, by Solyman's order, espousing his cause, in in opposition to Ferdinand, Castaldo, the Austrian general, was obliged to abandon Transylvania to Isabella and the Turks.

133 Marriage between Philip of Spain and Mary of England.

In order to counterbalance these and other losses, the emperor, in 1554, concerted a marriage between his son Philip and Mary of England, in hopes of adding that kingdom to his other dominions. Meanwhile the war between Henry and Charles was carried on with various success in the Low Countries, and in Italy much to the disadvantage of France. The French, under the command of Strozzi, were defeated in the battle of Merciano; Sienna was reduced by Medicino, the Florentine general, after a siege of ten months; and the gallant Sienese were subjected to the Spanish yoke. Much about the same time a plot was formed by the Franciscans, but happily discovered before it could be carried into execution, to betray Metz to the Imperialists. The father-guardian, and twenty other monks, received sentence of death on account of this conspiracy; but the guardian, before the time appointed for his execution, was murdered by his incensed accomplices, whom he had seduced; and six of the youngest were pardoned.

While war thus raged in Italy and the Low Countries, Germany enjoyed such profound tranquillity, as afforded the diet full leisure to confirm and perfect the plan of religious pacification agreed upon at Passau and referred to the consideration of the next meeting of the Germanic body. During the negotiation of this treaty, an event happened which astonished all Europe,

134 Charles resigns his dominions to his son Philip.

and confounded the reasonings of the wisest politicians. The emperor Charles V. though no more than 56, an age when objects of ambition operate with full force on the mind, and are generally pursued with the greatest ardour, had for some time formed the resolution of resigning his hereditary dominions to his son Philip. He now determined to put it in execution. Various have been the opinions of historians concerning a resolution so singular and unexpected; but the most probable seem to be, the disappointments which Charles had met with in his ambitious hopes, and the daily decline of his health. He had early in life been attacked with the gout; and the fits were now become so frequent and severe, that not only the vigour of his constitution was broken, but the faculties of his mind were sensibly impaired. He therefore judged it more decent to conceal his infirmities in some solitude, than to expose them any longer to the public eye; and as he was unwilling to forfeit the fame, or lose the acquisitions of his better years, by attempting to guide the reins of government when he was no longer able to hold them with steadiness, he determined to seek in the tranquillity of retirement, that happiness which he had in vain pursued amidst the tumults of war and the intrigues of state.

In consequence of this resolution, Charles, who had already ceded to his son Philip the kingdom of Naples and the duchy of Milan, assembled the states of the Low Countries at Brussels; and seating himself for the last time in the chair of state, he explained to his subjects the reasons of his resignation, and solemnly devolved his authority upon Philip. He recounted with dignity, but without ostentation, all the great things which he had undertaken and performed since the commencement of his administration. "I have dedicated (observed he), from the 17th year of my age, all my thoughts and attention to public objects, reserving no portion of my time for the indulgence of ease, and very little for the enjoyment of private pleasure. Either in a pacific or hostile manner, I have visited Germany nine times, Spain six times, France four times, Italy seven times, the Low Countries ten times, England twice, Africa as often; and while my health permitted me to discharge the duty of a sovereign, and the vigour of my constitution was equal in any degree to the arduous office of governing such extensive dominions, I never shunned labour, nor repined under fatigue; but now, when my health is broken, and my vigour exhausted by the rage of an incurable distemper, my growing infirmities admonish me to retire; nor am I so fond of reigning, as to retain the sceptre in an impotent hand, which is no longer able to protect my subjects. Instead of a sovereign worn out with diseases (continued he), and scarce half alive, I give you one in the prime of life, already accustomed to govern, and who adds to the vigour of youth all the attention and sagacity of maturer years." Then turning towards Philip, who fell on his knees, and kissed his father's hand, "It is in your power (said Charles), by a wise and virtuous administration, to justify the extraordinary proof which I give this day of my paternal affection, and to demonstrate that you are worthy of the extraordinary confidence which I repose in you. Perserve (added he) an inviolable regard for religion; maintain the Catholic faith in its purity; let the laws of your country be sacred in your eyes; encroach not on the rights of your people; and if the time should ever come when you shall wish to enjoy the tranquillity of private life, may you have a son to whom you can resign your sceptre with as much satisfaction as I give up mine to you." A few weeks after, he resigned to Philip the sovereignty of Spain and America; reserving nothing to himself out of all these vast possessions but an annual pension of 100,000 crowns.

Charles was now impatient to embark for Spain, where he had fixed on a place of retreat; but by the advice of his physicians, he put off his voyage for some months, on account of the severity of the season; and, by yielding to their judgment, he had the satisfaction before he left the Low Countries of taking a considerable step towards a peace with France. This he ardently longed for; not only on his son's account, whose administration he wished to commence in quietness, but that he might have the glory, when quitting the world, of restoring to Europe that tranquillity which his ambition had banished out of it almost from the time that he assumed the reins of government.

The great bar to such a pacification, on the part of France, was the treaty which Henry had concluded with the Pope; and the emperor's claims were too numerous to hope for adjusting them suddenly. A truce of five years was therefore proposed by Charles; during which term, without discussing their respective pretensions, each should retain what was in his possession; and Henry, through the persuasion of the constable Montmorency, who represented the imprudence of sacrificing the true interests of his kingdom to the rash engagements that he had come under with Paul, authorised his ambassadors to sign at Vaucelles a treaty, which

135 A truce of five years concluded with France.

Spain.

which would insure to him for so considerable a period the important conquest which he had made on the German frontier, together with the greater part of the duke of Savoy's dominions.

The Pope, when informed of this transaction, was no less filled with terror and astonishment than rage and indignation. But he took equal care to conceal his fear and his anger. He affected to approve highly of the truce; and he offered his mediation, as the common father of Christendom, in order to bring about a definitive peace. Under this pretext, he appointed cardinal Rebibo his nuncio to the court of Brussels, and his nephew cardinal Caraffa to that of Paris. The public instructions of both were the same; but Caraffa, besides these, received a private commission, to spare neither intreaties, promises, nor bribes, in order to induce the French monarch to renounce the truce and renew his engagements with the holy see. He flattered Henry with the conquest of Naples; he gained by his address the Guises, the queen, and even the famous Diana of Poictiers, duchess of Valentinois, the king's mistress; and they easily swayed the king himself, who already leaned to that side towards which they wished to incline him. All Montmorency's prudent remonstrances were disregarded; the nuncio (by powers from Rome) absolved Henry from his oath of truce; and that weak prince signed a new treaty with the Pope; which rekindled with fresh violence the flames of war, both in Italy and the Low Countries.

136 Quarrel between the pope and king Philip.

No sooner was Paul made acquainted with the success of this negotiation than he proceeded to the most indecent extremities against Philip. He ordered the Spanish ambassador to be imprisoned; he excommunicated the Colonnas, because of their attachment to the imperial house; and he considered Philip as guilty of high treason, and to have forfeited his right to the kingdom of Naples, which he was supposed to hold of the holy see, for afterward affording them a retreat in his dominions.

Alarmed at a quarrel with the Pope, whom he had been taught to regard with the most superstitious veneration, as the vicegerent of Christ and the common father of Christendom, Philip tried every gentle method before he made use of force. He even consulted some Spanish divines on the lawfulness of taking arms against a person so sacred. They decided in his favour; and Paul continuing inexorable, the duke of Alva, to whom the negotiations as well as the war had been committed, entered the ecclesiastical state at the head of 10,000 veterans, and carried terror to the gates of Rome.

The haughty pontiff, though still inflexible and undaunted in himself, was forced to give way to the fears of the cardinals, and a truce was concluded for 40 days. Mean time the duke of Guise arriving with a supply of 20,000 French troops, Paul became more arrogant than ever, and banished all thoughts from his mind but those of war and revenge. The duke of Guise, however, who had precipitated his country into this war, chiefly from a desire of gaining a field where he might display his own talents, was able to perform nothing in Italy worthy of his former fame. He was obliged to abandon the siege of Civetella; he could not bring the duke of Alva to a general engagement; his army perished by diseases; and the Pope neglected to furnish the necessary reinforcements. He begged to be recalled; and France stood in need of his abilities.

Philip, though willing to have avoided a rupture, was no sooner informed that Henry had violated the truce of Vaucelles, than he determined to act with such vigour, as should convince Europe that his father had not erred in resigning to him the reins of government. He immediately assembled in the Low Countries a body of 50,000 men, and obtained a supply of 10,000 from England, which he had engaged in his quarrel; and as he was not ambitious of military fame, he gave the command of his army to Emanuel Philibert duke of Savoy, one of the greatest generals of that warlike age.

The duke of Savoy kept the enemy for some time in suspense with regard to his destination; at last he seemed to threaten Champagne; towards which the French drew all their troops; then turning suddenly to the right, he advanced by rapid marches into Picardy, and laid siege to St Quintin. It was deemed in those times a town of considerable strength; but the fortifications had been much neglected, and the garrison did not amount to a fifth part of the number requisite for its defence: it must therefore have surrendered in a few days, if the admiral de Coligny had not taken the gallant resolution of throwing himself into it with such a body of men as could be collected on a sudden. This he effected in spite of the enemy, breaking through their main body. The place, however, was closely invested; and the constable Montmorency, anxious to extricate his nephew out of that perilous situation, in which his zeal for the public had engaged him, as well as to save a town of such importance, rashly advanced to its relief with forces one half inferior to those of the enemy. His army was cut in pieces, and he himself made prisoner. 137 The French entirely defeated at St Quintin.

The cautious temper of Philip on this occasion saved France from devastation, if not ruin. The duke of Savoy proposed to overlook all inferior objects, and march speedily to Paris, which, in its present consternation, he could not have failed to make himself master of; but Philip, afraid of the consequences of such a bold enterprise, desired him to continue the siege of St Quintin, in order to secure a safe retreat in case of any disastrous event. The town, long and gallantly defended by Coligny, was at last taken by storm; but not till France was in a state of defence.

Philip was now sensible that he had lost an opportunity which could never be recalled, of distressing his enemy, and contented himself with reducing Horn and Catelet; which petty towns, together with St Quintin, were the sole fruits of one of the most decisive victories gained in the 16th century. The Catholic king, however, continued in high exultation on account of his success; and as all his passions were tinged with superstition, he vowed to build a church, a monastery, and a palace, in honour of St Laurence, on the day sacred to whose memory the battle of St Quintin had been fought. He accordingly laid the foundation of an edifice, in which all these were included, and which he continued to forward at vast expence, for 22 years. The same principle which dictated the vow dictated the building. It was so formed as to resemble a gridiron—on which culinary instrument, according to the legendary tale,

Spain.

St Laurence had suffered martyrdom. Such is the origin of the famous escurial near Madrid, the royal residence of the kings of Spain.

The first account of that fatal blow which France had received at St Quintin, was carried to Rome by the courier whom Henry had sent to recal the duke of Guise. Paul remonstrated warmly against the departure of the French army; but Guise's orders were peremptory. The arrogant pontiff therefore found it necessary to accommodate his conduct to the exigency of his affairs, and to employ the mediation of the Venetians, and of Cosmo de Medici, in order to obtain peace. The first overtures of this nature were eagerly

138 Peace concluded.

listened to by the Catholic king, who still doubted the justice of his cause, and considered it as his greatest misfortune to be obliged to contend with the Pope. Paul agreed to renounce his league with France; and Philip stipulated on his part, that the duke of Alva should repair in person to Rome, and after asking pardon of the holy father in his own name and in that of his master, for having invaded the patrimony of the church, should receive absolution from that crime. Thus Paul, thro' the superstitious timidity of Philip, not only finished an unpropitious war without any detriment to the apostolic see, but saw his conqueror humbled at his feet: and so excessive was the veneration of the Spaniards in that age for the papal character, that the duke of Alva, the proudest man perhaps of his time, and accustomed from his infancy to converse with princes, acknowledged, that when he approached Paul, he was so much overawed, that his voice failed, and his presence of mind forsook him.

139 Consequences of the war in Italy.

But though this war, which at its commencement threatened mighty revolutions, was terminated without occasioning any alteration in those states which were its immediate object, it produced effects of considerable consequence in other parts of Italy. In order to detach Octavio Farnese, duke of Parma, from the French interests, Philip restored to him the city of Placentia and its territory, which had been seized by Charles V. and he granted to Cosmo de Medici the investiture of Sienna, as an equivalent for the sums due to him. By these treaties, the balance of power among the Italian states was poised with more equality, and rendered less variable than it had been since it received the first violent shock from the invasion of Charles VIII. and Italy henceforth ceased to be the theatre on which the monarchs of Spain, France, and Germany, contended for fame and dominion. Their hostilities, excited by new objects, stained other regions of Europe with blood, and made other states feel, in their turn, the miseries of war.

140 The French unsuccessful in the Low Countries.

The duke Guise, who left Rome the same day that his adversary the duke of Alva made his humiliating submission to the Pope, was received in France as the guardian angel of the kingdom. He was appointed lieutenant-general in chief, with a jurisdiction almost unlimited; and, eager to justify the extraordinary confidence which the king had reposed in him, as well as to perform something suitable to the high expectations of his countrymen, he undertook in winter the siege of Calais. Having taken that place, he next invested Thionville in the duchy of Luxembourg, one of the strongest towns on the frontiers of the Netherlands; and forced it to capitulate after a siege of three weeks. But the advantages on this quarter were more than balanced by an event which happened in another part of the Low Countries. The mareschal de Termes governor of Calais, who had penetrated into Flanders and taken Dunkirk, was totally routed near Gravelines, and taken prisoner by count Egmont. This disaster obliged the duke of Guise to relinquish all his other schemes, and hasten towards the frontiers of Picardy, that he might there oppose the progress of the enemy.

The eyes of all France were now turned towards the duke of Guise, as the only general on whose arms victory always attended, and in whose conduct as well as good fortune they could confide in every danger. His strength was nearly equal to the duke of Savoy's, each commanding about 40,000 men. They encamped at the distance of a few leagues from one another; and the French and Spanish monarchs having joined their respective armies, it was expected that, after the vicissitudes of war, a decisive battle would at last determine which of the rivals should take the ascendant for the future in the affairs of Europe. But both monarchs, as if by agreement, stood on the defensive; neither of them discovering any inclination, though each had it in his power, to rest the decision of a point of such importance on the issue of a single battle.

141 Peace concluded between Henry and Philip.

During this state of inaction, peace began to be mentioned in each camp, and both Henry and Philip discovered an equal disposition to listen to any overture, that tended to re-establish it. The private inclinations of both kings concurred with their political interests and the wishes of their people. Philip languished to return to Spain, the place of his nativity; and peace only could enable him, either with decency or safety, to quit the Low Countries. Henry was now desirous of being freed from the avocations of war, that he might have leisure to turn the whole force of his government towards suppressing the opinions of the reformers, which were spreading with such rapidity in Paris and the other great towns, that they began to grow formidable to the established church. Court-intrigues conspired with these public and avowed motives to hasten the negotiation, and the abbey of Cercamp was fixed on as the place of congress.

142 Death of Charles V.

While Philip and Henry were making these advances towards a treaty which restored tranquillity to Europe, Charles V. whose ambition had so long disturbed it, but who had been for some time dead to the world, ended his days in the monastery of St Justus in Estremadura, which he had chosen as the place of his retreat, as is particularly related under the article Charles V.

143 Revolt of the United Provinces.

After the death of Charles, the kingdom of Spain soon lost great part of its consequence. Though Charles had used all his interest to get his son Philip elected emperor of Germany, he had been totally disappointed; and thus the grandeur of Philip II. never equalled that of his father. His dominions were also considerably abridged by his tyrannical behaviour in the Netherlands. In consequence of this, the United Provinces revolted; and after a long and bloody war obtained their liberty*. In this quarrel Elizabeth of England took part against Philip, which brought on a war with Spain. The great losses he sustained in these wars exhausted the kingdom both of men and money, notwithstanding the great sums imported from America. Indeed, the discovery and conquest of that country hath much impoverished, instead

* See United Provinces.

ſtead of enriching Spain; for thus the inhabitants have been rendered lazy and averſe from every kind of manufacture or traffic, which only can be a durable ſource of riches and ſtrength to any nation. The ruin of the kingdom in this reſpect, however, was completed by Philip III. who, at the inſtigation of the inquiſition, and by the advice of his prime miniſter the duke of Lerma, expelled from the kingdom all the Moreſcoes or Moors, deſcendants of the ancient conquerors of Spain. Thirty days only were allowed them to prepare for their departure, and it was death to remain beyond that time. The reaſon for this barbarous decree was, that theſe people were ſtill Mahometans in their hearts, though they conformed externally to the rites of Chriſtianity, and thus might corrupt the true faith. The Moreſcoes, however, choſe themſelves a king, and attempted to oppoſe the royal mandate; but, being almoſt entirely unprovided with arms, they were ſoon obliged to ſubmit, and all baniſhed the kingdom. By this violent and impolitic meaſure, Spain loſt almoſt a million of induſtrious inhabitants; and as the kingdom was already depopulated by bloody wars, by repeated emigrations to America, and enervated by luxury, it now ſank into a ſtate of languor from whence it has never recovered.

144 Expulſion of the Moors and its bad conſequences to Spain.

145 Revolt of Portugal, &c.

In conſequence of this languor, and the maladminiſtration of the Spaniſh governors, Portugal, which had been reduced by Philip II. revolted, and has ever ſince been an independent kingdom‡. However, the memory of what Spain once was, remained for a conſiderable time, and the power of that kingdom long continued to be feared after it had ceaſed to be powerful. In the time of queen Anne, a Britiſh army was ſeen for the firſt time in Spain, in order to ſupport Charles of Auſtria againſt Philip the grandſon of Louis XIV. The ill ſucceſs of that attempt is related under the article BRITAIN, n° 342—359; and thus the crown of Spain fell to a branch of the houſe of Bourbon, in conſequence of which the courts of France and Spain generally acted in the cloſeſt concert till the revolution, which at preſent aſtoniſhes Europe, put an end to monarchial government in the former country. The wars of theſe two courts with BRITAIN are related under that article and AMERICA; and theſe, with an unſucceſsful attempt on Algiers, and the threatened war reſpecting *NOOTKA Sound* (ſee that article), conſtitute the moſt important part of the Spaniſh hiſtory till the depoſition and execution of Louis XVI. of France. On that event Spain joined her forces to theſe of the Empire, Britain, and Pruſſia, to chaſtiſe the Convention, and prevent thoſe democratical principles which had pervaded France from being ſpread through the other nations of Europe. We cannot ſay that her exertions added much to the ſtrength of the alliance; and being unable to defend herſelf againſt the furious inroads of the republican troops, ſhe was glad to make a ſeparate peace with the Convention. See REVOLUTION.

‡ See Portugal, n° 18, et ſeq.

146 Air and climate of Spain.

The air of Spain, during the months of June, July, and Auguſt, is exceſſively hot in the day-time; but the reſt of the year it is pleaſant and temperate. Even during the above months it is very cool in the ſhade; and ſo cold in the night, that it makes a traveller ſhiver; and in the day-time the violent heat continues only for about four or five hours. In the north, on the mountains, and near the ſea-coaſt, the air is much leſs ſultry in ſummer than in the ſouth, eſpecially in the lower parts of the country, and at a diſtance from the ſea. It ſeldom rains here, except about the equinoxes: the froſts are very gentle towards the ſouth; but on the mountains in the north and north-eaſt the air is very ſharp in winter.

147 Soil and produce.

Though there are ſome ſandy barren deſerts in the ſouth, and many barren mountains in the north, yet in the greater part of the country, particularly in the valleys and plains, the ſoil is good, producing a great variety of rich wines, oil, and fruits; ſuch as oranges, lemons, prunes, citrons, almonds, raiſins, dates, figs, cheſnuts, pomegranates, capers, pears, and peaches; but not a ſufficiency of grain, which is chiefly owing to the neglect of tillage. Wheat and barley are the moſt common grain; the former of which is ſaid by ſome to be the beſt in Europe. There is not much flax, hemp, oats, or hay, in Spain: but there is plenty of honey, ſalt, fine wool, ſilk, and cotton; and, in ſome places, of rice and ſugar-canes. Here alſo are abundance of mules, and, in ſome provinces, of horſes, together with deer, wild-fowl, and other game, chamois and other goats, but few horned cattle. Wolves are almoſt the only wild beaſts in the country. The herb kali, which is uſed in making ſalt, ſoap, and glaſs, grows in great plenty on the ſea-ſhore. The wild bulls, uſed in their bull-fights, are bred in Andaluſia. The ſeas about Spain are well ſtored with fiſh; among which is the anchovy, in the Mediterranean. We may gueſs at the number of ſheep here by that of the ſhepherds, which is ſaid to be about forty thouſand. The ſheep that bear the fine wool move regularly, every ſummer, from ſouth to north, along the mountains, which yield a great variety of ſweet herbs and plants, and return again towards winter. During this progreſs, large quantities of ſalt are diſtributed among them, and all poſſible care is taken both of their health and fleeces.

148 Mountains, minerals, &c.

The chief mountains are the Pyrenees, which ſtretch from the Mediterranean to the Atlantic ocean, but not in a direct line, for near 200 miles: their breadth is, in ſome places, not leſs than 80. That called the *Pic de Midi* is of a prodigious height. Over theſe mountains there are only about five paſſages out of Spain into France, and theſe alſo narrow; even the valleys between the mountains are covered with thick and lofty woods. The other chains in Spain are the Sierra d'Occa, Sierra Molino, Sierra Moreno, and Sierra Novada or the ſnowy mountains. Near Gibraltar, oppoſite to Mount Abyla in Africa, ſtands the celebrated Mount Calpe: theſe were anciently called *Hercules's pillars*. The mountains yield great quantities of timber for ſhipping, which are conveyed by the Ebro and other rivers to the Mediterranean. According to the ancient and modern writers, they abound alſo with gold, ſilver, iron, lead, tin, cinnabar, quickſilver, alum, vitriol, copperas, lapis calaminaris, &c. beſides gems, and mineral waters both hot and cold. The gold and ſilver mines are not worked at preſent, but thoſe of iron are. The neglect of the former is owing partly to the indolence of the Spaniards, and partly to the gold and ſilver imported from America. Beſides the rivers Minho, Douro, Tagus, Monda, Lima, and Guadiana, mentioned in Portugal, but which have their ſources in Spain, the most considerable are the Ebro, formerly *Iberus*, Guadalavier anciently *Turia*, Guadalquiver or *Bœtis*, Segura, and Xucar.

149 Religion. The Spaniards are zealous Romanists. Nowhere is there more pomp, farce, and parade, in what regards religion; and nowhere less true Christianity. Their zeal and their superstition exceed that of any other Roman Catholic country, unless perhaps we should except Portugal. Nowhere did the inquisition reign with greater terror; there being no subject who was not liable to be prosecuted by the *holy office*, as it is called; however, the powers of that tribunal are now greatly diminished even in Spain. There are eight archbishops in Spain, seven in America, and one in Asia at Manilla; each of which has his suffragan bishops. The archbishop of Toledo is primate, chancellor of Castile, and, by virtue of his office, privy-councellor. He is said to have a revenue of 100,000l. Sterling *per annum*, or more. The king nominates all archbishops and bishops; and since 1753 all small benefices are also in his gift. He has also lately obtained a power to tax ecclesiastical possessions, according to his pleasure and the exigency of affairs. Though the rest of the nation is poor, the clergy are immensely rich, and their revenues of all kinds very great. Most of the towns and estates belong to them, and are exempt from all public burdens; yet their avarice is insatiable, especially that of the Mendicant friars, though they profess poverty. Their commerce, which is free from all duties and imposts, is also a rich fund to them. Though the Spaniards are naturally men of wit and of an elevated genius, yet little progress in the sciences is to be expected from them, while the clergy use their utmost efforts to keep them in ignorance, branding all literary researches with the name of heresy, and inveighing against the seats of the muses as the schools of hell, where the devil teaches sorcery. There are 22 universities, and several academies, in Spain; but so constituted, and under such restrictions, that they can never attain to any measure of true learning. There are few printing-houses in Spain; and most of the books in that language are published in other countries.

150 Trade and manufactures. In regard to trade and manufactures, the Spaniards are far from making such a figure as might be expected. Most of the laborious work in their husbandry, manufactures, and handicrafts, is performed by the French, especially in the two Castiles and the midland provinces, the natives being either too lazy or too proud to stoop to such employments. By these means, the French usually return with large fortunes to their own country. The chief manufactures of Spain are those of silk, wool, iron, copper, and other hardwares; but these fall far short of the flourishing condition to which they might be brought: hence a great part of the treasures of America go to the foreign merchants, who supply them with goods for that part of the world. However, it is certain, that Spain, since it hath had princes of the house of Bourbon upon the throne, hath improved its revenues, increased its forces by sea and land, and applied itself more than it did before to manufactures and husbandry; having shaken off, in some measure, that idle indolent disposition which rendered it so contemptible in the eyes of other nations; but it will be a long time before they will be able to supply the wants of their own country, and those of America, in any great degree. Spain is extremely well situated for trade: but most of its produce is exported by foreigners, except what is carried to the Indies; and even with regard to that trade, they are little better than factors to the English, French, Dutch, and Italians. Smuggling, which was formerly carried to a great height, is now in a great measure suppressed. Since the year 1750, the exportation of silver hath been allowed on the payment of 3 *per cent*. From 1735 almost to 1756, the flotas and galleons were discontinued, and the trade to America carried on in register-ships, which any merchant might send, on permission obtained from the council of the Indies: but then the flotas and galleons were restored. The Assogue-ships are two vessels which carry quicksilver on the king's account to Vera Cruz. There is a company which has an exclusive grant for trading to the Caraccas; and another for trading to Porto Rico, the Bay of Honduras, the province of Guatimala and Hispaniola; but the Spanish part of the last, it is said, hath been lately ceded to the French. One ship, and sometimes two, sails annually from Manilla, in the island of Luconia, one of the Philippines, for Acapulco in Mexico: her cargo, which belongs to the convents, consists of the principal commodities of that part of the world; but the return from Acapulco is for the most part made in money, and amounts to a vast sum, as appeared from the treasure found on board the Acapulco ship taken by Lord Anson. In return for the manufactures sent to America, the Spaniards receive gold, silver, cochineal, indigo, the cocoa or chocolate nut, logwood and other dyeing woods, sugar, tobacco, snuff, and other productions of that part of the world; supplying most part of Europe and Asia with the silver which they bring from thence in their galleons. In the time of the Moors and Goths, this kingdom was exceedingly populous. It is said to have then contained between twenty and thirty millions; whereas now it does not contain above nine: and this, among other causes, is owing to the pride and laziness of the inhabitants, want of manufactures and good regulations, neglect of the mines and agriculture, the expulsion of the Moors, the peopling of America, heavy taxes, the great number of convents, excessive venery, and the consequent infecundity of both sexes. Their debauchery and sterility are partly occasioned by their way of living; for they make great use of spices, and drink a great deal of chocolate, and strong wine mixed with brandy. The causes assigned for the want of people in Spain will account in some measure for its poverty; notwithstanding it is computed that it receives one year with another, setting aside other sums, above 26 millions of pieces of eight, in registered gold and silver. As most of the manufactures that are sent to America are furnished by Britain, France, Italy, and Holland, so a great part of the treasure brought home by the galleons is paid to the merchants of those nations.

The constitution of Spain is at present an absolute hereditary monarchy, where the females inherit in default of the males. The king, in his title, enumerates most of the provinces and particular parts of the dominions he has been or is possessed of. In speaking of him, he is commonly called his *Catholic Majesty*, or the *Catholic King*. The hereditary prince is commonly styled *Prince of Asturias*, and the other royal children *Infants*. The kings of Spain are never crowned; they seem 151 Constitution and government.

Spain.

seem to have a power to dispose of the crown to what branch of the royal family they please. For the administration of the government and of justice, here are several councils and tribunals; as the junto or cabinet-council, the privy-council, the council of war, the council of Castile, the council of the inquisition, the council of finances, the council of the Indies, the seven courts of royal audiences, &c.

Bourgoanne's Travels in Spain.

The general history of Spain proves how great an influence the Cortes had in former times in the most important affairs of government; such as war or peace, and the levying of taxes. But during a long course of years they have not been assembled, except for the sake of form; and the sovereigns, without violence, or formally rejecting their intervention, have found means to elude their authority. They promulgate from the throne certain ordinances under the name of *Pragmatics*, the preambles of which give us to understand, that they claim the same authority as if they had been published in the assembly of the Cortes; who are never convoked but at the accession of a new monarch, to administer to him an oath in the name of the nation, and to swear fidelity to him. As this event happened so lately as the month of September 1789, when the present king of Spain received the homage of all his subjects in the church of St Jerome at Madrid, it may not be unacceptable to give an account of the usual mode of assembling them.

"On this occasion letters of convocation are sent to all the Grandees; to all persons bearing titles of Castile; to all the prelates; and to every city which has a right to send deputies to the Cortes. The two first classes represent the nobility; the priests sit in the name of the clergy; and the cities, which depute one of their magistrates, represent the people." Except on the above-mentioned occasion, the Cortes of the whole kingdom have been assembled but twice during the present century, and only once upon public business, in the year 1713, when Philip V. convoked them to give their approbation to the Pragmatic Sanction, which changed the order of succession to the throne. They are still consulted, for the sake of form, in certain cases; but then, the members of which they are composed correspond with each other without assembling. At their breaking up in 1713, it was regulated, that they should be represented by a permanent committee, whose office it should be to watch over the administration of that part of the taxes known by the name of *Millones*, and which had been granted under Philip II. with the formal consent of the Cortes, upon certain conditions, which the monarch swore to observe. They retained the administration of these imposts until the year 1718, when cardinal Alberoni, whose ardent and imperious genius was irritated at such shackles, transferred it to the hands of the sovereign. From that time, the assemblies of the deputies of the kingdom have received no more of the revenues of the state than is necessary to pay the salaries and defray the expences of the members. These are eight in number, and are chosen in the following manner: All the provinces of Castile unite to nominate six; Catalonia and Majorca appoint one; and the regencies of Valentia and Arragon elect the eighth. These deputies hold their places six years, at the end of which a new election takes place in the same manner. As a relict of their ancient rights, they still retain the privilege of being, by virtue of their places, members of the council of finances, by which the sovereign communicates to the nation the necessity of levying any new tax; and the approbation they are supposed to give to the royal resolution, is a shadow of the consent of the Cortes, without which taxes could not formerly be either levied or augmented. But it is easy to perceive how feeble this rampart of liberty must be; which is only formed of a small number of citizens, who possess but little real power; are under the control of government, from which they expect favours and preferments; and who, after all, represent the most numerous indeed, but least respected, part of the nation. The provinces of Biscay and Navarre, which have assemblies and particular privileges, send also, on some occasions, deputies to the throne; but they do not make a part of the body of the deputies of the kingdom, and their constituents fix at pleasure the object and duration of their temporary mission.

The administration of Spain is divided into six principal departments. The minister for foreign affairs is in many respects the directing minister, and receives, as a mark of distinction, the title of secretary of state. The minister of war has but a circumscribed authority. He is president of the council of war, which is rather a tribunal than a board of administration; but the inspectors of the infantry, and those of the cavalry, dragoons, and provincial regiments, draw up a statement of whatever relates to the corps of which they have the direction; and the minister at war has only to present the memorials they give in to the king. The marine minister has no associates. The chiefs of the three departments of Ferrol, Carthagena, and Cadiz, and inspectors of the marine, are named by the king, on the representation of the minister; but the marine ordinances prepared by him alone, require only the sanction of the king. The minister of the finances should properly be under the inspection of the superintendant-general of that department; but these two offices were some time since united, and will probably be so continued; for the separation of them would multiply, without necessity, the springs of government; and the interests of the state require that they should be simplified as much as permanent forms, those sacred bulwarks of justice and property, will admit.

The higher nobility consist of counts, marquises, and dukes. The grandees, who have precedence of all others, next the king and princes of the blood, are named out of these. They have the privilege of being covered in the king's presence, who styles them in his letters *Illustrious*; and in speaking to them or of them, *their Eminencies*: but there are others besides the grandees who are covered in the king's presence; as cardinals, nuncios, archbishops, the grand prior of Castile and the grand prior of Malta, the generals of the orders of St Dominic and St Francis, ambassadors of crowned heads, the knights of the golden fleece, and of the three military orders of St James, Calatrava, and Alcantara, when the king assists at their respective chapters in quality of grandmaster. No grandee can be apprehended for any crime but by the express order of the king; and they have many other privileges besides these. The inferior nobility style themselves *Cavelleros* and *Hidalgos*.

Of the orders in Spain, that of the golden fleece is the

152 Orders of knighthood. the principal: which was instituted in 1430 by Philip the good duke of Burgundy, and is common now to the kings of Spain and the house of Austria. The order of St Jago de Compostella was instituted in the year 1175 by Ferdinand II. king of Leon. The order of Calatrava was founded by Sancho III. of Castile. The order of Alcantara owes its institution to Ferdinand II. king of Leon. The three last orders have large commanderies or estates annexed to them. The masters of them were once so powerful, that they disputed the king's authority over them; whereupon the king procured those masterships to be conferred on himself by the Pope, that they might no longer assume an independency of the state. The knights of these three orders are esteemed noblemen.

153 Revenues. In the last century, the revenues of Spain amounted to 32 or 33 millions of livres; but afterwards they were so reduced, that they did not exceed seven or eight millions. At present, the revenues of the crown arising in Spain are computed at five millions Sterling *per annum*, besides what arises from America. The silver mines there are inexhaustible; and of the produce of these a fifth belongs to the king. The taxes in Spain are numerous and heavy. The land forces, in time of peace, are computed at about 80,000: and in time of war, must be much more numerous. Their navy at present cannot be ascertained.

154 Language. The language of this country, especially that spoken in Castile, which is by far the purest, approaches the nearest to the Latin of any language in Europe, mixed with Arabic words and terminations introduced by the Moors. In some provinces, the vulgar tongue is a dialect of the old French, or rather Gascon, which is little understood in the others. In Biscay, the language is said to be a dialect of the Gothic or Celtic, and to have some analogy with the Welch and Irish. As to what regards the character of the Spaniards, they do not want either an inclination or capacity for the sciences; but have hardly an opportunity of acquiring any true learning or knowledge, at least in their schools and universities. They are admired for their secrecy, constancy, gravity, patience in adversity, and loyalty. They are also said to be true to their word, great enemies to lying, and so nice and jealous in point of honour, that they will stick at nothing to wipe off any stain that is cast upon it. Among their vices and defects are reckoned their pride and contempt of foreigners, their indolence, laziness, lust, bigotry, and credulity in believing the feigned miracles and legends of their monks. They are also said to be extremely passionate, jealous, and vindictive; and are noted, above any other European nation, for despising and neglecting agriculture, arts, and manufactures.

155 Some directions for travelling in Spain. We will here subjoin some directions for travelling in Spain by Mr. Townsend, a late respectable traveller; as they will enable the reader to form a more distinct notion of the state of that country than he could obtain from general description.

Townsend's Travels, vol. I. "To travel commodiously in Spain, a man should have a good constitution, two good servants, letters of credit for the principal cities, and a proper introduction to the best families, both of the native inhabitants and of strangers settled in the country.

"The language will be easily acquired.

"His servants should be a Spaniard and a Swiss, of which one should be sufficiently acquainted with the art of cooking, and with the superior art of providing for the journey; which implies a perfect knowledge of the country through which he is to pass, that he may secure a stock of wine, bread, and meat, in places where these excel, and such a stock as may be sufficient to carry him through the districts in which these are not to be obtained. For himself, his servants, and his baggage, he should purchase three strong mules, able to support the load which is to be put upon them. In his baggage he should have sheets, a mattress, a blanket, and a quilt, a table-cloth, knives, forks, and spoons, with a copper vessel sufficiently capacious to boil his meat. This should be furnished with a cover and lock. Each of the servants should have a gun slung by the side of his mule.

"To travel as an economist in Spain, a man must be contented to take his chance for conveyance, and either go by the post, wherever it is established; or join with officers, going to their various stations; to hire a coach, or quietly resign himself to a calash, a calasine, a horse, a mule, or a borrico. This last is the most convenient for the purpose of crossing the country, or of wandering among the mountains. If he is to traverse any district infested by banditti, it will be safe for him to go by the common carriers, in which case he will be mounted on a good mule, and take the place which would have been occupied by some bale of goods. Any one, who is fond of botany, for short excursions, will make choice of a borrico. This is always to be had when, as in some villages, neither horse nor mule are to be obtained. I have used this honourable appellation for the most patient of all animals, because I would not shock the delicacy of a young traveller, by telling him, at his first setting out, that he may sometimes find himself under the necessity of riding upon an ass. He must, however, know, for his consolation, that an ass does not appear so contemptible in Spain as in the colder regions of the north.

"The best time for him to begin this expedition is in autumn, when he may go by Bayonne, Burgos, Valladolid, and Segovia, hastening to the court at St Ildefonso. Here he is to procure letters for the chief cities in Spain. On these will depend the whole pleasure of his excursion. During the winter he may see all the south of Spain, Toledo, Cordova, Seville, Cadiz, Gibraltar, Malaga, Granada, Carthagena, Murcia, Alicant, Valencia, and Barcelona. Returning by Zaragoza to Aranjuez in the spring, he may follow the Merino flock to the mountains of the north, whilst the country, on which he has turned his back, is rendered unfit for travelling, by the dissolving heats, by want of provisions, and by malignant fevers. This season will be best employed in Galicia, the Asturias, and the provinces of Biscay, taking Salamanca and Leon in the way."

New Spain. See Mexico.

SPALATRO, or Spalatto, a rich, populous, and strong town of the republic of Venice, capital of Venetian Dalmatia, with a good harbour and an archbishop's see. Here are the ruins of the palace of Dioclesian, of which the late Mr Robert Adam published in 1764 a splendid account, enriched with 71 folio plates. In 1784, Spalatro was nearly depopulated by the plague. It is strong by situation, being built on a peninsula, which is joined to Terra Firma by a neck of land half a mile over. It is seated on the Gulf of Venice, 35 miles south-

ſouth-eaſt of Sebenico, and 102 north-weſt of Raguſa. E. Long. 17. 31. N. Lat. 44. 4.

SPAN, a meaſure taken from the ſpace between the thumb and the tip of the little finger when both are ſtretched out. The ſpan is eſtimated at three hand's breadths or nine inches.

SPANDRELL, the ſolid work on each haunch of an arch, to keep it from ſpreading.

SPANHEIM (Ezekiel), a learned writer in the 17th century, was born at Geneva in 1629; and in 1642 went to Leyden to ſtudy. Here he diſtinguiſhed himſelf to great advantage; and his reputation ſpreading, Charles Louis elector palatine ſent for him to be tutor to his only ſon. This taſk our author diſcharged to the entire ſatisfaction of the elector; by whom he was alſo employed in divers negotiations at foreign courts. He afterwards entered into the ſervice of the elector of Brandenburgh, who in 1680 ſent him envoy-extraordinary to the court of France, and ſoon after made him a miniſter of ſtate. After the peace of Ryſwic, he was again ſent on an embaſſy to France, where he continued from the year 1697 to 1702. The elector of Brandenburgh having during that interval aſſumed the title of *King of Pruſſia*, conferred on him the title and dignity of a baron. In 1702 he left France; and went ambaſſador to England, where he had been ſeveral times. Here he died in 1710, aged 81 years. It is ſurpriſing, that in diſcharging the duties of a public miniſter with ſo much exactneſs, and amidſt ſo many different journeys, he could find time enough to write the ſeveral books publiſhed by him. It may be ſaid of him that he acquitted himſelf in his negotiations like a perſon who had nothing elſe in his thoughts; and that he wrote like a man who had ſpent his whole time in his ſtudy. The principal of his works are, 1. *De præſtantia et uſu numiſmatum antiquorum*; the beſt edition of which is in two volumes folio. 2. Several letters or diſſertations on ſcarce and curious medals. 3. A preface and notes to the edition of the emperor Julian's works, printed at Leipſic in 1696, folio.

SPANIEL, in zoology. See Canis.

SPAR, in mineralogy, a name given to thoſe earths which break eaſily into rhomboidal, cubical, or laminated fragments with poliſhed ſurfaces. As the term *ſpar* is thus applied to ſtones of different kinds, without any regard to the ingredients of which they are compoſed, ſome additional term muſt be uſed to expreſs the conſtituent parts as well as the figure; for inſtance, calcareous ſpar, gypſeous ſpar, &c. The ſpars found in Britain and Ireland are of four different ſpecies; opaque, refracting, diaphanous, and ſtalactitical. 1. The opaque ſpar is rhomboidal, hexangular, and triangular, of various colours, and is found in mines in Wales, Derbyſhire, &c. and at Ovens near Cork. 2. The refracting ſpar is rhomboidal, ſhows objects ſeen through it double, and ſometimes 8, 12, or 16 images at once. It is frequent in the lead mines of Derbyſhire, Yorkſhire, &c. 3. Diaphanous ſpar is rhomboidal, triangular, hexangular, pyramidal or columnar; and is found in mines, quarries, and caverns, in many different places. 4. Stalactitical ſpar, icicle or drop-ſtone, is formed by the running or dropping of water, containing a large proportion of calcareous earth. It is opaque, generally laminated, but from accidental circumſtances aſſumes various forms. It occurs at Knarſborough in Yorkſhire, and at Ovens near Cork.

A new ſpecies of ſpar has lately been found in the Eaſt Indies, which, from its extreme hardneſs, approaching to that of a diamond, is called *adamantine ſpar*. It was diſcovered by Dr Black of Edinburgh to be a diſtinct ſpecies. Happening one day to viſit a lapidary, it was ſhown to him among other ſpecimens as a ſtone that was uſed in the Eaſt Indies for poliſhing gems, and grinding other hard ſubſtances. Dr Black immediately ſingled out a ſpecimen which he ſent to Mr Greville, who requeſted M. Klaproth to analyze it.

There are two varieties of this ſpar; one of them comes from China, and cryſtallizes in hexagonal priſms without pyramids, the length of the ſides varying from ſix to twelve lines; their breadth being about nine, of a grey colour with different ſhades. Though the entire pieces are opaque, the thin laminæ are tranſparent, and when broken, its ſurface appears ſlightly ſtriated. Its cryſtals are covered with a very fine and ſtrongly adhering cruſt, compoſed of ſcales of ſilvery mica, mixed with particles of red feld-ſpar. Sometimes the ſurface has martial pyrites or yellow ſulphuret of iron adhering to it. Its hardneſs is ſo great, that it not only cuts glaſs as eaſily as the diamond, but even ſcratches rock-cryſtal and other very hard ſtones. Its ſpecific gravity is to that of water as 3710 to 1000. Sometimes it contains cryſtallized grains of magnetic oxyd of iron, which may be ſeparated from the ſtone when pulverized by means of the loadſtone.

The other kind found in Hindoſtan is of a whiter colour, and of a more laminated texture than the former: the grains of iron contained in it are likewiſe of a ſmaller ſize than thoſe of the former; they are not diffuſed through its ſubſtance, but only adhere to its ſurface.

This ſpar is exceedingly difficult to analyze. To do ſo, M. Klaproth was obliged to melt it no leſs than 12 times with 15 parts of ſoda or mineral alkali, in a ſilver crucible; the heat being each time continued for five hours as ſtrong as the crucible could bear. After each fuſion the maſs was ſoftened by boiling diſtilled water, filtering and precipitating by acids the ſmall quantity of earth which the alkali had diſſolved; and laſtly, that portion which had not been decompoſed was digeſted at different times with concentrated and boiling acids. By this tedious proceſs he at length found, that the ſpar conſiſted of alumine and another kind of earth, in the proportion to 2 to 1, the nature of which is not underſtood. It is not ſiliceous earth, as it does not combine with fixed alkalis in a melting heat; and for want of opportunities to make a ſufficient number of experiments, our author was unable to determine whether it be a ſixth ſimple earth, or a compoſition of two or more earths which he was not able to ſeparate.

From a letter of M. Morveau to Mr Crell, it appears that this ſtone is alſo found in France. A ſmall bit of this was tried by him in preſence of Mr Wedgewood, and he found that its ſpecific gravity was ſuperior to the ſpar of China, being no leſs than 4.1803, and the true adamantine ſpar of China gave 3.8222.

SPARGANIUM, bur-reed, in botany: A genus of plants belonging to the claſs of *monœcia*, and to the order of *triandria*; and in the natural ſyſtem ranged under the 3d order, *Calamariæ*. The amentum of the male flower is roundish, the calyx is triphyllous, and there is no corolla. The amentum of the female flower resembles that of the male. The stigma is bifid; the fruit is a dry berry containing one seed. There are two species, the erectum and natans, both of them natives of Great Britain and Ireland. 1. The *Erectum*, great bur-reed, has a stem two or three feet high, erect, firm, and branched; the lower leaves are triangular, the upper ones plain. The male heads are much smaller than the female. This species flowers in July, and is frequent on the banks of rivers and lakes and near stagnant waters. 2. The *Natans*, floating or little bur-reed, has a stalk about two feet long. The leaves float, are about a foot long, one-fourth of an inch wide at the base, and one-eighth in the middle, and end in a point. The male sphœrules are generally three, and all sessile; the female are commonly three, the two lower being supported on peduncles, the uppermost sessile. It flowers in July, and grows in pools and lakes, but is rare.

SPARMANNIA, in botany; a genus of plants belonging to the class of *polyandria*, and to the order of *monogynia*. The corolla consists of four petals, and is bent back; the nectaria are numerous, and swell a little; the calyx is quadriphyllous; the capsule is angulated, quinquelocular and echinated. There is only one species, the *Africana*.

SPARROW, in ornithology. See Fringilla.

Sparrow-Hawk, in ornithology. See Falco.

Sparrow-Grass. See Asparagus.

SPARRY-acid. See *Flour-Acid*, and Chemistry-*Index*.

SPARTA, or Lacedæmon, the capital of the country of Laconia in Greece, an ancient and most renowned state, the inhabitants of which have been in all ages celebrated for the singularity of their laws and character.—The history of Sparta for many ages is entirely fabulous; and the authentic accounts commence only with the celebrated lawgiver Lycurgus, who flourished about 870 B. C. See the article Lycurgus.

1 The history of Sparta mostly fabulous till the time of Lycurgus.

After his death, the first important transaction which we find mentioned in the Spartan history is the Messenian war, which commenced in the year 752 B. C. and ended in the total reduction of the Messenian territory, as related under the article Messenia. During this period, according to some authors, a great change took place in the government of Sparta. This was the creation of the ephori, which is ascribed to one of the kings named *Theopompus*. This man perceiving that there was a necessity for leaving magistrates to execute the laws, when the kings were obliged to be in the field, appointed the magistrates abovementioned, who afterwards made so great a figure in the state (see Ephori). One great privilege of the ephori was, that they did not rise up at the presence of the kings, as all other magistrates did: another was, that if the kings offended against the laws, the ephori took cognizance of the offence, and inflicted a suitable punishment. From the first election of the ephori, the year was denominated, as at Athens, from the first election of the archons.

The conquest of Messenia gave Sparta the superiority over the rest of the states, excepting only that of Athens, which for a long time continued to be a very troublesome rival; but the contests between these two rival states have been so fully related under the article Attica, that nothing more is requisite to be added in this place.—In the time of the Persian war, Leonidas the Spartan king distinguished himself in such a manner, as to become the admiration not only of that but of every succeeding age. It being resolved in a general council to defend the straits of Thermopylæ against the Persians, 7000 § foot were put under the command of Leonidas, of whom, however, only 300 were Spartans. Leonidas did not think it practicable to defend the pass against such multitudes as the Persian king commanded; and therefore privately told his friends, that his design was to devote himself to death for his country.

2 Leonidas undertakes to defend the straits of Thermopylæ against the Persians.

§ See Anacharsis's Travels, vol. i. p. 468.

Xerxes advancing near the straits, was strangely surprised to find that the Greeks were resolved to dispute his passage; for he had always flattered himself, that on his approach they would betake themselves to flight, and not attempt to oppose his innumerable forces. However, Xerxes still entertaining some hopes of their flight, waited four days without undertaking any thing, on purpose to give them time to retreat. During this time, he used his utmost endeavours to gain and corrupt Leonidas, promising to make him master of all Greece if he would come over to his interest. His offers being rejected with contempt and indignation, the king ordered him by an herald to deliver up his arms. Leonidas, in a style and with a spirit truly laconical, answered, "Come thyself, and take them." Xerxes, at this reply, transported with rage, commanded the Medes and Cissians to march against them, take them all alive, and bring them to him in fetters. The Medes, not able to stand the shock of the Greeks, soon betook themselves to flight: and in their room Hydarnes was ordered to advance with that body which was called *Immortal*, and consisted of 10,000 chosen men; but when these came to close with the Greeks, they succeeded no better than the Medes and Cissians, being obliged to retire with great slaughter. The next day the Persians, reflecting on the small number of their enemies, and supposing so many of them to be wounded that they could not possibly maintain a second fight, resolved to make another attempt; but could not by any efforts make the Greeks give way; on the contrary, they were themselves put to a shameful flight. The valour of the Greeks exerted itself on this occasion in a manner so extraordinary, that Xerxes is said to have three times leaped from his throne, apprehending the entire destruction of his army.

3 The Persians repulsed with great slaughter

Xerxes having lost all hopes of forcing his way through troops that were determined to conquer or die, was extremely perplexed and doubtful what measures he should take in this posture of affairs; when one Epialtes, in expectation of a great reward, came to him, and discovered a secret passage to the top of the hill which overlooked and commanded the Spartan forces. The king immediately ordered Hydarnes thither with his select body of 10,000 Persians; who marching all night, arrived at break of day, and possessed themselves of that advantageous post. The Phocæans, who defended this pass, being overpowered by the enemy's numbers, retired with precipitation to the very top of the mountain, prepared to die gallantly. But Hydarnes neglecting to pursue them, marched down the mountain with all possible expedition, in order to attack those who defended the straits in the rear. Leonidas being now apprised that it was impossible to bear up against the enemy, obliged the rest of his allies to retire: but he staid himself, with the Thespians, Thebans, and 300 Lace-

4 They are shown a way over the hill to surround the Greeks.

Sparta. Lacedemonians, all resolved to die with their leader; who being told by the oracle, that either Sparta should be destroyed or the king lose his life, determined without the least hesitation to sacrifice himself for his country. The Thebans indeed remained against their inclination, being detained by Leonidas as hostages; for they were suspected to favour the Persians. The Thespians, with their leader Demophilus, could not by any means be prevailed upon to abandon Leonidas and the Spartans. The augur Megistias, who had foretold the event of this enterprize, being pressed by Leonidas to retire, sent home his only son; but remained himself, and died by Leonidas. Those who staid did not feed themselves with any hopes of conquering or escaping, but looked upon Thermopylæ as their graves; and when Leonidas, exhorting them to take some nourishment, said, that they should all sup together with Pluto, with one accord they set up a shout of joy, as if they had been invited to a banquet.

Xerxes, after pouring out a libation at the rising of the sun, began to move with the whole body of his army, as he had been advised by Epialtes. Upon their approach, Leonidas advanced to the broadest part of the passage, and fell upon the enemy with such undaunted courage and resolution, that the Persian officers were obliged to stand behind the divisions they commanded, in order to prevent the flight of their men. Great numbers of the enemy falling into the sea, were drowned, others were trampled under foot by their own men, and a great many killed by the Greeks; who knowing they could not avoid death upon the arrival of those who were advancing to fall upon their rear, exerted their utmost efforts. In this action fell the brave Leonidas; which Abrocomes and Hyperanthes, two of the brothers of Xerxes, observing, advanced with great resolution to seize his body, and carry it in triumph to Xerxes. But the Lacedemonians, more eager to defend it than their own lives, repulsed the enemy four times, killed both the brothers of Xerxes, with many other commanders of distinction, and rescued the body of their beloved general out of the enemy's hands. But in the mean time, the army that was led by the treacherous Epialtes, advancing to attack their rear, they retired to the narrowest place of the passage, and drawing all together except the Thebans, posted themselves on a rising ground. In this place they made head against the Persians, who poured in upon them on all sides, till at length, not vanquished, but oppressed and overwhelmed by numbers, they all fell, except one who escaped to Sparta, where he was treated as a coward and traitor to his country; but afterwards made a glorious reparation in the battle of Platæa, where he distinguished himself in an extraordinary manner. Some time after, a magnificent monument was erected at Thermopylæ, in honour of those brave defenders of Greece, with two inscriptions; the one general, and relating to all those who died on this occasion, importing, that the Greeks of Peloponnesus, to the number only of 4000, made head against the Persian army, consisting of 3,000,000. The other related to the Spartans in particular, and was composed by the poet Simonides, to this purport: "Go, passenger, and acquaint the Spartans that we died here in obedience to their just commands." At those tombs a funeral oration was yearly pronounced in honour of the dead heroes, and public games performed with great solemnity, wherein none but the Lacedemonians and Thespians had any share, to show that they alone were concerned in the glorious defence of Thermopylæ.

5 Leonidas killed with all his men.

6 A dreadful earthquake in Sparta.

At the end of the 77th Olympiad, a most dreadful earthquake happened at Sparta, in which, according to Diodorus, 20,000 persons lost their lives; and Plutarch tells us, that only five houses were left standing in the whole city. On this occasion the Helotes or slaves, whom the Spartans had all along treated with the utmost cruelty, attempted to revenge themselves, by taking up arms, and marching directly to the ruins of the city, in hopes of cutting off at once those who had escaped from the earthquake. But in this they were prevented by the prudence of the Spartan king Archidamus; for he, observing that the citizens were more desirous of preserving their effects than taking care of their own lives, caused an alarm to be sounded, as if he had known that an enemy was at hand. On this the citizens armed themselves in haste with such weapons as they could come at; and having marched a little way from the city, met the Helotes, whom they soon compelled to retire. The latter, however, knowing that they had now no mercy to expect from those who had already treated them with such cruelty, resolved to defend themselves to the last. Having therefore seized a sea-port town in Messenia, they from thence made such incursions into the Spartan territories, that they compelled those imperious masters to ask assistance from the Athenians. This was immediately granted; but when the Spartans saw that the skill of the Athenians in besieging towns was much greater than their own, they became jealous, and dismissed their allies, telling them, that they had now no farther occasion for their services. On this the Athenians left them in disgust; and as the Helotes and Messenians did not choose to come to an engagement with a Spartan army in the field, but took shelter in their fortified places, the war was protracted for ten years and upwards. At last the Helotes were reduced to their former misery; and the Messenians were obliged to leave Peloponnesus, on pain of being made slaves also. These poor people were then received by the Athenians, who granted them Naupactus for their residence, and afterwards brought them back to a part of their own country, from whence in the course of the Peloponnesian war they had driven the Spartans.

7 War with the Helotes.

8 With the Athenians and Persians.

In the year 431 B. C. the Peloponnesian war commenced; of which a full account has been given under the article ATTICA, n° 116—165. It ended most unfortunately for the Athenians; their city being taken and dismantled, as related in the article abovementioned. Thus were the Spartans raised to the highest pitch of glory; and, in the reign of Agesilaus, they seemed to be on the point of subverting the Persian empire, as related under the article PERSIA, n° 34. But here their good fortune and their views of empire were suddenly checked. Agesilaus had carried on the war in Asia with the greatest success; and as he would hearken to no terms of accommodation, a Persian governor named *Tithraustes*, having first attempted in vain to bribe the king, dispatched Timocrates the Rhodian with 50 talents into Greece, in order to try whether he could there meet with any persons less incorruptible than the Spartan monarch. This agent found many who inclined to accept his offers; particularly in Thebes, Corinth, and Argos. By distributing the money in a proper manner, he inflamed the inhabitants of these three cities against the Spartans; and of all others the Thebans came into his terms with the greatest readiness. They saw that their antagonists would not of their own accord break with any of the states of Greece, and did not choose to begin the war themselves, because the chiefs of the Persian faction were unwilling to be accountable for the event. For this reason they persuaded the Locrians to invade a small district which lay in dispute betwixt the Phocians and themselves. On this the Phocians invaded Locris; the Locrians applied to the Thebans, and the Phocians to the Spartans. The latter were glad of an opportunity of breaking with the Thebans; but met with a much warmer reception than they expected. Their old general Lysander, who had reduced Athens, was defeated and killed, with the loss of 1000 men: on which disaster Agesilaus was recalled, and obliged to relinquish all hopes of conquering the Persians. His return changed the fortune of the war so much, that all the states began to grow weary of a contest from which nobody derived any advantage except the king of Persia. In a short time a treaty was concluded, known in history by the name of the *peace of Antalcidas*. The terms of this treaty were highly disadvantageous and dishonourable to the Greeks§; for even the Spartans, though successful in Greece, had lost a great battle at sea with the Persian fleet under Conon the Athenian, which entirely broke their power in Asia.

9 A general combination against Sparta.

10 Peace of Antalcidas.

§ See Persia, n° 37.

By the peace of Antalcidas, the government of Bœotia was taken from the Thebans, which they had for a long time enjoyed; and by this they were so much provoked, that at first they absolutely refused to accede to the treaty; but as Agesilaus made great preparations to invade them, they thought proper at last to comply. However, it was not long before a new war commenced, which threatened the total subversion of the Spartan state. As, by the peace of Antalcidas, the king of Persia had in a manner guaranteed the sovereignty of Greece to Sparta, this republic very soon began to exercise its power to the utmost extent. The Mantineans were the first who felt the weight of their resentment, although they had been their allies and confederates. In order to have a pretence for making war against them, they commanded them to quit their city, and to retire into five old villages which, they said, had served their forefathers, and where they would live in peace themselves, and give no umbrage to their neighbours. This being refused, an army was sent against them to besiege their city. The siege was continued through the summer with very little success on the part of the Spartans; but having during the winter season dammed up the river on which the city stood, the water rose to such an height, as either to overflow or throw down the houses; which compelled the Mantineans to submit to the terms prescibed to them, and to retire into the old villages. The Spartan vengeance fell next on the Phliasians and Olynthians, whom they forced to come into such measures as they thought proper. After this they fell on the Thebans; and, by attempting to seize on the Piræum, drew the Athenians also into the quarrel. But here their career was stopped: the Thebans had been taught the art of war by Chabrias the Athenian; so that even Agesilaus himself took the command of the Spartan army in vain. At sea they were defeated by Timotheus the son of Conon; and by land the battle of Leuctra put an end to the superiority which Sparta had held over Greece for near 500 years. See Leuctra.

11 Hostilities recommenced.

12 The power of Sparta entirely broken.

After this dreadful defeat, the Spartans had occasion to exert all their courage and resolution. The women and nearest relations of those who were killed in battle, instead of spending their time in lamentations, shook each other by the hand, while the relations of those who had escaped from the battle hid themselves among the women; or if they were obliged to go abroad, they appeared in tattered clothes, with their arms folded, and their eyes fixed on the ground. It was a law among the Spartans, that such as fled from battle should be degraded from their honours, should be constrained to appear in garments patched with divers colours, to wear their beards half-shaved, and to suffer any to beat them who pleased, without resistance. At present, however, this law was dispensed with; and Agesilaus by his prudent conduct kept up the spirits of the people, at the same time that by his skill in military affairs he checked the progress of the enemy. Yet, during the lifetime of Epaminondas the Theban general, the war went on greatly to the disadvantage of the Spartans; but he being killed at the battle of Mantinea, all parties became quickly desirous of peace. Agesilaus did not long survive; and with him, we may say, perished the glory of Sparta. Soon after this all the states of Greece fell under the power of Alexander the Great; and the Spartans, as well as the rest, having become corrupt, and lost their martial spirit, became a prey to domestic tyrants, and to foreign invaders. They maintained their ground, however, with great resolution against the celebrated Pyrrhus king Epirus; whom they repulsed for three days successively, though not without assistance from one of the captains of Antigonus. Soon after this one of the kings of Sparta named *Agis*, perceiving the universal degeneracy that had taken place, made an attempt to restore the laws and discipline of Lycurgus, by which he supposed the state would be restored to its former glory. But though at first he met with some appearance of success, he was in a short time tried and condemned by the ephori as a traitor to his country. Cleomenes, however, who ascended the throne in 216 B. C. accomplished the reformation which Agis had attempted in vain. He suppressed the ephori; cancelled all debts; divided the lands equally, as they had been in the time of Lycurgus; and put an end to the luxury which prevailed among the citizens. But at last he was overborne by the number of enemies which surrounded him; and being defeated in battle by Antigonus, he fled to Egypt, where he put an end to his own life. With him perished every hope of retrieving the affairs of Sparta: the city for the present fell into the hands of Antigonus; after which a succession of tyrants took place; till at last all disturbances were ended by the Romans, who reduced Macedon and Greece to provinces of their empire, as has been related under these articles.

13 Agis and Cleomenes attempt in vain to restore it.

It remains now only to say something concerning the character, manners, and customs of the Spartans, which, as they were founded on the laws of Lycurgus, may best be learned from a view of these laws.

14 Institutions of Lycurgus.

The institutions of Lycurgus were divided into 12 tables

Sparta.

tables. The first comprehended such of the Spartan laws as regarded religion. The statues of all the gods and goddesses were represented in armour, even to Venus herself; the reason of which was, that the people might conceive a military life the most noble and honourable, and not attribute, as other nations did, sloth and luxury to the gods. As to sacrifices, they consisted of things of very small value; for which Lycurgus himself gave this reason, That want might never hinder them from worshipping the gods. They were forbidden to make long or rash prayers to the heavenly powers, and were injoined to ask no more than that they might live honestly and discharge their duty. Graves were permitted to be made within the bounds of the city, contrary to the custom of most of the Greek nations; nay, they buried close by their temples, that all degrees of people might be made familiar with death, and not conceive it such a dreadful thing as it was generally esteemed elsewhere: on the same account, the touching of dead bodies, or assisting at funerals, made none unclean, but were held to be as innocent and honourable duties as any other. There was nothing thrown into the grave with the dead body; magnificent sepulchres were forbidden; neither was there so much as an inscription, however plain or modest, permitted. Tears, sighs, outcries, were not allowed in public, because they were thought dishonourable in Spartans, whom their lawgiver would have to bear all things with equanimity. Mourning was limited to 11 days; on the 12th the mourner sacrificed to Ceres, and threw aside his weeds. In favour of such as were slain in the wars, however, and of women who devoted themselves to a religious life, there was an exception allowed as to the rules before-mentioned; for such had a short and decent inscription on their tombs. When a number of Spartans fell in battle, at a distance from their country, many of them were buried together under one common tomb; but if they fell on the frontiers of their own state, then their bodies were carefully carried back to Sparta, and interred in their family-sepulchres.

15 His laws concerning religion.

16 Concerning the division of land.

II. Lycurgus divided all the country of Laconia into 30,000 equal shares: the city of Sparta he divided into 9000, as some say; into 6000, as others say; and, as a third party will have it, into 4500. The intent of the legislator was, that property should be equally divided among his citizens, so that none might be powerful enough to oppress his fellows, or any be in such necessity, as to be therefrom in danger of corruption. With the same view he forbade the buying or selling these possessions. If a stranger acquired a right to any of these shares, he might quietly enjoy it, provided he submitted to the laws of the republic. The city of Sparta was unwalled; Lycurgus trusting it rather to the virtue of its citizens than to the art of masons. As to the houses, they were very plain; for their ceilings could only be wrought by the axe, and their gates and doors only by the saw; and their utensils were to be of a like stamp, that luxury might have no instruments among them.

17 Of the citizens, children, &c.

III. The citizens were to be neither more nor less than the number of city-lots; and if at any time there happened to be more, they were to be led out in colonies. As to children, their laws were equally harsh and unreasonable; for a father was directed to carry his new-born infant to a certain place, where the gravest men of his tribe looked upon the infant; and if they perceived its limbs straight, and thought it had a wholesome look, then they returned it to its parents to be educated; otherwise it was thrown into a deep cavern at the foot of the mountain Taygetus. This law seems to have had one very good effect, viz. making women very careful, when they were with child, of either eating, drinking, or exercising, to excess: it made them also excellent nurses; for which they were in mighty request throughout Greece. Strangers were not allowed to reside long in the city, that they might not corrupt the Spartans by teaching them new customs. Citizens were also forbidden to travel, for the same reason, unless the good of the state required it. Such as were not bred up in their youth according to the law, were not allowed the liberty of the city, because they held it unreasonable, that one who had not submitted to the laws in his youth should receive the benefit of them when a man. They never preferred any stranger to a public office; but if at any time they had occasion for a person not born a Spartan, they first made him a citizen, and then preferred him.

18 Of celibacy and marriage.

IV. Celibacy in men was infamous, and punished in a most extraordinary manner; for the old bachelor was constrained to walk naked, in the depth of winter, through the market-place: while he did this, he was obliged to sing a song in disparagement of himself; and he had none of the honours paid him which otherwise belonged to old age, it being held unreasonable, that the youth should venerate him who was resolved to leave none of his progeny behind him, to revere them when they grew old in their turn. The time of marriage was also fixed; and if a man did not marry when he was of full age, he was liable to an action; as were such also as married above or below themselves. Such as had three children had great immunities; such as had four were free from all taxes whatsoever. Virgins were married without portions; because neither want should hinder a man, nor riches induce him, to marry contrary to his inclinations. When a marriage was agreed on, the husband committed a kind of rape upon his bride. Husbands went for a long time, secretly and by stealth, to the beds of their wives, that their love might not be quickly and easily extinguished. Husbands were allowed to lend their wives; but the kings were forbid to take this liberty. Some other laws of the like nature there were, which as they were evidently against modesty, so they were far from producing the end for which Lycurgus designed them; since, though the men of Sparta were generally remarkable for their virtue, the Spartan women were as generally decried for their boldness and contempt of decency.

19 Education of their children.

V. It was the care of Lycurgus, that, from their very birth, the Lacedemonians should be inured to conquer their appetites: for this reason he directed, that nurses should accustom their children to spare meals, and now and then to fasting; that they should carry them, when 12 or 13 years old, to those who should examine their education, and who should carefully observe whether they were able to be in the dark alone, and whether they had got over all other follies and weaknesses incident to children. He directed, that children of all ranks should be brought up in the same way; and that none should be more favoured in food than another, that they might not, even in their

infancy,

Sparta.

infancy, perceive any difference between poverty and riches, but consider each other as equals, and even as brethren, to whom the same portions were assigned, and who, through the course of their lives, were to fare alike: the youths alone were allowed to eat flesh; older men ate their black broth and pulse; the lads slept together in chambers, and after a manner somewhat resembling that still in use in Turkey for the Janizaries; their beds, in the summer, were very hard, being composed of the reeds plucked by the hand from the banks of the Eurotas: in winter their beds were softer, but by no means downy, or fit to indulge immoderate sleep. They ate altogether in public; and in case any abstained from coming to the tables, they were fined. It was likewise strictly forbidden for any to eat or drink at home before they came to the common meal; even then each had his proper portion, that every thing might be done there with gravity and decency. The black broth was the great rarity of the Spartans, which was composed of salt, vinegar, blood, &c. so that, in our times, it would be esteemed a very unsavory soup. If they were moderate in their eating, they were so in their drinking also; thirst was the sole measure thereof; and never any Lacedemonian thought of drinking for pleasure: as for drunkenness, it was both infamous and severely punished; and, that young men might perceive the reason, slaves were compelled to drink to excess, that the beastliness of the vice might appear. When they retired from the public meal, they were not allowed any torches or lights, because it was expected, that men who were perfectly sober should be able to find their way in the dark: and, besides, it gave them a facility of marching without light; a thing wonderfully useful to them in time of war.

20
Of their diet, clothing, &c.

VI. As the poor ate as well as the rich, so the rich could wear nothing better than the poor: they neither changed their fashion nor the materials of their garments; they were made for warmth and strength, not for gallantry and show: and to this custom even their kings conformed, who wore nothing gaudy in right of their dignity, but were contented that their virtue should distinguish them rather than their clothes. The youths wore a tunic till they were twelve years old; afterwards they had a cloak given them, which was to serve them a year: and their clothing was, in general, so thin, that a Lacedemonian vest became proverbial. Boys were always used to go without shoes; but when they grew up, they were indulged with them, if the manner of life they led required it; but they were always inured to run without them, as also to climb up and slip down steep places with bare feet: nay, the very shoe they used was of a particular form, plain and strong. Boys were not permitted to wear their hair; but when they arrived at the age of twenty, they suffered their hair and beard to grow. Baths and anointing were not much in use among the Lacedemonians; the river Eurotas supplied the former, and exercise the latter. In the field, however, their sumptuary laws did not take place so strictly as in the city; for when they went to war, they wore purple habits; they put on crowns when they were about to engage the enemy; they had also rings, but they were of iron; which metal was most esteemed by this nation. Young women wore their vests or jerkins only to their knees, or, as some think, not quite so low; a custom which both Greek and Roman authors censure as indecent. Gold, precious stones, and other costly ornaments, were permitted only to common women; which permission was the strongest prohibition to women of virtue, or who affected to be thought virtuous. Virgins went abroad without veils, with which married women, on the contrary, were always covered. In certain public exercises, in which girls were admitted as well as boys, they were both obliged to perform naked. Plutarch apologises for this custom, urging, that there could be no danger from nakedness to the morals of youth whose minds were fortified and habituated to virtue. One of Lycurgus's principal views in his institutions, was to eradicate the very seeds of civil dissension in his republic. Hence proceeded the equal division of estates injoined by him; hence the contempt of wealth, and the neglect of other distinctions, as particularly birth, he considering the people of his whole state as one great family; distinctions which, in other commonwealths, frequently produce tumults and confusions that shake their very foundation.

21
Obedience to their superiors.

VII. Though the Spartans were always free, yet it was with this restriction, that they were subservient to their own laws, which bound them as strictly in the city as soldiers, in other states, were bound by the rules of war in the camp. In the first place, strict obedience to their superiors was the great thing required in Sparta. This they looked upon as the very basis of government; without which neither laws nor magistrates availed much. Old age was an indubitable title to honour in Sparta: to the old men the youth rose up whenever they came into any public place; they gave way to them when they met them in the streets, and were silent whenever their elders spoke. As all children were looked upon as the children of the state, so all the old men had the authority of parents: they reprehended whatever they saw amiss, not only in their own, but in other people's children; and by this method Lycurgus provided, that as youth are everywhere apt to offend, they might be nowhere without a monitor. The laws went still further: if an old man was present where a young one committed a fault, and did not reprove him, he was punished equally with the delinquent. Amongst the youths there was one of their own body, or at most two years older than the rest, who was styled *iren*: he had authority to question all their actions, to look strictly to their behaviour, and to punish them if they did amiss; neither were their punishments light, but, on the contrary, very severe; whereby the youth were made hardy, and accustomed to bear stripes and rough usage. Silence was a thing highly commended at Sparta, where modesty was held to be a most becoming virtue in young people; nor was it restrained only to their words and actions, but to their very looks and gestures; Lycurgus having particularly directed, that they should look forward, or on the ground, and that they should always keep their hands within their robes. A stupid inconsiderate person, one who would not listen to instruction, but was careless of whatever the world might say of him, the Lacedemonians treated as a scandal to human nature; with such an one they would not converse, but threw him off as a rotten branch and worthless member of society.

22
Learning.

VIII. The plainness of their manners, and their being so very much addicted to war, made the Lacedemonians

Sparta.

monians less fond of the sciences than the rest of the Greeks. A soldier was the only reputable profession in Sparta; a mechanic or husbandman was thought a low fellow. The reason of this was, that they imagined professions which required much labour, some constant posture, being continually in the house, or always about a fire, weakened the body and depressed the mind: whereas a man brought up hardily, was equally fit to attend the service of the republic in time of peace, and to fight its battles when engaged in war. Such occupations as were necessary to be followed for the benefit of the whole, as husbandry, agriculture, and the like, were left to their slaves the Helotes; but for curious arts, and such as served only to luxury, they would not so much as suffer them to be introduced in their city; in consequence of which, rhetoricians, augurs, bankers, and dealers in money, were shut out. The Spartans admitted not any of the theatrical diversions among them; they would not bear the representation of evil even to produce good; but other kinds of poetry were admitted, provided the magistrates had the perusal of pieces before they were handed to the public.

Above all things, they affected brevity of speech, and accustomed their children, from their very infancy, never to express themselves in more words than were strictly necessary; whence a concise and sententious oratory is to this day styled *Laconic*. In writing they used the same conciseness; of which we have a signal instance in a letter of Archidamus to the Eleans, when he understood that they had some thoughts of assisting the Arcadians. It ran thus: "Archidamus to the Eleans: It is good to be quiet." And therefore Epaminondas thought that he had reason to glory in having forced the Spartans to abandon their monosyllables, and to lengthen their discourses.

The greatest part of their education consisted in giving their youth right ideas of men and things: the iren or master proposed questions, and either commended the answers that were made him, or reproved such as answered weakly. In these questions, all matters, either of a trivial or abstruse nature, were equally avoided; and they were confined to such points as were of the highest importance in civil life; such as, Who was the best man in the city? Wherein lay the merit of such an action? and, Whether this or that hero's fame was well-founded? Harmless raillery was greatly encouraged; and this, joined to their short manner of speaking, rendered laconic replies universally admired.

Music was much encouraged; but in this, as in other things, they adhered to that which had been in favour with their ancestors; nay, they were so strict therein, that they would not permit their slaves to learn either the tune or the words of their most admired odes; or, which is all one, they would not permit them to sing them if they had learned them. Though the youth of the male sex were much cherished and beloved, as those that were to build up and continue the future glory of the state, yet in Sparta it was a virtuous and modest affection, untinged with that sensuality which was so scandalous at Athens. The good effects of this part of Lycurgus's institutions were seen in the union that reigned among his citizens; and which was so extraordinary, that even in cases of competition, it was hardly known that rivals bore ill-will to each other; but, on the contrary, their love to the same person begat a secondary friendship among themselves, and united them in all things which might be for the benefit of the person beloved.

Some authors have accused this great lawgiver of encouraging theft in his institutions; which, they say, was not held scandalous among the Spartans, if it were so dexterously managed as that the person was not detected in it. But this is certain, and seems to be a strong contradiction of the heinous charge, that when a theft was discovered, it was punished with the utmost severity: a person even suspected of it would endure the heaviest punishments rather than acknowledge it, and be branded with so base a crime.

23 Exercises.

IX. The exercises instituted by law fall under the ninth table. In these all the Greeks were extremely careful, but the Lacedemonians in a degree beyond the rest; for if a youth, by his corpulence, or any other means, became unfit for these exercises, he underwent public contempt at least, if not banishment.—Hunting was the usual diversion of their children; nay, it was made a part of their education, because it had a tendency to strengthen their limbs, and to render those who practised it supple and fleet: they likewise bred up dogs for hunting with great care. They had a kind of public dances, in which they exceedingly delighted, and which were common alike to virgins and young men: indeed, in all their sports, girls were allowed to divert themselves with the youth; insomuch that, at darting, throwing the quoit, pitching the bar, and such-like robust diversions, the women were as dexterous as the men. For the manifest oddity of this proceeding, Lycurgus assigned no other reason, than that he sought to render women, as well as men, strong and healthy, that the children they brought forth might be so too. Violent exercises, and a laborious kind of life, were only enjoined the youth; for when they were grown up to men's estate, that is, were upwards of 30 years old, they were exempted from all kinds of labour, and employed themselves wholly either in affairs of state or in war. They had a method of whipping, at a certain time, young men in the temple of Diana, and about her altar; which, however palliated, was certainly unnatural and cruel. It was esteemed a great honour to sustain these flagellations without weeping, groaning, or showing any sense of pain; and the thirst of glory was so strong in these young minds, that they very frequently suffered death without shedding a tear or breathing a sigh. A desire of overcoming all the weaknesses of human nature, and thereby rendering his Spartans not only superior to their neighbours, but to their species, runs through many of the institutions of Lycurgus; which principle, if well attended to, thoroughly explains them, and without attending to which it is impossible to give any account of them at all.

24 Money, &c.

X. Gold and silver were, by the constitutions of Lycurgus, made of no value in Sparta. He was so well apprized of the danger of riches, that he made the very possession of them venal; but as there was no living without some sort of money, that is, some common measure or standard of the worth of things, he directed an iron coinage, whereby the Spartans were supplied with the useful money, and at the same time had no temptation to covetousness afforded them; for a very small sum was sufficient to load a couple of horses, and

a great

a great one must have been kept in a barn or warehouse. The coming in of all foreign money was also prohibited, that corruption might not enter under the name of commerce. The most ancient method of dealing, viz. by barter, or exchange of one commodity for another, was preserved by law in Sparta long after it had been out of date everywhere else. Interest was a thing forbidden in the Spartan commonwealth; where they had also a law against alienation of lands, accepting presents from foreigners, even without the limits of their own country, and when their authority and character might well seem to excuse them.

25 Courts of Justice.

XI. Such of the laws of Sparta as related to courts of justice may be brought under the 11th table. Thirty years must have passed over the head of him who had a right to concern himself in juridical proceedings. Young men were thought unfit for them; and it was even held indecent, and of ill report, for a man to have any fondness for law-suits, or to be busying himself at the tribunals, when he had no affairs there of his own. By these rules Lycurgus thought to shut out litigiousness, and to prevent that multiplicity of suits which is always scandalous in a state. As young people were not permitted to inquire about the laws of other countries, and as they were hindered from hearing judicial proceedings in their courts, so they were likewise forbidden to ask any questions about, or to endeavour to discover, the reasons of the laws by which themselves were governed. Obedience was their duty; and to that alone they would have them kept. Men of abandoned characters, or who were notoriously of ill fame, lost all right of giving their votes in respect of public affairs, or of speaking in public assemblies; for they would not believe that an ill man in private life could mean his country better than he did his neighbour.

26 Military service.

XII. Till a man was 30 years old, he was not capable of serving in the army, as the best authors agree; though some think that the military age is not well ascertained by ancient writers. They were forbidden to march at any time before the full-moon; the reason of which law is very hard to be discovered, if indeed it had any reason at all, or was not rather founded on some superstitious opinion, that this was a more lucky conjuncture than any other. They were likewise fordidden to fight often against the same enemy; which was one of the wisest maxims in the political system of Lycurgus: and Agesilaus, by offending against it, destroyed the power of his country, and lost her that authority which for many ages she maintained over the rest of Greece; for, by continually warring against the Thebans, to whom he had an inveterate hatred, he at last beat them into the knowledge of the art of war, and enabled them, under the command of Epaminondas, to maintain for a time the principality of Greece. Maritime affairs they were forbidden to meddle with, though the necessity of things compelled them, in process of time, to transgress this institution, and by degrees to transfer to themselves the dominion of the sea as well as of the land: but, after the Peloponnesian war, they again neglected naval affairs, from a persuasion that sailors and strangers corrupted those with whom they conversed. As they never fortified Sparta, they were not ready to undertake sieges: fighting in the field was their proper province, and, while they could overcome their enemies there, they rightly conceived that nothing could hurt them at home. In time of war, they relaxed somewhat of their strict manner of living, in which they were singular. The true reason for this was, in all probability, that war might be less burdensome to them; for, as we have more than once observed, a strong desire to render them bold and warlike was the reigning passion of their legislator. They were forbidden to remain long encamped in the same place, as well to hinder their being surprised, as that they might be more troublesome to their enemies, by wasting every corner of their country. They slept all night in their armour; but their outguards were not allowed their shields, that, being unprovided of defence, they might not dare to sleep. In all expeditions they were careful in the performance of religious rites; and, after their evening meal was over, the soldiers sung together hymns to their gods. When they were about to engage, the king sacrificed to the muses, that, by their assistance, they might be enabled to perform deeds worthy of being recorded to latest times. Then the army advanced in order to the sound of flutes, which played the hymn of Castor. The king himself sung the pæan, which was the signal to charge. This was done with all the solemnity imaginable; and the soldiers were sure either to die or conquer: indeed they had no other choice; for if they fled they were infamous, and in danger of being slain, even by their own mothers, for disgracing their families. In this consisted all the excellency of the Spartan women, who, if possible, exceeded in bravery the men, never lamenting over husbands or sons, if they died honourably in the field; but deploring the shame brought on their house, if either the one or the other escaped by flight. The throwing away a shield also induced infamy; and, with respect to this, mothers, when they embraced their departing sons, were wont to caution them, that they should either return armed as they were, or be brought back so when they were dead; for, as we have observed, such as were slain in battle were nevertheless buried in their own country. When they made their enemies fly, they pursued no longer than till victory was certain; because they would seem to fight rather for the honour of conquering, than of putting their enemies to death. According to their excellent rules of war, they were bound not to spoil the dead bodies of their enemies; but in process of time, this, and indeed many other of their most excellent regulations, fell into desuetude. He who overcame by stratagem, offered up an ox to Mars; whereas he who conquered by force, offered up only a cock; the former being esteemed more manly than the latter. After 40 years service, a man was, by law, no longer required to go into the field; and consequently, if the military age was 30, the Spartans were not held invalids till they were 70.

SPARTIANUS (Ælius), a Latin historian, who wrote the lives of Adrian, Caracalla, and four other Roman emperors. He lived under the reign of Dioclesian, about the year 290.

SPARTIUM, Broom, in botany: A genus of plants belonging to the class of *diadelphia*, and order of *decandria*; and in the natural system arranged under the 32d order, *Papilionaceæ*. The stigma is longitudinal and woolly above: the filaments adhere to the germen. The calyx is produced downwards. There are 16 species, the

Spartium. the scoparium, contaminatum, sepiarium, junceum, monospermum, sphœrocarpon, purgans, aphyllum, scorpius, angulatum, patens, supranulium, complicatum, radiatum, cytisoides, and spinosum. All these, except the scoparium, are exotics, chiefly from Spain, Portugal, Italy, &c.—the *scoparium*, or common broom, has ternate solitary leaves; the branches angular, and without prickles.

Uses. The common broom is used for a variety of purposes. It has been of great benefit sometimes in dropsical complaints. The manner in which Dr Cullen administered it was this: He ordered half an ounce of fresh broom tops to be boiled in a pound of water till one half of the water was evaporated. He then gave two table-spoonfuls of the decoction every hour till it operated both by stool and urine. By repeating these doses every-day, or every second day, he says some dropsies have been cured. Dr Mead relates, that a dropsical patient, who had taken the usual remedies, and been tapped three times without effect, was cured by taking half a pint of the decoction of green broom tops, with a spoonful of whole mustard-seed every morning and evening. "An infusion of the seeds drunk freely (says Mr Withering) has been known to produce similar happy effects; but whoever expects these effects to follow in every dropsical case, will be greatly deceived. I knew them succeed in one case that was truly deplorable; but out of a great number of cases in which the medicine had a fair trial, this proved a single instance.

The flower buds are in some countries pickled, and eaten as capers; and the seeds have been used as a bad substitute for coffee. The branches are used for making besoms, and tanning leather. They are also used instead of thatch to cover houses. The old wood furnishes the cabinet-maker with beautiful materials for vaneering. The tender branches are in some places mixed with hops for brewing, and the macerated bark may be manufactured into cloth.

The *junceum*, or Spanish broom, grows naturally in the southern provinces of France, as well as other parts of the south of Europe. It grows in the poorest soils, on the steepest declivities of the hills in a stony soil, where hardly any other plant could vegetate. In a few years it makes a vigorous shrub; insinuating its roots between the interstices of the stones, it binds the soil, and retains the small portion of vegetable earth scattered over these hills, which the autumnal rains would otherwise wash away. It is most easily raised from seed, which is usually sown in January, after the ground has received a slight dressing.

Journal de Physique.

This shrub serves two useful purposes. Its branches yield a thread of which linen is made, and in winter support sheep and goats.

In manufacturing thread from broom, the youngest plants are cut in the month of August, or after harvest, and gathered together in bundles, which at first are laid in the sun to dry: they are then beaten with a piece of wood, washed in a river or pond, and left to steep in the water for about four hours. The bundles thus prepared are taken to a little distance from the water, and laid in a hollow place made for them, where they are covered with fern or straw, and remain thus to steep for eight or nine days; during which time, all that is necessary, is to throw a little water once a-day on the heap, without uncovering the broom. After this, the bundles are well washed, the green rind of the plant or epidermis comes off, and the fibrous part remains; each bundle is then beaten with a wooden hammer upon a stone, to detach all the threads, which are at the same time carefully drawn to the extremity of the branches. After this operation, the faggots are untied, and spread upon stones or rocks till they are dry. The twigs must not be peeled till they are perfectly dry; they are then dressed with the comb, and the threads are separated according to their fineness, and spun upon a wheel. Spartium, Sparus.

The linen made of this thread serves various purposes in rural economy. The coarsest is employed in making sacks and other strong cloths for carrying grain or seeds. Of the finest is made bed, table, and body linen. The peasants in several places use no other, for they are unacquainted with the culture of hemp or flax, their soil being too dry and too barren for raising them. The cloth made with the thread of the broom is very useful; it is as soft as that made of hemp; and it would perhaps look as well as that made of flax if it was more carefully spun. It becomes white in proportion as it is steeped. The price of the finest thread, when it is sold, which seldom happens, is generally about a shilling a pound.

The other use to which this broom is applied, is to maintain sheep and goats during winter. In the mountains of Lower Languedoc these animals have no other food from November to April, except the leaves of trees preserved. The branches of this broom therefore are a resource the more precious, that it is the only fresh nourishment which at that season the flocks can procure, and they prefer it at all times to every other plant. In fine weather the sheep are led out to feed on the broom, where it grows; but in bad weather the shepherds cut the branches, and bring them to the sheep-folds. There is, however, an inconvenience attending the continued use of this food. It generally produces inflammation in the urinary passages. But this inconvenience is easily removed by cooling drink, or a change of food, or by mixing the broom with something else.

It is perhaps needless to add, that it differs much from the broom that is common every where in the north of Europe, though this too, in many places, is used for food to cattle. Both of them produce flowers that are very much resorted to by bees, as they contain a great quantity of honey juice. And this should be another inducement to the cultivation of the Spanish broom.

SPARUS, Gilthead, in natural history; a genus of animals belonging to the class of *pisces*, and the order of *thoracici*. The fore-teeth and dog-teeth are very strong; the grinders are obtuse and thick set; the lips are folded over; there are five rays in the gill membrane; and the opercula are scaly: the body is compressed; the lateral line is crooked behind; and the pectoral fins are roundish.

Gmelin enumerates 39 species, of which only three are found in the British seas, the pagrus, auratus, and dentatus. 1. The *pagrus*, or sea-bream, is of a reddish colour. The skin forms a sinus at the roots of the dorsal and anal fins. The body is broad; the back and belly ridged. There is only one dorsal fin. 2. The *auratus*, or gilt-bream. The head and sides of it are gilt, and there is a golden spot between the eyes shaped like a half moon; there is also a black purple spot on the gills; and it weighs from eight lb. to ten lb. It is one of the *pisces saxatiles*, or fish that haunts deep waters on bold rocky shores. They feed chiefly on shell-fish, which they comminute with their teeth before they swallow; the teeth of this genus in particular being adapted for that purpose: the grinders are flat and strong, like those of certain quadrupeds: besides which there are certain bones in the lower part of the mouth that assist in grinding their food. They are but a coarse fish: they were known to the Romans, who did not esteem them unless they were fed with Lucrine oysters, as Martial informs us,

Non omnis laudem pretiumque AURATA *meretur,*
Sed qui solus erit concha Lucrina cibus.
Lib. xiii. Ep. 90.

3. The *dentatus*, toothed sea-bream, is black above, and of a silvery appearance below. The eyes and gills are very large. There are nine rows of teeth in the lower jaw, and one in the upper.

In the account of Captain Cook's voyage published by Mr Forster, we are informed, that the giltheads are sometimes poisonous, owing to their feeding on certain species of the raja, which have an extremely acrid and stimulating property.

SPASM, a convulsion. See MEDICINE, n° 278.

SPATHA, in botany, a sheath; a species of calyx which bursts lengthwise, and protrudes a stalk supporting one or more flowers, which commonly have no perianthium or flower-cup.

SPATHACEÆ (from *spatha*, "a sheath"), the name of the ninth order in Linnæus's Fragments of a Natural Method consisting of plants whose flowers are protruded from a spatha or sheath. See BOTANY, p. 458.

SPATHELIA, in botany; a genus of plants belonging to the class of *pentandria*, and to the order of *trigynia*. The calyx is pentaphyllous; the petals are five; the capsule is three-edged and trilocular; the seeds solitary. There is only one species, the *simplex*, which is a native of Jamaica, and was introduced into the botanic gardens of Britain in 1778 by Dr Wright, late of Jamaica.

SPAW. See SPA.

SPAWN, in natural history, the eggs of fishes or frogs. See FISH and RANA.

SPAVENTO. See SCANTO.

SPAVIN, in the manege, a disease in horses, being a swelling or stiffness, usually in the ham, occasioning a lameness. See FARRIERY, § 29.

SPAYING, or SPADING, the operation of castrating the females of several kinds of animals, as sows, bitches, &c. to prevent any further conception, and promote their fattening. It is performed by cutting them in the mid flank, on the left side, with a sharp knife or lancet, taking out the uterus, and cutting it off, and so stitching up the wound, anointing the part with tar, and keeping the animal warm for two or three days. The usual way is to make the incision aslope, two inches and a half long; that the fore-finger may be put in towards the back, to feel for the ovaries, which are two kernels as big as acorns on both sides of the uterus, one of which is drawn to the wound, and thus both taken out.

SPEAKER *of the House of Commons*, a member of the house elected by a majority of votes thereof to act as chairman or president in putting questions, reading briefs, or bills, keeping order, reprimanding the refractory, adjourning the house, &c. See PARLIAMENT.

SPEAKING, the art or act of expressing one's thoughts in articulate sounds or words. See GRAMMAR, LANGUAGE, READING, and ORATORY, Part iv.

SPEAKING-Trumpet. See TRUMPET.

SPEAR-MINT, in botany. See MENTHA.

SPEAR-Wort. See RANUNCULUS.

SPECIAL, something that is particular, or has a particular designation; from the Latin *species*, in opposition to the *general*, from *genus*.

SPECIES, in logic, a relative term, expressing an idea which is comprised under some general one called a *genus*. See LOGIC, n° 68.

SPECIES, in commerce, the several pieces of gold, silver, copper, &c. which having passed their full preparation and coinage, are current in public. See MONEY.

SPECIFIC, in philosophy, that which is peculiar to any thing, and distinguishes it from all others.

SPECIFICS, in medicine. By specifics is not meant such as infallibly and in all patients produce salutary effects. Such medicines are not to be expected, because the operations and effects of remedies are not formally inherent in them, but depend upon the mutual action and reaction of the body and medicine upon each other; hence the various effects of the same medicine in the same kind of disorders in different patients, and in the same patient at different times. By specific medicines we understand such medicines as are more infallible than any other in any particular disorder.

SPECIFIC GRAVITY, is a term much employed in the discussions of modern physics. It expresses the weight of any particular kind of matter, as compared with the weight of the same bulk of some other body of which the weight is supposed to be familiarly known, and is therefore taken for the standard of comparison. The body generally made use of for this purpose is pure water. See HYDROSTATICS, Sect. III.

The specific gravity of bodies is a very interesting question both to the philosopher and to the man of business. The philosopher considers the weights of bodies as measures of the number of material atoms, or the quantity of matter which they contain. This he does on the supposition that every atom of matter is of the same weight, whatever may be its sensible form. This supposition, however, is made by him with caution, and he has recourse to specific gravity for ascertaining its truth in various ways. This shall be considered by and by. The man of business entertains no doubt of the matter, and proceeds on it as a sure guide in his most interesting transactions. We measure commodities of various kinds by tons, pounds, and ounces, in the same manner as we measure them by yards, feet, and inches, or by bushels, gallons, and pints; nay, we do this with much greater confidence, and prefer this measurement to all others, whenever we are much interested to know the exact proportions of matter that bodies contain. The weight of a quantity of grain is allowed to inform us much more exactly of its real quantity of useful matter than the most accurate measure of its bulk. We see many circumstances which can vary the bulk of a quantity of matter, and these are frequently such as we cannot

not regulate or prevent; but we know very few indeed that can make any ſenſible change in this weight without the addition or abſtraction of other matter. Even taking it to the ſummit of a high mountain, or from the equator to the polar region, will make no change in its weight as it is aſcertained by the balance, becauſe there is the ſame real diminution of weight in the pounds and ounces uſed in the examination.

Notwithſtanding the unavoidable change which heat and cold make in the bulk of bodies, and the permanent varieties of the ſame kind of matter which are cauſed by different circumſtances of growth, texture, &c. moſt kinds of matter have a certain conſtancy in the denſity of their particles, and therefore in the weight of a given bulk. Thus the purity of gold, and its degree of adulteration, may be inferred from its weight, it being purer in proportion as it is more denſe. The denſity, therefore, of different kinds of tangible matter becomes characteriſtic of the kind, and a teſt of its purity; it marks a particular appearance in which matter exiſts, and may therefore be called, with propriety, Specific.

But this denſity cannot be directly obſerved. It is not by comparing the diſtances between the atoms of matter in gold and in water that we ſay the firſt is 19 times denſer than the laſt, and that an inch of gold contains 19 times as many material atoms as an inch of water; we reckon on the equal gravitation of every atom of matter whether of gold or of water; therefore the weight of any body becomes the indication of its material denſity, and the weight of a given bulk becomes ſpecific of that kind of matter, marking its kind, and even aſcertaining its purity in this form.

It is evident that, in order to make this compariſon of general uſe, the ſtandard muſt be familiarly known, and muſt be very uniform in its denſity, and the compariſon of bulk and denſity muſt be eaſy and accurate. The moſt obvious method would be to form, with all nicety, a piece of the ſtandard matter of ſome convenient bulk, and to weigh it very exactly, and keep a note of its weight: then, to make the compariſon of any other ſubſtance, it muſt be made into a maſs of the ſame preciſe bulk, and weighed with equal care; and the moſt convenient way of expreſſing the ſpecific gravity would be to conſider the weight of the ſtandard as unity, and then the number expreſſing the ſpecific gravity is the number of times that the weight of the ſtandard is contained in that of the other ſubſtance. This compariſon is moſt eaſily and accurately made in fluids. We have only to make a veſſel of known dimenſions equal to that of the ſtandard which we employ, and to weigh it when empty, and then when filled with the fluid. Nay, the moſt difficult part of the proceſs, the making a veſſel of the preciſe dimenſions of the ſtandard, may be avoided, by uſing ſome fluid ſubſtance for a ſtandard. Any veſſel will then do; and we may enſure very great accuracy by uſing a veſſel with a ſlender neck, ſuch as a phial or matraſs: for when this is filled to a certain mark in the neck, any error in the eſtimation by the eye will bear a very ſmall proportion to the whole. The weight of the ſtandard fluid which fills it to this mark being carefully aſcertained, is kept in remembrance. The ſpecific gravity of any other fluid is had by weighing the contents of this veſſel when filled with it, and dividing the weight by the weight of the ſtandard. The quotient is the ſpecific gravity of the fluid. But in all other caſes this is a very difficult problem: it requires very nice hands, and an accurate eye, to make two bodies of the ſame bulk. An error of one hundredth part in the linear dimenſions of a ſolid body makes an error of a 30th part in its bulk; and bodies of irregular ſhapes and friable ſubſtance, ſuch as the ores of metals, cannot be brought into convenient and exact dimenſions for meaſurement.

From all theſe inconveniences and difficulties we are freed by the celebrated Archimedes, who, from the principles of hydroſtatics diſcovered or eſtabliſhed by him, deduced the accurate and eaſy method which is now univerſally practiſed for diſcovering the ſpecific gravity and denſity of bodies. (See Archimedes and Hydrostatics, no 11.) Inſtead of meaſuring the bulk of the body by that of the diſplaced fluid (which would have been impoſſible for Archimedes to do with any thing like the neceſſary preciſion), we have only to obſerve the loſs of weight ſuſtained by the ſolid. This can be done with great eaſe and exactneſs. Whatever may be the bulk of the body, this loſs of weight is the weight of an equal bulk of the fluid; and we obtain the ſpecific gravity of the body by ſimply dividing its whole weight by the weight loſt: the quotient is the ſpecific gravity when this fluid is taken for the ſtandard, even though we ſhould not know the abſolute weight of any given bulk of this ſtandard. It alſo gives us an eaſy and accurate method of aſcertaining even this fundamental point We have only to form any ſolid body into an exact cube, ſphere, or priſm, of known dimenſions, and obſerve what weight it loſes when immerſed in this ſtandard fluid. This is the weight of the ſame bulk of the ſtandard to be kept in remembrance; and thus we obtain, by the by, a moſt eaſy and accurate method for meaſuring the bulk or ſolid contents of any body, however irregular its ſhape may be. We have only to ſee how much weight it loſes in the ſtandard fluid; we can compute what quantity of the ſtandard fluid will have this weight. Thus ſhould we find that a quantity of ſand, or a furze buſh, loſes 250 ounces when immerſed in pure water, we learn by this that the ſolid meaſure of every grain of the ſand, or of every twig and prickle of the furze, when added into one ſum, amounts to the fourth part of a cubic foot, or to 432 cubic inches.

To all theſe advantages of the Archimedean method of aſcertaining the ſpecific gravity of bodies, derived from his hydroſtatical doctrines and diſcoveries, we may add, that the immediate ſtandard of compariſon, namely, water, is, of all the ſubſtances that we know, the fitteſt for the purpoſe of an univerſal ſtandard of reference. In its ordinary natural ſtate it is ſufficiently conſtant and uniform in its weight for every examination where the utmoſt mathematical accuracy is not wanted; all its variations ariſe from impurities, from which it may at all times be ſeparated by the ſimple proceſs of diſtillation: and we have every reaſon to think that when pure, its denſity, when of the ſame temperature, is invariable.

Water is therefore univerſally taken for the unit of that ſcale on which we meaſure the ſpecific gravity of bodies, and its weight is called 1. The ſpecific gravity of any other body is the real weight in pounds and ounces, when of the bulk of one pound or one ounce of water. It is therefore of the firſt importance, in all discussions respecting the specific gravity of bodies, to have the precise weight of some known bulk of pure water. We have taken some pains to examine, and compare the experiments on this subject, and shall endeavour to ascertain this point with the precision which it deserves. We shall reduce all to the English cubic foot and avoirdupois ounce of the Exchequer standard, on account of a very convenient circumstance peculiar to this unit, viz. that a cubic foot contains almost precisely a thousand ounces of pure water, so that the specific gravity of bodies expresses the number of such ounces contained in a cubit foot.

We begin with a trial made before the house of commons in 1696 by Mr Everard. He weighed 2145,6 cubic inches of water by a balance, which turned sensibly with 6 grains, when there were 30 pounds in each scale. The weights employed were the troy weights, in the deposit of the Court of Exchequer, which are still preserved, and have been most scrupulously examined and compared with each other. The weight was 1131 ounces 14 penny weights. This wants just 11 grains of a thousand avoirdupois ounces for 1728 cubic inches, or a cubic foot; and it would have amounted to that weight had it been a degree or two colder. The temperature indeed is not mentioned; but as the trial was made in a comfortable room, we may presume the temperature to have been about 55° of Fahrenheit's thermometer. The dimensions of the vessel were as accurate as the nice hand of Mr Abraham Sharp, Mr Flamstead's assistant at Greenwich, could execute, and it was made by the Exchequer standard of length.

This is confided in by the naturalists of Europe as a very accurate standard experiment, and it is confirmed by many others both private and public. The standards of weight and capacity employed in the experiment are still in existence, and publicly known, by the report of the Royal Society to parliament in 1742, and by the report of a committee of the house of commons in 1758. This gives it a superiority over all the measures which have come to our knowledge.

The first experiment, made with proper attention, that we meet with, is by the celebrated Snellius, about the year 1615, and related in his *Eratosthenes Batavus*. He weighed a Rhinland cubic foot of distilled water, and found it 62,79 Amsterdam pounds. If this was the ordinary weight of the shops, containing 7626 English troy grains, the English cubic foot must be 62 pounds 9 ounces, only one ounce more than by Everard's experiment. If it was the Mint pound, the weight was 62 pounds 6 ounces. The only other trials which can come into competition with Mr Everard's are some made by the Academy of Sciences at Paris. Picart, in 1691, found the Paris cubic foot of the water of the fountain d'Arcueil to weigh 69,588 pounds *poids de Paris*. Du Hamel obtained the very same result; but Mr Monge, in 1783, says that filtered rain-water of the temperature 12° (Reaumur) weighs 69,3792. Both these measures are considerably below Mr Everard's, which is 62,5, the former giving 62,053, and the latter 61,868. M. Lavoisier states the Paris cubic foot at 70 pounds, which makes the English foot 62,47. But there is an inconsistency among them which makes the comparison impossible. Some changes were made in 1688, by royal authority, in the national standards, both of weight and length; and the academicians are exceedingly puzzled to this day in reconciling the differences, and cannot even ascertain with perfect assurance the lineal measures which were employed in their most boasted geodeticial operations.

Such variations in the measurements made by persons of reputation for judgment and accuracy engaged the writer of this article some years ago to attempt another. A vessel was made of a cylindrical form, as being more easily executed with accuracy, whose height and diameter were 6 inches, taken from a most accurate copy of the Exchequer standard. It was weighed in distilled water of the temperature 55° several times without varying 2 grains, and it lost 42895 grains. This gives for the cubic foot 998,74 ounces, deficient from Mr Everard's an ounce and a quarter; a difference which may be expected, since Mr Everard used the New River water without distillation.

We hope that these observations will not be thought superfluous in a matter of such continual reference, in the most interesting questions both to the philosopher and the man of business; and that the determination which we have given will be considered as sufficiently authenticated.

Let us, therefore, for the future take water for the standard, and suppose that, when of the ordinary temperature of summer, and in its state of greatest natural purity, viz. in clean rain or snow, an English cubic foot of it weighs a thousand avoirdupois ounces of 437,5 troy grains each. Divide the weight of any body by the weight of an equal bulk of water, the quotient is the specific gravity of that body; and if the three first figures of the decimal be accounted integers, the quotient is the number of avoirdupois ounces in a cubic foot of the body. Thus the specific gravity of the very finest gold which the refiner can produce is 19,365, and a cubic foot of it weighs 19365 ounces.

But an important remark must be made here. All bodies of homogeneous or unorganised texture expand by heat, and contract by cooling. The expansion and contraction by the same change of temperature is very different in different bodies. Thus water, when heated from 60° to 100°, increases its volume nearly $\frac{1}{107}$ of its bulk, and mercury only $\frac{1}{145}$, and many substances much less. Hence it follows, that an expriment determines the specific gravity only in that very temperature in which the bodies are examined. It will therefore be proper always to note this temperature; and it will be convenient to adopt some very useful temperature for such trials in general; perhaps about 64° of Fahrenheit's thermometer is as convenient as any. It may always be procured in these climates without inconvenience. A temperature near to freezing would have some advantages, because water changes its bulk very little between the temperature 32° and 45°. But this temperature cannot always be obtained. It will much conduce to the facility of the comparison to know the variation which heat produces on pure water. The following table, taken from the observations of Dr Blagden and Mr Gilpin (Phil. Transf. 1792) will answer this purpose.

Thofe gentlemen obferved the expanfion of water to be very anomalous between 32° and 45°. This is diftinctly feen during the gradual cooling of water to the point of freezing. It contracts for a while, and then fuddenly expands. But we feldom have occafion to meafure fpecific gravities in fuch temperature.

The reader is now fufficiently acquainted with the principles of this hydroftatical method of determining the fpecific gravity of bodies, and can judge of the propriety of the forms which may be propofed for the experiment.

The fpecific gravity of a fluid may be determined either by filling with it a veffel with a narrow neck, or by weighing a folid body that is immerfed in it. It is hard to fay which is the beft way. The laft is not fubject to any error in filling, becaufe we may fufpend the folid by a fine wire, which will not difplace any fenfible quantity of the fluid; and if the folid is but a little heavier than the fluid, the balance being loaded only with the excefs, will be very fenfible to the fmalleft want of equilibrium. But this advantage is perhaps compenfated by an obftruction to the motion of the folid up or down in the fluid, arifing from vifcidity. When the weight in the oppofite fcale is yet too fmall, we flowly add more, and at laft grain by grain, which gradually brings the beam to the level. When it is exactly level, the weight in the fcale is fomewhat too great; for it not only balances the preponderance of the folid, but alfo this vifcidity of the fluid. But we may get rid of this error. Add a fmall quantity more; this will bring the beam over to the other fide. Now put as much into the fcale on the fame fide with the folid; this will not reftore the beam to its level. We muft add more till this be accomplifhed; and this addition is the meafure of the vifcidity of the fluid, and muft be fubtracted from the weight that was in the other fcale when the beam came *firft* to a level. This effect of vifcidity is not infenfible, with nice apparatus, even in the pureft water, and in many fluids it is very confiderable—and, what is worfe, it is very changeable. It is greatly diminifhed by heat; and this is an additional reafon for making thofe trials in pretty warm temperatures. But for fluids of which the vifcidity is confiderable, this method is by no means proper; and we muft take the other, and weigh them in a veffel with a narrow neck. Mercury muft alfo be treated in this way, becaufe we have no folid that will fink in it but gold and platina.

It is not fo eafy as one would imagine to fill a veffel precifely to the fame degree upon every trial. But if we do not operate on too fmall quantities, the unavoidable error may be made altogether infignificant, by having the neck of the veffel very fmall. If the veffel hold a pound of water, and the neck do not exceed a quarter of an inch (and it will not greatly retard the operation to have it half this fize), the examinator muft be very carelefs indeed to err one part in two thoufand; and this is perhaps as near as we can come with a balance. We muft always recollect that the capacity of the veffel changes by heat, and we muft know this variation, and take it into the account. But it is affectation to regard (as Mr Homberg would make us believe that he did) the diftenfion of the veffel by the preffure of the fluid. His experiments of this kind have by no means the confiftency with each other that fhould convince us that he did not commit much greater errors than what arofe from diftenfion.

In examining either folids or fluids, we muft be careful to free their furface, or that of the veffel in which the fluid is to be weighed, from air, which frequently adheres to it in a peculiar manner, and, by forming a bubble, increafes the apparent bulk of the folid, or diminifhes the capacity of the veffel. The greateft part of what appears on thofe occafions feems to have exifted in the fluid in a ftate of chemical union, and to be fet at liberty by the fuperior attraction of the fluid for the contiguous folid body. Thefe air bubbles muft be carefully brufhed off by hand. All greafy matters muft be cleared off for the fame reafon: they prevent the fluid from coming into contact.

We muft be no lefs careful that no water is imbibed by the folid, which would increafe its weight without increafing its bulk. In fome cafes, however, a very long maceration and imbibition is neceffary. Thus, in examining the fpecific gravity of the fibrous part of vegetables, we fhould err exceedingly if we imagined it as fmall as appears at firft. We believe that in moft plants it is at leaft as great as water, for after long maceration they fink in it.

It is almoft needlefs to fay that the niceft and moft fenfible balances are neceffary for this examination. Balances are even conftructed on purpofe, and fitted with feveral pieces of apparatus, which make the examination eafy and neat. We have defcribed (fee Balance) Mr Gravefande's as one of the moft convenient of any. His contrivance for obferving the fractions of a grain is extremely ingenious and expeditious, efpecially for detecting the effect of vifcidity.

The hydrometer, or aecometer, is another inftrument for afcertaining the fpecific gravity of fluids. This very pretty inftrument is the invention of a lady, as eminent for intellectual accomplifhments as fhe was admired for her beauty. Hypatia, the learned daughter of the celebrated mathematician Theon of Alexandria, became fo eminent for her mathematical knowledge, that fhe was made public profeffor of the fcience in the firft fchool in the world. She wrote a commentary on the works of Apollonius and of Diophantus, and compofed Aftronomical Tables; all of which are loft. Thefe rare accom-

accomplishments, however, could not save her from the fury of the fanatics of Alexandria, who cut her in pieces for having taken an offensive part in a dispute between the governor and patriarch.—We have described some of the most approved of these instruments in the article HYDROMETER, and shall in this place make a few observations on the principles of their construction, not as they are usually made, accommodated to the examination of particular liquors, but as indicators of pure specific gravity. And we must premise, that this would, for many reasons, be the best way of constructing them. The very ingenious contrivances for accommodating them to particular purposes are unavoidably attended with many sources of error, both in their adjustment by the maker and in their use; and all that is gained by a very expensive instrument is the saving the trouble of inspecting a table. A simple scale of specific gravity would expose to no error in construction, because all the weights but one, or all the points of the scale but one, are to be obtained by calculation, which is incomparably more exact than any manual operation, and the table can always be more exact than any complex observation. But a still greater advantage is, that the instruments would by this means be fitted for examining all liquors whatever, whereas at present they are almost useless for any but the one for which they are constructed.

Hydrometers are of two kinds. The most simple and the most delicate are just a substitute for the hydrostatical balance. They consist of a ball (or rather an egg or pear-shaped vessel, with moves more easily through the fluid) A (fig. 1.) having a foot projecting down from it, terminated by another ball B, and a slender stalk or wire above, carrying a little dish C. The whole is made so light as to float in the lightest fluid we are acquainted with; such as vitriolic or muriatic æther, whose specific gravity is only 0,73. This number should be marked on the dish, indicating that this is the specific gravity of the fluid in which the instrument floats, sinking to the point D of the stem. The ball B is made heavy, and the foot is of some length, that the instrument may have stability, and swim erect, even if considerably loaded above; and, for the same reason, it must be made very round, otherwise it will lean to a side. When put into a heavier liquor, its buoyancy will cause it to float with a part of the ball above the surface. Weights are now put into the scale C, till the instrument sink to D. The weight put into the scale, added to the weight of the instrument, is the weight of the displaced fluid. This compared with the weight of the whole when the instrument is swimming in pure water, gives the specific gravity of the fluid. All trouble of calculation may be avoided by marking the weights with such numbers as shall indicate the specific gravity at once. Thus having loaded the instrument so as to sink it to D in pure water, call the whole weight 1000; then weigh the instrument itself, and say, "as the weight when swimming in water is to its present weight, so is 1000 to a 4th proportional." This is the specific gravity of the liquor which would float the unloaded instrument. Suppose this to be 730. The hydrometer would just float in muriatic æther, and this should be marked on the side. Now make a set of small weights, and mark them not by their weights in grains, but in such units that 270 of them shall be equal to the weight which fits the instrument for pure water.

Plate CCCCLXXII.

Suppose that, in order to float this instrument in a certain brandy, there are required 186 in these small weights. This added to 730 gives 916 for the specific gravity, and shows it to be precisely excise proof spirit. Nine weights, viz. 256, 128, 64, 32, 16, 8, 4, 2, 1, will suffice for all liquors from æther to the strongest worts. And that the trouble in changing the weights may be greatly lessened, let a few circles *a, b, c, d, e,* be marked on the top of a ball. When we see it float unloaded at the article C for instance, we know it will require at least 128 to sink it to D that on the stem.

If the weights to be added above are considerable, it raises the centre of gravity so much, that a small want of equilibrium, by laying the weights on one side, will produce a great inclination of the instrument, which is unsightly. Instead therefore of making them loose weights, it is proper to make them round plates, with a small hole in the middle, to go on a pin in the middle of the scale. This will keep the instrument always upright. But unless the hydrometer is of a considerable size, it can hardly be made so as to extend from the lightest to the heaviest fluid which we may have occasion to examine, even though we except mercury. Some of the mineral acids are considerably more than twice the weight of æther. When there is such a load at top, the hydrometer is very apt to overset, and inclines with the smallest want of equilibrium. Great size is inconvenient even to the philosopher, because it is not always in his power to operate on a quantity of fluid sufficient to float the instrument. Therefore two, or perhaps three, are necessary for general examination. One may reach from æther to water; another may serve for all liquors of a specific gravity between 1 and $1\frac{1}{2}$; and a third, for the mineral acids, may reach from this to 2. If each of these be about two solid inches in capacity, we may easily and expeditiously determine the specific gravity within one ten thousandth part of the truth: and this is precision enough for most purposes of science or business.

The chief questions are, 1. To ascertain the specific gravity of an unknown fluid. This needs no farther explanation. 2. To ascertain the proportion of two fluids which are known to be in a mixture. This is done by discovering the specific gravity of the mixture by means of the hydromoter, and then deducing the proportion from a comparison of this with the specific gravities of the ingredients.

In this mode of examination the bulk is always the same; for the hydrometer, is immerged in the different fluids to the same depth. Now if an inch, for example, of this bulk is made up of the heaviest fluid, there is an inch wanting of the lightest; and the change made in the weight of the mixture is the difference between the weight of an inch of the heaviest and of an inch of the lightest ingredients. The number of inches therefore of the heaviest fluid is proportional to the addition made to the weight of the mixture. Therefore let B and b be the bulks of the heaviest and lightest fluids in the bulk β of the mixture; and let D, d, and δ be the densities, or the weights, or the specific gravities (for they are in one ratio)

ratio) of the heavy fluid, the light fluid, and the mixture (their bulk being that of the hydrometer). We have $\beta = B + b$. The addition which would have been made to the bulk β, if the lightest fluid were changed entirely for the heaviest, would be $D - d$; and the change which is really made is $\delta - d$. Therefore $\beta : b = D - d : \delta - d$. For similar reasons we should have $\beta : B = D - d : D - \delta$; or, in words, "*the difference between the specific gravities of the two fluids, is to the difference between the specific gravities of the mixture and of the lightest fluid, as the bulk of the whole to the bulk of the heaviest contained in the mixture*;" and "*the difference of the specific gravities of the two fluids, is to the difference of the specific gravities of the mixture and of the heaviest fluids, as the bulk of the whole to that of the lightest contained in the mixture.*" This is the form in which the ordinary business of life requires the answer to be expressed, because we generally reckon the quantity of liquors by bulk, in gallons, pints, quarts. But it would have been equally easy to have obtained the answer in pounds and ounces; or it may be had from their bulks, since we know their specific gravities.

The hydrometer more commonly used is the ancient one of Hypatia, consisting of a ball, A (fig. 2.), made steady by an addition B, below it like the former, but having a long stem CF above. It is so loaded that it sinks to the top F of the stem in the lightest of all the fluids which we propose to measure with it, and to sink only to C in the heaviest. In a fluid of intermediate specific gravity it will sink to some point between C and F.

In this form of the hydrometer the weight is always the same, and the immediate information given by the instrument is that of different bulks with equal weight. Because the instrument sinks till the bulk of the displaced fluid equals it in weight, and the additions to the displaced fluid are all made by the stem, it is evident that equal bulks of the stem indicate equal additions of volume. Thus the stem becomes a scale of bulks to the same weight.

The only form in which the stem can be made with sufficient accuracy is cylindrical or prismatical. Such a stem may be made in the most accurate manner by wire-drawing, that is, passing it through a hole made in a hardened steel plate. If such a stem be divided into equal parts, it becomes a scale of bulks in arithmetical progression. This is the easiest and most natural division of the scale; but it will not indicate densities, specific gravities, or weights of the same bulk in arithmetical progression. The specific gravity is as the weight divided by the bulk. Now a series of divisors (the bulks), in arthmetical progression, applied to the same dividend (the bulk and weight of the hydrometer as it floats in water), will not give a series of quotients (the specific gravities) in arithmetical progression: they will be in what is called *harmonic progression*, their differences continually diminishing. This will appear even when physically considered. When the hydrometer sinks a tenth of an inch near the top of the stem, it displaces one tenth of an inch of a light fluid, compared with that displaced by it when it is floating with all the stem above the surface. In order therefore that the divisions of the stem may indicate equal changes of specific gravity, they must be in a series of harmonic progressionals increasing. The point at which the instrument floats in pure water should be marked 1000, and those above it 999, 998, 997, &c.; and those below the water mark must be numbered 1001, 1002, 1003, &c. Such a scale will be a very apposite picture of the densities of fluids, for the density or vicinity of the divisions will be precisely similar to the density of the fluids. Each interval is a bulk of fluid of the same weight. If the whole instrument were drawn out into wire of the size of the stem, the length from the water mark would be 1000.

Such are the rules by which the scale must be divided. But there must be some points of it determined by experiment, and it will be proper to take them as remote from each other as possible. For this purpose let the instrument be accurately marked at the point where it stands, in two fluids, differing as much in specific gravity as the instrument will admit. Let it also be marked where it stands in water. Then determine with the utmost precision the specific gravities of these fluids, and put their values at the corresponding points of the scale. Then the intermediate points of the scale must be computed for the different intervening specific gravities, or it must be divided from a pattern scale of harmonic progressionals in a way well known to the mathematical instrument-makers. If the specific gravities have been accurately determined, the value 1000 will be found to fall precisely in the water mark. If we attempt the division entirely by experiment, by making a number of fluids of different specific gravities, and marking the stem as it stands in them, we shall find the divisions turn out very anomalous. This is however the way usually practised; and there are few hydrometers, even from the best maker, that hold true to a single division or two. Yet the method by computation is not more troublesome; and one scale of harmonic progressionals will serve to divide every stem that offers. We may make use of a scale of equal parts for the stem, with the assistance of two little tables. One of these contains the specific gravities in harmonic progression, corresponding to the arithmetical scale of bulks on the stem of the hydrometer; the other contains the divisions and fractions of a division of the scale of bulks, which correspond to an arithmetical scale of specific gravities. We believe this to be the best method of all. The scale of equal parts on the stem is so easily made, and the little table is so easily inspected, that it has every advantage of accuracy and dispatch, and it gives, by the way, an amusing view of the relation of the bulks and densities.

We have hitherto supposed a scale extending from the lightest to the heaviest fluid. But unless it be of a very inconvenient length, the divisions must be very minute. Moreover, when the bulk of the stem bears a great proportion to that of the body, the instrument does not swim steady; it is therefore proper to limit the range of the instrument in the same manner as those of the first kind. A range from the density of æther to that of water may be very well executed in an instrument of very moderate size, and two others will do for all the heavier liquors; or an equal range in any other densities as may suit the usual occupations of the experimenter.

To avoid the inconveniences of a hydrometer with a very long and slender stem, or the necessity of having a series of them, a third sort has been contrived, in which

Specific Gravity.

which the principle of both are combined. Suppose a hydrometer with a stem, whose bulk is $\frac{1}{10}$th of that of the ball, and that it sinks in æther to the top of the stem; it is evident that in a fluid which is $\frac{1}{10}$th heavier, the whole stem will emerge; for the bulk of the displaced fluid is now $\frac{1}{11}$th of the whole less, and the weight is the same as before, and therefore the specific gravity is $\frac{1}{10}$th greater.

Thus we have obtained a hydrometer which will indicate, by means of divisions marked on the stem, all specific gravities from 0,73 to 0,803; for 0,803 is $\frac{1}{10}$th greater than 0,73. These divisions must be made in harmonic progression, as before directed for an entire scale, placing 0,73 at the top of the stem and 0,803 at the bottom.

When it floats at the lowest division, a weight may be put on the top of the stem, which will again sink it to the top. This weight must evidently be 0,073, or $\frac{1}{10}$th of the weight of the fluid displaced by the unloaded instrument. The hydrometer, thus loaded, indicates the same specific gravity, by the top of the stem, that the unloaded instrument indicates by the lowest division. Therefore, when loaded, it will indicate another series of specific gravities, from 0,803 to 0,8833 (=0,803 + 0,0803), and will float in a liquor of the specific gravity 0,8833 with the whole stem above the surface.

In like manner, if we take off this weight, and put on 1=0,0803, it will sink the hydrometer to the top of the stem; and with this new weight it will indicate another series of specific gravities from 0,8833 to 0,97163 (= 0,8833 + 0,08833). And, in the same manner, a third weight = 08833 will again sink it to the top of the stem, and fit it for another series of specific gravities up to 1,068793. And thus, with three weights, we have procured a hydrometer fitted for all liquors from æther to a wort for a malt liquor of two barrels *per* quarter. Another weight, in the same progression, will extend the instrument to the strongest wort that is brewed.

This is a very commodious form of the instrument, and is now in very general use for examining spirituous liquors, worts, ales, brines, and many such articles of commerce. But the divisions of the scale are generally adapted to the questions which naturally occur in the business. Thus, in the commerce of strong liquors, it is usual to estimate the article by the quantity of spirit of a certain strength which the liquor contains.—This we have been accustomed to call proof spirit, and it is such that a wine gallon weighs 7 pounds 12 ounces; and it is by this strength that the excise duties are levied. Therefore the divisions on the scale, and the weights which connect the successive repetitions of the scale, are made to express at once the number of gallons or parts of a gallon of proof spirits contained in a gallon of the liquor. Such instruments save all trouble of calculation to the exciseman or dealer; but they limit the use of a very delicate and expensive instrument to a very narrow employment. It would be much better to adhere to the expression either of specific gravity or of bulk; and then a very small table, which could be comprised in the smallest case for the instrument, might render it applicable to every kind of fluid.

The reader cannot but have observed that the successive weights, by which the short scale of the instrument is extended to a great range of specific gravities, do not increase by equal quantities. Each difference is the weight of the liquor displaced by the graduated stem of the instrument when it is sunk to the top of the scale. It is a determined aliquot part of the whole weight of the instrument so loaded, (in our example it is always $\frac{1}{11}$th of it). It increases therefore in the same proportion with the preceding weight of the loaded instrument. In short, both the successive additions, and the whole weights of the loaded instrument, are quantities in geometrical progression; and, in like manner, the divisions on the scale, if they correspond to equal differences of specific gravity, must also be unequal.—This is not sufficiently attended to by the makers; and they commit an error here, which is very considerable when the whole range of the instrument is great. For the value of one division of the scale, when the largest weight is on, is as much greater than its value, when the instrument is not loaded at all, as the full loaded instrument is heavier than the instrument unloaded. No manner whatever of dividing the scale will correspond to equal differences of specific gravity through the whole range with different weights; but if the divisions are made to indicate equal *proportions* of gravity when the instrument is used without a weight, they will indicate equal *proportions* throughout. This is evident from what we have been just now saying; for the proportion of the specific gravities corresponding to any two immediately succeeding weights is always the same.

The best way, therefore, of constructing the instrument, so that the same divisions of the scale may be accurate in all its successive repetitions with the different weights, is to make these divisions in geometrical progression. The corresponding specific gravities will also be in geometric proportion. These being all inserted in a table, we obtain them with no more trouble than by inspecting the scale which usually accompanies the hydrometer. This table is of the most easy construction; for the ratio of the successive bulks and specific gravities being all equal, the differences of the logarithms are equal.

This will be illustrated by applying it to the example already given of a hydrometer extending from 0,73 to 1,068793 with three weights. This gives four repetitions of the scale on the stem. Suppose this scale divided into 10 parts, we have 40 specific gravities.—Let these be indicated by the numbers 0, 1, 2, 3, &c. to 40. The mark 0 is affixed to the top of the stem, and the divisions downwards are marked 1, 2, 3, &c. the lowest being 10. These divisions are easily determined. The stem, which we may suppose 5 inches long, was supposed to be $\frac{1}{10}$th of the capacity of the ball. It may therefore be considered as the extremity of a rod of 11 times its length, or 55 inches; and we must find nine mean proportionals between 50 and 55 inches. Subtract each of these from 55 inches, and the remainders are the distances of the points of division from 0, the top of the scale. The smallest weight is marked 10, the next 20, and the third 30. If the instrument loaded with the weight 20 sinks in some liquor to the mark 7, it indicates the specific gravity 27, that is, the 27th of 40 mean proportionals between 0,73 and 1,068793, or 0,944242. To obtain all these intermediate specific gravities, we have only to subtract 9.8633229, the logarithm

Specific Gravity.

garithm of 0,73, from that of 1,068793, viz. 0,0288937, and take 0,0041393, the 40th part of the difference. Multiply this by 1, 2, 3, &c. and add the logarithm of 0,73 to each of the products. The sums are the logarithms of the specific gravities required. These will be found to proceed so equably, that they may be interpolated ten times by a simple table of proportional parts without the smallest sensible error. Therefore the stem may be divided into a hundred parts very sensible to the eye (each being nearly the 20th of an inch), and 400 degrees of specific gravity obtained within the range, which is as near as we can examine this matter by any hydrometer. Thus the specific gravities corresponding to n° 26, 27, 28, 29, are as follow:

		1st Diff.	2d Diff.
26	0,93529		
		895	
27	0,94424		9
		904	
28	0,95328		9
		913	
29	0,96241		

Nay, the trouble of inspecting a table may be avoided, by forming on a scale the logarithms of the numbers between 7300 and 1068,793, and placing along side of it a scale of the same length divided into 400 equal parts, numbered from 0 to 400. Then, looking for the mark shown by the hydrometer on this scale of equal parts, we see opposite to it the specific gravity.

We have been thus particular in the illustration of this mode of construction, because it is really a beautiful and commodious instrument, which may be of great use both to the naturalist and to the man of business.—A table may be comprised in 20 octavo pages, which will contain the specific gravities of every fluid which can interest either, and answer every question relative to their admixture with as much precision as the observations can be made. We therefore recommend it to our readers, and we recommend the very example which we have given as one of the most convenient. The instrument need not exceed eight inches in length, and may be contained in a pocket case of 2 inches broad and as many deep, which will also contain the scale, a thermometer, and even the table for applying it to all fluids which have been examined.

It is unfortunate that no graduated hydrometer can be made so easily for the examination of the corrosive mineral acids (A). These must be made of glass, and we cannot depend on the accurate cylindric form of any glass stem. But if any such can be procured, the construction is the same. The divided scale may either be on thin paper pasted on the inside of the stem, or it may be printed on the stem itself from a plate, with ink made of a metallic calx, which will attach itself to the glass with a very moderate heat. We would recommend common white enamel, or arsenical glass, as the fittest material for the whole instrument; and the ink used, in taking the impression of the scale, may be the same that is used for the low-priced printing on Delft ware pottery.—First form the scale on the stem. Then, having measured the solid contents of the graduated part as exactly as possible, and determined on the general shape of the ball and counterpoise below, calculate its size, so that it may be a little less than ten times that of the stem. The glass-blower can copy this very nearly, and join it to the stem. Then make two brines or other liquors, which shall have specific gravities in the ratio of 10 to 11. Load the instrument so that it may sink to 0 in the lightest. When put into the heaviest, it should rise to 10. If it does not rise so high, the immersed part is too small. Let the glass blower enlarge the ball of the counterpoise a little. Repeat this trial till it be exact. Nothing now remains but to form the weights: And here we observe, that when the instrument is to have a very great range, as for examining all states of the vitriolic acid, it has a chance of being very tottering when loaded with the greatest weight on the top of so long a scale. To avoid this, Mr Quin and others have added some of their weights below.—But this will not suit the present construction, because it will alter the proportion between the bulks of the stem and immersed part. Therefore let these weights consist of cylinders of metal small enough to go into the stem, and let them be soldered to the end of long wires, which will let them go to the bottom, and leave a small hook or ring at top. These can lie alongside of the instrument in its case. This is indeed the best construction for every hydrometer, because it makes it incomparably more steady. The instrument is poised by small shot or mercury. But it will be much better to do it with Newton's fusible metal (three parts of tin, five parts of lead, and eight parts of bismuth) in coarse filings. When the exact quantity has been put in, the instrument may be set in a vessel of oil, and this kept on the fire till all is completely melted. It soon freezes again, and remains fast. If this metal is not to be had, let a few bits of sealing-wax be added to the mercury or shot, to make up the counterpoise. When heated, it will float a-top, and when it freezes again it will keep all fast. Thus we shall make a very complete and cheap instrument.

There is yet another method of examining the specific gravities of fluids, first proposed by Dr Wilson, late professor of astronomy in the university of Glasgow. This is by a series of small glass bubbles, differing equally, or according to some rule, from each other in specific gravity, and each marked with its proper number. When these are thrown into a fluid which is to be examined, all those which are heavier than the fluid will fall to the bottom. Then holding the vessel in the hand, or near a fire or candle, the fluid expands, and one of the floating bubbles begins to sink. Its specific gravity, therefore, was either equal to, or a little less than, that of the fluid; and the degree of the thermometer, when it began to sink, will inform us how much it was deficient, if we know the law of expansion of the liquor: Sets of these bubbles fitted for the examination of spirituous liquors, with a little treatise showing the manner of using them, and calculating by the thermometer, are made by Mr Brown, an ingenious artist of Glasgow, and are often used by the dealers in spirits, being found both accurate and expeditious.

Also, though a bubble or two should be broken, the strength of spirits may easily be had by means of the remainder, unless two or three in immediate succession be

(A) It would be worth while to try copper enamelled.

be wanting: for a liquor which anſwers to N° 4 will ſink N° 2 by heating it a few degrees, and therefore N° 3 may be ſpared. This is a great advantage in ordinary buſineſs. A nice hydrometer is not only an expenſive inſtrument, but exceedingly delicate, being ſo very thin. If broken or even bruiſed, it is uſeleſs, and can hardly be repaired except by the very maker.

As the only queſtion here is, to determine how many gallons of exciſe proof ſpirits is contained in a quantity of liquor, the artiſt has conſtructed this ſeries of bubbles in the ſimpleſt manner poſſible, by previouſly making 40 or 50 mixtures of ſpirits and water, and then adjuſting the bubbles to theſe mixtures. In ſome ſets the number on each bubble is the number of gallons of proof ſpirits contained in 100 gallons of the liquor. In other ſets the number on each bubble expreſſes the gallons of water which will make a liquor of this ſtrength, if added to 14 gallons of alcohol. Thus, if a liquor anſwers to N° 4, then 4 gallons of water added to 14 gallons of alcohol will make a liquor of this ſtrength. The firſt is the beſt method; for we ſhould be miſtaken in ſuppoſing that 18 gallons, which anſwer to N° 4, contains exactly 14 gallons of alcohol: it contains more than 14, for a reaſon to be given by and by.

By examining the ſpecific gravity of bodies, the philoſopher has made ſome very curious diſcoveries. The moſt remarkable of theſe is the change which the denſity of bodies ſuffers by mixture. It is a moſt reaſonable expectation, that when a cubic foot of one ſubſtance is mixed *any how* with a cubic foot of another, the bulk of the mixture will be two cubic feet; and that 18 gallons of water joined to 18 gallons of oil will fill a veſſel of 36 gallons. Accordingly this was never doubted; and even Archimedes, the moſt ſcrupulous of mathematicians, proceeded on this ſuppoſition in the ſolution of his famous problem, the diſcovery of the proportion of ſilver and gold in a mixture of both. He does not even mention it as a poſtulate that *may* be granted him, ſo much did he conceive it to be an axiom. Yet a little reflection ſeems ſufficient to make it doubtful, and to require examination. A box filled with muſket-balls will receive a conſiderable quantity of ſmall ſhot, and after this a conſiderable quantity of fine ſand, and after this a conſiderable quantity of water. Something like this might happen in the admixture of bodies of porous texture. But ſuch ſubſtances as metals, glaſs, and fluids, where no diſcontinuity of parts can be perceived, or was ſuſpected, ſeem free from every chance of this kind of introſuſception. Lord Bacon, however, without being a naturaliſt or mathematician *ex profeſſo*, inferred from the mobility of fluids that they conſiſted of diſcrete particles, which muſt have pores interpoſed, whatever be their figure. And if we aſcribe the different denſities, or other ſenſible qualities, to difference in ſize or figure of thoſe particles, it muſt frequently happen that the ſmaller particles will be lodged in the interſtices between the larger, and thus contribute to the weight of the ſenſible maſs without increaſing its bulk. He therefore ſuſpects that mixtures will be in general leſs bulky than the ſum of their ingredients.

Accordingly, the examination of this queſtion was one of the firſt employments of the Royal Society of London, and long before its inſtitution had occupied the attention of the gentlemen who afterwards compoſed it. The regiſter of the Society's early meetings contains many experiments on this ſubject, with mixtures of gold and ſilver, of other metals, and of various fluids, examined by the hydroſtatical balance of Mr Boyle. Dr Hooke made a prodigious number, chiefly on articles of commerce, which were unfortunately loſt in the fire of London.

It was ſoon found, however, that Lord Bacon's conjecture had been well founded, and that bodies changed their denſities very ſenſibly in many caſes. In general, it was found that bodies which had a ſtrong chemical affinity increaſed in denſity, and that their admixture was accompanied with heat.

By this diſcovery it is manifeſt that Archimedes had not ſolved the problem of detecting the quantity of ſilver mixed with the gold in King Hiero's crown, and that the phyſical ſolution of it requires experiments made on all the kinds of matter that are mixed together. We do not find that this has been done to this day, although we may affirm that there are few queſtions of more importance. It is a very curious fact in chemiſtry, and it would be moſt deſirable to be able to reduce it to ſome general laws: For inſtance, to aſcertain what is the proportion of two ingredients which produces the greateſt change of denſity. This is important in the ſcience of phyſics, becauſe it gives us conſiderable information as to the mode of action of thoſe natural powers or forces by which the particles of tangible matter are united. If this introſuſception, concentration, compenetration, or by whatever name it be called, were a mere reception of the particles of one ſubſtance into the interſtices of thoſe of another, it is evident that the greateſt concentration would be obſerved when a ſmall quantity of the recipiend is mixed with, or diſſeminated through, a great quantity of the other. It is thus that a ſmall quantity of fine ſand will be received into the interſtices of a quantity of ſmall ſhot, and will increaſe the weight of the bagful without increaſing its bulk. The caſe is nowiſe different when a piece of freeſtone has grown heavier by imbibing or abſorbing a quantity of water. If more than a certain quantity of ſand has been added to the ſmall ſhot, it is no longer concealed. In like manner, various quantities of water may combine with a maſs of clay, and increaſe its ſize and weight alike. All this is very conceivable, occaſioning no difficulty.

But this is not the caſe in any of the mixtures we are now conſidering. In all theſe, the firſt additions of either of the two ſubſtances produce but an inconſiderable change of general denſity; and it is in general moſt remarkable, whether it be condenſation or rarefaction, when the two ingredients are nearly of equal bulks. We can illuſtrate even this difference, by reflecting on the imbibition of water by vegetable ſolids, ſuch as timber. Some kinds of wood have their weight much more increaſed than their bulks; other kinds of wood are more enlarged in bulk than in weight. The like happens in grains. This is curious, and ſhows in the moſt unqueſtionable manner that the particles of bodies are not in contact, but are kept together by forces which act at a diſtance. For this diſtance between the centres of the particles is moſt evidently ſuſceptible of variation; and this variation is occaſioned by the introduction of another ſubſtance, which, by acting on the particles by attraction or repulſion, diminiſhes or increaſes their mutual actions, and makes new diſtances neceſ-

Specific Gravity.

necessary for bringing all things again into equilibrium. We refer the curious reader to the ingenious theory of the Abbé Boscovich for an excellent illustration of this subject. (*Theor. Phil. Nat.* § de Solutione Chemica).

This question is no less important to the man of business. Till we know the condensation of those metals by mixture, we cannot tell the quantity of alloy in gold and silver by means of their specific gravity; nor can we tell the quantity of pure alcohol in any spirituous liquor, or that of the valuable salt in any solution of it. For want of this knowledge, the dealers in gold and silver are obliged to have recourse to the tedious and difficult test of the assay, which cannot be made in all places or by all men. It is therefore much to be wished, that some persons would institute a series of experiments in the most interesting cases: for it must be observed, that this change of density is not always a small matter; it is sometimes very considerable and paradoxical. A remarkable instance may be given of it in the mixture of brass and tin for bells, great guns, optical speculums, &c. The specific gravity of cast brass is nearly 8,006, and that of tin is nearly 7,363. If two parts of brass be mixed with one of tin, the specific gravity is 8,917; whereas, if each had retained its former bulk, the specific gravity would have been only 7,793 $\left(=\frac{2\times 8{,}006+7{,}363}{3}\right)$. A mixture of equal parts should have the specific gravity 7,684; but it is 8,441. A mixture of two parts tin with one part brass, instead of being 7,577, is 8,027.

In all these cases there is a great increase of specific gravity, and consequently a great condensation of parts or contraction of bulk. The first mixture of eight cubic inches of brass, for instance, with four cubic inches of tin, does not produce 12 cubic inches of bell-metal, but only $10\frac{1}{2}$ nearly, having shrunk $\frac{1}{7}$. It would appear that the distances of the brass particles are most affected, or perhaps it is the brass that receives the tin into its pores; for we find that the condensations in these mixtures are nearly proportional to the quantities of the brass in the mixtures. It is remarkable that this mixture with the lightest of all metals has made a composition more heavy and dense than brass can be made by any hammering.

The most remarkable instance occurs in mixing iron with platina. If 10 cubic inches of iron are mixed with $1\frac{1}{4}$ of platina, the bulk of the compound is only $9\frac{1}{4}$ inches. The iron therefore has not simply received the platina into its pores: its own particles are brought nearer together. There are similar results in the solution of turbith mineral, and of some other salts, in water. The water, instead of rising in the neck of the vessel, when a small quantity of the salt has been added to it, sinks considerably, and the two ingredients occupy less room than the water did alone.

The same thing happens in the mixture of water with other fluids and different fluids with each other: But we are not able to trace any general rule that is observed with absolute precision. In most cases of fluids the greatest condensation happens when the bulks of the ingredients are nearly equal. Thus, in the mixture of alcohol and water, we have the greatest condensation when $16\frac{1}{2}$ ounces of alcohol are mixed with 20 ounces of water, and the condensation is about $\frac{1}{40}$ of the whole bulk of the ingredients. It is extremely various in different substances, and no classification of them can be made in this respect.

Specific Gravity.

A dissertation has been published on this subject by Dr Hahn of Vienna, intitled *De Efficacia Mixtionis in mutandis Corporum Voluminibus*, in which all the remarkable instances of the variation of density have been collected. All that we can do (as we have no directing principle) is to record such instances as are of chief importance, being articles of commerce.

The first that occurs to us is the mixtures of alcohol and water in the composition of spirituous liquors. This has been considered by many with great care. The most scrupulous examination of this, or perhaps of any mixture, has been lately made by Dr Blagden (now Sir Charles Blagden) of the Royal Society, on the requisition of the Board of Excise. He has published an account of the examination in the Philosophical Transactions of London in 1791 and 1792. We shall give an account of it under the article SPIRITUOUS *Liquors*; and at present only select one column, in order to show the condensation. The alcohol was almost the strongest that can be produced, and its specific gravity, when of the temperature 60°, was 0,825. The whole mixtures were of the same temperature.

Column 1. contains the pounds, ounces, or other measures by weight, of alcohol in the mixture. Column 2. contains the pounds or ounces of water. Column 3. is the sum of the bulks of the ingredients, the bulk of a pound or ounce of water being accounted 1. Column 4. is the observed specific gravity of the mixture, taken from Dr Blagden's dissertation. Column 5. is the specific gravity which would have been observed if the ingredients had each retained its own specific gravity. This we calculated by dividing the sum of the two numbers of the first and second columns by the corresponding number of the third. Column 6. is the difference of column 4. and column 5. and exhibits the condensation.

0	20	20,0000	1,0000	1,0000	

It is to be remarked, that the condenſation is greateſt when $16\frac{1}{2}$ ounces of alcohol have been added to 20 of water, and the condenſation is $\frac{2633}{91835}$, or nearly $\frac{1}{36}$th of the computed denſity. Since the ſpecific gravity of alcohol is 0,825, it is evident that $16\frac{1}{2}$ ounces of alcohol and 20 ounces water have equal bulks. So that the condenſation is greateſt when the ſubſtances are mixed in equal volumes; and 18 gallons of alcohol mixed with 18 gallons of water will produce not 36 gallons of ſpirits, but 35 only.

We may alſo obſerve, that this is the mixture to which the revenue-laws refer, declaring it to be *one to ſix* or *one in ſeven* under proof, and to weigh 7 pounds 13 ounces per gallon. This proportion was probably ſelected as the moſt eaſily compoſed, viz. by mixing equal meaſures of water and of the ſtrongeſt ſpirit which the known proceſſes of diſtillation could produce. Its ſpecific gravity is 0,939 very nearly.

We muſt conſider this elaborate examination of the mixture of water and alcohol as a ſtandard ſeries of experiments, to which appeal may always be made, whether for the purpoſes of ſcience or of trade. The regularity of the progreſſion is ſo great, that in the column which we have examined, viz. that for temperature 60°, the greateſt anomaly does not amount to one part in ſix thouſand. The form of the ſeries is alſo very judiciouſly choſen for the purpoſes of ſcience. It would perhaps have been more directly ſtereometrical had the proportions of the ingredients been ſtated in bulks, which are more immediately connected with denſity. But the author has aſſigned a very cogent reaſon for his choice, viz. that the proportion of bulks varies by a change of temperature, becauſe the water and ſpirits follow different laws in their expanſion by heat.

This is a proper opportunity for taking notice of a miſtake which is very generally made in the concluſions drawn from experiments of this kind. Equal additions of the ſpirit or water produce a ſeries of ſpecific gravities, which decreaſe or increaſe by differences continually diminiſhing. Hence it is inferred that there is a contraction of bulk. Even Dr Lewis, one of the moſt accompliſhed naturaliſts, advances this poſition, in a diſſertation on the pot-aſh of America; and it conſiderably affects his method for eſtimating the ſtrength of the pot-aſh leys. But that it is a miſtake, appears plainly from this, that although we add for ever equal quantities of the ſpirits, we ſhall never produce a *mixture* which has as ſmall a ſpecific gravity as alcohol. Therefore the ſeries of ſucceſſive gravities muſt approximate to this without end, like the ordinates of a hyperbolic curve referred to its aſſymptote.

That this may appear in the moſt general terms, let w repreſent the weight of the conſtant quantity of water in the mixture, and let a be the weight of the ſmall addition of ſpirits. Alſo let w repreſent the bulk of this quantity of water, and b the bulk of the ſmall addition of alcohol. The weight of the mixture is $w+a$, and its bulk is $w+b$, and its ſpecific gravity is $\frac{w+a}{w+b}$. If we now add a ſecond equal quantity of ſpirits, the weight will be $w+2a$, and if the ſpirit retains its denſity unchanged, the bulk will be $w+2b$, and the ſpecific gravity is $\frac{w+2a}{w+2b}$: and after any number m of ſuch equal additions of ſpirits, the ſpecific gravity will be $\frac{w+ma}{w+mb}$. Divide the numerator of this fraction by its denominator, and the quotient or ſpecific gravity will be $1+\frac{m\times\overline{a-b}}{w+mb}$. This conſiſts of the conſtant part 1, and the variable part $\frac{m(a-b)}{w+mb}$. We need attend only to this part. If its denominator were conſtant, it is plain that the ſucceſſive ſpecific gravities would have equal differences, each being $=\frac{a-b}{w+mb}$, becauſe m increaſes by the continual addition of an unit, and $a-b$ is a conſtant quantity. But the denominator $w+mb$ continually increaſes, and therefore the value of the fraction $\frac{a-b}{w+mb}$ continually diminiſhes.

Therefore the gradual diminution of the increments or decrements of ſpecific gravity, by equal additions of one ingredient to a conſtant meaſure of the other, is not of itſelf an indication of a change of denſity of either of the ingredients; nor proves that in very diluted mixtures a greater proportion of one ingredient is abſorbed or lodged in the interſtices of the other, as is generally imagined. This muſt be aſcertained by comparing each ſpecific gravity with the gravity expreſſed by $1+\frac{w+m(a-b)}{w+mb}$.

This ſeries of ſpecific gravities reſembles ſuch a numerical ſeries as the following, 1; ....; 1,156; 1,163; 1,+69; &c. the terms of which alſo conſiſt of the conſtant integer 1, and the decimal fractions 0,156; 0,163; 0,169; &c. The fraction $\frac{m(a-b)}{w+mb}$ expreſſes this decimal part. Call this d, or make $d=\frac{m(a-b}{w+mb}$. This will give us $b=\frac{ma-wd}{m(1+d)}$. Now a is the weight of the added ingredient, and d is the variable part of the ſpecific gravity obſerved; and thus we learn whether

Specific Gravity.

ther *b*, the bulk of the added ingredient, ſuffers any change. We ſhall have occaſion by and by to reſume the conſideration of this queſtion, which is of the firſt moment in the theory of ſpecific gravities, and has great influence in many tranſactions of commerce.

This ſeries of ſpecific gravities is not ſo well fitted for commercial tranſactions. In theſe the uſual queſtion is, how many gallons of alcohol is there in a caſk, or ſome number of gallons of ſpirit? and it is more directly anſwered by means of a table, formed by mixing the ingredients in aliquant parts of one conſtant bulk. The following table, conſtructed from the experiments of Mr Briſſon of the academy of Paris, and publiſhed in the Memoirs for 1769, is therefore inſerted.

W.	A.	Denſity obſerved.	Denſity computed.	Condenſation.	Bulk of 10,000 grains.
0	16	0,8371	0,8371		1,0000
1	15	0,8527	0,8473	63	0,9937
2	14	0,8674	0,8575	115	0,9885
3	13	0,8815	0,8677	157	0,9844
4	12	0,8947	0,8778	189	0,9811
5	11	0,9075	0,8880	214	0,9786
6	10	0,9199	0,8982	235	0,9765
7	9	0,9317	0,9084	251	0,9749
8	8	0,9427	0,9186	256	0,9744
9	7	0,9519	0,9287	243	0,9757
10	6	0,9598	0,9389	217	0,9783
11	5	0,9674	0,9491	189	0,9811
12	4	0,9733	0,9593	144	0,9856
13	3	0,9791	0,9695	99	0,9901
14	2	0,9852	0,9796	57	0,9943
15	1	0,9919	0,9898	21	0,9979
16	0	1,0000	1,0000		1,0000

In this table the whole quantity of ſpirituous liquor is always the ſame. The firſt column is the number of meaſures (gallons, pints, inches, &c.) of water in the mixture; and column 2d gives the meaſures of alcohol. Column 3d is the ſpecific gravity which was obſerved by Mr Briſſon. Column 4th is the ſpecific gravity which would have been obſerved if the ſpirits, or water, or both, had retained their ſpecific denſity unchanged. And the 5th column marks the augmentation of ſpecific gravity or denſity in parts of 10,000. A 6th column is added, ſhowing the bulk of the 16 cubic meaſures of the two ingredients. Each meaſure may be conceived as the 16th part of 10,000, or 625; and we may ſuppoſe them cubic inches, pints, gallons, or any ſolid meaſure.

This table ſcarcely differs from Sir Charles Blagden's; and the very ſmall difference that may be obſerved, ariſes from Mr Briſſon's having uſed an alcohol not ſo completely rectified. Its ſpecific gravity is 0,8371, whereas the other was only 0,8250.

Here it appears more diſtinctly that the condenſation is greateſt when the two ingredients are of equal bulk.

Perhaps this ſeries of ſpecific gravities is as declarative as the other, whether or not there is a change of denſity induced on either of the ingredients. The whole bulk being always the ſame, it is plain that the ſucceſſive equal additions to one of the ingredients is a ſucceſſive equal abſtraction of the other. The change produced, therefore, in the weight of the whole, is the difference between the weight of the ingredient which is taken out and the weight of the equal meaſure of the other which ſupplies its place. Therefore, if neither ingredient changes its denſity by mixture, the weights of the mixtures will be in arithmetical progreſſion. If they are not, there is a variation of denſity in one or both the ingredients.

We ſee this very clearly in the mixtures of water and alcohol. The firſt ſpecific gravity differs from the ſecond by 156, and the laſt differs from the preceding by no more than 81. Had neither of the denſities changed, the common difference would have been 102. We obſerve alſo, that the augmentation of ſpecific gravity, by the ſucceſſive addition of a meaſure of water, grows leſs and leſs till 12 meaſures of water is mixed with 4 of alcohol, when the augmentation is only 58, and then it increaſes again to 81.

It alſo appears, that the addition of one meaſure of water to a quantity of alcohol produces a greater change of denſity than the mixture of one meaſure of alcohol to a quantity of water. Hence ſome conclude, that the water diſappears by being lodged in the interſtices of the ſpirit. But it is more agreeable to the juſteſt notions which we can form of the internal conſtitution of tangible bodies to ſuppoſe that the particles of water diminiſh the diſtances between the particles of alcohol by their ſtrong attractions, and that this diminution (exceedingly minute in itſelf) becomes ſenſible on account of the great number of particles whoſe diſtances are thus diminiſhed. This is merely a probability founded on this, that it would require a much greater diminution of diſtances if it was the particles of water which had their diſtances thus diminiſhed. But the greater probability is, that the condenſation takes place in both.

We have been ſo particular in our conſideration of this mixture, becauſe the law of variation of denſity has, in this inſtance, been aſcertained with ſuch preciſion by the elaborate examination of Sir Charles Blagden, ſo that it may ſerve as an example of what happens in almoſt every mixture of bodies. It merits a ſtill farther diſcuſſion, becauſe it is intimately connected with the action of the corpuſcular forces; and an exact knowledge of the variations of diſtance between the particles will go far to aſcertain the law of action of theſe forces. But the limits of a Work like this will not permit us to dwell longer on this ſubject. We proceed therefore to give another uſeful table.

The vitriolic or ſulphuric acid is of extenſive uſe in manufactures under the name of oil of vitriol. Its value depends entirely on the ſaline ingredient, and the water is merely a vehicle for the acid. This, being much denſer than water, affects its ſpecific gravity, and thus gives us a method of aſcertaining its ſtrength.

The ſtrongeſt oil of vitriol that can be eaſily manufactured contains $612\frac{1}{20}$ grains of dry acid, united with $387\frac{1}{20}$ grains of water, which cannot be ſeparated from it by diſtillation, making 1000 grains of OIL OF VITRIOL. Its ſpecific gravity in this ſtate is 1,877.

The following table ſhows its ſpecific gravity at the temperature 55°, when diluted by the ſucceſſive addition of parts of water by weight.

Specific Gravity.

Ol. Vit.		Water.	Specific Gravity. Observed.	Calculated.	Cond.
10	×	0	1,877	1,877	,000
		4	1,644	1,501	,143
		8	1,474	1,350	,124
		12	1,381	1,269	,112
		16	1,320	1,219	,101
		20	1,274	1,184	,090
		24	1,243	1,159	,084
		28	1,211	1,140	,071
		32	1,195	1,125	,070
		36	1,183	1,113	,070
		40	1,172	1,103	,070
		50	1,148	1,084	,064
		60	1,128	1,069	,059

Here is obferved a much greater condenfation than in the mixture of alcohol and water. But we cannot affign the proportion of ingredients which produces the greateft condenfation; becaufe we cannot, in any cafe, fay what is the proportion of the faline and watery ingredients. The ftrongeft oil of vitriol is already a watery folution; and it is by a confiderable and uncertain detour that Mr Kirwan has affigned the proportion of 612 and 388 nearly. If this be the true ratio, it is unlike every other folution that we are acquainted with; for in all folutions of falts, the falt occupies lefs room in its liquid form than it did when folid; and here it would be greatly the reverfe.

This folution is remarkable alfo for the copious emergency of heat in its dilutions with more water. This has been afcribed to the great fuperiority of water in its capacity for heat; but there are facts which render this very doubtful. A veffel of water, and another of oil of vitriol, being brought from a cold room into a warm one, they both imbibe heat, and rife in their temperature; and the water employs nearly the fame time to attain the temperature of the room.

Aquafortis or nitrous acid is another fluid very much employed in commerce; fo that it is of importance to afcertain the relation between its faline ftrength and its fpecific gravity. We owe alfo to Mr Kirwan a table for this purpofe.

The moft concentrated ftate into which it can eafily be brought is fuch, that 1000 grains of it confifts of 563 grains of water and 437 of dry acid. In this ftate its fpecific gravity is 1,557. Let this be called *nitrous acid.*

Nitr. Ac.		Water.			
10	×	0	1,557	1,557	
		1	1,474	1,474	
		6	1,350	1,273	0,077
		11	1,269	1,191	0,078
		16	1,214	1,147	0,067
		21	1,175	1,120	0,055
		26	1,151	1,101	0,050
		31	1,127	1,087	0,040
		36	1,106	1,077	0,029
		41	1,086	1,068	0,018

There is not the fame uniformity in the denfities of this acid in its different ftates of dilution. This feems owing to the variable proportion of the deleterious and vital air which compofe this acid. It is more denfe in proportion as it contains more of the latter ingredient.

The proportions of the aeriform ingredients of the muriatic acid are fo very variable, and fo little under our command, that we cannot frame tables of its fpecific gravity which would enable us to judge of its ftrength.

It is a general property of thefe acids, that they are more expanfible by heat as they are more concentrated.

There is another clafs of fluids which it would be of great confequence to reduce to fome rules with refpect to fpecific gravity, namely, the folutions of falts, gums, and refins. It is interefting to the philofopher to know in what manner falts are contained in thefe watery folutions, and to difcover the relation between their ftrength and denfity; and to the man of bufinefs it would be a moft defirable thing to have a criterion of the quantity of falt in any brine, or of extractible matter in a decoction. It would be equally defirable to thofe who are to purchafe them as to thofe who manufacture or employ them. Perhaps we might afcertain in this way the value of fugar, depending on the quantity of fweetening matter which it contains; a thing which at prefent refts on the vague determination of the eye or palate. It would therefore be doing a great fervice to the public, if fome intelligent perfon would undertake a train of experiments with this view. Accuracy alone is required; and it may be left to the philofophers to compare the facts, and draw the confequences refpecting the internal arrangement of the particles.

One circumftance in the folution of falts is very general; and we are inclined, for ferious reafons, to think it univerfal: this is a diminution of bulk. This indeed in fome falts is inconfiderable. Sedative falt, for inftance, hardly fhows any diminution, and might be confidered as an exception, were it not the fingle inftance. This circumftance, and fome confiderations connected with our notions of this kind of folution, difpofe us to think that this falt differs in contraction from others only in degree, and that there is fome, though it was not fenfible, in the experiments hitherto made.

Thefe experiments, indeed, have not been numerous. Thofe of Mr Achard of Berlin, and of Dr Richard Watfon of Cambridge, are perhaps the only ones of which we have a defcriptive narration, by which we can judge of the validity of the inferences drawn from them. The fubject is not fufceptible of much accuracy; for falts in their folid form are feldom free from cavities and fhivery interftices, which do not admit the water on their firft immerfion, and thereby appear of greater bulk when we attempt to meafure their fpecific gravity by weighing them in fluids which do not diffolve them, fuch as fpirits of turpentine. They alfo attach to themfelves, with confiderable tenacity, a quantity of atmofpheric air, which merely adheres, but makes no part of their compofition. This efcapes in the act of folution, being fet at liberty by the ftronger affinity of the water. Sal gem, however, and a few others, may be very accurately meafured; and in thefe inftances the degree of contraction is very conftant.

The following experiments of Dr Watfon appear to us the moft inftructive as to this circumftance. A glafs veffel was ufed, having a flender cylindrical neck, and holding 67 ounces of pure water when filled to a certain

tain mark. The neck above this mark had a ſcale of equal parts paſted on it. It was filled to the mark with water. Twenty-four pennyweights of ſalt were thrown into it as ſpeedily as poſſible, and the bulk of the ſalt was meaſured by the elevation of the water. Every thing was attended to which could retard the immediate ſolution, that the error ariſing from the ſolution of the firſt particles, before the reſt could be put in, might be as ſmall as poſſible; and in order that both the abſolute bulk and its variations might be obtained by ſome known ſcale, 24 pennyweights of water were put in. This raiſed the ſurface 58 parts of the ſcale. Now we know exactly the bulk of 24 pennyweights of pure water. It is 2,275 cubic inches; and thus we obtain every thing in abſolute meaſures: And by comparing the bulk of each ſalt, both at its firſt immerſion and after its complete ſolution, we obtain its ſpecific gravity, and the change made on it in paſſing from a ſolid to a fluid form. The following table is an abſtract of theſe experiments. The firſt column of numbers is the elevation of the ſurface immediately after immerſion; the ſecond gives the elevation when the ſalt is completely diſſolved; and the third and fourth columns are the ſpecific gravities of the ſalts in theſe two ſtates.

Twenty-four Pennyweights.	I.	II.	III.	IV.

The inſpection of this liſt naturally ſuggeſts two ſtates of the caſe as particularly intereſting to the philoſopher ſtudying the theory of ſolution. The firſt ſtate is when the lixivium approaches to ſaturation. In the very point of ſaturation any addition of ſalt retains its bulk unchanged. In diluted brines, we ſhall ſee that the denſity of the fluid ſalt is greater, and gradually diminiſhes as we add more ſalt. It is an important queſtion, Whether this diminution goes on continually, till the fluid denſity of the ſalt is the ſame with its ſolid denſity? or, Whether there is an abrupt paſſage from ſome degree of the one to the fixed degree of the other, as we obſerve in the freezing of iron, the ſetting of ſtucco, and ſome other inſtances?

The other intereſting ſtate is that of extreme dilution, when the differences between the ſucceſſive denſities bear a great proportion to the denſities themſelves, and thus enable the mathematician to aſcertain with ſome preciſion the variations of corpuſcular force, in conſequence of a variation of diſtance between the particles. The ſketch of an inveſtigation of this important queſtion given by Boſcovich, in his Theory of Natural Philoſophy, is very promiſing, and ſhould incite the philoſophical chemiſt to the ſtudy. The firſt thing to be done is to compare the law of ſpecific gravity; that is, the relation between the ſpecific gravity and quantity of ſalt held in ſolution.

Wiſhing to make this work as uſeful as poſſible, we have ſearched for experiments, and trains of experiments, on the denſity of the many brines which make important articles of commerce; but we were mortified by the ſcantineſs of the information, and diſappointed in our hopes of being able to combine the detached obſervations, ſuited to the immediate views of their authors, in ſuch a manner as to deduce from them ſcales (as they may be called) of their ſtrength. We rarely found theſe detached obſervations attended with circumſtances which would connect them with others; and there was frequently ſuch a diſcrepancy, nay oppoſition, in ſerieſes of experiments made for aſcertaining the relation between the denſity and the ſtrength, that we could not obtain general principles which enable us to conſtruct tables of ſtrength *à priori*.

Mr Lambert, one of the firſt mathematicians and philoſophers of Europe, in a diſſertation in the Berlin Memoirs (1762), gives a narration of experiments on the brines of common ſalt, from which he deduces a very great condenſation, which he attributes to an abſorption in the weak brines of the ſalt, or a lodgment of its particles in the interſtices of the particles of water. Mr Achard of the ſame academy, in 1785, gives a very great liſt of experiments on the bulks of various brines, made in a different way, which ſhew no ſuch introſuſception; and Dr Watſon, formerly profeſſor of chemiſtry at Cambridge, and now biſhop of Landaff, thinks this confirmed by experiments which he narrates in his Chemical Eſſays. We ſee great reaſon for heſitating our aſſent to either ſide, and do not think the experiments deciſive. We incline to Mr Lambert's opinion; for this reaſon, that in the ſucceſſive dilutions of oil of vitriol and aquafortis there is a moſt evident and remarkable condenſation. Now what are theſe but brines, of which we have not been able to get the ſaline ingredient in a ſeparate form? The experiments of Mr Achard and Dr Watſon were made in ſuch a way that a ſingle grain in the meaſurement bore too great a proportion to the whole change of ſpecific gravity. At the ſame time, ſome of Dr Watſon's are ſo ſimple in their nature that it is very difficult to withhold the aſſent.

In this ſtate of uncertainty, in a ſubject which ſeems to us to be of public importance, we thought it our duty to undertake a train of experiments to which recourſe may always be had. Works like this are ſeldom conſidered as ſources of original information; and it is thought ſufficient when the knowledge already diffused is judiciously compiled. But a due respect for the public, and gratitude for the very honourable reception hitherto given to our labours, induce us to exert ourselves with honest zeal to merit the continuance of public favour. We assure our readers that the experiments were made with care, and on quantities sufficiently large to make the unavoidable irregularities in such cases quite insignificant. The law of density was ascertained in each substance in two ways. We dissolved different portions of salt in the same quantity of water, and examined the specific gravity of the brine by weighing it in a vessel with a narrow neck. The portions of salt were each of them one-eighth of what would make a nearly saturated solution of the temperature 55. We did not make the brine stronger, that there might be no risk of a precipitation in form of crystals. We considered the specific gravities as the ordinates of a curve, of which the abscissæ were the numbers of ounces of dry salt contained in a cubic foot of the brine. Having thus obtained eight ordinates corresponding to 1, 2, 3, 4, 5, 6, 7, and 8 portions of salt, the ordinates or specific gravities for every other proportion of salt were had by the usual methods of interposition.

The other method was, by first making a brine nearly saturated, in which the proportion of salt and water was exactly determined. We then took out one-eighth of the brine, and filled up the vessel with water, taking care that the mixture should be complete; for which purpose, besides agitation, the diluted brine was allowed to remain 24 hours before weighing. Taking out one-eighth of the brine also takes out one eighth of the salt; so that the proportion of salt and water in the diluted brine was known. It was now weighed, and thus we determined the specific gravity for a new proportion of salt and water.

We then took out one-seventh of the brine. It is evident that this takes out one-eighth of the original quantity of salt; an abstraction equal to the former. We filled the vessel with water with the same precautions; and in the same manner we proceeded till there remained only one-eighth of the original quantity of salt.

The specific gravities by these two methods agreed extremely well. In the very deliquescent salts the first method exhibited some small irregularities, arising from the unequal quantities of water which they had imbibed from the atmosphere. We therefore confided most in the experiments made with diluted brines.

That the reader may judge of the authority of the tables which we shall insert, we submit to his inspection one series of experiments.

Two thousand one hundred and eighty-eight grains of very pure and dry (but not decrepitated) common salt, prepared in large crystals, were dissolved in 6562 grains of distilled water of the temperature 55°. A small matrass with a narrow neck, which held 4200 grains of distilled water, was filled with this brine. Its contents weighed 5027 grains. Now 6562 + 2188 : 2118 = 5027 : 1256,75. Therefore the bottle of brine contained 1256,75 grains of salt dissolved in 3770,25 grains of water. Its specific gravity is $= \frac{5027}{4200}$, or 1,196905; and a cubic foot of brine weighs 1196,9 ounces avoirdupois. Also 5027 : 1256,75 = 1196,9 : 299,28. Therefore a cubic foot of this brine contains 299,28 ounces of perfectly dry salt.

The subsequent steps of the process are represented as follows.

Salt.	Brine.	Water.	Wt. of Cub. Ft.	Salt in Cub. Ft.
8)1256,75 157,1	8)5027 628,4	3770,25 $=\frac{1}{8}$ of brine.	1196,9	299,28 37,41$\frac{1}{8}$
	4398,6 527,4	Remains. Water to fill it again.		
7)1099,6 157,1	7)4926,0 703,7	2d Brine. $\frac{1}{7}$ taken out.	1172,7	261,87 37,41
	4222,3 604,7	Water added.		
942,5 157,1	6)4827,0 804,5	3d Brine Taken out.	1149,3	224,46
	4022,5 706,5	Remains. Water added.		
785,4 157,1	5)4729,0 946	4th Brine. Taken out.	1125,9	187,05
	3783 847	Remains. Water added.		
628,3 157,1	4)4630 1157,5	5th Brine. Taken out.	1102,3	149,64
	3472,5 1054,5	Remains. Water added.		
471,2 157,1	3)4527 1509	6th Brine. Taken out.	1077,9	112,23
	3018 1405	Remains. Water added.		
314,1 157,1	2)4423 2212	7th Brine. Taken out.	1053,3	74,82
	2211 2102	Remains. Water added.		
157,0	4313	8th Brine.	1027,9	37,41

Thus, by repeated abstraction of brine, so as always to take out $\frac{1}{8}$th of the salt contained in one constant bulk, we have obtained a brine consisting of 157 grains of salt united with 4313—157, or 4156 grains of water. Its specific gravity is $\frac{4313}{4200}$, = 1,0279, and a cubic foot of its weight 1028 ounces, and contains $37\frac{4}{10}$ ounces of dry salt. In like manner may the specific gravity, the weight of a cubic foot, and the salt it contains, be estimated for the intermediate brines.

When these eight quantities of salt contained in a cubic foot are made the abscissæ, and the weights of the cubic foot of brine are the corresponding ordinates, the curve

curve will be found to be extremely regular, resembling a hyperbolic arch whose assymptote makes an angle of 30° with the axis. Ordinates were then interpolated analytically for every 10 ounces of contained salt, and thus the table was constructed. We did not, however, rest it on one series alone; but made others, in which $\frac{1}{4}$th of the salt was repeatedly abstracted. They agreed, in the case of common salt, with great exactness, and in some others there were some very inconsiderable irregularities.

To show the authority of the tables of strength was by no means our only motive for giving an example of the process. It may be of use as a pattern for similar experiments. But, besides, it is very instructive. We see, in the first place, that there is a very sensible change of density in one or both of the ingredients. For the series is of that nature (as we have formerly explained), that if the ingredients retained their densities in every proportion of commixture, the specific gravities would have been in arithmetical progression; whereas we see that their differences continually diminish as the brines grow more dense. We can form some notion of this by comparing the different brines. Thus in the first brine, weighing 5027 grains, there are 3770 grains of water in a vessel holding 4200. If the density of the water remains the same, there is left for the salt only as much space as would hold 430 grains of water. In this space are lodged 1257 grains of salt, and its specific gravity, in its liquid form, is $\frac{1257}{430}=2,8907$ very nearly. But in the 8th brine the quantity of water is 4156, the space left for 157 grains of salt is only the bulk of 44 grains of water, and the density of the salt is $\frac{157}{44}=3,568$, considerably greater than before. This induced us to continue the dilution of the brine as follows, beginning with the 8th brine.

157	2)4313	8th brine.
78,5	2156,5	
	2156,5	
	2105,5	
78,5	2)4262,0	9th brine
39,7	2131	
	2131	
	2102	
39,7	2)4233	10th brine
	2116,5	
	2116,5	
	2102	
19,8	4218	11th brine.

This last brine contains 4198,2 grains of water, leaving only the bulk of 1,8 grains of water to contain 19,8 of salt, so that the salt is ten times denser than water. This will make the strength 243 instead of 210 indicated by the specific gravity. But we do not pretend to measure the densities with accuracy in these diluted brines. It is evident from the process that a single grain of excess or defect in taking out the brine and replacing it with water has a sensible proportion to the whole variation. But we see with sufficient evidence, that from the strong to the weak brines the space left for the portion of salt is continually diminishing. In the first dilution $527\frac{1}{2}$ grains of water were added to fill up the vessel; but $\frac{1}{8}$th of its contents of pure water is only 525: so that here is a diminution of $2\frac{1}{2}$ grains in the space occupied by the remaining salt. The subsequent additions are 604,7; 706,5; 857; 1054,5; 1405; 2102; 2105,5; 2102; 2102; instead of 600; 700; 840; 1050; 1400; 2100; 2100; 2100; 2100. Nothing can more plainly show the condensation in general, though we do not learn whether it happens in one or both of the ingredients; nor do the experiments show with sufficient accuracy the progression of this diminution. The excesses of the added water being only six or seven grains, we cannot expect a nice repartition. When the brine is taken out, the upper part of the vessel remains lined with a briny film containing a portion of salt and water, perhaps equal or superior to the differences. Had our time permitted, we should have examined this matter with scrupulous attention, using a vessel with a still narrower neck, and in each dilution abstracting one half of the brine. The curve, whose abscissæ and ordinates represent the weight of the contained salt and the weight of a constant bulk of the brine, exhibits the best and most synoptical view of the law of condensation, because the position of the tangent in any point, or the value of the symbol $\frac{\dot{x}}{\dot{y}}$, always shows the rate at which the specific gravity increases or diminishes. We are inclined to think that the curve in all cases is of the hyperbolic kind, and complete; that is, having the tangent perpendicular to the axis at the beginning of the curve. The mathematical reader will easily guess the physical notions which incline us to this opinion; and will also see that it is hardly possible to discover this experimentally, because the mistake of a single grain in the very small ordinates will change the position of the tangent many degrees. It was for this reason that we thought it useless to prosecute the dilution any farther. But we think that it may be prosecuted much farther in Dr Watson's or Mr Achard's method, viz. by dissolving equal weights of salt in two vessels, of very different capacities, having tubular necks, in which the change of bulk may be very accurately observed. We can only conclude, that the condensation is greatest in the strongest brines, and probably attains its maximum when the quantities of true saline matter and water are nearly equal, as in the case of vitriolic acid, &c.

We consider these experiments as abundantly sufficient for deciding the question "Whether the salt can be received into the pores of the water, or the water into the pores of the salt, so as to increase its weight without increasing its bulk?" and we must grant that it may. We do not mean that it is simply lodged in the pores as sand is lodged in the interstices of small shot; but the two together occupy less room than when separate. The experiments of Mr Achard were insufficient for a decision, because made on so small a quantity as 600 grains of water. Dr Watson's experiments have, for the most part, the same defect. Some of them, however, are of great value in this question, and are very fit for ascer-

Specific Gravity.

taining the specific gravity of dissolving salts. In one of them (not particularly narrated) he found that a quantity of dissolved salt occupied the same bulk in two very different states of dilution. We cannot pretend to reconcile this with our experiments. We have given these as they stood; and we think them conclusive, because they were so numerous and so perfectly consistent with each other; and their result is so general, that we have not found an exception. Common salt is by no means the most remarkable instance of condensation. Vegetable alkali, sal ammoniac, and some others, exhibit much greater condensation.

We thought this a proper opportunity of considering this question, which is intimately connected with the principles of chemical solution, and was not perhaps considered in sufficient detail under the article CHEMISTRY. We learn from it in general, that the quantities of salt in brines increase at somewhat a greater rate than their specific gravities. This difference is in many cases of sensible importance in a commercial view. Thus an alkaline lixivium for the purposes of bleaching or soap-making, whose specific gravity is 1,234, or exceeds that of water by 234, contains 361 ounces of salt in a cubic foot; a ley, which exceeds the weight of water twice as much, or 468 ounces *per* cubic foot, contains 777 ounces of salt, which exceeds the double of 361 by 55 ounces more than 7 *per cent.* Hence we learn, that hydrometers for discovering the strength of brines, having equal divisions on a cylindrical stem, are very erroneous; for even if the increments of specific gravity were proportional to the quantities of salt in a gallon of brine, the divisions at the bottom of the stem ought to be smaller than those above.

The construction of the following table of strengths from the above narrated series of brines is sufficiently obvious. Column 1st is the specific gravity as discovered by the balance or hydrometer, and also is the number of ounces in a cubic foot of the brine. Col. 2d is the ounces of the dry salt contained in it.

Table of Brines of Common Salt.

Weight Cub. Ft. Brine.	Salt in Cub. F.	Weight Cub. Ft. Brine.	Salt in Cub. F.
1,000	0	1,115	170
1,008	10	1,122	180
1,015	20	1,128	190
1,022	30	1,134	200
1,029	40	1,140	210
1,036	50	1,147	220
1,043	60	1,153	230
1,050	70	1,159	240
1,057	80	1,165	250
1,064	90	1,172	260
1,070	100	1,178	270
1,077	110	1,184	280
1,083	120	1,190	290
1,090	130	1,197	300
1,096	140	1,203	310
1,103	150	1,206	316
1,109	160	1,208	320

The table differs considerably from Mr Lambert's. The quantities of salt corresponding to any specific gravity are about $\frac{1}{18}$th less than in his table. But the reader will see that they correspond with the series of experiments above narrated; and these were but a few of many which all corresponded within an hundredth part. The cause of the difference seems to be, that most kinds of common salt contain magnesian salts, which contain a very great proportion of water necessary for their crystallization. The salt which we used was of the purest kind, but such as may be had from every salt work, by Lord Dundonald's very easy process, viz. by passing through it a saturated solution boiling hot, which carries off with it about $\frac{4}{5}$ths of all the bitter salts. Our aim being to ascertain the quantities of pure sea-salt, and to learn by the by its relation to water in respect of density, we thought it necessary to use the purest salt. We also dried it for several days in a stove, so that it contained no water not absolutely necessary for its crystallization. An ounce of such salt will communicate a greater specific gravity to water than an ounce of a salt that is less pure, or that contains extraneous water.

The specific gravity 1,090 is that of ordinary pickles, which are estimated as to strength by floating an egg.

We cannot raise the specific gravity higher than 1,206 by simply dissolving salt in cold water. But it will become much denser, and will even attain the specific gravity 1,240 by boiling, then holding about 366 ounces in the cubic foot of hot brine. But it will deposit by cooling, and when of the temperature 55° or 60°, hardly exceeds 1,206. We obtained a brine by boiling till the salt grained very rapidly. When it cooled to 60°, its specific gravity was 1,2063; for a vessel which held 3506 grains of distilled water held 4229 of this brine. This was evaporated to dryness, and there were obtained 1344 grains of salt. By this was computed the number interposed between 310 and 320 in the table. We have however raised the specific gravity to 1,217, by putting in no more salt than was necessary for this density, and using heat. It then cooled down to 60° without quitting any salt; but if a few grains of salt be thrown into this brine, it will quickly deposit a great deal more, and its density will decrease to 1,206. We find this to hold in all salts; and it is a very instructive fact in the theory of crystallization; it resembles the effect which a magnet produces upon iron filings in its neighbourhood. It makes them temporary magnets, and causes them to arrange themselves as if they had been really made permanent magnets. Just so a crystal already formed disposes the rest to crystallize. We imagine that this analogy is complete, and that the forces are similar in both cases.

The above table is computed for the temperature 55°; but in other temperatures the strength will be different on two accounts, viz. the expansion of the brine and the dissolving power of the water. Water expands about 40 parts in 1000 when heated from 60° to 212°. Saturated brine expands about 48 parts, or $\frac{1}{5}$th more than water; and this excess of expansion is nearly proportional to the quantity of salt in the brine. If therefore any circumstance should oblige us to examine a brine in a temperature much above 60°, allowance should be made for this. Thus, should the specific gravity of brine of the temperature 130 (which is nearly half way between 60 and 212) be 1,140, we must increase it by 20 (half of 40); and having found the strength 240 corresponding to this corrected specific gravity, we must correct it again by adding 1 to the specific gravity for every 45 ounces of salt.

But

Specific Gravity.

But a much greater and more uncertain correction is necessary on account of the variation of the dissolving power of water by heat. This indeed is very small in the case of sea-salt in comparison with other salts. We presume that our readers are apprised of this peculiarity of sea-salt, that it dissolves nearly in equal quantities in hot or in cold water. But although water of the temperature 60 will not dissolve more than 320 or 325 ounces of the purest and dryest sea-salt, it will take up above 20 ounces more by boiling on it. When thus saturated to the utmost, and allowed to cool, it does not quit any of it till it is far cooled, viz. near to 60°. It then deposits this redundant salt, and holds the rest till it is just going to freeze, when it lets it go in the instant of freezing. If evaporated in the state in which it continues to hold the salt, it will yield above 400 ounces *per* cubic foot of brine, in good crystals, but rather overcharged with water. And since in this state the cubic foot of brine weighs about 1220 ounces, it follows, that 820 ounces of water will, by boiling, dissolve 400 of crystallized salt.

The table shows how much any brine must be boiled down in order to grain. Having observed its specific gravity, find in the table the quantity of salt corresponding. Call this x. Then, since a boiling hot graining or saturated solution contains 340 ounces in the cubic foot of brine, say $340 : 1000 = x : \frac{1000}{340}x$. This is the bulk to which every cubic foot (valued at 1000) must be boiled down. Thus suppose the brine has the specific gravity 1109. It holds 160 ounces *per* foot, and we must boil it down to $\frac{1000 \times 160}{340}$ or 471; that is, we must boil off $\frac{529}{1000}$ of every cubic foot or gallon.

These remarks are of importance in the manufacture of common salt; they enable us to appreciate the value of salt springs, and to know how far it may be prudent to engage in the manufacture. For the doctrine of latent heat assures us, that in order to boil off a certain quantity of water, a certain quantity of heat is indispensably necessary. After the most judicious application of this heat, the consumption of fuel may be too expensive.

The specific gravity of sea-water in these climates does not exceed 1,03, or the cubic foot weighs 1030 ounces, and it contains about 41 ounces of salt. The brine-pits in England are vastly richer; but in many parts of the world brines are boiled for salt which do not contain above 10 or 20 ounces in the cubic foot.

In buying salt by weight, it is of importance to know the degree of humidity. A salt will appear pretty dry (if free from magnesia salts) though moistened with 1 *per cent.* of water; and it is found that incipient humidity exposes it much to farther deliquescence. A much smaller degree of humidity may be discovered by the specific gravity of a brine made with a few ounces of the salt. And the inspection of the table informs us that the brine should be weak; for the differences of specific gravity go on diminishing in the stronger brines: 300 ounces of dry salt dissolved in 897 ounces of water should give the specific gravity 1197. Suppose it be but 1190, the quantity of salt corresponding is only 290; but when mixed with 897 ounces of water, the weight is 1197, although the weight of the cubic foot is only 1190. There is therefore more than a cubic foot of the brine, and there is as much salt as will make more than a cubic foot of the weight 1190. There is $290 \times \frac{1197}{1190}$, or $291\frac{2}{3}$ ounces, and there is $8\frac{1}{3}$ ounces of water attached to the salt.

Specific Gravity.

The various informations which we have pointed out as deducible from a knowledge of the specific gravity of the brines of common salt, will serve to suggest several advantages of the knowledge of this circumstance in other lixivia. We shall not therefore resume them, but simply give another table or two of such as are most interesting. Of those alkaline leys are the chief, being of extensive use in bleaching, soap-making, glass-making, &c.

We therefore made a very strong ley of the purest vegetable alkali that is ever used in the manufactories, not thinking it necessary, or even proper, to take it in its state of utmost purity, as obtained from cubic nitre and the like. We took salt of tartar from the apothecary, perfectly dry, of which 3983 grains were dissolved in 3540 grains of distilled water; and after agitation for several days, and then standing to deposit sediment, the clear ley was decanted. It was again agitated; because, when of this strength, it becomes, in a very short time, rarer above and denser at the bottom. A flask containing 4200 grains of water held 6165 of this ley when of the temperature 55°. Its specific gravity was therefore 1,4678, and the 6165 grains of ley contained 3264 grains of salt. We examined its specific gravity in different states of dilution, till we came to a brine containing 51 grains of salt, and 4189 grains of water, and the contents of the flask weighed 4240 grains: its specific gravity was therefore 1,0095. In this train of experiments the progression was most regular and satisfactory; so that when we constructed the curve of specific gravities geometrically, none of the points deviated from a most regular curve. It was considerably more incurvated near its commencement than the curve for sea-salt indicating a much greater condensation in the diluted brines. We think that the following table, constructed in the same manner as that for common salt, may be depended on as very exact.

Weight of Cub. Foot oz.	Salt cont. oz.	Weight of Cub. Foot oz.	Salt cont. oz.	Weight of Cub Foot oz.	Salt cont. oz.
1000	0	1224	340	1417	680
1016	20	1236	360	1428	700
1031	40	1248	380	1438	720
1045	60	1259	400	1449	740
1058	80	1270	420	1460	760
1071	100	1281	440	1471	780
1084	120	1293	460	1482	800
1098	140	1305	480	1493	820
1112	160	1317	500	1504	840
1125	180	1329	520	1515	860
1138	200	1340	540	1526	880
1150	220	1351	560	1537	900
1162	240	1362	580	1547	920
1174	260	1372	600	1557	940
1187	280	1384	620	1567	960
1200	300	1395	640	1577	980
1212	320	1406	660	1586	1000

We see the same augmentation of the density of the salt in the diluted brines here as in the case of common salt. Thus a brine, of which the cubic foot weighs 1482 ounces, or which has the specific gravity 1,482, contains 800 ounces of dry alkali and 682 of water. Therefore, if we suppose the density of the water unchanged, there remains the bulk of 318 ounces of water to receive 840 ounces of salt: its density is therefore $\frac{800}{318}$, = 2,512 nearly. But in the brine whose weight *per* foot is only 1016 there are 20 ounces of salt, and therefore 996 of water; and there is only four ounce-measures of water, that is, the bulk of four ounces of water, to receive 20 ounces of salt. Its specific gravity therefore is $\frac{20}{4}$, = 5, almost twice as great as in the strong brine. Accordingly Mr Achard is disposed to admit the absorption (as it is carelessly termed) in the case of sal tart. But it is a general (we think an universal) fact in the solution of salts. It must be carefully distinguished from the first contraction of bulk which salts undergo in passing from a solid to a fluid form. The contraction now under consideration is analogous to the contraction of oil of vitriol when diluted with water; for oil of vitriol must be considered as a very strong brine which we cannot dephlegmate by distillation, and therefore cannot obtain the dry saline ingredient in a separate form, so as to observe its solid density, and say how much it contracts in first becoming fluid. The way of conceiving the first contraction in the act of solution as a lodging of the particles of the one ingredient on the interstices of the other, "*ou ils se nichent, en augmentant le poids sans affecter le volume de la saumure,*" as Eller and Lambert express themselves, is impossible here, when both are fluids. Indeed it is but a slovenly way of thinking in either case, and should be avoided, because inadvertent persons are apt to use as a physical principle what is merely a mode of speech.

We learn from the table, that a hydrometer with equidistant divisions on a cylindrical or prismatical stem is still more erroneous than in the brines of common salt.

We learn from the experiments of Kirwan, Lavoisier, and others, that dry salt of tartar contains about $\frac{1}{4}$th of its weight of fixed air. In many applications of this salt to the purposes of manufacture, this ingredient is of no use. In some it is hurtful, and must be abstracted by lime. Soap-maker's ley consists of the pure alkaline salt dissolved in water. It is therefore of importance to ascertain its quantity by means of the specific gravity of the brine. For this purpose, we took a ley of sal tart. whose specific gravity was 1,20417, containing 314 oz. of mild alkali in a cubic foot of ley, and we rendered it nearly caustic by lime. The specific gravity was then 1,1897. This is a very unexpected result. Nothing is employed with more success than quicklime for dephlegmating any watery fluid. We should rather have expected an increase of specific gravity by the abstraction of some of the water of the menstruum, and perhaps the water of the crystallization, and the aerial part of the salt. But we must ascribe this to the great density in which the fixed air exists in the mild alkali.

It is unnecessary to give similar tables for all the salts, unless we were writing a dissertation on the theory of their solution. We shall only observe, that we examined with particular attention sal ammoniac, because Mr Achard, who denies what is called the absorption of salts, finds himself obliged to allow something like it in this salt. It does not, however, differ from those of which we have given an account in detail in any other respect than this, that the changes of fluid density are much less than in others (instead of being greater, as Achard's experiments seem to indicate) in all brines of moderate strength. But in the very weak brines there is indeed a remarkable difference; and if we have not committed an error in our examination, the addition of one part of sal ammoniac to 64 of water occupies less room than the water alone. We think that we have met with this as an accidental remark by some author, whose work we do not recollect. But we do not choose to rest so much on our form of the experiment in such weak brines. The following mixtures will abundantly serve for constructing the table of its strength: Sal ammoniac = 960 grains was dissolved in 3506 grains of water, making a brine of 4466 grains. A phial which held 1600 grains water held 1698 of this brine. It contained $\frac{1698 \times 960}{4466}$, or 365 grains of salt. The specific gravity was $\frac{1698}{1600}$, = 1,061, and the cubic foot weighed 1061 ounces. It also contained $\frac{1061 \times 365}{1698}$, or 228 ounces of salt. By repeated abstraction of brine, and replacing with water, we had the following series:

Series.		Brine.	Sp. Gr.	Oz. Salt in Cub. F.
Weight of brine,	*1st,*	1698	1,061	228
After taking out $\frac{1}{4}$,	*2d,*	1676	1,048	171
After taking out $\frac{1}{3}$,	*3d,*	1653	1,033	114
After taking out $\frac{1}{2}$,	*4th,*	1630	1,019	57
After taking out $\frac{1}{2}$,	*5th,*	1616	1,010	$28\frac{1}{2}$
$\frac{1}{2}$,	*6th,*	1610	1,0063	$14\frac{1}{4}$
$\frac{1}{2}$,	*7th,*	1605	1,0038	$7\frac{1}{8}$

This series is extremely regular, and the progress of density may be confidently deduced from it.

From the whole of this disquisition on the relation between the specific gravities of brines and the quantities of salt contained, we see in general that it may be guessed at, with a useful degree of precision, from the density or specific gravity of saturated solutions. We therefore conclude with a list of the specific gravities of several saturated solutions, made with great care by the bishop of Landaff.—The temperature was 42°. The first numerical column is the density of saturated brine, and the next is the density of a brine consisting of 12 parts (by weight) of water and one of salt. From this may be inferred the quantity in the saturated solution, and from this again may be inferred the quantity corresponding to inferior densities.

SPEC-

SPECTACLES, in dioptrics, a machine consisting of two lenses set in silver, horn, &c. to assist the defects of the organ of sight. Old people, and others who have flat eyes, use convex spectacles, which cause the rays of light converge so as to meet upon the retina: whereas myopes, or short sighted people, use concave lenses for spectacles, which causes the rays to diverge, and prevent their meeting ere they reach the retina. See OPTICS, n° 73.

OCULAR SPECTRA, images presented to the eye after removing them from a bright object, or closing them. When any one has long and attentively looked at a bright object, as at the setting sun, on closing his eyes, or removing them, an image, which resembles in form the object he was attending to, continues some time to be visible. This appearance in the eye we shall call the ocular spectrum of that object.

Phil. Trans. 1786

These ocular spectra are of four kinds: 1st, Such as are owing to a less sensibility of a defined part of the retina or spectra from the defect of sensibility. 2d, Such as are owing to a greater sensibility of a defined part of the retina, or spectra from excess of sensibility. 3d, Such as resemble their object in its colour as well as form; which may be termed direct ocular spectra. 4th, Such as are of a colour contrary to that of their object, which may be termed reverse ocular spectra.

SPECTRE, an apparition, something made preternaturally visible to human sight, whether the ghosts of dead men or beings superior to man.

A belief that supernatural beings sometimes make themselves visible, and that the dead sometimes revisit the living, has prevailed among most nations, especially in the rudest stages of society. It was common among the Jews, among the Greeks, and among the Romans, as we find from the Scriptures, and from the poems of Homer and Virgil. Celestial appearances were indeed so often exhibited to the Jews, that the origin of their belief is not difficult to be explained.—The Divine Being manifested himself to each of the Patriarchs by some sensible sign, generally by a flame of fire, as he did to Moses. Under this semblance also did he appear to the Israelites during their abode in the desert, and after they obtained a settlement in the land of Canaan. Nor did they believe that heavenly beings alone assumed a sensible appearance: They believed that deceased men also sometimes revisited this world. When Saul went to consult the witch at Endor, he asked her to bring up the person whom he should name unto her; a proof that he considered his demand as easy to be performed, and therefore that he probably acted under the influence of popular opinion. The same opinions had been generally entertained at a much earlier period; for necromancy and witchcraft, the arts by which the dead were supposed to be raised, had been prohibited while the Israelites were in the wilderness, and yet untainted with the vices of the Canaanites. They must therefore have derived them from Egypt, the cradle of superstition, as well as of the arts and sciences.

Among the Greeks and Romans the apparition of spectres was generally believed. On innumerable occasions the gods are said to have discovered themselves to the eyes of mortals, to have held conferences, and to have interposed their aid. The ghosts of the dead, too, are said to have appeared. When Æneas, amidst the distraction and confusion of his mind in flying from the destruction of Troy, had lost his wife by the way, he returned in search of her. Her shade appeared to him (for she herself had been slain) with the same aspect as before, but her figure was larger. She endeavoured to assuage the grief of her unhappy husband, by ascribing her death to the appointment of the gods, and by foretelling the illustrious honours which yet awaited him. But when Æneas attempted to clasp her in his arms, the phantom immediately vanished into air. From this story we may observe, that the ancients believed that the umbræ or shades, retained nearly the same appearance after death as before; that they had so far the resemblance of a body as to be visible; that they could think and speak as formerly, but could not be touched. This description applies equally well to those shades which had passed the river Styx, and taken up their residence in the infernal regions. Such were the shades of Dido, of Deiphobus, and all those which Æneas met with in his journey through the subterraneous world.

It appears from the writings of modern travellers who have visited rude and savage nations, that the belief of spectres is no less common among them. Mr Bruce tells us, that the priest of the Nile affirmed, that he had more than once seen the spirit of the river in the form of an old man with a white beard. Among the Mahometans the doctrine of spectres seems to be reduced to a regular system, by the accounts which they give of genii. Whoever has read the Arabian Nights' Entertainments must have furnished his memory with a thousand instances of this kind. Their opinions concerning genii seem to be a corrupted mixture of the doctrines of the Jews and ancient Persians. In Christian countries, too, notwithstanding the additional light which their religion has spread, and the great improvement in the sciences to which it has been subservient, the belief of ghosts and apparitions is very general, especially among the lower ranks. They believe that evil spirits sometimes make their appearance in order to terrify wicked men, especially those who have committed murder.—They suppose that the spirits of dead men assume a corporeal appearance, hover about church yards and the houses of the deceased, or haunt the places where murders have been committed. (See GHOST.) In some places it is believed that beings have been seen bearing a perfect resemblance to men alive. In the Highlands of Scotland, what is called the second sight is still believed by many (see *SECOND Sight*); viz. that future events are foretold by certain individuals by means of spectral representation.

So general has the belief of spectres been, that this circumstance alone may be thought by some sufficient to prove that it must have its foundation in human nature, or must rest upon rational evidence. When any doctrine has been universally received by all nations, by generations living several thousand years from one another, and by people in all the different stages of society, there is certainly the strongest presumption to conclude that such a doctrine has its foundations in reason and in truth. In this way we argue in favour of the existence of a God, concerning moral distinction, and the doctrine of a future state: and certainly so far we argue well. But if the same argument be applied to idolatry, to sacrifices, or to apparitions, we shall find that it is applied improperly. Idolatry was very general among ancient nations; so was the offering of sacrifices, Spectre. so was polytheism: but they were by no means universal. Should we allow, for the sake of shortening the argument, that all ancient nations were polytheists and idolaters, and presented oblations to their imaginary deities, all that could be concluded from this concession is, that they fell into these mistakes from their ignorance and from the rude state of society, from which their imperfect knowledge of theology and moral philosophy was never able to rescue them. These erroneous notions fled before the brightness of the Christian system; while the doctrines of the existence of God, of moral distinction, and of a future state, have been more thoroughly confirmed and ascertained. The same thing may be said of the belief of spectres. However generally it has been adopted in the first stages of society, or by civilized nations who had made but little progress in the study of divine things, it has been rejected, we may say invariably, wherever theology and philosophy have gone hand in hand.

As all popular and long established opinions are objects of curiosity and research for the philosopher, we think the belief of spectres worthy of some attention even in this light. It will therefore, we hope, give some satisfaction to the philosophical reader to see a short account of the sources or principles from which this belief is derived. But as the belief of spectres is connected with other opinions which appear to us highly injurious to religion; opinions which have been supported by many learned men, and which are still believed by some men of literary education—it will also be proper, in the first place, to consider the evidence on which this belief rests, in which we must consider both their probability and credibility.

In the present investigation we mean to set aside altogether the celestial appearances recorded in Scripture, as being founded on unquestionable evidence, and perfectly agreeable to those rules by which the Deity acts in the usual course of his Providence. The Israelites, during the existence of their state, were immediately under the authority of God, not only as the moral governor of the world, but as the King of Israel. In the infancy of the world, while men were rude and unenlightened, and entirely under the influence of idolatry, many revelations were necessary to preserve in their minds pure ideas of the nature of God, and of the worship due to Him. They were necessary also to pave the way for that illustrious dispensation which the Lord Jesus came from Heaven to diffuse over the world. Every celestial appearance recorded in Scripture was exhibited for some wise and important purpose, which must be apparent to every person who considers these appearances with attention. But when the Scriptures were written and published, and the Christian religion fully established, revelation ceased, and miracles and heavenly messages were no longer requisite. What credit then ought we to give to those marvellous stories related in ancient authors concerning prodigies in the heavens, and the apparition of angels both good and bad?

It is not pretended that any of those prodigies and appearances were exhibited for purposes equally great and important with those which are described in Scripture: And can we suppose that the all-wise Governor of the World would permit his angels to render themselves visible to the eye of man for no purpose at all, or for a purpose which might have been equally well accomplished without their interposition? Would this be consistent with perfect wisdom, or would it be consistent even with the excellence and superiority of understanding which we are taught to ascribe to these elevated beings? The whole will of God is revealed to us in the Scriptures; what further use for the visible interposition of angels? It may be objected, Are they not all ministering spirits sent forth to minister for them who shall be heirs of salvation§? We answer, That angels may animate and support good men by an invisible interposition. But the Apostle is not speaking of celestial spirits. The word αγγελος signifies "a messenger;" and in Scripture often refers to men. In the passage which we are now reviewing it certainly is applied with much more propriety to men than to angels: for the Apostle is stating a comparison between *the Prophets*, by whom God, at sundry times and in divers manners, spake in time past to the fathers, and *the Son*, by whom he hath spoken in these last days.

§ Heb. i. 14.

And if God has given no commission to his angels to deliver to men since the publication of the Christian religion, is there any probability that he would give any commission or any licence to evil spirits? It will be said, that this doctrine is clearly taught in the New Testament, in these words, "The devil goeth about as a roaring lion seeking whom he may devour." We will not avail ourselves of the interpretation of some, who say that the word *devil*, which in the Greek language signifies an *adversary*, or *slanderer*, refers here to some human being, who was a violent enemy of the Christians. All that can be deduced from these words, upon the supposition that they refer to a malignant spirit, is merely that he goeth about seducing men to vice. But it is not by assuming a hideous form, and presenting himself to the midnight traveller, that such a purpose is to be accomplished. A spirit may probably have direct access to our minds without the intervention of any thing corporeal; and by exciting our passions may plunge us into vice, which is the only object such a being is supposed to have in view. None of the marvellous stories which we have heard concerning the apparition of evil spirits lead us to conclude that they appear to entice men to commit crimes. We never heard of any evil spirits that required men to steal, to perpetrate robbery or murder. They only appeared to terrify some crazy timorous individuals, who have whims and fancies enow of their own to agitate their minds, though no preternatural vision should ever appear to them. It is not consistent, therefore, with the character of God, and what he has revealed to us of his will, to believe that he would commission good angels, or permit evil angels, to appear to men since the propagation of the Gospel, or indeed at any former period of the world, unless some great and mighty purpose was to be fulfilled. It is not consistent with what we know of the nature of good or bad angels to suppose, that though permission were granted them occasionally to show themselves to men, that they would appear in that way which storytellers describe.

It is equally improbable that the spirits of the dead who have removed from this world should again be permitted to visit it. At death men undergo as great, perhaps a greater change, than when they came first into the light of the sun. Is it not therefore as improbable that a man should return in a visible corporeal form

form after death, as that, after having arrived at manhood, he should return to the state in which he was before his birth? Such changes as these are evidently made permanent by the invariable laws of nature. But suppose it were possible, for what purpose should they return? To describe to us what is passing in the other world, to animate us to virtue, by informing us of the rewards which there await the good; or to alarm us, by describing the punishment of the wicked. These seem important reasons. But Divine Providence has wisely thrown a veil over futurity. We know every thing of the other world from the Scripture which it is proper for us at present to know. And as to incentives to virtue, we are already blessed with a number sufficiently great and powerful for moral beings, who are to act from rational motives, and not from compulsion. "He that will not hear Moses and the prophets, will not be persuaded though one rose from the dead."

Luke xvi. 31.

There is one strong objection against the probability of spectres, which is sufficient to prove that they are not intelligent creatures; or at least that they possess so small a degree of intelligence, that they are unqualified to act with prudence, to propose any end to themselves, or use the proper means to accomplish that end. Ghosts often appear in order to discover some crime that has been committed: but they never appear to a magistrate, or person in authority, but to some illiterate clown, who happens to live near the place where the crime was perpetrated; to some person who has no connection with the affair at all, and who in general is the most improper in the world for making the discovery. For instance, in Glanville's *Saducismus triumphatus* (a book written in the last century by a chaplain of Charles II. in support of the common opinions respecting witchcraft and apparitions), we have the following story: James Haddock, a farmer, was married to Elenor Welsh, by whom he had a son. After the death of Haddock, his wife married one Davis; and both agreed to defraud the son by the former marriage of a lease bequeathed to him by his father. Upon this the ghost of Haddock appeared to one Francis Taverner the servant of lord Chichester, and desired him to go to Elenor Welsh, and to inform her that it was the will of her former husband that their son should enjoy the lease. Taverner did not at first execute this commission; but he was continually haunted by the apparition in the most hideous shapes, which even threatened to tear him in pieces, till at last he delivered the message. Now, had this spectre had the least common sense, it would have appeared first to Elenor Welsh and her husband Davis, and frightened them into compliance at once, and not have kept poor Taverner in such constant disquietude, who had no concern in the matter.

Another very odd circumstance respecting apparitions in general must not be omitted, which is, that they have no power to speak till they are addressed. In the 27th of Glanville's Relations we read of an old woman that appeared often to David Hunter, a neat-herd, at the house of the Bishop of Down and Conners. Whenever she appeared, he found himself obliged to follow her; and for three quarters of a year poor David spent the whole of almost every night in scampering up and down through the woods after this old woman. How long this extraordinary employment might have continued, it is impossible to guess, had not David's violent fatigue made him one night exclaim, "Lord bless me! would I were dead!—shall I never be delivered from this misery!" On which the phantom replied, "Lord bless me too! It was happy you spoke first, for till then I had no power to speak though I have followed you so long." Then she gave him a message to her two sons, though David told her he remembered nothing about her. David, it seems, neglected to deliver the message; at which the old beldam was so much provoked, that she returned and hit him a hearty blow on the shoulder, which made him cry out, and then speak to her. Now if she could not speak till David addressed her, why might she not have applied this oratorial medicine the first time she appeared to him? It would have saved both herself and him many a weary journey; and certainly David would much rather have had even half a dozen of blows from her choppy fists than have wanted so many nights sleep. To complete the story, we must add, that when David's wife found it impossible to keep him from following the troublesome visitor, she trudged after him, but never was gratified with a sight of the enchantress. David's little dog too was a dutiful attendant on his master during his pilgrimage.

It is remarked by Glanville, that ghosts are generally very eager to be gone. Indeed they are often so much so, that they do not stay to tell their errand. One would be induced from this, as well as the circumstances already mentioned, to think that they are the stupidest and dullest of the dead that assume the appearance of ghosts; unless we adopt the ingenious solution of Glanville, "That it is a very hard and painful thing for them to force their thin and tenuious bodies into a visible consistence; that their bodies must needs be exceedingly compressed; and that therefore they must be in haste to be delivered from the unnatural pressure."

With respect to the *evidence* in favour of spectres, if examined ever so slightly, it will be found very defective. They only appear to one person at a time; they are seen only in the night; they are visible only to ignorant, illiterate, and credulous persons, and never present themselves before men of education and learning.

That spectres only appear to one person at a time, even though there are more in company, is an objection against the credibility of their appearance quite insurmountable. How is it possible that two men of eyesight equally good, directing their eyes to the same spot, should not see so large an object as that of a man or woman at a small distance equally well? Some will tell us that a mist is cast over the eyes of the one, while the view of the other is free from obstruction. But how is this to be proved? and besides what purpose would it serve? Ghosts have seldom any secrets to disclose; they might be proclaimed to a multitude with as much propriety as confined to one person. Shall we be told, that the spectre has the power of becoming visible to some, and of remaining invisible to others? This cannot be allowed without adopting opinions destructive to revealed religion; for it would be a miracle; and we cannot be persuaded, without evidence, that God would empower any inferior being to control at pleasure the wise laws which he has ordained for governing the world. To him who is of a different opinion, we would

would recommend Farmer on Miracles; a book in which this question is fully examined.

Spectres appear only in the night. But why should they shun the light of the sun? Those mischievous ghosts that Glanville mentions might indeed have some reason to choose midnight for the execution of their pranks, as they would be more easily detected in open day. Such was the roguish drummer that haunted Mr Mompesson's house, who beat his drum all night, threw the old gentlewoman's clothes about the room, hid her Bible in the ashes, plucked the clothes off the bed, and amused himself with tossing about Mr Mompesson's shoes. But why should a grave serious ghost appear at midnight? Might it not deliver its message with as much ease and more success in the day-time? In the day-time it would not excite much fear; it would be listened to therefore with more attention; and did it choose to exhibit itself before a number of witnesses, its grievances would be more speedily redressed, because more persons would interest themselves in seeing justice done to the injured ghost.

Spectres not only choose the most improper time, but the most improper persons. To render the testimony of any person credible, he must not only be a man of veracity, but he must have sufficient ability to judge of the subject to which he is to bear witness. It is not on the evidence of an ignorant illiterate person, who has more fancy and fear than judgment, that we are to rest our belief of what is supernatural. It is also worthy of remark, that we have never heard of a ghost appearing to any person who did not previously believe their existence. A man must be prejudiced in favour of this opinion, or he will never see a ghost. But sensible men know, that he who has been accustomed to hear frightful stories of ghosts and apparitions gliding thro' a church-yard, or haunting some particular place, can scarcely pass through a church-yard or haunted spot without conjuring up in his imagination the hideous phantoms which he has been accustomed to associate with such places. Is it strange, then, that an ignorant man, with a mind uncultivated and uninformed, with all the prejudices of the nursery about him, should imagine he sees ghosts in those places where he believes they hover, especially in the dead hour of midnight, when, with the sligheft aid of the imagination, a cow may be turned into a monstrous phantom, and the reflection of the beams of the moon from a little water be converted into a ghost with a winding-sheet? But why should apparitions shun men of understanding and learning? Why should learning be formidable to them (A)? It was not so with the celestial messengers mentioned in the Scriptures: they appeared to the patriarchs and prophets; and the miracles there recorded were performed in the most public places, before the eyes of Rabbins, of Scribes, and Pharisees. Indeed this circumstance is sufficient to destroy the evidence of spectres. They have never been seen by any but men of weak or distempered minds, or by men who have previously believed in them.

Having now considered the evidence on which the belief of spectres rests, we will endeavour to give some account of the foundation of it. To trace an opinion that has prevailed so generally in the world to its source, is a labour not unworthy of the philosopher, even tho' the opinion be false. It is always gratifying to detect the causes of error: it is no less useful; for in order to refute error, it is often sufficient to point out the sources from which it has sprung. To reach the origin of the belief of spectres is not more difficult than to account for idolatry or polytheism. In the infant state of the intellectual powers every thing is considered as possessing life and intelligence. The child beats the stool over which he has fallen with the same passion that he would treat his companion: The young girl talks to her doll as if it understood her: The savages ascribe every change which they observe on the face of nature to the action of some animated being. As knowledge advances, they single out those beings which seem to produce the most striking effects, arrange them into some kind of order, and divide the government of the world among them. Unable, at the same time, to conceive any notion of a pure spirit, they imagine those divinities are corporeal beings. This is the foundation of idolatry. The belief of spectres is but another step. That these animated corporeal beings, to whom they address their prayers, and who preside over the world, should on particular occasions display themselves to the human eye, is what they must be previously disposed to expect. Hence the numberless appearances of the heathen gods, of the Persian and Mahometan genii. The belief

(A) The celebrated historian De Thou had a very singular adventure at Saumur, in the year 1598. One night, having retired to rest very much fatigued, while he was enjoying a sound sleep, he felt a very extraordinary weight upon his feet, which, having made him turn suddenly, fell down and awakened him. At first he imagined that it had been only a dream, but hearing soon after some noise in his chamber, he drew aside the curtains, and saw, by help of the moon, which at that time shone very bright, a large white figure walking up and down, and at the same time observed upon a chair some rags, which he thought belonged to thieves who had come to rob him. The figure then approaching his bed, he had the courage to ask it what it was. "I am (said it) the Queen of Heaven." Had such a figure appeared to any credulous ignorant man in the dead of night and made such a speech, would he not have trembled with fear, and have frightened the whole neighbourhood with a marvellous description of it? But De Thou had too much understanding to be so imposed upon. Upon hearing the words which dropped from the figure, he immediately concluded that it was some mad woman, got up, called his servants, and ordered them to turn her out of doors; after which he returned to bed and fell asleep. Next morning he found that he had not been deceived in his conjecture, and that having forgot to shut his door, this female figure had escaped from her keepers, and entered his apartment. The brave Schomberg, to whom De Thou related his adventure some days after, confessed that in such a case he would not have shown so much courage. The king also, who was informed of it by Schomberg, made the same acknowledgement.

Spectre.

belief of ghosts may be easily deduced from the opinions entertained respecting a future state. These opinions are founded on that essential doctrine of natural religion, that there is another world in which men shall exist when death has removed them hence. This doctrine has been universally received both by savage and civilized nations; but, as might be expected, men have formed very different sentiments concerning the nature of a future state, of the situation and employments of departed spirits, according to the degree of knowledge which they possessed. But the general opinion in ancient and rude nations was, that departed spirits retained the same external appearance, the same passions and principles as before. Nothing therefore was more natural than the opinion, that they might occasionally revisit this world, from an anxious desire to alleviate the sufferings of those beloved friends and relations whom they had left behind them, or to communicate from the unseen world what might be important to their welfare. Upon such an errand did Creüsa appear to Æneas. The apparition of the ghosts of murderers is easily explained upon the same general principles. The remorse and horror of mind which the murderer feels are supposed to haunt him in the other world, and to render his situation there intolerable (especially if the murder was never detected and punished), till he return and give information against himself. In this way, then, we think it highly probable the belief of spectres has originated. But many other causes concur to confirm and propagate this belief. These are, imperfect vision united with fear, dreams, opium, diseases, drunkenness, and artifice.

1. Indistinct vision is one source of apparitions, especially when the mind is under the influence of fear. It is well known, that the sense of seeing conveys no idea of distance till improved by experience and observation; and how we come at length to distinguish objects at a distance from those that are near, has been explained in another place (see METAPHYSICS, n° 50).

In the day-time we seldom commit mistakes, because we know the object at which we look; but at night, when we see objects obscurely, and know not what they are, we have no distinct idea either of their distances or of their magnitude. We may mistake a bush that is near us for a tree at a distance; or if the imagination be under the influence of fear, it will easily convert it into a gigantic figure. "It is generally asserted (says Buffon) that these figures exist only in the imagination; yet they may have a real existence in the eye; for whenever we have no other mode of judging of an unknown object but by the angle it forms in the eye, its magnitude will uniformly increase in proportion to its propinquity. If it appears, when at the distance of 20 or 30 paces, to be only a few feet high, its height, when within two or three feet of the eye, will be many fathoms. An object of this kind must naturally excite terror and astonishment in the spectator, till he approches and recognises it by actual feeling; for the moment a man knows an object, the gigantic appearance it assumed in the eye instantly diminishes, and its apparent magnitude is reduced to its real dimensions. But if, instead of approaching such an object, the spectator flies from it, he can have no other idea of it but from the image which it formed in his eye; and, in this case, he may affirm with truth that he saw an object terrible in its aspect, and enormous in its size. Thus the notions concerning spectres is founded in nature, and depend not, as some philosophers affirm, upon the imagination alone."

Buffon's Natural History, vol. iii. p. 13.

In addition to these observations of Buffon, we may take notice, that objects are always magnified in a fog; so that when a fog happens in the night-time, objects may be magnified to an enormous size. But, at any rate, whether there be fog in the night or not, there is such a great analogy between darkness and a fog, that if the latter deceive us with respect to the size of objects, the former will also deceive us. The writer of this article was passing the Frith of Forth at Queensferry, near Edinburgh, one morning which was extremely foggy. Though the water be only two miles broad, the boat did not get within sight of the southern shore till it approached very near it. He then saw to his great surprise a large perpendicular rock, where he knew the shore was low and almost flat. As the boat advanced a little nearer, the rock seemed to split perpendicularly into portions, which separated at a little distance from one another. He next saw these perpendicular divisions move; and upon approaching a little nearer, found it was a number of people standing on the beach, waiting the arrival of the ferry-boat.

2. Dreams are another fertile source of apparitions. It is well known to every person, that while the mind is under the influence of a dream it considers it as much a reality as it does any particular action while awake. Now if a person of a weak superstitious mind should have a very lively dream, which interests his passions, particularly the passion of fear, it may make so deep an impression, that he may be firmly convinced that he has actually seen with his eyes what has only passed before his imagination (See APPARITION) (B). We shall here tell a story, by way of illustration, which we have received on unquestionable authority. An East Indian captain had an honest faithful servant named *John*, for whom he had a great regard. John died, if we recollect right, on a voyage from England to the East Indies during a French war. As the ship approached the place of its destination the captain had a dream, in which John appeared to him, and earnestly besought him not to sail to the port for which he was bound, as it was in the hands of the French. The captain, though not addicted to superstition, thought it prudent to follow this admonition; and after landing at a different port, he was informed that the place to which he had intended to steer was, according to the information of the dream, captured by the French. On the voyage home, the captain had a second dream, in which John again appeared to him, and gave him notice

(B) When the thoughts are much troubled, and when a person sleeps without the circumstances of going to bed, or putting off his clothes, as when he nods in his chair, it is very difficult, as Hobbes remarks, to distinguish a dream from a reality. On the contrary, he that composes himself to sleep, in case of any uncouth or absurd fancy, easily suspects it to have been a dream.—*Leviathan*, par. i. c. 1.

fice that he ſhould ſoon die, and that the ſhip ſhould be taken in the mouth of the Channel by the French. Next morning the captain called his firſt mate, told him his dream, which he believed was prophetic, and delivered his papers, that he might take proper care of them after his deceaſe. Every thing happened exactly as the dream had foretold; the captain died, and the veſſel was taken by a French man of war in the mouth of the Channel. This dream, wonderful as it appears, is eaſily explained. In the voyage out to India, nothing was more natural than that the captain ſhould ſometimes be thinking, that amidſt the various chances of war, the port to which he was bound might be taken; perhaps it was a place of conſequence, which the French might be eager to poſſeſs. The captain being accuſtomed to revolve theſe thoughts in the day-time, they would naturally return at night; the regret which he felt for the loſs of a faithful ſervant might mingle with his apprehenſions, and thus produce the dream. Perhaps the advice was ſuch as John would have given had he been alive. It is equally eaſy to explain the cauſe of the dream in the paſſage home. The captain, we are told, was very ill, and thought himſelf dying, at the very time he had the ſecond dream, and therefore did not expect to reach England. This part of the dream, then, was only his own thoughts, delivered by his ſervant. As to the other part, that his ſhip ſhould be taken in the mouth of the Channel, it may be thought unaccountable how the very place ſhould be foreſeen. But we muſt recollect, that the mouth of the Channel, being over againſt the coaſt of France, was by far the moſt dangerous place in the whole paſſage; and that, therefore, the captain had more reaſon to be afraid of loſing his ſhip there than in any other place. The uſe which we mean to make of this ſtory is this: Had the captain been a man of a weak mind, he would certainly have conſidered the dream as a reality, and believed, that inſtead of having dreamed of the things on which his imagination had dwelled, he had actually ſeen his ſervant return from the dead, and heard him deliver the meſſage. But, on the other hand, the captain, though he believed the dream was prophetic, mentioned it without any ſigns of fear; and no man of courage and reflection ever ſees an apparition. This ſight is reſerved for the weak, the timid, and ſuperſtitious. Of this many inſtances might be mentioned.

3. Spectres are ſometimes alſo occaſioned by opium. Gaſſendi the philoſopher found a number of people going to put a man to death for having intercourſe with the devil; a crime which the poor wretch readily acknowledged. Gaſſendi begged of the people that they would permit him firſt to examine the wizard before putting him to death. They did ſo; and Gaſſendi, upon examination, found that the man firmly believed himſelf guilty of this impoſſible crime. He even offered to Gaſſendi to introduce him to the devil. The philoſopher agreed; and when midnight came, the man gave him a pill, which he ſaid it was neceſſary to ſwallow before ſetting off. Gaſſendi took the pill, but gave it to his dog. The man having ſwallowed his, fell into a profound ſleep; during which he ſeemed much agitated by dreams. The dog was affected in a ſimilar manner. When the man awoke, he congratulated Gaſſendi on the favourable reception he had met with from his ſable highneſs. It was with difficulty Gaſſendi convinced him that the whole was a dream, the effect of ſoporific medicines, and that he had never ſtirred from one ſpot during the whole night.

4. That diſeaſes, eſpecially the night-mare, the hypochondria, hyſteric paſſion, and madneſs, are another ſource of ſpectres, we have the ſtrongeſt reaſon to affirm. Perſons ſubject to the night mare often imagine that they ſee ſpectres. This is ſtill more the caſe with hypochondriac and hyſteric perſons, and thoſe who are in any degree deranged in their intellects. A fact which fell within the obſervation of the writer of this article will both prove and illuſtrate this aſſertion. In a village in one of the midland counties of Scotland, lived a widow diſtinguiſhed among her neighbours for decency of manners, integrity, and reſpect for religion. She affirmed, that for ſeveral nights together ſhe had heard a ſupernatural voice exclaiming aloud, *Murder! murder!* This was immediately reported through the neighbourhood; all were alarmed, and looked around them with ſolicitude for the detection of the murder which they ſuppoſed to have been committed; and it was not long till a diſcovery ſeemed actually to be made. It was reported, that a gentleman, who had relations at no great diſtance, and had been reſiding in the Weſt Indies, had lately arrived with a conſiderable fortune; that he had lodged in an inn about three miles off; and that he had afterwards been ſeen entering a houſe in the village where the widow lived, from which he had never returned. It was next affirmed, that a tradeſman paſſing the church-yard about twelve at midnight had ſeen four men carry a dead corpſe into that cemetery. Theſe three facts being joined together ſeemed perfectly to agree and to confirm one another, and all believed ſome horrible murder had been committed. The relations of the gentleman thought they were called upon to make inquiry into the truth of theſe allegations: they accordingly came firſt to the church-yard, where, in company with the ſexton, they examined all the graves with great care, in order to diſcover whether any of them had been lately dug, or had the appearance of containing more than one coffin. But this ſearch was to no purpoſe, for no alteration had been made upon the graves. It was next reported that the murdered man had been buried in a plantation about a mile diſtant from the village. As the alarm was now very general, a number of the inhabitants propoſed of their own accord to explore it. They accordingly ſpread themſelves over the wood, and ſearched it with care, but no grave nor new dug earth was found. The writer of this article, who was then a boy at ſchool, was along with them. The matter did not reſt here: The perſon who was ſaid to have ſeen four men carry a dead corpſe into the church-yard at midnight was ſummoned to appear before a meeting of the juſtices of the peace. Upon examination he denied any knowledge of the affair, but referred the court to another perſon from whom he had received his information. This perſon was examined, and the reſult was the ſame as the former. In ſhort, one perſon had heard it from another, who had received it from a third, who had heard it from a fourth; but it had received a little embelliſhment from every perſon who

repeated

Spectre. repeated it. It turned out to be the same with Smollet's story of the three black crows, which some body was said to have vomited.

Upon inquiry at the inn where the West Indian gentleman had lodged, no such gentleman had been seen there. It was found afterwards he had never left the West Indies. Still, however, the veracity of the widow was not disputed; and some dark and secret transaction was suspected. But the whole affair was at length explained by discovering that she was somewhat deranged by melancholy. And the cries which she had at first imagined she had heard were afterwards imitated by some roguish person, who was highly amused with spreading terror among the credulous.

5. Drunkenness also has the power of creating spectres. Its natural effect in most cases is to derange the understanding, to throw it off its guard, and to give full scope to that passion which has a natural disposition to gain an ascendancy; and sometimes it excites passions which scarcely seem to exist at any other time. It makes some men licentious, some furious, some all benevolence and kindness, some from being cowards it renders undaunted heroes. It seldom, if ever, excites fear; and therefore it may be thought strange that men should imagine they see ghosts when intoxicated. But it must be remarked, that the ghost which the drunkard sees, he sees not with the same alarm and terror as men who are sober. He is not afraid of them. He has the courage to converse with them, and even to fight with them, if they give him provocation. A man returning home intoxicated, affirmed that he had met with the devil; and that after a severe encounter he had vanquished him and brought him to the ground, to which he had nailed him fast by driving his staff through his body. Next morning the staff was found stuck with great violence into a heap of turfs!

6. Many apparitions of spectres have no other origin than the artifices of the waggish or self-interested. Dr Plot, in his Natural History of Oxfordshire, relates a marvellous story, which will illustrate this assertion. Soon after the murder of King Charles I. a commission was appointed to survey the king's house at Woodstock, with the manor, park, woods, and other demesnes to that manor belonging; and one Collins, under a feigned name, hired himself as secretary to the commissioners, who, upon the 13th of October 1649, met, and took up their residence in the king's own rooms. His majesty's bed-chamber they made their kitchen, the council hall their pantry, and the presence chamber was the place where they sat for the dispatch of business. His majesty's dining-room they made their wood-yard, and stored it with the wood of the famous royal-oak from the High Park, which, that nothing might be left with the name of king about it, they had dug up by the roots, and split and bundled up into faggots for their firing. Things being thus prepared, they sat on the 16th of the same month for the dispatch of business; and in the midst of their first debate there entered a large black dog (as they thought), which made a dreadful howling, overturned two or three of their chairs, and then crept under a bed and vanished. This gave them the greater surprise, as the doors were kept constantly locked, so that no real dog could get in or out. The next day their surprise was increased, when sitting at dinner in a lower room, they heard plainly the noise of persons walking over their heads, though they well knew the doors were all locked, and there could be no body there. Presently after they heard also all the wood of the king's oak brought by parcels from the dining-room, and thrown with great violence into the presence chamber; as also all the chairs, stools, tables, and other furniture, forcibly hurled about the room; their papers, containing the minutes of their transactions, were torn, and the ink-glass broken. When all this noise had ceased, Giles Sharp, their secretary, proposed to enter first into these rooms; and in presence of the commissioners, from whom he received the key, he opened the doors, and found the wood spread about the room, the chairs tossed about and broken, the papers torn, the ink-glass broken (as has been said), but not the least track of any human creature, nor the least reason to suspect one, as the doors were all fast, and the keys in the custody of the commissioners. It was therefore unanimously agreed, that the power who did this mischief must have entered the room at the key-hole. The night following, Sharp the secretary, with two of the commissioners servants, as they were in bed in the same room, which room was contiguous to that where the commissioners lay, had their bed's feet lifted up so much higher than their heads, that they expected to have their necks broken, and then they were let fall at once with so much violence as shook the whole house, and more than ever terrified the commissioners. On the night of the 19th, as all were in bed in the same room for greater safety, and lights burning by them, the candles in an instant went out with a sulphureous smell, and that moment many trenchers of wood were hurled about the room, which next morning were found to be the same their honours had eaten on the day before, which were all removed from the pantry, though not a lock was found opened in the whole house. The next night they still fared worse; the candles went out as before, the curtains of their honours' beds were rattled to and fro with great violence; their honours received many cruel blows and bruises, by eight great pewter-dishes and a number of wooden trenchers being thrown on their beds, which being heaved off, were heard rolling about the room, though in the morning none of these were to be seen. This night likewise they were alarmed with the tumbling down of oaken billets about their beds, and other frightful noises; but all was clear in the morning, as if no such thing happened. The next night the keeper of the king's house and his dog lay in the commissioners room, and then they had no disturbance. But on the night of the 22d, though the dog lay in the room as before, yet the candles went out, a number of brick-bats fell from the chimney into the room, the dog howled piteously, their bed clothes were all stripped off, and their terror increased. On the 24th they thought all the wood of the king's oak was violently thrown down by their bed-sides; they counted 64 billets that fell, and some hit and shook the beds in which they lay; but in the morning none were found there, nor had the door been opened where the billet wood was kept. The next night the candles were put out, the curtains rattled, and a dreadful crack like thunder was heard; and one of the servants running in haste, thinking his master was killed, found three dozen of trenchers laid smoothly under the quilt by him. But all this was nothing to what succeeded afterwards: The 29th,

29th, about midnight, the candles went out, something walked majestically through the room, and opened and shut the windows; great stones were thrown violently into the room, some of which fell on the beds, others on the floor; and at about a quarter after one a noise was heard as of forty cannon discharged together, and again repeated at about eight minutes distance. This alarmed and raised all the neighbourhood, who coming into their honours' room, gathered up the great stones, fourscore in number, and laid them by in the corner of a field, where, in Dr Plot's time, who reports this story, they were to be seen. This noise, like the discharge of cannon, was heard through all the country for 16 miles round. During these noises, which were heard in both rooms together, the commissioners and their servants gave one another over for lost, and cried out for help; and Giles Sharp, snatching up a sword, had well nigh killed one of their honours, mistaking him for the spirit, as he came in his shirt from his own room to theirs. While they were together, the noise was continued, and part of the tiling of the house was stript off, and all the windows of an upper room were taken away with it. On the 30th at midnight something walked into the chamber treading like a bear; it walked many times about, then threw the warming-pan violently on the floor; at the same time a large quantity of broken glass, accompanied with great stones and horses' bones, came pouring into the room with uncommon force. These were all found in the morning to the astonishment and terror of the commissioners, who were yet determined to go on with their business. But on the first of November the most dreadful scene of all ensued: Candles in every part of the room were lighted up, and a great fire made; at midnight, the candles all yet burning, a noise like the bursting of a cannon was heard in the room, and the burning billets were tossed about by it even into their honours' beds; who called Giles and his companions to their relief, otherwise the house had been burnt to the gound; about an hour after the candles went out as usual, the crack as if many cannon was heard, and many pailfuls of green stinking water were thrown upon their honours' beds; great stones were also thrown in as before, the bed curtains and bedsteads torn and broken, the windows shattered, and the whole neighbourhood alarmed with the most dreadful noises; nay, the very rabbit-stealers that were abroad that night in the warren were so terrified, that they fled for fear and left their ferrets behind them. One of their honours this night spoke, and, *in the name of God, asked what it was, and why it disturbed them so?* No answer was given to this; but the noise ceased for a while, when the spirit came again; and, as they all agreed, *brought with it seven devils worse than itself.* One of the servants now lighted a large candle, and set it in the door-way between the two chambers, to see what passed; and as he watched it, he plainly saw a hoof striking the candle and candlestick into the middle of the room, and afterwards making three scrapes over the snuff, scraped it out. Upon this the same person was so bold as to draw a sword; but he had scarce got it out when he felt another invisible hand holding it too, and pulling it from him; and at length prevailing, struck him so violently on the head with the pummel, that he fell down for dead with the blow. At this instant was heard another burst like the discharge of the broadside of a ship of war, and at about a minute or two's distance each no less than 19 more such: these shook the house so violently, that they expected every moment it would fall upon their heads. The neighbours, on this, as has been said, being all alarmed, flocked to the house in great numbers, and all joined in prayer and psalm-singing; during which the noise still continued in the other rooms, and the discharge of cannons was heard as from without, though no visible agent was seen to discharge them. But what was the most alarming of all, and put an end to their proceedings effectually, happened the next day as they were all at dinner, when a paper, in which they had signed a mutual agreement to reserve a part of the premises out of the general survey, and afterwards to share it equally amongst themselves, (which paper they had hid for the present under the earth in a pot in one corner of the room, and in which an orange-tree grew), was consumed in a wonderful manner, by the earth's taking fire with which the pot was filled, and burning violently with a blue fume, and an intolerable stench; so that they were all driven out of the house, to which they could never be again prevailed upon to return.

This wonderful contrivance was all the invention of the memorable Joseph Collins of Oxford, otherwise called *Funny Joe*, who having hired himself as secretary, under the name of *Giles Sharp*, by knowing the private traps belonging to the house, and the help of *pulvis fulminans* and other chemical preparations, and letting his fellow-servants into the scheme, carried on the deceit without discovery to the very last; insomuch that the late Dr Plot, in his Natural History, relates the whole for fact, and concludes in this grave manner, "That though tricks have been often played in affairs of this kind, many of the things above related are not reconcileable with juggling; such as the loud noises, beyond the power of man to make without such instruments as were not there; the tearing and breaking the beds; the throwing about the fire; the hoof treading out the candle; and the striving for the sword, and the blow the man received from the pummel of it."

SPECULARIS LAPIS, in natural history, a genus of talcs, composed of large plates visibly separate, and of extreme thinness; and each fissile again separated into a number of plates still finer. (See TALC.) Of this genus there are three species: 1. The white shining specularis, with large and broad leaves, commonly called *isinglass and Muscovy glass*; its lamellæ, or leaves, are extremely thin, elastic, and transparent; it makes not the least effervescence with aquafortis, and is not easily calcined in the fire. It is imported in great quantities; the miniature-painters cover their pictures with it; the lantern-makers sometimes use it instead of horn; and minute objects are usually preserved between two plates of it, for examination by the microscope. 2. The bright brown specularis, with broad leaves; a very valuable species, though inferior to the former. 3. The purple bright specularis, with broad leaves, which is the most elegant of all the talcs, and not less beautifully transparent than the first kind.

SPECULATIVE, something relating to the theory of some art or science, in contradistinction to practical.

SPECULUM for reflecting telescopes, is made of a kind of white copper consisting of 32 parts fine-

red

Speculum ‖ Speed.

red copper, 1 of brass, 15 of grain-tin, and 3 of white arsenic. The process given by the late J. Edwards, who was rewarded by the Board of Longitude for disclosing it to the public, was published in the Nautical Almanack for 1787, and is as follows: Melt the copper in a large crucible, employing some black flux, composed of two parts of tartar and one of nitre; when melted, add to it the brass and the silver. Let the pure tin be melted in another crucible, also with some black flux. Take them both from the fire, and pour the melted tin into the fused mass in the large crucible. Stir the whole well with a dry spatula of birch, and pour off the fused metal immediately into a large quantity of cold water. The sudden chill of the water will cause the fluid metal to divide into an infinite number of small particles, which will cool instantly.

Cronstedt's Mineralogy, vol. ii. p. 712.

2. If the copper be completely saturated, the fracture of one piece of this mixed metal will appear bright, and of a glossy look, resembling the face of pure quicksilver. But if it is of a brown reddish colour, it wants a little more tin. To ascertain the required proportion, melt a small quantity, known by weight, of the mixed metal, with a known very small part of tin; and, if necessary, repeat the trial with different doses, till the fracture of the new mixture looks as already described. Having now ascertained the necessary addition of tin that is required, proceed to the last melting of the whole metal, together with the additional proportional dose of tin; fuse the whole, observing the same cautions as before; and you will find that the mixture will melt with a much less heat than that for the first fusion. Have ready as many ounces of white arsenic in coarse powder as there are pounds in the weight of the metal; wrap up the arsenic in a small paper, and put it, with a pair of tongs, into the crucible; stir it well with the spatula, retaining the breath to avoid the arsenical fumes or vapours (which however are not found to be hurtful to the lungs) till they disappear; take the crucible off the fire, clear away the dross from the top of the metal, pour in about one ounce of powdered rosin, with as much nitre, in order to give the metal a clean surface, and pour out the metal into the moulded flasks.

3. The speculum should be moulded with the concave surface downwards, and many small holes should be made through the sand upwards, to discharge the air. The moulding sand from Highgate near London, used by the founders, is as good as any for casting these metallic mirrors. The cast metal should be taken out from the sand of the flasks whilst it is hot, or else it may happen to crack if left to cool within. See Telescope.

Speculum, a looking glass or mirror, capable of reflecting the rays of the sun.

Speculum, in surgery, an instrument for dilating a wound, or the like, in order to examine it attentively. See Surgery.

SPEECH, in general, the art or act of expressing a person's thoughts by means of articulate sounds, which we call words. See Language, Grammar, Reading, and Oratory, part iv.

SPEED (John), an eminent English historian, was born at Farington, in Cheshire, in 1542. He was by profession a taylor, and freeman of the company of merchant-taylors in the city of London. In 1606, he published his Theatre of Great Britain, which was afterwards reprinted in folio, under the title of the *Theatre of the Empire of Great Britaine.* His Genealogies of Scripture were first bound up with the Bible in 1611, when the first edition of the present translation was printed. In 1614 appeared his *History of Great Britaine*, which has been translated into Latin; and in 1616 he published his *Cloud of Witnesses*, in octavo. He lived in marriage 57 years with his wife, by whom he had twelve sons and six daughters; and died in 1629. He was interred in the church of St. Giles's, Cripplegate, London, where a monument was erected to his memory.

Speedwell ‖ Spelling.

SPEEDWELL, in botany. See Veronica.

SPELL, a charm consisting of some words of occult power, generally attended with some ceremony.— In order to explain it, we will produce a few examples. On St Agnes's night, 21st of January, take a row of pins, and pull out every one, one after another, saying a Pater-noster on sticking a pin in your sleeve, and you will dream of him or her you shall marry.

Another method to see a future spouse in a dream. The party inquiring must lie in a different county from that in which he commonly resides, and on going to bed must knit the left garter about the right-legged stocking, letting the other garter and stocking alone; and as he rehearses the following verses, at every comma knit a knot:

Grose's Provincial Glossary.

This knot I knit,
To know the thing I know not yet;
That I may see
The man (woman) that shall my husband (wife) be;
How he goes, and what he wears,
And what he does all days and years.

Accordingly, in a dream, he will appear with the insignia of his trade or profession.

Another, performed by charming the moon, thus: At the first appearance of the new moon, immediately after the new year's day, (though some say any other new moon is as good), go out in the evening, and stand over the spars of a gate or stile, and, looking on the moon, repeat the following lines:

All hail to the moon! all hail to thee!
I prithee, good moon, reveal to me
This night who my husband (wife) must be.

Immediately after you must go to bed, when you will dream of the person destined for your future husband or or wife.

SPELLING, in grammar, that part of orthography which teaches the true manner of resolving words into their syllables.

All words are either simple or compound, as *use, disuse; done, undone;* and the rules for dividing each must be such as are derived from the analogy of language in general, or from the established custom of speaking; which, for the English language, are reduced to the following rules: 1. A consonant between two vowels must be joined with the latter in spelling, as *na-ture, ve-ri-ly, ge-ne-rous;* except, however, the letter *x*, which is joined to the first, as in *flax-en, ox-en*, &c. and compound words, as in *up on, un-used*, &c. 2. A double consonant must be divided, as in *let-ter, man-ner*, &c. 3. Those consonants which can begin a word must not be parted in spelling, as in *de-fraud,* *re-prove, di-stinct*; however, this rule is found sometimes to fail; for though *gn* begins a word, as *gnaw*, *gnat*, &c. yet it must be divided in spelling, as in *cog-ni-zance*, *ma-lig-ni-ty*, &c. 4. Those consonants which cannot begin a word must be divided, as *ld* in *seldom*, *lt* in *mul-ti-tude*, *mp* in *tem-per*, *rd* in *ar-dent*; but in final syllables there are exceptions, as *tl* in *ti-tle*, *dl* in *han-dle*, &c. 5. When two vowels come together, and are both of them distinctly sounded, they must be separated in spelling, as in *co-e-val*, *mu-tu-al*, &c. 6. The grammatical terminations or endings must be separated in spelling, as *ed* in *wing-ed*, *edst* in *de-li-ver-edst*, *ing* in *hear-ing*, *ance* in *de-li-ver-ance*, &c. 7. Compound words must be resolved into their simple or component words, as *up-on*, *in-to*, *ne-ver-the-less*, *not-with-stand-ing*, &c.

SPELMAN (Sir Henry), an eminent English antiquarian, was descended from an ancient family, and born at Cengham, near Lynn in Norfolk, about the year 1561. He was knighted by king James I. who had a particular esteem for him on account of his known capacity for business; and he employed him several times in Ireland on public affairs. When he was about 50 years of age, he went to reside in London; where falling into a study to which his own genius had always inclined him, he collected all such books and MSS. as concerned the subject of antiquities, either foreign or domestic. In 1626, he published the first part of his well-known Glossary, which he never carried beyond the letter L; because, as some have suggested, he had said things under "Magna charta," and "Maximum consilium," that could not then have appeared without giving offence. Upon his death all his papers came into the hands of his son Sir John Spelman, a gentleman who had abilities to have completed his father's design, if death had not prevented him. The second part was afterwards published by Sir William Dugdale; but with all the marks of a scanty unfinished performance. The next work he entered upon was an edition of the English Councils, of which he published the first volume about two years before his death, leaving the second volume, as well of this as of his Glossary, to be published by Sir William Dugdale. Sir Henry wrote several other things, all relating to ancient laws and customs, and died in 1641. His Posthumous Works were published in folio, 1698, under the inspection of Mr. Gibson, afterwards bishop of London.

SPELTER, in metallurgy, the same with ZINC.

SPENCE (Joseph), was fellow of New College, Oxford, where he took the degree of A. M. in 1727. About that time he became first known as an author, by an *Essay on Pope's Odyssey, in which some particular beauties and blemishes of that work are considered*; a work of great merit, and which for sound criticism and candid disquisition is almost without a parallel. He was elected professor of poetry by the university in 1728, and held that office ten years, which is as long as the statutes will allow. His History of Stephen Duck was first published in 1731; but it was afterwards much altered, and prefixed to an edition of Duck's poems.

About this time he travelled into Italy as tutor to the earl of Lincoln, afterwards duke of Newcastle.—In 1736 he republished Gorboduc, at Mr. Pope's desire, with a preface giving an account of the author, the earl of Dorset. He quitted his fellowship in 1742, upon being presented by the Society of New College to the rectory of Great Harwood in Buckinghamshire.—He never resided in his living; but paid it an annual visit, distributing large sums of money among the poor, and providing for many of their children. The same year he was made professor of modern history at Oxford. In 1747 he published *Polymetis*; or an inquiry concerning the agreement between the works of the Roman poets and the remains of ancient artists, being an attempt to illustrate them mutually from each other. This work was treated by Gray with a contempt which it did not deserve. He raises objections because the author did not illustrate his subject from Greek writers; that is, because he failed to execute what he never undertook. He was installed prebendary of the seventh stall at Durham the 24th May 1754. He published the same year, "An Account of the Life, Character, and Poems, of Mr Blacklock, student of philosophy at Edinburgh;" which was afterwards prefixed to his Poems. The prose pieces which he printed in the Museum he collected and published, together with some others, in a pamphlet called *Moralities*, by Sir Harry Beaumont. Under the same name he published "Crito, or a dialogue on beauty," and "A particular Account of the Emperor of China's Gardens near Pekin, in a letter from F. Attiret, a French missionary now employed by that Emperor to paint the apartments in those gardens, to his friend at Paris." Both these treatises are printed in Dodsley's fugitive pieces, as is also "A Letter from a Swiss Officer to his friend at Rome;" which Mr Spence first published in the Museum. In 1758 he published "A Parallel, in the Manner of Plutarch, between a most celebrated man of Florence and one scarce ever heard of in England." This was also inserted in the fugitive pieces. The same year he made a journey into Scotland, which he described in an affectionate letter to Mr Shenstone, published in Hall's Collection of Letters, 1778. In 1764 he was very well described by Mr James Ridley, in his admirable Tales of the Genii, under the name of *Phesoi Ecneps* (his name read backwards), dervise of the groves. A letter from Mr Spence to that ingenious moralist, under the same signature, is preserved in the 3d volume of "Letters of Eminent Persons." In 1768 he published "Remarks and Dissertations on Virgil, with some other classical observations, by the late Mr Holdsworth." On the 20th of August the same year he was unfortunately drowned in a canal in his garden at Byfleet in Surrey. He was found flat upon his face at the edge of the canal, where the water was so shallow as not even to cover his head. The accident, it was supposed, for he was quite alone, was owing to a fit.

The duke of Newcastle possesses some manuscript volumes of anecdotes collected by Mr Spence, from which Dr Johnson was permitted to insert many extracts in his Lives of the Poets.

SPENCER (Dr John), an eminent divine, was born in Kent in 1630, and educated at Cambridge. He was chosen fellow of his college, and took a doctor's degree in 1663. In 1667 he was chosen master of Corpus Christi College, and preferred to the deanery of Ely in 1677. He died on the 20th of May 1695. His works are, 1. The Righteous Ruler; a sermon on Proverbs xxix. 2. preached June 28. 1660. 2. A Discourse concerning Prodigies, wherein the vanity of presages by them is reprehended, and their true and proper ends asserted and vindicated.

vindicated. To this excellent work was afterwards added, A Difcourfe concerning vulgar prophecies, wherein the vanity of receiving them as the certain indications of any future event is expofed; and fome marks of diftinction between true and pretended prophets are laid down. 3. A Latin Differtation concerning Urim and Thummim. 4. His famous treatife *De legibus Hebræorum ritualibus et earum rationibus*. The intention of this book, as he informs us himfelf, was to vindicate the Deity from the imputation of acting from arbitrary and fantaftical motives. It has been highly and juftly efteemed both for the elegance of ftile and the uncommon erudition and found fenfe which it difplays. It has, however, (that part of it particularly which endeavours to deduce fome of the Jewifh ceremonies from the practices of their heathen neighbours), alarmed many perfons, as if fuch a doctrine, if it could be proved, would derogate from the Divine wifdom, and undermine revelation. But this is fo far from being the cafe, that Dr Spencer's attempt, whether fuccefsful or not, deferves the gratitude of Chriftians, becaufe it has a tendency to throw light on an important and difficult fubject.

SPENSER (Edmund), the poet, was born in London in the year 1553, and defcended from an ancient family of the Spenfers in Northamptonfhire. All we know concerning his education is, that he was admitted a fizer of Pembroke-hall in Cambridge, and matriculated in 1569. At this time began his intimacy with Mr Gabriel Harvey, a man of genius and a poet. In 1576, having completed his degrees in arts, he left the univerfity, as it is conjectured, for want of fubfiftence, and retired to the north of England. Here he had the misfortune to become enamoured of his Rofalind, who, after flattering his paffion for a time, at length preferred his happier rival. Spenfer continued in the country till the year 1578, when at the perfuafion of his friend Mr Harvey he removed to London, where that gentleman introduced him to Mr Sidney (afterwards Sir Philip Sidney). Concerning his firft introduction to Sir Philip, there is indeed a different ftory, which was firft told by the writer of his life, prefixed to his works in 1679, and tranfcribed by Hughes, Cibber, and feveral others; which, neverthelefs, is certainly not true. The purport of it is, that Spenfer, being unknown to this Mecænas of the age, went to Leicefter-houfe, and fent in the 9th canto of the firft book of the Fairy Queen; that, on reading part of it, Sir Philip ordered his fteward to give the bearer 50 l.; on reading a little farther 50 l. more; then 200 l. bidding him to make hafte and pay the money, left he fhould give the poet his whole eftate. The ftory tells prettily enough; but it is very certain, that the Fairy Queen was begun long after his acquaintance with Sir Philip. By this univerfal patron of genius, however, he was prefented to queen Elizabeth, who honoured him with the place of poet-laureat. About this time he finifhed his Shepherd's Calendar, which was firft printed in 1579; and in the following year, being recommended by his patron to the earl of Leicefter, he went to Ireland as fecretary to the lord Grey of Wilton, then appointed lord-lieutenant of that kingdom. Lord Grey was recalled in 1582, and with him Spenfer returned to London, where he continued till after the death of Sir Philip Sidney in 1586; a lofs which he bewailed to the end of his life. The following year, our poet, having obtained a royal grant of 3000 acres of forfeited lands in the county of Cork in Ireland, fet out for that kingdom, took poffeffion of his eftate, and fixed his refidence in the caftle of Kilcolman, which had belonged to the earl of Defmond. In this retirement he refumed his great work of the Fairy Queen; and continued in Ireland till, being vifited by his old friend Sir Walter Raleigh in 1589, he came over with him to England, but returned to Ireland the year following, where he fell in love with a country girl, and married her. Soon after his marriage, he paid another vifit to his native country, where we alfo find him in 1596. In the following year he returned once more to Kilcolman; but on the rebellion of Lord Tyrone, who ravaged the whole county of Cork, he was obliged to fly for fafety with his family to England, where, in the year 1599, he died in extreme poverty (A). He was buried in Weftminfter Abbey, according to his requeft, near Chaucer. A monument was erected to his memory by Ann countefs of Dorfet. We know but little of his character as a man; as a poet, confidering the age in which he lived, he deferves our utmoft veneration. He wrote various pieces befides thofe abovementioned. His whole works, with his life by Hughes, were publifhed in fix volumes 12mo, in 1715 and 1750.

SPERGULA, SPURREY, in botany: A genus of plants belonging to the clafs of *decandria*, and the order of *pentagynia*; and in the natural fyftem arranged under the 22d order, *caryophyllœæ*. The calyx is pentaphyllous; the petals five, and undivided; the capfule oval, unilocular, and containing five valves. There are five fpecies, the arvenfis, nodofa, pentandra, laricina, and faginoides; all of which are Britifh: 1. The *arvenfis*, corn-fpurrey, has linear furrowed leaves, from eight to twenty in a whirl. The flowers are fmall, white, and terminal. It is frequent in corn-fields. In Holland it is cultivated as food for cattle, and has the advantage of growing on the very pooreft foils; but does not afford a great deal of food. Poultry are fond of the feeds; and the inhabitants of Finland and Norway make bread of them when their crops of corn fail. Horfes, fheep, goats, and fwine, eat it. Cows refufe it.

2. The *nodofa*, knotted fpurrey. Several ftalks arife from one root, fometimes reclining and fometimes erect, and from three to five inches high. The leaves are fmoth, of a fine green, narrow, pointed, and oppofite. The flowers are white, terminal, with yellow antheræ.

3. *Pentandra*, fmall fpurrey. The leaves are very narrow, and grow in whirls at the joints. The feeds are black with a white circle. It flowers in July.

4. *Laricina*, larch-leaved fpurrey. Several ftalks arife

(A) This is Camden's account, and it has been generally believed; but Mr Malone, the laft editor of Shakefpeare's works, by examining the patent roll, 33 Eliz. p. 3. has difcovered, that in February 1790 1 Spenfer obtained from Queen Elizabeth an annuity or penfion of L. 50 during his life; a fum equivalent to L. 200 at prefent.

arise from one root, from an inch to an inch and a half high; the leaves are linear, subulate, and acuminated, somewhat hairy on the edges, and their points turned to one side of the stalk. The petals are white and about the length of the calyx. Lightfoot found this species on a hill in the isle of Bute. He is doubtful whether the *sagina procumbens*, var. β of Linnæus, be not the same plant with this. It flowers in July.

5. *Saginoides*, pearlwort spurrey, has smooth, linear, opposite leaves: the peduncles are solitary and very long. Aiton says it is a native of England, and flowers from June to August.

SPERM, the seed whereof an animal is formed. See PHYSIOLOGY.

SPERMACETI, a whitish, unctuous, flaky substance, prepared from oil, but chiefly from the brains of a species of whale called *physeter macrocephalus*.

The method of preparing spermaceti is kept a secret; but the process is said to be this: The brains being taken out of the animal, are then, as some say, melted over a gentle fire, poured into moulds, and when cold melted again; and this process is continued till they are purified. Others say, that after being pressed and drained they are more thoroughly purified by steeping them in a ley of alkaline salt and quicklime. The brains are then washed, and cut into thin flakes or slices with wooden knives. One fish is said to afford some tons of brains. Good spermaceti is glossy and semitransparent, in fine white flakes; soft and unctuous to the touch, yet dry and friable; in taste, somewhat like butter, and of a faint smell like that of tallow. Some adulterate it with wax; but the deceit is discovered, either by the smell of the wax or by the dulness of the colour. Some also sell a preparation of oil taken from the tail of the whale instead of that from the brain; but this kind turns yellow as soon as exposed to the air. Indeed it is apt in general to grow yellowish, and to contract a rancid fishy smell if not carefully secured from the air. The more perfectly it has been purified at first, the less susceptible it is of these alterations; and after it has been changed, it may be rendered white and sweet again by steeping it afresh in a ley of alkaline salt and quicklime. It melts in a small degree of heat, and congeals again as it cools.

Spermaceti is of use in medicine. Quincy says it is a noble remedy in the asthma, &c. though chiefly used in bruises, inward hurts, and after delivery. For internal use, it may be dissolved in aqueous liquors into the form of an emulsion, by trituration with almonds, the yolk or white of an egg, and more elegantly by mucilages; or made into a lohoch, by mixing two drams of it with a suitable quantity of yolk of egg, then adding half an ounce of fresh drawn oil of almonds, and an ounce of balsamic syrup. Spermaceti is not capable of being dissolved by caustic alkalis, and of forming soaps, like other oily matters: but it is altogether soluble in oils, and unites by liquefaction with wax and resins; and in these forms is applied externally. But it is certain, its greatest property, and that which makes it so much in vogue in many places, is its softening the skin. Whence it comes to be used by the ladies in pastes, washes, &c.

Spermaceti candles are of modern manufacture: they are made smooth, with a fine gloss, free from rings and scars, superior to the finest wax-candles in colour and lustre; and, when genuine, leave no spot or stain on the finest silk, cloth, or linen.

A method has been lately proposed by Mr Smith Gibbes of Magdalen college, Oxford, to convert animal muscle into a substance much resembling spermaceti. The process is remarkably simple: Nothing more is necessary than to take a dead carcase and expose it to a stream of running water: it will in a short time be changed to a mass of fatty matter. To remove the offensive smell, a quantity of nitrous acid may then be poured upon it, which uniting with the fetid matter, the fat is separated in a pure state. This acid indeed turns it yellow, but it may be rendered white and pure by the action of the oxygenated muriatic acid. Mr Gibbes brought about the same change in a much shorter time. He took three lean pieces of mutton and poured on them the three mineral acids, and he perceived that at the end of three days each was much altered; that in the nitrous acid was much softened, and on separating the acid from it, he found it to be exactly the same with that which he had before got from the water; that in the muriatic acid was not in that time so much altered; the vitriolic acid had turned the other black.

Phil. Trans. 1794.

SPERMACOCE, BUTTON-WOOD, in botany: A genus of plants belonging to the class of *tetrandria*, and order of *monogynia*; and in the natural system arranged under the 47th order, *stellatæ*. The corolla is monopetalous and funnel-shaped, and there are two bidentate seeds. The species are eight, tenuior, verticillata, hirta, articularis, stricta, hispida, procumbens, and spinosa.

SPERMATIC, in anatomy, something belonging to the sperm or seed.

SPEUSIPPUS, an Athenian philosopher, the nephew and successor of Plato. Contrary to the practice of Plato, Speusippus required from his pupils a stated gratuity. He placed statues of the graces in the school which Plato had built. On account of his infirm state of health, he was commonly carried to and from the academy in a vehicle. On his way thither he one day met Diogenes, and saluted him; the surly philosopher refused to return the salute, and told him, that such a feeble wretch ought to be ashamed to live; to which Speusippus replied, that he lived not in his limbs, but in his mind. At length, being wholly incapacitated, by a paralytic stroke, for the duties of the chair, he resigned it to Xenocrates. He is said to have been of a violent temper, fond of pleasure, and exceedingly avaricious. Speusippus wrote many philosophical works, which are now lost, but which Aristotle thought sufficiently valuable to purchase at the expence of three talents. From the few fragments which remain of his philosophy, it appears that he adhered very strictly to the doctrine of his master.

SPEY, a river of Scotland, rising from a lake of the same name in Badenoch, and, after a serpentine course of 76 miles, passes by Rothes castle, and falls into the German sea at Garnoch near Elgin. Mr Pennant tells us, that the Spey is a dangerous neighbour to Castle Gordon, overflowing frequently in a dreadful manner, as appears by its ravages far beyond its banks. The bed of the river is wide and full of gravel, and the channel very shifting. In 1746 the duke of Cumberland passed this river at Belly church, near Castle Gordon, when the channel was so deep as to take an officer, from whom

whom Mr Pennant had the account, and who was six feet four inches high, up to the breast. The banks are here very high and steep; so that had not the rebels been infatuated in such a manner as to neglect opposition, the passage must have been attended with considerable loss. On this river there is a great salmon-fishery; about 1700 barrels full are caught in the season, and the shore is rented for about 1200 l. *per annum*

SPHACELUS, in surgery and medicine, an absolute and perfect corruption or death of the parts.

SPHÆRANTHUS, in botany: A genus of plants belong to the class of *syngenesia*, and to the order of *polygamia segregata*; and in the natural system arranged under the 49th order, *Compositæ*. Each partial calyx contains eight florets; the florets are tubulated, the female being scarcely distinguishable. The receptacle is scaly; and thereis no pappus. The species are three, the indicus, africanus, and chinensis.

SPHAGNUM, BOG-MOSS, in botany; a genus of plants belonging to the class of *cryptogamia* and order of *musci*. The antheræ are globose; the mouth entire and closed by an operculum; the calyptra is wanting. There are three species, the palustre, alpinum, and arboreum, 1. The *palustre*, common bog-moss, grows on bogs in wide patches, so as frequently to cover a large portion of their surface. The stalks are from two inches to two feet long, irregularly surrounded with numerous, conical, pendant branches, and terminated with a rosaceous cluster of erect short ones. It is generally believed, that the roots and decayed stalks of this moss constitute a principal part of that useful bituminous substance called *peat*, which is the chief fuel of the northern reigions.—The Lapland matrons are well acquainted with moss. They dry and lay it in their cradle, to supply the place of bed, bolster, and every covering; and, being changed night and morning, it keeps the infant remarkably clean, dry, and warm. It is sufficiently soft of itself; but the tender mother, not satisfied with this, frequently covers the moss with the downy hairs of the rein-deer; and by that means makes a most delicate nest for the young babe. 2. The *alpinum*, green bog-moss. Its branches are subulate and erect; the antheræ are oval. It grows in mountain bogs in South Britain. 3. The *arboreum*, creeping bog-moss, is branched; the antheræ are numerous, sessile, hairy, and grow along the branches chiefly on one side. It is found on the trunks of trees.

Os SPHENOIDES, the seventh bone of the cranium or skull. See ANATOMY, n° 11.

SPHERE, is a solid contained under one uniform round surface, every point of which is equally distant from a certain point in the middle called its *centre*; and is formed by the revolution of a semicircle about its diameter. See GEOMETRY.

Projection of the SPHERE. See PROJECTION.

SPHERE, in astronomy, that concave orb or expanse which invests our globe, and in which the heavenly bodies appear to be fixed, and at an equal distance from the eye.

The better to determine the places of the heavenly bodies in the sphere, several circles are supposed to be described on the surface thereof, hence called the *circles of the sphere*: of these some are called *great circles*, as the equinoctial, ecliptic, meridian, &c. and others *small circles*, as the tropics, parallels, &c. See GEOGRAPHY, and ASTRONOMY, *passim*.

Armillary SPHERE. See GEOGRAPHY.

SPHERE *of Activity of a Body*, is that determinate space or extent to which, and no farther, the effluvia continually emitted from that body reach; and where they operate according to their nature.

SPHERES, in optics, the same with metalline mirrors, for telescopes or other purposes. See MIRROR.

SPHEROID, in geometry, a solid approaching to the figure of a sphere. It is generated by the entire revolution of a semi-ellipsis about its axis. When the revolution is made round the largest axis, the spheroid is called *prolate*; and when round the shortest, *oblate*. This last is the figure of the earth, and probably of all the planets.

SPHEX, ICHNEUMON WASP, or *Savage*; a genus of insects belonging to the order of *hymenopteræ*. The mouth is armed with entire jaws, but contains no tongue; the mandibles are horny, crooked, dentated; the lip horny, the apex membranaceous. The palpi or feelers are four. The antennæ have from 10 to 16 joints. The wings of both sexes are extended without folds, and laid horizontally on the back. The sting is sharp, and concealed within the abdomen. There are 97 species, of which two only are natives of Britain and Ireland, the viatica and cribraria. 1. The *viatica* is black: the antennæ are short and thick: the three first segments of the abdomen red-brown; the pedicle is short: the length half an inch. 2. The *cribraria* is black, with yellow ringlets on the abdomen: the antennæ are short, and turned backwards: the fore-legs are broad, with, an appendix like a shield.

The manner of living is different in the various species, and so is the general form of the body and their haunts; but though the method of life be utterly different, yet the same manners appear innate and inherent in all. They agree in being the fiercest of all flies: they will attack insects much larger than themselves, and this whether they be defenceless or armed, as they are provided with a sting. The strength in all this savage kind is great; their jaws are hard and sharp, and in their sting lies a poison suddenly fatal to the creatures with whom they engage. The savage seizes hardily on the animal he attacks, and gives a stroke of amazing force; after which he falls down as if himself were killed, but it is to rest from his fatigue, and enjoy his victory. He keeps a steady eye on the creature he has struck till it dies, which happens in a few minutes, and then drags it to the nest to feed the young. The number of other insects they destroy is scarce to be conceived; the mouth of their cave is like that of a giant in the days of yore, strewed with the remains of prey. The eyes, the filament that serves as a brain, and a small part of the contents of the body, are all the savage eats, and he will kill 50 for a meal.

SPHINCTER, in anatomy, a term applied to a kind of circular muscles, or muscles in form of rings, which serve to close and draw up several orifices of the body, and prevent the excretion of the contents.

SPHINX (fab. hist.), a monster which had the head and breasts of a woman, the body of a dog, the tail of a serpent, the wings of a bird, the paws of a lion, and an human voice. It sprang from the union of Orthos with the Chimæra, or of Typhon with Echidna. The Sphinx had been ſent into the neighbourhood of Thebes by Juno, who wiſhed to puniſh the family of Cadmus, which ſhe perſecuted with immortal hatred, and it laid this part of Bœotia under continual alarms, by propoſing enigmas, and devouring the inhabitants if unable to explain them. In the midſt of their conſternation the Thebans were told by the oracle, that the ſphinx would deſtroy herſelf as ſoon as one of the enigmas ſhe propoſed was explained. In this enigma ſhe wiſhed to know what animal walked on four legs in the morning, two at noon, and three in the evening. Upon this Creon king of Thebes promiſed his crown and his ſiſter Jocaſta in marriage to him who could deliver his country from the monſter by a ſucceſsful explanation of the enigma. It was at laſt happily explained by Œdipus, who obſerved, that man walked on his hands and feet when young, or in the morning of life, at the noon of life he walked erect, and in the evening of his days he ſupported his infirmities upon a ſtick. (*Vid. Oedipus.*) The ſphinx no ſooner heard this explanation than ſhe daſhed her head againſt a rock, and immediately expired. Some mythologiſts wiſh to unriddle the fabulous traditions about the ſphinx by the ſuppoſition that one of the daughters of Cadmus, or Laius, infeſted the country of Thebes by her continual depredations, becauſe ſhe had been refuſed a part of her father's poſſeſſions. The lion's paw expreſſed, as they obſerve, her cruelty, the body of the dog her laſciviouſneſs, her enigmas the ſnares ſhe laid for ſtrangers and travellers, and her wings the diſpatch ſhe uſed in her expeditions.

Lempriere's Bibliotheca Claſſica.

Among the Egyptians the ſphinx was the ſymbol of religion, by reaſon of the obſcurity of its myſteries; and on the ſame account the Romans placed a ſphinx in the pronaos or porch of their temples. Sphinxes were uſed by the Egyptians to ſhow the beginning of the water's riſing in the Nile: with this view, as it had the head of a woman and body of a lion, it ſignified that the Nile began to ſwell in the months of July and Auguſt, when the ſun paſſes through the ſigns of Leo and Virgo. There are ſeveral of theſe ſtill to be ſeen; one in particular, near the pyramids, much ſpoken of by the ancients; being of a prodigious ſize, and cut out of the rock; the head and neck appear only at preſent, the reſt of the body being hid in the ſand. This, according to Thevenot, is 26 feet high, and 15 feet from the ear to the chin: but Pliny aſſures us, the head was no leſs than 102 feet in circumference, and 62 feet high from the belly, and that the body was 143 feet long, and was thought to be the ſepulchre of king Amaſis.

The learned Mr Bryant * obſerves, that the ſphinx ſeems to have been originally a vaſt rock of different ſtrata; which, from a ſhapeleſs maſs, the Egyptians faſhioned into an object of beauty and veneration. The Egyptians uſed this figure in their building; from them the Greeks derived it, and afterwards improved it into an elegant ornament. It is alſo frequently uſed in modern architecture.

* Ancient Mythology, vol. iii. p. 532.

It is proper to obſerve, that the ſphinx of the Egyptians is ſaid in the Aſiatic Reſearches † to have been found in India. Colonel Pearſe was told by Murari Pandit, a man of learning among the Hindoos, that the ſphinx there called *ſingh* is to appear at the end of the world, and as ſoon as he is born will prey on an elephant: he is therefore figured ſeizing an elephant in his claws; and the elephant is made ſmall, to ſhow that the *ſingh*, even a moment after his birth, will be very large in proportion to it. But in oppoſition to this account given by Murari Pandit, the late Sir William Jones, the learned and illuſtrious preſident of the Aſiatic Society, was aſſured by ſeveral Brahmans, that the figure taken for a ſphinx was a repreſentation of a lion ſeizing a young elephant. This point therefore requires farther inveſtigation.

† Vol. ii. p. 334.

Sphinx, *Hawk-Moth*, in natural hiſtory; a genus of inſects belonging to the order of *lepidopteræ*. The antennæ are ſhaped ſomewhat like a priſm, and are more ſlender at each end than at the middle. The tongue is generally thruſt out: the two palpi are bent back, and the wings deflexed. There are about 165 ſpecies already diſcovered, of which ten are found in Great Britain and Ireland.

1. The *ocellata*, eyed willow hawk-moth. There is no trunk; the wings are indented. Above, 1ſt wings dark and light-brown, marbled; 2d, red, with a large yellow-black eye. Beneath, a large red triangle from the baſe of the 1ſt wings. The breadth one inch and an half. Caterpillar ſmooth, green, and oblique white lines on the ſides, and a poſterior horn. The eggs are green. It lives on willows. 2. *Populi*, poplar-hawk-moth. The wings are ſcalloped, bluiſh grey, and waved with dark lines. On the firſt wings a long white ſpot, and the baſe of the 2d red-brown. Wings reverſed. Length one inch. A long ſpiral trunk caterpillar green, ſmooth, with oblique white ſpots, and a poſterior horn. It lives on poplars and willows. 3. *Tiliæ*, lime hawk-moth. No trunk: the wings are ſcalloped: the antennæ are white on the upper ſide, yellow on the under. Above, 1ſt wings grey-brown, with two irregular large green ſpots; 2d, wings orange. Beneath greeniſh grey. Caterpillar green, ſhagreened, with a poſterior horn. 4. *Convolvuli*, unicorn, or bindweed hawk-moth. The antennæ are long and thick: the trunk very long and ſpiral. Above, body marked with black and red belts; wings entire, brown-grey, with black zig-zag tranſverſe lines. The breadth three inches. Caterpillar ſmooth, green, with a poſterior horn. 5. *Liguſtri*, privet hawk-moth. The antennæ are long, thick, and brown. Trunk long, ſpiral. 1ſt wings two inches long, narrow, entire, brown; 2d, ſhort, red, with black bars. The abdomen is red, with black rings. Caterpillar ſmooth, yellow-green, with a poſterior horn. 6. *Atropos*, jeſſamine hawk-moth. The wings are entire: the trunk long, ſpiral. Above, 1ſt wings brown, clouded with grey and yellow, and a yellowiſh ſpot in the centre; 2d, yellow, with two waved tranſverſe ſtripes. The abdomen is yellow, with ſeven black-brown belts. The thorax marked like a Death's-head. Length two inches. Caterpillar very large, yellow, with ſix green and orange oblique belts, and a poſterior horn. 7. *Elpenor*, elephant-moth. The wings are angular, entire. Above, 1ſt wings ſtriped tranſverſely with red and green; 2d, black at the baſe, and red outwards. The body red and green. Caterpillar ſmooth brown and yellow, with a poſterior horn, and a ſnout like a hog. It lives on vines, convolvulus, &c. 8. *Stellatarum*, large bee moth. The antennæ are thick towards the ends, brown.

brown. The trunk is ſpiral: the wings are ſhort and entire: the body is thick, brown, and hairy. Firſt wings are brown, waved; 2d, red-brown. It reſembles a large bee. Caterpillar ſmooth, with a poſterior blue horn, tipt with red. It lives on gallium. 9. *Tipuliformis*, ſmall bee moth. The thorax is yellow beneath: the wings are ſhort, with black veins. The abdomen black, bearded, yellow at the extremity. Caterpillar on the lonicera. 10. *Filipendulæ*, burnet moth. The antennæ, legs, and body, are black. Second wings red, with a greeniſh border. Firſt wings bluiſh green, with ſix red ſpots, in pairs. Length eight lines. Caterpillar yellow, with black ſpots. It lives on graſs.

The name *ſphinx* is given to this genus on account of the ſingular attitudes of their caterpillars, who apply the hinder part of their body to a branch of a tree, holding the reſt of it erect, like the fabulous ſphinx. Moſt of them ſpin their cod under ground, making them up with ſmall parcels of earth and grains of corn interwoven with threads. The ſphinges fly either early in the morning, or after ſunſet in the evening. They fly heavily and ſluggiſhly, often emitting a kind of ſound.

SPIGELIA, Worm-grass, in botany: A genus of plants belonging to the claſs of *pentandria*, and order of *monogynia*; and in the natural ſyſtem arranged under the 47th order, *Stellatæ*. The corolla is funnel-ſhaped; the capſule is didymous, bilocular, and polyſpermous. There are two ſpecies, the anthelmia and marilandica.

The *anthelmia* has a herbaceous ſtem, and its higheſt leaves are fourfold.

"The effects of this medicine (ſays Dr Browne) are theſe: It firſt procures ſleep, almoſt as certainly, and in an equal degree, with opium; the eyes ſeem to be diſtended, and ſparkle as it were before the eruption of the ſmall-pox or meaſles, which may be eaſily obſerved after the ſleep is over; the pulſe grows regular and riſes, the fever cools, the ſymptoms appear more favourable, and the worms are generally diſcharged by the uſe of the ſubſequent purgatives (if not before) in great quantities, often above 100 at a time; but when a few only come away, which is ſeldom, and theſe alive, the ſame doſes are again repeated, which ſeldom or never fail. I never ſaw this medicine fail when there was the leaſt probability of ſucceſs; nay, often prove ſucceſsful when there was not the leaſt reaſon to expect it. I have been, however, cautious in ordering it for children; for though I never knew it at all hurtful, its effect upon the eyes has often deterred me from ordering it to children, whoſe fibres are weak and relaxed, and in whom the fevers from this ſource are ſeldom ſo vehement as to hinder the adminiſtration of other medicines, likely as effectual in other caſes of this nature. This plant is generally had in low dry lands, after they have been turned up ſome months, and after great rains; its taſte is herbaceous, and ſomewhat clammy, its growth is ſoft and ſudden, its ſtalk hollow, ſmooth, and roundiſh. Its herbaceous taſte and ſudden growth would alone make me think it capable of little or no action had not hundreds of careful obſervations ſatisfied me to the contrary."

The *marilandica*, perennial worm-graſs, or Indian pink. The beſt deſcription of this plant which we have ſeen is given by Dr Woodville, in his Medical Botany; a work which exhibits a complete ſyſtematic view of the medicinal effects of vegetables. Its ſtem is four-cornered; all the leaves oppoſite.

Dr Garden, in a letter to the late Dr Hope, profeſſor of botany in the univerſity of Edinburgh, dated 1763, gives the following account of the virtues of this plant. "About 40 years ago, the anthelmintic virtues of the root of this plant were diſcovered by the Indians; ſince which time it has been much uſed here by phyſicians, practitioners, and planters; yet its true doſe is not generally aſcertained. I have given it in hundreds of caſes, and have been very attentive to its effects. I never found it do much ſervice, except when it proved gently purgative. Its purgative quality naturally led me to give it in febrile diſeaſes, which ſeemed to ariſe from viſcidity in the *primæ viæ*; and, in theſe caſes, it ſucceeded to admiration, even when the ſick did not void worms.

"I have of late, previous to the uſe of the Indian pink, given a vomit, when the circumſtances of the caſe permitted it; and I have found this method anſwer ſo well, that I think a vomit ſhould never be omitted. I have known half a dram of this root purge as briſkly as the ſame quantity of rhubarb; at other times I have known it, though given in large quantities, produce no effect upon the belly: in ſuch caſes, it becomes neceſſary to add a grain or two of ſweet mercury, or ſome grains of rhubarb; but it is to be obſerved, that the ſame happy effects did not follow its uſe in this way, as when it was purgative without addition. The addition, however, of the purgative renders its uſe ſafe, and removes all danger of convulſions of the eyes although neither *ol. rutæ*, *ſabinæ*, or any other nervous ſubſtance, is given along with it. It is, in general, ſafer to give it in large doſes than in ſmall; for, from the latter, more frequently the giddineſs, dimneſs of the ſight, and convulſions, &c. follow; whereas, from large doſes, I have not known any other effect than its proving emetic or violently cathartic. To a child of two years of age, who had been taking 10 grains of the root twice a-day, without having any other effect than making her dull and giddy, I preſcribed 22 grains morning and evening, which purged her briſkly, and brought away five large worms. After ſome months an increaſed doſe had the ſame good effects. I prefer the root to the other parts of the plant; of which, when properly dried, I gave from 12 to 60 or 70 grains in ſubſtance. In infuſion, it may be given to the quantity of two, three, or four drams, twice a-day. I have found that, by keeping, the plant loſes its virtue in part; for 40 grains of the root which has not been gathered above two months, will operate as ſtrongly as 60 which has been kept for 15 months."

In Dr Garden's ſubſequent letters, addreſſed to Dr Hope, in the years 1764 and 1766, the efficacy of this root in worm caſes is further confirmed; and he obſerves, that the root keeps better than he at firſt thought (having lately uſed it ſeveral years old with great ſucceſs). In what he calls continued or remitting low worm fevers, he found its efficacy promoted by the addition of *rad. ſepentar virg.*

SPICE, any kind of aromatic drug that has hot and pungent qualities: ſuch are pepper, nutmeg, ginger, cinnamon, cloves, &c.

SPICE-*Islands*, in the East Indies. See BANDA, *Molucca-Islands*, and CEYLON.

SPIDER, in zoology. See ARANEA.

SPIDERWORT, in botany. See PHALANGIUM.

SPIGNEL, in botany. See ATHAMANTA.

SPIKE, or *Oil of Spike*, a name given to an essential oil distilled from lavender, and much used by the varnish-makers and the painters in enamel.

SPIKENARD, in botany. See NARDUS.

SPILANTHUS, in botany; a genus of plants belonging to the class of *syngenesia*, and to the order of *polygamia æqualis*. The common calyx is erect; the leaflets numerous, sub-equal, and oblong, the two exterior being longer than the rest. The compound corolla is uniform and tubular; the florets are hermaphrodite and equal; the proper corolla is funnel-shaped. The filaments are five in number, and short. The antheræ cylindrical and tubular. The seeds are vertical, oblong, flat, and covered with chaff. The receptacle is paleaceous and conical. There are seven species, the urens, pseudo-acmella, acmella, salivaria, atriplicifolia, insipida, and oleracea.

SPINA CERVINA, the same as the rhamnus catharticus. See RHAMNUS.

SPINA *Ventosa*, in surgery, that species of corruption of the bones which takes its rise in the internal parts, and by degrees enlarges the bone, and raises it into a tumor. See SURGERY.

SPINACIA, SPINAGE, in botany: A genus of plants belonging to the class of *diœcia*, and to the order of *pentandria;* and in the natural system arranged under the 12th order, *Holoraceæ*. The male calyx is quinquepartite; there is no corolla: the female calyx is quadrifid; no corolla; there are four styles, and one seed within the indurated calyx, There are only two species, the oleracea and fera. 1. The *oleracea*, common spinage, has sessile fruits and sagittated leaves. It has been cultivated in Britain since 1568, but it is not known from what country it was originally brought. When intended for winter use, it should be sown on an open spot of ground in the latter end of July; observing to do it if possible when the weather is rainy. When the young plants are come up, the weeds must be destroyed, and the plants left at about five inches asunder. The ground being kept clear of weeds, the spinage will be fit for use in October. The way of gathering it to advantage is only to take off the longest leaves, leaving those in the centre to grow bigger; and at this rate a bed of spinage will furnish the table for a whole winter, till the spinage sown in spring is become fit for use, which is common in April. 2. The *fera*, wild spinage, produces its fruit on footstalks.

SPINAGE, or SPINACH. See SPINACIA.

SPINÆ, in botany, thorns, rigid prickles: a species of *arma*, growing on various parts of certain plants for their defence; *spinæ ramorum arcent pecora*. On the branches we find examples in the pyrus, prunus, citrus, hippophaes, gmelina, rhamnus, lycium, &c.; on the leaves in the aloe, agave, yucca, ilex, hippomane, theophrasta, carlina, &c.; on the calyx, in the carduus, cnicus, centauria, moluccella, galeopsis, &c.; on the fruit, in the trapa, tribulus, murex, spinacia, agremonia, datura, &c.

SPINAL MARROW. See ANATOMY, Part V. n° 132.

SPINALIS, in anatomy, the name of several muscles, &c. of the spine.

SPINDLE-TREE, in botany. See EUONYMUS.

SPINE, SPINA DORSI. See ANATOMY, n° 30.

SPINE, in botany. See SPINÆ.

SPINELLO, a Tuscan painter, of great repute in his time. He painted a picture of the fallen angles, in which he drew so horrid a picture of Lucifer, that it frightened him so much as to affect his senses ever after. He flourished about the year 1380.

SPINET, or SPINNET, a musical instrument ranked in the second or third place among harmonious instruments. It consists of a chest or belly made of the most porous and resinous wood to be found, and a table of fir glued on slips of wood called *summers*, which bear on the sides. On the table is raised two little prominences, or bridges, wherein are placed so many pins as there are chords or strings to the instrument. It is played on by two ranges of continued keys, the former range being the order of the diatonic scale, and that behind the order of the artificial notes or semitones. The keys are so many flat pieces of wood, which, touched and pressed down at the end, make the other raise a jack which strike and sound the strings by means of the end of a crow's quill, wherewith it is armed. The 30 first strings are of brass, the other more delicate ones of steel or iron-wire; they are all stretched over the two bridges already mentioned. The figure of the spinet is a long square or parallelogram; some call it an *harp couched*, and the harp an *inverted spinet*. See the article HARP.

This instrument is generally tuned by the ear, which method of the practical musicians is founded on a supposition that the ear is a perfect judge of an octave and a fifth. The general rule is to begin at a certain note, as C, taken towards the middle of the instrument, and tuning all the octaves up and down, and also the fifths, reckoning seven semitones to each fifth, by which means the whole is tuned. Sometimes to the common or fundamental play of the spinet is added another similar one in unison, and a third in octave to the first, to make the harmony the fuller; they are either played separately or together by means of a stop: these are called *double* or *triple spinets;* sometimes a play of violins is added, by means of a bow, or a few wheels parallel to the keys, which press the strings and make the sound last as long as the musician pleases, and heighten and soften them more or less, as they are more or less pressed. The harpsichord is a kind of spinet, only with another disposition of the keys (see the article HARPSICHORD). The instrument takes its name from the small quill ends which touch the strings, resembling *spinæ* or thorns.

SPINIFEX, in botany; a genus of plants belonging to the class of *polygamia* and order of *monœcia*. The hermaphrodite flowers have a calyx with bivalved biflorous glumes, the valvelets being parallel to the rachis; the corolla is bivalved and awnless; there are three stamina and two styles. In the male flowers the calyx is common with the hermaphrodite; the corolla and stamina are similar. There is only one species, the squarrosus.

SPINNING, in commerce, the act or art of reducing silk, flax, hemp, wool, hair, or other matters, into thread. Spinning is either performed on the wheel, or with a distaff and spindle, or with other machines

proper

Mr. Antis's improved Spinning Wheel

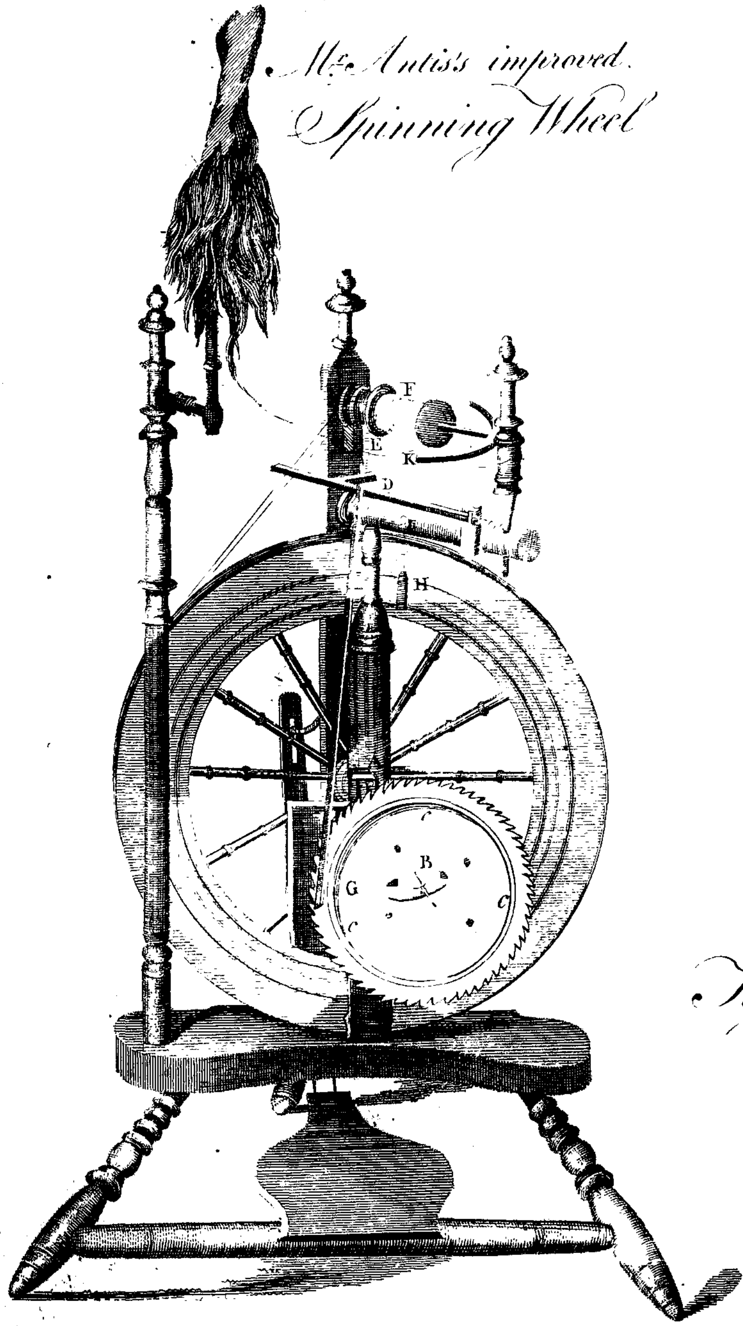

Fig. 1.

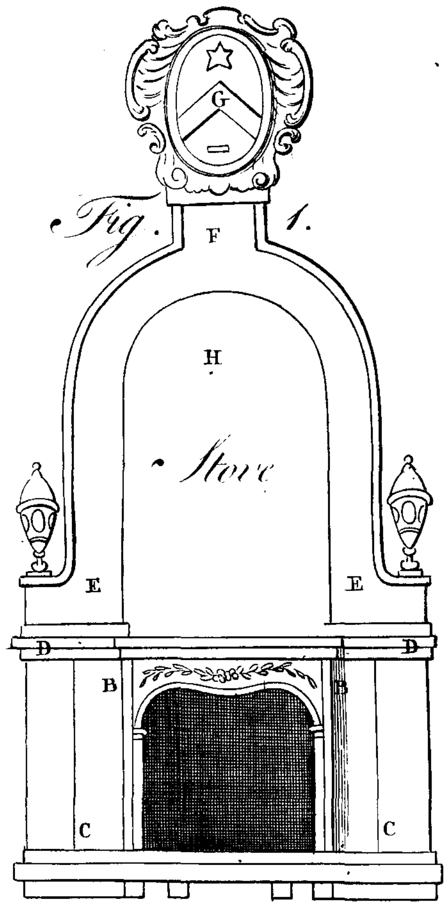

Fig. 2.

Vallance sc

proper for the feveral kinds of working. Hemp, flax, nettle-thread, and other like vegetable matters, are to be wetted in fpinning: filks, wools, &c. are fpun dry, and do not need water; yet there is a way of fpinning or reeling filk as it comes off the cafes or balls, where hot and even boiling water is to be ufed (fee SILK). The vaft variety, and the importance of thofe branches of the manufactures which are produced from cotton, wool, and flax, fpun into yarn, together with the cheapnefs of provifions, and the low price of labour in many foreign countries, which are rivals in trade, have occafioned many attempts in Britain to render fpinning more eafy, cheap, and expeditious. For which fee *COTTON Spinning* and *COTTON Mills*.

Tranf. of the Society for the encouragement of Arts, &c.

These contrivances have in fome parts of Scotland been applied to the fpinning of flax; but a very confiderable improvement has lately been made by Mr Antis of Fulneck near Leeds of the common fpinning wheel. It is well known, that hitherto much time has been loft by ftopping the wheel in order to fhift the thread from one ftaple on the flyer to another; but in Mr Antis's wheel the bobbin is made to move backwards and forwards fo as to prevent the neceffity of this perpetual interruption, as well as to obviate the danger of breaking the thread and lofing the end. This is effected by the axis of the great wheel being extended through the pillar next the fpinner, and formed into a pinion of one leaf A, which takes into a wheel B, feven inches diameter, having on its periphery 97 teeth; fo that 97 revolutions of the great wheel caufes one of the leffer wheel. On this leffer wheel is fixed a ring of wire *c c c*; which, being fupported on fix legs, ftands obliquely to the wheel itfelf, touching it at one part, and projecting nearly three quarters of an inch at the oppofite one: near the fide of this wheel is an upright lever C, about 15 inches long, moving on a centre, three inches from its lower extremity, and connected at the top to a fliding bar D; from which rifes an upright piece of brafs E, which working in the notch of a pulley drives the bobbin F backward and forward, according as the oblique wire forces a pin G in or out, as the wheel moves round. To regulate and affift the alternate motion, a weight H hangs by a line to the fliding bar, and paffing over a pulley I rifes and falls as the bobbin advances or recedes, and tends conftantly to keep the pin in contact with the wire. It is evident, from this defcription, that one ftaple only is wanted to the flyer; which, being placed near the extremity K, the thread paffing through it is by the motion of the bobbin laid regularly thereon. For this invention the Society inftituted at London for the Encouragement of Arts, &c. gave the author a premium of twenty guineas.

Plate CCCCLXXIV.

SPINOSUS CAULIS, in botany; a ftem covered with ftrong woody prickles, whofe roots are not fuperficial, but proceeding from the body of the ftem. When applied to a leaf, *fpinofum folium*, it indicates the margin running out into rigid points or prickles *quod margine exit in acumina duriora, rigida pungentia*.

SPINOUS, in botany. See SPINOSUS.

SPINOUS Fifhes, fuch as have fome of the rays of the back fins running out into thorns or prickles, as the perch, &c.

SPINOZA (Benedict), was born at Amfterdam the 24th November 1632. His father was a Jew of Portugal, by profeffion a merchant. After being taught Latin by a phyfician, he applied himfelf for many years to the ftudy of theology, and afterwards devoted himfelf entirely to philofophy. He began very early to be diffatisfied with the Jewifh religion; and as his temper was open, he did not conceal his doubts from the fynagogue. The Jews, it is faid, offered to tolerate his infidelity, and even promifed him a penfion of a thoufand dollars *per annum*, if he would remain in their fociety, and continue outwardly to practife their ceremonies. But if this offer was really made, he rejected it, perhaps from his averfion to hypocrify, or rather becaufe he could not endure the reftraint which it would have impofed. He alfo refufed the legacy of a very confiderable fortune, to the prejudice of the natural heirs; and he learned the art of polifhing glafs for fpectacles, that he might fubfift independently of every one.

He would probably have continued in the fynagogue for fome time longer, if it had not been for an accident. As he was returning home one evening from the theatre, he was ftabbed by a Jew: the wound was flight; but the attempt naturally led Spinoza to conclude that the Jews had formed the defign of affaffinating him. After leaving the fynagogue, he became a Chriftian, and frequented the churches of the Lutherans and Calvinifts. He now devoted himfelf more than ever to his favourite philofophical fpeculations; and finding himfelf frequently interrupted by the vifits of his friends, he left Amfterdam, and fettled at the Hague, where he often continued for three months together without ever ftirring from his lodging. During his refidence in that city, his hoftefs, who was a Lutheran, afked him one day if fhe could be faved while fhe continued in her religion? "Yes (replied Spinoza), provided you join to your religion a peaceable and virtuous life." From this anfwer it has been concluded that he was a Chriftian in appearance only, while in reality he regarded all religions as indifferent. But this conclufion would be too fevere, even if the woman had been a Mahometan. His *Tractatus Theologico-politicus* which was publifhed about that time, is a better proof of his infincerity than a thoufand fuch conclufions; for this book contains all thofe doctrines in embryo which were afterwards unfolded in his *Opera Pofthuma*, and which are generally confidered as a fyftem of atheifm.

His fame, which had now fpread far and wide, obliged him fometimes to interrupt his philofophical reveries. Learned men vifited him from all quarters. While the prince of Condé commanded the French army in Utrecht, he intreated Spinoza to vifit him; and though he was abfent when the philofopher arrived, he returned immediately, and fpent a confiderable time with him in converfation. The elector Palatine offered to make Spinoza profeffor of philofophy at Heidelberg; which, however, he declined.

He died of a confumption at the Hague on the 21ft February 1677, at the age of 45. He life was a perpetual contradiction to his opinions. He was temperate, liberal, and remarkably difinterefted; he was fociable, affable, and friendly. His converfation was agreeable and inftructive, and never deviated from the ftricteft propriety.

The only edition of the works of Spinoza that we have feen is in two volumes fmall 4to; the former of which was printed at Hamburg in the year 1670, and the latter we know not where, in 1677, a few months after his death. In the *Tractatus Theologico-politicus*, already mentioned, he treats of *prophecy* and *prophets*; and of the *call of the Hebrews*, whom he affirms to have been distinguished from other nations only by the admirable form of their government, and the fitness of their laws for long preserving their political state. He is likewise of opinion, or at least pretends to be so, that God may, in what we call a *supernatural way*, have given political institutes to other nations as well as to the Hebrews, who were, he says, at no time a peculiar people to the Supreme Lord of heaven and earth; for, according to him, all history, sacred and profane, testifies that every nation was blessed with the light of prophecy. That light indeed, if his notions of it be just, was of very little value. He labours to prove, that the prophets were distinguished from other men only by their piety and virtue; that their revelations depended wholly on their imaginations and the dispositions of their minds; that they were often grossly ignorant and highly prejudiced; that the speculative opinions of one prophet are seldom in unison with those of another; and that their writings are valuable to us only for the excellent rules which he acknowledges they contain respecting the practice of piety and virtue. He then proceeds to treat of the divine law and of miracles; and endeavours to prove that no miracle, in the proper sense of the word, can have been at any time performed; because every thing happens by a necessity of nature, the result of the divine decrees, which are from all eternity necessary themselves. He acknowledges, that in the Scriptures, which he professes to admit as true history, miracles are often mentioned; but he says that they were only singular events which the sacred historians *imagined* to be miraculous: and he then gives some very extraordinary rules for interpreting the books of the Old and New Testaments where they treat of miracles, or appear to foretel future events. See our articles MIRACLE and PROPHECY.

Having thus divested the Scriptures of every thing characteristic of a revelation from heaven, he next calls in question their authenticity. He affirms, in contradiction to the clearest internal evidence, that the Pentateuch and all the other historical books must have been written by one man; and that man, he thinks, could not have flourished at a period earlier than that of Ezra. The grounds of this opinion are unworthy of the talents of Spinoza; for that he had talents is incontrovertible. His principal objection to the authenticity of the Pentateuch is, that Moses is made to speak of himself in the third person, and to talk of the Canaanites being then in the land; and because he finds in his writings, as well as in the books of Joshua, Judges, Ruth, Samuel, &c. places designed by names which he supposes they had not in the early ages of which these books contain the history, he concludes that these writings must be one compilation from ancient records made at a very late period; more especially as the author often speaks of things of great antiquity remaining to this day. The books of Esther, Ezra, Nehemiah and Chronicles, must have been compiled, he thinks, under the Maccabees; and he seems to consider as of equal value with them the story of Tobit, and the other two apocryphal treatises intitled the Wisdom of Solomon and Ecclesiasticus.

These senseless cavils, worthy only of one of those modern freethinkers whose learning, in the opinion of Bishop Warburton, is not sufficient to carry them even to the confines of rational doubt, we have sufficiently obviated in another place (see SCRIPTURE, n° 8—31.) Spinoza urges them against the other books of the Old Testament. The prophecies of Isaiah, Jeremiah, Ezekiel, Daniel, Hosea, and Jonah, are, as we have them, only fragments, he says, of the writings of those men compiled by the Pharisees under the second temple from ancient and voluminous records.

In the midst of this dogmatical scepticism, if we may use such a phrase, he bears such a testimony to the last chapters of the book of Daniel, as we should not have looked for in the writings either of a Jew or of a Deist. After detailing the various hypotheses which in his time were held respecting the author and the intention of the book of *Job*; in which, he says, MOMUS is called SATAN, he proceeds in these words: 'Transeo ad Danielis librum; hic sine dubio ex cap. 8. ipsius Danielis scripta continet. Undenam autem priora septem capita descripta fuerint, nescio*;" thus admitting the famous prophecy of the seventy weeks. The canon of the Old Testament, he says, was finally settled by rabbins of the Pharisaical sect, who wished to exclude from it the books of *Proverbs*, *Ecclesiastes*, and *Ezekiel*, as they had actually excluded others of equal value; but the three books in question were inserted by the influence of two of the rabbins of greater wisdom and integrity than the rest.

* Tractatus, cap. x. p. 130.

That so paradoxical a writer, who had been originally a Jew, and was now almost a Deist, should have treated the New Testament with as little ceremony as the Old, will not surprise the intelligent reader. He begins his remarks, however, with affirming, that no man can peruse the Christian Scriptures, and not acknowledge the apostles to have been prophets; but he thinks that their mode of prophesying was altogether different from that which prevailed under the Mosaic dispensation; and that the gift, whatever it was, forsook them the instant that they left off *preaching*, as their *writings* have to him every appearance of human compositions. This distinction between Christian and Jewish prophecy is the more wonderful, that he founds it principally on the dissimilarity of *style* visible in the writings of the Old and New Testaments; though, in his second chapter, which treats of the works of the Jewish prophets, he says expressly, "Stylus deinde prophetiæ pro eloquentia cujusque prophetæ variabat, prophetiæ enim Ezekielis et Amosis non sunt, ut illæ Esaiæ, Nachumi, eleganti, sed rudiore stylo scriptæ." That the Hebrew scholar may be convinced of the truth of this remark he recommends to him to study diligently the writings of these prophets, and to consider the occasions on which their prophecies were uttered: "Quæ si omnia recte perpendentur (says he) facile ostendant, Deum nullum habere stylum peculiarem dicendi, sed tantum pro eruditione, et capacitate prophetæ datenus esse elegantem, compendiosum, severum, rudem, prolixum, et obscurum." Another objection brought by Spinoza against the prophecies of the New Testament arises from the authors of them having been at at all times masters of themselves. This, says he, was peculiarly the case of St Paul, who often confirms his doctrine by *reasoning*, which the Jewish prophets never condescended to do, as it would have submitted their dogmas to the examination of *private judgment*. Yet, with singular inconsistency, he affirms, that the Jewish prophets could not know that the impressions made on their imaginations proceeded from God, but by a sign given them, which by their own *reason* or *judgment* they knew would never be vouchsafed to an impious or a wicked man.

After these very free remarks on the Scriptures of the Old and New Testaments, he naturally enough expresses a suspicion, that by those who consider the Bible as the epistle of God sent from heaven to men, he will be thought to have sinned against the Holy Ghost by vilifying his dictates. This leads him to inquire in what sense the Scriptures are the word of God; and he gravely determines them to be so only as they *actually* contribute to make men more virtuous and holy. It is not enough that they are *calculated* to improve virtue and holiness: for should the words of the languages in which they are written acquire in process of time a signification different from what they had originally; should mankind lose all knowledge of these languages; or even should they agree to neglect the books, whether from ignorance or from wilfulness—those books would cease to be the word of God, and become nothing better than waste paper and ink; just as the two tables, which Moses broke on observing the idolatry of his countrymen, were not the covenant between Jehovah and the Israelites, but merely two pieces of stone! The Scriptures, however, are the word of God, because they teach the true religion of which God is the author; and they have taught it in such a manner, he says, that it can never be lost or corrupted whatever becomes of the books of the Old and New Testaments, or of the languages in which they are written. The whole of religion, as the Scriptures themselves testify, consists in the love of God above all things, and of our neighbours as ourselves: whence it follows, that we must believe that God exists, and watcheth over all things by his providence; that he is omnipotent, and has decreed the pious to be ultimately happy, and the impious miserable; and that our final salvation depends solely on His grace or favour. These truths, with their necessary consequences, are the word of God: they are clearly taught in the Scriptures, and can never be corrupted; but every thing else in these volumes is vain, he says, and of no greater importance to us than facts related in any other ancient and authentic history.

Such are the opinions which were entertained of revelation by a man whom a critic, writing in a Christian country, and professing to be a zealous Christian himself, has lately pronounced to have been a *chosen vessel*. For what purpose he was *chosen* it is not easy to conceive. His religion, as it appears in the *Tractatus*, is the worst kind of Deism; and his politics are such as the monthly critics are not wont to teach, and such as we trust shall never be seriously taught by any honest man. By the law of nature, he says, every man before the formation of civil government has an unquestionable right to whatever appears eligible either to his reason or to his appetites; and may get possession of it by *intreaty*, by *violence*, by *fraud*, or by *any other means* attended with less trouble to himself *(sive vi, sive dolo, sive precibus, sive quocunque demum modo facilius poterit)*; and may treat as an enemy every person who shall attempt to obstruct his purpose. But when men agree to devolve this right upon others, and to constitute a political state, which both reason and appetite must persuade them to do, then are they in duty bound to obey every mandate of the government, however absurd it may be *(omnia mandata tametsi absurdissima)*, as long as that government can enforce its edicts, and no longer; for, according to him, right and power are so inseparably united, that when a government loses its power, it has no longer the smallest claim to obedience. This doctrine, he says, is most *obviously* just when taught of democratical governments; but it is in fact equally true of monarchies and aristocracies: "Nam quisquis summam habet potestatem, sive unus sit, sive pauci, sive denique omnes, certum est ei summum jus *quicquid velit imperandi*, competere: et præterea quisquis potestatem se defendendi, sive sponte, sive *vi coactus*, in alium transtulit, eum suo jure naturali plane cessisse, et consequenter eidem ad omnia absolute parere decrevisse quod omnia præstare tenetur, quamdiu rex, sive nobiles, sive populus summam, quam acceperunt, potestatem, quæ juris transferendi fundamentum fuit, conservant; nec his plura addere opus est*." We heartily agree with him, that to this precious conclusion it is needless to add a single word.

* Tract. cap. xvi. p. 181.

Taking our leave therefore of his *Tractatus Theologico-politicus*, we shall now give our readers a short account of his *Opera Posthuma*. These consist of, 1. ETHICA, *more geometrico demonstrata*; 2. POLITICA; 3. DE EMENDATIONE INTELLECTUS; 4. EPISTOLÆ, *et ad eas* RESPONSIONES; 5. COMPENDIUM GRAMMATICES LINGUÆ HEBRÆÆ.

The ETHICA are divided into five parts, which treat in order, *de* DEO; *de natura et origine* MENTIS; *de origine et natura* AFFECTUUM; *de* SERVITUTE *humana seu de* AFFECTUUM VIRIBUS; *de* POTENTIA INTELLECTUS, *seu de* LIBERTATE *humana*. As the author professes to tread in the footsteps of the geometers, and to deduce all his conclusions by rigid demonstration from a few self-evident truths, he introduces his work, after the mannner of Euclid with a collection of *definitions* and *axioms*. These are couched in terms generally ambiguous; and therefore the reader will do well to consider attentively in what sense, if in any, they can be admitted; for it will not be found easy to grant his premises, and at the same time refuse his conclusions. His definition of substance, for instance, is so expressed as to admit of two senses; in one of which it is just, whilst in the other it is the parent of the most impious absurdity. We shall give it in his own words: "Per substantiam intelligo id, quod in se est, et per se concipitur: hoc est id, cujus conceptus non indiget conceptu alterius rei, a quo formari debeat." If by this be meant, that a substance is that which we can conceive by itself without *attending* to any thing else, or *thinking* of its formation, the definition, we believe, will be admitted by every reflecting mind as sufficiently distinguishing the thing defined from an attribute, which, he says, is that which we perceive *of* a substance, and which we certainly cannot conceive as existing by itself. Thus the writer of this article can shut his eyes and contemplate in idea the small 4to volume now before

Spinoza. fore him, without attending to any thing else, or thinking of its paradoxical author, or even of the Great Being who created the matter both of him and of it; but he cannot for an instant contemplate the yellow colour of its vellum boards without thinking of triple extension, or, in other words, of body. The book therefore is a *substance*, because conceivable by itself; the colour is an *attribute* or *quality*, because it cannot be conceived by itself, but necessarily leads to the conception of something else. But if Spinoza's meaning be, that nothing is a substance but what is conceived as existing from eternity, independent of every thing as a cause, his definition cannot be admitted: for every man conceives that which in himself thinks, and wills, and is conscious, as a substance; at the same time that he has the best evidence possible that he existed not as a conscious, thinking, and active being, from eternity.

His fourth axiom is thus expressed: "Effectus cognitio a cognitione causæ dependet, et eandem involvit;" and his fifth, "Quæ nihil commune cum se invicem habent, etiam per se invicem intelligi non possunt, sive conceptus unius alterius conceptum non involvit." The former of these propositions, so far from being self-evident, is not even true; and the latter is capable of two senses very different from each other. That every effect proceeds from *a cause*, is indeed an axiom; but surely we may know the effect accurately, though we be ignorant of the *particular* cause from which it proceeds (see PHILOSOPHY, n° 36; and PHYSICS, n° 91, &c.); nor does the knowledge of the one by any means involve the knowledge of the other. If different things have nothing in common, it is indeed true that the knowledge of one of them will not give us an *adequate conception* of the other; but it will in many cases compel us to believe, that the other *exists* or has existed. A parcel of gunpowder lying at rest has nothing in common with the velocity of a cannon-ball; yet when we know that a ball has been driven with velocity from a cannon, we infer with certainty that there has been a parcel of powder at rest in the chamber of that cannon.

It is upon such ambiguous definitions and axioms as these that Spinoza has raised his pretended demonstrations, that one substance cannot produce another; that every substance must necessarily be infinite; that no substance exists or can be conceived besides God; and that extended substance or body is one of the infinite *attributes* of God. We shall not waste our own time or the reader's with a formal confutation of these impious absurdities. We trust they are sufficiently confuted in the other articles of this work (see METAPHYSICS, Part III. PROVIDENCE, and THEOLOGY, Part I.); and whoever wishes for a more particular examination of the author's principles, may find it in Dr Clarke's Demonstration of the Being and Attributes of God. The truth, however, is, that no man will need the assistance of that eminent metaphysician to discover the fallacy of the reasoning by which they are attempted to be proved, if he affix *any one precise meaning* to the definitions and axioms, and adhere to that meaning steadily thro' the whole process of the pretended demonstrations.

By way of apology for this jargon, it has been lately said, that "Spinoza takes the word *substance* in its most simple and perfect sense; which is necessary, as he writes mathematically, and proposes a simple idea as the foundation of his theory. What is the proper signification of a substance? Is it not that which stands alone, which has the cause of its existence within itself? I wish that this simple meaning of the word could be universally admitted in philosophy. Strictly speaking, no worldly thing is a substance; since all mutually depend on each other, and finally on God, who, in this exalted sense, is the only *substance*. The word *modification* sounds harsh and improper, and therefore it cannot be expected to gain a place in philosophy; but if the school of Leibnitz may term matter the *appearance of substances* why may not Spinoza be allowed a bolder term? Worldly substances are kept in union by divine power, as it was by divine power that they had existence. They represent also, if you please, *modified* appearances of divine power; each according to the station, the time, and the organs, in and with which it appears. The phrase used by Spinoza is concise, and it gives an unity and simplicity to his whole system, however strange it may sound in our ears."

Spinoza. Herder's Dialogues concerning God.

From this account of Spinozism, one who had never looked into the works of the author would be led to suppose that his system is the same with that of Berkeley; which, denying the existence of material substance, attributes all our perceptions of what we call the qualities of body to the immediate agency of the Deity on our minds (see METAPHYSICS, Part II. Chap. 3.) But Spinoza's doctrine is very different. According to him, bodies are either attributes or affections of God; and as he says there is but one extended substance, he affirms that substance to be indivisible, and employs a long scholium† to prove that those are mistaken who suppose it finite and not *essential to the Deity*. That we do not misrepresent his sentiments, the learned reader will be convinced by the two following definitions, with which he introduces that part of his ethics which treats of the nature and origin of mind. 1. "Per corpus intelligo modum, qui Dei essentiam, quatenus, ut res extensa consideratur, certo et determinato modo exprimit." 2. "Ad essentiam alicujus rei id pertinere dico, quo dato res necessario ponitur, et quo sublato res necessario tollitur; vel id, sine quo res, et vice versa quod sine re nec esse nec concipi potest." In conformity with these definitions, he attempts to prove that God is an extended as well as a thinking substance; that as a thinking substance he is the cause of the *idea* of a circle, and as an extended substance of the *circle* itself; and that the minds of men are not substances, but certain modifications of the divine attribute; or, as he sometimes expresses it, "Quod humanæ mentis actuale constituit, est idea rei singularis actu existentis." Hence, he says, it follows that the human mind is a part of the intellect of the infinite God; so that when we speak of the human mind perceiving this or that, we can only mean that God, not as he is infinite, but as he appears in the human mind or constitutes its essence, has this or that idea; and when we speak of God's having this or that idea, we must conceive of Him not only as constituting the human mind, but as, together with it, having the idea of something else (A). In another place he tells us, that the human mind is nothing but the *idea* which

† See his Prop. xv. &c.

Prop. ii. vii. xi. Part 2.

(A) Hinc sequitur mentem humanam partem esse infiniti intellectus Dei; ac proinde cum dicimus, mentem humanam which God has of the human body as actually exifting; that this *idea* of the body, and the *body* itfelf, are one and the fame thing; and that thinking and extended fubftances are in reality but one and the fame fubftance, which is fometimes comprehended under one attribute of the Deity, and fometimes under another *.

* Prop. vii. xiii. xxi. Part 2.

If this impious jargon be not Atheifm, or as it has been fometimes called Pantheifm, we know not what it is (fee Pantheism). According to Spinoza, there is but one fubftance, which is extended, infinite, and indivifible. That fubftance indeed he calls God; but he labours to prove that it is corporeal; that there is no difference betwen mind and matter; that both are attributes of the Deity varioufly confidered; that the human foul is a part of the intellect of God; that the fame foul is nothing but the idea of the human body; that this idea of the body, and the body itfelf, are one and the fame thing; that God could not exift, or be conceived, were the vifible univerfe annihilated; and therefore that the vifible univerfe is either the one fubftance, or at leaft an effential attribute or modification of that fubftance. He fometimes indeed fpeaks of the *power* of this fubftance; but when he comes to explain himfelf, we find that by power he means nothing but blind neceffity ‡; and though he frequently talks of the *wifdom* of God, he feems to make ufe of the word without meaning. This we think evident from the long appendix to his 36 propofition; in which he labours to prove that the notion of final caufes is an idle figment of the imagination, fince, according to him, nothing but the prejudices of education could have led men to fancy that there is any real diftinction between *good* and *evil*, *merit* and *demerit*, *praife* and *reproach*, *order* and *confufion*; that *eyes* were given them that they might be enabled to *fee*; *teeth* for the purpofe of chewing their *food*; *herbs* and *animals* for the *matter* of that *food*; that the *fun* was formed to give *light*, or the *ocean* to nourifh *fifhes*. If this be true, it is impoffible to difcover wifdom in the operations of his *one fubftance*; fince, in common apprehenfion, it is the very characteriftic of folly to act without any end in view.

‡ Prop. xxxiii. Part 1.

Such are the reveries of that writer, whofe works a German philofopher of fome name has lately recommended to the public, as calculated to convey to the mind more juft and fublime conceptions of God than are to be found in moft other fyftems. The recommendation has had its effect. A literary journalift of Britain, reviewing the volume in which it is given, feels a peculiar fatisfaction from the difcovery that Spinoza, inftead of a formidable enemy to the caufe of virtue and religion, was indeed their warmeft friend; and pioufly hopes that we fhall become more cautious not to fuffer ourfelves to be deceived by empty names, which thofe who *cannot* reafon (Sir Ifaac Newton and Dr Clarke perhaps) give to thofe who can (Hobbes, we fuppofe, and Spinoza). But though we have the honour to think on this queftion with our illuftrious countrymen, we have no defire to depict Spinoza as a *reprobate*, which the critic fays has often been done by ignorance and enthufiafm. We admit that his conduct in active life was irreproachable; and for his fpeculative opinions, he muft ftand or fall to his own Mafter. His *Ethics* appear to us indeed a fyftem fhockingly impious; and in the tract intitled Politica, *power* and *right* are confounded as in the former volume; but in the treatife De Intellectus Emendatione, are fcattered many precepts of practical wifdom, as well as fome judicious rules for conducting philofophical inveftigation; and we only regret, that the reader muft wade to them through pages of fatalifm, fcepticifm, and palpable contradictions. His *Compendium Grammatices Linguæ Hebrææ*, though left imperfect, appears to have fo much merit, that it is to be wifhed he had fulfilled his intention of writing a philofophical grammar of that language, inftead of wafting his time on abftrufe fpeculations, which though they feem not to have been injurious to his own virtue, are certainly not calculated to promote the virtue of others, or to increafe the fum of human happinefs.

SPIRÆA, in botany: A genus of plants belonging to the clafs of *icofandria*, and to the order of *pentagynia*; and in the natural fyftem arranged under the 26th order, *Pomaceæ*. The calyx is quinquefid; there are five petals; and the capfule is polyfpermous. There are 18 fpecies; of which two only are Britifh, the filipendula and ulmaria. 1. The *filipendula*, dropwort, has pinnated leaves; the leaflets are ferrated; the ftalk is herbaceous, about a foot and a half high, terminated with a loofe umbel of white flowers, often tinged with red. The petals are generally fix, and the fegments of the calyx are reflexed: the ftamina are 30 or more; the germina 12 or upwards. It grows in mountainous paftures. 2. The *ulmaria*, meadow-fweet. The leaves have only two or three pair of pinnæ, with a few fmaller ones intermixed; the extreme one being larger than the reft, and divided into three lobes. The calyx is reddifh; the petals white, and the number of capfules from fix to ten twifted in a fpiral. The tuberous pea, like roots of the filipendula dried and reduced to powder, have been ufed inftead of bread in times of fcarcity. Hogs are very fond of thefe roots. Cows, goats, fheep, and fwine, eat the plant; but horfes refufe it. The flowers of the ulmaria have a fragrant fcent, which rifes in diftillation. The whole plant indeed is extremely fragrant, fo that the common people of Sweden ftrew their floors with it on holydays. It has alfo an aftringent quality, and has been found ufeful in dyfenteries, ruptures, and in tanning of leather.

SPIRAL, in geometry, a curve line of the circular kind, which in its progrefs recedes from its centre.

SPIRE, in architecture, was ufed by the ancients for the bafe of a column, and fometimes for the aftragal or tore; but among the moderns it denotes a fteeple that continually diminifhes as it afcends, whether conically or pyramidally.

SPIRIT, in metaphyfics, an incorporeal being or intelligence;

humanam hoc vel illud percipere, nihil aliud dicimus quam quod Deus, non quatenus infinitus eft, fed quatenus per naturam humanæ mentis explicatur, five quatenus humanæ mentis effentium conftituit, hanc vel illam habet ideam: et cum dicimus Deum hanc vel illam ideam habere, non tantum, quatenus naturam humanæ mentis conftituet; fed quatenus fimul cum mente humana alterius rei etiam habet ideam. *Corol.* prop. xi. part 2.

intelligence; in which sense God is said to be a spirit, as are angels and the human soul. See METAPHYSICS, Part III.

SPIRIT, in chemistry and pharmacy, a name applied to every volatile liquid which is not insipid like phlegm or water; and hence the distinction into acid, alkaline, and vinous spirits. See PHARMACY-*Index*.

SPIRIT *of Wine*. See CHEMISTRY-*Index*, DISTILLATION, and PHARMACY-*Index*

SPIRITS, or ANIMAL SPIRITS. See ANATOMY, Part V. n° 136, and PHYSIOLOGY, n° 185.

SPIRITUAL, in general, something belonging to or partaking of the nature of spirit. See SPIRIT.

SPIRITUOUS LIQUORS have in all nations been considered as a proper subject of heavy taxation for the support of the state. This has naturally occasioned a nice examination of their strength. It having been at last found that this was intimately connected with the specific gravity, this has been examined with the most scrupulous attention to every circumstance which could affect it, so that the duties might be exactly porportioned to the quantity of spirit in any strong liquor, independent on every other circumstance of flavour or taste, or other valued quality. The chemist at last found that the basis of all strong liquors is the same, produced by the vinous fermentation of pure saccharine matter dissolved in water. He also found, that whether this vegetable salt be taken as it is spontaneously formed in the juices of plants and fruits, or as it may be formed or extricated from farinaceous fruits and roots by a certain part of the process of vegetation, it produces the same ardent spirit, which has always the same density in every mixture with water. The minute portions of aromatic oils, which are in some degree inseparable from it, and give it a different flavour according to the substance from which it was obtained, are not found to have any sensible effect on its density or specific gravity. This seems very completely established in consequence of the unwearied attempts of the manufacturers to lessen the duties payable on their goods by mixtures of other substances, which would increase their density without making them less palatable. The vigilance of the revenue officers was no less employed to detect every such contrivance. In short, it is now an acknowledged point, that the specific gravity is an accurate test of the strength.

But though this is true in general, we cannot derive much benefit from it, unless we know the precise relation between the strength and the density of a spirituous liquor. Do they increase *pari passu*, or by what law are they connected? It was natural to expect that equal additions of ardent spirits or alcohol to a given quantity of water would produce equal diminutions of density. Areometers were accordingly made on this principle above 200 years ago, as may be seen in the works of Gaspar Schottus, Sturmius, Agricola, and other old authors. But when mathematical physics became more generally known, this was easily discovered to be erroneous; and it was shown (we think first by Mr Boyle) that equal additions to the specific gravity would be produced by successively taking out of any vessel a certain measure of alcohol and replacing it with an equal measure of water. This was the most convenient discovery for all parties, because then the duties payable on a cask of spirits would be in the exact proportion of the diminution of its density. But it was soon found by those who were appointed guardians of the revenue that this conclusion was erroneous, and that a mixture which appeared by this rule to contain 35 gallons of alcohol, did really contain $35\frac{1}{4}$. This they found by actually making such a mixture: 18 gallons of alcohol mixed with 18 of water produced only 35 gallons of spirits. The revenue officers, finding that this condensation was most remarkable in mixtures of equal parts of water and the strongest spirits which could then be procured, determined to levy the duties by this mixture; because, whether the spirituous liquor was stronger or weaker than this, it would appear, by its specific gravity, rather stronger than it really was. This sagacious observation, and the simplicity of the composition, which could at all times be made for comparison, seem to be the reasons for the excise officers selecting this mode of estimating the strength and levying the duties. A mixture of nearly equal measures of water and alcohol is called PROOF SPIRIT, and pays a certain duty *per* gallon; and the strength of a spirituous liquor is estimated by the gallons, not of alcohol, but of proof spirit which the cask contains. But because it might be difficult to procure at all times this proof spirit for comparison, such a mixture was made by order of the board of excise: and it was found, that when six gallons of it was mixed with one gallon of water, a wine gallon of the mixture weighed 7 pounds 13 ounces avoirdupois. The board therefore declared, that the spirituous liquor of which the gallon weighed 7 pounds 13 ounces should be reckoned 1 to 6 or 1 in 7 under proof. This is but an aukward and complex formula; it was in order to suit matters to a mode of examination which had by time obtained the sanction of the board. Mr Clarke, an ingenious artist of that time, had made a hydrometer incomparably more exact than any other, and constructed on mathematical principles, fit for computation. This had a set of weights corresponding to the additions of water or proof spirit, and the mixture 1 to 6 or 1 in 7 was the only one which weighed an exact number of ounces *per* gallon without a fraction.

Thus stands the excise law; and Clark's hydrometer is still the instrument of authority, although others have been since constructed by DICAS QUIN, and others, which are much more ingenious and convenient. The mathematician who examines Dicas's hydrometer, with its sliding scale, by which it is adjusted to the different temperatures, and points out the condensations, will perceive a beautiful and sagacious combination of quantities, which he will find it difficult to bring under any analytical formula. Perhaps Quin's may have some perference in respect of conveniency; but *facile inventis addere*. Mr Dicas's was original.

As naturalists became more accustomed to exact observation in every topic of inquiry, the condensation which obtains in the mixture of different substances became more familiarly known. This evidently affects the present question; and both the excise and the distillers are interested in its accurate decision. This occasioned an application to the Royal Society; and a most scrupulous examination of the strength of spirituous liquors was made by Sir Charles Blagden and Mr Gilpin, of which they have given a very particular account in the PHILOSOPHICAL TRANSACTIONS for 1790 and 1792

We have taken notice of this in the article SPECIFIC GRAVITY, Spirituous Liquors.

GRAVITY, mentioning such circumstances of the results as suited our purposes of physical discussion. At present we give the general result in the table of specific gravity, as peculiarly belonging to spirituous liquors, affording the most exact account of their density in every state of dilution of alcohol with water. And as the relation between the proportion of ingredients and the density is peculiar to every substance, so that scarcely any inference can be made from one to another, the reader will consider the tables here given as characteristic with respect to alcohol. In all solutions of salts we found that the condensation increases continually with the dilution, whereas it is greatest when equal bulks of water and alcohol are mixed: yet we do not consider this as an exception; for it is certain, that in the strongest brine the saline ingredient bears but a small proportion to the water—and when we mix two solutions, the condensation is greatest when they are nearly equal in bulk. But we think ourselves entitled to infer, that alcohol is not a dilution of a substance in a quantity of water; but that water, in a certain proportion, not very distant from what we can produce by slow distillation, is an ingredient of alcohol, or is one of it component parts, and not merely a vehicle or menstruum. We therefore imagine that proof spirit contains nearly equal bulks of water and ardent spirits.

The great difficulty in this examination arose from the very dissimilar expansions of water and alcohol by heat. This determined Sir Charles Blagden to estimate the proportions of ingredients by weight, and made it absolutely necessary to give a scale of specific gravity and strength for every temperature. For it must be remarked, that the question (whether in commerce or philosophy) always is, "How many gallons of alcohol and of water, taken just now and mixed together, will produce a hundred gallons of the spirit we are examining!" The proportion of these two will be different according to the temperature of both. As many mixtures therefore must have been made in each proportion as there were temperatures considered; but by taking the ingredients by weight, and examining the density of the compound in one temperature, it is then heated and cooled, and its change of density observed. Calculation then can tell us the change in the proportion of the bulks or numbers of gallons in the mixture, by means of a previous table showing the expansions of water and of alcohol.

The alcohol selected for this examination had the specific gravity 0,825. This is not the purest that can be procured; some was produced of 0,816, of 0,814, and 0,813, both obtained from rum, from brandy, and from malt spirit. We are informed that Dr Black has obtained it of the specific gravity 0,8 by digesting alcohol with fixed ammoniac (muriatic acid united with lime) made very dry. It dephlegmates alcohol very powerfully without decomposing it, which always happens when we use caustic alkali. Alcohol of 0,825 was chosen because expressed by a number of easy management in computation.

The examination commenced by ascertaining the expansions of water and alcohol. The temperature 60° of Fahrenheit's scale was selected for the general temperature of comparison, being easily attainable even in cold weather, and allowing the examinator to operate at ease. The first and last copartments of the tables contain the weights and specific gravities of alcohol and water from every fifth degree of heat from 30° to 100°. From these we have constructed the two following little tables of expansion. The bulk of 1000 ounces, pounds, or other weight of water and of alcohol of the temperature 60°, occupies the bulks expressed in the tables for every other temperature. Water could not be easily or usefully examined when of the temperature 30°, because it is with great difficulty kept fluid in that temperature. It is very remarkable, that when it can be so kept, it expands instead of contracting; while cooling down from 35° or thereabouts, and as it approaches to 32°, it expands rapidly. We observe the same thing in the crystallization of Glauber salt, martial vitriol, and some others, which contain much water in their crystals. We observe, on the other hand, a remarkable contraction in the zeolite just before its beginning to swell into bubbles by a red heat.

Heat	Bulk of 100,000 ounces. Of Water.	Diff.	Of Alcohol.	Diff.
30°			119195	
35	99910		119514	319

95	100500	96	123773	380
100	100608	108	124157	384

This being premised, the examination was conducted in the following manner. It was determined to mix 100 parts by weight of pure alcohol with five, ten, fifteen, twenty, parts of distilled water, till they were compouuded in equal quantities, and then to mix 100 parts of distilled water with 95, 90, 85, 80, &c. parts of alcohol, till they were mixed in the proportion of 100 to 5. Thus a series of mixtures would be obtained, extending from pure alcohol to pure water. This series would be such, that the examinations would be most frequent in the cases most usual in the commerce of strong liquors. A set of phials, fitted with ground stoppers, were provided, of sizes fit to hold the intended mixtures. These mixtures were made by suspending the phial to the arm of a very nice balance, in the opposite scale of which (besides the counterpoise of the phial) there was placed the weight 100. Spirit was then poured into the phial till it exactly balanced the weight 100. The weight for the water to be added was then put into the opposite scale, and water was poured into the phial by means of a slender glass funnel, by small quantities at a time, and the phial frequently agitated to promote the mixture. When the additional weight was exactly balanced, the phial was taken off, its stopper put in, and leather tied over it, and it was set by, for at least a month, that the mixture and the whole procefs of condenfation might be completed. The fame method was followed in the mixtures where the water was predominant.

When the ingredients of thefe mixtures were judged to have completely incorporated, their fpecific gravity was examined by weighing with the moft fcrupulous precifion the contents of a veffel which held 2925 troy grains of water, of the temperature 60°. The balance was fo exceedingly fenfible, that the 50th part of a grain greatly deranged its pofition when loaded with the fcales and their contents. It was conftructed by Mr Ramfden, and fome account of its exquifite fenfibility may be feen in the *Journal de Phyfique*, vol. xxxiii. This quantity of materials was therefore thought abundantly fufficient for afcertaining the denfity of the liquor. It is needlefs to detail the precautions which were taken for having the contents of the weighing bottle brought to the precife temperature proper for the experiment. They were fuch as every perfon converfant with fuch things is accuftomed to take—The bottle had a flender neck, and being put on a lathe, a mark was made round it with a diamond. The bottle was filled till the bottom of the hollow furface of the fluid was in the plane of this mark; and to judge of the accuracy attainable in filling the bottle, the operation was feveral times repeated and the contents weighed, without the difference of $\frac{1}{50}$th of a grain in 2925. The only fource of error which was to be guarded againft was air-bubbles adhering to the infide of the bottle, or moifture condenfing (in the experiments with low temperatures) on the outfide. Both of thefe were attended to as much as poffible.

This method of determining the fpecific gravity was preferred to the ufual method, obferving the weight loft by a lump of glafs when fufpended in water; for Mr Gilpin had been enabled, by means of this nice balance, to difcover, even in pure water and in alcohol, want of perfect fluidity. Something like vifcidity rendered the motion of a lumpe of glafs through the liquor fenfibly fluggifh, fo that when the balance was brought to a level, there was not a perfect equilibrium of weights: (See what we have faid of this matter in Specific Gravity). Mr Gilpin alfo tried the ingenious inftrument propofed for fuch experiments by Mr Ramfden, and defcribed by him in a pamphlet on this very fubject; and he found the anomalies of experiment much greater than in this method by weighing.—Indeed the regular progreffion of weights to be feen in the annexed tables is an unqueftionable proof of the fufficiency of the method; and it has the evident advantage of all other methods in point of fimplicity and practicability without any uncommon apparatus. Any perfon poffeffed of a good ordinary balance and a fet of exact weights may examine all queftions of this kind, by weiging pure water and the liquor which he may have occafion to examine in a common 6 or 8 ounce phial. For this reafon, it is recommended (in preference to all hydrometers) to the board of excife to provide this fimple apparatus in every principal office.

Every experiment was made at leaft three times; and the mean refult (which never differed one grain from the extreme) was taken.

From thefe experiments the annexed tables were conftructed. The firft is the fimple abftract of the experiments, containing the weights of the contents of the bottle of every mixture. The fecond contains the fpecific gravities deduced from them.

We have faid that the experiments appear furprifingly accurate. This we fay on the authority of the regular progreffion of the fpecific gravity in any of the horizontal rows. In the feries, for inftance, for the temperature 60°, the greateft anomaly is in the mixture of 50 parts of fpirit with 100 of water. The fpecific gravity is 95804, wanting 3 or 4 of the regular progreffion. This does not amount to 1 in 18000.

TABLE

TABLE I.—*Weights at the different Degrees of Temperature.*

We

We formerly obferved, that the feries of mixtures chofen by Sir Charles Blagden, for the advantages attending it in making the experiment, was not fuited for folving the queftions which commonly occur in the fpirit bufinefs. He accordingly fuggefts the propriety of forming tables in a convenient feries from the data furnifhed by thefe experiments, indicating the proportion of ingredients contained in fome conftant weight or bulk.

To facilitate the conftruction of fuch tables, it is neceffary to confider the fubject in the moft general manner. Therefore let a reprefent the conftant number 100. Let w and s reprefent the quantities of water and fpirit by weight in any mixture; that is, the pounds, ounces, or grains of each. Let x reprefent the quantity *per cent.* of fpirits alfo by weight; that is, the number of pounds of fpirits contained in 100 pounds of the mixture; and let y be its quantity *per cent.* in gallons, or the number of gallons contained in 100 gallons of the unmixed ingredients. Let m be the bulk of a pound of fpirit of any given temperature, the bulk of a pound of water *of the fame temperature* being accounted 1.

Then $w+s$ is the weight of any mixture, and $w+ms$ is its bulk.

We have the following proportions: 1. $w+s:s=a:x$, and $x=\frac{as}{w+s}$ (Equation 1ft); and hence s may be found when x the per centage in weight is given, for $s=\frac{wx}{a-x}$ (Equation 2.)

2. $w+ms:ms=a:y$, and $y=a\frac{ms}{w+ms}$. (Equation 3d); and s may be found when y, the per centage in gallons, is given: for $s=\frac{my}{a-y}$ (Equation 4th.)

The ufual queftions which can be folved from thefe experiments are,

1. To afcertain the quantity of fpirits *per cent.* in bulk from obfervation of the fpecific gravity, or to tell how many gallons of fpirit are in 100 gallons of mixture.

Look for the fpecific gravity in the table, and at the head of the column will be found the w and s correfponding. If the precife fpecific gravity obferved is not in the tables, the s muft be found by interpolation. And here it is proper to remark, that taking the fimple proportional parts of fpecific gravity will not be fufficiently exact, efpecially near the beginning or the end of the table, becaufe the denfities correfponding to the feries of mixtures do not change uniformly. We muft have recourfe to the general rules of interpolation, by means of firft and fecond differences or be provided with a fubfidiary table of differences. A good deal of practice in computations of this kind fuggefted the following method of making fuch interpolations with great difpatch and abundant accuracy. On a plate of wood, or metal, or ftiff card-paper, draw a line EF (fig. 3.), as a fcale of equal parts, reprefenting the leading or equable arithmetical feries of any table. (In the prefent cafe EF is the fcale on which s is computed.)—Through every point of divifion draw the perpendiculars BA, EC, FD, &c. Make one of them AB more confpicuous than the reft, and diftinguifh the others

Plate CCCCLXXII.

alfo in fuch fort, that the eye fhall readily catch their diftance from the principal line AB. Let CPL be a thin flip of whalebone, of uniform breadth and thicknefs, alfo divided into equal parts properly diftinguifhable. Laftly, let there be a pin P fixed near the middle of the principal line AB.

Now fuppofe that a value of s is to be interpolated by means of an obferved fpecific gravity not in the table. Look for the neareft to it, and note its diftance from the preceding and the following. Let thefe be PH and PK on the flexible fcale. Alfo take notice of the lines K 10 and H 10, whofe diftances from AB are equal to the conftant difference between the fucceffive values of S, or to any eafily eftimated multiple of it (as in the prefent cafe we have taken 10 and 10, inftead of 5 and 5, the running difference of Sir Charles Blagden's table). Then, leaning the middle point P of the whalebone on the pin P in the board, bend it, and place it flantwife till the points K and H fall fomewhere on the two parallels K 10 and H 10. No matter how oblique the pofition of the whalebone is. It will bend in fuch a manner that its different points of divifion (reprefenting different fpecific gravities) will fall on the parallels which reprefent the correfponding values of s. We can fay that all this may be done in lefs than half a minute, and lefs time than is neceffary for infpecting a table of proportional parts, and not the tenth part of that neceffary for interpolating by fecond differences. Yet it is exact enough (if of the fize of a duodecimo page) for interpolating three decimal places This is ten times more exact than the prefent cafe requires. To return from this digreffion.

Having thus found s in the table, we get x or y by the equations $\frac{as}{w+s}=x$, and $a\frac{ms}{w+ms}=y$.

But here a material circumftance occurs. The weight of alcohol s, and its per centage x, was rightly determined by the fpecific gravity, becaufe it was interpolated between two values, which were experimentally connected with this fpecific gravity. But in making the tranfition from x to y, we only give the per centage in gallons before mixture, but not the number of gallons of alcohol contained in an hundred gallons of mixed liquor. For when we have taken $\overline{a-y}$ and y inftead of w and s, they will indeed make a fimilar compound when mixed, becaufe the proportion of their ingredients is the fame. But they will not make 100 gallons of this compound, becaufe there is a fhrinking or condenfation by mixture, and the fpecific gravity by which we interpolated s is the phyfical or real fpecific gravity correfponding to w and s; while $\frac{w+s}{w\times ms}$, the fpecific gravity implied in the value of y, is the mathematical denfity independent on this condenfation. Since therefore y, together with $\overline{a-y}$, make lefs than 100 gallons of the compound, there muft in 100 gallons of it be more alcohol than is expreffed by y.

Let G be the mathematical fpecific gravity ($=\frac{w+s}{w+ms}$), and g the phyfical or real obferved fpecific gravity (which we cannot exprefs algebraically); and let z be the gallons of alcohol really contained in 100 gallons of the compound. The bulk being inverfely as the denfity or fpecific gravity, it is evident that the

bulk

bulk of the compound must be to 100 gallons as g to G. And since we want to make it still up to 100 gallons, we must increase it in the proportion of G to g. And because this augmentation must be of the same strength with this contracted liquor, both ingredients must be increased in the proportion of G to g, and we must have $G : g = y : z$, and $z = g \times \frac{y}{G}$. Now, instead of y, write $a \frac{ms}{w+ms}$, and instead of $\frac{1}{G}$ write $\frac{w+ms}{w+s}$, which are respectively equal to them. This gives us $z = g\,a \times \frac{w+ms}{w+s} \times \frac{ms}{w+s}, = g\,a \times \frac{ms}{w+s}$.

All this will be illustrated by an example.

Suppose that we have observed the specific gravity of a spirituous liquor of the temperature 60° to be 0,94128. Looking into Sir Charles Blagden's table, we find the gravities 0,94018 and 0,94296, and the s corresponding to them is 80 and 75, the water in each mixture being 100. By interpolation we obtain the s corresponding to 0,94128, *viz.* 78. At this temperature $m = \frac{1}{0{,}825}, = 1{,}21212$, and $ms = 94{,}54545$. Therefore $z = 0{,}94128 \times 100 \times \frac{94{,}54545}{194{,}54545}, = 49{,}997$, or very nearly 50.

We have seen even persons not unacquainted with subjects of this kind puzzled by this sort of paradox. z is said to be the per centage of spirit in the compound. The compound has the same proportion of ingredients when made up to 100 gallons as before, when y was said to be its per centage, and yet y and z are not the same. The fact is, that although z is the number of gallons of alcohol really contained in 100 gallons of the compound, and this alcohol is in the same proportion as before to the water, this proportion is is not that of 50 to 50: for if the ingredients were separated again, there would be 50 gallons of alcohol and 52,876 of water.

The proportion of the ingredients in their separate state is had by the 3d Equation $y = a\frac{ms}{w+ms}$, which is equivalent to $G\,a\frac{ms}{w+s}$. For the present example y will be found 48,599, and $a - y$, or the water per cent. 51,401, making 100 gallons of unmixed ingredients. We see then that there has been added 1,398 gallons of alcohol; and since both ingredients are augmented in the proportion of G to g, there have also been added 1,478 of water, and the whole addition for making up the 100 gallons of compound is 2,876 gallons; and if the ingredients of the compound were separate, they would amount to 102,876 gallons. This might have been found at the first, by the proportion, $G : g - G = 100 :$ (*The addition.*)

The next question which usually occurs in business is to find what density will result from any proposed mixture *per* gallon. This question is solved by means of the equation $\frac{wy}{m(a-y)} = s$. In this examination it will be most convenient to make $w = a$. If the value of s found in this manner falls on a value in the tables, we have the specific gravity by inspection. If not, we must interpolate.

N. B. The value of m, which is employed in these reductions, varies with the temperature. It is always obtained by dividing the specific gravity of alcohol of that temperature by the specific gravity of water of the same temperature. The quotient is the real specific gravity of alcohol for that temperature. Both of these are to be had in the first and last copartments of Sir Charles Blagden's table.

These operations for particular cases give the answers to particular occasional questions. By applying them to all the numbers in the table, tables may be constructed for solving every question by inspection.

There is another question which occurs most frequently in the excise transactions, and also in all compositions of spirituous liquors, viz. What strength will result from a mixture of two compounds of known strength, or mixing any compound with water? To solve questions of this kind by the table so often quoted, we must add into one sum the water *per* gallon of the different liquors. In like manner, take the sum of the spirits, and say, as the sum of the waters is to that of the alcohols, so is a to s; and operate with a and s as before.

Analogous to this is the question of the duties. These are levied on proof spirit; that is, a certain duty is charged on a gallon of proof spirit; and the gauger's business is to discover how many gallons of proof spirit there is in any compound. The specification of proof spirit in our excise laws is exceedingly obscure and complex. A gallon weighing 7 pounds 13 ounces (at 55°) is accounted 1 to 6 under proof. The gallon of water contains 58476 grains, and this spirit is 54688. Its density therefore is 0,93523 at 55°, or (as may be inferred from the table) 0,9335 at 60°. This density corresponds to a mixture of 100 grains of water with 93,457 of alcohol. If this be supposed to result from the mixture of 6 gallons of alcohol with 1 of water (as is supposed by the designation of 1 to 6 under proof), the gallon of proof spirits consists of 100 parts of spirits by weight, mixed with 75 parts of water. Such a spirit will have the density 0,9162 nearly.

This being premised, in order to find the gallons of proof spirits in any mixture, find the quantity of alcohol by weight, and then say, as 100 to 175, so is the alcohol in the compound to the proof spirit that may be made of it, and for which the duties must be paid.

We have considered this subject at some length, because it is of great importance in the spirit-trade to have these circumstances ascertained with precision; and because the specific gravity is the only sure criterion that can be had of the strength. Firing of gunpowder, or producing a certain bubble by shaking, are very vague tests; whereas, by the specific gravity, we can very securely ascertain the strength within one part in 500, as will presently appear.

Sir Charles Blagden, or Mr Gilpin, have published* a most copious set of tables, calculated from these valuable experiments. In these, computations are made for every unit of the hundred, and for every degree of the thermometer. But these tables are still not in the most commodious form for business. Mr John Wilson, an ingenious gentleman residing at Dundee, has just published

* Philos. Transf. 1794.

Spirituous Liquors.

lished at Edinburgh tables somewhat similar, founded on the same experiments. Both of these tables show the quantities by measure corresponding to every unit by weight of Sir Charles Blagden's experiments, and for every degree of temperature. They also show the *per centage* of alcohol, and the condensation or the quantity lost by mixture. But as they both retain the original series of parts by weight, which is very unusual, the spirit traders will find considerable difficulty in making use of them. Retaining this series also causes all the *per centage* numbers (which are the only interesting ones to the reader) to be fractional, and no answer can be had without a double interpolation.

We have therefore calculated a table in the form in which it must be most useful and acceptable to those who are engaged in the spirit trade, showing at once the specific gravity which results from any proportion of admixture in hundredth parts of the whole. This answers immediately the chief questions in the terms in which they are usually conceived and proposed. The two first or leading columns show the proportion in gallons, pints, or other cubic measures, of the mixture, the whole quantity being always 100. The second column shows the corresponding specific gravity: so that we can either find the proportion of the ingredients by the observed specific gravity, or find the gravity resulting from any proportion of the ingredients. A third column shows how much the hundred measures of the two ingredients fall short of making an hundred measures of the compound. A simple proportion, which can be done without the pen, will determine what part of this deficiency must be made up by spirit. The use of this table must now be so familiar to the reader's mind, that we need not give further instructions about it.

This is followed by another similar table, giving an immediate answer to the most usual question, "How many measures of alcohol are there really contained in 100 measures? This is also accompanied by a column of condensation. It would have been somewhat more elegant, had the specific gravities in this table made the equable series and leading column. But we did not advert to this till we had computed the table, and the labour was too great to be repeated for slight reasons. The tables are only for the temperature 60°. To this the spirituous liquors can always be brought in these climates; and in cases where we cannot, a moment's inspection of Sir Charles Blagden's table will point out very nearly (or exactly, by a short computation) the necessary corrections.

"In the first table, of which the sole intention is to point out the proportion of ingredients, the specific gravities are computed only to four places, which will always give the answer true to $\frac{1}{8000}$th part. In the last, which is more immediately interesting to the merchant in his transactions with the excise office, the computation is carried one place further."

The consideration of the first of these two tables will furnish some useful information to the reader who is interested in the philosophy of chemical mixture, and who endeavours to investigate the nature of those forces which connect the particles of tangible matter. These vary with the distance of the particle; and therefore the law of their action, like that of universal gravitation, is to be discovered by measuring their sensible effects at their various distances. Their change of distance is seen in the change of density or specific gravity.

Did the individual densities of the water and spirit remain unchanged by mixture, the specific gravity would change by equal differences in the series of mixtures on which this table is constructed; for the bulk being always the same, the change of specific gravity must be the difference between the weight of the gallon of water which is added and that of the gallon of spirit which is taken out. The whole difference of the specific gravities of spirits and water being 1,750 parts in 10,000, the augmentation by each successive change of a measure of spirit for a measure of water would be the 100th part of this, or 17,5. But, by taking the successive differences of density as they occur in the table, we see that they are vastly greater in the first additions of water, being then about 29; after which they gradually diminish to the medium quantity $17\frac{1}{2}$, when water and spirits are mixed in nearly equal bulks. The differences of specific gravity still diminish, and are reduced to 9, when about 75 parts of water are mixed with 25 of spirit. The differences now increase again; and the last, when 99 parts of water are mixed with 1 part of spirit, the difference from the specific gravity of pure water is above 14.

The mechanical effect, therefore, of the addition of a measure of water to a great quantity of spirit is greater than the similar effect of the addition of a measure of spirits to a great quantity of water. What we call mechanical effect is the local motion, the change of distance of the particles, that the corpuscular forces may again be in equilibrio. Observe, too, that this change is greater than in the proportion of the distance of the particles;

particles; for the denſity of water is to that of ſpirits nearly as 6 to 5, and the changes of ſpecific gravity are nearly as 6 to 3.

We alſo ſee that the changing cauſe, which produces the abſolute condenſation of each ingredient, ceaſes to operate when 75 parts of water have been mixed with 25 of alcohol: for the variation of ſpecific gravity, from diminiſhing comes now to increaſe; and therefore, in this particular ſtate of compoſition, is equable. Things are now in the ſame ſtate as if we were mixing two fluids which did not act on each other, but were mutually diſſeminated, and whoſe ſpecific gravities are nearly as 9 to 10; for the variation 9 of ſpecific gravity may be conſidered as the 100th part of the whole difference, in the ſame manner as 17,5 would have been had water and alcohol ſuſtained no contraction.

The imagination is greatly aſſiſted in the contemplation of geometrical quantity by exhibiting it in its own form. Specific gravity, being an expreſſion of denſity (a notion purely geometrical), admits of this illuſtration.

Plate CCCCLXXII. Therefore let AB (fig. 4.) repreſent the bulk of any mixture of water and alcohol. The ſpecific gravity of water may be repreſented by a line of ſuch a length, that AB ſhall be the difference between the gravities of alcohol and water. Suppoſe it extended upwards, towards *a*, till B *a* is to A *a* as 10,000 to 8250. It will ſuit our purpoſe better to repreſent it by a parallelogram *a* B F *e*, of any breadth BF. In this caſe the difference of the ſpecific gravities of alcohol and water will be expreſſed by the parallelogram ABFE. If there were no change produced in the denſity of one or both ingredients, the ſpecific gravity of the compound would increaſe as this parallelogram does, and AGHE would be the augmentation correſponding to the mixture of the quantity A G of alcohol with the quantity GB of water, and ſo of other mixtures. But, to expreſs the augmentation of denſity as it really obtains, we muſt do it by ſome curvilineal area DABCHD, which varies at the rate determined by Sir Charles Blagden's experiments. This area muſt be preciſely equal to the rectangle ABFE. It muſt therefore fall without it in ſome places, and be deficient in others. Let DMHKC be the curve which correſponds with theſe experiments. It is evident to the mathematical reader, that the ordinates LM, GH, IK, &c. of this curve are in the ultimate ratio of the differences of the obſerved ſpecific gravities. If A α, $\alpha\beta$, &c. are each $=5$, the little ſpaces A $\alpha\,\delta$ D, $\alpha\,\beta\,b\,\delta$, &c. will be preciſely equal to the differences of the ſpecific gravities 0,8250; 0,8387; 0,8516; &c. correſponding to the different mixtures of water and alcohol. The curve cuts the ſide of the parallelogram in K, where the ordinate GK expreſſes the mean variation of denſity 0,0017,5. IK is the ſmalleſt variation. The condenſation may be expreſſed by drawing a curve *d m* G *k f* parallel to DMGKF, making D d=AE. The condenſation is now repreſented by the ſpaces comprehended between this laſt curve and the abſciſſa AGB, reckoning thoſe negative which lie on the other ſide of it. This ſhows us, not only that the condenſation is greateſt in the mixture AG×GB, but alſo that in mixing ſuch a compound with another AI×IB, there is a rarefaction. Another curve ANPOB may be drawn, of which the ordinates LN, GP, IO, &c. are proportional to the areas AL *m d*, AG*m*D, A I *k* G *m* D (=AG *m d*—G I *k*), &c. This curve ſhows the whole condenſation.

This manner of repreſenting the ſpecific gravities of mixtures will ſuggeſt many curious inferences to ſuch as will conſider them in the manner of Boſcovich, with a view to aſcertain the nature of the forces of coheſion and chemical affinities: And this manner of viewing the ſubject becomes every day more promiſing, in conſequence of our improvements in chemical knowledge; for we now ſee, that mechaniſm, or motive forces, are the cauſes of chemical action. We ſee in almoſt every caſe, that chemical affinities are comparable with mechanical preſſures; becauſe the converſion of a liquid into a vapour or gas is prevented by atmoſpheric preſſure, and produced by the great chemical agent heat. The action of heat, therefore, or of the cauſe of heat, is a mechanical action, and the forces are common mechanical forces, with which we are familiarly acquainted.

"It may be alſo remarked in the column of contractions, that in the beginning the contractions augment nearly in the proportion of the quantity of ſpirits (but more ſlowly); whereas, in the end, the contractions are nearly in the duplicate proportion of the quantity of water. This circumſtance deſerves the conſideration of the philoſopher. We have repreſented it to the eye by the curve α *g b d*."

We ſhould here take ſome notice of the attempt made to elude ſome part of the duties, by adding ſome ingredient to the ſpirits. But our information on this ſubject is not very exact; and beſides it would be doing no ſervice to the trader to put fraud more in his power. There are ſome ſalts which make a very great augmentation of denſity, but they render the liquor unpalatable. Sugar is frequently uſed with this view; 16 grains of refined ſugar diſſolved in 1000 grains of proof ſpirits gave it no ſuſpicious taſte, and increaſed its ſpecific gravity from 0,920 to 0,925, which is a very great change, equivalent to the addition of 9 grains of water to a mixture of 100 grains of alcohol and 80 of water.

SPITHEAD, a road between Portſmouth and the Iſle of Wight, where the royal navy of Great Britain frequently rendezvous.

SPITTLE, in phyſiology. See SALIVA.

SPITZBERGEN. See GREENLAND, n° 10.

SPLACHNUM, in botany: A genus of plants belonging to the claſs of *cryptogamia*, and order of *muſci*. The antheræ are cylindrical, and grow on a large coloured apophyſis or umbraculum. The calyptra is caducous. The female ſtar grows on a ſeparate ſtem. There are ſix ſpecies, the rubrum, luteum, ſphæricum, ampullaceum, vaſculoſum, anguſtatum. Two of theſe are natives of Britain.

1. The *ampullaceum*, or crewet ſplachnum, is found in bogs and marſhes, and often upon cow-dung. It grows in thick tufts, and is about two inches high. The leaves are oval lanceolate, terminated with a long point or beard. The top of the filament or peduncle ſwells into the form of an inverted cone, which Linnæus terms an *apophyſis* or *umbraculum*; upon the top of which is placed a cylindrical anthera, like the neck of a crewet. The calyptra is conical, and reſembles a ſmall extinguiſher.

2. The *vaſculoſum*, or acorn-ſhaped ſplachnum, is found upon bogs and cow-dung, and upon the points of

rocks on the top of the Highland mountains, as on Ben Lomond, and in the Isle of Sky, and elsewhere. This differs little from the preceding, and perhaps is no more than a variety. The filaments are about an inch high. The leaves oval-acute, not so lanceolate and bearded as the other. The apophysis, and the anthera at the top of it, form together nearly an oval figure, not unlike an acorn in its cup, the apophysis being transversely semi-oval, and of a blood-red colour, the anthera short and conical. The calyptra is the same as that of the other. The operculum is short and obtuse, and the rim of the anthera has eight large horizontal cilia. The anthera of the other is also ciliated, but not so distinctly. It is an elegant moss, and very distinguishable on account of its orange-coloured filaments and dark-red capsules.

SPLEEN, in anatomy. See ANATOMY, nº 99.

Spleen-Wort. See ASPLENIUM.

SPLENETIC, a person afflicted with an obstruction of the spleen.

SPLENT, or SPLINT, among farriers, a callous insensible excrescence, breeding on the shank-bone of horses. See FARRIERY, Sect. xxxi.

SPLICING, in the sea-language, is the untwisting the ends of two cables or ropes, and working the several strands into one another by a fidd, so that they become as strong as if they were but one rope.

SPOILS, whatever is taken from the enemy in time of war. Among the ancient Greeks, the spoils were divided among the whole army; only the general's share was largest: but among the Romans, the spoils belonged to the republic.

SPOLETTO, a duchy of Italy, bounded on the north by the Marquisate of Ancona and duchy of Urbino, on the east by Farther Abruzzo, on the south by Sabina and the patrimony of St Peter, and on the west by Orvietano and Perugino. It is about 55 miles in length and 40 in breadth. It was anciently a part of Umbria, and now belongs to the Pope.—The name of the capital city is also *Spoletto*. It was formerly a large place, but in 1703 was ruined by an earthquake; from whence it has never recovered itself.

SPOLIATION, in ecclesiastical law, is an injury done by one clerk or incumbent to another, in taking the fruits of his benefice without any right thereunto, but under a pretended title. It is remedied by a decree to account for the profits so taken. This injury, when the *jus patronatus*, or right of advowson, doth not come in debate is cognizable in the spiritual court: as if a patron first presents A to a benefice, who is instituted and inducted thereto; and then, upon pretence of a vacancy, the same patron presents B to the same living, and he also obtains institution and induction. Now if A disputes the fact of the vacancy, then that clerk who is kept out of the profits of the living, whichever it be, may sue the other in the spiritual court for spoliation, or taking the profits of his benefice. And it shall there be tried, whether the living were or were not vacant; upon which the validity of the second clerk's pretensions must depend. But if the right of patronage comes at all into dispute, as if one patron presented A, and another patron presented B, there the ecclesiastical court hath no cognizance, provided the tithes sued for amount to a fourth part of the value of the living, but may be prohibited at the instance of the patron by the king's writ of *indicavit*. So also if a clerk, without any colour of title, ejects another from his parsonage, this injury must be redressed in the temporal courts: for it depends upon no question determinable by the spiritual law (as plurality of benefices or no plurality, vacancy or no vacancy), but is merely a civil injury.

SPONDEE, in ancient poetry, a foot consisting of two long syllables, as *omnes*.

SPONDIAS, BRASILIAN or JAMAICA PLUM, in botany; a genus of plants belonging to the class of *decandria*, and order of *pentagynia*. The calyx is quinquedentate. The corolla pentapetalous. The fruit contains a quinquelocular kernel. There are only two species, the mombin and myrobalanus, which appear so much confounded in the descriptions of different botanists, that we do not venture to present them to our readers.

SPONGIA, SPONGE, in natural history; a genus of animals belonging to the class of *vermes*, and order of *zoophyta*. It is fixed, flexible, and very torpid, growing in a variety of forms, composed either of reticulated fibres, or masses of small spines interwoven together and clothed with a living gelatinous flesh, full of small mouths or holes on its surface, by which it sucks in and throws out the water. Fifty species have already been discovered, of which 10 belong to the British coasts.

1. *Oculata*, or branched sponge, is delicately soft and very much branched; the branches are a little compressed, grow erect, and often united together. They have rows of cells on each margin, that project a little. This species is of a pale yellow colour, from five to ten inches high. The fibres are reticulated, and the flesh or gelatinous part is so tender, that when it is taken out of the water it soon dries away. It is very common round the sea-coast of Britain and Ireland. This description will be better understood by Plate CCCCLXXV. fig. 2. At *b*, *b*, along the edges and on the surface of the branches, are rows of small papillary holes, through which the animal receives its nourishment.

2. *Cristata*, or cock's-comb sponge, is flat, erect, and soft, growing in the shape of cock's combs, with rows of little holes along the tops, which project a little. It abounds on the rocks to the eastward of Hastings in Sussex, where it may be seen at low-water. It is commonly about three inches long, and two inches high, and of a pale yellowish colour. When put into a glass vessel of sea-water, it has been observed to suck in and squirt out the water through little mouths along the tops, giving evident signs of life.

3. *Stuposa*, tow-sponge, or downy branched sponge, is soft like tow, with round branches, and covered with fine pointed hairs. It is of a pale yellow colour, and about three inches high. It is frequently thrown on the shore at Hastings in Sussex. Fig. 2. represents this sponge; but it is so closely covered with a fine down, that the numerous small holes in its surface are not discernible.

4. *Dichotoma*, dichotomous or forked sponge, is stiff, branched, with round, upright, elastic branches, covered with minute hairs. It is found on the coast of Norway, and also, according to Berkenhout, on the Cornish and Yorkshire coasts. It is of a pale yellow colour, and full of very minute pores, guarded by minute spines. Fig. 3.

5. *Urens*.

SPONGES.

Plate CCCCLXXV.

Fig. 1

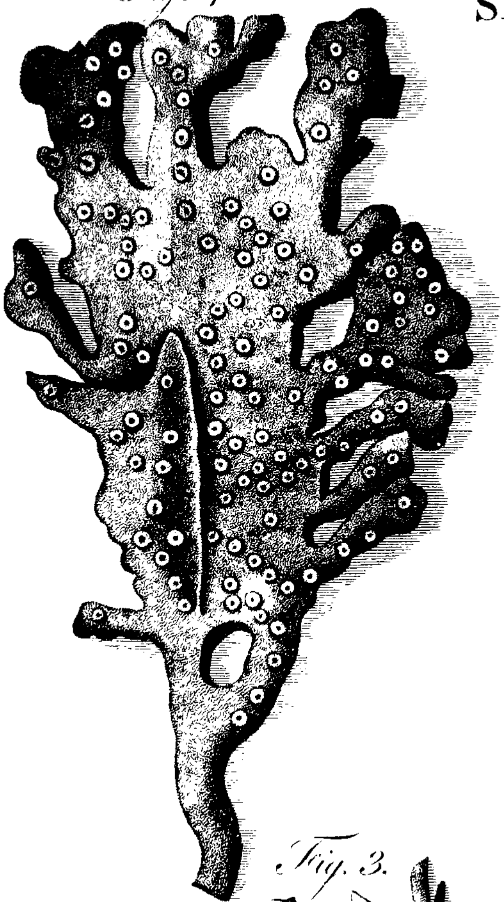

Fig. 2.

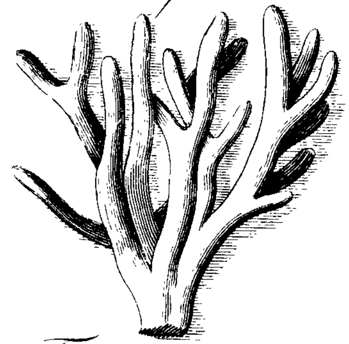

Fig. 3.

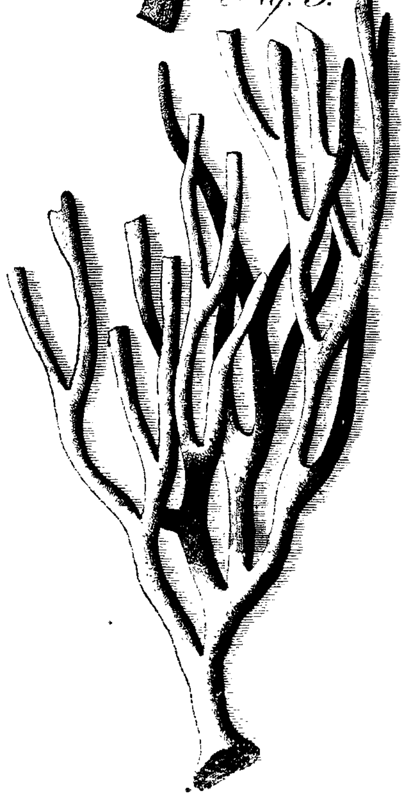

Fig. 1.

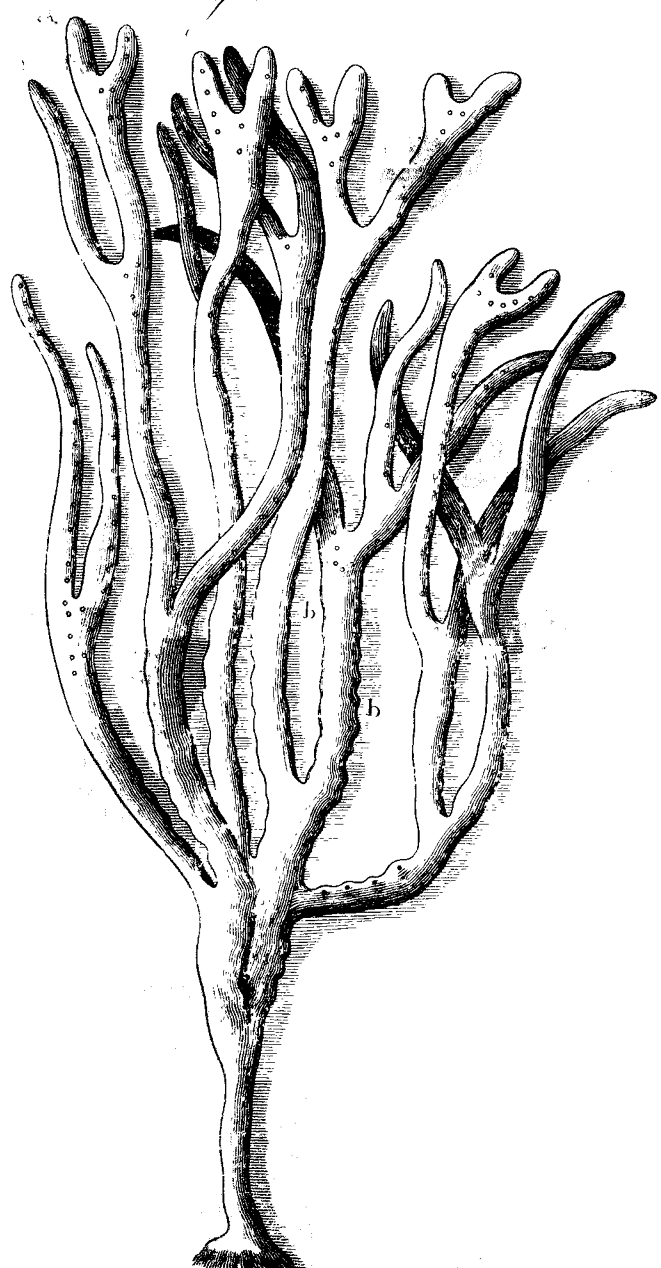

5. *Urens* or *tomentosa*, stinging sponge, or crumb of bread sponge, is of many forms, full of pores, very brittle and soft, and interwoven with very minute spines. It is full of small protuberances, with a hole in each, by which it sucks in and throws out the water. It is very common on the British coast, and is frequently seen surrounding fucuses. It is found also on the shores of North America, Africa, and in the East Indies. When newly taken out of the sea, it is of a bright orange colour, and full of gelatinous flesh; but when dry, it becomes whitish, and when broken has the appearance of crumb of bread. If rubbed on the hand, it will raise blisters; and if dried in an oven, its power of stinging is much increased, especially that variety of it which is found on the sea-coast of North America.

6. *Palmata*, palmated sponge, is like a hand with fingers a little divided at the top. The mouths are a little prominent, and irregularly disposed on the surface. It is found on the beach at Brighthelmstone. It is of a reddish colour, inclining to yellow, and of the same soft wooly texture with the spongia oculata, fig. 4.

7. *Coronata*, coronet sponge, is very small, consisting of a single tube surrounded at top by a crown of little spines. The tube is open at the top. The rays that compose the little crown are of a bright, shining pearl colour; the body is of a pale yellow. It has been found in the harbour of Emsworth, between Sussex and Hampshire.

8. *Botryoides*, grape sponge, is very tender and branched, as if in bunches: the bunches are hollow, and are made up of oblong oval figures having the appearance of grapes; and each bunch is open at top. This species is of a bright, shining colour. The openings at the top are evidently the mouths by which the animal imbibes and discharges moisture. When the surface is very much magnified, it appears covered with little masses of triple, equidistant, shining spines.

9. *Lacustris*, creeping sponge, has erect, cylindrical, and obtuse branches. It is found in lakes in Sweden and England.

10. *Fluviatilis*, river sponge, is green, erect, brittle, and irregularly disposed in numerous branches. It abounds in many parts of Europe, in the fresh rivers of Russia and England, but particularly in the river Thames. It scarcely exhibits any symptoms of life, is of a fishy smell: its pores or mouths are sometimes filled with green gelatinous globules. It differs very little from the lacustris.

So early as the days of Aristotle sponges were supposed to possess animal life; the persons employed in collecting them having observed them shrink when torn from the rocks, thus exhibiting symptoms of sensation. The same opinion prevailed in the time of Pliny: But no attention was paid to this subject till Count Marsigli examined them, and declared them vegetables. Dr Peysonell, in a paper which he sent to the Royal Society in the year 1752, and in a second in 1757, affirmed they were not vegetables, but the production of animals; and has accordingly described the animals, and the process which they performed in making the sponges. Mr Ellis, in the year 1762, was at great pains to discover these animals. For this purpose he dissected the spongia urens, and was surprised to find a great number of small worms of the genus of nereis or sea-scolopendra, which had pierced their way through the soft substance of the sponge in quest of a safe retreat. That this was really the case, he was fully assured of, by inspecting a number of specimens of the same sort of sponge, just fresh from the sea. He put them into a glass filled with sea-water; and then, instead of seeing any of the little animals which Dr Peysonell described, he observed the papillæ or small holes with which the papillæ are surrounded contract and dilate themselves. He examined another variety of the same species of sponge, and plainly perceived the small tubes inspire and expire the water. He therefore concluded, that the sponge is an animal, and that the ends or openings of the branched tubes are the mouths by which it receives its nourishment, and discharges its excrements.

SPONSORS, among Christians, are those persons who, in the office of baptism, answer or are sureties for the persons baptized.

SPONTANEOUS, a term applied to such motions of the body and operations of the mind as we perform of ourselves without any constraint.

SPOON BILL, in ornithology. See PLATALEA.

SPOONING, in the sea language, is said of a ship, which being under sail in a storm at sea, is unable to bear it, and consequently forced to go right before the wind.

SPORADES, among ancient astronomers, a name given to such stars as were not included in any constellation.

SPORADIC DISEASES, among physicians, are such as seize particular persons at any time or season, and in any place; in which sense they are distinguished from epidemical and endemical diseases.

SPOTS, in astronomy, certain places of the sun's or moon's disk, observed to be either more bright or dark than the rest; and accordingly called *faculæ* & *maculæ*. See ASTRONOMY-*Index*.

SPOTSWOOD (John), archbishop of St Andrew's in Scotland, was descended from the lairds of Spotswood in the Merse, and was born in the year 1565. He was educated in the university of Glasgow, and succeeded his father in the parsonage of Calder when but 18 years of age. In 1601 he attended Lodowick duke of Lennox as his chaplain, in an embassy to the court of France for confirming the ancient amity between the two nations, and returned in the ambassador's retinue through England. When he entered into the archbishopric of Glasgow, he found there was not 100 l. Sterling of yearly revenue left; yet such was his care for his successors, that he greatly improved it, and much to the satisfaction of his diocese. After having filled this see 11 years, he was raised to that of St Andrew's in 1615, and made primate and metropolitan of all Scotland. He presided in several assemblies for restoring the ancient discipline, and bringing the church of Scotland to some sort of uniformity with that of England. He continued in high esteem with king James I. nor was he less valued by king Charles I. who was crowned by him in 1633, in the abbey-church of Holyroodhouse. In 1635, upon the death of the earl of Kinnoul chancellor of Scotland, our primate was advanced to that post; but had scarcely held it four years, when the confusions beginning in Scotland, he was obliged to retire into England; and being broken with age, grief, and sickness, died at London in 1639, 1639, and was interred in Westminster-abbey. He wrote A History of the Church of Scotland from the year 203 to the reign of king James VI. in folio.

SPOUT, or *Water-Spout*. See *Water Spout*.

Spout-*Fish*. See Solen.

SPRAT (Dr Thomas), bishop of Rochester, was born in 1636. He had his education at Oxford, and after the Restoration entered into holy orders. He became fellow of the Royal Society, chaplain to George duke of Buckingham, and chaplain in ordinary to king Charles II. In 1667 he published the History of the Royal Society, and a Life of Mr Cowley; who, by his last will, left to his care his printed works and MSS. which were accordingly published by him. In 1668 he was installed prebendary of Westminster; in 1680, was appointed canon of Windsor; in 1683, dean of Westminster; and in 1684, consecrated to the bishopric of Rochester. He was clerk of the closet to king James II.; in 1685, was made dean of the chapel royal; and the year following, was appointed one of the commissioners for ecclesiastical affairs. In 1692 his lordship, with several other persons, was charged with treason by two men, who drew up an association, in which they whose names were subscribed declared their resolution to restore king James; to seize the princess of Orange, dead or alive; and to be ready with 30,000 men to meet king James when he should land. To this they put the name of Sancroft, Sprat, Marlborough, Salisbury, and others. The bishop was arrested, and kept at a messenger's, under a strict guard, for eleven days. His house was searched, and his papers seized, among which nothing was found of a treasonable appearance, except one memorandum, in the following words: *Thorough-paced doctrine*. Being asked at his examination the meaning of the words, he said that, about 20 years before, curiosity had led him to hear Daniel Burgess preach; and that being struck with his account of a certain kind of doctrine, which he said *entered at one ear, and pacing through the head went out at the other*, he had inserted the memorandum in his table-book, that he might not lose the substance of so strange a sermon. His innocence being proved, he was set at liberty, when he published an account of his examination and deliverance; which made such an impression upon him, that he commemorated it through life by an yearly day of thanksgiving. He lived to the 79th year of his age, and died May 20. 1713. His works, besides a few poems of little value, are, "The History of the Royal Society;" "The Life of Cowley;" "The Answer to Sorbiere;" "The History of the Rye-house Plot;" "The Relation of his own Examination;" and a volume of "Sermons." Dr Johnson says, "I have heard it observed, with great justness, that every book is of a different kind, and that each has its distinct and characteristical excellence."

Sprat, in ichthyology. See Clupea.

SPRAY, the sprinkling of the sea, which is driven from the top of a wave in stormy weather. It differs from spoon-drift, as being only blown occasionally from the broken surface of a high wave; whereas the latter continues to fly horizontally along the sea, without intermission, during the excess of a tempest or hurricane.

SPRING, in natural history, a fountain or source of water rising out of the ground.

Many have been the conjectures of philosophers concerning the origin of fountains, and great pains have been taken both by the members of the Royal Society and those of the Academy of Sciences at Paris, in order to ascertain the true cause of it. It was Aristotle's opinion, and held by most of the ancient philosophers after him, that the air contained in the caverns of the earth, being condensed by cold near its surface, was thereby changed into water; and that it made its way through, where it could find a passage. But we have no experience of any such transmutation of air into water.

Those who imagine that fountains owe their origin to waters brought from the sea by subterraneous ducts, give a tolerable account how they lose their saltness by percolation as they pass through the earth: but they find great difficulty in explaining by what power the water rises above the level of the sea to near the tops of mountains, where springs generally abound; it being contrary to the laws of hydrostatics, that a fluid should rise in a tube above the level of its source. However, they have found two ways whereby they endeavour to extricate themselves from this difficulty. The one is that of Des Cartes, who imagines, that after the water is become fresh by percolation, it is raised out of the caverns of the earth in vapour towards its surface; where meeting with rocks near the tops of mountains in the form of arches or vaults, it sticks to them, and runs down their sides, (like water in an alembic), till it meets with proper receptacles, from which it supplies the fountains. Now this is a mere hypothesis, without foundation or probability: for, in the first place, we know of no internal heat of the earth to cause such evaporation; or if that were allowed, yet it is quite incredible that there should be any caverns so smooth and void of protuberances as to answer the ends of an alembic, in collecting and condensing the vapours together in every place where fountains arise. There are others (as Varenius, &c.) who suppose that the water may rise through the pores of the earth, as through capillary tubes by attraction. But hereby they show, that they are quite unacquainted with what relates to the motion of a fluid through such tubes: for when a capillary tube opens into a cavity at its upper end, or grows larger and larger, so as to cease to be capillary at that end, the water will not ascend through that tube into the cavity, or beyond where the tube is capillary; because that part of the periphery of the cavity, which is partly above the surface of the water and partly below it, is not of the capillary kind. Nay, if the cavity is continually supplied with water, it will be attracted into the capillary tube, and run down it as through a funnel, if the lower end is immerged in the same fluid, as in this case it is supposed to be.

It has been a generally received opinion, and much espoused by Mariotte (a diligent observer of nature), that the rise of springs is owing to the rains and melted snow. According to him, the rain-water which falls upon the hills and mountains, penetrating the surface, meets with clay or rocks contiguous to each other; along which it runs, without being able to penetrate them, till, being got to the bottom of the mountain, or to a considerable distance from the top, it breaks out of the ground, and forms springs.

In order to examine this opinion, Mr Perrault, De la Hire, and D. Sideleau, endeavoured to make an estimate

Spring. estimate of the quantity of rain and snow that falls in the space of a year, to see whether it would be sufficient to afford a quantity of water equal to that which is annually discharged into the sea by the rivers. The result of their inquiries was, that the quantity of rain and snow which fell in a year into a cylindrical vessel would fill it (if secured from evaporating) to the height of about nineteen inches. Which quantity D. Sideleau showed was not sufficient to supply the rivers; for that those of England, Ireland, and Spain, discharge a greater quantity of water annually, than the rain, according to that experiment, is able to supply. Besides which, another observation was made by them at the same time, viz. that the quantity of water raised in vapour, one year with another, amounted to about thirty-two inches, which is thirteen more than falls in rain: a plain indication that the water of fountains is not supplied by rain and melted snow.

Thus the true cause of the origin of fountains remained undiscovered, till Dr Halley, in making his celestial observations upon the tops of the mountains at St Helena, about 800 yards above the level of the sea, found, that the quantity of vapour which fell there (even when the sky was clear) was so great, that it very much impeded his observations, by covering his glasses with water every half quarter of an hour; and upon that he attempted to determine by experiment the quantity of vapour exhaled from the surface of the sea, as far as it rises from heat, in order to try whether that might be a sufficient supply for the water continually discharged by fountains. The process of his experiment was as follows: He took a vessel of water salted to the same degree with that of sea water, in which he placed a thermometer; and by means of a pan of coals brought the water to the same degree of heat, which is observed to be that of the air in our hottest summer; this done, he fixed the vessel of water with the thermometer in it to one end of a pair of scales, and exactly counterpoised it with weights on the other: then, at the end of two hours, he found, by the alteration made in the weight of the vessel, that about a sixtieth part of an inch of the depth of the water was gone off in vapour; and therefore, in twelve hours, one-tenth of an inch would have gone of. Now this accurate observer allows the Mediterranean Sea to be forty degrees long, and four broad, (the broader parts compensating for the narrower, so that its whole surface is 160 square degrees); which, according to the experiment, must yield at least 5,280,000,000 tons of water: in which account no regard is had to the wind and the agitation of the surface of the sea, both which undoubtedly promote the evaporation.

It remained now to compare this quantity of water with that which is daily conveyed into the same sea by the rivers. The only way to do which was to compare them with some known river; and accordingly he takes his computation from the river Thames; and, to avoid all objections, makes allowances, probably greater than what were absolutely necessary.

The Mediterranean receives the following considerable rivers, viz. the Iberus, the Rhone, the Tyber, the Po, the Danube, the Niester, the Borysthenes, the Tanais, and the Nile. Each of these he supposes to bring down ten times as much water as the Thames, whereby he allows for smaller rivers which fall into the same sea. The Thames, then, he finds by mensuration to discharge about 20,300,000 tons of water a-day. If therefore the above-said nine rivers yield ten times as much water as the Thames doth, it will follow, that all of them together yield but 1827 millions of tons in a day, which is but little more than one-third of what is proved to be raised in vapour out of the Mediterranean in the same time. We have therefore from hence a source abundantly sufficient for the supply of fountains.

Now having found that the vapour exhaled from the sea is a sufficient supply for the fountains, he proceeds in the next place to consider the manner in which they are raised; and how they are condensed into water again, and conveyed to the sources of springs.

In order to this he considers, that if an atom of water was expanded into a shell or bubble, so as to be ten times as big in diameter as when it was water, that atom would become specifically lighter than air; and therefore would rise so long as the warmth which first separated it from the surface of the water should continue to distend it to the same degree; and consequently, that vapours may be raised from the surface of the sea in that manner, till they arrive at a certain height in the atmosphere, at which they find air of equal specific gravity with themselves. Here they will float till, being condensed by cold, they become specifically heavier than the air, and fall down in dew; or being driven by the winds against the sides of mountains (many of which far surpass the usual height to which the vapours would of themselves ascend), are compelled by the stream of the air to mount up with it to the tops of them; where being condensed into water, they presently precipitate, and gleeting down by the crannies of the stones, part of them enters into the caverns of the hills; which being once filled, all the overplus of water that comes thither runs over by the lowest place, and breaking out by the sides of the hills forms single springs. Many of these running down by the valleys between the ridges of the hills, and coming to unite, form little rivulets or brooks: many of these again meeting in one common valley, and gaining the plain ground, being grown less rapid, become a river; and many of these being united in one common channel, make such streams as the Rhine and the Danube; which latter, he observes, one would hardly think to be a collection of water condensed out of vapour, unless we consider how vast a tract of ground that river drains, and that it is the sum of all those springs which break out on the south side of the Carpathian mountains, and on the north side of the immense ridge of the Alps, which is one continued chain of mountains from Switzerland to the Black Sea.

Thus one part of the vapours which are blown on the land is returned by the rivers into the sea from whence it came. Another part falls into the sea before it reaches the land; and this is the reason why the rivers do not return so much water into the Mediterranean as is raised in vapour. A third part falls on the low lands, where it affords nourishment to plants; yet it does not rest there, but is again exhaled in vapour by the action of the sun, and is either carried by the winds to the sea to fall in rain or dew there, or else to the mountains to become the sources of springs.

However, it is not to be supposed that all fountains are owing to one and the same cause; but that some proceed from rain and melted snow, which, subsiding through

Spring.

through the surface of the earth, makes its way into certain cavities, and thence issues out in the form of springs; because the waters of several are found to increase and diminish in proportion to the rain which falls: that others again, especially such as are salt, and spring near the sea-shore, owe their origin to sea-water percolated through the earth; and some to both these causes: though without doubt most of them, and especially such as spring near the tops of high mountains, receive their waters from vapours, as before explained.

This reasoning of Dr Halley's is confirmed by more recent observations and discoveries. It is now found, that though water is a tolerable conductor of the electric fluid, dry earth is an electric *per se*, consequently the dry land must always be in an electrified state compared with the ocean, unless in such particular cases as are mentioned under the article EARTHQUAKE, n° 82. It is also well known, that such bodies as are in an electrified state, whether *plus* or *minus*, will attract vapour, or other light substances that come near them. Hence the vapours that are raised from the ocean must necessarily have a tendency to approach the land in great quantity, even without the assistance of the wind, though this last must undoubtedly contribute greatly towards the same purpose, as Dr Halley justly observes. In like manner, the higher grounds are always in a more electrified state than the lower ones: and hence the vapours having once left the ocean and approached the shore, are attracted by the high mountains; of which Mr Pennant gives an instance in Snowdon. Hence we may see the reason why springs are so common in the neighbourhood of mountains, they being so advantageously formed in every respect for collecting and condensing the vapours into water.

The heat of springs is generally the same with the mean temperature of the atmosphere. The mean temperature of the south of England is 48°; in Scotland, near Edinburgh, it is 45°; in the north of Ireland it is 48°, and on the south coast about 51°. At Upsal, in Sweden, it is 43°, and in Paris 53°. According to accurate experiments made by eminent philosophers, the heat of the springs in these different countries corresponds with the medium temperature. We have not heard that similar experiments have been made in other countries, or we should have been careful to collect them. We do not, however, doubt but they have been made in most countries of Europe; yet we suspect little attention has been paid to this subject within the tropical regions.

Though this coincidence of the heat of springs with the mean temperature of the climate where they flow, seems to be a general fact, yet it admits of many exceptions. In many parts of the world there are springs which not only exceed the mean temperature, but even the strongest meridian heat ever known in the torrid regions. The following table will give a distinct notion of the degrees of heat which different springs have been found to possess, according to the experiments of philosophers. It is necessary to remark, that experiments made upon the same springs, made by different persons, vary a little from one another, which may be owing to many accidents easily accounted for. Where this is the case, we shall mention both the lowest and highest degree of heat which has been ascribed to the same spring, according to Fahrenheit's thermometer.

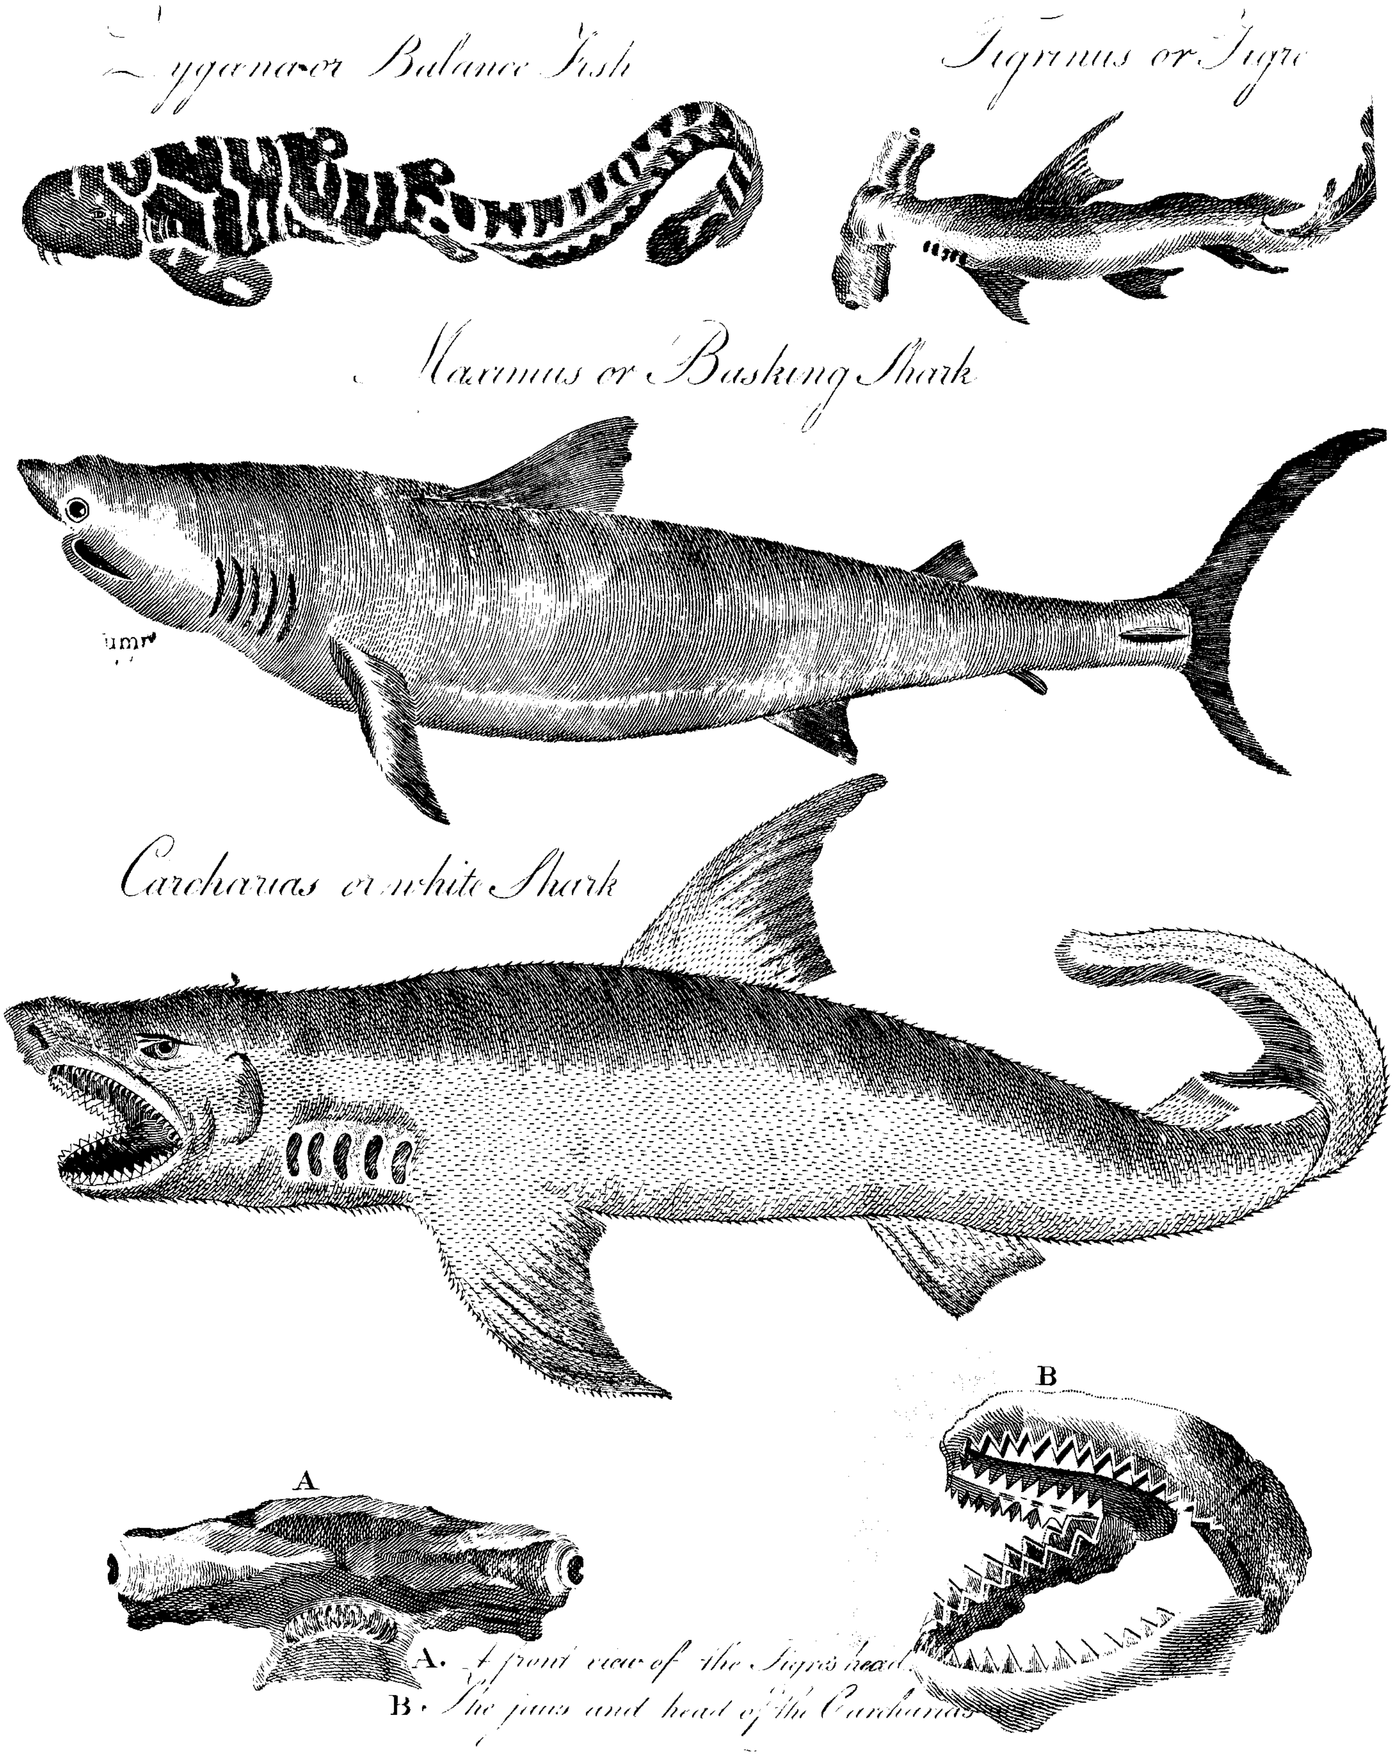
In cold countries, where congelation takes place, the heat of the earth is considerably above the freezing point, and continues so through the whole year. From experiments that have been made in mines and deep pits, it appears that this heat is uniform and stationary at a certain depth. But as the heat of these springs far exceeds the common heat of the internal parts of the earth, it must be occasioned by causes peculiar to certain places; but what these causes are it is no easy matter to determine. We are certain, indeed, that hot springs receive their heat from some subterranean cause; but it is a matter of difficulty to investigate how this heat is produced and preserved. Theories, however, have been formed on this subject. The subterranean heat has been ascribed to the electrical fluid, and to a great body of fire in the centre of the earth: But we suspect that the nature of the electrical fluid and its effects are not sufficiently understood. As to the supposition that the heat of springs is owing to a central fire, it is too hypothetical to require any refutation. From what then does this heat originate, and whence is the fuel which has produced it for so many ages? To enable us to answer these questions with precision, more information is necessary than we have hitherto obtained respecting the structure of the internal parts of the earth. It is peculiarly requisite that we should be made acquainted with the fossils which are most common in those places where hot springs abound. We should then perhaps discover that hot springs always pass thro' bodies of a combustible nature. It is well known to chemists, that when water is mixed with the vitriolic acid, a degree of heat is produced superior to that of boiling water. It is also an established fact, that when water meets with pyrites, that is, a mixture of sulphur and iron, a violent inflammation takes place. If, therefore, we could prove that these materials exist in the strata from which hot springs are derived, we should be enabled to give a satisfactory account of this curious phenomenon. As some apology for this supposition, we may add, that most of the hot springs mentioned above have been found by analysis to be impregnated with sulphur, and some of them with iron. It must, however, be acknowledged, that the hot springs of Iceland, which are 212°, the heat of boiling water, according to an accurate analysis of their contents by the ingenious Dr Black, were neither found to contain iron nor sulphur. It will therefore, perhaps, be necessary that we should wait with patience, and continue to collect facts, till the sciences of chemistry and mineralogy shall be so far advanced as to enable us to form a permanent theory on this subject.

Gray's Letters from Germany and Switzerland.

Springs are of different kinds. Some are perennial, or



Zygaena or Balance Fish
Tigrinus or Tigre
Maximus or Basking Shark
Carcharias or white Shark
B
A
A. A front view of the Tigre's head
B. The jaws and head of the Carcharias

or continue to flow during the whole year; others flow only during the rainy seasons; some ebb and flow. At Torbay there is one of this kind, which ebbs and flows five or six inches every hour. There is another near Coriso in Italy, which ebbed and flowed three times a day in the time of Pliny, and continues to do so still. A spring near Henly sometimes flows for two years together, and then dries up for an equal period. The cause of this is explained under the article HYDROSTATICS, n° 26. For the ingredients found in springs, see *MINERAL Waters*, and WATER.

SPRING, in mechanics, denotes a thin piece of tempered steel, or other elastic substance, which being wound up serves to put machines in motion by its elasticity, or endeavours to unbend itself; such is the spring of a watch, clock, or the like.

SPRING, *Ver*, in cosmography, denotes one of the seasons of the year; commencing, in the northern parts of the world, on the day the sun enters the first degree of Aries, which is about the 10th day of March, and ending when the sun leaves Gemini; or, more strictly and generally, the spring begins on the day when the distance of the sun's meridian altitude from the zenith, being on the increase, is at a medium between the greatest and least. The end of the spring coincides with the beginning of summer. See SUMMER.

SPRING Tide. See ASTRONOMY-*Index*, and TIDE.

Burning SPRINGS. See *BURNING-Springs*.

SPRINGER, or *SPRING-Bok*, in zoology. See CAPRA.

SPRIT, a small boom or pole which crosses the sail of a boat diagonally, from the mast to the upper hindmost corner of the sail, which it is used to extend and elevate; the lower end of the sprit rests in a sort of wreath or collar called the *smotter*, which encircles the mast in that place.

SPRITSAIL. See SAIL and SHIP.

SPRITSAIL-Topsail. See SAIL and SHIP.

SPRUCE-TREE. See PINUS.

SPRUCE-Beer, a cheap and wholesome liquor, which is thus made: Take of water 16 gallons, and boil the half of it. Put the water thus boiled, while in full heat, to the reserved cold part, which should be previously put into a barrel or other vessel; then add 16 pounds of treacle or molasses, with a few table spoonfuls of the essence of spruce, stirring the whole well together; add half a pint of yeast, and keep it in a temperate situation, with the bung hole open, for two days, till the fermentation be abated. Then close it up or bottle it off, and it will be fit for being drunk in a few days afterwards. In North America, and perhaps in other countries, where the black and white spruce-firs abound, instead of adding the *essence* of the spruce at the same time with the molasses, they make a decoction of the leaves and small branches of these trees, and find the liquor equally good. It is a powerful antiscorbutic, and may prove very useful in long sea voyages.

SPUNGE, or SPONGE. See SPONGIA.

SPUNGING, in gunnery, the cleaning of the inside of a gun with a spunge, in order to prevent any sparks of fire from remaining in it, which would endanger the life of him that should load it again.

SPUN-YARN, among sailors, is a kind of line made from rope yarn, and used for seizing or fastening things together.

SPUNK, in botany. See BOLETUS.

SPUR, a piece of metal consisting of two branches encompassing a horseman's heel, and a rowel in form of a star, advancing out behind to prick the horse.

SPUR-Winged Water Hen. See PARRA.

SPURGE, in botany. See EUPHORBIA.

SPURGE-Laurel. See DAPHNE.

SPURREY, in botany. See SPERGULA.

SPY, a person hired to watch the actions, motions, &c. of another; particularly what passes in a camp. When a spy is discovered, he is hanged immediately.

SQUADRON, in military affairs, denotes a body of horse whose number of men is not fixed; but is usually from 100 to 200.

SQUADRON of Ships, either implies a detachment of ships employed on any particular expedition, or the third part of a naval armament.

SQUADS, in a military sense, are certain divisions of a company into so many squads, generally into three or four. The use of forming companies into as many squads of inspection as it has serjeants and corporals, is proved by those regiments who have practised that method; as by it the irregularity of the soldiers is considerably restrained, their dress improved, and the discipline of the regiment in general most remarkably forwarded. Every officer should have a roll of his company by squads.

SQUALL, a sudden and violent blast of wind, usually occasioned by the interruption and reverberation of the wind from high mountains. These are very frequent in the Mediterranean, particularly that part of it which is known by the name of the *Levant*, as produced by the repulsion and new direction which the wind meets with in its passage between the various islands of the Archipelago.

SQUALUS, SHARK, in ichthyology; a genus arranged by Linnæus under the class of *amphibia*, and the order of *nantes*, but by Gmelin referred to the class of *pisces*, and order of *chondropterygii*. The head is obtuse; on the sides of the neck there is from 4 to 7 semilunar spiracles. The eyes are oblong, vertical, half covered, and before the *foramen temporale*. The mouth is situated in the anterior and lower part of the head, and is armed with several rows of teeth, which are serrated, acute, partly moveable and partly fixed, and unequal in form. The body is oblong, tapering and rough, with very tender prickles. The ventral fins are much less than the pectoral, and are situated round the anus and genitals. There are 32 species; the isabella canicula or greater dog-fish; catulus or smaller dog-fish; stellaris; galeus or tope; mustelus or smooth hound; cirratus; barbatus or barbu; tigrinus or tigre; Africanus or galonré; ocellatus or oeillé; zygæna or balance-fish; tiburo or pantouflier of Broussonet; griseus or griset; vulpes or sea fox; longicaudus; glaucus or blue shark; cornubius, porbeagle, or beaumaris-shark; cinereus or perlon; maximus; carcharias or white shark; pristis or scie; spinosus or bouelé; acanthias or picked dog fish; fernandinus; spinax or sagre; squamosus or ecailleux; centrina or humantin; indicus; Americanus or liche; squatina or angel fish; massasa; and kumal. The following are the most remarkable:

1 The *isabella* has a wrinkly spotted skin, and the anterior dorsal fin is perpendicular to the abdominal fins. The body is somewhat flat; the head short, large, and obtuse.

Squalus.

obtufe. The teeth are difpofed in fix rows, compreffed, fhort, and triangular, having a notch on each fide of their bafes. The eyes are funk; the iris is of a copper colour, and the pupil is black and oblong. The fins of the back are almoft fquare; the caudal fin is divided into two lobes and the lateral line is parallel to the back. The upper part of the body is of a reddifh afh-colour, with blackifh fpots difpofed irregularly. The under part is of a dirty white hue. This fpecies is found near New Zealand, and is about 2½ feet long.

2. *Canicula*, greater dog-fifh, or fpotted fhark, is diftinguifhed by large noftrils, which are covered by a lobe and worm-fhaped flap, or by the pofition of the anal fin, which is at an equal diftance from the anus and tail. The body is fpotted; the head is fmall, with a fhort fnout; the eyes are oblong; the iris whitifh; the mouth is large and oblong, armed with three rows of teeth; the tongue is cartilaginous; the anus is before the middle of the body; the firft dorfal fin is behind the ventral fins; the other, which is lefs, is almoft oppofite the anal fin; the caudal fin is narrow and marginated. This fpecies is found in almoft every fea, is about four feet long, extremely voracious, generally feeding on fifhes, and is long lived. The fkin, which is fpotted like a leopard's, is ufed when dried for various purpofes.

3. *Catulus*, fmaller dog fifh, has a large head; the pupil of the eyes is black; the iris white; the fnout is of a bright hue; the mouth, which is large, is fituated between the noftrils, and is armed with four rows of teeth, ferrated with three points bent inwards; thofe in the middle between the two mandibles are longer than the reft. The tongue is broad and fmooth; the fpiracles are five; the back is tapering and yellowifh; the fides are fomewhat compreffed; the tail longer than the body, and the caudal fin is narrow and marginated; the anterior anal and dorfal fins are behind the ventral; the pofterior dorfal fin is oppofite to the anal. It inhabits the Mediterranean, Northern, and Indian Ocean, and is two or three feet long.

4. *Stellaris*, or greater cat fifh. The head is marked with points; the abdominal fins are united and fharp at the apex; the dorfal fins extend almoft to the tail; the fkin is reddifh, marked with black fpots of different fizes, and is of a dirty afh colour below. It is from two to fix feet long; refembles the canicula, but diftinguifhed by larger and fewer fpots, by a fnout fomewhat longer, a tail fomewhat fhorter, and noftrils almoft fhut. It brings forth 19 or 20 young at a time. It inhabits the European feas, living chiefly on fhell fifh, mollufcæ, and other fmall fifhes. The dorfal fins are equal; the anterior one being behind the middle of the body, and the pofterior one being a little behind the anal.

5. *Tigrinus*, or tigre, is about 15 feet long; the body is long, of unequal thicknefs, black, interfperfed with white ftripes and fpots, irregularly and tranfverfely.— The head is large; the mouth low and tranfverfe, the upper jaw having two curls; the upper lip is thick and prominent; there are five fpiracles on each fide, the two laft being united fo as to give the appearance only of four; the mandibles are armed with very fmall pointed teeth; the tongue is fhort and thick; the eyes fmall and oblong; the pupil azure coloured; the iris black. The abdomen is broad; the pectoral fins are broad, and rounded at the extremity. The anterior dorfal is oppofite to the ventral fins, and the pofterior dorfal fin to the anal. The tail is compreffed on both fides, and the fin which terminates it is hollow. The tigrinus is found in the Indian Ocean, and lives chiefly on fhell fifh. See Plate CCCCLXXVI. fig. 1.

7. *Zygæna, marteau*, or balance-fifh, is frequently fix feet long, and weighs 500 lbs. The head is elongated on each fide; the fore part is bent back, and convex both above and below. At the extremities of the elongated part are the eyes, which are large, prominent, and directed downwards; the iris is of a golden colour; the mouth is arched, and near the beginning of the trunk. It has a horrible appearance from the teeth, which are arranged in three or four rows, and are broad, pointed, and ferrated on both fides. The tongue is thick, broad, and like a man's. The trunk is long and tapering: the fins are femicircular on the margin, and black at the bafis; the ventral fins are feparate; the anal and pofterior dorfal fins are fmall; the anterior dorfal fin is large, and near the head; the caudal is long.— This fpecies inhabits the Mediterranean Sea and the Indian Ocean. It is one of the moft voracious of the whole tribe. See fig. 2.

8. *Vulpes*, or fea-fox, is moft remarkable for the great length of its tail, the body being about feven feet and the tail fix feet long. The head is fhort and conical; the eyes are large; the jaws are armed in a dreadful manner with three rows of triangular, compreffed, and pointed teeth; the tongue is blunt; the lateral line is ftraight. The anterior dorfal fin is placed about the middle of the back; the pofterior, which confifts of two pointed lobes, is oppofite to the anal fin; the ventral fins are very near one another; the anal is acuminated; the inferior lobe of the tail is about a foot long; the upper, which is fhaped like a fcythe, is five times longer. This fpecies inhabits the Mediterranean, the coaft of Scotland, and England. It is covered with fmall fcales; its back is afh-coloured, belly whitifh. It is extremely voracious. The ancients ftyled this fifh αλωπηξ, and *vulpes*, from its fuppofed cunning. They believed, that when it had the misfortune to have taken a bait, it fwallowed the hook till it got at the cord, which it bit off, and fo efcaped.

6. *Glaucus*, or blue fhark, is about feven feet long. The colour of the back is a fine blue; the belly a filvery white; the head is flat; the eyes fmall and roundifh; the teeth are almoft triangular, elongated, and pointed, but not ferrated. The anus is very near the tail; the anterior dorfal fin is fituated before the ventral fins, about the middle of the body, and is almoft triangular; the pofterior dorfal fin is equal to the anal fin, and is placed nearer the tail; the pectoral fins are large, long, and marginated; and the ventral are blue above and white below; the caudal is blue, divided into two lobes, of which the fuperior is much longer than the inferior lobe. This fpecies is frequent in every fea, and is fierce, but not very deftructive in the northern feas.

10. The *maximus*, bafking fhark, or the fun-fifh of the Irifh. This fpecies has been long known to the inhabitants of the fouth and weft of Ireland and Scotland, and thofe of Caernarvonfhire and Anglefea; but having never been confidered in any other than a commercial view, is defcribed by no Englifh writer except Mr Pennant; and, what is worfe, miftaken for and confounded with the luna of Rondeletius, the fame

Squalus.

that our Engliſh writers call the ſun-fiſh. The Iriſh and Welſh give it the ſame name, from its lying as if to ſun itſelf on the ſurface of the water; and for the ſame reaſon Mr Pennant calls it the baſking ſhark. It was long taken for a ſpecies of whale, till Mr Pennant pointed out the bronchial orifices on the ſides, and the perpendicular ſite of the tail. Theſe are migratory fiſh, or at leaſt it is but in a certain number of years that they are ſeen in multitudes on the Welſh ſeas, though in moſt ſummers a ſingle, and perhaps a ſtrayed fiſh appears. They inhabit the northern ſeas, even as high as the arctic circle. They viſited the bays of Caernarvonſhire and Angleſea in vaſt ſhoals in the ſummers of 1756 and a few ſucceeding years, continuing there only the hot months; for they quitted the coaſt about Michaelmas, as if cold weather was diſagreeable to them. Some old people ſay they recollect the ſame ſort of fiſh viſiting theſe ſeas in vaſt numbers about 40 years ago. They appear in the Frith of Clyde, and among the Hebrides, in the month of June, in ſmall droves of ſeven or eight, but oftener in pairs. They continue in thoſe ſeas till the latter end of July, when they diſappear.

Fig. 3.

They have nothing of the fierce and voracious nature of the ſhark kind, and are ſo tame as to ſuffer themſelves to be ſtroked; they generally lie motionleſs on the ſurface, commonly on their bellies, but ſometimes, like tired ſwimmers, on their backs. Their food ſeems to conſiſt entirely of ſea plants, no remains of fiſh being ever diſcovered in the ſtomachs of numbers that were cut up, except ſome green ſtuff, the half digeſted parts of algæ, and the like. Linnæus ſays it feeds on meduſæ.

At certain times, they are ſeen ſporting on the waves, and leaping with vaſt agility ſeveral feet out of the water. They ſwim very deliberately, with the dorſal fins above water. Their length is from three to twelve yards, and ſometimes even longer. Their form is rather ſlender, like others of the ſhark kind. The upper jaw is much longer than the lower, and blunt at the end. The tail is very large, and the upper part remarkably longer than the lower. The colour of the upper part of the body is a deep leaden; the belly white. The ſkin is rough like ſhagreen, but leſs ſo on the belly than the back. In the mouth, towards the throat, is a very ſhort ſort of whale-bone. The liver is of a great ſize, but that of the female is the largeſt; ſome weigh above 1000 pounds, and yield a great quantity of pure and ſweet oil, fit for lamps and alſo much uſed to cure bruiſes, burns, and rheumatic complaints. A large fiſh has afforded to the captors a profit of 20 l. They are viviparous; a young one about a foot in length being found in the belly of a fiſh of this kind. The meaſurements of one found dead on the ſhore of Loch Ranza in the iſle of Arran were as follows: The whole length, 27 feet 4 inches; firſt dorſal fin, 3 feet; ſecond, 1 foot; pectoral fin, 4 feet; ventral, 2 feet; the upper lobe of the tail, 5 feet; the lower, 3.

They will permit a boat to follow them, without accelerating their motion till it comes almoſt within contact when a harponeer ſtrikes his weapon into them, as near to the gills as poſſible. But they are often ſo inſenſible as not to move till the united ſtrength of two men have forced in the harpoon deeper. As ſoon as they perceive themſelves wounded, they fling up their tail and plunge headlong to the bottom; and frequently coil the rope round them in their agonies, attempting to diſengage the harpoon by rolling on the ground, for it is often found greatly bent. As ſoon as they diſcover that their efforts are in vain, they ſwim away with amazing rapidity, and with ſuch violence, that there has been an inſtance of a veſſel of 70 tons having been towed away againſt a freſh gale. They ſometimes run off with 200 fathoms of line, and with two harpoons in them; and will employ the fiſhers for 12, and ſometimes for 24 hours, before they are ſubdued. When killed, they are either hauled on ſhore, or, if at a diſtance from land, to the veſſel's ſide. The liver (the only uſeful part), is taken out, and melted into oil in kettles provided for that purpoſe. A large fiſh will yield eight barrels of oil, and two of worthleſs ſediment.

Squalus.

11. *Carcharias, requin*, or white ſhark, is often 30 feet long, and according to Gillius weighs 4000 pounds. The mouth of this fiſh is ſometimes furniſhed with a ſix-fold row of teeth, flat, triangular, and exceedingly ſharp at their edges, and finely ſerrated. Mr Pennant had one rather more than an inch and a half long. Grew ſays, that thoſe in the jaws of a ſhark two yards in length are not half an inch; ſo that the fiſh to which this tooth belonged muſt have been ſix yards long, provided the teeth and body keep pace in their growth.

This dreadful apparatus, when the fiſh is in a ſtate of repoſe, lies quite flat in the mouth; but when he ſeizes his prey, he has power of erecting them by the help of a ſet of muſcles that join them to the jaw. The mouth is placed far beneath; for which reaſon theſe, as well as the reſt of the kind, are ſaid to be obliged to turn on their backs to ſeize their prey; which is an obſervation as ancient as the days of Pliny. The eyes are large; the back broad, flat, and ſhorter than that of other ſharks. The tail is of a ſemilunar form, but the upper part is longer than the lower. It has vaſt ſtrength in the tail, and can ſtrike with great force; ſo that the ſailors inſtantly cut it off with an axe as ſoon as they draw one on board. The pectoral fins are very large, which enables it to ſwim with great ſwiftneſs. The colour of the whole body and fins is a light aſh. The ancients were acquainted with this fiſh; and Oppian gives a long and entertaining account of its capture. Their fleſh is ſometimes eaten, but is eſteemed coarſe and rank.—They are the dread of the ſailors in all hot climates, where they conſtantly attend the ſhips in expectation of what may drop over-board: a man that has that misfortune periſhes without redemption; they have been ſeen to dart at him like gudgeons at a worm. A maſter of a Guinea ſhip informed Mr Pennant, that a rage of ſuicide prevailed among his new-bought ſlaves, from a notion the unhappy creatures had, that after death they ſhould be reſtored again to their families, friends, and country. To convince them at leaſt that they ſhould not reanimate their bodies, he ordered one of their corpſes to be tied by the heels to a rope and lowered into the ſea; and though it was drawn up again as faſt as the united force of the crew could be exerted, yet in that ſhort ſpace the ſharks had devoured every part but the feet, which were ſecured at the end of the cord.

Fig. 4.

Swimmers very often periſh by them; ſometimes

they

Squalus. they lose an arm or leg, and sometimes are bit quite asunder, serving but for two morsels for this ravenous animal: a melancholy tale of this kind is related in a West-India ballad, preserved in Dr Percy's Relics of ancient English Poetry.

This species inhabits the abyss of the ocean, and only appears on the surface when allured by its prey. It is the most voracious of all animals, not even it is said sparing its own offspring, and often swallowing its prey entire. At the famous naval battle of the 12th of April 1782, when the Cæsar, one of the French ships of the line, was set on fire, the sailors threw themselves into the sea, Sir Charles Douglas observed great numbers of these sharks, which lay between the French and British fleets, instantly seize on the unhappy victims. He several times saw two of them disputing about their prey, each seizing a leg, and at length disappearing, dragging the body along with them. Notwithstanding the continued roar of artillery, he heard distinctly the cries of these unhappy men.

12. *Pristice scie*, or saw-fish, is sometimes 15 feet long, smooth, black on the upper parts, ash coloured on the sides, and white underneath. The head is flat and conical; the beak or snout projecting from the nose is about five feet long, covered with a coriaceous skin, and armed on each side, generally with 24 long, strong, and sharp-pointed teeth; but the number varies with age. The teeth are granulated; the eyes large, the iris of a golden colour, and the spiracles five. The anterior dorsal fin corresponds to those of the belly; the posterior is situated in the middle, between the former and apex of the tail; the pectoral fins are broad and long; the caudal is shorter than in the other species. It inhabits all the seas from Greenland to Brazil: and is found also in the Indian Ocean. It is harmless.

13. *Spinax*, *sagre*, or picked dog-fish, takes its name from a strong and sharp spine placed just before each of the back-fins, distinguishing it at once from the rest of the British sharks. The nose is long, and extends greatly beyond the mouth, but is blunt at the end. The teeth are disposed in two rows, are small and sharp, and bend from the middle of each jaw towards the corners of the mouth. The back is of a brownish ash-colour; the belly white.—It grows to the weight of about 20 pounds. This species swarms on the coasts of Scotland, where it is taken, split, and dried; and is a food among the common people. It forms a sort of inland commerce, being carried on women's backs 14 or 16 miles up the country, and sold or exchanged for necessaries.

14. *Squatina*, angel-fish, is from six to eight feet long, has a large head; teeth broad at their base, but slender and very sharp above, and disposed in five rows all round the jaws. Like those of all sharks, they are capable of being raised or depressed by means of muscles uniting them to the jaws, not being lodged in sockets as the teeth of cetaceous fish are. The back is of a pale ash-colour, and very rough; along the middle is a prickly tuberculated line: the belly is white and smooth. The pectoral fins are very large, and extend horizontally from the body to a great distance; they have some resemblance to wings, whence its name. The ventral fins are placed in the same manner, and the double penis is placed in them; which forms another character of the males in this genus.

This is the fish which connects the genus of rays and sharks, partaking something of the character of both; yet is an exception to each in the situation of the mouth, which is placed at the extremity of the head. It is a fish not unfrequent on most British coasts, where it prowls about for prey like others of the kind. It is extremely voracious; and, like the ray, feeds on flounders and flat fish, which keep at the bottom of the water. It is extremely fierce, and dangerous to be approached. Mr Pennant mentions a fisherman whose leg was terribly torn by a large one of this species, which lay within his nets in shallow water, and which he went to lay hold of incautiously. The aspect of these, as well as the rest of the genus, have much malignity in them: their eyes are oblong, and placed lengthwise in their head, sunk in it, and overhung by the skin, and seem fuller of malevolence than fire. Their skin is very rough; the ancients made use of it, to polish wood and ivory, as we do at present that of the greater dog-fish. The flesh is now but little esteemed on account of its coarseness and rankness; yet Archestratus (as quoted by Athenæus, p. 319.), speaking of the fish of Miletus, gives this the first place, in respect to delicacy, of the whole cartilaginous tribe. They grow to a great size; being sometimes near an hundred weight.

Sharks are seldom destructive in the temperate regions; it is in the torrid zone that their ravages are most frequent. In the west Indies accidents happen from them almost every day.

"During the American war in 1780, while the Pallas frigate was lying in Kingston harbour, a young North American jumped overboard one evening to make his escape, and perished by a shark in a shocking manner. Moseley on Tropical Diseases.

"He had been captured in a small vessel, lost all his property, and was detained by compulsion in the English navy, to serve in a depredatory war against his country. But he, animated with that spirit which pervaded every bosom in America, resolved, as soon as he arrived at some port, to release himself from the mortifying state of employing his life against his country, which, as he said when dying, he was happy to lay down, as he could not employ it against her enemies.

"He plunged into the water; the Pallas was a quarter of a mile from the shore. A shark perceived him, and followed him, very quietly, till he came to a state of rest, near the shore; where, as he was hanging by a rope, that moored a vessel to a wharf, scarcely out of his depth, the shark seized his right leg, and stripped the flesh entirely away from the bones, and took the foot off at the ancle. He still kept his hold, and called to the people in the vessel near him, who were standing on the deck and saw the affair. The shark then seized his other leg, which the man by his struggling disengaged, from his teeth, but with the flesh cut through down to the bone, into a multitude of narrow slips. The people in the vessel threw billets of wood into the water, and frightened the shark away. The young man was brought on shore. Dr Moseley was called to him; but he had lost so much blood before any assistance could be given him, that he expired before the mangled limbs could be taken off.

"A few weeks before this accident happened, a shark, of 12 feet in length, was caught in the harbour; and on being opened, the entire head of a man was found in his ſtomach. The ſcalp, and fleſh of the face, were macerated to a ſoſt pulpy ſubſtance; which, on being touched, ſeparated entirely from the bones. The bones were ſomewhat ſoftened, and the ſutures looſened."

The following extraordinary inſtance of intrepidity and friendſhip is well worth recording. It is given on the authority of Mr Hughes, who publiſhed a natural hiſtory of Barbadoes. About the latter end of Queen Anne's wars, captain John Beanis, commander of the York Merchant, arrived at Barbadoes from England. Having diſembarked the laſt part of his lading, which was coals, the ſailors, who had been employed in that dirty work, ventured into the ſea to waſh themſelves; there they had not been long before one on board eſpied a large ſhark making toward them, and gave them notice of their danger; upon which they ſwam back, and all reached the boat except one: him the monſter overtook almoſt within reach of the oars, and griping him by the ſmall of his back, ſoon cut him aſunder, and as ſoon ſwallowed the lower part of his body; the remaining part was taken up and carried on board, where a comrade of his was, whoſe friendſhip with the deceaſed had been long diſtinguiſhed by a reciprocal diſcharge of all ſuch endearing offices as implied an union and ſympathy of ſouls. When he ſaw the ſevered trunk of his friend, it was with an horror and emotion too great for words to paint. During this affecting ſcene, the inſatiate ſhark was ſeen traverſing the bloody ſurface in ſearch of the remainder of his prey; the reſt of the crew thought themſelves happy in being on board, he alone unhappy, that he was not within reach of the deſtroyer. Fired at the ſight, and vowing that he would make the devourer diſgorge, or be ſwallowed himſelf in the ſame grave, he plunges into the deep, armed with a ſharp-pointed knife. The ſhark no ſooner ſaw him, but he made furiouſly towards him; both equally eager, the one of his prey, the other of revenge. The moment the ſhark opened his rapacious jaws, his adverſary dexterouſly diving, and graſping him with his left hand ſomewhat below the upper fins, ſucceſsfully employed his knife in his right hand, giving him repeated ſtabs in the belly; the enraged ſhark, after many unavailing efforts, finding himſelf overmatched in his own element, endeavoured to diſengage himſelf, ſometimes plunging to the bottom, then mad with pain, rearing his uncouth form, now ſtained with his own ſtreaming blood, above the foaming waves. The crews of the ſurrounding veſſels ſaw the unequal combat, uncertain from which of the combatants the ſtreams of blood iſſued; till at length the ſhark, much weakened by the loſs of blood, made towards the ſhore, and with him his conqueror; who, fluſhed with an aſſurance of victory, puſhed his foe with redoubled ardour, and, by the help of an ebbing tide, dragged him on ſhore, ripped up his bowels, and united and buried the ſevered carcaſe of his friend."

"It is evident (ſays Dr Moſeley, to whoſe valuable work we are indebted for the ſtory of the American related above), that digeſtion in theſe animals is not performed by trituration, nor by the muſcular action of the ſtomach; though nature has furniſhed them with a ſtomach of wonderful force and thickneſs, and far exceeding that of any other creature. Whatever their force of digeſtion is, it has no effect upon their young ones, which always retreat into their ſtomachs in time of danger.

"That digeſtion is not performed by heat in fiſh, is equally evident. Being on the Banks of Newfoundland in Auguſt 1782, I opened many cod-fiſh, and ripped up their ſtomachs juſt as they came alive out of the water; in which were generally found ſmall oyſters, muſcles, cockles, and crabs, as well as ſmall fiſhes of their own and other ſpecies. The coldneſs of the ſtomach of theſe fiſhes is far greater than the temperature of the water out of which they are taken; or of any other part of the fiſh, or of any other ſubſtance of animated nature I ever felt. On wrapping one of them round my hand, immediately on being taken out of the fiſh, it cauſed ſo much aching and numbneſs that I could not endure it long."

SQUAMARIA, in botany. See LATHRÆA.

SQUAMOUS, in anatomy, a name given to the ſpurious or falſe ſutures of the ſkull, becauſe compoſed of ſquamæ, or ſcales like thoſe of fiſhes.

SQUARE, in geometry, a quadrilateral figure both equilateral and equiangular. See GEOMETRY.

SQUARE Root. See ALGEBRA, Part I. Chap. iv. and ARITHMETIC, n° 33. and 34.

Hollow SQUARE, in the military art, a body of foot drawn up with an empty ſpace in the middle, for the colours, drums, and baggage, faced and covered by the pikes every way, to keep off the horſe.

SQUARE, among mechanics, an inſtrument conſiſting of two rules or branches, faſtened perpendicularly at one end of their extremities, ſo as to form a right angle. It is of great uſe in the deſcription and menſuration of right angles, and laying down perpendiculars.

SQUARE-Rigged, an epithet applied to a ſhip whoſe yards are very long. It is alſo uſed in contradiſtinction to all veſſels whoſe ſails are extended by ſtays or lateen-yards, or by booms and gaffs; the uſual ſituation of which is nearly in the plane of the keel; and hence.

SQUARE-Sail, is a ſail extended to a yard which hangs parallel to the horizon, as diſtinguiſhed from the other ſails which are extended by booms and ſtays placed obliquely. This ſail is only uſed in fair winds, or to ſcud under in a tempeſt. In the former caſe, it is furniſhed with a large additional part called the *bonnet*, which is then attached to its bottom, and removed when it is neceſſary to SCUD. See SCUDDING.

SQUATINA. See SQUALUS.

SQUILL, in botany. See SCILLA.

SQUILLA, the name of a ſpecies of cancer. See CANCER.

SQUINTING. See MEDICINE, n° 383.

SQUIRREL, in zoology. See SCIURUS.

STABBING, in law. The offence of mortally ſtabbing another, though done upon ſudden provocation, is puniſhed as murder; the benefit of clergy being taken away from it by ſtatute. (See MURDER). For by Ja. I. c. 8. when one thruſts or ſtabs another, not then having a weapon drawn, or who hath not then firſt ſtricken the party ſtabbing, ſo that he dies thereof within ſix months after, the offender ſhall not have the benefit of clergy, though he did it not of malice aforethought. This ſtatute was made on account of the frequent quarrels and ſtabbings with ſhort daggers between the Scotch and the Engliſh, at the ac-

Stachys.

ceſſion of James I.; and being therefore of a temporary nature, ought to have expired with the miſchief which it meant to remedy. For, in point of ſolid and ſubſtantial juſtice, it cannot be ſaid that the mode of killing, whether by ſtabbing, ſtrangling, or ſhooting, can either extenuate or enhance the guilt; unleſs where, as in the caſe of poiſoning, it carries with it internal evidence of cool and deliberate malice. But the benignity of the law hath conſtrued the ſtatute ſo favourably in behalf of the ſubject, and ſo ſtrictly when againſt him, that the offence of ſtabbing now ſtands almoſt upon the ſame footing as it did at the common law. Thus, (not to repeat the caſes mentioned under MANSLAUGHTER, of ſtabbing an adultereſs, &c. which are barely manſlaughter, as at common law), in the conſtruction of this ſtatute it hath been doubted, whether, if the deceaſed had ſtruck at all before the mortal blow given, this does not take it out of the ſtatute, tho' in the preceding quarrel the ſtabbed had given the firſt blow; and it ſeems to be the better opinion, that this is not within the ſtatute. Alſo it hath been reſolved, that the killing a man, by throwing a hammer or other weapon, is not within the ſtatute; and whether a ſhot with a piſtol be ſo or not is doubted. But if the party ſlain had a cudgel in his hand, or had thrown a pot or a bottle, or diſcharged a piſtol at the party ſtabbing, this is a ſufficient reaſon for having a weapon drawn on his ſide within the words of the ſtatute.

Blackſt. Comment. vol. iv. p. 193.

STACHYS, in botany: a genus of plants belonging to the claſs of *didynamia*, and order of *gymnoſpermia*; and in the natural ſyſtem arranged under the 42d order, *Verticillatæ*. The upper lip of the corolla is arched; the lower lip reflexed, and the larger intermediate lacinia is marginated. The ſtamina, after ſhedding the farina, are bent towards the ſides. There are 17 ſpecies, the ſylvatica, paluſtris, alpina, germanica, lanata, cretica, glutinoſa, orientalis, palæſtina, maritima, æthiopica, hirta, canarienſis, recta, annua, and arvenſis. Four only are natives of Britain.

1. *Sylvatica*, hedge-nettle. The plant is hairy all over, erect, a yard high, and branched; the hairs are jointed. The flowers are of a deep red colour, ſix or eight in a whirl, which terminates in a long ſpike deſtitute of leaves. The leaves are heart-ſhaped, and grow on footſtalks. The whole plant has a ſtrong fetid ſmell. It grows commonly in woods and ſhady places, and flowers in July or Auguſt. 2. *Paluſtris*, clown's all-heal. The roots are white and tuberous. The ſtalk is branched at the bottom, and two or three feet high. The flowers are red or purple, from ſix to ten in a whirl, ending in a long ſpike. The leaves are ſeſſile, narrow, pointed, and in part ſurrounding the ſtem. This plant has a fetid ſmell and bitter taſte, and is reckoned a good vulnerary. It grows on the ſides of rivers and lakes, in low moiſt grounds, and ſometimes in corn fields. 3. *Germanica*, baſe hore-hound. The ſtem is downy, and about two feet high. The leaves are white, downy, wrinkled, and indented. The flowers are white, purpliſh within, and grow in multiflorous whirls. It grows in England. 4. *Arvenſis*, corn-ſtachys, petty ironwort, or all-heal. The ſtalk is 10 or 12 inches high, ſquare, branched, and hairy. The leaves are heart-ſhaped, obtuſe, bluntly ſerrated, and leſs hairy. The calyx is hairy and ſeſſile, and deeply divided into five acute dents of equal length. The flowers are fleſh-coloured, and grow from three to ſix in a whirl. The lower lip is trifid; the middle ſegment ſpotted with red, but not emarginated according to the character of the genus. It is frequent in corn-fields, and grows from June to Auguſt.

Stadium, Stadtholder.

STADIUM, an ancient Greek long meaſure, containing 125 geometrical paces, or 625 Roman feet, correſponding to our furlong. The word is ſaid to be formed from the Greek word ςασις "a ſtation," or ἱςημι "to ſtand," becauſe it is reported that Hercules having run a ſtadium at one breath, ſtood ſtill at the end of it. The Greeks uſually meaſured diſtances by ſtadia, which they called ςαδιασμος. Stadium alſo ſignified the courſe on which their races were run.

STADTHOLDER, the principal magiſtrate or governor of the Seven United Provinces, until this office was aboliſhed by the republican influence of France; but as the prince of Orange is at this time in alliance with Great Britain, our readers will probably not be ill pleaſed with a ſhort account of his ſeveral powers and claims. To render that account the more intelligible, we ſhall trace the office of Stadtholder from its origin.

The Seven Provinces of the Low Countries were long governed by princes inveſted with the ſovereignty, though limited in their powers, and under various titles; as *Counts of Holland, Dukes of Guelder, Biſhop of Utrecht*, &c. When theſe countries fell to the princes of the houſe of Burgundy, and afterwards to thoſe of Auſtria, who had many other dominions, the abſence of the ſovereign was ſupplied by a ſtadtholder or governor, veſted with very ample powers. Theſe ſtadtholders or lieutenants had the adminiſtration of the government, and preſided in the courts of juſtice, whoſe juriſdiction was not at that time confined merely to the trial of cauſes, but extended to affairs of ſtate. The ſtadtholders ſwore allegiance to the princes at their inauguration, jointly with the ſtates of the provinces they governed. They likewiſe took an oath to the ſtates, by which they promiſed to maintain their fundamental laws and privileges.

It was upon this footing that William the Firſt, prince of Orange, was made governor and lieutenant-general of Holland, Zealand, and Utrecht, by Philip the Second, upon his leaving the Low Countries to go into Spain. The troubles beginning ſoon after, this prince found means to bring about an union, in 1576, between Holland and Zealand; the ſtates of which two provinces put into his hands, as far as was in their power, the ſovereign authority (for ſo long time as they ſhould remain in war and under arms), upon the ſame footing as Holland had intruſted him with in the year before. In 1581 the ſame authority was again renewed to him by Holland, as it was ſoon after by Zealand likewiſe; and in 1584, being already elected count of Holland, upon certain conditions he would have been formally inveſted with the ſovereignty, had not a wretch, hired and employed by the court of Spain, put an end to his life by a horrid aſſaſſination.

In the preamble of the inſtruments by which the ſtates in 1581 conferred the ſovereign authority upon prince William the Firſt, we find theſe remarkable words, which are there ſet down as fundamental rules: "That all republics and communities ought to preſerve, maintain, and fortify themſelves by unanimity; which being impoſſible to be kept up always among ſo

many

Stadtholder.

many members, often differing in inclinations and sentiments, it is consequently necessary that the government should be placed in the hands of one single chief magistrate." Many good politicians, and the greatest part of the inhabitants of these provinces, have, since the establishment of the republic, looked upon the stadtholderian government as an essential part of her constitution; nor has she been without a stadtholder but twice, that is to say, from the end of 1650 to 1672, and again from March 1702 till April 1747. The provinces of Friesland and Groningen, with Ommelands, have always had a stadtholder without interruption: their instructions, which are now no longer in force, may be seen in Aitzema; but formerly the powers of the stadtholder of these provinces were confined within narrower bounds, and till William the Fourth there was no stadtholder of the seven provinces together.

The stadtholder cannot declare war nor make peace, but he has, in quality of captain-general of the union, the command in chief of all the forces of the state (A); and military persons are obliged to obey him in every thing that concerns the service. He is not limited by instructions, but he has the important power of giving out orders for the march of troops, and the disposition of all matters relative to them. He not only directs their marches, but provides for the garrisons, and changes them at pleasure. All military edicts and regulations come from him alone; he constitutes and authorizes the high council of war of the United Provinces, and, as captain-general of every province, disposes of all military officers, as far as the rank of colonel inclusively. The higher posts, such as those of velt-marshals, generals, lieutenant-generals, major-generals, are given by the states-general, who choose the persons recommended by his highness. He makes the governors, commandants, &c. of towns and strong places of the republic, and of the barrier. The persons nominated present their instruments of appointment to their high mightinesses, who provide them with commissions. The states-general have likewise great regard to the recommendation of the prince stadtholder in the disposition of those civil employments which are in their gift.

The power of the stadtholder as high-admiral, extends to every thing that concerns the naval force of the republic, and to all the other affairs that are here within the jurisdiction of the admiralty. He presides at these boards either in person or by his representatives; and as chief of them all in general, and of every one in particular, he has power to make their orders and instructions be observed by themselves and others. He bestows the posts of lieutenant-admiral, vice-admiral, and rear-admiral, who command under him; and he makes likewise post-captains.

The stadtholder grants likewise letters of grace, pardon, and abolition, as well for the crime called *Communia Delicta*, as for military offences. In Holland and Zealand these letters are made out for crimes of the first sort, in the name of the states, with the advice of his highness. In military offences he consults the high council of war, and upon the *communia delicta* he takes the advice of the courts of justice, of the counsellors, committees of the provinces, of the council of state, and the tribunals of justice in the respective towns, according to the nature of the case.

In the provinces of Holland and Zealand, the stadtholder elects the magistrates of the towns annually, out of a double number that are returned to him by the towns themselves.

When any of those offices become vacant, which, at the time there was no governor, were in the disposal of the states of Holland, or as formerly in that of the chamber of accounts, the stadtholder has his choice of two, or, in some cases, of three candidates, named by their noble and great mightiness. He chooses likewise the counsellors, inspectors of the dykes of Rynland, Delfland, and Scheeland, out of three persons presented to him by the boards of the counsellors inspectors; which boards are of very ancient establishment in Holland.

His highness presides in the courts of Holland, and in the courts of justice of the other provinces; and his name is placed at the head of the proclamations and acts, called in Dutch *Mandamenten*, or *Provisien van Justitie*. In Overyssel and in the province of Utrecht the possessors of fiefs hold of the prince stadtholder. He is supreme curator of the universities of Guelder, Friesland, and Groningen; grand forester and grand veneur in Guelder, in Holland, and other places. In the province of Utrecht, his highness, by virtue of the regulation of 1674, disposes of the provostships and other benefices which remain to the chapters, as also of the canonical prebends that fall in the months which were formerly the papal months.

By the first article of the council of state of the United Provinces, the stadtholder is the first member of it, and has a right of voting there, with an appointment of 25,000 guilders a-year. He assists also as often as he thinks it for the service of the state, at the deliberations of the states general, to make propositions to them, and sometimes also at the conferences which the deputies of their high mightinesses hold in their different committees, in consequence of their standing orders. He likewise assists at the assemblies of the states of each particular province, and at that of the counsellor's committees. In Guelder, Holland, and Utrecht, his highness has a share of the sovereignty, as chief or president of the body of nobles; and in Zealand, where he possesses the marquisate of Veer and Flushing, as first noble, and representing the whole nobility. In his absence he has in Zealand his representatives, who have the first place and the first voice in all the councils, and the first of whom is always first deputy from the province to the assembly of their high mightinesses.

In 1749 the prince stadtholder was created by the states-

(A) In time of war, however, the states have always named deputies for the army, to accompany the stadtholders in the field, and to serve them as counsellors in all their enterprises, particularly in the most important affairs, such as giving battle, or undertaking a siege, &c. This was always practised till the accession of king William the Third to the crown of Great Britain, and after his death was continued with regard to the general in chief of the army of the republic. In 1747 and 1748 there were likewise deputies with the army, but with more limited power.

ftates-general, governor-general and supreme director of the East and West India companies; dignities which give him a great deal of authority and power, and which had never been conferred upon any of his predecessors, nor have they hitherto been made hereditary. He has his representatives in the several chambers of the company, and chooses their directors out of a nomination of three qualified persons. The prince enjoyed this prerogative in Zealand from the time of his elevation to the stadtholderate.

The revenues of the stadtholderate of the seven United Provinces are reckoned (including the 25,000 guilders which the prince enjoys annually as the first member of the council of state, and what he has from the India company's dividends) to amount to 300,000 guilders a year. As captain-general of the union, his serene highness has 120,000 guilders *per annum*, besides 24,000 from Friesland, and 12,000 from Groningen, in quality of captain-general of these provinces. In times of war the state allows extraordinary sums to the captain-general for the expence of every campaign.

To all these powers and privileges the prince of Orange had a legal and constitutional right; but he has been divested of them by the late revolution, and the government of that country modelled on the plan of the French republic, by whose armies chiefly the revolution was effected.

STÆHELINA, in botany: A genus of plants belonging to the class of *syngenesia*, and order of *polygamia æqualis*; and in the natural system arranged under the 49th order, *Compositæ*. The receptacle is paleaceous, the chaff being very short; the pappus is branchy, and the antheræ caudated. There are eight species, the gnaphaloides, dubia, arborescens, fruticosa, ilicifolia, corymbosa, chamæpeuce, and imbricata.

STAFF, an instrument ordinarily used to rest on in walking. The staff is also frequently used as a kind of natural weapon both of offence and defence; and for several other purposes.

Staff, a light pole erected in different parts of a ship, whereon to hoist and display the colours.

The principal of these is reared immediately over the stern, to display the ensign; another is fixed on the bowsprit, to extend the jack; three more are erected at the three mast heads, or formed by their upper ends, to show the flag or pendant of the respective squadron or division to which the ship is appropriated. See Ensign, Mast, Jack, and Pendant.

Staff, in military matters, consists of a quarter-master-general, adjutant-general, and majors of brigade. The staff properly exists only in time of war. See *Quarter Master General*, &c.

Regimental Staff, consists in the adjutant, quarter-master, chaplain, surgeon, &c.

Staff, in music, five lines, on which, with the intermediate spaces, the notes of a song or piece of music are marked.

Fore-Staff. See *Fore-Staff*.

STAFFA, one of the Hebrides or Western Islands of Scotland, remarkable for its basaltic pillars. It was visited by Sir Joseph Banks, who communicated the following account of it to Mr Pennant.

"The little island of Staffa lies on the west coast of Mull, about three leagues north-east from Iona, or Icolumbkill: its greatest length is about an English mile, and its breadth about half a one. On the west side of the island is a small bay where boats generally land; a little to the southward of which the first appearance of pillars are to be observed: they are small; and instead of being placed upright, lie down on their sides, each forming a segment of a circle. From thence you pass a small cave, above which the pillars, now grown a little larger, are inclining in all directions: in one place in particular, a small mass of them very much resembles the ribs of a ship. From hence having passed the cave, which, if it is not low-water, you must do in a boat, you come to the first ranges of pillars, which are still not above half as large as those a little beyond. Over against this place is a small island, called in Erse *Boo sha-la*, separated from the main by a channel not many fathoms wide. This whole island is composed of pillars without any stratum above them; they are still small, but by much the neatest formed of any about the place.

"The first division of the island, for at high water it is divided into two, makes a kind of a cone, the pillars converging together towards the centre: on the other they are in general laid down flat: and in the front next to the main, you see how beautifully they are packed together, their ends coming out square with the bank which they form. All these have their transverse sections exact, and their surfaces smooth; which is by no means the case with the large ones, which are cracked in all directions. I much question, however, if any pillar in this whole island of Boo-sha-la is two feet in diameter.

"The main island opposite to Boo-sha-la, and farther towards the north-west, is supported by ranges of pillars pretty erect, and, though not tall (as they are not uncovered to the base), of large diameters; and at their feet is an irregular pavement, made by the upper sides of such as have been broken off, which extends as far under water as the eye can reach. Here the forms of the pillars are apparent: these are of three, four, five, six, and seven sides; but the number of five and six are by much the most prevalent. The largest I measured was of seven; it was four feet five inches in diameter.

"The surfaces of these large pillars, in general, are rough and uneven, full of cracks in all directions; the transverse figures in the upright ones never fail to run in their true directions. The surfaces upon which we walked were often flat, having neither concavity nor convexity; the larger number, however, were concave, though some were very evidently convex. In some places, the interstices within the perpendicular figures were filled up with a yellow spar: in one place, a vein passed in among the mass of pillars, carrying here and there small threads of spar. Though they were broken and cracked through in all directions, yet their perpendicular figures might easily be traced: from whence it is easy to infer, that whatever the accident might have been that caused the dislocation, it happened after the formation of the pillars.

"From hence proceeding along shore, you arrive at Fingal's cave. Its dimensions I have given in the form of a table:

Staffa.

	Feet.	In.
Length of the cave from the rock without,	371	6
From the pitch of the arch,	250	0
Breadth of ditto at the mouth,	53	7
At the farther end,	20	0
Height of the arch at the Mouth,	117	6
At the end,	70	0
Height of an outside pillar,	39	6
Of one at the north-west corner,	54	0
Depth of water at the mouth,	18	0
At the bottom,	9	0

"The cave runs into the rock in the direction of north-east by east by the compass.

"Proceeding farther to the north-west, you meet with the highest ranges of pillars; the magnificent appearance of which is past all description. Here they are bare to their very basis, and the stratum below them is also visible: in a short time, it rises many feet above the water, and gives an opportunity of examining its quality. Its surface is rough, and has often large lumps of stone sticking in it as if half immersed: itself, when broken, is composed of a thousand heterogeneous parts, which together have very much the appearance of a lava: and the more so, as many of the lumps appear to be of the very same stone of which the pillars are formed. This whole stratum lies in an inclined position, dipping gradually towards the south-east. As hereabouts in the situation of the highest pillars, I shall mention my measurements of them, and the different strata in this place, premising, that the measurements were made with a line, held in the hand of a person who stood at the top of the cliff, and reaching to the bottom; to the lower end of which was tied a white mark, which was observed by one who staid below for the purpose: when this mark was set off from the water, the person below noted it down, and made signal to him above, who made then a mark in his rope: whenever this mark passed a notable place, the same signal was made, and the name of the place noted down as before: the line being all hauled up, and the distances between the marks measured and noted down, gave, when compared with the book kept below the distances, as for instance in the cave:

"N° 1. in the book below, was called from the water to the foot of the first pillar in the book above; n° 1. gave 36 feet 8 inches, the highest of that ascent, which was composed of broken pillars.

"N° 1. Pillar at the west corner of Fingal's cave.

		Feet.	In.
1	From the water to the foot of the pillar,	12	10
2	Height of the pillar,	37	3
3	Stratum above the pillar,	66	9

"N° 2. Fingal's cave.

1	From the water to the foot of the pillar,	36	8
2	Height of the pillar,	39	6
3	From the top of the pillar to the top of the arch,	31	4
4	Thickness of the stratum above,	34	4
	By adding together the three first measurements, we got the height of the arch from the water,	117	6

"N° 3. Corner pillar to the westward of Fingal's cave.

Stratum below the pillar of lava-like matter,	11	0
Length of pillar,	54	0
Stratum above the pillar,	61	6

"N° 4. Another pillar to the westward.

Stratum below the pillar,	17	1
Height of the pillar,	50	0
Stratum above,	51	1

"N° 5. Another pillar farther to the westward.

Stratum below the pillar,	19	8
Height of the pillar,	55	1
Stratum above,	54	7

Staffa ‖ Stafford-shire.

"The stratum above the pillars, which is here mentioned, is uniformly the same, consisting of numberless small pillars, bending and inclining in all directions, sometimes so irregularly that the stones can only be said to have an inclination to assume a columnar form; in others more regular, but never breaking into or disturbing the stratum of large pillars, whose tops everywhere keep an uniform and regular line.

"Proceeding now along the shore round the north end of the island, you arrive at *Oua na scarve*, or the Corvorant's Cave. Here the stratum under the pillars is lifted up very high; the pillars above it are considerably less than those at the north-west end of the island, but still very considerable. Beyond is a bay, which cuts deep into the island, rendering it in that place not more than a quarter of a mile over. On the sides of this bay, especially beyond a little valley, which almost cuts the island into two, are the stages of pillars, but small; however, having a stratum between them exactly the same as that above them, formed of innumerable little pillars, shaken out of their places, and leaning in all directions.

"Having passed this bay, the pillars totally cease; the rock is of a dark-brown stone, and no signs of regularity occur till you have passed round the south-east end of the island (a space almost as large as that occupied by the pillars), which you meet again on the west side, beginning to form themselves irregularly, as if the stratum had an inclination to that form, and soon arrive at the bending pillars where I began.

"The stone of which the pillars are formed, is a coarse kind of basaltes, very much resembling the Giant's Causeway in Ireland, though none of them are near so neat as the specimens of the latter which I have seen at the British Museum; owing chiefly to the colour, which in ours is a dirty brown, in the Irish a fine black; indeed the whole production seems very much to resemble the Giant's Causeway."

STAFFORD, the county town of Staffordshire, in W. Long. 2. 0. N. Lat. 55. 0. It stands on the river Sow, has two parish-churches, a fine square market-place, and a flourishing cloth manufacture. It sends two members to parliament, and is 135 miles from London.

STAFFORDSHIRE, a county of England, bounded on the south by Worcestershire, by Cheshire and Derbyshire on the north, by Warwickshire and Derbyshire on the east, and Shropshire and Cheshire on the west. The length is reckoned 62 miles, the breadth 53, and the circumference 180. It contains 5 hundreds, 150 parishes, 810,000 acres, and 18 market towns. The air, except in those parts that are called the Moorlands, and Woodlands, and about the mines, is good, especially upon the hills, where it is accounted very

very fine. The soil in the northern mountainous parts is not fertile; but in the middle, where it is watered by the Trent, the third river in England, it is both fruitful and pleasant, being a mixture of arable and meadow grounds. In the south, it abounds not only with corn, but with mines of iron and pits of coal. The principal rivers of this country, besides the Trent, which runs almost thro' the middle of it, and abounds with salmon, are the Dove and Tame, both of which are well stored with fish. In this country are also a great many lakes, or meres and pools, as they are called; which, having streams either running into them or from them, cannot be supposed to be of any great prejudice to the air; they yield plenty of fish. In divers parts of the county are medicinal waters, impregnated with different sorts of minerals, and consequently of different qualities and virtues; as those at Hints and Bresfordhouse, which are mixed with bitumen; those at Ingestre, Codsalwood, and Willough-bridge park, which are sulphureous. Of the saline kind are the Brine-pits at Chertley, Epsom, Pensnet-close, of which very good salt is made. There is a well at Newcastle-under-Line that is said to cure the king's evil; another called *Elderwell* near Blemhill, said to be good for sore eyes; and a third called the *Spa*, near Wolverhampton.

Great flocks of sheep are bred in this country, especially in the moorlands, or mountains of the northern part of it; but the wool is said to be somewhat coarser than that of many other counties. Of this wool, however, they make a variety of manufactures, particularly felts. In the low grounds along the rivers are rich pastures for black cattle; and vast quantities of butter and cheese are made. In the middle and southern parts not only grain of all kinds, but a great deal of hemp and flax are raised. This country produces also lead, copper, iron; marble, alabaster, millstones, limestone; coal, salt, and marles of several sorts and colours; brick-earth, fullers-earth, and potters-clay §, particularly a sort used in the glass-manufacture at Amblecot, and sold at seven-pence a bushel; tobacco-pipe-clay; a sort of reddish earth called *slip*, used in painting divers vessels; red and yellow ochres; fire-stones for hearths of iron furnaces, ovens, &c.; iron-stones of several sorts; bloodstones, or hæmatites, found in the brook Tent, which, when wet a little, will draw red lines like ruddle; quarry-stones, and grind-stones. For fuel the county is well supplied with turf, peat, and coal of several sorts, as cannel-coal, peacock-coal, and pit-coal. The peacock-coal is so called, because, when turned to the light, it displays all the colours of the peacock's tail; but it is fitter for the forge than the kitchen. Of the pit-coal there is an inexhaustible store: it burns into white ashes, and leaves no such cinder as that of the Newcastle coal. It is not used for malting till it is charred, and in that state it makes admirable winter-fuel for a chamber.

§ See Stone-Ware.

This county is in the diocese of Litchfield and Coventry, and the Oxford circuit. It sends ten members to parliament; namely, two for the county, two for the city of Litchfield, two for Stafford, two for Newcastle-under-Line, and two for Tamworth.

STAG, in zoology. See Cervus.

Stag-Beetle. See Lucanus.

STAGE, in the modern drama, the place of action and representation included between the pit and the scenes, and answering to the proscenium or pulpitum of the ancients. See Playhouse and Theatre.

STAGGERS. See Farriery, § xiii.

STAHL (George Ernest), an eminent German chemist, was born in Franconia in 1660, and chosen professor of medicine at Hall, when a university was founded in that city in 1694. The excellency of his lectures while he filled that chair, the importance of his various publications, and his extensive practice, soon raised his reputation to a very great height. He received an invitation to Berlin in 1716, which having accepted, he was made counsellor of state and physician to the king. He died in 1734, in the 75th year of his age. Stahl is without doubt one of the greatest men of which the annals of medicine can boast: his name marks the commencement of a new and more illustrious era in chemistry. He was the author of the doctrine of phlogiston, which, though now completely overturned by the discoveries of Lavoisier and others, was not without its use; as it served to combine the scattered fragments of former chemists into a system, and as it gave rise to more accurate experiments and a more scientific view of the subject, to which many of the subsequent discoveries were owing. This theory maintained its ground for more than half a century, and was received and supported by some of the most eminent men which Europe has produced; a sufficient proof of the ingenuity and the abilities of its author. He was the author also of A Theory of Medicine, founded upon the notions which he entertained of the absolute dominion of mind over body; in consequence of which, he affirmed, that every muscular action is a voluntary act of the mind, whether attended with consciousness or not. This theory he and his followers carried a great deal too far, but the advices at least which he gives to attend to the state of the mind of the patient are worthy of the attention of physicians.

His principal works are, 1. *Experimenta et Observationes Chemicæ et Physicæ*, Berlin, 1731, 8vo. 2. *Dissertationes Medicæ*, Hall, 2 vols 4to. This is a collection of theses. 3. *Theoria Medica vera*, 1737, 4to. 4. *Opusculum Chymico-physico medicum*, 1740, 4to. 5. A Treatise on Sulphur, both Inflammable and Fixed, written in German. 6. *Negotium Otiosum*, Hall, 1720, 4to. It is in this treatise chiefly that he establishes his system concerning the action of the soul upon the body. 7. *Fundamenta Chymicæ Dogmaticæ et Experimentalis*, Nuremberg, 1747, 3 vols 4to. 8. A Treatise on Salts, written in German. 9. *Commentarium in Metallurgiam Beccheri*, 1723.

STAINING *or* Colouring *of* Bone, Horn, Marble, Paper, Wood, &c. See these articles.

STAIRCASE, in architecture, an ascent inclosed between walls, or a balustrade consisting of stairs or steps, with landing places and rails, serving to make a communication between the several stories of a house. See Architecture, n° 89, &c.

STALACTITÆ, in natural history, crystalline spars formed into oblong, conical, round, or irregular bodies, composed of various crusts, and usually found hanging in form of isicles from the roofs of grottoes, &c.

STALAGMITIS, in botany: a genus of the *monœcia* order, belonging to the *polygamia* class of plants; and in the natural method ranking under the 38th order, *Tricoccæ*. The calyx is either quadriphyllous or hexaphyllous

hexaphyllous; the corolla consists of four or of six petals: the receptacle is fleshy, and somewhat square-shaped; the filaments about 30. In the hermaphrodite flower the *stylus* is short, thick, and erect; the fruit is a berry of a globular shape, unilocular, and crowned with the *stylus* and *stigma*: they contain three oblong jointed triangular seeds. Of this there is only one species, viz. the *Cambogioides*, a native of the East Indies and of the warmer parts of America. From this plant is obtained the gutta cambogia, or gum gamboge of the shops. See Gamboge.

Till very lately botanists were at a loss for the true nature of the plant which yields this gum. Koenig, a native of Ireland, and an excellent botanist, travelled over a great part of India, and collected a great number of new plants, and among the rest the stalagmitis. These he bequeathed to Sir Joseph Banks president of the Royal Society.

STALE, among sportsmen, a living fowl put in a place to allure and bring others where they may be taken. For want of these, a bird shot, its entrails taken out, and dried in an oven in its feathers, with a stick thrust through to keep it in a convenient posture, may serve as well as a live one.

Stale is also a name for the urine of cattle.

Animated STALK. This remarkable animal was found by Mr Ives at Cuddalore: and he mentions several kinds of it; some appearing like dry straws tied together, others like grass; some have bodies much larger than others, with the addition of two scaly imperfect wings; their neck is no bigger than a pin, but twice as long as their bodies; their heads are like those of an hare, and their eyes vertical and very brisk. They live upon flies, and catch these insects very dexterously with the two fore-feet, which they keep doubled up in three parts close to their head, and dart out very quick on the approach of their prey; and when they have caught it, they eat it very voraciously, holding it in the same manner as a squirrel does its food. On the outer joints of the fore-feet are several very sharp hooks for the easier catching and holding of their prey; while, with the other feet, which are four in number, they take hold of trees or any other thing, the better to surprise whatever they lie in wait for. They drink like a horse, putting their mouths into the water. Their excrements, which are very white, are almost as large as the body of the animal, and as the natives say, dangerous to the eyes.

STALLION, or Stone-horse, in the manege, an horse designed for the covering of mares, in order to propagate the species. See Equus.

STAMFORD, an ancient town of Lincolnshire in England; seated on the river Welland, on the edge of Northamptonshire. It is a large handsome place, containing six parish-churches, several good streets, and fine buildings. It had formerly a college, the students of which removed to Brazen-Nose college in Oxford. It has no considerable manufactories, but deals chiefly in malt. W. Long. 0. 31. N. Lat. 52. 42.

STAMINA, in botany, are those upright filaments which, on opening a flower, we find within the corolla surrounding the pistillum. According to Linnæus, they are the male organs of generation, whose office it is to prepare the pollen. Each stamen consists of two distinct parts, viz. the filamentum and the anthera.

Stamina, in the animal body, are defined to be those simple original parts which existed first in the embryo or even in the seed; and by whose distinction, augmentation, and accretion by additional juices, the animal body at its utmost bulk is supposed to be formed.

STAMP-duties, a branch of the perpetual revenue. See Revenue.

In Great Britain there is a tax imposed upon all parchment and paper, whereon any legal proceedings or private instruments of almost any nature whatsoever are written; and also upon licences for retailing wines, of all denominations; upon all almanacs, newspapers, advertisements, cards, dice, &c. These imposts are very various; being higher or lower, not so much according to the value of the property transferred, as according to the nature of the deed. The highest do not exceed six pounds upon every sheet of paper or skin of parchment; and these high duties fall chiefly upon grants from the crown, and upon certain law proceedings, without any regard to the value of the subject. There are in Great Britain no duties on the registration of deeds or writings, except the fees of the officers who keep the register; and these are seldom more than a reasonable recompense for their labour. The crown derives no revenue from them.

Smith's Wealth of Nations, vol. iii.

The stamp-duties constitute a tax which, though in some instances it may be heavily felt, by greatly increasing the expence of all mercantile as well as legal proceedings, yet (if moderately imposed) is of service to the public in general, by authenticating instruments, and rendering it much more difficult than formerly to forge deeds of any standing; since, as the officers of this branch of the revenue vary their stamps frequently, by marks perceptible to none but themselves, a man that would forge a deed of King William's time, must know and be able to counterfeit the stamp of that date also. In France and some other countries the duty is laid on the contract itself, not on the instrument in which it is contained; as also in England (besides the stamps on the indentures), a tax is laid, by statute 8 Ann, c. 9. on every apprentice-fee; of 6 d. in the pound if it be 50 l. or under, and 1 s. in the pound if a greater sum: but this tends to draw the subject into a thousand nice disquisitions and disputes concerning the nature of his contract, and whether taxable or not; in which the farmers of the revenue are sure to have the advantage. The general method in England answers the purposes of the state as well, and consults the ease of the subject much better The first institution of the stamp-duties was by statute 5 and 6 W. and M. c. 21. and they have since, in many instances, been increased to five times their original amount.

STANCHION, or Stanchions, a sort of small pillars of wood or iron used for various purposes in a ship; as to support the decks, the quarter-rails, the nettings, the awnings, &c. The first of these are two ranges of small columns fixed under the beams, throughout the ship's length between decks; one range being on the starboard and the other on the larboard side of the hatchways. They are chiefly intended to support the weight of the artillery.

STAND, in commerce, a weight from two hundred and an half to three hundred of pitch.

STANDARD, in war, a sort of banner or flag,

 borne

Standard, Stanhope.

borne as a signal for the joining together of the several troops belonging to the same body.

STANDARD, in commerce, the original of a weight, measure, or coin, committed to the keeping of a magistrate, or deposited in some public place, to regulate, adjust, and try the weights used by particular persons in traffic. See MONEY.

STANHOPE (Philip Dormer, earl of Chesterfield), was born in 1695, and educated in Trinity-hall, Cambridge; which place he left in 1714, when, by his own account, he was an absolute pedant. In this character he went abroad, where a familiarity with good company soon convinced him he was totally mistaken in almost all his notions: and an attentive study of the air, manner, and address of people of fashion, soon polished a man whose predominant desire was to please; and who, as it afterwards appeared, valued exterior accomplishments beyond any other human acquirement. While Lord Stanhope, he got an early seat in parliament; and in 1722, succeeded to his father's estate and titles. In 1728, and in 1745, he was appointed ambassador extraordinary and plenipotentiary to Holland: which high character he supported with the greatest dignity: serving his own country, and gaining the esteem of the states-general. Upon his return from Holland, he was sent lord-lieutenant of Ireland; and during his administration there, gave general satisfaction to all parties. He left Dublin in 1746, and in October succeeded the earl of Harrington as secretary of Sate, in which post he officiated until February 6th 1748. Being seized with a deafness in 1752 that incapacitated him for the pleasures of society, he from that time led a private and retired life, amusing himself with books and his pen; in particular, he engaged largely as a volunteer in a periodical miscellaneous paper called *The World*, in which his contributions have a distinguished degree of excellence. He died in 1773, leaving a character for wit and abilities that had few equals. He distinguished himself by his eloquence in parliament on many important occasions; of which we have a characteristic instance, of his own relating. He was an active promoter of the bill for altering the style; on which occasion, as he himself writes in one of his letters to his son, he made so eloquent a speech in the house, that every one was pleased, and said he had made the whole very clear to them; "when (says he), God knows, I had not even attempted it. I could just as soon have talked Celtic or Sclavonian to them, as astronomy; and they would have understood me full as well." Lord Macclesfield, one of the greatest mathematicians in Europe, and who had a principal hand in framing the bill, spoke afterwards, with all the clearness that a thorough knowledge of the subject could dictate; but not having a flow of words equal to Lord Chesterfield, the latter gained the applause from the former, to the equal credit of the speaker and the auditors. The high character Lord Chesterfield supported during life, received no small injury soon after his death, from a fuller display of it by his own hand. He left no issue by his lady, but had a natural son, Philip Stanhope, Esq; whose education was for many years a close object of his attention, and who was afterwards envoy extraordinary at the court of Dresden, but died before him. When Lord Chesterfield died, Mr Stanhope's widow published a course of letters, written by the father to the son, filled with instructions suitable to the different gradations of the young man's life to whom they were addressed. These letters contain many fine observations on mankind, and rules of conduct: but it is observable that he lays a greater stress on exterior accomplishments and address, than on intellectual qualifications and sincerity; and allows greater latitude to fashionable pleasures than good morals will justify, especially in paternal instruction. Hence it is that a celebrated writer §, and of manners somewhat different from those of the polite earl of Chesterfield, is said to have observed of these letters that "they inculcate only the morals of a whore, with the manners of a dancing-master."

§ Dr Johnson.

STANHOPE (Dr George), an eminent divine, was born at Hertishorn in Derbyshire, in the year 1660. His father was rector of that place, vicar of St Margaret's church in Leicester, and chaplain to the earls of Chesterfield and Clare. His grandfather Dr George Stanhope was chaplain to James I. and Charles I.; had the chancellorship of York, where he was also a canon residentiary, held a prebend, and was rector of Weldrake in that county. He was for his loyalty driven from his home with eleven children; and died in 1644. Our author was sent to school, first at Uppingham in Rutland, then at Leicester; afterwards removed to Eaton; and thence chosen to King's college in Cambridge, in the place of W. Cleaver. He took the degree of B. A. in 1681; M. A. 1658; was elected one of the syndics for the university of Cambridge, in the business of Alban Francis, 1687; minister of Quoi near Cambridge, and vice-proctor, 1688; was that year preferred to the rectory of Tring in Hertfordshire, which after some time he quitted. He was in 1689 presented to the vicarage of Lewisham in Kent by Lord Dartmouth, to whom he had been chaplain, and tutor to his son. He was also appointed chaplain to King William and Queen Mary, and continued to enjoy that honour under Queen Anne. He commenced D. D. July 5th 1697, performing all the offices required to that degree publicly and with great applause. He was made vicar of Deptford in 1703; succeeded Dr Hooper as dean of Canterbury the same year; and was thrice chosen prolocutor of the lower house of convocation. His uncommon diligence and industry, assisted by his excellent parts, enriched him with a large stock of polite, solid, and useful learning. His discourses from the pulpit were equally pleasing and profitable; a beautiful intermixture of the clearest reasoning with the purest diction, attended with all the graces of a just elocution. The good Christian, the solid divine, and the fine gentleman, in him were happily united. His conversation was polite and delicate, grave without preciseness, facetious without levity. His piety was real and rational, his charity great and universal, fruitful in acts of mercy, and in all good works. He died March 18th 1728, aged 68 years; and was buried in the chancel of the church at Lewisham. The dean was twice married: 1. to Olivia Cotton, by whom he had one son and four daughters. His second lady, who was sister to Sir Charles Wager, survived him, dying October 1st 1730, aged about 54. One of the dean's daughters was married to a son of bishop Burnet. Bishop Moore of Ely died the day before Queen Anne; who, it has been said, designed our dean for that see

Stanhope, Stanislaus. fee when it should become vacant. Dr Felton says, "The late dean of Canterbury is excellent in the whole. His thoughts and reasoning are bright and solid. His style is just, both for the purity of the language and for the strength and beauty of expression; but the periods are formed in so peculiar an order of the words, that it was an observation, nobody could pronounce them with the same grace and advantage as himself." His writings, which are an inestimable treasure of piety and devotion are, A Paraphrase and Comment upon the Epistles and Gospels, 4 vols. 1705, 8vo. Sermons at Boyle's Lectures, 1706, 4to. Fifteen Sermons, 1700, 8vo. Twelve Sermons on several Occasions, 1727, 8vo. Thomas à Kempis 1696, 8vo. Epictetus's Morals, with Simplicius's Comment, and the Life of Epictetus, 1700, 8vo. Parson's Christian Directory, 1716, 8vo. Rochefoucault's Maxims, 1706, 8vo. A Funeral Sermon on Mr Richard Sare, Bookseller, 1724; two editions 4to. Twenty Sermons, published singly between the years 1692 and 1724. Private Prayers for every Day in the Week, and for the several Parts of each Day; translated from the Greek Devotions of Bishop Andrews, with additions, 1730. In his translations, it is well known, Dr Stanhope did not confine himself to a strict and literal version: he took the liberty of paraphrasing, explaining, and improving upon his author; as will evidently appear (not to mention any other work) by the slightest perusal of St Augustine's Meditations, and the Devotions of Bishop Andrews.

STANISLAUS (Leczinski), king of Poland, was born at Leopold the 20th of October 1677. His father was a polish nobleman, distinguished by his rank and the important offices which he held, but still more by his firmness and courage. Stanislaus was sent ambassador in 1704 by the assembly of Warsaw, to Charles XII. of Sweden, who had conquered Poland. He was at that time 27 years old, was general of Great Poland, and had been ambassador extraordinary to the Grand Signior in 1699. Charles was so delighted with the frankness and sincerity of his deportment, and with the firmness and sweetness which appeared in his countenance, that he offered him the crown of Poland, and ordered him to be crowned at Warsaw in 1705. He accompanied Charles XII. into Saxony, where a treaty was concluded with King Augustus in 1705, by which that prince resigned the crown, and acknowledged Stanislaus king of Poland. The new monarch remained in Saxony with Charles till 1707, when they returned into Poland and attacked the Russians, who were obliged to evacuate that kingdom in 1708. But Charles being defeated by Peter the Great in 1709, Augustus returned into Poland, and being assisted by a Russian army, obliged Stanislaus to retire first into Sweden, and afterwards into Turkey. Soon after he took up his residence at Weissenburg, a town in Alsace. Augustus dispatched Sum his envoy to France to complain of this; but the duke of Orleans, who was then regent, returned this answer: "Tell your king, that France has always been the asylum of unhappy princes." Stanislaus lived in obscurity till 1725, when Louis XV. espoused the princess Mary his daughter. Upon the death of King Augustus in 1733, he returned to Poland in hopes of remounting the throne of that kingdom. A large party declared for him; but his competitor the young elector of Saxony, being supported by the Emperor Charles VI. and the Empress of Russia, was chosen king, though the majority was against him. Dantzic, to which Stanislaus had retired, was quickly taken, and the unfortunate prince made his escape in disguise with great difficulty, after hearing that a price was set upon his head by the Russians. When peace was concluded in 1736 between the Emperor and France, it was agreed that Stanislaus should abdicate the throne, but that he should be acknowledged king of Poland and grand duke of Lithuania, and continue to bear these titles during life; that all his effects and those of the queen his spouse should be restored; that an amnesty should be declared in Poland for all that was past, and that every person should be restored to his possessions, rights, and privileges: that the elector of Saxony should be acknowledged king of Poland by all the powers who acceded to the treaty: that Stanislaus should be put in peaceable possession of the duchies of Lorrain and Bar; but that immediately after his death these duchies should be united for ever to the crown of France. Stanislaus succeeded a race of princes in Lorrain, who were beloved and regretted: and his subjects found their ancient sovereigns revived in him. He tasted then the pleasure which he had so long desired, the pleasure of making men happy. He assisted his new subjects; he embellished Nancy and Lunéville; he made useful establishments; he founded colleges and built hospitals. He was engaged in these noble employments, when an accident occasioned his death. His night-gown caught fire and burnt him so severely before it could be extinguished, that he was seized with a fever, and died the 23d of February 1766. His death occasioned a public mourning: the tears of his subjects indeed are the best eulogium upon this prince. In his youth he had accustomed himself to fatigue, and had thereby strengthened his mind as well as his constitution. He lay always upon a kind of mattress, and seldom required any service from his domestics. He was temperate, liberal, adored by his vassals and perhaps the only nobleman in Poland who had any friends. He was in Lorrain what he had been in his own country, gentle, affable, compassionate, treating his subjects like equals, participating their sorrows and alleviating their misfortunes. He resembled completely the picture of a philosopher which he himself has drawn. "The true philosopher (said he) ought to be free from prejudices, and to know the value of reason: he ought neither to think the higher ranks of life of more value than they are, nor to treat the lower orders of mankind with greater contempt than they deserve: he ought to enjoy pleasures without being a slave to them, riches without being attached to them, honours without pride or vanity: he ought to support disgraces without either fearing or courting them: he ought to reckon what he possesses sufficient for him, and regard what he has not as useless: he ought to be equal in every fortune, always tranquil, always gay: he ought to love order, and to observe it in all his actions: he ought to be severe to himself, but indulgent to others: he ought to be frank and ingenuous without rudeness, polite without falsehood, complaisant without baseness: he ought to have the courage to disregard every kind of glory, and to reckon as nothing even philosophy itself." Such was Stanislaus in every situation. His temper was affectionate,

ate,

ate. He told his treaſurer one day to put a certain officer on his liſt, to whom he was very much attached: "In what quality (ſaid the treaſurer) ſhall I mark him down?" "As my friend" (replied the monarch.) A young painter conceiving hopes of making his fortune if his talents were made known to Staniſlaus, preſented him with a picture, which the courtiers criticiſed ſeverely. The prince praiſed the performance, and paid the painter very generouſly: then turning to his courtiers, he ſaid, "Do ye not ſee, gentlemen, that this poor man muſt provide for his family by his abilities? if you diſcourage him by your cenſures, he is undone. We ought always to aſſiſt men; we never gain any thing by hurting them." His revenues were ſmall; but were we to judge of him by what he did, we ſhould probably reckon him the richeſt potentate in Europe. A ſingle inſtance will be ſufficient to ſhow the well judged economy with which his benevolent plans were conducted. He gave 18,000 crowns to the magiſtrates of Bar to be employed in purchaſing grain, when at a low price, to be ſold out again to the poor at a moderate rate when the price ſhould riſe above a certain ſum. By this arrangement (ſay the authors of *Dictionaire Hiſtorique*), the money increaſes continually, and its good effects may in a ſhort time be extended over the whole province.

He was a protector of the arts and ſciences: he wrote ſeveral works of philoſophy, politics, and morality, which were collected and publiſhed in France in 1765, in 4 vols, 8vo. under the title of *Oeuvres du Philoſophe Bienfaiſant*, "the works of the Benevolent Philoſopher."

STANITZAS, villages or ſmall diſtricts of the banks of the Don, inhabited by Coſſacs.

STANLEY (Thomas), a very learned Engliſh writer in the 17th century, was the ſon of Sir Thomas Stanley of Cumberlow-Green in Herefordſhire, knight. He was born at Cumberlow ahout 1644, and educated in his father's houſe, whence he removed to the univerſity of Cambridge. He afterwards travelled; and, upon his return to England, proſecuted his ſtudies in the Middle Temple. He married, when young, Dorothy, the eldeſt daughter of Sir James Engan of Flower, in Northamptonſhire. He wrote, 1. A volume of Poems. 2. Hiſtory of Philoſophy, and Lives of the Philoſophers. 3. A Tranſlation of Eſchylus, with a Commentary; and ſeveral other works. He died in 1678.

STANNARIES, the mines and works where tin is dug and purified; as in Cornwall, Devonſhire, &c.

STANNARY COURTS, in Devonſhire and Cornwall, for the adminiſtration of juſtice among the tinners therein. They are held before the lord-warden and his ſubſtitutes, in virtue of a privilege granted to the workers in the tin-mines there, to ſue and be ſued only in their own courts, that they may not be drawn from their buſineſs, which is highly profitable to the public, by attending their law-ſuits in other courts. The privileges of the tinners are confirmed by a charter, 33 Edw. I. and fully expounded by a private ſtatute, 50 Edw. III. which has ſince been explained by a public act, 16 Car. I. c. 15. What relates to our preſent purpoſe is only this: That all tinners and labourers in and about the ſtannaries ſhall, during the time of their working therein, *bona fide*, be privileged from ſuits of other courts, and be only pleaded in the ſtannary court in all matters, excepting pleas of land, life, and member. No writ of error lies from hence to any court in Weſtminſter-hall; as was agreed by all the judges, in 4 Jac. I. But an appeal lies from the ſteward of the court to the under-warden; and from him to the lord-warden; and thence to the privy-council of the prince of Wales, as duke of Cornwall, when he hath had livery or inveſtiture of the ſame. And from thence the appeal lies to the king himſelf, in the laſt reſort.

Blackſtone's Comment. vol. iii. p. 79 and 80.

STANNUM, TIN. See CHEMISTRY-*Index*, and TIN.

STANZA, in poetry, a number of lines regularly adjuſted to each other; ſo much of a poem as contains every variation of meaſure or relation of rhyme uſed in that poem.

STAPHYLEA, BLADDER-NUT, in botany: A genus of plants belonging to the claſs of *pentandria*, and order of *trigynia*; and in the natural ſyſtem arranged under the 23d order, *trihilatæ*. The calyx is quinquepartite. There are five petals. The capſules are three, inflated and joined together by a longitudinal ſuture. The ſeeds are two, and are globoſe with a ſcar. There are two ſpecies, the pinnata and trifolia. The *pinnata*, or bladder-nut-tree, is a tall ſhrub or tree. The leaves are pinnated; the pinnæ are generally five, oblong, pointed, and notched round the edges. The flowers are white, and grow in whirls on long pendulous footſtalks. This plant flowers in June, and is frequent in hedges about Pontefract and in Kent. The *trifolia*, or three-leaved bladder-nut, is a native of Virginia.

STAPHYLINUS, a genus of animals belonging to the claſs of *inſectæ*, and order of *coleoptera*. The antennæ are moniliform; the feelers four in number; the elytra are not above half the length of the abdomen; the wings are folded up and concealed under the elytra; the tail or extremity of the abdomen is ſingle, is provided with two long veſicles which the inſect can ſhoot out or draw back at pleaſure. Gmelin enumerates 117 ſpecies, of which five only are natives of Great Britain; the murinus, maxilloſus, rufus, riparius, chryſomelinus.

1. *Murinus*. The head is depreſſed. The colour is grey, clouded with black. The length is ſix lines. It lives among horſe-dung. 2. The *maxilloſus* is black, with aſh-coloured ſtripes, and jaws as long as the head. It inhabits the woods. 3. *Rufus* is of an orange-colour; but the poſterior part of the elytra and abdomen is black, as are alſo the thighs at their baſe. 4. *Riparius* is of a reddiſh brown colour; but the elytra are azure-coloured; and the head, antennæ, and two laſt rings of the abdomen, are black. It is frequent on the banks of rivers in Europe. 5. *Chryſomelinus* is black; the thorax, elytra, and feet being teſtaceous. It is found in the north of Europe.

The inſects have a peculiarity to be met with in almoſt every ſpecies of this genus, which is, that they frequently turn up their tail, or extremity of the abdomen, eſpecially if you chance to touch them; in which caſe the tail is ſeen to riſe immediately, as if the inſect meant to defend itſelf by ſtinging. Yet that is not the place where the inſect's offenſive weapons are ſituated. Its tail has no ſting, but in recompenſe it bites and pinches ſtrongly with its jaws; and care muſt be taken, eſpecially in laying hold of the larger ſpecies. Their jaws are ſtrong, ſhoot out beyond the head, and are ſubſervient to the animal in ſeizing and deſtroying

Barbut's Genera Inſectorum.

its

its prey. It feeds on all other insects it can catch: even frequently two staphylini of the same species bite and tear each other. Though this insect has very small elytra, yet its wings are large; but they are curiously folded up, and concealed under the elytra. The insect unfolds and expands them when he chooses to fly, which he does very lightly. Among the small species of this genus, there are several whose colours are lively and singularly intermingled.

Some of them are found upon flowers, but they chiefly inhabit the dung of cows. Their larvæ, which resemble them so much as to be scarce distinguishable, live in damp places under ground. They are by some called *Rove beetles*.

STAPLE, primarily signifies a public place or market, whither merchants, &c. are obliged to bring their goods to be bought by the people; as the Greve, or the places along the Seine, for sale of wines and corn, at Paris, whither the merchants of other parts are obliged to bring those commodities.

Formerly, the merchants of England were obliged to carry their wool, cloth, lead, and other like staple commodities of that realm, in order to expose them by wholesale; and these staples were appointed to be constantly kept at York, Lincoln, Newcastle upon Tyne, Norwich, Westminster, Canterbury, Chichester, Winchester, Exeter, and Bristol; in each whereof a public mart was appointed to be kept, and each of them had a court of the mayor of the staple, for deciding differences, held according to the law-merchant, in a summary way.

STAR, in astronomy, a general name for all the heavenly bodies, which, like so many brilliant studs, are dispersed throughout the whole heavens. The stars are distinguished, from the phenomena of their motion, &c. into fixed, and erratic or wandering stars: these last are again distinguished into the greater luminaries, viz. the sun and moon; the planets, or wandering stars, properly so called; and the comets; which have been all fully considered and explained under the article ASTRONOMY. As to the fixed stars, they are so called, because they seem to be fixed, or perfectly at rest, and consequently appear always at the same distance from each other.

Falling STARS, in meteorology, fiery meteors which dart through the sky in form of a star. See METEOR.

Twinkling of the STARS. See OPTICS, n° 21. *et seq.*

STAR, is also a badge of honour, worn by the knights of the garter, bath, and thistle. See GARTER.

STAR of Bethlehem, in botany. See ORNITHOGALUM.

Court of STAR-CHAMBER, (*camera stellata*), a famous, or rather infamous, English tribunal, said to have been so called either from a Saxon word signifying to *steer* or govern; or from its punishing the *crimen stellionatus*, or cosenage; or because the room wherein it sat, the old council-chamber of the palace of Westminster, (Lamb. 148.) which is now converted into the lottery-office, and forms the eastern side of New Palace-yard, was full of windows; or, (to which Sir Edward Coke, 4. Inst. 66. accedes), because *haply* the roof thereof was at the first garnished with gilded *stars*. As all these are merely conjectures, (for no stars are now in the roof, nor are any said to have remained there so late as the reign of queen Elizabeth), it may be allowable to propose another conjectural etymology, as plausible perhaps as any of them. It is well known, that, before the banishment of the Jews under Edward I. their contracts and obligations were denominated in our ancient records *starra* or *starrs*, from a corruption of the Hebrew word, *shetar*, a covenant. (Tovey's *Angl. Judaic*. 32. Selden. tit. of hon. ii. 34. *Uxor Ebraic*. i. 14.) These starrs, by an ordinance of Richard the First preserved by Hoveden, were commanded to be enrolled and deposited in chests under three keys in certain places; one, and the most considerable, of which was in the king's exchequer at Westminster: and no starr was allowed to be valid, unless it were found in some of the said repositories. (*Memorand. in Scac' P. 6. Edw.* I. prefixed to Maynard's year-book of Edw. II. fol. 8. Madox hist. exch. c. vii. § 4, 5, 6.) The room at the exchequer, where the chests containing these starrs were kept, was probably called the *star-chamber*; and, when the Jews were expelled the kingdom, was applied to the use of the king's council, sitting in their judicial capacity. To confirm this, the first time the star-chamber is mentioned in any record, it is said to have been situated near the receipt of the exchequer at Westminster: (the king's council, his chancellor, treasurer, justices, and other sages, were assembled *en la chaumbre des esteilles pres la resceipt al Westminster. Claus.* 41 *Edw.* III. *m.* 13.) For in process of time, when the meaning of the Jewish *starrs* were forgotten, the word *star-chamber* was naturally rendered in law French, *la chaumbre des esteilles*, and in law Latin *camera stellata*; which continued to be the style in Latin till the dissolution of that court.

Blackst. Comment. vol. iv. p. 266.

This was a court of very ancient original; but new-modelled by statutes 3 Hen. VII. c. 1. and 21 Hen. VIII. c. 20. consisting of divers lords spiritual and temporal, being privy counsellors, together with two judges of the courts of common-law, without the intervention of any jury. Their jurisdiction extended legally over riots, perjury, misbehaviour of sheriffs, and other notorious misdemeanors, contrary to the laws of the land. Yet this was afterwards (as lord Clarendon informs us) stretched "to the asserting of all proclamations and orders of state; to the vindicating of illegal commissions and grants of monopolies; holding for honourable that which pleased, and for just that which profited; and becoming both a court of law to determine civil rights, and a court of revenue to enrich the treasury: the council-table by proclamations enjoining to the people that which was not enjoined by the laws, and prohibiting that which was not prohibited; and the star-chamber, which consisted of the same persons in different rooms, censuring the breach and disobedience to those proclamations by very great fines, imprisonments, and corporal severities: so that any disrespect to any acts of state, or to the persons of statesmen, was in no time more penal, and the foundations of right never more in danger to be destroyed." For which reasons, it was finally abolished by statute 16 Car. I. c. 10. to the general joy of the whole nation. See *KING's Bench*. There is in the British Museum (Harl. MSS. Vol. I. n° 126.) a very full, methodical, and accurate account of the constitution and course of this court, compiled by William Hudson of Gray's Inn, an eminent practitioner therein. A short account of the same, with copies

copies of all its proceſs, may alſo be found in 18 Rym. Foed. 192, &c.

Star-Board, the right ſide of the ſhip when the eye of the ſpectator is directed forward.

Star-Fiſh. See Asterias.

Star-ſhot, a gelatinous ſubſtance frequently found in fields, and ſuppoſed by the vulgar to have been produced from the meteor called a *falling-ſtar:* but, in reality is the half-digeſted food of herons, ſea-mews, and the like birds; for theſe birds have been found, when newly ſhot, to diſgorge a ſubſtance of the ſame kind.

Star-Stone, in natural hiſtory, a name given to certain extraneous foſſil ſtones, in form of ſhort, and commonly ſomewhat crooked, columns compoſed of ſeveral joints, each reſembling the figure of a radiated ſtar, with a greater or ſmaller number of rays in the different ſpecies: they are uſually found of about an inch in length, and of the thickneſs of a gooſe-quill. Some of them have five angles or rays, and others only four; and in ſome the angles are equidiſtant, while in others they are irregularly ſo: in ſome alſo they are ſhort and blunt, while in others they are long, narrow, and pointed; and ſome have their angles very ſhort and obtuſe. The ſeveral joints in the ſame ſpecimen are uſually all of the ſame thickneſs; this, however, is not always the caſe: but in ſome they are larger at one end, and in others at the middle, than in any other part of the body; and ſome ſpecies, have one of the rays bifid, ſo as to emulate the appearance of a ſix rayed kind.

Star-Thiſtle, in botany. See Centaurea.

Star-Wort, in botany. See Aster.

STARCH, a fecula or ſediment, found at the bottom of veſſels wherein wheat has been ſteeped in water, of which fecula, after ſeparating the bran from it, by paſſing it through ſieves, they form a kind of loaves, which being dried in the ſun or an oven, is afterwards cut into little pieces, and ſo ſold. The beſt ſtarch, is white, ſoft, and friable, and eaſily broken into powder. Such as require fine ſtarch, do not content themſelves, like the ſtarchmen, with refuſe wheat, but uſe the fineſt grain. The proceſs is as follows: The grain, being well cleaned, is put to ferment in veſſels full of water, which they expoſe to the ſun while in its greateſt heat; changing the water twice a-day, for the ſpace of eight or twelve days, according to the ſeaſon. When the grain burſts eaſily under the finger, they judge it ſufficiently fermented. The fermentation perfected, and the grain thus ſoftened, it is put, handful by handful, into a canvas-bag, to ſeparate the flour from the huſks; which is done by rubbing and beating it on a plank laid acroſs the mouth of an empty veſſel that is to receive the flour.

As the veſſels are filled with this liquid flour, there is ſeen ſwimming at top a reddiſh water, which is to be carefully ſcummed off from time to time, and clean water is to be put in its place, which, after ſtirring the whole together, is alſo to be ſtrained through a cloth or ſieve, and what is left behind put into the veſſel with new water, and expoſed to the ſun for ſome time. As the ſediment thickens at the bottom, they drain off the water four or five times, by inclining the veſſel, but without paſſing it through the ſieve. What remains at bottom is the ſtarch, which they cut in pieces to get out, and leave it to dry in the ſun. When dry, it is laid up for uſe.

STARK (Dr William), known to the public by a volume containing *Clinical and Anatomical Obſervations*, with ſome curious *Experiments on Diet*, was born at Mancheſter in the month of July 1740; but the family from which he ſprang was Scotch, and reſpectable for its antiquity. His grandfather John Stark of Killermont was a covenanter; and having appeared in arms againſt his ſovereign at the battle of Bothwell bridge in the year 1679, became obnoxious to the government, and to conceal himſelf, withdrew into Ireland. There is reaſon to believe that he had not imbibed either the extravagant zeal or the ſavage manners of the political and religious party to which he adhered; for after reſiding a few years in the country which he had choſen for the ſcene of his baniſhment, he married Elizabeth daughter of Thomes Stewart Eſq; of Balydrone in the north of Ireland; who, being deſcended of the noble family of Galloway, would not probably have matched his daughter to ſuch an exile as a ruthleſs fanatic of the laſt century. By this lady Mr Stark had ſeveral children; and his ſecond ſon Thomas, who ſettled at Mancheſter as a wholeſale linen-draper, and married Margaret Stirling, daughter of William Stirling, Eſq; of Northwood ſide, in the neighbourhood of Glaſgow, was the father of the ſubject of this article. Another of his ſons, the reverend John Stark, was miniſter of Lecropt in Perthſhire; and it was under the care, of this gentleman that our author received the rudiments of his education, which, when we conſider the character of the maſter, and reflect on the relation between him and his pupil, we may preſume was calculated to ſtore the mind of Dr Stark with thoſe virtuous principles which influenced his conduct through life.

From Lecropt young Stark was ſent to the univerſity of Glaſgow, where, under the tuition of the Doctors Smith and Black, with other eminent maſters, he learned the rudiments of ſcience, and acquired that mathematical accuracy, that logical preciſion, and that contempt of hypotheſes, with which he proſecuted all his future ſtudies. Heaving choſen phyſic for his profeſſion, he removed from the univerſity of Glaſgow to that of Edinburgh, where he was ſoon diſtinguiſhed, and honoured with the friendſhip of the late Dr Cullen; a man who was not more eminently conſpicuous for the ſuperiority of his own genius, than quick-ſighted in perceiving, and liberal in encouraging, genius in his pupils. Having finiſhed his ſtudies at Edinburgh, though he took there no degree, Mr Stark, in the year 1765, went to London, and devoted himſelf entirely to the ſtudy of phyſic and the elements of ſurgery; and looking upon anatomy as one of the principal pillars of both theſe arts, he endeavoured to complete with Dr Hunter what he had begun with Dr Monro; and under theſe two eminent profeſſors he appears to have acquired a high degree of anatomical knowledge. He likewiſe entered himſelf about this time a pupil at St George's hoſpital; for being diſguſted, as he often confeſſed, with the inaccuracy or want of candour obſervable in the generality of practical writers, he determined to obtain an acquaintance with diſeaſes at a better ſchool and from an abler maſter; and to have from his own experience a ſtandard, by which he might judge of the experience

Stark.

perience of others. With what industry he prosecuted this plan, and with what success his labours were crowned, may be seen in a series of *Clinical and Anatomical Observations*, which were made by him during his attendance at the hospital, and were published after his death by his friend Dr Carmichael Smyth. These observations give the public no cause to complain of want of candour in their author; for whatever delicacy he may have observed, when relating the cases of patients treated by other physicians, he has related those treated by himself with the utmost impartiality. Whilst attending the hospital, he likewise employed himself in making experiments on the blood, and other animal fluids; and also in a course of experiments in chemical pharmacy; but though accounts of these experiments were left behind him, we believe they have not yet been given to the public.

In the year 1767 Mr Stark went abroad and obtained the degree of M. D. in the university of Leyden, publishing an inaugural dissertation on the dysentery. On his return to London, he recommenced his studies at the hospital; and when Dr Black was called to the chemical chair in Edinburgh, which he has long filled with so much honour to himself and credit to the university. Dr Stark was solicited by several members of the university of Glasgow to stand a candidate for their professorship of the theory and practice of physic, rendered vacant by Dr Black's removal to Edinburgh. This however Dr Stark declined, being influenced by the advice of his English friends, who wished to detain him in London, and having likewise some prospects of an appointment in the hospital.

In the mean time he had commenced (1769) a series of experiments on diet, which he was encouraged to undertake by Sir John Pringle and Dr Franklin, whose friendship he enjoyed, and from whom he received many hints respecting both the plan and its execution. These experiments, or rather the imprudent zeal with which he prosecuted them, proved in the opinion of his friends, fatal to himself; for he began them on the 12th of July 1769 in perfect health and vigour, and from that day, though his health varied, it was seldom if ever good, till the 23d of February 1770, when he died, after suffering much uneasiness. His friend and biographer Dr Smyth thinks, that other causes, particularly chagrin and disappointment had no small share in hastening his death; and as the Doctor was intimately acquainted with his character and disposition, his opinion is probably well-founded, though the pernicious effects of the experiments are visible in Dr Stark's own journal. When he entered upon them, the weight of his body was 12 stone 3 lb. avoirdupois, which in a very few days was reduced to 11 stone 10 lb 8 oz: and though some kinds of food increased it, by much the greater part of what he used had a contrary effect, and it continued on the whole to decrease till the day of his death. This indeed can excite no wonder. Though the professed object of his experiments was to prove that a *pleasant* and varied diet is equally conducive to health with a more strict and simple one, most of the dishes which he ate during these experiments were neither pleasant nor simple, but compounds, such as every stomach must nauseate. He began with *bread* and *water;* from which he proceeded to *bread, water,* and *sugar;* then to *bread, water,* and *oil of olives;* then to *bread* and *water* with *milk;* afterwards he tried *bread* and *water* with *roasted goose; bread* and *water* with *boiled beef; stewed lean of beef* with the *gravy* and *water* without bread; *stewed lean of beef* with the *gravy, oil of fat* or *suet* and *water; flour, oil of suet, water* and *salt; flour, water* and *salt;* and a number of others infinitely more disagreeable to the stomach than even these, such as *bread, fat of bacon ham, infusion of tea* with *sugar;* and *bread* or *flour* with *honey* and the infusion of *rosemary*. But though we consider Dr Stark's experiments as whimsical, it cannot be denied that they indicate eccentricity of genius in the person who made them; and such of our readers as think genius hereditary, may perhaps be of opinion, that he derived a ray from the celebrated Napier the inventor of the logarithms, who was his ancestor by both parents. At any rate, these experiments, of which a full account is given in the same volume with his clinical and anatomical observations, display an uncommon degree of fortitude, perseverance, self-denial, and zeal for the promoting of useful knowledge in their author; and with respect to his moral character, we believe it is with great justice that Dr Smyth compares him to Cato by applying to him what was said of that virtuous Roman by Sallust.—" Non divitiis cum divite, neque factione cum factioso; sed cum strenuo virtute, cum modesto pudore, cum innocente abstinentia certabat; esse, quam videri, bonus malebat*."

Stark ‖ Statice.

STARLING. See Sturnus.

STATE of a Controversy. See Oratory, Part I. n° 14.

STATES, or Estates, a term applied to several orders or classes of people assembled to consult of matters for the public good.

Thus states-general is the name of an assembly consisting of the deputies of the seven United Provinces. These are usually 30 in number, some provinces sending two, others more; and whatever resolution the states-general take, must be confirmed by every province, and by every city and republic in that province, before it has the force of a law. The deputies of each province, of what number soever they be, have only one voice, and are esteemed as but one person, the votes being given by provinces. Each province presides in the assembly in its turn, according to the order settled among them. Guelderland presides first, then Holland, &c.

States of Holland are the deputies of eighteen cities, and one representative of the nobility, constituting the states of the province of Holland: the other provinces have likewise their states, representing their sovereignty; deputies from which make what they call the states-general. In an assembly of the states of a particular province, one dissenting voice prevents their coming to any resolution.

STATICE Thrift, in botany: A genus of plants belonging to the class of *pentandria*, and order of *pentagynia;* and in the natural system ranging under the 48th order, *aggregatæ*. The calyx is monophyllous, entire, folded, and scariose. There are five petals, with one superior seed. There are 22 species, the armeria, pseudarmeria, limonium, incana, cordata, reticulata, echioides, speciosa, tatarica, echinus, flexuosa, purpurata, minuta, suffruticosa, monopetala, aurea, ferulacea, linifolia, pruinosa, sinuata, mucronata, and lobata. Three of these are British plants.

1. The *armeria,* thrift, or sea gilly-flower, has a simple naked

naked ſtem about ſix inches high. The radical leaves are like graſs. The flowers are terminal, pale red, with a round head, and not very large. The plant flowers in July or Auguſt, and grows in meadows near the ſea.

2. *Limonium*, ſea-lavender. The ſtem is naked, branched, and about a foot high. The radical leaves are long, pointed, and grow on footſtalks. The flowers are blue, and grow on long ſpikes on the tops of the branches. It grows on the ſea-coaſt in South-Britain.

3. *Reticulata*, matted ſea-lavender. The ſtem is proſtrate, and terminated by a panicle of flowers. The branches are naked, barren, and bent back. The leaves are wedge-ſhaped. This ſpecies is alſo found on the ſea-coaſt of South Britain.

STATICS, a term which the modern improvements in knowledge have made it neceſſary to introduce into phyſico mathematical ſcience. It was found convenient to diſtribute the doctrines of univerſal mechanics into two claſſes, which required both a different mode of conſideration and different principles of reaſoning.

Till the time of Archimedes little ſcience of this kind was poſſeſſed by the ancients, from whom we have received the firſt rudiments. His inveſtigation of the centre of gravity, and his theory of the lever, are the foundations of our knowledge of common mechanics; and his theory of the equilibrium of floating bodies contains the greateſt part of our hydroſtatical knowledge. But it was as yet limited to the ſimpleſt caſes; and there were ſome in which Archimedes was ignorant, or was miſtaken. The marquis Guido Ubuldi, in 1578, publiſhed his theory of mechanics, in which the doctrines of Archimedes were well explained and conſiderably augmented. Stevinus, the celebrated Dutch engineer, publiſhed about 20 years after an excellent ſyſtem of mechanics, containing the chief principles which now form the ſcience of equilibrium among ſolid bodies. In particular, he gave the theory of inclined planes, which was unknown to the ancients, though it is of the very firſt importance in almoſt every machine. He even ſtates in the moſt expreſs terms the principle afterwards made the foundation of the whole of mechanics, and publiſhed as a valuable diſcovery by Varignon, viz. that three forces, whoſe directions and intenſities are as the ſides of a triangle, balance each other. His theory of the preſſure of fluids, or hydroſtatics, is no leſs eſtimable, including every thing that is now received as a leading principle in the ſcience. When we conſider the ignorance, even of the moſt learned, of that age in mechanical or phyſico mathematical knowledge, we muſt conſider thoſe performances as the works of a great genius, and we regret that they are ſo little known, being loſt in a crowd of good writings on thoſe ſubjects which appeared ſoon after.

Hitherto the attention had been turned entirely to equilibrium, and the circumſtances neceſſary for producing it. Mechanicians indeed ſaw, that the energy of a machine might be ſomehow meaſured by the force which could be oppoſed or overcome by its intervention: but they did not remark, that the force which prevented its motion, but did no more than prevent it, was an *exact* meaſure of its energy, becauſe it was in immediate equilibrio with the preſſure exerted by that part of the machine with which it was connected. If this oppoſed force was leſs, or the force acting at the other extremity of the machine was greater, the mechanicians knew that the machine would move, and that work would be performed; but what would be the rate of its motion or its performance they hardly pretended to conjecture. They had not ſtudied the action of moving forces, nor conceived what was done when motion was communicated.

The great Galileo opened a new field of ſpeculation in his work on Local Motion. He there conſiders a change of motion as the indication and exact and adequate meaſure of a moving force; and he conſiders every kind of preſſure as competent to the production of ſuch changes.—He contented himſelf with the application of this principle to the motion of bodies by the action of gravity, and gave the theory of projectiles, which remains to this day without change, and only improved by conſidering the changes which are produced in it by the reſiſtance of the air.

Sir Iſaac Newton took up this ſubject nearly as Galileo had left it. For, if we except the theory of the centrifugal forces ariſing from rotation, and the theory of pendulums, publiſhed by Huygens, hardly any thing had been added to the ſcience of motion. Newton conſidered the ſubject in its utmoſt extent; and in his mathematical principles of natural philoſophy he conſiders every conceivable variation of moving force, and determines the motion reſulting from its action.—His firſt application of theſe doctrines was to explain the celeſtial motions; and the magnificence of this ſubject cauſed it to occupy for a while the whole attention of the mathematicians. But the ſame work contained propoſitions equally conducive to the improvement of common mechanics, and to the complete underſtanding of the mechanical actions of bodies. Philoſophers began to make theſe applications alſo. They ſaw that every kind of work which is to be performed by a machine may be conſidered abſtractedly as a retarding force; that the impulſe of water or wind, which are employed as moving powers, act by means of preſſures which they exert on the impelled point of the machine; and that the machine itſelf may be conſidered as an aſſemblage of bodies moveable in certain limited circumſtances, with determined directions and proportions of velocity. From all theſe conſiderations reſulted a general abſtract condition of a body acted on by known powers. And they found, that after all conditions of equilibrium were ſatisfied, their remains a ſurplus of moving force. They could now ſtate the motion which will enſue, the new reſiſtance which this will excite, the additional power which this will abſorb; and they at laſt determined a new kind of equilibrium, not thought of by the ancient mechanicians, between the reſiſtance to the machine performing work and the moving power, which exactly balance each other, and is indicated, not by the *reſt*, but by the *uniform motion* of the machine.—In like manner, the mathematician was enabled to calculate that preciſe motion of water which would completely abſorb, or, in the new language, balance the ſuperiority of preſſure by which water is forced through a ſluice, a pipe, or canal, with a conſtant velocity.

Thus the general doctrines of motion came to be conſidered in two points of view, according as they balanced each other in a ſtate of reſt or of uniform motion. Theſe two ways of conſidering the ſame ſubject required both different principles and a different manner of reaſoning. The firſt has been named STATICS, as expreſſing preffing that reft which is the teft of this kind of equilibrium. The fecond has been called DYNAMICS or UNIVERSAL MECHANICS, becaufe the different kinds of motion are characteriftic of the powers or forces which produce them. A knowledge of both is indifpenfably neceffary for acquiring any ufeful practical knowledge of machines: and it was ignorance of the doctrines of accelerated and retarded motions which made the progrefs of practical mechanical knowledge fo very flow and imperfect. The mechanics, even of the moderns, before Galileo, went no further than to ftate the proportion of the power and refiftance which would be balanced by the intervention of a given machine, or the proportion of the parts of a machine by which two known forces may balance each other. This view of the matter introduced a principle, which even Galileo confidered as a mechanical axiom, viz. that *what is gained in force by means of a machine is exactly compenfated by the additional time which it obliges us to employ*. This is falfe in every inftance, and not only prevents improvement in the conftruction of machines, but leads us into erroneous maxims of conftruction. The true principles of dynamics teach us, that there is a certain proportion of the machine, dependent on the kind and proportion of the power and refiftance, which enables the machine to perform the greateft poffible work.

It is highly proper therefore to keep feparate thefe two ways of confidering machines, that both may be improved to the utmoft, and then to blend them together in every practical difcuffion.

Statics therefore is preparatory to the proper ftudy of mechanics; but it does not hence derive all its importance. It is the fole foundation of many ufeful parts of knowledge. This will be beft feen by a brief enumeration.

1. It comprehends all the doctrines of the excitement and propagation of preffure through the parts of folid bodies, by which the energies of machines are produced. A preffure is exerted on the impelled point of a machine, fuch as the float-boards or buckets of a mill-wheel. This *excites* a preffure at the pivots of its axle, which act on the points of fupport. This muft be underftood, both as to direction and intenfity, that it may be effectually refifted. A preffure is alfo excited at the acting tooth of the cog wheel on the fame axle, by which it urges round another wheel, exciting fimilar preffures on its pivots and on the acting tooth perhaps of a third wheel.—Thus a preffure is ultimately excited in the working point of the machine, perhaps a wiper, which lifts a heavy ftamper, to let it fall again on fome matter to be pounded. Now ftatics teaches us the intenfities and directions of all thofe preffures, and therefore how much remains at the working point of the machine unbalanced by refiftance.

2. It comprehends every circumftance which influences the ftability of heavy bodies; the inveftigation and properties of the centre of gravity; the theory of the conftruction of arches, vaults, and domes; the attitudes of animals.

3. The ftrength of materials, and the principles of conftruction, fo as to make the proper adjuftment of ftrength and ftrain in every part of a machine, edifice, or ftructure of any kind. Statics therefore furnifhes us with what may be called *a theory of carpentry*, and gives us proper inftructions for framing floors, roofs, centres, &c.

4. Statics comprehends the whole doctrine of the preffure of fluids, whether liquid or aeriform, whether arifing from their weight or from any external action. Hence therefore we derive our knowledge of the ftability of fhips, or their power of maintaining themfelves in a pofition nearly upright, in oppofition to the action of the wind on their fails. We learn on what circumftances of figure and ftowage this quality depends, and what will augment or diminifh it.

Very complete examples will be given in the remaining part of this work of the advantages of this feparate confideration of the condition of a machine at reft and in working motion; and in what yet remains to be delivered of the hydraulic doctrines in our account of *WATER-Works* in general, will be perceived the propriety of ftating apart the equilibrium which is indicated by the uniform motion of the fluid. The obfervations too which we have to make on the ftrength of the materials employed in our edifices or mechanical ftructures, will be examples of the inveftigation of thofe powers, preffures, or ftrains, which are excited in all their parts.

STATISTICS, a word lately introduced to exprefs a view or furvey of any kingdom, county, or parifh.

A Statiftical view of Germany was publifhed in 1790 by Mr B. Clarke; giving an account of the imperial and territorial conftitutions, forms of government, legiflation, adminiftration of juftice, and of the ecclefiaftical ftate; with a fketch of the character and genius of the Germans; a fhort inquiry into the ftate of their trade and commerce; and giving a diftinct view of the dominions, extent, number of inhabitants to a fquare mile; chief towns, with their fize and population; revenues, expences, debts, and military ftrength of each ftate. In Pruffia, in Saxony, Sardinia, and Tufcany, attempts have alfo been made to draw up ftatiftical accounts; but they were done rather with a view of afcertaining the prefent ftate of thefe countries, than as the means of future improvement.

A grand and extenfive work of this kind, founded on a judicious plan, conducted by the moft patriotic and enlightened motives, and drawn up from the communications of the whole body of the clergy, was undertaken in Scotland in the year 1790 by Sir John Sinclair of Ulbfter, one of the moft ufeful members of his country. Many praifes are heaped upon genius and learning; but to genius and learning no applaufe is due, except when exerted for the benefit of mankind: but gratitude and praife is due to him whofe talents fhine only in great undertakings, whofe happinefs feems to confift in patriotic exertions, and whofe judgment is uniformly approved by his fuccefs. A work of this kind, fo important in its object, fo comprehenfive in its range, fo judicious in its plan, and drawn up by more than 900 men of literary education, many of them men of great genius and learning, muft be of immenfe value. Sixteen volumes octavo are already publifhed; and it is fuppofed that the work will be completed in two or three additional volumes.

The great object of this work is to give an acurate view of the ftate of the country, its agriculture, its manufactures, and its commerce; the means of improvement, of which they are refpectively capable; the amount of the population of a ftate, and the caufes of its increafe or decreafe; the manner in which the territory of a country is poffeffed and cultivated; the nature and amount of the various productions of the foil; the value of the perfonal wealth or ftock of the inhabitants, and how it can be augmented; the difeafes to which the people are fubject, their caufes and their cure; the occupations of the people; where they are entitled to encouragement, and where they ought to be fuppreffed; the condition of the poor, the beft mode of maintaining them, and of giving them employment; the ftate of fchools, and other inftitutions, formed for purpofes of public utility; the ftate of the villages and towns, and the regulations beft calculated for their police and good government; the ftate of the manners, the morals, and the religious principles of the people, and the means by which their temporal and eternal interefts can beft be promoted.

To fuch of our readers as have not an opportunity of perufing this national work, or of examining its plan, we will prefent the fcheme for the ftatiftical account of a parochial diftrict which Sir John Sinclair publifhed for the confideration of the clergy, and which has been generally followed by them, though often with great improvements.

The name of the parifh and its origin; fituation and extent of the parifh; number of acres; defcription of the foil and furface; nature and extent of the fea-coaft; lakes, rivers, iflands, hills, rocks, caves, woods, orchards, &c.; climate and difeafes; inftances of longevity; ftate of property; number of proprietors; number of refiding proprietors; mode of cultivation; implements of hufbandry; manures; feedtime and harveft; remarkable inftances of good and bad feafons; quantity and value of each fpecies of crop; total value of the whole produce of the diftrict; total real and valued rent; price of grain and provifions; total quantity of grain and other articles confumed in the parifh; wages and price of labour; fervices, whether exacted or abolifhed; commerce; manufactures; manufacture of kelp, its amount, and the number of people employed in it; fifheries; towns and villages; police; inns and alehoufes; roads and bridges; harbours; ferries, and their ftate; number of fhips and veffels; number of feamen; ftate of the church; ftipend, manfe, glebe, and patron; number of poor; parochial funds, and the management of them; ftate of the fchools, and number of fcholars; ancient ftate of population; caufes of its increafe or decreafe; number of families; exact amount of the number of fouls now living; divifion of the inhabitants; 1. by the place of their birth; 2. by their ages; 3. by their religious perfuafions; 4. by their occupations and fituation in life; 5. by their refidence, whether in town, village, or in the country; number of houfes; number of uninhabited houfes; number of dove-cots, and to what extent they are deftructive to the corps; number of horfes, their nature and value; number of cattle, their nature and value; number of fheep, their nature and value; number of fwine, their nature and value; minerals in general; mineral fprings; coal and fuel; eminent men; antiquities; parochial records; mifcellaneous obfervations; character of the people; their manners, cuftoms, ftature, &c.; advantages and difadvantages; means by which their fituation could be meliorated.

If fimilar furveys (fays the public-fpirited editor of this work) were inftituted in the other kingdoms of Europe, it might be the means of eftablifhing, on fure foundations, the principles of that moft important of all fciences, viz. political or ftatiftical philofophy; that is, the fcience, which, in preference to every other, ought to be held in reverence. No fcience can furnifh, to any mind capable of receiving ufeful information, fo much real entertainment; none can yield fuch important hints, for the improvement of agriculture, for the extenfion of commercial induftry, for regulating the conduct of individuals, or for extending the profperity of the ftate; none can tend fo much to promote the general happinefs of the fpecies.

STATIUS (Publius Papinius), a celebrated Latin poet of the firft century, was born at Naples, and was the fon of Statius, a native of Epirus, who went to Rome to teach poetry and eloquence, and had Domitian for his fcholar. Statius the poet alfo obtained the favour and friendfhip of that prince; and dedicated to him his Thebais and Achilleis; the firft in twelve books, and the laft in two. He died at Naples about the year 100. Befides the above poems, there are alfo ftill extant his *Sylvæ*, in five books; the ftyle of which is purer, more agreeable, and more natural, than that of his Thebais and Achilleis.

STATUARY, a branch of fculpture, employed in the making of ftatues. See SCULPTURE and the next article.

Statuary is one of thofe arts wherein the ancients furpaffed the moderns; and indeed it was much more popular, and more cultivated, among the former than the latter. It is difputed between ftatuary and painting, which of the two is the moft difficult and the moft artful.

Statuary is alfo ufed for the artificer who makes ftatues. Phidias was the greateft ftatuary among the ancients, and Michael Angelo among the moderns.

STATUE, is defined to be a piece of fculpture in full relievo, reprefenting a human figure. Daviler more fcientifically defines ftatue a reprefentation, in high relievo and infulate, of fome perfon diftinguifhed by his birth, merit, or great actions, placed as an ornament in a fine building, or expofed in a public place, to preferve the memory of his worth. In Greece one of the higheft honours to which a citizen could afpire was to obtain a ftatue.

Statues are formed with the chifel, of feveral matters, as ftone, marble, plafter, &c. They are alfo caft of various kinds of metal, particularly gold, filver, brafs, and lead. For the method of cafting ftatues, fee the article *FOUNDERY of Statues*.

Statues are ufually diftinguifhed into four general kinds. The firft are thofe lefs than the life; of which kind we have feveral ftatues of great men, of kings, and of gods themfelves. The fecond are thofe equal to the life; in which manner it was that the ancients, at the public expence, ufed to make ftatues of perfons eminent for virtue, learning, or the fervices they had done. The third are thofe that exceed the life; among which thofe that furpaffed the life once and a half were for kings and emperors; and thofe double the life, for heroes. The fourth kind were thofe that exceeded the life twice, thrice, and even more, and were called *coloffufes*. See COLOSSUS.

Every ftatue refembling the perfon whom it is intended to reprefent, is called *ftatua iconica*. Statues acquire various other denominations. 1. Thus, allegorical ftatue is that which, under a human figure, or other fymbol, repre-

represents something of another kind; as a part of the earth, a season, age, element, temperament, hour, &c. 2. Curule statues, are those which are represented in chariots drawn by bigæ or quadrigæ, that is, by two or four horses; of which kind there were several in the circuses, hippodromes, &c. or in cars, as we see some, with triumphal arches on antique medals. 3. Equestrian statue, that which represents some illustrious person on horseback, as that famous one of Marcus Aurelius at Rome; that of king Charles I. at Charing-cross; King George II. in Leicester-Square, &c. 4. Greek statue, denotes a figure that is naked and antique; it being in this manner the Greeks represented their deities, athletæ of the olympic games, and heroes; the statues of heroes were particularly called *Achillean statues*, by reason of the great number of figures of Achilles in most of the cities of Greece. 5. Hydraulic statue, is any figure placed as an ornament of a fountain or grotto, or that does the office of a *jet d'eau*, a cock, spout, or the like, by any of its parts, or by any attribute it holds: the like is to be understood of any animal serving for the same use. 6. Pedestrian statue, a statue standing on foot; as that of king Charles II. in the Royal Exchange, and of king James II. in the Privy-Gardens. 7. Roman statue, is an appellation given to such as are clothed, and which receive various names from their various dresses. Those of emperors, with long gowns over their armour, were called *statuæ paludatæ*: those of captains and cavaliers, with coats of arms, *thoracatæ*; those of soldiers with cuirasses, *loricatæ*; those of senators and augurs, *trabeatæ*; those of magistrates with long robes, *togatæ*; those of the people with a plain tunica, *tunicatæ*; and, lastly, those of women with long trains, *stolatæ*.

In repairing a statue cast in a mould, they touch it up with a chisel, graver, or other instrument, to finish the places which have not come well off: they also clear off the barb, and what is redundant in the joints and projectures.

STATURE. See Dwarf and Giant.

STATUTE, in its general sense, signifies a law, ordinance, decree, &c. See Law, &c.

Statute, in English laws and customs, more immediately signifies an act of parliament made by the three estates of the realm; and such statutes are either general, of which the courts at Westminster must take notice without pleading them; or they are special and private, which last must be pleaded.

STAVESACRE, in botany; a species of Delphinium.

STAY, a large strong rope employed to support the mast on the fore-part, by extending from its upper end towards the fore part of the ship, as the shrouds are extended to the right and left, and behind it. See Mast, Rigging, and Shroud.

The stay of the fore-mast *a*, fig. 3. plate CCLXXVI. which is called the *fore stay*, reaches from the mast-head towards the bowsprit end: the main-stay *b* extends over the forecastle to the ship's stem; and the mizen stay *c* is stretched down to that part of the main-mast which lies immediately above the quarter-deck: the fore-top-mast stay *d* comes also to the end of the bowsprit, a little beyond the fore-stay: the main-top-mast stay *e* is attached to the head or hounds of the fore-mast; and the mizen-top-mast stay comes also to the hounds of the main-mast: the fore top-gallant stay comes to the outer end of the jib-boom; and the main-top-gallant stay is extended to the head of the fore-top-mast.

Stay-Sail, a sort of triangular sail extended upon a stay. See Sail.

STEAM, is the name given in our language to the visible moist vapour which arises from all bodies which contain juices easily expelled from them by heats not sufficient for their combustion. Thus we say, the steam of boiling water, of malt, of a tan-bed, &c. It is distinguished from smoke by its not having been produced by combustion, by not containing any soot, and by its being condensible by cold into water, oil, inflammable spirits, or liquids composed of these. 1 Definition.

We see it rise in great abundance from bodies when they are heated, forming a white cloud, which diffuses itself and disappears at no very great distance from the body from which it was produced. In this case the surrounding air is found loaded with the water or other juices which seem to have produced it, and the steam seems to be completely soluble in air, as salt is in water, composing while thus united a transparent elastic fluid. 2 Appears like a white cloud

But in order to its appearance in the form of an opaque white cloud, the mixture with or dissemination in air seems absolutely necessary. If a tea-kettle boils violently, so that the steam is formed at the spout in great abundance, it may be observed, that the visible cloud is not formed at the very mouth of the spout, but at a small distance before it, and that the vapour is perfectly transparent at its first emission. This is rendered still more evident by fitting to the spout of the tea-kettle a glass pipe of any length, and of as large a diameter as we please. The steam is produced as copiously as without this pipe, but the vapour is transparent through the whole length of the pipe. Nay, if this pipe communicate with a glass vessel terminating in another pipe, and if the vessel be kept sufficiently hot, the steam will be as abundantly produced at the mouth of this second pipe as before, and the vessel will be quite transparent. The visibility therefore of the matter which constitutes the steam is an accidental or extraneous circumstance, and requires the admixture with air; yet this quality again leaves it when united with air by solution. It appears therefore to require a *dissemination* in the air. The appearances are quite agreeable to this notion: for we know that one perfectly transparent body, when minutely divided and diffused among the parts of another transparent body, but not dissolved in it, makes a mass which is visible. Thus oil beat up with water makes a white opaque mass. 3 When disseminated in air.

In the mean time, as steam is produced, the water gradually wastes in the tea-kettle, and will soon be totally expended, if we continue it on the fire. It is reasonable therefore to suppose, that this steam is nothing but water changed by heat into an aerial or elastic form. If so, we should expect that the privation of this heat would leave it in the form of water again. Accordingly this is fully verified by experiment; for if the pipe fitted to the spout of the tea-kettle be surrounded with cold water, no steam will issue, but water will continually trickle from it in drops; and if the process be conducted with the proper precautions, the water which we thus obtain from the pipe will be found 4 Is again converted into water by cold.

equal in quantity to that which disappears from the tea-kettle.

5 Its appearances explained.

This is evidently the common process for distilling; and the whole appearances may be explained by saying, that the water is converted by heat into an elastic vapour, and that this, meeting with colder air, imparts to it the heat which it carried off as it arose from the heated water, and being deprived of its heat it is again water. The particles of this water being vastly more remote from each other than when they were in the tea-kettle, and thus being disseminated in the air, become visible, by reflecting light from their anterior and posterior surfaces, in the same manner as a transparent salt becomes visible when reduced to a fine powder. This disseminated water being presented to the air in a very extended surface, is quickly dissolved by it, as pounded salt is in water, and again becomes a transparent fluid, but of a different nature from what it was before, being no longer convertible into water by depriving it of its heat.

Accordingly this opinion, or something very like it, has been long entertained. Muschenbroeck expressly says, that the water in the form of vapour carries off with it all the heat which is continually thrown in by the fuel. But Dr Black was the first who attended minutely to the whole phenomena, and enabled us to form distinct notions of the subject. He had discovered that it was not sufficient for converting ice into water that it be raised to that temperature in which it can no longer remain in the form of ice. A piece of ice of the temperature 32° of Fahrenheit's thermometer will remain a very long while in air of the temperature 50° before it be all melted, remaining all the while of the temperature 32°, and therefore continually absorbing heat from the surrounding air. By comparing the time in which the ice had its temperature changed from 28° to 32° with the subsequent time of its complete liquefaction, he found that it absorbed about 130 or 140 times as much heat as would raise its temperature one degree; and he found that one pound of ice, when mixed with one pound of water 140 degrees warmer, was just melted, but without rising in its temperature above 32°. Hence he justly concluded, that water differed from ice of the same temperature by containing, as a constituent ingredient, a great quantity of fire, or of the cause of heat, united with it in such a way as not to quit it for another colder body, and therefore so as not to go into the liquor of the thermometer and expand it. Considered therefore as the possible cause of heat, it was latent, which Dr Black expressed by the abbreviated term LATENT HEAT. If any more heat was added to the water it was not latent, but would readily quit it for the thermometer, and, by expanding the thermometer, would show what is the degree of this *redundant* heat, while fluidity alone is the indication of the *combined* and latent heat.

6 And the cause of its conversion, by Dr Black's discovery of latent heat.

Dr Black, in like manner, concluded, that in order to convert water into an elastic vapour, it was necessary, not only to increase its uncombined heat till its temperature is 212°, in which state it is just ready to become elastic; but also to pour into it a great quantity of fire, or the cause of heat, which combines with every particle of it, so as to make it repel, or to recede from, its adjoining particles, and thus to make it a particle of an elastic fluid. He supposed that this additional heat might be combined with it so as not to quit it for the thermometer; and therefore so as to be in a latent state, having elastic fluidity for its sole indication.

7 The temperature at which it is produced, and the quantity of heat which it absorbs.

This opinion was very consistent with the phenomenon of boiling off a quantity of water. The application of heat to it causes it gradually to rise in its temperature till it reaches the temperature 212°. It then begins to send off elastic vapour, and is slowly expended in this way, continuing all the while of the same temperature. The steam also is of no higher temperature, as appears by holding a thermometer in it. We must conclude that this steam contains all the heat which is expended in its formation. Accordingly the scalding power of steam is well known; but it is extremely difficult to obtain precise measures of the quantity of heat absorbed by water during its conversion into steam. Dr Black endeavoured to ascertain this point, by comparing the time of raising its temperature a certain number of degrees with the time of boiling it off by the same external heat; and he found that the heat latent in steam, which balanced the pressure of the atmosphere, was not less than 800 degrees. He also directed Dr Irvine of Glasgow to the form of an experiment for measuring the heat actually extricated from such steam during its condensation in the refrigeratory of a still, which was found to be not less than 774 degrees. Dr Black was afterwards informed by Mr Watt, that a course of experiments, which he had made in each of these ways with great precision, determined the latent heat of steam under the ordinary pressure of the atmosphere to be about 948 or 950 degrees. Mr Watt also found that water would distil with great ease *in vacuo* when of the temperature 70°; and that in this case the latent heat of the steam is not less than 1200 or 1300 degrees: and a train of experiments, which he had made by distilling in different temperatures, made him conclude that the sum of the sensible and latent heats is a constant quantity. This is a curious and not an improbable circumstance; but we have no information of the particulars of these experiments. The conclusion evidently presupposes a knowledge of that particular temperature in which the water has no heat; but this is a point which is still *sub judice*.

8 Steam, by being combined with heat, becomes elastic and

This conversion of liquids (for is not confined to water, but obtains also in ardent spirits, oils, mercury, &c.) is the cause of their boiling. The heat is applied to the bottom and sides of the vessel, and gradually accumulates in the fluid, in a sensible state, uncombined, and ready to quit it and to enter into any body that is colder, and to diffuse itself between them. Thus it enters into the fluid of a thermometer, expands it, and thus gives us the indication of the degree in which it has been accumulated in the water; for the thermometer swells as long as it continues to absorb sensible heat from the water: and when the sensible heat in both is in equilibrio, in a proportion depending on the nature of the two fluids, the thermometer rises no more, because it absorbs no more heat or fire from the water; for the particles of water which are in immediate contact with the bottom, are now (by this gradual expansion of liquidity) at such distance from each other, that their laws of attraction for each other and for heat are totally changed. Each particle either no longer attracts, or perhaps it repels its adjoining particle, and now accumulates round itself a great number of the particles of heat,

Steam.

heat, and forms a particle of elastic fluid, so related to the adjoining new formed particles, as to repel them to a distance at least a hundred times greater than their distances in the state of water. Thus a mass of elastic vapour of sensible magnitude is formed. Being at least ten thousand times lighter than an equal bulk of water, it must rise up through it, as a cork would do, in form of a transparent ball or bubble, and getting to the top, it dissipates, filling the upper part of the vessel with vapour or steam. Thus, by tossing the liquid into bubbles, which are produced all over the bottom and sides of the vessel, it produces the phenomenon of ebullition or boiling. Observe, that during its passage up through the water, it is not changed or condensed; for the surrounding water is already so hot that the sensible or uncombined heat in it, is in equilibrio with that in the vapour, and therefore it is not disposed to absorb any of that heat which is combined as an ingredient of this vapour, and gives it its elasticity. For this reason, it happens that water will not boil till its whole mass be heated up to 212°; for if the upper part be colder, it robs the rising bubble of that heat which is necessary for its elasticity, so that it immediately collapses again, and the surface of the water remains still. This may be perceived by holding water in a Florence flask over a lamp or choffer. It will be observed, some time before the real ebullition, that some bubbles are formed at the bottom, and get up a very little way, and then disappear. The distances which they reach before collapsing increase as the water continues to warm farther up the mass, till at last it breaks out into boiling. If the handle of a tea-kettle be grasped with the hand, a tremor will be felt for some little time before boiling, arising from the little succussions which are produced by the collapsing of the bubbles of vapour. This is much more violent, and is really a remarkable phenomenon, if we suddenly plunge a lump of red hot iron into a vessel of cold water, taking care that no red part be near the surface. If the hand be now applied to the side of the vessel, a most violent tremor is felt, and sometimes strong thumps: these arise from the collapsing of very large bubbles. If the upper part of the iron be too hot, it warms the surrounding water so much, that the bubbles from below come up through it uncondensed, and produce ebullition without this succussion. The great resemblance of this tremor to the feeling which we have during the shock of an earthquake has led many to suppose that these last are produced in the same way, (See EARTHQUAKE, n° 88—98); and their hypothesis, notwithstanding the objections which we have elsewhere stated to it, is by no means unfeasible.

9 And produces the phenomenon of boiling.

10 The noise observed in the boiling of a tea-kettle explained.

It is owing to a similar cause that violent thumps are sometimes felt on the bottom of a tea-kettle, especially one which has been long in use. Such are frequently crusted on the bottom with a stony concretion. This sometimes is detached in little scales. When one of these is adhering by one end to the bottom, the water gets between them in a thin film. Here it may be heated considerably above the boiling temperature, and it suddenly rises up in a large bubble, which collapses immediately. A smooth shilling lying on the bottom will produce this appearance very violently, or a thimble with the mouth down.

11 Water will not boil unless the fire be applied to the bottom or sides of the vessel.

In order to make water boil, the fire must be applied to the bottom or sides of the vessel. If the heat be applied at the top of the water, it will waste away without boiling; for the very superficial particles are first supplied with the heat necessary for rendering them elastic, and they fly off without agitating the rest (A).

12 No fluid can boil till the elasticity of the vapour overcome the pressure of the incumbent bodies.

Since this disengagement of vapour is the effect of its elasticity, and since this elasticity is a determined force when the temperature is given, it follows, that fluids cannot boil till the elasticity of the vapour overcomes the pressure of the incumbent fluid and of the atmosphere. Therefore, when this pressure is removed or diminished, the fluids must sooner overcome what remains, and boil at a lower temperature. Accordingly it is observed that water will boil in an exhausted receiver when of the heat of the human body. If two glass balls A and B (fig. 1.) be connected by a slender tube, and one of them A be filled with water (a small opening or pipe *b* being left at top of the other), and this be made to boil, the vapour produced from it will drive all the air out of the other, and will at last come out itself, producing steam at the mouth of the pipe. When the ball B is observed to be occupied by transparent vapour, we may conclude that the air is completely expelled. Now shut the pipe by sticking it into a piece of tallow or bees-wax; the vapour in B will soon condense, and there will be a vacuum. The flame of a lamp and blow-pipe being directed to the little pipe, will cause it immediately to close and seal hermetically. We now have a pretty instrument or toy called a PULSE GLASS. Grasp the ball A in the hollow of the hand; the heat of the hand will immediately expand the bubble

Plate CCCCLXXVIII.

(A) We explained the opaque and cloudy appearance of steam, by saying that the vapour is condensed by coming into contact with the cooler air. There is something in the form of this cloud which is very inexplicable. The particles of it are sometimes very distinguishable by the eye; but they have not the smart star like brilliancy of very small drops of water, but give the fainter reflection of a very thin film or vesicle like a soap-bubble. If we attend also to their motion, we see them descending very slowly in comparison with the descent of a solid drop; and this vesicular constitution is established beyond a doubt by looking at a candle through a cloud of steam. It is seen surrounded by a faint halo with prismatical colours, precisely such as we can demonstrate by optical laws to belong to a collection of vesicles, but totally different from the halo which would be produced by a collection of solid drops. It is very difficult to conceive how these vesicles can be formed of watery particles, each of which was surrounded with many particles of fire, now communicated to the air, and how each of these vesicles shall include within it a ball of air; but we cannot refuse the fact. We know, that if, while linseed-oil is boiling or nearly boiling, the surface be obliquely struck with the ladle, it will be dashed into a prodigious number of exceedingly small vesicles, which will float about in the air for a long while. Mr Saussure was (we think) the first who distinctly observed this vesicular form of mists and clouds; and he makes considerable use of it in explaining several phenomena of the atmosphere.

ble of vapour which may be in it, and this vapour will drive the water into B, and then will blow up through it for a long while, keeping it in a ſtate of violent ebullition, as long as there remains a drop or film of water in A. But care muſt be taken that B is all the while kept cold, that it may condenſe the vapour as faſt as it riſes through the water. Touching B with the hand, or breathing warm on it, will immediately ſtop the ebullition in it. When the water in A has thus been diſſipated, graſp B in the hand; the water will be driven into A, and the ebullition will take place there as it did in B. Putting one of the balls into the mouth will make the ebullition more violent in the other, and the one in the mouth will feel very cold. This is a pretty illuſtration of the rapid abſorption of the heat by the particles of water which are thus converted into elaſtic vapour. We have ſeen this little toy ſuſpended by the middle of the tube like a balance, and thus placed in the inſide of a window, having two holes *a* and *b* cut in the pane, in ſuch a ſituation that when A is full of water and preponderates, B is oppoſite to the hole *b*. Whenever the room became ſufficiently warm, the vapour was formed in A, and immediately drove the water into B, which was kept cool by the air coming into the room through the hole *b*. By this means B was made to preponderate in its turn, and A was then oppoſite to the hole *a*, and the proceſs was now repeated in the oppoſite direction; and this amuſement continued as long as the room was warm enough.

13 Liquors differ much in the temperature neceſſary for their ebullition.

We know that liquors differ exceedingly in the temperatures neceſſary for their ebullition. This forms the great chemical diſtinction between volatile and fixed bodies. But the difference of temperature in which they boil, or are converted into permanently elaſtic vapour, under the preſſure of the atmoſphere, is not a certain meaſure of their differences of volatility. The natural boiling point of a body is that in which it will be converted into elaſtic vapour under no preſſure, or *in vacuo*. The boiling point in the open air depends on the law of the elaſticity of the vapour in relation to its heat. A fluid A may be leſs volatile, that is, may require more heat to make it boil *in vacuo*, than a fluid B: But if the elaſticity of the vapour of A be more increaſed by an increaſe of temperature than that of the vapour of B, A may boil at as low, or even at a lower temperature, in the open air, than B does; for the increaſed elaſticity of the vapour of A may ſooner overcome the preſſure of the atmoſphere. Few experiments have been made on the relation between the temperature and the elaſticity of different vapours. So long ago as the year 1765, we had occaſion to examine the boiling points of all ſuch liquors as we could manage in an air-pump; that is, ſuch as did not produce vapours which deſtroyed the valves and the leathers of the piſtons: and we thought that the experiments gave us reaſon to conclude that the elaſticity of all the vapours was affected by heat nearly in the ſame degree.

14 Difference between their boiling points in air and in vacuo about 120°.

For we found that the difference between their boiling points in the air and *in vacuo* was nearly the ſame in all, namely, about 120 degrees of Fahrenheit's thermometer. It is exceedingly difficult to make experiments of this kind: The vapours are ſo condenſible, and change their elaſticity ſo prodigiouſly by a trifling change of temperature, that it is almoſt impoſſible to examine this point with preciſion. It is, however, as we ſhall ſee by and by, a ſubject of conſiderable practical importance in the mechanic arts; and an accurate knowledge of the relation would be of great uſe alſo to the diſtiller: and it would be no leſs important to diſcover the relation of their elaſticity and denſity, by examining their compreſſibility, in the ſame manner as we have aſcertained the relation in the caſe of what we call *aerial fluids*, that is, ſuch as we have never obſerved in the form of liquids or ſolids, except in conſequence of their union with each other or with other bodies. In the article PNEUMATICS we took notice of it as ſomething like a natural law, that all theſe airs, or gaſes as they are now called, had their elaſticity very nearly, if not exactly proportional to their denſity. This appears from the experiments of Achard, of Fontana, and others, on vital air, inflammable air, fixed air, and ſome others. It gives us ſome preſumption to ſuppoſe that it holds in all elaſtic vapours whatever, and that it is connected with their elaſticity; and it renders it ſomewhat probable that they are all elaſtic, only becauſe the cauſe of heat (the matter of fire if you will) is elaſtic, and that their law of elaſticity, in reſpect of denſity, is the ſame with that of fire.

15 To what the elaſticity of fluids may be owing.

But it muſt be obſerved, that although we thus aſſign the elaſticity of fire as the immediate cauſe of the elaſticity of vapour, in the ſame way, and on the ſame grounds, that we aſcribe the fluidity of brine to the fluidity of the water which holds the ſolid ſalt in ſolution, it does not follow that this is owing, as is commonly ſuppoſed, to a repulſion or tendency to recede from each other exerted by the particles of fire. We are as much entitled to infer a repulſion of unlimited extent between the particles of water; for we ſee that by its means a ſingle particle of ſea-ſalt becomes diſſeminated through the whole of a very large veſſel. If water had not been a viſible and palpable ſubſtance, and the ſalt only had been viſible and palpable, we might have formed a ſimilar notion of chemical ſolution. But we, on the contrary, have conſidered the *quaquaverſum* motion or expanſion of the ſalt as a diſſemination among the particles of water; and we have aſcribed it to the ſtrong attraction of the atoms of ſalt for the atoms of water, and the attraction of theſe laſt for each other, thinking that each atom of ſalt accumulates round itſelf a multitude of watery atoms, and by ſo doing muſt recede from the other ſaline atoms. Nay, we farther ſee, that by forces which we naturally conſider as attractions, an expanſion may be produced of the whole maſs, which will act againſt external mechanical forces. It is thus that wood ſwells with almoſt inſuperable force by imbibing moiſture; it is thus that a ſponge immerſed in water becomes really an elaſtic compreſſible body, reſembling a blown bladder; and there are appearances which warrant us to apply this mode of conception to elaſtic fluids.— When air is ſuddenly compreſſed, a thermometer included in it ſhows a riſe of temperature; that is, an appearance of heat now redundant which was formerly combined. The heat ſeems to be ſqueezed out as the water from the ſponge.

16 Aſcribed by ſome to attraction, but improperly.

Accordingly this opinion, that the elaſticity of ſteam and other vapours is owing merely to the attraction for fire, and the conſequent diſſemination of their particles through the whole maſs of fire, has been entertained by many naturaliſts, and it has been aſcribed entirely to attraction. We by no means pretend to decide; but we think the analogy by far too ſlight to found any confident opinion on it. The aim is to ſolve phenomena by attraction only, as if it were of more eaſy conception than repulſion. Conſidered merely as facts, they are quite on a par. The appearances of nature in which we obſerve actual receſſes of the parts of body from each other, are as diſtinct, and as frequent and familiar, as the appearances of actual approach. And if we attempt to go farther in our contemplation, and to conceive the way and the forces by which either the approximations or receſſes of the atoms are produced, we muſt acknowledge that we have no conception of the matter; and we can only ſay, that there is a cauſe of theſe motions, and we call it a force, as in every caſe of the production of motion. We call it attraction or repulſion juſt as we happen to contemplate an acceſs or a receſs. But the analogy here is not only ſlight, but imperfect, and fails moſt in theſe caſes which are moſt ſimple, and where we ſhould expect it to be moſt complete. We can ſqueeze water out of a ſponge, it is true, or out of a piece of green wood; but when the white of an egg, the tremella, or ſome gums, ſwell to a hundred times their dry dimenſions by imbibing water, we cannot ſqueeze out a particle. If fluidity (for the reaſoning muſt equally apply to this as to vaporouſneſs) be owing to an accumulation of the extended matter of fire, which gradually expanded the ſolid by its very minute additions; and if the accumulation round a particle of ice, which is neceſſary for making it a particle of water, be ſo great in compariſon of what gives it the expanſion of one degree, as experiment obliges us to conclude—it ſeems an inevitable conſequence that all fluids ſhould be many times rarer than the ſolids from which they were produced. But we know that the difference is trifling in all caſes, and in ſome (water, for inſtance, and iron) the ſolid is rarer than the fluid.

17
More probably owing to a mutual repulſion between the particles of fire.

Many other arguments (each of them perhaps of little weight when taken alone, but which are all ſyſtematically connected) concur in rendering it much more probable that the matter of fire, in cauſing elaſticity, acts immediately by its own elaſticity, which we cannot conceive in any other way than as a mutual tendency in its particles to recede from each other; and we doubt not but that, if it could be obtained alone, we ſhould find it an elaſtic fluid like air. We even think that there are caſes in which it is obſerved in this ſtate. The elaſtic force of gunpowder is very much beyond the elaſticity of all the vapours which are produced in its deflagration, each of them being expanded as much as we can reaſonably ſuppoſe by the great heat to which they are expoſed. The writer of this article exploded ſome gunpowder mixed with a conſiderable portion of finely powdered quartz, and another parcel mixed with fine filings of copper. The elaſticity was meaſured by the penetration of the ball which was diſcharged, and was great in the degree now mentioned. The experiment was ſo conducted, that much of the quartz and copper was collected; none of the quartz had been melted, and ſome of the copper was not melted. The heat, therefore, could not be ſuch as to explain the elaſticity by expanſion of the vapours; and it became not improbable that fire was acting here as a detached chemical fluid by its own elaſticity. But to return to our ſubject.

There is one circumſtance in which we think our own experiments ſhow a remarkable difference (at leaſt in degree) between the condenſible and incondenſible vapours. It is well known, that when air is very ſuddenly expanded, cold is produced, and heat when it is ſuddenly condenſed. When making experiments with the hopes of diſcovering the connection between the elaſticity and denſity of the vapours of boiling water, and alſo of boiling ſpirits of turpentine, we found the change of denſity accompanied by a change of temperature vaſtly greater than in the caſe of incoercible gaſes. When the vapour of boiling water was ſuddenly allowed to expand into five times its bulk, we obſerved the depreſſion of a large and ſenſible air thermometer to be at leaſt four or five times greater than in a ſimilar expanſion of common air of the ſame temperature. The chemical reader will readily ſee reaſons for expecting, on the contrary, a ſmaller alteration of temperature, both on account of the much greater rarity of the fluid, and on account of a partial condenſation of its water, and the conſequent diſengagements of combined heat.

18
Probably a great difference between condenſible and incondenſible vapours;

19
And alſo ſome difference in the chemical inſtitution of vapour.

This difference in the quantity of fire which is combined in the vapours and gaſes is ſo conſiderable as to authorize us to ſuppoſe that there is ſome difference in the chemical conſtitution of vapours and gaſes, and that the connection between the ſpecific baſes of the vapour and the fire which it contains is not the ſame in air, for inſtance as in the vapour of boiling water; and this difference may be the reaſon why the one is eaſily condenſible by cold, while the other has never been exhibited in a liquid or ſolid form, except by means of its chemical union with other ſubſtances. In this particular inſtance we know that there is an eſſential difference—that in vital or atmoſpheric air there is not only a prodigious quantity of fire which is not in the vapour of water, but that it alſo contains light, or the cauſe of light, in a combined ſtate. This is fully evinced by the great diſcovery of Mr Cavendiſh of the compoſition of water. Here we are taught that water (and conſequently its vapour) conſiſts of air from which the light and greateſt part of the fire have been ſeparated. And the ſubſequent diſcoveries of the celebrated Lavoiſier ſhow, that almoſt all the condenſible gaſes with which we are acquainted conſiſt either of airs which have already loſt much of their fire (and perhaps light too), or of matters in which we have no evidence of fire or light being combined in this manner.

This conſideration may go far in explaining this difference in the condenſibility of theſe different ſpecies of aerial fluids, the gaſes and the vapours; and it is with this qualification only that we are diſpoſed to allow that all bodies are condenſible into liquids or ſolids by abſtracting the heat. In order that vital air may become liquid or ſolid, we hold that it is not ſufficient that a body be preſented to it which ſhall ſimply abſtract its heat. This would only abſtract its uncombined fire.—But another, and much larger portion remains chemically combined by means of light. A chemical affinity muſt be brought into action which may abſtract, not the fire from the oxygen (to ſpeak in the language of Mr Lavoiſier), but the oxygen from the fire and light. And our production is not the detached baſis of air, but detached heat and light, and the formation of an oxyd of ſome kind.

General obſervations.

To proſecute the chemical conſideration of Steams farther than theſe general obſervations, which are applicable to all, would be almoſt to write a treatiſe of chemiſtry, and would be a repetition of many things which have been treated of in ſufficient detail in other

Steam.

articles of this work. We ſhall therefore conclude this article with ſome other obſervations, which are alſo general, with reſpect to the different kinds of coercibe vapours, but which have a particular relation to the following article.

20 Steam riſes at different temperatures, according as the air is heavy or light,

Steam or vapour is an elaſtic fluid, whoſe elaſticity balances the preſſure of the atmoſphere; and it has been produced from a ſolid or liquid body raiſed to a ſufficient temperature for giving it this elaſticity; that is, for cauſing the fluid to boil. This temperature muſt vary with the preſſure of the air. Accordingly it is found, that when the air is light (indicated by the barometer being low), the fluid will boil ſooner. When the barometer ſtands at 30 inches, water boils at the temperature 212°. If it ſtand ſo low as 28 inches, water will boil at 208½. In the plains of Quito, or at Gondar in Abyſſinia, where the barometer ſtands at about 21 inches, water will boil at 195°. Highly rectified alcohol will boil at 160°, and vitriolic æther will boil at 88° or 89°. This is a temperature by no means uncommon in theſe places; nay, the air is frequently warmer. Vitriolic æther, therefore, is a liquor which can hardly be known in thoſe countries. It is hardly poſſible to preſerve it in that form. If a phial have not its ſtopper firmly tied down, it will be blown out, and the liquor will boil and be diſſipated in ſteam. On the top of Chimboracao, the human blood muſt be diſpoſed to give out air-bubbles.

21 As fluids boil under the preſſure of the vapour which aſcends from them, the concluſion mentioned in n° 14. is only a groſs approximation.

We ſaid ſome time ago, that we had concluded, from ſome experiments made in the receiver of an air-pump, that fluids boil *in vacuo* at a temperature nearly 120 degrees lower than that neceſſary for their boiling in the open air. But we now ſee that this muſt have been but a groſs approximation; for in theſe experiments the fluids were boiling under the preſſure of the vapour which they produced, and which could not be abſtracted by working the pump. It appears from the experiments of Lord Charles Cavendiſh, mentioned in the article Pneumatics, that water of the temperature 72° was converted into elaſtic vapour, which balanced a preſſure of ¾ths of an inch of mercury, and in this ſtate it occupied the receiver, and did not allow the mercury in the gauge to ſink to the level. As faſt as this was abſtracted by working the air-pump, more of it was produced from the ſurface of the water, ſo that the preſſure continued the ſame, and the water did not boil. Had it been poſſible to produce a vacuum above this water, it would have boiled for a moment, and would even have continued to boil, if the receiver could have been kept very cold.

22 Account of experiments to determine the relation between the temperature of vapour and its elaſticity.

Upon reading theſe experiments, and ſome very curious ones of Mr Nairne, in the Phil. Tranſ. vol. lxvii. the writer of this article was induced to examine more particularly the relation between the temperature of the vapour and its elaſticity, in the following manner:

ABCD (fig. 2.) is the ſection of a ſmall digeſter made of copper. Its lid, which is faſtened to the body with ſcrews, is pierced with three holes, each of which had a ſmall pipe ſoldered into it. The firſt hole was furniſhed with a braſs ſafety-valve V, nicely fitted to it by grinding. The area of this valve was exactly ¼th of an inch. There reſted on the ſtalk at top of this valve the arm of a ſteelyard carrying a ſliding weight. This arm had a ſcale of equal parts, ſo adjuſted to the weight that the number on the ſcale correſponded to the inches of mercury, whoſe preſſure on the under ſurface of the valve is equal to that of the ſteelyard on its top; ſo that when the weight was at the diviſion 10, the preſſure of the ſteelyard on the valve was juſt equal to that of a column of mercury 10 inches high and ¼th of an inch baſe. The middle hole contained a thermometer T firmly fixed into it, ſo that no vapour could eſcape by its ſides. The ball of this thermometer was but a little way below the lid. The third hole received occaſionally the end of a glaſs-pipe S G F, whoſe deſcending leg was about 36 inches long. When this ſyphon was not uſed, the hole was properly ſhut with a plug.

Steam.

The veſſel was half filled with diſtilled water which had been purged of air by boiling. The lid was then fixed on, having the third hole S plugged up. A lamp being placed under the veſſel, the water boiled, and the ſteam iſſued copiouſly by the ſafety-valve. The thermometer ſtood at 213, and a barometer in the room at 29,9 inches. The weight was then put on the fifth diviſion. The thermometer immediately began to riſe; and when it was at 220, the ſteam iſſued by the ſides of the valve. The weight was removed to the 10th diviſion; but before the thermometer could be diſtinctly obſerved, the ſteam was iſſuing at the valve. The lamp was removed farther from the bottom of the veſſel, that the progreſs of heating might be more moderate; and when the ſteam ceaſed to iſſue from the valve, the thermometer was at 227. The weight was now ſhifted to 15; and by gradually approaching the lamp, the ſteam again iſſued, and the thermometer was at 232½. This mode of trial was continued all the way to the 75th diviſion of the ſcale. The experiments were then repeated in the contrary order; that is, the weight being ſuſpended at the 75th diviſion, and the ſteam iſſuing ſtrongly at the valve, the lamp was withdrawn, and, the moment the ſteam ceaſed to come out, the thermometer was obſerved. The ſame was done at the 70th, 65th, diviſion, &c. Theſe experiments were ſeveral times repeated both ways; and the means of all the reſults for each diviſion are expreſſed in the following table, where column 1ſt expreſſes the elaſticity of the ſteam, being the ſum of 29,9, and the diviſion of the ſteelyard; column 2d expreſſes the temperature of the ſteam correſponding to this elaſticity.

I.	II.

A very different proceſs was neceſſary for aſcertaining the elaſticity of the ſteam in lower temperatures, and conſequently under ſmaller preſſures than that of the atmoſphere. The glaſs ſyphon SGF was now fixed into its hole in the lid of the digeſter. The water was made to boil ſmartly for ſome time, and the ſteam iſſued copiouſly both at the valve and at the ſyphon. The

lower

Steam.

lower end of the ſyphon was now immerſed into a broad ſaucer of mercury, and the lamp inſtantly removed, and every thing was allowed to grow cold. By this the ſteam was gradually condenſed, and the mercury roſe in the ſyphon, without ſenſibly ſinking in the ſaucer. The valve and all the joints were ſmeared with a thick clammy cement, compoſed of oil, tallow, and roſin, which effectually prevented all ingreſs of air The weather was clear and froſty, the barometer ſtanding at 29,84, and the thermometer in the veſſel at 42°. The mercury in the ſyphon ſtood at 29,7, or ſomewhat higher, thus ſhowing a very complete condenſation. The whole veſſel was ſurrounded with pounded ice, of the temperature 32°. This made no ſenſible change in the height of the mercury. A mark was now made at the ſurface of the mercury. One obſerver was ſtationed at the thermometer, with inſtructions to call out as the thermometer reached the diviſions 42, 47, 52, 57, and ſo on by every five degrees till it ſhould attain the boiling heat. Another obſerver noted the correſponding deſcents of the mercury by a ſcale of inches, which had its beginning placed at 29,84 from the ſurface of the mercury in the ſaucer.

The pounded ice was now removed, and the lamp placed at a conſiderable diſtance below the veſſel, ſo as to warm its contents very ſlowly. Theſe obſervations being very eaſily made, were ſeveral times repeated, and their mean reſults are ſet down in the following table: Only obſerve, that it was found difficult to note down the deſcents for every fifth degree, becauſe they ſucceeded each other ſo faſt. Every 10th was judged ſufficient for eſtabliſhing the law of variation. The firſt column of the table contains the temperature, and the ſecond the deſcent (in inches) of the mercury from the mark 29,84.

32°	☿
40	0,1
50	0,2
60	0,35
70	0,55
80	0,82
90	1,18
100	1,61
110	2,25
120	3,00
130	3,95
140	5,15
150	6,72
160	8,65
170	11,05
180	14,05
190	17,85
200	22,62
210	28,65

Four or five numbers at the top of the column of elaſticities are not ſo accurate as the others, becauſe the mercury paſſed pretty quickly through theſe points. But the progreſs was extremely regular through the remaining points; ſo that the elaſticities correſponding to temperatures above 70° may be conſidered as very accurately aſcertained.

Not being altogether ſatisfied with the method employed for meaſuring the elaſticity in temperatures above that of boiling water, a better form of experiment was adopted. (Indeed it was the want of other apparatus which made it neceſſary to employ the former). A glaſs tube was procured of the form repreſented in fig. 3. having a little ciſtern L, from the top and bottom of which proceeded the ſyphons K and MN. The ciſtern contained mercury, and the tube MN was of a ſlender bore, and was about ſix fet two inches long. The end K was firmly fixed in the third hole of the lid, and the long leg of the ſyphon was furniſhed with a ſcale of inches, and firmly faſtened to an upright poſt.

Steam.

The lamp was now applied at ſuch a diſtance from the veſſel as to warm it ſlowly, and make the water boil, the ſteam eſcaping for ſome time through the ſafety valve. A heavy weight was then ſuſpended on the ſteelyard; ſuch as it was known that the veſſel would ſupport, and at the ſame time, ſuch as would not allow the ſteam to force the mercury out of the long tube. The thermometer began immediately to riſe, as alſo the mercury in the tube MN. Their correſpondent ſtations are marked in the following table:

Temp.	Elaſt^y.
212°	0,0
220	5,9
230	14,6
240	25,0
250	36,9
260	50,4
270	64,2
280	106,0

This form of the experiment is much more ſuſceptible of accuracy than the other, and the meaſures of elaſticity are more to be depended on. In repeating the experiment, they were found much more conſtant; whereas, in the former method, differences occured of two inches and upwards.

We may now connect the two ſets of experiments into one table, by adding to the numbers in this laſt table the conſtant height, 29,9, which was the height of the mercury in the barometer during the laſt ſet of obſervations.

In

Steam.

23 Which agree well with those of Mr Achard.

In the memoirs of the Royal Academy of Berlin for 1782, there is an account of some experiments made by Mr Achard on the elastic force of steam, from the temperature 32° to 212°. They agree extremely well with those mentioned here, rarely differing more that two or three tenths of an inch. He also examined the elasticity of the vapour produced from alcohol, and found, that when the elasticity was equal to that of the vapour of water, the temperature was about 35° lower. Thus, when the elasticity of both was measured by 28,1 inches of mercury, the temperature of the watery vapour was 209°, and that of the spirituous vapour was 173°. When the elasticity was 18,5, the temperature of the water was 189,5, and that of the alcohol 154,6. When the elasticity was 11,05, the water was 168°, and the alcohol 134°,4. Observing the difference between the temperatures of equally elastic vapours of water and alcohol not to be constant, but gradually to diminish, in Mr Achard's experiments, along with the elasticity, it became interesting to discover whether and at what temperature this difference would vanish altogether. Experiments were accordingly made by the writer of this article, similar to those made with water. They were not made with the same scrupulous care, nor repeated as they deserved, but they furnished rather an unexpected result. The following table will give the reader a distinct notion of them:

Temp.	Elast.
32°	0,0
40	0,1
60	0,8
80	0,8
100	3,9
120	6,9
140	12,2
160	21,3
180	34,
200	52,4
220	78,5
240	115,

24 An unexpected result in comparing the temperatures of equally elastic vapours of water and alcohol.

We say that the result was unexpected; for as the natural boiling point seemed by former experiments to be in all fluids about 120° or more below their boiling point in the ordinary pressure of the atmosphere, it was reasonable to expect that the temperature at which they ceased to emit sensibly elastic steam would have some relation to their temperatures when emitting steam of any determinate elasticity. Now as the vapour of alcohol of elasticity 30 has its temperature about 36° lower than the temperature of water equally elastic, it was to be expected that the temperature at which it ceased to be sensibly affected would be several degrees lower than 32°. It is evident, however, that this is not the case. But this is a point that deserves more attention, because it is closely connected with the chemical relation between the element (if such there be) of fire and the bodies into whose composition it seems to enter as a constituent part. What is the temperature 32°, to make it peculiarly connected with elasticity? It is a temperature assumed by us for our own conveniency, on account of the familiarity of water in our experiments. Æther, we know, boils in a temperature far below this, as appears from Dr Cullen's experiments narrated in the Essays Physical and Literary of Edinburgh. On the faith of former experiments, we may be pretty certain that it will boil in vacuo at the temperature—14°, because in the air it boils at + 106°. Therefore we may be certain, that the steam or vapour of æther, when of the temperature 32°, will be very sensibly elastic. Indeed Mr Lavoisier says, that if it be exposed in an exhausted receiver in winter, its vapour will support mercury at the height of 10 inches. A series of experiments on this vapour similar to the above would be very instructive. We even wish that those on alcohol were more carefully repeated. If we draw a curve line, of which the abscissa is the line of temperatures, and the ordinates are the corresponding heights of the mercury in these experiments on water and alcohol, we shall observe that although they both sensibly coincide at 32°, and have the abscissa for their common tangent, a very small error of observation may be the cause of this, and the curve which expresses the elasticity of spirituous vapour may really intersect the other, and go backwards considerably beyond 32°.

25 These experiments give rise to important reflections.

This range of experiments gives rise to some curious and important reflections. We now see that no particular temperature is necessary for water assuming the form of permanently elastic vapour; and that it is highly probable that it assumes this form even at the temperature 32°; only its elasticity is too small to afford us any sensible measure. It is well known that even ice evaporates (see experiments to this purpose by Mr Wilson in the Philosophical Transactions, when a piece of polished metal covered with hoar-frost became perfectly clear by exposing it to a dry frosty wind). Vol. lxx.

Even mercury evaporates, or is converted into elastic vapour, when all external pressure is removed. The dim film which may frequently be observed in the upper part of a barometer which stands near a stream of air, is found to be small globules of mercury sticking to the inside of the tube. They may be seen by the help of a magnifying glass, and are the best test of a well made barometer. They will be entirely removed by causing the mercury to rise along the tube. It will lick them all up. They consist of mercury which had evaporated in the void space, and was afterwards condensed by the cold glass. But the elasticity is too small to occasion a sensible depression of the column, even when considerably warmed by a candle.

26 Spontaneous evaporation produced by the dissolving power of the air.

Many philosophers accordingly imagine, that spontaneous evaporation in low temperatures is produced in this way. But we cannot be of this opinion, and must still think that this kind of evaporation is produced by the dissolving power of the air. When moist air is suddenly rarefied, there is always a precipitation of water. This is most distinctly seen when we work an air-pump briskly. A mist is produced, which we see plainly fall to the bottom of the receiver. But by this new doctrine the very contrary should happen, because the tendency of water to appear in the elastic form is promoted by removing the external pressure; and we really imagine that more of it now actually becomes simple elastic watery vapour. But the mist or precipitation shows incontrovertibly, that there had been a previous solution. Solution is performed by forces which act in the way of attraction; or, to express it more safely, solutions are accompanied by the mutual approaches of the particles of the menstruum and solvend: all such tendencies are *observed* to increase by a diminution of distance. Hence it *must* follow, that air of double density will dissolve more than twice as much water. Therefore when we suddenly rarefy saturated air (even though

its

its heat should not diminish) some water must be let go. What may be its quantity we know not; but it *may be more* than what would now become elastic by this diminution of surrounding pressure; and it is not unlikely but this may have some effect in producing the vesicles which we found so difficult to explain. These may be filled with pure watery vapour, and be floating in a fluid composed of water dissolved in air. An experiment of Fontana's seems to put this matter out of doubt. A distilling apparatus AB (fig. 4.) was so contrived, that the heat was applied above the surface of the water in the alembic A. This was done by inclosing it in another vessel CC, filled with hot water. In the receiver B there was a sort of barometer D, with an open cistern, in order to see what pressure there was on the surface of the fluid. While the receiver and alembic contained air, the heat applied at A produced no sensible distillation during several hours: But on opening a cock E in the receiver at its bottom, and making the water in the alembic to boil, steam was produced which soon expelled all the air, and followed it through the cock. The cock was now shut, and the whole allowed to grow cold by removing the fire, and applying cold water to the alembic. The barometer fell to a level nearly. Then warm water was allowed to get into the outer vessel CC. The barometer rose a little, and the distillation went on briskly without the smallest ebullition in the alembic. The conclusion is obvious: while there was air in the receiver and communicating pipe, the distillation proceeded entirely by the dissolving power of this air. Above the water in the alembic it was quickly saturated; and this saturation proceeded slowly along the still air in the communicating pipe, and at last might take place thro' the whole of the receiver. The sides of the receiver being kept cold, should condense part of the water dissolved in the air in contact with them, and this should trickle down the sides and be collected. But any person who has observed how long a crystal of blue vitriol will lie at the bottom of a glass of still water before the tinge will reach the surface, will see that it must be next to impossible for distillation to go on in these circumstances; and accordingly none was observed. But when the upper part of the apparatus was filled with pure watery vapour, it was supplied from the alembic as fast as it was condensed in the receiver, just as in the pulse glass.

27
A certain law in the dilatation of aeriform fluids by heat.

Another inference which may be drawn from these experiments is, that Nature seems to affect a certain law in the dilatation of aeriform fluids by heat. They seem to be dilatable nearly in proportion of their present dilatation. For if we suppose that the vapours resemble air, in having their elasticity in any given temperature proportional to their density, we must suppose that if steam of the elasticity 60, that is, supporting 60 inches of mercury, were subjected to a pressure of 30 inches, it would expand into twice its present bulk. The augmentation of elasticity therefore is the measure of the bulk into which it would expand in order to acquire its former elasticity. Taking the increase of elasticity therefore as a measure of the bulk into which it would expand under one constant pressure, we see that equal increments of temperature produce nearly equal multiplications of bulk. Thus if a certain diminution of temperature diminishes its bulk $\frac{1}{4}$th, another equal diminution of temperature will diminish this new bulk $\frac{1}{4}$th very nearly. Thus in our experiments, the temperatures 110°, 140°, 170°, 200°, 230°, are in arithmetical progression, having equal differences; and we see that the corresponding elasticities 2,25, 5,15, 11,05, 22,62, 44,7, are very nearly in the continued proportion of 1 to 2. The elasticity corresponding to the temperature 260 deviates considerably from this law, which would give 88 or 89 instead of 80; and the deviation increases in the higher temperatures. But still we see that there is a considerable approximation to this law; and it will frequently assist us to recollect, that whatever be the present temperature, an increase of 30 degrees doubles the elasticity and the bulk of watery vapour.

That 4° will increase the elasticity from	1 to $1\frac{1}{10}$
8 - - -	1 to $1\frac{1}{5}$
10 - - - -	1 to $1\frac{1}{4}$
$12\frac{1}{2}$ - - -	1 to $1\frac{1}{3}$
18 - - -	1 to $1\frac{1}{2}$
22 - - - -	1 to $1\frac{2}{3}$
24 - - - -	1 to $1\frac{3}{4}$
26 - - - -	1 to $1\frac{4}{5}$

This is sufficiently exact for most practical purposes. Thus an engineer finds that the injection cools the cylinder of a steam engine to 192°. It therefore leaves a steam whose elasticity is $\frac{3}{5}$ths of its full elasticity, = 18 inches ☿. But it is better at all times to have recourse to the table. Observe, too, that in the lower temperatures, *i. e.* below 110°, this increment of temperature does more than double the elasticity.

28
Obtains more remarkably in the incoercible vapours,

This law obtains more remarkably in the incoercible vapours; such as vital air, atmospheric air, fixed air, &c. all of which have also their elasticity proportional to their bulk inversely: and perhaps the deviation from the law in steams is connected with their chemical difference of constitution. If the bulk were always augmented in the same proportion by equal augmentations of temperature, the elasticities would be accurately represented by the ordinates of a logarithmic curve, of which the temperatures are the corresponding abscissæ; and we might contrive such a scale for our thermometer, that the temperatures would be the common logarithms of the elasticities, or of the bulks having equal elasticity; or, with our present scale, we may find such a multiplier m for the number x of degrees of our thermometer (above that temperature where the elasticity is equal to unity), that this multiple shall be the common logarithm of the elasticity y; so that $m\,x = \log.\,y$.

But our experiments are not sufficiently accurate for determining the temperature where the elasticity is measured by 1 inch; because in these temperatures the elasticities vary by exceedingly small quantities. But if we take 11,04 for the unit of elasticity, and number our temperature from 170°, and make $m = 0{,}010035$, we shall find the product $m\,x$ to be very nearly the logarithm of the elasticity. The deviations, however, from this law, are too great to make this equation of any use. But it is very practicable to frame an equation which shall correspond with the experiments to any degree of accuracy; and it has been done for air in a translation of General Roy's Measurement of the Base at Hounslow Heath into French by Mr Prony. It is as follows: Let x be the degrees of Reaumur's ther-

thermometer; let y be the expanſion of 10,000 parts of air; let e be $= 10$, $m = 2{,}7976$, $n = 0{,}01768$: then $y = e^{m+nx} - 627\,5$. Now e being $= 10$, it is plain that e^{m+nx} is the number, of which $m + nx$ is the common logarithm. This formula is very exact as far as the temperature 60°: but beyond this it needs a correction; becauſe air, like the vapour of water, does not expand in the exact proportion of its bulk.

29 And is conſiderably approximated to in the augmentation of the bulk or elaſticity of elaſtic vapours.

We obſerve this law conſiderably approximated to in the augmentation of the bulk or elaſticity of elaſtic vapours; that is, it is a fact that a given increment of temperature makes very nearly the ſame proportional augmentation of bulk and elaſticity. This gives us ſome notion of the manner in which the ſuppoſed expanding cauſe produces the effect. When vapour of the bulk 4 is expanded into a bulk 5 by addition of 10 degrees of ſenſible heat, a certain quantity of fire goes into it, and is accumulated round each particle, in ſuch a manner that the temperature of each, which formerly was m, is now $m + 10$. Let it now receive another equal augmentation of temperature. This is now $m + 20$, and the bulk is $\frac{5 \times 5}{4}$ or $6\frac{1}{4}$, and the arithmetical increaſe of bulk is $1\frac{1}{4}$. The abſolute quantity of fire which has entered it is greater than the former, both on account of the greater augmentation of ſpace and the greater temperature. Conſequently if this vapour be compreſſed into the bulk 5, there muſt be heat or fire in it which is not neceſſary for the temperature $m + 20$, far leſs for the temperature $m + 10$. It muſt therefore emerge, and be diſpoſed to enter a thermometer which has already the temperature $m + 20$: that is, the vapour muſt grow hotter by compreſſion; not by ſqeezing out the heat, like water out of a ſponge, but becauſe the law of attraction for heat is deranged. It would be a very valuable acquiſition to our knowledge to learn with preciſion the quantity of ſenſible heat produced in this way; but no ſatisfactory experiments have yet been made. M. Lavoiſier, with his chemical friends and colleagues, were buſily employed in this inquiry; but the wickedneſs of their countrymen has deprived the world of this and many other important additions which we might have expected from this celebrated and unfortunate philoſopher. He had made, in conjunction with M. de la Place, a numerous train of accurate and expenſive experiments for meaſuring the quantity of latent or combined heat in elaſtic vapours. This is evidently a very important point to the diſtiller and practical chemiſt. This heat muſt all come from the fuel; and it is greatly worth while to know whether any ſaving may be made of this article. Thus we know that diſtillation will go on either under the preſſure of the air, or in an alembic and receiver from which the air has been expelled by ſteam; and we know that this laſt may be conducted in a very low temperature, even not exceeding that of the human body. But it is uncertain whether this may not employ even a greater quantity of fuel, as well as occaſion a great expence of time. We are diſpoſed to think, that when there is no air in the apparatus, and when the condenſation can be ſpeedily performed, the proportion of fuel expended to the fluid which comes over will diminiſh continually as the heat, and conſequently the denſity of the ſteam, is augmented; becauſe in this caſe the quantity of combined heat muſt be leſs. In the mean time, we earneſtly recommend the trial of this mode of diſtillation in veſſels cleared of air. It is undoubtedly of great advantage to be able to work with ſmaller fires; and it would ſecure us againſt all accidents of blowing off the head of the ſtill, often attended with terrible conſequences (B).

We muſt not conclude this article without taking notice of ſome natural phenomena which ſeem to owe their origin to the action of elaſtic ſteam.

We have already taken notice of the reſemblance of the tremor and ſucceſſions obſerved in the ſhocks of many earthquakes to thoſe which may be felt in a veſſel where water is made to boil internally, while the breaking out of the ebullition is ſtifled by the cold of the upper parts; and we have likewiſe ſtated the objections which are uſually made to this theory of earthquakes. We may perhaps reſume the ſubject under the article Volcano; but in the mean time we do not heſitate to ſay, that the wonderful appearances of the Geyzer ſpring in Iceland (ſee Huer; and Iceland, n° 3—5.) are undoubtedly produced by the expanſion of ſteam in ignited caverns. Of theſe appearances we ſuppoſe the whole train to be produced as follows.

30 Explanation of the phenomena of the Geyzer ſpring in Iceland by the force of ſteam.

A cavern may be ſuppoſed of a ſhape analogous to CBDEF (fig. 5.), having a perpendicular funnel AB iſſuing from a depreſſed part of the roof. The part F may be lower than the reſt, remote, and red-hot. Such places we know to be frequent in Iceland. Water may be continually trickling into the part CD. It will fill it up to B, and even up to E e, and then trickle ſlowly along into F. As ſoon as any gets into contact with an ignited part, it expands into elaſtic ſteam, and is partly condenſed by the cold ſides of the cavern, which it gradually warms, till it condenſes no more. This produc-

(B) We earneſtly recommend this ſubject to the conſideration of the philoſopher. The laws which regulate the formation of elaſtic vapour, or the general phenomena which it exhibits, give us that link which connects chemiſtry with mechanical philoſophy. Here we ſee chemical affinities and mechanical forces ſet in immediate oppoſition to each other, and the one made the indication, characteriſtic, and meaſure of the other. We have not the leaſt doubt that they make but one ſcience the Science of Univerſal Mechanics; nor do we deſpair of ſeeing the phenomena of ſolution, precipitation, cryſtallization, fermentation, nay animal and vegetable ſecretion and aſſimilation, ſucceſsfully inveſtigated, as caſes of local motion, and explained by the agency of central forces. Something of this kind, and that not inconſiderable, was done when Dr Cullen firſt ſhowed how the double affinities might be illuſtrated by the aſſiſtance of numbers. Dr Black gave to this hint (for it was little more) that elegant preciſion which characterizes all his views. Mr Kirwan has greatly promoted this ſtudy by his numerous and ingenious examples of its application; and the moſt valuable paſſages of the writings of Mr Lavoiſier, are thoſe where he traces with logical preciſion the balancings of force which appear in the chemical phenomena. It is from the ſimilar balancings and conſequent meaſurements, which may be obſerved and obtained in the preſent caſe, that we are to hope for admiſſion into this almoſt unbounded ſcience of contemplation. We have another link equally intereſting and promiſing, viz. the production of heat by friction. This alſo highly deſerves the conſideration of the mathematical philoſopher.

production of steam hinders not in the smallest degree the trickling of more water into F, and the continual production of more steam. This now presses on the surface of the water in CD, and causes it to rise gradually in the funnel BA; but slowly, because its cold surface is condensing an immense quantity of steam. We may easily suppose that the water trickles faster into F than it is expended in the production of steam; so that it reaches farther into the ignited part, and may even fall in a stream into some deeper pit highly ignited. It will now produce steam in vast abundance, and of prodigious elasticity; and at once push up the water thro' the funnel in a solid jet, and to a great height. This must continue till the surface of the water sinks to BD. If the lower end of the funnel have any inequalities or notches, as is most likely, the steam will get admission along with the water, which in this particular place is boiling hot, being superficial, and will get to the mouth of the funnel, while water is still pressed in below. At last the steam gets in at B on all sides; and as it is converging to B, along the surface of the water, with prodigious velocity it sweeps along with it much water, and blows it up through the funnel with great force. When this is over, the remaining steam blows out unmixed with water, growing weaker as it is expelled, till the bottom of the funnel is again stopped by the water increasing in the cavern CBD. All the phenomena above ground are perfectly conformable to the necessary consequences of this very probable construction of the cavern. The feeling of being lifted up, immediately before the jet, in all probability is owing to a real heaving up of the whole roof of the cavern by the first expansion of the great body of steam. We had an accurate description of the phenomena from persons well qualified to judge of these matters who visited these celebrated springs in 1789.

Steam-Engine, is the name of a machine which derives its moving power from the elasticity and condensibility of the steam of boiling water. It is the most valuable present which the arts of life have ever received from the philosopher. The mariner's compass, the telescope, gunpowder, and other most useful servants to human weakness and ingenuity, were the productions of chance, and we do not exactly know to whom we are indebted for them; but the steam-engine was, in the very beginning, the result of reflection, and the production of a very ingenious mind; and every improvement it has received, and every alteration in its construction and principles, were also the results of philosophical study.

1 Steam-engine invented by the Marquis of Worcester.

The steam-engine was beyond all doubt invented by the marquis of Worcester during the reign of Cha. II. This nobleman published in 1663 a small book intitled A Century of Inventions; giving some obscure and enigmatical account of an hundred discoveries or contrivances of his own, which he extols as of great importance to the public. He appears to have been a person of much knowledge and great ingenuity: but his description or accounts of these inventions seem not so much intended to instruct the public, as to raise wonder; and his encomiums on their utility and importance are to a great degree extravagant, resembling more the puff of an advertising tradesman than the patriotic communications of a gentleman. The marquis of Worcester was indeed a projector, and very importunate and mysterious withal in his applications for public encouragement. His account, however, of the steam-engine, although by no means fit to give us any distinct notions of its structure and operation, is exact as far as it goes, agreeing precisely with what we now know of the subject. It is N° 68. of his inventions. His words are as follow: "This admirable method which I propose of raising water by the force of fire has no bounds if the vessels be strong enough: for I have taken a cannon, and having filled it $\frac{3}{4}$ths full of water, and shut up its muzzle and touch-hole, and exposed it to the fire for 24 hours, it burst with a great explosion. Having afterwards discovered a method of fortifying vessels internally, and combined them in such a way that they filled and acted alternately, I have made the water spout in an uninterrupted stream 40 feet high; and one vessel of rarefied water raised 40 of cold water. The person who conducted the operation had nothing to do but turn two cocks; so that one vessel of water being consumed, another begins to force, and then to fill itself with cold water, and so on in succession."

2 But first reduced to practice by Captain Savary.

It does not appear that the noble inventor could ever interest the public by these accounts. His character as a projector, and the many failures which persons of this turn of mind daily experience, probably prejudiced people against him, and prevented all attention to his projects. It was not till towards the end of the century, when experimental philosophy was prosecuted all over Europe with uncommon ardour, that these notions again engaged attention. Captain Savary, a person also of great ingenuity and ardent mind, saw the reality and practicability of the marquis of Worcester's project. He knew the great expansive power of steam, and had discovered the inconceivable rapidity with which it is reconverted into water by cold; and he soon contrived a machine for raising water, in which both of these properties were employed. He says, that it was entirely his own invention. Dr Desaguliers insists that he only copied the marquis's invention, and charges him with gross plagiarism, and with having bought up and burned the copies of the marquis's book, in order to secure the honour of the discovery to himself. This is a very grievous charge, and should have been substantiated by very distinct evidence. Desaguliers produces none such; and he was much too late to know what happened at that time. The argument which he gives is a very foolish one, and gave him no title to consider Savary's experiment as a falsehood; for it might have happened precisely as Savary relates, and not as it happened to Desaguliers. The fact is, that Savary obtained his patent of invention after a hearing of objections, among which the discovery of the marquis of Worcester was not mentioned: and it is certain that the account given in the Century of Inventions could instruct no person who was not sufficiently acquainted with the properties of steam to be able to invent the machine himself.

3 Papin has no claim to the invention as the French pretend.

Captain Savary obtained his patent *after having actually erected* several machines, of which he gave a description in a book intitled The Miner's Friend, published in 1696, and in another work published in 1699. Much about this time Dr Papin, a Frenchman and fellow of the Royal Society, invented a method of dissolving bones and other animal solids in water, by confining them

them in close vessels, which he called DIGESTERS, so as to acquire a great degree of heat. For it must be observed in this place, that it had been discovered long before (in 1684) by Dr Hooke, the most inquisitive experimental philosopher of that inquisitive age, that water could not be made to acquire above a certain temperature in the open air; and that as soon as it begins to boil, its temperature remains fixed, and an increase of heat only produces a more violent ebullition, and more rapid waste. But Papin's experiments made the elastic power of steam very familiar to him: and when he left England and settled as professor of mathematics at Marpurgh, he made many aukward attempts to employ this force in mechanics, and even for raising water. It appears that he had made experiments with this view in 1698, by order of Charles Landgrave of Hesse. For this reason the French affect to consider him as the inventor of the steam-engine. He indeed published some account of his invention in 1707; but he acknowledges that Captain Savary had also, and without any communication with him, invented the same thing. Whoever will take the trouble of looking at the description which he has given of these inventions, which are to be seen in the *Acta Eruditorum Lipsiæ*, and in Leupold's *Theatrum Machinarum*, will see that they are most aukward, absurd, and impracticable. His conceptions of natural operations were always vague and imperfect, and he was neither philosopher nor mechanician.

We are thus anxious about the claim of those gentlemen, because a most respectable French author, Mr Bossut, says in his *Hydrodynamique*, that the first notion of the steam-engine was *certainly* owing to Dr Papin, who had not only invented the digester, but had in 1695 published a little performance describing a machine for raising water, in which the pistons are moved by the vapour of boiling water alternately dilated and condensed. Now the fact is, that Papin's first publication was in 1707, and his piston is nothing more than a floater on the surface of the water, to prevent the waste of steam by condensation; and the return of the piston is not produced, as in the steam engine, by the condensation of the steam, but by admitting the air and a column of water to press it back into its place. The whole contrivance is so aukward, and so unlike any distinct notions of the subject, that it cannot do credit to any person. We may add, that much about the same time Mr Amontons contrived a very ingenious but intricate machine, which he called a *fire-wheel*. It consisted of a number of buckets placed in the circumference of a wheel, and communicating with each other by very intricate circuitous passages. One part of this circumference was exposed to the heat of a furnace, and another to a stream or cistern of cold water. The communications were so disposed, that the steam produced in the buckets on one side of the wheel drove the water into buckets on the other side, so that one side of the wheel was always much heavier than the other; and it must therefore turn round, and may execute some work. The death of the inventor, and the intricacy of the machine, caused it to be neglected. Another member of the Parisian academy of sciences (Mr Deslandes) also presented to the academy a project of a steam-wheel, where the impulsive force of the vapour was employed; but it met with no encouragement.

4
Mr Amontons's fire-wheel.

The English engineers had by this time so much improved Savary's first invention, that it supplanted all others. We have therefore no hesitation in giving the honour of the first and complete invention to the marquis of Worcester; and we are not disposed to refuse Captain Savary's claim to originality as to the construction of the machine, and even think it probable that his own experiments made him see the whole independent of the marquis's account.

Captain Savary's engine, as improved and simplified by himself, is as follows.

5
Captain Savary's steam-engine described.

Plate CCCCLXXVII.

A (fig. 6.) represents a strong copper boiler properly built up in a furnace. There proceeds from its top a large steam-pipe B, which enters into the top of another strong vessel R called the RECEIVER. This pipe has a cock at C called the STEAM-COCK. In the bottom of the receiver is a pipe F, which communicates sidewise with the rising pipe KGH. The lower end H of this pipe is immersed in the water of the pit or well, and its upper part K opens into the cistern into which the water is to be delivered. Immediately below the pipe of communication F there is a valve G, opening when pressed from below, and shutting when pressed downwards. A similar valve is placed at I, immediately above the pipe of communication. Lastly, there is a pipe ED which branches off from the rising pipe, and enters into the top of the receiver. This pipe has a cock D called the INJECTION-COCK. The mouth of the pipe ED has a nozzle *f* pierced with small holes, pointing from a centre in every direction. The keys of the two cocks C and D are united, and the handle *g h* is called the REGULATOR.

Let the regulator be so placed that the steam-cock C is open and the injection-cock D is shut; put water into the boiler A, and make it boil strongly. The steam coming from it will enter the receiver, and gradually warm it, much steam being condensed in producing this effect. When it has been warmed so as to condense no more, the steam proceeds into the rising pipe; the valve G remains shut by its weight; the steam lifts the valve I, and gets into the rising pipe, and gradually warms it. When the workman feels this to be the case, or hears the rattling of the valve I, he immediately turns the steam-cock so as to shut it, the injection-cock still remaining shut (at least we may suppose this for the present). The apparatus must now cool, and the steam in the receiver collapses into water. There is nothing now to balance the pressure of the atmosphere; the valve I remains shut by its weight; but the air incumbent on the water in the pit presses up this water through the suction-pipe H G, and causes it to lift the valve G, and flow into the receiver R, and fill it to the top, if not more than 20 or 25 feet above the surface of the pit water.

The steam-cock is now open. The steam which, during the cooling of the receiver, has been accumulating in the boiler, and acquiring a great elasticity by the action of the fire, now rushes in with great violence, and, pressing on the surface of the water in the receiver, causes it to shut the valve G and open the valve I by its weight alone, and it now flows into the rising pipe, and would stand on a level if the elasticity of the steam were no more than what would balance the atmospherical pressure. But it is much more than this, and therefore it *presses* the water out of the receiver into the rising pipe,

pipe, and will even cause it to come out at K, if the elasticity of the steam is sufficiently great. In order to ensure this, the boiler has another pipe in its top, covered with a *safety*-valve V, which is kept down by a weight W suspended on a steelyard L M. This weight is so adjusted that its pressure on the safety-valve is somewhat greater than the pressure of a column of water V *k* as high as the point of discharge K. The fire is so regulated that the steam is always issuing a little by the loaded valve V. The workman keeps the steam-valve open till he hears the valve I rattle. This tells him that the water is all forced out of the receiver, and that the steam is now following it. He immediately turns the regulator which shuts the steam-cock, and now, for the first time, opens the injection-cock. The cold water trickles at first through the holes of the nozzle *f*, and falling down through the steam, begins to condense it; and then its elasticity being less than the pressure of the water in the pipe K E D *f*, the cold water spouts in all directions through the nozzle, and, quick as thought, produces a complete condensation. The valve G now opens again by the pressure of the atmosphere on the water of the pit, and the receiver is soon filled with cold water. The injection-cock is now shut, and the steam-cock opened, and the whole operation is now repeated; and so on continually.

This is the simple account of the process, and will serve to give the reader an introductory notion of the operation; but a more minute attention must be paid to many particulars before we can see the properties and defects of this ingenious machine.

6
Defects of this machine such,

The water is driven along the rising pipe by the elasticity of the steam. This must in the boiler, and every part of the machine, exert a pressure on every square inch of the vessels equal to that of the upright column of water. Suppose the water to be raised 100 feet, about 25 of this may be done in the suction-pipe; that is, the upper part of the receiver may be about 25 feet above the surface of the pit-water. The remaining 75 must be done by forcing, and every square inch of the boiler will be squeezed out by a pressure of more than 30 pounds. This very moderate height therefore requires very strong vessels; and the Marquis of Worcester was well aware of the danger of their bursting. A copper boiler of six feet diameter must be $\frac{8}{10}$ths of an inch thick to be just in equilibrio with this pressure: and the soldered joint will not be able to withstand it, especially in the high temperature to which the water must be heated in order to produce steam of sufficient elasticity. By consulting the table of the elasticity of steam deduced from our experiments mentioned in the preceding article, we see that this temperature must be at least 280° of Fahrenheit's thermometer. In this heat soft solder is just ready to melt, and has no tenacity; even spelter solder is considerably weakened by it. Accordingly, in a machine erected by Captain Savary at York Buildings in London, the workman having loaded the safety-valve a little more than usual to make the engine work more briskly, the boiler burst with a dreadful explosion, and blew up the furnace and adjoining parts of the building as if it had been gunpowder. Mr Savary succeeded pretty well in raising moderate quantities of water to small heights, but could make nothing of deep mines. Many attempts were made, on the Marquis's principle, to strengthen the vessels from within by radiated bars and by hoops, but in vain. Very small boilers or evaporators were then tried, kept red hot, or nearly so, and supplied with a slender stream of water trickling into them; but this afforded no opportunity of making a collection of steam during the refrigeration of the receiver, so as to have a magazine of steam in readiness for the next forcing operation; and the working of such machines was always an employment of great danger and anxiety.

7
That it can be employed with advantage only in certain situations.

The only situation in which this machine could be employed with perfect safety, and with some effect, was where the whole lift did not exceed 30 or 35 feet. In this case the greatest part of it was performed by the suction-pipe, and a very manageable pressure was sufficient for the rest. Several machines of this kind were erected in England about the beginning of this century. A very large one was erected at a salt-work in the south of France. Here the water was to be raised no more than 18 feet. The receiver was capacious, and it was occasionally supplied with steam from a small salt-pan constructed on purpose with a cover. The entry of the steam into the receiver merely allowed the water to run out of it by a large valve, which was opened by the hand, and the condensation was produced by the help of a small forcing pump also worked by the hand. In so particular a situation as this (and many such may occur in the endless variety of human wants), this is a very powerful engine; and having few moving and rubbing parts, it must be of great durability. This circumstance has occasioned much attention to be given to this first form of the engine, even long after it was supplanted by those of a much better construction. A very ingenious attempt was made very lately to adapt this construction to the uses of the miners. The whole depth of the pit was divided into lifts of 15 feet, in the same manner as is frequently done in pump-machines. In each of these was a suction pipe 14 feet long, having above it a small receiver like R, about a foot high, and its capacity somewhat greater than that of the pipe. This receiver had a valve at the head of the suction-pipe, and another opening outwards into the little cistern, into which the next suction-pipe above dipped to take in water. Each of these receivers sent up a pipe from its top, which all met in the cover of a large vessel above ground, which was of double the capacity of all the receivers and pipes. This vessel was close on all sides. Another vessel of equal capacity was placed immediately above it, with a pipe from its bottom passing through the cover of the lower vessel and reaching near to the bottom. This upper vessel communicates with the boiler, and constitutes the receiver of the steam-engine. The operation is as follows: The lower vessel is full of water. Steam is admitted into the upper vessel, which expels the air by a valve, and fills the vessel. It is then condensed by cold water. The pressure of the atmosphere would cause it to enter by all the suction-pipes of the different lifts, and press on the surface of the water in the lower receiver, and force it into the upper one. But because each suction-pipe dips in a cistern of water, the air presses this water before it, raises it into each of the little receivers which it fills, and allows the spring of the air (which was formerly in them, but which now passes up into the lower receiver) to force the water out of the lower receiver into the upper one. When this has been completed, the steam is again admitted into the upper receiver. This allows the water to run back into the lower receiver, and the air returns into the small receivers in the pit, and allows the water to run out of each into its proper cistern. By this means the water of each pipe has been raised 15 feet. The operation may thus be repeated continually.

The contrivance is ingenious, and similar to some which are to be met with in the hydraulics of Schottus, Sturmius, and other German writers. But the operation must be exceedingly slow; and we imagine that the expence of steam must be great, because it must fill a very large and very cold vessel, which must waste a great portion of it by condensation. We see by some late publications of the very ingenious Mr Blackey, that he is still attempting to maintain the reputation of this machine by some contrivance of this kind; but we imagine that they will be ineffectual, except in some very particular situations.

8 Occasions great waste of steam and fuel.

For the great defect of the machine even when we can secure it against all risk of bursting, is the prodigious waste of steam, and consequently of fuel. Daily experience shows, that a few scattered drops of cold water is sufficient for producing an almost instantaneous condensation of a great quantity of steam. Therefore when the steam is admitted into the receiver of Savary's engine, and comes into contact with the cold top and cold water, it is condensed with great rapidity; and the water does not *begin* to subside till its surface has become so hot that it condenses no more steam. It may now begin to yield to the pressure of the incumbent steam; but as soon as it descends a little, more of the cold surface of the receiver comes into contact with the steam, and condenses more of it, and the water can descend no farther till this addition of cold surface is heated up to the state of evaporation. This rapid condensation goes on all the while the water is descending. By some experiments frequently repeated by the writer of this article, it appears that no less than $\frac{11}{12}$ths of the whole steam is uselessly condensed in this manner, and not more than $\frac{1}{12}$th is employed in allowing the water to descend by its own weight; and he has reason to think that the portion thus wasted will be considerably greater, if the steam be employed to *force* the water out of the receiver to any considerable height.

Observe, too, that all this waste must be repeated in every succeeding stroke; for the whole receiver must be cooled again in order to fill itself with water.

9 The attempts made to diminish this waste unsuccessful.

Many attempts have been made to diminish this waste; but all to little purpose, because the very filling of the receiver with cold water occasions its sides to condense a prodigious quantity of steam in the succeeding stroke. Mr Blackey has attempted to lessen this by using two receivers. In the first was oil; and into this only the steam was admitted. This oil passed to and fro between the two receivers, and never touched the water except in a small surface. But this hardly produced a sensible diminution of the waste: for it must now be observed, that there is a necessity for the first cylinder's being cooled to a considerable degree below the boiling point; otherwise, though it will condense much steam, and allow the water to rise into the receiver, there will be a great diminution of the height of suction, unless the vessel be much cooled. This appears plainly by inspecting the table of elasticity. Thus, if the vessel be cooled no lower than 180°, we should lose one half of the pressure of the atmosphere; if cooled to 120, we should still lose $\frac{1}{10}$th. The inspection of this table is of great use for understanding and improving this noble machine; and without a constant recollection of the elasticity of steam corresponding to its actual heat, we shall never have a notion of the niceties of its operation.

10 The astonishing rapidity with which steam is condensed.

The rapidity with which the steam is condensed is really astonishing. Experiments have been made on steam-vessels of six feet in diameter and seven feet high; and it has been found, that about four ounces of water, as warm as the human blood, will produce a complete condensation in less than a second; that is, will produce all the condensation that it is capable of producing, leaving an elasticity about $\frac{1}{5}$ of the elasticity of the air. In another experiment with the same steam vessel, no cold water was allowed to get into it, but it was made to communicate by a long pipe four inches in diameter with another vessel immersed in cold water. The condensation was so rapid that the time could not be measured: it certainly did not exceed half a second. Now this condensation was performed by a very trifling surface of contact. Perhaps we may explain it a little in this way: When a mass of steam, in immediate contact with the cold water, is condensed, it leaves a void, into which the adjoining steam instantly expands; and by this very expansion its capacity for heat is increased, or it grows cold, that is, abstracts the heat from the steam situated immediately beyond it. And in this expansion and refrigeration it is itself partly condensed or converted into water, and leaves a void, into which the circumjacent steam immediately expands, and produces the same effect on the steam beyond it. And thus it may happen that the abstraction of a small quantity of heat from an inconsiderable mass of steam may produce a condensation which may be very extensive. Did we know the change made in the capacity of steam for heat by a given change of bulk, we should be able to tell exactly what would be the effect of this local actual condensation. But experiment has not as yet given us any precise notions on this subject. We think that this rapid condensation to a great distance by a very moderate actual abstraction of heat is a proof that the capacity of steam for heat is prodigiously increased by expansion. We say a *very moderate actual abstraction* of heat, because very little heat is necessary to raise four ounces of blood-warm water to a boiling temperature, which will unfit it for condensing steam. The remarkable phenomenon of snow and ice produced in the Hungarian machine, when the air condensed in the receiver is allowed to blow through the cock (see PNEUMATICS), shows this to be the case in moist air, that is, in air holding water in a state of chemical solution. We see something very like it in a thunder-storm. A small black cloud sometimes appears in a particular spot, and in a very few seconds spreads over many hundred acres of sky, that is, a precipitation of water goes on with that rapid diffusion. We imagine that this increase of capacity or demand for heat, and the condensation that must ensue if this demand is not supplied, is much more remarkable in pure watery vapours, and that this is a capital distinction of their constitution from vapours dissolved in air.

The

Steam-Engine.

The reader must now be so well acquainted with what passes in the steam-vessel, and with the exterior results from it, as readily to comprehend the propriety of the changes which we shall now describe as having been made in the construction and principle of the steam engine.

11 Attempts to improve the steam-engine.

Of all places in England the tin-mines of Cornwall stood most in need of hydraulic assistance; and Mr Savary was much engaged in projects for draining them by his steam-engine. This made its construction and principles well known among the machinists and engineers of that neighbourhood. Among these were a Mr Newcomen, an iron-monger or blacksmith, and Mr Cawley a glazier at Dartmouth in Devonshire, who had dabbled much with this machine. Newcomen was a person of some reading, and was in particular acquainted with the person, writings, and projects of his countryman Dr Hooke. There are to be found among Hooke's papers, in the possession of the Royal Society, some notes of observations, for the use of Newcomen his countryman, on Papin's boasted method of transmitting to a great distance the action of a mill by means of pipes. Papin's project was to employ the mill to work two air-pumps of great diameter. The cylinders of these pumps were to communicate by means of pipes with equal cylinders furnished with pistons, in the neighbourhood of a distant mine. These pistons were to be connected, by means of levers, with the piston-rods of the mine. Therefore, when the piston of the air-pump at the mill was drawn up by the mill, the corresponding piston at the side of the mine would be pressed down by the atmosphere, and thus would raise the piston-rod in the mine, and draw the water. It would appear from these notes, that Dr Hooke had dissuaded Mr Newcomen from erecting a machine on this principle, of which he had exposed the fallacy in several discourses before the Royal Society. One passage is remarkable. "Could he (meaning Papin) make a speedy vacuum under your second piston, your work is done."

It is highly probable that, in the course of this speculation, it occurred to Mr Newcomen that the vacuum he so much wanted might be produced by steam, and that this gave rise to his new principle and construction of the steam-engine. The specific desideratum was in Newcomen's mind; and therefore, when Savary's engine appeared, and became known in his neighbourhood many years after, he would readily catch at the help which it promised.

Savary however claims the invention as his own; but Switzer, who was personally acquainted with both, is positive that Newcomen was the inventor. By his principles (as a quaker) being averse from contention, he was contented to share the honour and the profits with Savary, whose acquaintance at court enabled him to procure the patent in 1705, in which all the three were associated. Posterity has done justice to the modest inventor, and the machine is universally called NEWCOMEN'S ENGINE. Its principle and mode of operation may be clearly conceived as follows.

12 Description of Newcomen's.

Let A (fig. 7.) represent a great boiler properly built in a furnace. At a small height above it is a cylinder CBBC of metal, bored very truly and smoothly. The boiler communicates with this cylinder by means of the throat or steam-pipe NQ. The lower aperture of this pipe is shut by the plate N, which is ground very flat, so as to apply very accurately to the whole circumference of the orifice. This plate is called the regulator or steam-cock, and it turns horizontally round an axis *b a* which passes through the top of the boiler, and is nicely fitted to the socket, like the key of a cock, by grinding. The upper end of this axis is furnished with a handle *b* T.

A piston P is suspended in this cylinder, and made air-tight by a packing of leather or soft rope, well filled with tallow; and, for greater security, a small quantity of water is kept above the piston. The piston rod PD is suspended by a chain which is fixed to the upper extremity F of the arched head FD of the great lever or WORKING BEAM HK, which turns on the gudgeon O. There is a similar arched head EG at the other end of the beam. To its upper extremity E is fixed a chain carrying the pump-rod XL, which raises the water from the mine. The load on this end of the beam is made to exceed considerably the weight of the piston P at the other extremity.

At some small height above the top of the cylinder is a cistern W called the INJECTION CISTERN. From this descends the INJECTION PIPE ZSR, which enters the cylinder through its bottom, and terminates in a small hole R, or sometimes in a nozzle pierced with many smaller holes diverging from a centre in all directions. This pipe has at S a cock called the INJECTION COCK, fitted with a handle V.

At the opposite side of the cylinder, a little above its bottom, there is a lateral pipe, turning upwards at the extremity, and there covered by a clack-valve *f*, called the SNIFTING VALVE, which has a little dish round it to hold water for keeping it air-tight.

There proceeds also from the bottom of the cylinder a pipe *d e g h* (passing behind the boiler), of which the lower end is turned upwards, and is covered with a valve *h*. This part is immersed in a cistern of water Y, called the HOT WELL, and the pipe itself is called the EDUCTION PIPE. Lastly, the boiler is furnished with a safety-valve called the PUPPET CLACK (which is not represented in this sketch for want of room), in the same manner as Savary's engine. This valve is generally loaded with one or two pounds on the square inch, so that it allows the steam to escape when its elasticity is $\frac{1}{10}$th greater than that of common air. Thus all risk of bursting the boiler is avoided, and the pressure outwards is very moderate; so also is the heat. For, by inspecting the table of vaporous elasticity, we see that the heat corresponding to 32 inches of elasticity is only about 216° of Fahrenheit's thermometer.

These are all the essential parts of the engine, and are here drawn in the most simple form, till our knowledge of their particular offices shall show the propriety of the peculiar forms which are given to them. Let us now see how the machine is put in motion, and what is the nature of its work.

13 How the machine is put in motion, and the nature of the work.

The water in the boiler being supposed to be in a state of strong ebullition, and the steam issuing by the safety-valve, let us consider the machine in a state of rest, having both the steam-cock and injection cock shut. The resting position or attitude of the machine must be such as appears in this sketch, the pump rods preponderating, and the great piston being drawn up to the top of the cylinder. Now open the steam cock by turning the handle T of the regulator. The steam from the boiler

Steam-Engine.

boiler will immediately rush in, and flying all over the cylinder, will mix with the air. Much of it will be condensed by the cold surface of the cylinder and piston, and the water produced from it will trickle down the sides, and run off by the eduction-pipe. This condensation and waste of steam will continue till the whole cylinder and piston are made as hot as boiling water. When this happens, the steam will begin to open the snifting valve *f*, and issue through the pipe; slowly at first and very cloudy, being mixed with much air. The blast at *f* will grow stronger by degrees, and more transparent, having already carried off the greatest part of the common air which filled the cylinder. We supposed that the water was boiling briskly, so that the steam was issuing by the safety-valve which is in the top of the boiler, and through every crevice. The opening of the steam-cock puts an end to this at once, and it has sometimes happened that the cold cylinder abstracts the steam from the boiler with such astonishing rapidity, that the pressure of the atmosphere has burst up the bottom of the boiler. We may here mention an accident of which we were witnesses, which also shows the immense rapidity of the condensation. The boiler was in a frail shed at the side of the engine-house; a shoot of snow from the top of the house fell down and broke through the roof of the shed, and was scattered over the head of the boiler, which was of an oblong or oval shape. In an instant the sides of it were squeezed together by the pressure of the atmosphere.

When the manager of the engine perceives that not only the blast at the snifting valve is strong and steady, but that the boiler is now fully supplied with steam of a proper strength, appearing by the renewal of the discharge at the safety-valve, he shuts the steam cock, and opens the injection-cock S by turning its handle V. The pressure of the column of water in the injection-pipe ZS immediately forces some water through the spout R. This coming in contact with the pure vapour which now fills the cylinder, condenses it, and thus makes a partial void, into which the more distant steam immediately expands, and by expanding collapses (as has been already observed). What remains in the cylinder no longer balances the atmospherical pressure on the surface of the water in the injection-cistern, and therefore the water spouts rapidly through the hole R by the joint action of the column ZS and the unbalanced pressure of the atmosphere; at the same time the snifting valve *f* and the eduction valve *h* are shut by the unbalanced pressure of the atmosphere. The velocity of the injection water must therefore rapidly increase, and the jet will dash (if single) against the bottom of the piston, and be scattered through the whole capacity of the cylinder. In a very short space of time, therefore, the condensation of the steam becomes universal, and the elasticity of what remains is almost nothing. The whole pressure of the atmosphere is exerted in the upper surface of the piston, while there is hardly any on its under side. Therefore, if the load on the outer end E of the working beam is inferior to this pressure, it must yield to it. The piston P must descend, and the pump piston L must ascend, bringing along with it the water of the mine, and the motion must continue till the great piston reaches the bottom of the cylinder; for it is not like the motion which would take place in a cylinder of air rarefied to the same degree. In this last case, the impelling force would be continually diminished, because the capacity of the cylinder is diminished by the descent of the piston, and the air in it is continually becoming more dense and elastic. The piston would stop at a certain height, where the elasticity of the included air, together with the load at E, would balance the atmospherical pressure on the piston. But when the contents of the cylinder are pure vapour, and the continued stream of injected cold water keeps down its temperature to the same pitch as at the beginning, the elasticity of the remaining steam can never increase by the descent of the piston, nor exceed what corresponds to this temperature. The impelling or accelerating force therefore remains the same, and the descent of the piston will be uniformly accelerated, if there is not an increase of resistance arising from the nature of the work performed by the other end of the beam. This circumstance will come under consideration afterwards, and we need not attend to it at present. It is enough for our present purpose to see, that if the cylinder has been completely purged of common air before the steam-cock was shut, and if none has entered since, the piston will descend to the very bottom of the cylinder. And this may be frequently observed in a good steam-engine where every part is air-tight. It sometimes happens, by the pit pump drawing air, or some part of the communication between the two strains giving way, that the piston comes down with such violence as to knock out the bottom of the cylinder with the blow.

14 The piston does not begin to descend the moment the injection is made.

The only observation which remains to be made on the motion of the piston in descending is, that it does not begin at the instant the injection is made. The piston was kept at the top by the preponderancy of the outer end of the working beam, and it must remain there till the difference between the elasticity of the steam below it and the pressure of the atmosphere exceeds this preponderancy. There must therefore be a small space of time between the beginning of the condensation and the beginning of the motion. This is very small, not exceeding the third or the fourth part of a second; but it may be very distinctly observed by an attentive spectator. He will see, that the instant the injection-cock is opened, the cylinder will sensibly rise upwards a little by the pressure of the air on its bottom. Its whole weight is not nearly equal to this pressure; and instead of its being necessary to *support* it by a strong floor, we must *keep it down* by strong joists loaded by heavy walls. It is usual to frame these joists into the posts which carry the axis of the working-beam, and are therefore loaded with the whole strain of the machine. This rising of the cylinder shows the instantaneous commencement of the condensation; and it is not till *after* this has been distinctly observed that the piston is seen to start, and begin to descend.

15 The circumstances that succeed the descent of the piston.

When the manager sees the piston as low as he thinks proper, he shuts the injection-cock, and opens the steam-cock. The steam has been accumulating above the water in the boiler during the whole time of the piston's descent, and is now rushing violently through the puppet clack. The moment therefore that the steam-cock is opened, it rushes violently into the cylinder, having an elasticity greater than that of the air. It therefore immediately blows open the snifting valve, and allows (at least) the water which had come in by the former injection, and what arose from the conden-

sed

ſed ſteam, to deſcend by its own weight through the eduction pipe *d e g h* to open the valve *h*, and to run out into the hot well. And we muſt eaſily ſee that this water is boiling hot; for while lying in the bottom of the cylinder, it will condenſe ſteam till it acquires this temperature, and therefore cannot run down till it condenſes no more. There is ſtill a waſte of ſteam at its firſt admiſſion, in order to heat the inſide of the cylinder and the injected water to the boiling temperature: but the ſpace being ſmall, and the whole being already very warm, this is very ſoon done; and when things are properly conſtructed, little more ſteam is wanted than what will warm the cylinder; for the eduction-pipe receives the injection water even during the deſcent of the piſton, and it is therefore removed pretty much out of the way of the ſteam.

16 Effect of the firſt puff of entering ſteam

This firſt puff of the entering ſteam is of great ſervice: it drives out of the cylinder the vapour which it finds there. This is ſeldom pure watery vapour: all water contains a quantity of air in a ſtate of chemical union. The union is but feeble, and a boiling heat is ſufficient for diſengaging the greateſt part of it by increaſing its elaſticity. It may alſo be diſengaged by ſimply removing the external preſſure of the atmoſphere. This is clearly ſeen when we expoſe a glaſs of water in an exhauſted receiver. Therefore the ſmall ſpace below the piſton contains watery vapour mixed with all the air which had been diſengaged from the water in the boiler by ebullition and all that was ſeparated from the injection water by the diminution of external preſſures. All this is blown out of the cylinder by the firſt puff of ſteam. We may obſerve in this place, that waters differ exceedingly in the quantity of air which they hold in a ſtate of ſolution. All ſpring water contains much of it: and water newly brought up from deep mines contains a great deal more, becauſe the ſolution was aided in theſe ſituations by great preſſures. Such waters ſparkle when poured into a glaſs.

17 Of great conſequence to the good performance of a ſteam-engine, that the water employed contain little air.

It is therefore of great conſequence to the good performance of a ſteam-engine to uſe water containing little air, both in the boiler and in the injection-ciſtern. The water of running brooks is preferable to all others, and the freer it is from any ſaline impregnation it generally contains leſs air. Such engines as are ſo unfortunately ſituated that they are obliged to employ the very water which they have brought up from great depths, are found greatly inferior in their performance to others. The air collected below the piſton greatly diminiſhes the accelerating force, and the expulſion of ſuch a quantity requires a long continued blaſt of the beſt ſteam at the beginning of every ſtroke. It is adviſable to keep ſuch water in a large ſhallow pond for a long while before uſing it.

18 How the piſton riſes.

Let us now conſider the ſtate of the piſton. It is evident that it will ſtart or begin to riſe the moment the ſteam-cock is opened; for at that inſtant the exceſs of atmoſpherical preſſure, by which it was kept down in oppoſition to the preponderancy of the outer end of the beam, is diminiſhed. The piſton is therefore *dragged* upwards, and it will riſe even although the ſteam which is admitted be not ſo elaſtic as common air. Suppoſe the mercury in the barometer to ſtand at 30 inches, and that the preponderancy at the outer end of the beam in $\frac{1}{9}$th of the preſſure of the air on the piſton, the piſton will not riſe if the elaſticity of the ſteam is not equal to 30—$\frac{30}{9}$, that is, to 26,7 inches nearly; but if it is juſt this quantity, the piſton will riſe as faſt as this ſteam can be ſupplied through the ſteam-pipe, and the velocity of its aſcent depends entirely on the velocity of this ſupply. This obſervation is of great importance; and it does not ſeem to have occurred to the mathematicians, who have paid moſt attention to the mechaniſm of the motion of this engine. In the mean time, we may clearly ſee that the entry of the ſteam depends chiefly on the counter weight at E: for ſuppoſe there was none, ſteam no ſtronger than air would not enter the cylinder at all; and if the ſteam be ſtronger, it will enter only by the exceſs of its ſtrength. Writers on the ſteam-engine (and even ſome of great reputation) familiarly ſpeak of the ſteam giving the piſton a puſh: But this is ſcarcely poſſible. During the riſe of the piſton the ſniſting valve is never obſerved to blow; and we have not heard any well atteſted accounts of the piſton-chains ever being ſlackened by the upward preſſure of the ſteam, even at the very beginning of the ſtroke. During the riſing of the piſton the ſteam is (according to the common conception and manner of ſpeaking) *ſucked in*, in the ſame way that air is ſucked into a common ſyrenge or pump when we draw up the piſton; for in the ſteam engine the piſton is really drawn up by the counter weight. But it is ſtill more ſucked in, and requires a more copious ſupply, for another reaſon. As the piſton deſcended only in conſequence of the inſide of the cylinder's being ſufficiently cooled to condenſe the ſteam, this cooled ſurface muſt again be preſented to the ſteam during the riſe of the piſton, and muſt condenſe ſteam a ſecond time. The piſton cannot riſe another inch till the part of the cylinder which the piſton has already quitted has been warmed up to the boiling point, and ſteam muſt be expended in this warming. The inner ſurface of the cylinder is not only of the heat of boiling water while the piſton riſes, but is alſo perfectly dry; for the film of water left on it by the aſcending piſton muſt be completely evaporated, otherwiſe it will be condenſing ſteam. That the quantity thus waſted is conſiderable, appears by the experiments of Mr Beighton. He found that five pints of water were boiled off in a minute, and produced 16 ſtrokes of an engine whoſe cylinder contained 113 gallons of 282 inches each; and he thence concluded that ſteam was 2886 times rarer than water. But in no experiment made with ſcrupulous care on the expanſion of boiling water does it appear that the denſity of ſteam exceeds $\frac{1}{10,000}$th of the denſity of water. Deſaguliers ſays that it is above 14,000 times rarer than water. We have frequently attempted to meaſure the weight of ſteam which filled a very light veſſel, which held 12,600 grains of water, and found it always leſs than one grain; ſo that we have no doubt of its being much more than 10,000 times rarer than water. This being the caſe, we may ſafely ſuppoſe that the number of gallons of ſteam, inſtead of being 16 times 113, were nearly five times as much; and that only $\frac{1}{5}$th were employed in allowing the piſton to riſe, and the remaining $\frac{4}{5}$ths were employed to warm the cylinder.

19 Its aſcent chiefly owing to the weight of the pit piſton-rods.

The moving force during the aſcent of the piſton muſt be conſidered as reſulting chiefly, if not ſolely, from the preponderating weight of the pit piſton-rods. The office of this is to return the ſteam-piſton to the top

top of the cylinder, where it may again be preſſed down by the air, and make another working ſtroke by raiſing the pump rods. But the counter-weight at E has another ſervice to perform in this uſe of the engine; namely, to return the pump piſtons into their places at the bottom of their reſpective working barrels, in order that they alſo may make a working ſtroke. This requires force independent of the friction and inertia of the moving parts; for each piſton muſt be puſhed down through the water in the barrel, which muſt riſe through the piſton with a velocity whoſe proportion to the velocity of the piſton is the ſame with that of the bulk of the piſton to the bulk of the perforation through which the water riſes through the piſton. It is enough at preſent to mention this in general terms: we ſhall conſider it more particularly afterwards, when we come to calculate the performance of the engine, and to deduce from our acquired knowledge maxims of conſtruction and improvement.

20 The aſcent of the piſton differs greatly from the deſcent.

From this general conſideration of the aſcent of the piſton, we may ſee that the motion differs greatly from the deſcent. It can hardly be ſuppoſed to accelerate, even if the ſteam in the cylinder were in a moment annihilated. For the reſiſtance to the deſcent of the piſton is the ſame with the weight of the column of water, which would cauſe it to flow through the box of the pump piſton with the velocity with which it really riſes through it, and muſt therefore increaſe as the ſquare of that velocity increaſes; that is, as the ſquare of the velocity of the piſton increaſes. Independent of friction, therefore, the velocity of deſcent through the water muſt ſoon become a maximum, and the motion become uniform. We ſhall ſee by and by, that in ſuch a pump as is generally uſed this will happen in leſs than the 10th part of a ſecond. The friction of the pump will diminiſh this velocity a little, and retard the time of its attaining uniformity. But, on the other hand, the ſupply of ſteam which is neceſſary for this motion, being ſuſceptible of no acceleration from its previous motion, and depending entirely on the briſkneſs of the ebullition, an almoſt inſtantaneous ſtop is put to acceleration.

Accordingly, any perſon who obſerves with attention the working of a ſteam-engine, will ſee that the riſe of the piſton and deſcent of the pump-rods is extremely uniform, whereas the working ſtroke is very ſenſibly accelerated. Before quitting this part of the ſubject, and leſt it ſhould afterwards eſcape our recollection, we may obſerve that the counter weight is different during the two motions of the pump-rods.

21 The counter weight is different during the two motions of the pump-rods.

While the machine is making a working ſtroke, it is lifting not only the column of water in the pump, but the abſolute weight of the piſtons and piſton-rods alſo: but while the pump-rods are deſcending, there is a diminution of the counter weight by the whole weight loſt by the immerſion of the rod in water. The wooden rods which are generally uſed, ſoaked in water, and joined by iron ſtraps, are heavier, and but a little heavier than water, and they are generally about one-third of the bulk of the water in the pumps.

Theſe two motions complete the period of the operation; and the whole may be repeated by ſhutting the ſteam cock and opening the injection-cock whenever the piſton has attained the proper height. We have been very minute in our attention to the different circumſtances, that the reader may have a diſtinct notion of the ſtate of the moving forces in every period of the operation. It is by no means ſufficient that we know in general that the injection of cold water makes a void which allows the air to preſs down the piſton, and that the readmiſſion of the ſteam allows the piſton to riſe again. This lumping and ſlovenly way of viewing it has long prevented even the philoſopher from ſeeing the defects of the conſtruction, and the methods of removing them.

22 Difference between Savary's and Newcomen's machines.

We now ſee the great difference between Savary's and Newcomen's engine in reſpect of principle. Savary's was really an engine which raiſed water by the force of ſteam; but Newcomen's raiſes water entirely by the preſſure of the atmoſphere, and ſteam is employed merely as the moſt expeditious method of producing a void, into which the atmoſpherical preſſure may impel the *firſt mover* of his machine. The elaſticity of the ſteam is not the firſt mover.

23 Superiority of Newcomen's.

We ſee alſo the great ſuperiority of this new machine. We have no need of ſteam of great and dangerous elaſticity; and we operate by means of very moderate heats, and conſequently with much ſmaller quantities of fuel; and there is no bounds to the power of this machine. How deep ſoever a mine may be, a cylinder may be employed of ſuch dimenſions that the preſſure of the air on its piſton may exceed in any degree the weight of the column of water to be raiſed. And laſtly, this form of the machine renders it applicable to almoſt every mechanical purpoſe; becauſe a ſkilful mechanic can readily find a method of converting the reciprocating motion of the working beam into a motion of any kind which may ſuit his purpoſe. Savary's engine could hardly admit of ſuch an immediate application, and ſeems almoſt reſtricted to raiſing water.

24 Gradually improved

Inventions improve by degrees. This engine was firſt offered to the public in 1705. But many difficulties occurred in the execution, which were removed one by one; and it was not till 1712 that the engine ſeemed to give confidence in its efficacy. The moſt exact and unremitting attention of the manager was required to the preciſe moment of opening and ſhutting the cocks; and neglect might frequently be ruinous, by beating out the bottom of the cylinder, or allowing the piſton to be wholly drawn out of it. Stops were contrived to prevent both of theſe accidents; then ſtrings were uſed to connect the handles of the cocks with the beam, ſo that they ſhould be turned whenever it was in certain poſitions. Theſe were gradually changed and improved into detents and catches of different ſhapes;

25 And ſimplified.

at laſt, in 1717, Mr Beighton, a very ingenious and well informed artiſt, ſimplified the whole of theſe ſubordinate movements, and brought the machine into the form in which it has continued, without the ſmalleſt material change, to the preſent day. We ſhall now deſcribe one of theſe improved engines, copying almoſt exactly the drawings and deſcription given by Boſſut in his *Hydrodynamique*; theſe being by far the moſt accurate and perſpicuous of any that have been publiſhed.

Plate CCCCLXXVIII.

Fig. 8. n° 1. is a perſpective view of the boiler cylinder, and all the parts neceſſary for turning the cocks. Fig. 8. n° 2. is a vertical ſection of the ſame; and the ſame pieces of both are marked with the ſame letters of reference.

The

Steam-Engine.

26
Deſcription of Beighton's ſteam-engine.

The rod X of the piſton P is ſuſpended from the arch of the working-beam, as was repreſented in the preceding ſketch (fig. 7). An upright bar of timber FG is alſo ſeen hanging by a chain. This is ſuſpended from a concentric arch of the beam, as may be ſeen alſo in the ſketch at φ ι. This bar is called the *plug-beam*, and it muſt riſe and fall with the piſton, but with a ſlower motion. The uſe of this plug-beam is to give motion to the different pieces which turn the cocks.

The ſteam pipe K is of one piece with the bottom of the cylinder, and riſes within it an inch or two, to prevent any of the cold injection water from falling into the boiler. The lower extremity Z of the ſteam-pipe penetrates the head of the boiler, projecting a little way. A flat plate of braſs, in ſhape reſembling a racket or battledore, called the *regulator*, applies itſelf exactly to the whole circumference of the ſteam-pipe, and completely excludes the ſteam from the cylinder. Being moveable round an upright axis, which is repreſented by the dotted lines at the ſide of the ſteam-pipe in the profile, it may be turned aſide by the handle *i*, nº 1. The profile ſhows in the ſection of this plate a protuberance in the middle. This reſts on a ſtrong flat ſpring, which is fixed below it athwart the mouth of the ſteam-pipe. This ſpring preſſes it ſtrongly towards the ſteam-pipe, cauſing it to apply very cloſe; and this knob ſlides along the ſpring, while the regulator turns to the right or left.

We have ſaid that the injection water is furniſhed from a ciſtern placed above the cylinder. When this ciſtern cannot be ſupplied by pipes from ſome more elevated ſource, its water is raiſed by the machine itſelf. A ſmall lifting pump *i k* (fig. 7.), called the *jack-head* or *jacquette*, is worked by a rod γ ι, ſuſpended from a concentric arch ι γ near the outer end of the working beam. This forces a ſmall portion of the pit water along the riſing pipe *i* L M into the injection ciſtern.

In figure 8. nº 1 and 2. the letters QM 3′ repreſent the pipe which brings down the water from the injection ciſtern. This pipe has a cock at R to open or ſhut the paſſage of this water. It ſpouts through the jet 3′, and daſhing againſt the bottom of the piſton, it is diſperſed into drops, and ſcattered through the whole capacity of the cylinder, ſo as to produce a rapid condenſation of the ſteam.

An upright poſt A may be obſerved in the perſpective view of the cylinder, &c. This ſupports one end B of a horizontal iron axis BC. The end C is ſupported by a ſimilar poſt, of which the place only is marked by the dotted lines A, that the pieces connected with this axis may not be hid by it. A kind of ſtirrup *a b c d* hangs from this axis, ſupported by the hooks *a* and *d*. This ſtirrup is croſſed near the bottom by a round bolt or bar *e*, which paſſes through the eyes or rings that are at the ends of the horizontal fork *h f g*, whoſe long tail *h* is double, receiving between its branches the handle *i* of the regulator. It is plain from this conſtruction, that when the ſtirrup is made to vibrate round the horizontal axis BC, on which it hangs freely by its hooks, the bolt *e* muſt pull or puſh the long fork *h f g* backwards and forwards horizontally, and by ſo doing will move the regulator round its axis by means of the handle *i*. Both the tail of the fork and the handle of the regulator are pierced with ſeveral holes, and a pin is put through them which unites them by a joint. The motion of the handle may be increaſed or diminiſhed by chooſing for the joint a hole near to the axis or remote from it; and the exact poſition at which the regulator is to ſtop on both ſides is determined by pins ſtuck in the horizontal bar on which the end of the handle appears to reſt.

This alternate motion of the regulator to the right and left is produced as follows: There is fixed to the axis BC a piece of iron *o k l*, called the Y, on account of its reſemblance to that letter of the alphabet inverted. The ſtalk *o* carries a heavy lump *p* of lead or iron; and a long leather ſtrap *q p r* is faſtened to *p* by the middle, and the two ends are faſtened to the beam above it, in ſuch a manner that the lump may be alternately catched and held up to the right and left of the perpendicular. By adjuſting the length of the two parts of the ſtrap, the Y may be ſtopped in any deſired poſition. The two claws *k* and *l* ſpread out from each other, and from the line of the ſtalk, and they are of ſuch length as to reach the horizontal bolt *e*, which croſſes the ſtirrup below, but not to reach the bottom of the fork *h f g*. Now ſuppoſe the ſtirrup hanging perpendicularly, and the ſtalk of the Y alſo held perpendicular; carry it a little outward from the cylinder, and then let it go. It will tumble farther out by its weight, without affecting the ſtirrup till the claw *l* ſtrikes on the horizontal bolt *e*, and then it puſhes the ſtirrup and the fork towards the cylinder, and opens the regulator. It ſets it in motion with a ſmart jerk, which is an effectual way of overcoming the coheſion and friction of the regulator with the mouth of the ſteam-pipe. This puſh is adjuſted to a proper length by the ſtrap *q p*, which ſtops the Y, when it has gone far enough. If we now take hold of the ſtalk of the Y, and move it up to the perpendicular, the width between its claws is ſuch as to permit this motion, and ſomething more, without affecting the ſtirrup. But when puſhed ſtill nearer to the cylinder, it tumbles towards it by its own weight, and then the claw *k* ſtrikes the bolt *e*, and drives the ſtirrup and fork in the oppoſite direction, till the lump *p* is catched by the ſtrap *r p*, now ſtretched to its full length, while *q p* hangs ſlack. Thus by the motion of the Y the regulator is opened and ſhut. Let us now ſee how the motion of the Y is produced by the machine itſelf. To the horizontal axis BC are attached two ſpanners or handles *m* and *n*. The ſpanner *m* paſſes through a long ſlit in the plug-beam, and is at liberty to move upwards or downwards by its motion round the axis BC. A pin π which goes through the plug-beam catches hold of *m* when the beam riſes along with the piſton; and the pin is ſo placed, that when the beam is within an inch or two of its higheſt riſe, the pin has lifted *m* and thrown the ſtalk of the Y paſt the perpendicular. It therefore tumbles over with great force, and gives a ſmart blow to the fork, and immediately ſhuts the regulator. By this motion the ſpanner *m* is removed out of the neighbourhood of the plug-beam. But the ſpanner *n*, moving along with it in the ſame direction, now comes into the way of the pins of the plug-beam. Therefore, when the piſton deſcends again by the condenſation of the ſteam in the cylinder, a pin marked & in the ſide of the plug-beam catches hold of the tail of the ſpanner *n*, and by preſſing it down raiſes the lump on the ſtalk

ſtalk of the Y till it paſſes the perpendicular, and it then falls down, outwards from the cylinder, and the claw *l* again drives the fork in the direction *h i*, and opens the ſteam valve. This opening and ſhutting of the ſteam valve is executed in the preciſe moment that is proper, by placing the pins *π* and & at a proper height in the plug-beam. For this reaſon, it is pierced through with a great number of holes, that the places of theſe pins may be varied at pleaſure. This, and a proper curvature of the ſpanners *m* and *n*, make the adjuſtment as nice as we pleaſe.

The injection-cock R is managed in a ſimilar manner. On its key may be obſerved a forked arm *s t*, like a crab's claw; at a little diſtance above it is the gudgeon or axis *u* of a piece *y u z'*, called the hammer or the F, from its reſemblance to that letter. It has a lump of metal *y* at one end, and a ſpear *u s* projects from its middle, and paſſes between the claws *s* and *t* of the arm of the injection-cock. The hammer *y* is held up by a notch in the underſide of a wooden lever DE, moveable round the centre D, and ſupported at a proper height by a ſtring *r* E made faſt to the joiſt above it.

Suppoſe the injection-cock ſhut, and the hammer in the poſition repreſented in the figure. A pin *β* of the plug-frame riſes along with the piſton, and catching hold of the detent DE, raiſes it, and diſengages the hammer *y* from its notch. This immediately falls down, and ſtrikes a board L put in the way to ſtop it. The ſpear *u s*, takes hold of the claw *t*, and forces it aſide towards *x*, and opens the injection-cock. The piſton immediately deſcends, and along with it the plug-frame. During its deſcent the pin *β* meets with the tail *u z'* of the hammer, which is now raiſed conſiderably above the level, and brings it down along with it, raiſing the lump *y*, and gradually ſhutting the injection-cock, becauſe the ſpear takes hold of the claw *s* of its arm. When the beam has come to its loweſt ſituation, the hammer is again engaged in the notch of the detent DE, and ſupported by it till the piſton again reaches the top of the cylinder.

In this manner the motions of the injection-cock are alſo adjuſted to the preciſe moment that is proper for them. The different pins are ſo placed in the plug-frame, that the ſteam-cock may be completely ſhut before the injection-cock is opened. The inherent motion of the machine will give a ſmall addition to the aſcent of the piſton without expending ſteam all the while; and by leaving the ſteam rather leſs elaſtic than before, the ſubſequent deſcent of the piſton is promoted. There is a conſiderable propriety in the gradual ſhutting of the injection-cock. For after the firſt daſh of the cold water againſt the bottom of the piſton, the condenſation is nearly complete, and very little more water is needed; but a continual acceſſion of ſome is abſolutely neceſſary for completing the condenſation, as the capacity of the cylinder diminiſhes, and the water warms which is already injected.

In this manner the motion of the machine will be repeated as long as there is a ſupply of ſteam from the boiler, and of water from the injection ciſtern, and a diſcharge procured for what has been injected. We proceed to conſider how theſe conditions alſo are provided by the machine itſelf.

The injection ciſtern is ſupplied with water by the jackhead-pump, as we have already obſerved. From this ſource all the parts of the machine receive their reſpective ſupplies. In the firſt place, a ſmall branch 13, 13, is taken off from the injection-pipe immediately below the ciſtern, and conducted to the top of the cylinder, where it is furniſhed with a cock. The ſpout is ſo adjuſted, that no more runs from it than what will keep a conſtant ſupply of a foot of water above the piſton to keep it tight. Every time the piſton comes to the top of the cylinder, it brings this water along with it, and the ſurplus of its evaporation and leakage runs off by a waſte pipe 14, 14. This water neceſſarily becomes almoſt boiling hot, and it was thought proper to employ its overplus for ſupplying the waſte of the boiler. This was accordingly practiſed for ſome time. But Mr Beighton improved this economical thought, by ſupplying the boiler from the eduction-pipe 2, 2, the water of which muſt be ſtill hotter than that above the piſton. This contrivance required attention to many circumſtances, which the reader will underſtand by conſidering the perſpective and profile. The eduction-pipe comes out of the bottom of the cylinder at 1 with a perpendicular part, which bends ſidewiſe below, and is ſhut at the extremity 1. A deep cup 5 communicates with it, holding a metal valve nicely fitted to it by grinding, like the key of a cock. To ſecure its being always air-tight, a ſlender ſtream of water trickles into it from a branch 6 of the waſte pipe from the top of the cylinder. The eduction-pipe branches off at 2, and goes down to the hot well, where it turns up, and is covered with a valve. In the perſpective view may be obſerved an upright pipe 4, 4, which goes through the head of the boiler, and reaches to within a few inches of its bottom. This pipe is called the *feeder*, and riſes about three or four feet above the boiler. It is open at both ends, and has a branch 3, 3, communicating with the bottom of the cup 5, immediately above the metal valve, and alſo a few inches below the level of the entry 2 of the eduction-pipe. This communicating branch has a cock by which its paſſage may be diminiſhed at pleaſure. Now ſuppoſe the ſteam in the boiler to be very ſtrong; it will cauſe the boiling water to riſe in the feeding pipe above 3, and coming along this branch, to riſe alſo in the cup 5, and run over. But the height of this cup above the ſurface of the water in the boiler is ſuch, that the ſteam is never ſtrong enough to produce this effect. Therefore, on the contrary, any water that may be in the cup 5 will run off by the branch 3, 3, and go down into the boiler by the feeding pipe.

27 An ingenious contrivance.

Theſe things being underſtood, let us ſuppoſe a quantity of injected water lying at the bottom of the cylinder. It will run into the eduction-pipe, fill the crooked branch 1, 1, and open the valve in the bottom of the cup (its weight being ſupported by a wire hanging from a ſlender ſpring), and it will fill the cup to the level of the entry 2 of the eduction-pipe, and will then flow along 3, 3, and ſupply the boiler by the feeder 4, 4. What more water runs in at 1 will now go along the eduction-pipe 2, 2, to the hot well. By properly adjuſting the cock on the branch 3, 3, the boiler may be ſupplied as faſt as the waſte in ſteam requires. This is a moſt ingenious contrivance, and does great honour to Mr Beighton. It is not, however, of much importance. The ſmall quantity which the boiler requires may

may be immediately taken even from a cold ciſtern, without ſenſibly diminiſhing the production of ſteam: for the quantity of heat neceſſary for raiſing the ſenſible heat of cold water to the boiling temperature is quite inſignificant, when compared with the quantity of heat which muſt then be combined with it in order to convert the water into ſteam. No difference can be obſerved in the performance of ſuch engines and of thoſe which have their boilers ſupplied from a brook. It has, however, the advantage of being purged of air; and when an engine muſt derive all its ſupplies from pit water, the water from the eduction-pipe is vaſtly preferable to that from the top of the cylinder.

We may here obſerve, that many writers (among them the Abbé Boſſut), in their deſcriptions of the ſteam-engine, have drawn the branch of communication 3, 3, from the feeding pipe to a part of the crooked pipe 1, 1, lying below the valve in the cup 5. But this is quite erroneous; for, in this caſe, when the injection is made into the cylinder, and a vacuum produced, the water from the boiler would immediately ruſh up thro' the pipes 4, 3, and ſpout up into the cylinder: ſo would the external air coming in at the top of the feeder.

28
Which enables us to form ſome judgment of the internal ſtate of the engine during the performance.

This contrivance has alſo enabled us to form ſome judgment of the internal ſtate of the engine during the performance. Mr Beighton paid a minute attention to the ſituation of the water in the feeders and eduction-pipe of an engine, which ſeems to have been one of the beſt which has yet been erected. It was lifting a column of water whoſe weight was $\frac{4}{7}$ths of the preſſure of the air on its piſton, and made 16 ſtrokes, of 6 feet each, in a minute. This is acknowledged by all to be a very great performance of an engine of this form. He concluded that the elaſticity of the ſteam in the cylinder was never more than one-tenth greater or leſs than the elaſticity of the air. The water in the feeder never roſe more than three feet and a half above the ſurface of the boiling water, even though it was now lighter by $\frac{1}{27}$th than cold water. The eduction-pipe was only $4\frac{1}{2}$ feet long (vertically), and yet it always diſcharged the injection water completely, and allowed ſome to paſs into the feeder. This could not be if the ſteam was much more than $\frac{1}{10}$th weaker than air. By graſping this pipe in his hand during the riſe of the piſton, he could gueſs very well whereabouts the ſurface of the hot water in it reſted during the motion, and he never found it ſupported ſo high as four feet. Therefore the ſteam in the cylinder had at leaſt $\frac{8}{9}$ths of the elaſticity of the air. Mr Buat, in his examination of an engine which is erected at Montrelaix, in France, by an Engliſh engineer, and has always been conſidered as the pattern in that country, finds it neceſſary to ſuppoſe a much greater variation in the ſtrength of the ſteam, and ſays that it muſt have been $\frac{1}{5}$th ſtronger and $\frac{1}{5}$th weaker than common air. But this engine has not been nearly ſo perfect. Its lift was not more than $\frac{1}{2}$ of the preſſure of the atmoſphere, and it made but nine ſtrokes in a minute.—At W is a valve covering the mouth of a ſmall pipe, and ſurrounded with a cup containing water to keep it air-tight. This allows the air to eſcape which had been extricated from the water of laſt injection. It is driven out by the firſt ſtrong puff of ſteam which is admitted into the cylinder, and makes a noiſe in its exit. This valve is therefore called the ſnifting valve.

To finiſh our deſcription, we obſerve, that beſides the ſafety valve 9 (called the PUPPET-CLACK), which is loaded with about 3 pounds on the ſquare inch (though the engine will work very well with a load of 1 or 2 pounds), there is another DISCHARGER 10, 10, having a clack at its extremity ſupported by a cord. Its uſe is to diſcharge the ſteam without doors, when the machine gives over working. There is alſo a pipe S 8 near the bottom of the boiler, by which it may be emptied when it needs repairs or cleanſing.

There are two ſmall pipes 11, 11, and 12, 12, with cocks called GAGE-PIPES. The firſt deſcends to within two inches of the ſurface of the water in the boiler, and the ſecond goes about 2 inches below that ſurface. If both cocks emit ſteam, the water is too low, and requires a recruit. If neither give ſteam, it is too high, and there is not ſufficient room above it for a collection of ſteam. Laſtly, there is a filling pipe Q, by which the boiler may be filled when the machine is to be ſet to work.

29
This form of the engine has been continued for many years, the only change being the poſition of the boiler.

The engine has continued in this form for many years. The only remarkable change introduced has been the manner of placing the boiler. It is no longer placed below the cylinder, but at one ſide, and the ſteam is introduced by a pipe from the top of the boiler into a flat box immediately below the cylinder. The uſe of the box is merely to lodge the regulator, and give room for its motions. This has been a very conſiderable improvement. It has greatly reduced the height of the building. This was formerly a tower. The wall which ſupported the beam could hardly be built with ſufficient ſtrength for withſtanding the violent ſhocks which were repeated without ceaſing; and the buildings ſeldom laſted more than a very few years. But the boiler is now ſet up in an adjoining ſhed, and the gudgeons of the main beam reſt on the top of upright poſts, which are framed into the joiſts which ſupport the cylinder. Thus the whole moving parts of the machine are contained in one compact frame of carpentry, and have little or no connection with the ſlight walls of the building, which is merely a caſe to hold the machine, and protect it from the weather.

30
How to aſcertain the moſt advantageous proportion between the moving power and the load.

It is now time to inquire what is to be expected from this machine, and to aſcertain the moſt advantageous proportion between the moving power and the load that is to be laid on the machine.

It may be conſidered as a great pulley, and is indeed ſometimes ſo constructed, the arches at the ends of the working beam being completed to a circle. It muſt be unequally loaded that it may move. It is loaded, during the working ſtroke, by the preſſure of the atmoſphere on the piſton ſide, and by the column of water to be raiſed and the pump-gear on the pump ſide.—During the returning ſtroke it is loaded, on the piſton ſide, by a ſmall part of the atmoſpheric preſſure, and on the pump ſide by the pump gear acting as a counter weight. The load during the working ſtroke muſt therefore conſiſt of the column of water to be raiſed and this counter weight. The performance of the machine is to be meaſured only by the quantity of water raiſed in a given time to a given height. It varies, therefore, in the joint proportion of the weight of the column of water in the pumps, and the number of ſtrokes made by the machine in a minute. Each ſtroke conſiſts of two parts, which we have called the working and the returning ſtroke. It does not, therefore, depend ſimply on the velocity of the working ſtroke and the quantity

quantity of water raiſed by it. If this were all that is to be attended to, we know that the weight of the column of water ſhould be nearly $\frac{2}{5}$ths of the preſſure of the atmoſphere, this being the proportion which gives the maximum in the common pulley. But the time of the returning ſtroke is a neceſſary part of the whole time elapſed, and therefore the velocity of the returning ſtroke equally merits attention. This is regulated by the counter weight. The number of ſtrokes *per* minute does not give an immediate proof of the goodneſs of the engine. A ſmall load of water and a great counter weight will enſure this, becauſe theſe conditions will produce a briſk motion in both directions.—The proper adjuſtment of the preſſure of the atmoſphere on the piſton, the column of water to be raiſed, and the counter weight, is a problem of very great difficulty; and mathematicians have not turned much of their attention to the ſubject, although it is certainly the moſt intereſting queſtion that practical mechanics affords them.

31
Mr Boſſut's ſolution,

Mr Boſſut has ſolved it very ſhortly and ſimply, upon this ſuppoſition, that the working and returning ſtroke ſhould be made in equal times. This, indeed, is generally aimed at in the erection of theſe machines, and they are not reckoned to be well arranged if it be otherwiſe. We doubt of the propriety of the maxim. Suppoſing, however, this condition for the preſent, we may compute the loadings of the two ends of the beam as follows. Let a be the length of the inner arm of the working beam, or that by which the great piſton is ſupported. Let b be the outer arm carrying the pump rods, and let W be a weight equivalent to all the load which is laid on the machine. Let c^2 be the area of the piſton; let H be the height of a column of water having c^2 for its baſe, and being equal in weight to the preſſure exerted by the ſteam on the under ſide of the piſton; and let h be the preſſure of the atmoſphere on the ſame area, or the height of a column of water of equal weight. It is evident that both ſtrokes will be performed in equal times, if $h c^2 a - W b$ be equal to $(h - H) c^2 a + W b$. The firſt of theſe quantities is the energy of the machine during the working ſtroke, and the ſecond expreſſes the ſimilar energy during the returning ſtroke. This equation gives us $W = \frac{2 h c^2 a - H c^2 a}{2 b} = \frac{(2 h - H) c^2 a}{2 b}$. If we ſuppoſe the arms of the lever equal and $H = h$, we have $W = c^2 \frac{h}{2}$; that is, the whole weight of the outer end of the beam ſhould be half the preſſure of the air on the great piſton. This is nearly the uſual practice; and the engineers expreſs it by ſaying, that the engine is loaded with ſeven or eight pounds on the ſquare inch. This has been found to be nearly the moſt advantageous load. This way of expreſſing the matter would do well enough, if the maxim were not founded on erroneous notions, which hinder us from ſeeing the ſtate of the machine, and the circumſtances on which its improvement depends. The piſton bears a preſſure of 15 pounds, it is ſaid, on the ſquare inch, if the vacuum below it be perfect; but as this is far from being the caſe, we muſt not load it above the power of its vacuum, which very little exceeds eight pounds. But this is very far from the truth. When the cylinder is tight, the vacuum is not more than $\frac{1}{10}$th deficient, when the cylinder is cooled by the injection to the degree that is every day practicable, and the piſton really bears during its deſcent a preſſure very near to 14 pounds on the inch. The load muſt be diminiſhed, not on account of the imperfect vacuum, but to give the machine a reaſonable motion. We muſt conſider not only the moving force, but alſo the quantity of matter to be put in motion. This is ſo great in the ſteam-engine, that even if it were balanced, that is, if there were ſuſpended on the piſton arm a weight equal to the whole column of water and the counter weight, the full preſſure of the atmoſphere on the ſteam piſton would not make it move twice as faſt as it does.

32
Founded on an erroneous maxim.

33
And faulty in another reſpect.

This equation by Mr Boſſut is moreover eſſentially faulty in another reſpect. The W in the firſt member is not the ſame with the W in the ſecond. In the firſt it is the column of water to be raiſed, together with the counter weight. In the ſecond it is the counter weight only. Nor is the quantity H the ſame in both caſes, as is moſt evident. The proper equation for enſuring the equal duration of the two ſtrokes may be had in the following manner. Let it be determined by experiment what portion of the atmoſpheric preſſure is exerted on the great piſton during its deſcent. This depends on the remaining elaſticity of the ſteam. Suppoſe it $\frac{9}{10}$ths: this we may expreſs by $a h$, a being $= \frac{9}{10}$ths. Let it alſo be determined by experiment what portion of the atmoſpheric preſſure on the piſton remains unbalanced by the ſteam below it during its aſcent. Suppoſe this $\frac{1}{10}$th, we may expreſs this by $b h$. Then let W be the weight of the column of water to be raiſed, and c the counter weight. Then, if the arms of the beam are equal, we have the energy during the working ſtroke $= a h - W - c$, and during the returning ſtroke it is $= c - b h$. Therefore $c - b h = a h - W - c$; and $c = \frac{h(a + b) - W}{2}$; which, on the above ſuppoſition of the values of a and b, gives us $c = \frac{h - W}{2}$. We ſhall make ſome uſe of this equation afterwards; but it affords us no information concerning the moſt advantageous proportion of h and W, which is the material point.

34
Another way of conſidering the matter.

We muſt conſider this matter in another way: And that we may not involve ourſelves in unneceſſary difficulties, let us make the caſe as ſimple as poſſible, and ſuppoſe the arms of the working-beam to be of equal length.

We ſhall firſt conſider the adjuſtment of things at the outer end of the beam.

35
Adjuſtment of things at the outer end of the beam conſidered.

Since the ſole uſe of the ſteam is to give room for the action of the atmoſpheric preſſure by its rapid condenſibility, it is admitted into the cylinder only to allow the piſton to riſe again, but without giving it any impulſe. The pump-rods muſt therefore be returned to the bottom of the working barrels by means of a preponderancy at the outer end of the beam. It may be the weight of the pump-rods themſelves, or may be conſidered as making part of this weight. A weight at the end of the beam will not operate on the rods which are ſuſpended there by chains, and it muſt therefore be attached to the rods themſelves, but above their reſpective pump-barrels, ſo that it may not loſe part of its efficacy by immerſion in the water. We may conſider the whole under the notion of the pump-gear, and call it p. Its office is to depreſs the pump-rods with ſufficient

cient velocity, by overcoming the resistances arising from the following causes.

1. From the inertia of the beams and all the parts of the apparatus which are in motion during the descent of the pump-rods.

2. From the loss of weight sustained by the immersion of the pump-rods in water.

3. From the friction of all the pistons and the weight of the plug-frame.

4. From the resistance to the piston's motion, arising from the velocity which must be generated in the water in passing through the descending pistons.

The sum of all these resistances is equal to the pressure of some weight (as yet unknown), which we may call m.

When the pump-rods are brought up again, they bring along with them a column of water, whose weight we may call w.

It is evident that the load which must be overcome by the pressure of the atmosphere on the steam piston consists of w and p. Let this load be called L, and the pressure of the air be called P.

If p be $=$ L, no water will be raised; if p be $= o$, the rods will not descend: therefore there is some intermediate value of p which will produce the greatest effect.

In order to discover this, let g be the fall of a heavy body in a second.

The descending mass is p: but it does not descend with its full weight; because it is overcoming a set of resistances which are equivalent to a weight m, and the moving force is $p-m$. In order to discover the space through which the rods will descend in a second, when urged by the force $p-m$ (supposed constant, notwithstanding the increase of velocity, and consequently of m), we must institute this proportion $p : p-m = g : \frac{g(p-m)}{p}$.

The fourth term of this analogy is the space required.

Let t be the whole time of the descent in seconds. Then $1^2 : t^2 = \frac{g(p-m)}{p} : \frac{t^2 g(p-m)}{p}$. This last term is the whole descent or length of the stroke accomplished in the time t.

The weight of the column of water, which has now got above the piston, is $w, = L - p$. This must be lifted in the next working stroke through the space $\frac{t^2 g(p-m)}{p}$. Therefore the performance of the engine must be $\frac{t^2 g(p-m)(L-p)}{p}$.

That this may be the greatest possible, we must consider p as the variable quantity, and make the fluxion of the fraction $\frac{\overline{p-m} \times \overline{L-p}}{p} = o$.

This will be found to give us $p = \sqrt{Lm}$; that is, the counter weight or preponderancy of the outer end of the beam is $= \sqrt{Lm}$.

This gives us a method of determining m experimentally. We can discover by actual measurement the quantity L in any engine, it being equal to the unbalanced weights on the beam and the weight of the water in the pumps. Then $m = \frac{p^2}{L}$.

Also we have the weight of the column of water $= L-p, = L - \sqrt{Lm}$.

When therefore we have determined the load which is to be on the outer end of the beam during the working stroke, it must be distributed into two parts, which have the proportion of $\sqrt{Lm}$ to $L - \sqrt{Lm}$. The first is the counter weight, and the second is the weight of the column of water.

If m is a fraction of L, such as an aliquot part of it; that is, if

$$m = \frac{L}{1}, \frac{L}{4}, \frac{L}{9}, \frac{L}{16}, \frac{L}{25}, \text{\&c.}$$
$$p = \frac{L}{1}, \frac{L}{2}, \frac{L}{3}, \frac{L}{4}, \frac{L}{5}, \text{\&c.}$$

The circumstance which is commonly obtruded on us by local considerations is the quantity of water, and the depth from which it is to be raised; that is, w: and it will be convenient to determine every thing in conformity to this.

We saw that $w = L - \sqrt{Lm}$. This gives us $L = \pm\sqrt{wm + \frac{m^2}{4}} + \frac{m}{2} + w$, and the counter weight $p = \sqrt{wm + \frac{m^2}{4}} + \frac{m}{2}$.

36 Having thus ascertained that distribution of the load on the outer end of the beam which produces the greatest effect, we come now to consider what proportion of moving force we must apply, so that it may be employed to the best advantage, or so that any expence of power may produce the greatest performance. It will be so much the greater as the work done is greater, and the power employed is less; and will therefore be properly measured by the quotient of the work done divided by the power employed.

What proportion of moving force may be applied to the greatest advantage

The work immediately done is the lifting up the weight L. In order to accomplish this, we must employ a pressure P, which is greater than L. Let it be $= L + y$; also let s be the length of the stroke.

If the mass L were urged along the space s by the force $L+y$, it would acquire a certain velocity, which we may express by $\sqrt{s}$; but it is impelled only by the force y, the rest of P being employed in balancing L. The velocities which different forces generate by impelling a body along the same space are as the square roots of the forces. Therefore $\sqrt{L+y} : \sqrt{y} = \sqrt{s} : \frac{\sqrt{sy}}{\sqrt{L+y}}$. The fourth term of this analogy expresses the velocity of the piston at the end of the stroke. The quantity of motion produced will be had by multiplying this velocity by the mass L. This gives $\frac{L \times \sqrt{sy}}{\sqrt{L+y}}$; and this, divided by the power expended, or by $L+y$, gives us the measure of the performance; namely, $\frac{L\sqrt{sy}}{\overline{L+y} \times \sqrt{L+y}}$.

That this may be a maximum, consider y as the variable

Steam-Engine.

riable quantity, and make the fluxion of this formula $= o$. This will give us $y = \frac{L}{2}$.

Now $P = L + y, = L + \frac{L}{2}, = \frac{3}{2} L$. Therefore the *whole* load on the outer end of the beam, consisting of the water and the counter weight, must be $\frac{2}{3}$ds of the pressure of the atmosphere on the steam piston.

We have here supposed that the expenditure is the atmospheric pressure; and so it is if we consider it mechanically. But the expenditure of which we are sensible, and which we are anxious to employ to the best advantage, is fuel. Supposing this to be employed with the same judgment in all cases, we are almost intitled, by what we now know of the production of steam, to say that the steam produced is proportional to the fuel expended. But the steam requisite for merely filling the cylinder is proportional to the area of the piston, and therefore to the atmospheric pressure. The result of our investigation therefore is still just; but the steam wasted by condensation on the sides of the cylinder does not follow this ratio, and this is more than what is necessary for merely filling it. This deranges our calculations, and is in favour of large cylinders; but this advantage must be in a great measure compensated by a similar variation in the production of the steam; for in similar boilers of greater dimensions the fuel is less advantageously employed, because the surface to which the fuel is applied does not increase in the ratio of the capacity, just as the surface of the cylinder which wastes the steam. The rule may therefore be confided in as pretty exact.

37 These results agree with the most successful practice.

It is a satisfactory thing to observe these results agree very well with the most successful practice. By many changes and trials engineers have established maxims of construction, which are probably not very far from the best. It is a pretty general maxim, that the load of water should be $\frac{1}{2}$ of the atmospheric pressure. They call this loading the engine with $7\frac{1}{2}$ pounds on the inch, and they say that so small a load is necessary on account of the imperfect vacuum. But we have now seen that it is necessary for giving a reasonable velocity of motion. Since, in this practice, w is made $\frac{1}{2}$ or $\frac{6}{12}$ths of P, and L should be $\frac{8}{12}$ths of P, and L is $= w + p$; it follows, that the counter weight should be $\frac{1}{6}$th of P; and we have found this to be nearly the case in several very good engines.

It must be remarked, that in the preceding investigation we introduced a quantity M to express the resistances to the motion of the engine. This was done in order to avoid a very troublesome investigation. The resistances are of such a nature as to vary with the velocity, and most of them as the square of the velocity. This is the case with the resistance arising from the motion of the water through the pistons of the pumps, and that arising from the friction in the long lift during the working stroke. Had we taken the direct method, which is similar to the determination of the motion through a medium which resists in the duplicate ratio of the velocity, we must have used a very intricate exponential calculus, which few of our readers would have the patience to look at.

But the greatest part of the quantity m supposes a motion already known, and its determination depends on this motion. We must now show how its different component parts may be computed.

38 Resistance to the motion of the engine computed.

1. What arises from the inertia of the moving parts is by far the most considerable portion of it. To obtain it, we must find a quantity of matter which, when placed at the end of the beam, will have the same momentum of inertia with that of the whole moving parts in their natural places. Therefore (in the returning stroke) add together the weight of the great piston with its rod and chains; the pit pump rods, chains, and any weight that is attached to them; the arch-heads and iron-work at the ends of the beam, and $\frac{4}{9}$ths of the weight of the beam itself; also the plug-beam with its arch-head and chain, multiplied by the square of its distance from the axis, and divided by the square of half the length of the beam; also the jack-head pump-rod, chain, and arch-head, multiplied by the square of its distance from the axis, and divided by the square of the half-length of the beam. These articles added into one sum may be called M, and may be supposed to move with the velocity of the end of the beam. Suppose this beam to have made a six-foot stroke in two seconds, with an uniformly accelerated motion. In one second it would have moved $1\frac{1}{2}$ feet, and would have acquired the velocity of three feet per second. But in one second gravity would have produced a velocity of 32 feet in the same mass. Therefore the accelerating force which has produced the velocity of three feet is nearly $\frac{1}{11}$th of the weight. Therefore $\frac{M}{11}$ is the first constituent of m in the above investigation. If the observed velocity is greater or less than three feet per second, this value must be increased or diminished in the same proportion.

The second cause of resistance, viz. the immersion of the pump-rods in water, is easily computed, being the weight of the water which they displace.

The third cause, the friction of the pistons, &c. is almost insignificant, and must be discovered by experiment.

The fourth cause depends on the structure of the pumps. These pumps, when made of a proper strength, can hardly have the perforation of the piston more than a fourth part of the area of the working barrel; and the velocity with which the water passes through it is increased at least $\frac{1}{4}$th by the contraction (see PUMP). The velocity of the water is therefore five times greater than that of the piston. A piston 12 inches diameter, and moving one foot per second, meets with a resistance equal to 20 pounds; and this increases as the square of the diameter and as the square of the velocity. If the whole depth of the pit be divided into several lifts, this resistance must be multiplied by the number of lifts, because it obtains in each pump.

Thus we make up the value of m; and we must acknowledge that the method is still indirect, because it supposes the velocity to be known.

We may obtain it more easily in another way, but still with this circumstance of being indirect. We found that p was equal to $\sqrt{L m}$, and consequently $m = \frac{p^2}{L}$. Now in any engine L and p can always be had; and unless p deviates greatly from the proportion which we determined to be the best, the value of m thus obtained will not be very erroneous.

It

Steam-Engine.

39 Observations concerning something presumed in the investigation.

It was farther presumed in this investigation, that the motions both up and down were uniformly accelerated; but this cannot be the case when the resistances increase with the velocity. This circumstance makes very little change in the working-stroke, and therefore the theorem which determines the best relation of P to L may be confided in. The resistances which vary with the velocity in this case are a mere trifle when compared with the moving power y. These resistances are, 1st, The strangling of the water at the entry, and at the standing valve of each pump. This is about 37 pounds from a pump 12 inches diameter, and the velocity one foot per second, increasing in the duplicate ratio of the diameter and velocity; and, 2d, The friction of the water along the whole lift. This for a pump of the same size and with the same velocity, lifting 20 fathoms, is only about $2\frac{1}{4}$ pounds, and varies in the simple proportion of the diameter and the depth, and in the duplicate proportion of the velocity. The resistance arising from inertia is greater than in the returning stroke; because the M in this case must contain the momentum of the water both of the pit-pumps and the jackhead-pump: but this part of the resistance does not affect the uniform acceleration. We may therefore confide in the propriety of the formula $y=\frac{L}{2}$. And we may obtain the velocity of this stroke at the end of a second with great accuracy as follows. Let $2g$ be the velocity communicated by gravity in a second, and the velocity at the end of the first second of the steam piston's descent will be somewhat less than $\frac{y}{M}2g$; where M expresses the inertia of all the parts which are in motion during the descent of the steam piston, and therefore includes L. Compute the two resistances just mentioned for this velocity. Call this r. Then $\frac{y-\frac{1}{2}r}{M}\ 2g$ will give another velocity infinitely near the truth.

But the case is very different in the returning stroke, and the proper ratio of p to L is not ascertained with the same certainty: for the moving force p is not so great in proportion to the resistance m; and therefore the acceleration of the motion is considerably affected by it, and the motion itself is considerably retarded, and in a very moderate time it becomes sensibly uniform: for it is precisely similar to the motion of a heavy body falling through the air, and may be determined in the manner laid down in the article *Resistance of Fluids*, viz. by an exponential calculus. We shall content ourselves here with saying, that the resistances in the present case are so great that the motion would be to all sense uniform before the pistons have descended $\frac{1}{3}$d of their stroke, even although there were no other circumstance to affect it.

40 The motion affected by a circumstance that deserves particular consideration.

But this motion is affected by a circumstance quite unconnected with any thing yet considered, depending on conditions not mechanical, and so uncertain, that we are not yet able to ascertain them with any precision; yet they are of the utmost importance to the good performance and improvement of the engine, and therefore deserve a particular consideration.

The counter weight has not only to push down the pump-rods, but also to *drag* up the great piston. This it cannot do unless the steam be admitted into the cylinder. If the steam be no stronger than common air, it cannot enter the cylinder except *in consequence* of the piston's being dragged up. If common air were admitted into the cylinder, some force would be required to drag up the piston, in the same manner as it is required to draw up the piston of a common syringe; for the air would rush through the small entry of the cylinder in the same manner as through the small nozzle of the syringe. Some part of the atmospheric pressure is employed in driving in the air with sufficient velocity to fill the syringe, and it is only with the remainder that the admitted air presses on the under surface of the syringe. Therefore some of the atmospheric pressure on its upper surface is not balanced. This is felt by the hand which draws it up. The same thing must happen in the steam-engine, and some part of the counter weight is expended in drawing up the steam-piston. We could tell how much is thus expended if we knew the density of the steam; for this would tell us the velocity with which its elasticity would cause it to fill the cylinder. If we suppose it 12 times rarer than air, which it certainly is, and the piston rises to the top of the cylinder in two seconds, we can demonstrate that it will enter with a velocity not less than 1400 feet *per* second, whereas 500 feet is enough to make it maintain a density $\frac{9}{10}$ths of that of steam in equilibrio with the air. Hence it follows, that its elasticity will not be less than $\frac{9}{10}$ths of the elasticity of the air, and therefore not more than $\frac{1}{10}$th of counter weight will be expended in drawing up the steam-piston.

But all this is on the supposition that there is an unbounded supply of steam of undiminished elasticity. This is by no means the case. Immediately before opening the steam-cock, the steam was issuing through the safety-valve and all the crevices in the top of the boiler, and (in good engines) was about $\frac{1}{10}$th stronger or more elastic than air. This had been gathering during something more than the descent of the piston, viz, in about three seconds. The piston rises to the top in about two seconds; therefore about twice and a half as much steam as fills the dome of the boiler is now shared between the boiler and cylinder. The dome is commonly about six times more capacious than the cylinder. If therefore no steam is condensed in the cylinder, the density of the steam, when the piston has reached the top, must be about $\frac{1}{1}\frac{1}{6}$ths of its former density, and still more elastic than air. But as much steam is condensed by the cold cylinder, its elasticity must be less than this. We cannot tell how much less, both because we do not know how much is thus condensed, and because by this diminution of its pressure on the surface of the boiling water, it must be more copiously produced in the boiler; but an attentive observation of the engine will give us some information. The moment the steam-cock is opened we have a strong puff of steam through the snifting valve. At this time, therefore, it is still more elastic than air; but after this, the snifting valve remains shut during the whole rise of the piston, and no steam any longer issues though the safety-valve or crevices; nay, the whole dome of the boiler may be observed to sink.

41 The elasticity of the steam during the ascent of the piston greatly diminished.

These facts give abundant proof than the elasticity of the steam during the ascent of the piston is greatly diminished, and therefore much of the counter weight is expended in dragging up the steam-piston in opposition to the unbalanced part of the atmospheric pressure. The

motion

motion of the returning ſtroke is therefore ſo much deranged by this foreign and inappreciated circumſtance, that it would have been quite uſeleſs to engage in the intricate exponential inveſtigation, and we muſt ſit down contented with a leſs perfect adjuſtment of the counter weight and weight of water.—Any perſon who attends to the motion of ſteam-engine will perceive that the deſcent of the pump-rods is ſo far from being accelerated, that it is nearly uniform, and frequently it is ſenſibly retarded towards the end. We learn by the way, that it is of the utmoſt importance not only to have a quick production of ſteam, but alſo a very capacious dome, or empty ſpace above the water in the boiler. In engines where this ſpace was but four or five times the capacity of the cylinder, we have always obſerved a very ſenſible check given to the deſcent of the pump-rods after having made half their ſtroke. This obliges us to employ a greater counter weight, which diminiſhes the column of water, or retards the working ſtroke; it alſo obliges us to employ a ſtronger ſteam, at the riſk of burſting the boiler, and increaſes the expence of fuel.

42 How to know the elaſticity of the ſteam in the cylinder.

It would be a moſt deſirable thing to get an exact knowledge of the elaſticity of the ſteam in the cylinder; and this is by no means difficult. Take a long glaſs tube exactly calibered, and cloſe at the farther end. Put a ſmall drop of ſome coloured fluid into it, ſo as to ſtand at the middle nearly.—Let it be placed in a long box filled with water to keep it of a conſtant temperature. Let the open end communicate with the cylinder, with a cock between. The moment the ſteam-cock is opened, open the cock of this inſtrument. The drop will be puſhed towards the cloſe end of the tube, while the ſteam in the cylinder is more elaſtic than the air, and it will be drawn the other way while it is leſs elaſtic, and, by a ſcale properly adapted to it, the elaſticity of the ſteam correſponding to every poſition of the piſton may be diſcovered. The ſame thing may be done more accurately by a barometer properly conſtructed, ſo as to prevent the oſcillations of the mercury.

43 Neceſſary alſo to know the ſtate of the cylinder during the deſcent of the piſton.

It is equally neceſſary to know the ſtate of the cylinder during the deſcent of the ſteam-piſton. We have hitherto ſuppoſed P to be the full preſſure of the atmoſphere on the area of the piſton, ſuppoſing the vacuum below it to be complete. But the inſpection of our table of elaſticity ſhows that this can never be the caſe, becauſe the cylinder is always of a temperture far above 32°. We have made many attempts to diſcover its temperature. We have employed a thermometer in cloſe contact with the ſide of the cylinder, which ſoon acquired a ſteady temperature: this was never leſs than 145°. We have kept a thermometer in the water which lies on the piſton: this never ſunk below 135°. It is probable that the cylinder within may be cooled ſomewhat lower; but for this opinion we cannot give any very ſatisfactory reaſon. Suppoſe it cooled down to 120°; this will leave an elaſticity which would ſupport three inches of mercury. We cannot think therefore that the unbalanced preſſure of the atmoſphere exceeds that of 27 inches of mercury, which is about $13\frac{1}{3}$d pounds on a ſquare inch, or $10\frac{1}{2}$ on a circular inch. And this is the value which we ſhould employ in the equation $P = L + y$. This queſton may be decided in the ſame way as the other, by a barometer connected with the inſide of the cylinder.

And thus we ſhall learn the ſtate of the moving forces in every moment of the performance, and the machine will then be as open to our examination as any water or horſe mill; and till this be done, or ſomething equivalent, we can only gueſs at what the machine is actually performing, and we cannot tell in what particulars we can lend it a helping hand. We are informed that Meſſrs Watt and Boulton have made this addition to ſome of their engines; and we are perſuaded that, from the information which they have derived from it, they have been enabled to make the curious improvements from which they have acquired ſo much reputation and profit.

44 Quantity of cold water to be injected.

There is a circumſtance of which we have as yet taken no notice, viz. the quantity of cold water injected. Here we confeſs ourſelves unable to give any preciſe inſtuctions. It is clear at firſt ſight that no more than is abſolutely neceſſary ſhould be injected. It muſt generally be ſupplied by the engine, and this expends part of its power. An exceſs is much more hurtful by cooling the cylinder and piſton too much, and therefore waſting ſteam during the next riſe of the piſton. But the determination of the proper quantity requires a knowledge, which we have not yet acquired, of the quantity of heat contained in the ſteam in a latent form. As much water muſt be injected as will abſorb all this without riſing near to the boiling temperature. But it is of much more importance to know how far we may cool the cylinder with advantage; that is, when will the loſs of ſteam, during the next riſe of the piſton, compenſate for the diminution of its elaſticity during its preſent deſcent? Our table of elaſticities ſhows us, that by cooling the cylinder to 120°, we ſtill leave an elaſticity equal to $\frac{1}{10}$th of the whole power of the engine; if we cool it only to 140, we leave an elaſticity of $\frac{1}{5}$th; if we cool it to a blood-heat, we leave an elaſticity of $\frac{1}{20}$th. It is extremely difficult to chooſe among theſe varieties. Experience, however, informs us, that the beſt engines are thoſe which uſe the ſmalleſt quantities of injection water. We know an exceedingly good engine having a cylinder of 30 inches and a ſix-foot ſtroke, which works with ſomething leſs than $\frac{1}{5}$th of a cubic foot of water at each injection; and we imagine that the quantity ſhould be nearly in the proportion of the capacity of the cylinder. Deſaguliers obſerved, that a very good engine, with a cylinder of 32 inches, worked with 300 inches of water at each injection, which does not much exceed $\frac{1}{6}$th of a cubic foot. Mr Watt's obſervations, by means of the barometer, muſt have given him much valuable information in this particular, and we hope that he will not always withhold them from the public.

45 This examination, though not ſatisfactory, may direct the attention to the principal circumſtances.

We have gone thus far in the examination, in order ſeemingly to aſcertain the motion of the engine when loaded and balanced in any known manner, and in order to diſcover that proportion between the moving power and the load which will produce the greateſt quantity of work. The reſult has been very unſatisfactory, becauſe the computation of the returning ſtroke is acknowledged to be beyond our abilities. But it has given us the opportunity of directing the reader's attention to the leading circumſtances in this inquiry. By knowing the internal ſtate of the cylinder in machines of very different goodneſs, we learn the connection between the ſtate of the ſteam and the performance of the machine; and it is very poſſible that the reſult of a full examination may be, that in ſituations were fuel is expenſive, it may be proper to employ a weak ſteam which will expend leſs fuel, although leſs work is per-

formed

Steam-Engine.

formed by it. We ſhall ſee this confirmed in the cleareſt manner in ſome particular employments of the new engines invented by Watt and Boulton.

In the mean time, we ſee that the equation which we gave from the celebrated Abbé Boſſut is in every reſpect erroneous even for the purpoſe which he had in view. We alſo ſee that the equation which we ſubſtituted in its place, and which was intended for determining that proportion between the counter weight and the moving force, and the load which would render the working ſtroke and returning ſtroke of equal duration, is alſo erroneous, becauſe theſe two motions are extremely different in kind, the one being nearly uniform, and the other nearly uniformly accelerated. This being ſuppoſed true, in ſhould follow that the counter weight ſhould be reduced to one half; and we have found this to be very nearly true in ſome good engines which we have examined.

46 An erroneous maxim that the two motions are of equal duration.

We ſhall add but one obſervation more on this head. The practical engineers have almoſt made it a maxim, that the two motions are of equal duration. But the only reaſon which we have heard for the maxim, is, that it is aukward to ſee an engine go otherwiſe. But we doubt exceedingly the truth of this maxim, and, without being able to give any accurate determination, we think that the engine will do more work if the working ſtroke be made ſlower than the returning ſtroke. Suppoſe the engine ſo conſtructed that they are made in equal times; an addition to the counter weight will accelerate the returning ſtroke and retard the working ſtroke. But as the counter weight is but ſmall in proportion to the unbalanced portion of the atmoſpheric preſſure, which is the moving force of the machine. it is evident that this addition to the counter weight muſt bear a much greater proportion on the counter weight than it does to the moving force, and muſt therefore accelerate the returning ſtroke much more than it retards the working ſtroke, and the time of both ſtrokes taken together muſt be diminiſhed by this addition and the performance of the machine improved; and this muſt be the caſe as long as the machine is not extravagantly loaded. The beſt machine which we have ſeen, in reſpect of performance, raiſes a column of water whoſe weight is very nearly $\frac{2}{3}$ds of the preſſure of the atmoſphere on the piſton, making 11 ſtrokes of ſix feet each *per* minute, and the working ſtroke was almoſt twice as ſlow as the other. This engine had worked pumps of 12 inches, which were changed for pumps of 14 inches, all other things remaining the ſame. In its former ſtate it made from $12\frac{1}{2}$ to $13\frac{1}{2}$ ſtrokes *per* minute, the working ſtroke being conſiderably ſlower than the returning ſtroke. The load was increaſed, by the change of the pumps nearly in the proportion of 3 to 4. This had retarded the working ſtroke; but the performance was evidently increaſed in the proportion of 3×13 to 4×113 or of 39 to 44. About 300 pounds were added to the counter weight, which increaſed the number of ſtrokes to more than 12 *per* minute. No ſenſible change could be obſerved in the time of the working ſtroke. The performance was therefore increaſed in the proportion of 39 to 48. We have therefore no heſitation in ſaying, that the ſeemly equality of the two ſtrokes is a ſacrifice to fancy. The engineer who obſerves the working ſtroke to be ſlow, fears that his engine may be thought feeble and unequal to its work; a ſimilar notion has long miſled him in the conſtruction of water-mills, eſpecially of overſhot mills; and, even now, he is ſubmitting with heſitation and fear to the daily correction of experience.

Steam-Engine.

It is needleſs to engage more deeply in ſcientific calculations in a ſubject where ſo many of the data are ſo very imperfectly underſtood.

We venture to recommend as a maxim of conſtruction (ſuppoſing always a large boiler and plentiful ſupply of pure ſteam unmixed with air), that the load of work be not leſs than 10 pounds for every ſquare inch of the piſton, and the counter weight ſo proportioned that the time of the returning ſtroke may not exceed $\frac{2}{3}$ds of that of the working ſtroke. A ſerious objection may be made to this maxim, and it deſerves mature conſideration. Such a load requires the utmoſt care of the machine, that no admiſſion be given to the common air; and it precludes the poſſibility of its working in caſe the growth of water, or deepening the pit, ſhould make a greater load abſolutely neceſſary. Theſe conſiderations muſt be left to the prudence of the engineer. The maxim now recommended relates only to the beſt actual performance of the engine. 47 The load of work ſhould not be leſs than 10 pounds for every ſquare inch of the piſton.

Before quitting this machine, it will not be amiſs to give ſome eaſy rules, ſanctioned by ſucceſsful practice, for computing its performance. Theſe will enable any artiſt, who can go through ſimple calculations, to ſuit the ſize of his engine to the taſk which it is to perform. 48 Rules for computing the performance of the ſteam-engine.

The circumſtance on which the whole computation muſt be founded is the quantity of water which muſt be drawn in a minute and the depth of the mine; and the performance which may be expected from a good engine is at leaſt 12 ſtrokes per minute of ſix feet each, working againſt a column of water whoſe weight is equal to half of the atmoſpheric preſſure on the ſteam-piſton, or rather to 7,64 pounds on every ſquare inch of its ſurface.

It is moſt convenient to eſtimate the quantity of water in cubic feet, or its weight in pounds, recollecting that a cubic foot of water weighs $62\frac{1}{2}$ pounds. The depth of the pit is uſually reckoned in fathoms of ſix feet, and the diameter of the cylinder and pump is uſually reckoned in inches.

Let Q be the quantity of water to be drawn per minute in cubical feet, and f the depth of the mine in fathoms; let c be the diameter of the cylinder, and p that of the pump; and let us ſuppoſe the arms of the beam to be of equal length.

1ſt. To find the diameter of the pump, the area of the piſton in ſquare feet is $p^2 \times \frac{0,7854}{144}$. The length of the column drawn in one minute is 12 times 6 or 72 feet, and therefore its ſolid contents is $p^2 \times \frac{72 \times 0,7854}{144}$ cubical feet, or $p^2 \times 0,3927$ cubical feet. This muſt be equal to Q; therefore p^2 muſt be $\frac{Q}{0,3927}$ or nearly $Q \times 2\frac{1}{2}$. Hence this practical rule: Multiply the cubic feet of water which muſt be drawn in a minute by $2\frac{1}{2}$, and extract the ſquare root of the product: this will be the diameter of the pump in inches.

Thus ſuppoſe that 58 cubic feet muſt be drawn every minute; 58 multiplied by $2\frac{1}{2}$ gives 145, of which the

ſquare,

Steam-Engine.

square root is 12, which is the required diameter of the pump.

2. To find the proper diameter of the cylinder.

The piston is to be loaded with 7,64 pounds on every square inch. This is equivalent to six pounds on a circular inch very nearly. The weight of a cylinder of water an inch in diameter and a fathom in height is $2\frac{1}{24}$ pounds, or nearly two pounds. Hence it follows that $6c^2$ must be made equal to $2fp^2$, and that c^2 is equal to $\frac{2fp^2}{6}$, or to $\frac{fp^2}{3}$.

Hence the following rule: Multiply the square of the diameter of the pump-piston (found as above) by the fathoms of lift, and divide the product by 3, the square root of the quotient is the diameter of the cylinder.

Suppose the pit to which the foregoing pump is to be applied is 24 fathoms deep; then $\frac{24 \times 144}{3}$ gives 1152, of which the square root is 34 inches very nearly.

This engine constructed with care will certainly do the work.

Whatever is the load of *water* proposed for the engine, let 10 be the pounds on every circular inch of the steam-piston, and make $c^2 = p^2 \times \frac{2f}{m}$, and the square root will be the diameter of the steam-piston in inches.

To free the practical engineer as much as possible from all trouble of calculation, we subjoin the following TABLE *of the Dimensions and Power of the Steam Engine,* drawn up by Mr Beighton in 1717, and fully verified by practice since that time. The measure is in English ale gallons of 282 cubic inches.

49 Mr Beighton's table of the dimensions and power of the steam-engine.

The first part of the table gives the size of the pump suited to the growth of water. The second gives the size of the cylinder suited to the load of water. If the depth is greater than any in this table, take its fourth part, and double the diameter of the cylinder. Thus if 150 hogsheads are to be drawn in an hour from the depth of 100 fathoms, the last column of part first gives for 149.40 a pump of 7 inches bore. In a line with this, under the depth of 50 yards, which is $\frac{1}{4}$th of 100 fathoms, we find $20\frac{1}{2}$, the double of which is 41 inches for the diameter of the cylinder.

It is almost impossible to give a general rule for strokes of different lengths, &c. but any one who professes the ability to erect an engine, should surely know as much arithmetic as will accommodate the rule now given to any length of stroke.

We venture to say, that no ordinary engineer can tell *à priori* the number per minute which an engine will give. We took 12 strokes of six feet each for a standard, which a careful engineer may easily accomplish, and which an employer has a right to expect, the engine being loaded with water to half the pressure of the atmosphere: if the load be less, there is some fault—an improper counter weight, or too little boiler, or leaks, &c. &c.

50 Mr Fitzgerald's method of converting its reciprocating motion into a continued rotatory motion.

Such is the state in which Newcomen's steam-engine had continued in use for 60 years neglected by the philosopher, although it is the most curious object which human ingenuity has yet offered to his contemplation, and abandoned to the efforts of the unlettered artist. Its use has been entirely confined to the raising of water. Mr Keane Fitzgerald indeed published in the Philosophical Transactions a method of converting its reciprocating motion into a continued rotatory motion by employing the great beam to work a crank or a train of wheel-work. As the real action of the machine is confined to its working stroke, to accomplish this, it became necessary to connect with the crank or wheeled work a very large and heavy fly, which should accumulate in itself the whole pressure of the machine during its time of action, and therefore continue in motion, and urge forward the working machinery while the steam engine was going through its inactive returning stroke. This will be the case, provided that the resistance exerted by the working machine during the whole period of the working and returning stroke of the steam-engine, together with

Steam-Engine.

with the friction of both, does not exceed the whole pressure exerted by the steam-engine during its working stroke; and provided that the momentum of the fly, arising from its great weight and velocity, be very great, so that the resistance of the work, during one returning stroke of the steam-engine do not make any very sensible diminution of the velocity of the fly. This is evidently possible and easy. The fly may be made of any magnitude; and being exactly balanced round its axis, it will soon acquire any velocity consistent with the motion of the steam-engine. During the working stroke of the engine it is uniformly accelerated, and by its acquired momentum it produces in the beam the movement of the returning stroke; but in doing this, its momentum is shared with the inert matter of the steam-engine, and consequently its velocity diminished, but not entirely taken away. The next working stroke therefore, by pressing on it afresh, increases its remaining velocity by a quantity nearly equal to the whole that it acquired during the first stroke. We say *nearly*, but not quite equal, because the time of the second working stroke must be shorter than that of the first, on account of the velocity already in the machine. In this manner the fly will be more and more accelerated every succeeding stroke, because the pressure of the engine during the working stroke does more than restore to the fly the momentum which it lost in producing the returning movement of the steam-engine. Now suppose the working part of the machine to be added. The acceleration of the fly during each working stroke of the steam-engine will be less than it was before, because the impelling pressure is now partly employed in driving the working machine, and because the fly will lose more of its momentum during the returning stroke of the steam-engine, part of it being expended in driving the working machine. It is evident, therefore, that a time will come when the successive augmentation of the fly's velocity will cease; for, on the one hand, the continual acceleration diminishes the time of the next working stroke, and therefore the time of action of the accelerating power. The acceleration must diminish in the same proportion; and on the other hand, the resistance of the working machine generally, though not always, increases with its velocity. The acceleration ceases whenever the addition made to the momentum of the fly during a working stroke of the steam-engine is just equal to what it loses by driving the machine, and by producing the returning movement of the steam-engine.

51 An important addition;

This must be acknowledged to be a very important addition to the engine, and though sufficiently obvious, it is ingenious, and requires considerable skill and address to make it effective (B).

The movement of the working machine, or mill of whatever kind, must be in some degree hobbling or unequal. But this may be made quite insensible, by making the fly exceedingly large, and disposing the greatest part of its weight in the rim. By these means its momentum may be made so great, that the whole force required for driving the mill and producing the returning movement of the engine may bear a very small proportion to it. The diminution of its velocity will then be very trifling.

No counter weight is necessary here, because the returning movement is produced by the inertia of the fly. A counter weight may, however, be employed, and should be employed, viz. as much as will produce the returning movement of the steam-engine. It will do this better than the same force accumulated in the fly; for this force must be accumulated in the fly by the intervention of rubbing parts, by which some of it is lost; and it must be afterwards returned to the engine with a similar loss. But, for the same reason, it would be improper to make the counter weight also able to drive the mill during the returning stroke.

52 But seldom or never adopted.

By this contrivance Mr Fitzgerald hoped to render the steam-engine of most extensive use; and he, or others associated with him, obtained a patent excluding all others from employing the steam-engine for turning a crank. They also published proposals for erecting mills of all kinds driven by steam-engines, and stated very fairly their powers and their advantages. But their proposals do not seem to have acquired the confidence of the public; for we do not know of any mill ever having been erected under this patent.

53 The great expense of fuel

The great obstacle to this extensive use of the steam-engine is the prodigious expense of fuel. An engine having a cylinder of four feet diameter, working night and day, consumes about 3400 chaldron (London) of good coals in a year.

54 Limits the use of steam-engines.

This circumstance limits the use of steam-engines exceedingly. To draw water from coal-pits, where they can be stocked with unsaleable small coal, they are of universal employment: also for valuable mines, for supplying a great and wealthy city with water, and a few other purposes where a great expence can be borne, they are very proper engines; but in a thousand cases where their unlimited powers might be vastly serviceable, the enormous expences of fuel completely excludes them. We cannot doubt but that the attention of engineers was much directed to every thing that could promise a diminution of this expense. Every one had his particular nostrum for the construction of his furnace, and some were undoubtedly more successful than others. But science was not yet sufficiently advanced: It was not till Dr Black had made his beautiful discovery of latent heat, that we could know the intimate relation between the heat expended in boiling off a quantity of water and the quantity of steam that is produced.

(B) We do not recollect at present the date of this proposal of Mr Fitzgerald; but in 1781 the Abbé Arnal, canon of Alais in Languedoc, entertained a thought of the same kind, and proposed it for working lighters in the inland navigations; a scheme which has been thought practicable by many ingenious men. His brother, a major of engineers in the Austrian service, has carried the thing much farther, and applied it to manufactures; and the Aulic Chamber of mines at Vienna has patronized the project: (See *Journal Encyclopedique*, 1781). But these schemes are long posterior to Mr Fitzgerald's patent, and are even later than the erection of several machines driven by steam-engines which have been erected by Messrs Watt and Boulton. We think it our duty to state these particulars, because it is very usual for one man to assume the credit of another's inventions.

Much about the time of this discovery, viz. 1763, Mr James Watt, established in Glasgow in the commercial line, was amusing himself with repairing a working model of the steam-engine which belonged to the philosophical apparatus of the university. Mr Watt was a person of a truly philosophical mind, eminently conversant in all branches of natural knowledge, and the pupil and intimate friend of Dr Black. In

55 Mr Watt discovers that steam contains an immense quantity of heat

the course of the abovementioned amusement many curious facts in the production and condensation of steam occurred to him; and among others, that remarkable fact which is always appealed to by Dr Black as the proof of the immense quantity of heat which is contained in a very minute quantity of water in the form of elastic steam. When a quantity of water is heated several degrees above the boiling point in a close digester, if a hole be opened, the steam rushes out with prodigious violence, and the heat of the remaining water is reduced, in the course of three or four seconds, to the boiling temperature. The water of the steam which has issued amounts only to a very few drops; and yet these have carried off with them the whole excess of heat from the water in the digester.

56 In his attempts to find out a way to husband this heat,

Since then a certain quantity of steam contains so great a quantity of heat, it must expend a great quantity of fuel; and no construction of furnace can prevent this. Mr Watt therefore set his invention to work to discover methods of husbanding this heat. The cylinder of his little model was heated almost in an instant, so that it could not be touched by the hand. It could not be otherwise, because it condensed the vapour by abstracting its heat. But all the heat thus communicated to the cylinder, and wasted by it on surrounding bodies, contributed nothing to the performance of the engine, and must be taken away at every injection, and again communicated and wasted. Mr Watt quickly understood the whole process which was going on within the cylinder, and which we have considered so minutely, and saw that a very considerable portion of the steam must be wasted in warming the cylinder. His first attempts were made to ascertain how much was thus wasted, and he found that it was not less than three or four times as much as would fill the cylinder and work the engine. He attempted to diminish this waste by using wooden cylinders. But though this produced a sensible diminution of the waste, other reasons forced him to give them up. He then cased his metal cylinders in a wooden case with light wood ashes between. By this, and using no more injection than was absolutely necessary for the condensation, he reduced the waste almost one half. But by using so small a quantity of cold water, the inside of the cylinder was hardly brought below the boiling temperature; and there consequently remained in it a steam of very considerable elasticity, which robbed the engine of a proportional part of the atmospherical pressure. He saw that this was unavoidable as long as the condensation was performed in the cylinder. The thought struck

57 Discovers a method of condensing the steam at a little distance from the cylinder,

him to attempt the condensation in another place. His first experiment was made in the simplest manner. A globular vessel communicated by means of a long pipe of one inch diameter with the bottom of his little cylinder of four inches diameter and 30 inches long. This pipe had a stop cock, and the globe was immersed in a vessel of cold water. When the piston was at the top, and the cylinder filled with strong steam, he turned the cock. It was scarcely turned, nay he did not think it completely turned, when the sides of his cylinder (only strong tin-plate) were crushed together like an empty bladder. This surprised and delighted him. A new cylinder was immediately made of brass sufficiently thick, and nicely bored. When the experiment was repeated with this cylinder, the condensation was so rapid, that he could not say that any time was expended in it. But the most valuable discovery was, that the vacuum in the cylinder was, as he hoped, almost perfect. Mr Watt found, that when he used water in the boiler purged of air by long boiling, nothing that was very sensibly inferior to the pressure of the atmosphere on the piston could hinder it from coming quite down to the bottom of the cylinder. This alone was gaining a great deal, for in most engines the remaining elasticity of the steam was not less than $\frac{1}{5}$th of the atmospherical pressure, and therefore took away $\frac{1}{5}$th of the power of the engine.

58 And removes the difficulties which attended this improvement by means of pumps.

Having gained this capital point, Mr Watt found many difficulties to struggle with before he could get the machine to continue its motion. The water produced from the condensed steam, and the air which was extricated from it, or which penetrated through unavoidable leaks, behoved to accumulate in the condensing vessel, and could not be voided in any way similar to that adopted in Newcomen's engine. He took another method: He applied pumps to extract both, which were worked by the great beam. The contrivance is easy to any good mechanic; only we must observe, that the piston of the water-pump must be under the surface of the water in the condenser, that the water may enter the pump by its own weight, because there is no atmospherical pressure there to force it in. We must also observe, that a considerable force is necessarily expended here, because, as there is but one stroke for rarefying the air, and this rarefaction must be nearly complete, the air-pump must be of large dimensions, and its piston must act against the whole pressure of the atmosphere. Mr Watt, however, found that this force could be easily spared from his machine, already so much improved in respect of power.

59 Observations on the advantages of these discoveries.

Thus has the steam engine received a very considerable improvement. The cylinder may be allowed to remain very hot; nay, boiling hot, and yet the condensation be completely performed. The only elastic steam that now remains is the small quantity in the pipe of communication. Even this small quantity Mr Watt at last got rid of, by admitting a small jet of cold water up this pipe to meet the steam in its passage to the condenser. This both cooled this part of the apparatus in a situation where it was not necessary to warm it again, and it quickened the condensation. He found at last that the small pipe of communication was of itself sufficiently large for the condensation, and that no separate vessel, under the name of condenser, was necessary. This circumstance shows the prodigious rapidity of the condensation. We may add, that unless this had been the case, his improvement would have been vastly diminished; for a large condenser would have required a much larger air-pump, which would have expended much of the power of the engine. By these means the vacuum below the piston is greatly improved: for it will appear clear to any person who understands the subject, that as long as any part of the condenser is

Steam-Engine.

kept of a low temperature, it will abstract and condense the vapour from the warmer parts, till the whole acquires the elasticity corresponding to the coldest part. By the same means much of the waste is prevented, because the cylinder is never cooled much below the boiling temperature. Many engines have been erected by Mr Watt in this form, and their performance gave universal satisfaction.

We have contented ourselves with giving a very slight description without a figure of this improved engine, because we imagine it to be of very easy comprehension, and because it is only a preparation for still greater improvements, which, when understood, will at the same time leave no part of this more simple form unexplained.

60 Mr Watt makes the piston descend by the force of steam.

During the progress of these improvements Mr Watt made many experiments on the quantity and density of the steam of boiling water. These fully convinced him, that although he had greatly diminished the waste of steam, a great deal yet remained, and that the steam expended during the rise of the piston was at least three times more than what would fill the cylinder. The cause of this was very apparent. In the subsequent descent of the piston, covered with water much below the boiling temperature, the whole cylinder was necessarily cooled and exposed to the air. Mr Watt's fertile genius immediately suggested to him the expedient of employing the elasticity of the steam from the boiler to impel the piston down the cylinder, in place of the pressure of the atmosphere; and thus he restored the engine to its first principles, making it an engine *really, moved by steam.* As this is a new epoch in its history, we shall be more particular in the description; at the same time still restricting ourselves to the essential circumstances, and avoiding every peculiarity which is to be found in the prodigious varieties which Mr Watt has introduced into the machines which he has erected, every individual of which has been adapted to local circumstances, or diversified by the progress of Mr Watt's improvements.

Plate CCCCLXXVIII

61 Description of the machine after these improvements were added.

Let A (fig. 9.) represent the boiler. This has received great improvements from his complete acquaintance with the procedure of nature in the production of steam. In some of his engines the fuel has been placed in the midst of the water, surrounded by an iron or copper vessel, while the exterior boiler was made of wood, which transmits, and therefore wastes the heat very slowly. In others, the flame not only plays round the whole outside, as in common boilers, but also runs along several flues which are conducted through the midst of the water. By such contrivances the fire is applied to the water in a most extensive surface, and for a long time, so as to impart to it the greatest part of its heat. So skilfully was it applied in the Albion Mills, that although it was perhaps the largest engine in the kingdom, its unconsumed smoke was inferior to that of a very small brew-house. In this second engine of Mr Watt, the top of the cylinder is shut up by a strong metal plate *g h*, in the middle of which is a collar or box of leather *k l*, formed in the usual manner of a jack-head pump, through which the piston rod P D, nicely turned and polished, can move up and down, without allowing any air to pass by its sides. From the dome of the boiler proceeds a large pipe B C I O Q, which, after reaching the cylinder with its horizontal part B C, descends parallel to its side, sending off two branches, *viz.* I M to the top of the cylinder, and O N to its bottom. At I is a puppet valve opening from below upwards. At L, immediately below this branch, there is a similar valve, also opening from below upwards. The pipe descends to Q, near the bottom of a large cistern *c d e f*, filled with cold water constantly renewed. The pipe is then continued horizontally along the bottom of this cistern (but not in contact), and terminates at R in a large pump S T. The piston S has clack valves opening upwards, and its rod S *s*, passing through a collar of leathers at T, is suspended by a chain to a small arch head on the outer arm of the beam. There is a valve R in the bottom of this pump, as usual, which opens when pressed in the direction Q R, and shuts against a contrary pressure. This pump delivers its contents into another pump X Y, by means of the small pipe *t* X, which proceeds from its top. This second pump has a valve at X, and a clack in its piston Z as usual, and the piston rod Z *z* is suspended from another arch head on the outer arm of the beam. The two valves I and L are opened and shut by means of spanners and handles, which are put in motion by a plug frame, in the same manner as in Newcomen's engine.

Steam-Engine.

Lastly, there may be observed a crooked pipe *a b o*, which enters the upright pipe laterally a little above Q. This has a small jet hole at *o*; and the other end *a*, which is considerably under the surface of the water of the condensing cistern, is covered with a puppet valve *v*, whose long stalk *v u* rises above the water, and may be raised or lowered by hand or by the plug beam. The valves R and X and the clacks in the pistons S and Z are opened or shut by the pressures to which they are immediately exposed.

This figure is not an exact copy of any of Mr Watt's engines, but has its parts so disposed that all may come distinctly into view, and exactly perform their various functions. It is drawn in its quiescent position, the outer end of the beam preponderating by the counter weight, and the piston P at the top of the cylinder, and the pistons S and Z in their lowest situations.

In this situation let us suppose that a vacuum is (by any means) produced in all the space below the piston, the valve I being shut. It is evident that the valve R will also be shut, as also the valve *v*. Now let the valve I be opened. The steam from the boiler, as elastic as common air, will rush into the space above the piston, and will exert on it a pressure as great as that of the atmosphere. It will therefore press it down, raise the outer end of the beam, and cause it to perform the same work as an ordinary engine.

When the piston P has reached the bottom of the cylinder, the plug frame shuts the valve I, and opens L. By so doing the communication is open between the top and bottom of the cylinder, and nothing hinders the steam which is above the piston from going along the passage M L O N. The piston is now equally affected on both sides by the steam, even though a part of it is continually condensed by the cylinder, and in the pipe I O Q. Nothing therefore hinders the piston from being dragged up by the counter weight, which acts with its whole force, undiminished by any remaining unbalanced elasticity of steam. Here therefore this form of the engine has an advantage (and by no means

Steam-Engine.

a small one) over the common engines, in which a great part of the counter weight is expended in overcoming unbalanced atmospheric pressure.

Whenever the piston P arrives at the top of the cylinder, the valve L is shut by the plug frame, and the valves I and *v* are opened. All the space below the piston is at this time occupied by the steam which came from the upper part of the cylinder. This being a little wasted by condensation, is not quite a balance for the pressure of the atmosphere. Therefore, during the ascent of the piston, the valve R was shut, and it remains so. When, therefore, the valve *v* is opened, the cold water of the cistern must spout up through the hole *o*, and condense the steam. To this must be added the coldness of the whole pipe O Q S. As fast as it is condensed, its place is supplied by steam from the lower part of the cylinder. We have already remarked, that this successive condensation is accomplished with astonishing rapidity. In the mean time, steam from the boiler presses on the upper surface of the piston. It must therefore descend as before, and the engines must perform a second working stroke.

But in the mean time the injection water lies in the bottom of the pipe O Q R, heated to a considerable degree by the condensation of the steam; also a quantity of air has been disengaged from it and from the water in the boiler. How is this to be discharged?—This is the office of the pumps S T and X Y. The capacity of S T is very great in proportion to the space in which the air and water are lodged. When, therefore, the piston S has got to the top of its course, there must be a vacuum in the barrel of this pump, and the water and air must open the valve R and come into it. When the piston S comes down again in the next returning stroke, this water and air gets through the valve of the piston; and in the next working stroke they are discharged by the piston into the pump X Y, and raised by its piston. The air escapes at Y, and as much of the water as is necessary is delivered into the boiler by a small pipe Y *g* to supply its waste. It is a matter of indifference whether the pistons S and Z rise with the outer or inner end of the beam, but it is rather better that they rise with the inner end. They are otherwise drawn here, in order to detach them from the rest and show them more distinctly.

Such is Mr Watt's second engine. Let us examine its principles, that we may see the causes of its avowed and great superiority over the common engines.

62 Causes of its superiority over common engines are, the full operation of the counter weight,

We have already seen one ground of superiority, the full operation of the counter weight. We are authorized by careful examination to say, that in the common engines at least one-half of the counter weight is expended in counteracting an unbalanced pressure of the air on the piston during its ascent. In many engines, which are not the worst, this extends to $\frac{1}{7}$th of the whole pressure. This is evident from the exmination of the engine at Montrelais by Bossut. This makes a very great counter weight necessary, which exhausts a proportional part of the moving force.

63 And great saving of steam.

But the great advantage of Mr Watt's form is the almost total annihilation of the waste of steam by condensation in the cylinder. The cylinder is always boiling hot, and therefore prefectly dry. This must be evident to any person who understands the subject. By the time that Mr Watt had completed his improvements, his experiments on the production of steam had given him a pretty accurate knowledge of its density; and he found himself authorized to say, that the quantity of steam employed did not exceed twice as much as would fill the cylinder, so that not above one-half was unavoidably wasted. But before he could bring the engine to this degree of perfection, he had many difficulties to overcome: He inclosed the cylinder in an outer wooden case at a small distance from it. This diminished the expense of heat by communication to surrounding bodies. Sometimes he allowed the steam from the boiler to occupy this interval. This undoubtedly prevented all dissipation from the inner cylinder but in its turn it dissipated much heat by the outer case, and a very sensible condensation was observed between them. This has occasioned him to omit this circumstance in some of his best engines. We believe it was omitted in the Albion Mills.

The greatest difficulty was to make the great piston tight. The old and effectual method, by water lying on it, was inadmissible. He was therefore obliged to have his cylinders most nicely bored, perfectly cylindrical, and finely polished; and he made numberless trials of different soft substances for packing his piston, which should be tight without enormous friction, and which should long remain so, in a situation perfectly dry, and hot almost to burning.

After all that Mr Watt has done in this respect, he thinks that the greatest part of the waste of steam which he still perceives in his engines arises from the unavoidable escape by the sides of the piston during its descent.

But the fact is, that an engine of this construction, of the same dimensions with a common engine, making the same number of strokes of the same extent, does not consume above one fourth part of the fuel that is consumed by the best engines of the common form. It is also a very fortunate circumstance, that the performance of the engine is not immediately destroyed, nor indeed sensibly diminished, by a small want of tightness in the piston. In the common engine, if air get in, in this way, it immediately puts a stop to the work; but although even a considerable quantity of steam get past the piston during its descent, the rapidity of condensation is such, that hardly any diminution of pressure can be observed, and the waste of steam is the only inconvenience.

64 Another valuable property of it.

Mr Watt's penetration soon discovered another most valuable property of this engine. When an engine of the common form is erected, the engineer must make an accurate estimate of the work to be performed, and must proportion his engine accordingly. He must be careful that it be *fully* able to execute its task; but its power must not exceed its load in any extravagant degree. This would produce a motion which is too rapid, and which, being alternately in opposite directions, would occasion jolts which no building or machinery could withstand. Many engines have been shattered by the pumps drawing air, or a pump-rod breaking; by which accidents the steam-piston descends with such rapidity that every thing gives way. But in most operations of mining, the task of the engine increases, and it must be so constructed at first as to be able to bear this addition. It is very difficult to manage an engine that is much superior to its task; and the easiest way is,

to

Steam-Engine.

to have it almost full loaded, and to work it only during a few hours each day, and allow the pit water to accumulate during its repose. This increases the first cost, and wastes fuel during the inaction of the engine.

65 Is, that it can always be exactly fitted to the load which happens to be on it.

But this new engine can at all times be exactly fitted (at least during the working stroke) to the load of work that then happens to be on it. We have only to administer steam of a proper elasticity. At the first erection the engine may be equal to twice its task, if the steam admitted above the cylinder be equal to that of common boiling water; but when once the ebullition is fairly commenced, and the whole air expelled from all parts of the apparatus, it is evident, that by damping the fire, steam of half this elasticity may be continually supplied, and the water will continue boiling although its temperature does not exceed 185° of Fahrenheit's thermometer. This appears by inspecting our table of vaporous elasticity, and affords another argument for rendering that table more accurate by new experiments. We hope that Mr Watt will not withhold from the public the knowledge which he has acquired on this subject. It may very possibly result from an accurate investigation, that it would be advisable to work our steam-engines with weak steams, and that the diminution of work may be more than compensated by the diminution of fuel. It is more probable indeed, that it is Mr Watt's opinion, that the contrary is the case, and that it is much more economical to employ great heats. At any rate, the decision of this question is of great importance for improving the engine; and we see, in the mean time, that the engine can at all times be fitted so as to perform its task with a moderate and manageable motion, and that as the task increases we can increase the power of the engine.

66 One inconvenience

But the method now proposed has a great inconvenience. While the steam is weaker than the atmosphere, there is an external force tending to squeeze in the sides and bottom of the boiler. This could not be resisted when the difference is considerable, and common air would rush in through every crevice of the boiler and soon choke the engine: it must therefore be given up.

67 Remedied in some degree.

But the same effect will be produced by diminishing the passage from the steam into the cylinder. For this purpose, the puppet valve by which the steam enters the cylinder was made in the form of a long taper spigot, and it was lodged in a cone of the same shape; consequently the passage could be enlarged or contracted at pleasure by the distance to which the inner cone was drawn up.

68 But the remedy attended with some difficulties;

In this way several engines were constructed, and the general purpose of suiting the power of the engine to its task was completely answered; but (as the mathematical reader will readily perceive) it was extremely difficult to make this adjustment precise and constant. In a great machine like this, going by jerks, it was hardly possible that every successive motion of the valve should be precisely the same. This occasioned very sensible irregularities in the motion of the engine, which increased and became hazardous when the joints worked loose by long use.

69 Which Mr Watt's fertile genius completely removes.

Mr Watt's genius, always fertile in resources, found out a complete remedy for all those inconveniences. Making the valve of the ordinary form of a puppet clack, he adjusted the button of its stalk or tail so that it should always open full to the same height. He then regulated the pins of the plug-frame, in such a manner that the valve should shut the moment that the piston had descended a certain proportion (suppose one-fourth, one-third, one-half, &c.) of the cylinder. So far the cylinder was occupied by steam as elastic as common air. In pressing the piston farther down, it behoved the steam to expand, and its elasticity to diminish. It is plain that this could be done in any degree we please, and that the adjustment can be varied in a minute, according to the exigency of the case, by moving the plug pins.

In the mean time, it must be observed, that the pressure on the piston is continually changing, and consequently the accelerating force. The motion therefore will no longer be uniformly accelerated: it will approach much faster to uniformity; nay, it may be retarded, because although the pressure on the piston at the beginning of the stroke may exceed the resistance of the load, yet when the piston is near the bottom the resistance may exceed the pressure. Whatever may be the law by which the pressure on the piston varies, an ingenious mechanic may contrive the connecting machinery in such a way that the chains or rods at the outer end of the beam shall continually exert the same pressure, or shall vary their pressure according to any law he finds most convenient. It is in this manner that the watchmaker, by the form of the fuzee, produces an equal pressure on the wheel-work by means of a very unequal action of the main-spring. In like manner, by making the outer arch heads portions of a proper spiral instead of a circle, we can regulate the force of the beam at pleasure.

Thus we see how much more manageable an engine is in this form than Newcomen's was, and also more easily investigated in respect of its power in its various positions. The knowledge of this last circumstance was of mighty consequence, and without it no notion could be formed of what it could perform. This suggested to Mr Watt the use of the barometer communicating with the cylinder; and by the knowledge acquired by these means has the machine been so much improved by its ingenious inventor.

We must not omit in this place one deduction made by Mr Watt from his observations, which may be called a discovery of great importance in the theory of the engine.

70 A discovery of Mr Watt of great importance in the theory of the engine.

Let ABCD (fig. 10.) represent a section of the cylinder of a steam-engine, and EF the surface of its piston. Let us suppose that the steam was admitted while EF was in contact with AB, and that as soon as it had pressed it down to the situation EF the steam cock is shut. The steam will continue to press it down, and as the steam expands its pressure diminishes. We may express its pressure (exerted all the while the piston moves from the situation AB to the situation EF) by the line EF. If we suppose the elasticity of the steam proportional to its density, as is nearly the case with air, we may express the pressure on the piston in any other position, such as KL or DC, by Kl and Dc, the ordinates of a rectangular hyperbola Flc, of which AE, AB are the assymptotes, and A the centre. The accumulated pressure during the motion of the piston from EF to DC will be expressed by the area EFcDE, and the pressure during the whole motion by the area ABFcDA.

Now

Steam-Engine.

Now it is well known that the area EFeDE is equal to ABFE multiplied by the hyperbolic logarithm of $\frac{AD}{AE}$, $= L.\frac{AD}{AE}$, and the whole area ABFeDA is $= ABFE \times \left(1 + L.\frac{AD}{AE}\right)$.

Thus let the diameter of the piſton be 24 inches, and the preſſure of the atmoſphere on a ſquare inch be 14 pounds; the preſſure on the piſton is 6333 pounds. Let the whole ſtroke be 6 feet, and let the ſteam be ſtopped when the piſton has deſcended 18 inches, or 1,5 feet. The hyperbolic logarithm of $\frac{6}{1,5}$ is 1,3862943. Therefore the accumulated preſſure ABFcDA is = 6333 × 2,3862943, = 15114 pounds.

As few profeſſional engineers are poſſeſſed of a table of hyperbolic logarithms, while tables of common logarithms are or ſhould be in the hands of every perſon who is much engaged in mechanical calculations, let the following method be practiſed. Take the common logarithm of $\frac{AD}{AE}$, and multiply it by 2,3026; the product is the hyperbolic logarithm of $\frac{AD}{AE}$.

The accumulated preſſure while the piſton moves from AB to EF is 6333 × 1, or ſimply 6333 pounds. Therefore the ſteam while it expands into the whole cylinder adds a preſſure of 8781 pounds.

Suppoſe that the ſteam had got free admiſſion during the whole deſcent of the piſton, the accumulated preſſure would have been 6333 × 4, or 25332 pounds.

Here Mr Watt obſerved a remarkable reſult. The ſteam expended in this caſe would have been four times greater than when it was ſtopped at $\frac{1}{4}$th, and yet the accumulated preſſure is not twice as great, being nearly $\frac{5}{3}$ds. One fourth of the ſteam performs nearly $\frac{3}{5}$ths of the work, and an equal quantity performs more than twice as much work when thus admitted during $\frac{1}{4}$th of the motion.

This is a curious and an important information, and the advantage of this method of working a ſteam-engine increaſes in proportion as the ſteam is ſooner ſtopped; but the increaſe is not great after the ſteam is rarefied four times. The curve approaches near to the axis, and ſmall additions are made to the area. The expenſe of ſuch great cylinders is conſiderable, and may ſometimes compenſate this advantage.

Let the ſteam be ſtopped at	Its performance is mult.
$\frac{1}{2}$	1,7
$\frac{1}{3}$	2,1
$\frac{1}{4}$	2,4
$\frac{1}{5}$	2,6
$\frac{1}{6}$	2,8
$\frac{1}{7}$	3,
$\frac{1}{8}$	3,2
&c.	&c.

It is very pleaſing to obſerve ſo many unlooked-for advantages reſulting from an improvement made with the ſole view of leſſening the waſte of ſteam by condenſation. While this purpoſe is gained, we learn how to huſband the ſteam which is not thus waſted. The engine becomes more manageable, and is more eaſily adapted to every variation in its taſk, and all its powers are more eaſily computed.

The active mind of its ingenious inventor did not ſtop here: It had always been matter of regret that one half of the motion was unaccompanied by any work. It was a very obvious thing to Mr Watt, that as the ſteam admitted above the piſton preſſed it down, ſo ſteam admitted below the piſton preſſed it up with the ſame force, provided that a vacuum were made on its upper ſide. This was eaſily done, by connecting the lower end of the cylinder with the boiler and the upper end with the condenſer.

Plate CCCCLXXIX. 71 Deſcription of Mr Watt's ſteam-engine in its moſt improved ſtate.

Fig. 11. is a repreſentation of this conſtruction exactly copied from Mr Watt's figure accompanying his ſpecification. Here BB is a ſection of the cylinder, ſurrounded at a ſmall diſtance by the caſe IIII. The ſection of the piſton A, and the collar of leathers which embraces the piſton rod, gives a diſtinct notion of its conſtruction, of the manner in which it is connected with the piſton-rod, and how the packing of the piſton and collar contributes to make all tight.

From the top of the cylinder proceeds the horizontal pipe. Above the letter D is obſerved the ſeat of the ſteam valve, communicating with the box above it. In the middle of this may be obſerved a dark ſhaded circle. This is the mouth of the upper branch of the ſteam pipe coming from the boiler. Beyond D, below the letter N, is the ſeat of the upper condenſing valve. The bottom of the cylinder is made ſpherical, fitting the piſton, ſo that they may come into entire contact. Another horizontal pipe proceeds from this bottom. Above the letter E is the ſeat of the lower ſteam valve, opening into the valve box. This box is at the extremity of another ſteam pipe marked C, which branches off from the upper horizontal part, and deſcends obliquely, coming forward to the eye. The lower part is repreſented as cut open, to ſhow its interior conformation. Beyond this ſteam valve, and below the letter F, may be obſerved the ſeat of the lower condenſing valve. A pipe deſcends from hence, and at a ſmall diſtance below unites with another pipe GG, which comes down from the upper condenſing valve N. Theſe two eduction-pipes thus united go downwards, and open at L into a rectangular box, of which the end is ſeen at L. This box goes backward from the eye, and at its farther extremity communicates with the air-pump K, whoſe piſton is here repreſented in ſection with its butterfly valves. The piſton delivers the water and air laterally into another rectangular box M, darkly ſhaded, which box communicates with the pump I. The piſton-rods of this and of the air-pump are ſuſpended by chains from a ſmall arch head on the inner arm of the great beam. The lower part of the eduction-pipe, the horizontal box L, the air-pump K, with the communicating box M between it and the pump I, are all immerſed in the cold water of the condenſing ciſtern. The box L is made flat, broad, and ſhallow, in order to increaſe its ſurface and accelerate the condenſation. But that this may be performed with the greateſt expedition, a ſmall pipe H, open below (but occaſionally ſtopped by a plug valve) is inſerted laterally into the eduction-pipe G, and then divides into two branches; one of which reaches within a foot or two of the upper valve N, and the other approaches as near to the valve F.

As it is intended by this conſtruction to give the piſton a ſtrong impulſe in both directions, it will not be proper

proper to fuſpend its rod by a chain from the great beam; for it muſt not only pull down that end of the beam, but alſo puſh it upwards. It may indeed be ſuſpended by double chains like the piſtons of the engines for extinguiſhing fires; and Mr Watt has accordingly done ſo in ſome of his engines. But in his drawing from which this figure is copied, he has communicated the force of the piſton to the beam by means of a toothed rack OO, which engages or works in the toothed ſector QQ on the end of the beam. The reader will underſtand, without any farther explanation, how the impulſe given to the piſton in either direction is thus tranſmitted to the beam without diminution. The fly XX, with its pinion Y, which alſo works in the toothed arch QQ, may be ſuppoſed to be removed for the preſent, and will be conſidered afterwards.

We ſhall take the preſent opportunity of deſcribing Mr Watt's method of communicating the force of the ſteam-engine to any machine of the rotatory kind. VV repreſents the rim and arms of a very large and heavy metalline fly. On its axis is the concentric toothed wheel U. There is attached to the end of the great beam a ſtrong and ſtiff rod TT, to the lower end of which a toothed wheel W is firmly fixed by two bolts, ſo that it cannot turn round. This wheel is of the ſame ſize and in the ſame vertical plane with the wheel U; and an iron link or ſtrap (which cannot be ſeen here, becauſe it is on the other ſide of the two wheels) connects the centres of the two wheels ſo that the one cannot quit the other. The engine being in the poſition repreſented in the figure, ſuppoſe the fly to be turned once round by any external force in the direction of the darts. It is plain, that ſince the toothed wheels cannot quit each other, being kept together by the link, the inner half (that is, the half next the cylinder) of the wheel U will work on the inner half of the wheel W, ſo that at the end of the revolution of the fly the wheel W muſt have got to the top of the wheel U, and the outer end of the beam muſt be raiſed to its higheſt poſition. The next revolution of the fly will bring the wheel W and the beam connected with it to their firſt poſitions; and thus every two revolutions of the fly will make a complete period of the beam's reciprocating movements. Now, inſtead of ſuppoſing the fly to drive the beam, let the beam drive the fly. The motions muſt be perfectly the ſame, and the aſcent or deſcent of the piſton will produce one revolution of the fly.

A ſide view of this apparatus is given in fig. 12. marked by the ſame letters of reference. This ſhows the ſituation of parts which were fore-ſhortened in fig. 11. particularly the deſcending branch C of the ſteam pipe, and the ſituation and communications of the two pumps K and L. 8, 8 is the horizontal part of the ſteam pipe. 9 is a part of it whoſe box is repreſented by the dark circle of fig. 11. D is the box of the ſteam clack, and the little circle at its corner repreſents the end of the axis which turns it, as will be deſcribed afterwards. N is the place of the upper eduction valve. A part only of the upper eduction-pipe G is repreſented, the reſt being cut off, becauſe it would have covered the deſcending ſteam pipe CC. When continued down, it comes between the eye and the box E of the lower ſteam valve, and the box F of the lower eduction-valve.

Let us now trace the operation of this machine through all its ſteps. Recurring to fig. 11. let us ſuppoſe that the lower part of the cylinder BB is exhauſted of all elaſtic fluids; that the upper ſteam valve D and the lower eduction valve F are open, and that the lower ſteam valve E and upper eduction valve N are ſhut. It is evident that the piſton muſt be preſſed toward the bottom of the cylinder, and muſt pull down the end of the working beam by means of the toothed rack OO and ſector QQ, cauſing the other end of the beam to urge forward the machinery with which it is connected. When the piſton arrives at the bottom of the cylinder, the valves D and F are ſhut by the plug frame, and E and N are opened. By this laſt paſſage the ſteam gets into the eduction-pipe, where it meets with the injection water, and is rapidly condenſed. The ſteam from the boiler enters at the ſame time by E, and preſſing on the lower ſide of the piſton, forces it upwards, and by means of the toothed rack OO and toothed ſector QQ forces up that end of the working beam, and cauſes the other end to urge forward the machinery with which it is connected: and in this manner the operation of the engine may be continued for ever.

The injection water is continually running into the eduction-pipe, becauſe condenſation is continually going on, and therefore there is a continual atmoſpheric preſſure to produce a jet. The air which is diſengaged from the water, or enters by leaks, is evacuated only during the riſe of the piſton of the air-pump K. When this is very copious, it renders a very large air-pump neceſſary; and in ſome ſituations Mr Watt has been obliged to employ two air-pumps, one worked by each arm of the beam. This in every caſe expends a very conſiderable portion of the power, for the air-pump is always working againſt the whole preſſure of the atmoſphere.

It is evident that this form of the engine, by maintaining an almoſt conſtant and uninterrupted impulſion, is much fitter for driving any machinery of continued motion than any of the former engines, which were inactive during half of their motion. It does not, however, ſeem to have this ſuperiority when employed to draw water: But it is equally fitted for this taſk. Let the engine be loaded with twice as much as would be proper for it if a ſingle ſtroke engine, and let a fly be connected with it. Then it is plain that the power of the engine during the riſe of the ſteam piſton will be accumulated in the fly; and this, in conjunction with the power of the engine during the deſcent of the ſteam piſton, will be equal to the whole load of water.

In ſpeaking of the ſteam and eduction valves, we ſaid that they were all puppet valves. Mr Watt employed cocks, and alſo ſliding valves, ſuch as the regulator or ſteam-valves of the old engines. But he found them always loſe their tightneſs after a ſhort time. This is not ſurpriſing, when we conſider that they are always perfectly dry, and almoſt burning hot. He was therefore obliged to change them all for puppet clacks, which, when truly ground and nicely fitted in their motions at firſt, are not found to go out of order by any length of time. Other engineers now univerſally uſe them in the old form of the ſteam-engine, without the ſame reaſons, and merely by ſervile and ignorant imitation.

The way in which Mr Watt opens and ſhuts theſe valves is as follows. Fig. 13. repreſents a clack with its

Steam-Engine.

its seat and box. Suppose it one of the eduction valves. HH is part of the pipe which introduces the steam, and GG is the upper part of the pipe which communicates with the condenser. At EE may be observed a piece more faintly shaded than the surrounding parts. This is the seat of the valve, and is a brass or bell-metal ring turned conical on the outside, so as to fit exactly into a conical part of the pipe G G. These two pieces are fitted by grinding; and the cone being of a long taper, the ring sticks firmly in it, especially after having been there for some time and united by rust. The clack itself is a strong brass plate D, turned conical on the edge, so as to fit the conical or sloping inner edge of the seat. These are very nicely ground on each other with emery. This conical joining is much more obtuse than the outer side of the ring; so that although the joint is air-tight, the two pieces do not stick strongly together. The clack has a round tail D G, which is freely moveable up and down in the hole of a cross piece F F. On the upper side of the valve is a strong piece of metal D C firmly joined to it, one side of which is formed into a toothed rack. A is the section of an iron axle which turns in holes in the opposite sides of the valve-box, where it is nicely fitted by grinding, so as to be air-tight. Collets of thick leather, well soaked in melted tallow and rosin, are screwed on the outside of these holes to prevent all ingress of air. One end of this axis projects a good way without the box, and carries a spanner or handle, which is moved by the plug-frame. To this axis is fixed a strong piece of metal B, the edge of which is formed into an arch of a circle having the axis A in its centre, and is cut into teeth, which work in the teeth of the rack D C. K is a cover which is fixed by screws to the top of the box H J J H, and may be taken off in order to get at the valve when it needs repairs.

From this description it is easy to see that by turning the handle which is on the axis A, the sector B must lift up the valve by means of its toothed rack D C, till the upper end of the rack touch the knob or button K. Turning the handle in the opposite direction brings the valve down again to its seat.

This valve is extremely tight. But in order to open it for the passage of the steam, we must exert a force equal to the pressure of the atmosphere. This in a large engine is a very great weight. A valve of six inches diameter sustains a pressure not less than 400 pounds. But this force is quite momentary, and hardly impedes the motion of the engine; for the instant the valve is detached from its seat, although it has not moved the 100th part of an inch, the pressure is over. Even this little inconvenience has been removed by a delicate thought of Mr Watt. He has put the spanner in such a position when it *begins* to raise the valve, that its mechanical energy is almost infinitely great. Let Q R (fig. 14.) be part of the plug frame descending, and P one of its pins just going to lay hold of the spanner N O moveable round the axis N. On the same axis is another arm NM connected by a joint with the leader ML, which is connected also by a joint with the spanner L A that is on the axis A of the sector within the valve-box. Therefore when the pin P pushes down the spanner N O, the arm N M moves sidewise and pulls down the spanner A L, by means of the connecting rod. Things are so disposed, that when the cock is shut, L M and M N are in one straight line. The intelligent mechanic will perceive that, in this position, the force of the lever O N M is insuperable. It has this further advantage, that if any thing should tend to force open the valve, it would be ineffectual; for no force exerted at A, and transmitted by the rod LM, can possibly push the joint M out of its position. Of such importance is it to practical mechanics, that its professors should be persons of penetration as well as knowledge. Yet this circumstance is unheeded by hundreds who have servilely copied from Mr Watt, as may be seen in every engine that is puffed on the public as a discovery and an improvement. When these puppet valves have been introduced into the common engine, we have not seen one instance where this has been attended to; certainly because its utility has not been observed: and there is one situation where it is of more consequence than in Mr Watt's engine, viz. in the injection-cock. Here the valve is drawn back into a box, where the water is so aukwardly disposed round it that it can hardly get out of its way, and where the pressure even exceeds that of the atmosphere. Indeed this particular substitution of the button-valve for the cock is most injudicious.

We postponed any account of the office of the fly X X (fig. 11.), as it is not of use in an engine regulated by the fly V V. The fly X X is only for regulating the reciprocating motion of the beam when the steam is not admitted during the whole descent of the piston. This it evidently must render more uniform, accumulating a momentum equal to the whole pressure of the full supply of steam, and then sharing it with the beam during the rest of the descent of the piston.

72 Review of Mr Watt's three great improvements.

When a person properly skilled in mechanics and chemistry reviews these different forms of Mr Watt's steam-engine, he will easily perceive them susceptible of many intermediate forms, in which any one or more of the distinguishing improvements may be employed. The first great improvement was the condensation in a separate vessel. This increased the original powers of the engine, giving to the atmospheric pressure and to the counter weight their full energy; at the same time the waste of steam is greatly diminished. The next improvement by employing the pressure of the steam instead of that of the atmosphere, aimed only at a still farther diminution of the waste; but was fertile in advantages, rendering the machine more manageable, and particularly enabling us at all times, and without trouble, to suit the power of the engine to its load of work, however variable and increasing; and brought into view a very interesting proposition in the mechanical theory of the engine, viz. that the whole performance of a given quantity of steam may be augmented by admitting it into the cylinder only during a part of the piston's motion. Mr Watt has varied the application of this proposition in a thousand ways; and there is nothing about the machine which gives more employment to the sagacity and judgment of the engineer. The third improvement of the double impulse may be considered as the finishing touch given to the engine, and renders it as uniform in its action as any water-wheel. In the engine in its most perfect form there does not seem to be above one-fourth of the steam wasted by warming the apparatus; so that *it is not possible* to make it one-fourth part more powerful than it is at present. The only thing that seems susceptible of considerable improvement is

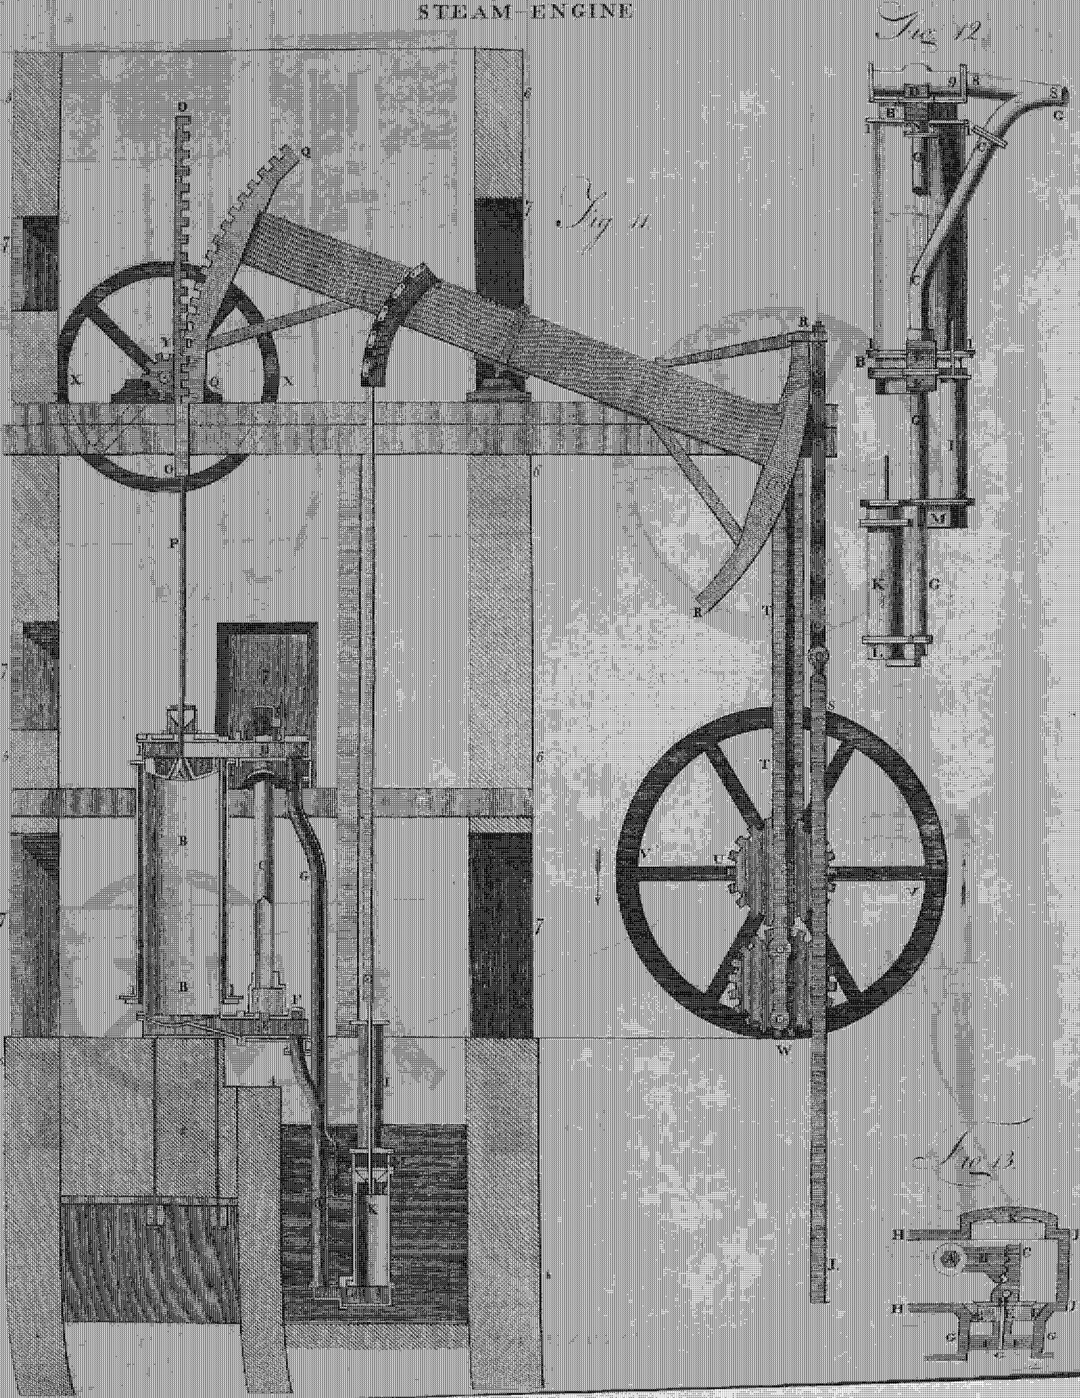
STEAM-ENGINE

Plate CCCCLXXIX



Steam-Engine.

73 The only improvement now wanting is to strengthen the great beam.

is the great beam. The enormous strains exerted on its arms require a proportional strength. This requires a vast mass of matter, not less indeed in an engine with a cylinder of 54 inches than three tons and a half, moving with the velocity of three feet in a second, which must be communicated in about half a second. This mass must be brought into motion from a state of rest, must again be brought to rest, again into motion, and again to rest, to complete the period of a stroke. This consumes much power; and Mr Watt has not been able to load an engine with more than 10 or 11 pounds on the inch and preserve a sufficient quantity of motion, so as to make 12 or 15 six-feet strokes in a second. Many attempts have been made to lessen this mass by using a light framed wheel, or a light frame of carpentry, in place of a solid beam. These have generally been constructed by persons ignorant of the true scientific principles of carpentry, and have fared accordingly. Mr Watt has made similar attempts; but found, that although at first they were abundantly strong, yet after a short time's employment the straps and bolts with which the wooden parts were connected cut their way into the wood, and the framing grew loose in the joints, and, without giving any warning, went to pieces in an instant. A solid massy simple beam, of sufficient strength, bends, and sensibly complains (as the carpenters express it), before it breaks. In all great engines, therefore, such only are employed, and in smaller engines he sometimes uses cast-iron wheels or pulleys; nay, he frequently uses no beam or equivalent whatever, but employs the steam piston-rod to drive the machinery to which the engine is applied.

74 Mr Watt associated with Mr Boulton.

We presume that our thinking readers will not be displeased with this rational history of the progress of this engine in the hands of its ingenious and worthy inventor. We owe it to the communications of a friend, well acquainted with him, and able to judge of his merits. The public see him always associated with the no less celebrated mechanic and philosopher Mr Boulton of Soho near Birmingham (see SOHO). They have shared the royal patent from the beginning; and the alliance is equally honourable to both.

75 Whence their profits are derived in erecting engines.

The advantages derived from the patent-right shew both the superiority of the engine and the liberal minds of the proprietors. They erect the engines at the expence of the employers, or give working drafts of all the parts, with instructions, by which any resident engineer may execute the work. The employers select the best engine of the ordinary kind in the kingdom, compare the quantities of fuel expended by each, and pay to Messrs Watt and Boulton one-third of the annual savings for a certain term of years. By this the patentees are excited to do their utmost to make the engine perfect; and the employer pays in proportion to the advantage he derives from it.

It may not be here improper to state the actual performance of some of these engines, as they have been ascertained by experiment.

76 What the actual performance of some of these engines is.

An engine having a cylinder of 31 inches in diameter, and making 17 double strokes per minute, performs the work of forty horses working night and day (for which three relays or 120 horses must be kept), and burns 11,000 pounds of Staffordshire coal *per* day. A cylinder of 19 inches, making 25 strokes of 4 feet each per minute, performs the work of 12 horses working constantly, and burns 3700 pounds of coals *per* day. A cylinder of 24 inches, making 22 strokes of 5 feet, burns 5500 pounds of coals, and is equivalent to the constant work of 20 horses. And the patentees think themselves authorized by experience to say in general, that these engines will raise more than 20,000 cubic feet of water 24 feet high for every hundred weight of good pit-coal consumed by them.

In consequence of the great superiority of Mr Watt's engines, both with respect to economy and manageableness, they have become of most extensive use; and in every demand of manufacture on a great scale they offer us an indefatigable servant, whose strength has no bounds. The greatest mechanical project that ever engaged the attention of man was on the point of being executed by this machine. The States of Holland were treating with Messrs Watt and Boulton for draining the Haerlem Meer, and even reducing the Zuyder Zee: and we doubt not but that it will be accomplished whenever that nation has sufficiently recovered from the convulsions of her revolution. Indeed such unlimited powers are afforded by this engine, that the engineer now thinks that no task can be proposed to him which he cannot execute with profit to his employer.

77 Proposed to drain the Haerlem Meer by the steam-engine.

78 The attempts to improve Mr Watt's engine in general of little advantage;

No wonder then that all classes of engineers have turned much of their attention to this engine; and seeing that it has done so much, that they try to make it do still more. Numberless attempts have been made to improve Mr Watt's engine; and it would occupy a volume to give an account of them, whilst that account would do no more than indulge curiosity. Our engineers by profession are in general miserably deficient in that accurate knowledge of mechanics and of chemistry which is necessary for understanding this machine; and we have not heard of one in Great Britain who can be put on a par with the present patentees in this respect. Most of the attempts of engineers have been made with the humble view of availing themselves of Mr Watt's discoveries, so as to construct a steam-engine superior to Newcomen's, and yet of a form sufficiently different from Watt's to keep it without the reach of his patent. This they have in general accomplished by performing the condensation in a place which, with a little stretch of fancy, not unfrequent in a court of law, may be called *part of the cylinder*.

79 And the success of these has not injured the other.

The success of most of these attempts has interfered so little with the interest of the patentees, that they have not hindered the erection of many engines which the law would have deemed encroachments. We think it our duty to give our opinion on this subject without reserve. These are most expensive undertakings, and few employers are able to judge accurately of the merits of a project presented to them by an ingenious artist. They may see the practicability of the scheme, by having a general notion of the expansion and condensation of steam, and they may be misled by the ingenuity apparent in the construction. The engineer himself is frequently the dupe of his own ingenuity; and it is not always dishonesty, but frequently ignorance, which makes him prefer his own invention or (as he thinks it) improvement. It is a most delicate engine, and requires much knowledge to see what does and what does not improve its performance. We have gone into the preceding minute investigation of Mr Watt's progress with the express purpose of making our readers fully masters of its principles, and have more than once pointed out the real improvements, that they may be firmly fixed and always ready in the mind. By having recourse to them, the reader may pronounce with confidence on the merits of any new construction, and will not be deceived by the puffs of an ignorant or dishonest engineer.

80 Exception in favour of Mr Hornblower.

We must except from this general criticism a construction by Mr Jonathan Hornblower near Bristol, on account of its singularity, and the ingenuity and real skill which appears in some particulars of its construction. The following short description will sufficiently explain its principle, and enable our readers to appreciate its merit.

Plate CCCCLXXX. 81 Description of his steam-engine.

A and B (fig. 15.) represent two cylinders, of which A is the largest. A piston moves in each, having their rods C and D moving through collars at E and F. These cylinders may be supplied with steam from the boiler by means of the square pipe G, which has a flanch to connect it with the rest of the steam-pipe. This square part is represented as branching off to both cylinders. *c* and *d* are two cocks, which have handles and tumblers as usual, worked by the plug-beam W. On the fore-side (that is, the side next the eye) of the cylinders is represented another communicating pipe, whose section is also square or rectangular, having also two cocks *a*, *b*. The pipe Y, immediately under the cock *b*, establishes a communication between the upper and lower parts of the small cylinder B, by opening the cock *b*. There is a similar pipe on the other side of the cylinder A, immediately under the cock *d*. When the cocks *c* and *a* are open, and the cocks *b* and *d* are shut, the steam from the boiler has free admission into the upper part of the cylinder B, and the steam from the lower part of B has free admission into the upper part of A; but the upper part of each cylinder has no communication with its lower part.

From the bottom of the great cylinder proceeds the eduction-pipe K, having a valve at its opening into the cylinder, which bends downwards, and is connected with the conical condenser L (c). The condenser is fixed on a hollow box M, on which stand the pumps N and O for extracting the air and water; which last runs along the trough T into a cistern U, from which it is raised by the pump V for recruiting the boiler, being already nearly boiling hot. Immediately under the condenser there is a spigot valve at S, over which is a small jet pipe, reaching to the bend of the eduction-pipe. The whole of the condensing apparatus is contained in a cistern R of cold water. A small pipe P comes from the side of the condenser, and terminates on the bottom of the trough T, and is there covered with a valve Q, which is kept tight by the water that is always running over it. Lastly, the pump-rods X cause the outer end of the beam to preponderate, so that the quiescent position of the beam is that represented in the figure, the pistons being at the top of the cylinders.

Suppose all the cocks open, and steam coming in copiously from the boiler, and no condensation going on in L; the steam must drive out all the air, and at last follow it through the valve Q. Now shut the valves *b* and *d*, and open the valve S of the condenser. The condensation will immediately commence. There is now no pressure on the under side of the piston of A, and it immediately descends. The communication between the lower part of B and the upper part of A being open, the steam will go from B into the space left by the piston of A. It must therefore expand, and its elasticity must diminish, and will no longer balance the pressure of the steam above the piston of B. This piston therefore, if not with-held by the beam, would descend till it is in equilibrio, having steam of equal density above and below it. But it cannot descend so far; for the cylinder A is wider than B, and the arm of the beam at which its piston hangs is longer than the arm which supports the piston of B: therefore when the piston of B has descended as far as the beam will permit it, the steam between the two pistons occupies a larger space than it did when both pistons were at the tops of their cylinders. Its density, therefore, and its elasticity, diminish as its bulk increases. It is therefore not a balance; for the steam on the upper side of B, and the piston B, *pulls* at the beam with all the difference of these pressures. The slightest view of the subject must show the reader, that as the pistons descend, the steam that is between them will grow continually rarer and less elastic, and that both pistons will pull the beam downwards.

Suppose now that each has reached the bottom of its cylinder. Shut the cock *a* and the eduction cock at the bottom of A, and open the cocks *b* and *d*. The communication being now established between the upper and lower part of each cylinder, nothing hinders the counter weight from raising the pistons to the top. Let them arrive there. The cylinder B is at this time filled with steam of the ordinary density, and the cylinder A with an equal absolute quantity of steam, but expanded into a larger space.

Shut the cocks *b* and *d*, and open the cock *a*, and the eduction cock at the bottom of A; the condensation will again operate, and the pistons descend. And thus the operation may be repeated as long as steam is supplied; and one full of the cylinder B of ordinary steam is expended during each working stroke.

Let us now examine the power of this engine. It is evident, that when both pistons are at the top of their respective cylinders, the active pressure (that is, the difference of the pressure on its two sides) on the piston of B is nothing, while that on the piston of A is equal to the full pressure of the atmosphere on its area. This, multiplied by the length of the arm by which it is supported, gives its mechanical energy. As the pistons descend, the pressure on the piston of B increases, while that on the piston of A diminishes. When both are at the bottom, the pressure on the piston of B is at its maximum, and that on the piston of A at its minimum.

Mr Hornblower saw that this must be a beneficial employment of steam, and preferable to the practice of condensing it while its full elasticity remained; but he has not considered it with the attention necessary for ascertaining the advantage with precision.

Let *a* and *b* represent the areas of the pistons of A and

(c) This, however, was stopped by Watt's patent; and the condensation must be performed as in Newcomen's engine, or at least in the cylinder A.

Steam-Engine.

and B, and let α and β be the lengths of the arms by which they are supported. It is evident, that when both pistons have arrived at the bottoms of their cylinders, the capacities of the cylinders are as $a\,\alpha$ and $b\,\beta$. Let this be the ratio of m to 1. Let $g\,h\,i\,k$ (fig. 16.) and $l\,m\,n\,o$ be two cylinders of equal length, communicating with each other, and fitted with a piston-rod $p\,q$, on which are fixed two pistons $a\,a$ and $b\,b$, whose areas are as m and 1. Let the distance between the pistons be precisely equal to the height of each cylinder, which height we shall call h. Let x be the space $g\,b$ or $b\,a$, through which the pistons have descended. Let the upper cylinder communicate with the boiler, and the lower cylinder with the condenser or vacuum V.

Any person in the least conversant in mechanics and pneumatics will clearly see that the strain or pressure on the piston rod $p\,q$ is precisely the same with the united energies of the two piston rods of Mr Hornblower's engine, by which they tend to turn the working beam round its axis.

The base of the upper cylinder being 1, and its height h, its capacity or bulk is $1\,h$ or h; and this expresses the natural bulk of the steam which formerly filled it, and is now expanded into the space $b\,h\,l\,a\,a\,m\,i\,b$. The part $b\,h\,i\,b$ is plainly $= h - x$, and the part $l\,a\,a\,m$ is $= m\,x$. The whole space therefore is $m\,x + h - x$, $= h + m\,x - x$, or $h + \overline{m-1}\,x$. Therefore the density of the steam between the pistons is $\frac{h}{h + \overline{m-1}\,x}$.

Let p be the downward pressure of the steam from the boiler on the upper piston $b\,b$. This piston is also pressed up with a force $= p\,\frac{h}{h + \overline{m-1}\,x}$ by the steam between the pistons. It is therefore, on the whole, pressed downward with a force $= p\left(1 - \frac{h}{h + \overline{m-1}\,x}\right)$. The lower piston $a\,a$, having a vacuum below it, is pressed downwards with a force $= p\,\frac{m\,h}{h + \overline{m-1}\,x}$. Therefore the whole pressure on the piston rod downwards is $= p\left(1 + \frac{m\,h}{h + \overline{m-1}\,x} - \frac{h}{h + \overline{m-1}\,x}\right)$, $= p\left(1 + \frac{\overline{m-1}\,h}{h + \overline{m-1}\,x}\right)$, $= p + \frac{p\,h\,\overline{m-1}}{h + \overline{m-1}\,x} = p + \frac{p\,h}{\frac{h}{m-1} + x}$.

This then is the momentary pressure on the piston rod corresponding to its descent x from its highest position. When the pistons are in their highest position, this pressure is equal to $m\,p$. When they are in their lowest position, it is $= p\,\frac{2\,m - 1}{m}$. Here therefore is an accession of power. In the beginning the pressure is greater than on a single piston in the proportion of m to 1; and at the end of the stroke, where the pressure is weakest, it is still much greater than the pressure on a single piston. Thus, if m be 4, the pressure at the beginning of the stroke is $4\,p$, and at the end it is $\frac{7}{4}\,p$, almost double, and in all intermediate positions it is greater. It is worth while to obtain the sum total of all the accumulated pressures, that we may compare it with the constant pressure on a single piston.

We may do this by considering the momentary pressure $p + \frac{p\,h}{\frac{h}{m-1} + x}$, as equal to the ordinate GF, H b, or M c, of a curve F b c (fig. 10.), which has for its axis the line GM equal to h the height of our cylinder. Call this ordinate y. We have $y = p + \frac{p\,h}{\frac{h}{m-1}\,x}$, and $y - p = \frac{p\,h}{\frac{h}{m-1} + x}$. Now it is plain that $\frac{p\,h}{\frac{h}{m-1} + x}$ is the ordinate of an equilateral hyperbola, of which $p\,h$ is the power or rectangle of the ordinate and abscis, and of which the abscis reckoned from the centre is $\frac{h}{m-1} + x$. Therefore make G E $= p$, and draw D E A parallel to M G, and make E A $= \frac{\text{G M}}{m-1}$, $= \frac{h}{m-1}$. The curve F b c is an equilateral hyperbola, having A for its centre and A D for its assymptote. Draw the other assymptote AB, and its ordinate FB. Since the power of the hyperbola is $= p\,h$, = GEDM (for GE $= p$, and GM $= h$); and since all the inscribed rectangles, such as AEFB, are equal to $p\,h$, it follows that AEFB is equal to GEDM, and that the area ABFcDA is equal to the area GFcMG, which expresses the accumulated pressure in Hornblower's engine.

We can now compute the accumulated pressure very easily. It is evidently $= p\,h \times \left(1 + \text{L.}\frac{\text{AD}}{\text{AE}}\right)$.

82 The accumulated pressure the same with that of Mr Watt's engine.

The intelligent reader cannot but observe that this is precisely the same with the accumulated pressure of a quantity of steam admitted in the beginnig, and stopped in Mr Watt's method, when the piston has descended through the mth part of the cylinder. In considering Mr Hornblower's engine, the thing was presented in so different a form that we did not perceive the analogy at first, and we were surprised at the result. We could not help even regretting it, because it had the appearance of a new principle and an improvement; and we doubt not but that it appeared so to the ingenious author; for we have had such proofs of his liberality of mind as permit us not to suppose that he saw it from the beginning, and availed himself of the difficulty of tracing the analogy. And as the thing may mislead others in the same way, we have done a service to the public by showing that this engine, so costly and so difficult in its construction, is no way superior in power to Mr Watt's simple method of stopping the steam. It is even inferior, because there must be a condensation in the communicating passages. We may add, that if the condensation is performed in the cylinder A, which it must be unless with the permission of Watt and Boulton, the engine cannot be much superior to a common engine; for much of the steam from below B will be condensed between the pistons by the coldness of the cylinder A; and this diminishes the down-

Steam-Engine.

downward preſſure on A more than it increaſes the downward preſſure on B. We learn however that, by confining the condenſation to a ſmall *part of the cylinder* A, Mr Hornblower has erected engines clear of Mr Watt's patent, which are conſiderably ſuperior to Newcomen's: ſo has Mr Symington.

83
Still, however, the engine diſcovers ingenuity and ſkill.

We ſaid that there was much ingenuity and real ſkill obſervable in many particulars of this engine. The diſpoſition and connection of the cylinders, and the whole condenſing apparatus, are contrived with peculiar neatneſs. The cocks are very ingenious; they are compoſed of two flat circular plates ground very true to each other, and one of them turns round on a pin through their centres; each is pierced with three ſectoral apertures, exactly correſponding with each other, and occupying a little leſs than one half of their ſurfaces. By turning the moveable plate ſo that the apertures coincide, a large paſſage is opened for the ſteam; and by turning it ſo that the ſolid of the one covers the aperture of the other, the cock is ſhut. Such regulators are now very common in the caſt iron ſtoves for warming rooms.

Mr Hornblower's contrivance for making the collars for the piſton rods air-tight is alſo uncommonly ingenious. This collar is in fact two, at a ſmall diſtance from each other. A ſmall pipe, branching off from the main ſteam-pipe, communicates with the ſpace between the collars. This ſteam, being a little ſtronger than the preſſure of the atmoſphere, effectually hinders the air from penetrating by the upper collar; and though a little ſteam ſhould get through the lower collar into the cylinder A, it can do no harm. We ſee many caſes in which this pretty contrivance may be of ſignal ſervice.

84
The greateſt improvement is the framing of the working beam.

But it is in the framing of the great working beam that Mr Hornblower's ſcientific knowledge is moſt conſpicuous; and we have no heſitation in affirming that it is ſtronger than a beam of the common form, and containing twenty times its quantity of timber. There is hardly a part of it expoſed to a tranverſe ſtrain, if we except the ſtrain of the pump V on the ſtrutt by which it is worked. Every piece is either puſhed or pulled in the direction of its length. We only fear that the bolts which connect the upper beam with the two iron bars under its ends will work looſe in their holes, and tear out the wood which lies between them. We would propoſe to ſubſtitute an iron bar for the whole of this upper beam. This working beam highly deſerves the attention of all carpenters and engineers. We have that opinion of Mr Hornblower's knowledge and talents, that we are confident that he will ſee the fairneſs of our examination of his engine, and we truſt to his candour for an excuſe for our criticiſm.

85
The reciprocating motion of the ſteam-engine is a defect ſtill to be remedied.

The reciprocating motion of the ſteam-engine has always been conſidered as a great defect; for though it be now obviated by connecting it with a fly, yet, unleſs it is an engine of double ſtroke, this fly muſt be an enormous maſs of matter moving with great velocity. Any accident happening to it would produce dreadful effects: A part of the rim detaching itſelf would have the force of a bomb, and no building could withſtand it. Many attempts have been made to produce a circular motion at once by the ſteam. It has been made to blow on the vanes of a wheel of various forms. But the rarity of ſteam is ſuch, that even if none is condenſed by the cold of the vanes, the impulſe is exceedingly feeble, and the expence of ſteam, ſo as to produce any ſerviceable impulſe, is enormous. Mr Watt, among his firſt ſpeculations on the ſteam-engine, made ſome attempts of this kind. One in particular was uncommonly ingenious. It conſiſted of a drum turning air-tight within another, with cavities ſo diſpoſed that there was a conſtant and great preſſure urging it in one direction. But no packing of the common kind could preſerve it air-tight with ſufficient mobility. He ſucceeded by immerſing it in mercury, or in an amalgam which remained fluid in the heat of boiling water; but the continual trituration ſoon calcined the fluid and rendered it uſeleſs. He then tried Parent's or Dr Barker's mill, incloſing the arms in a metal drum, which was immerſed in cold water. The ſteam ruſhed rapidly along the pipe which was the axis, and it was hoped that a great reaction would have been exerted at the ends of the arms; but it was almoſt nothing. The reaſon ſeems to be, that the greateſt part of the ſteam was condenſed in the cold arms. It was then tried in a drum kept boiling hot; but the impulſe was now very ſmall in compariſon with the expence of ſteam. This muſt be the caſe.

Steam-Engine, Steam-Kitchen.

86
Mr Watt's attempts to produce a circular motion by ſteam unſucceſsful.

Mr Watt has deſcribed in his ſpecification to the patent office ſome contrivances for producing a circular motion by the immediate action of the ſteam. Some of theſe produce alternate motions, and are perfectly analogous to his double ſtroke engine. Others produce a continued motion. But he has not given ſuch a deſcription of his valves for this purpoſe as can enable an engineer to conſtruct one of them. From any gueſs that we can form, we think the machine very imperfect; and we do not find that Mr Watt has ever erected a continuous circular engine. He has doubtleſs found all his attempts inferior to the reciprocating engine with a fly. A very crude ſcheme of this kind may be ſeen in the tranſactions of the Royal Society of Dublin, 1787. But although our attempts have hitherto failed, we hope that the caſe is not yet deſperate: We ſee different principles which have not yet been employed.

87
Still the caſe is not deſperate, for different principles may be employed.

88
Mr Watt's engine ſuggeſts the conſtruction of an excellent air-pump.

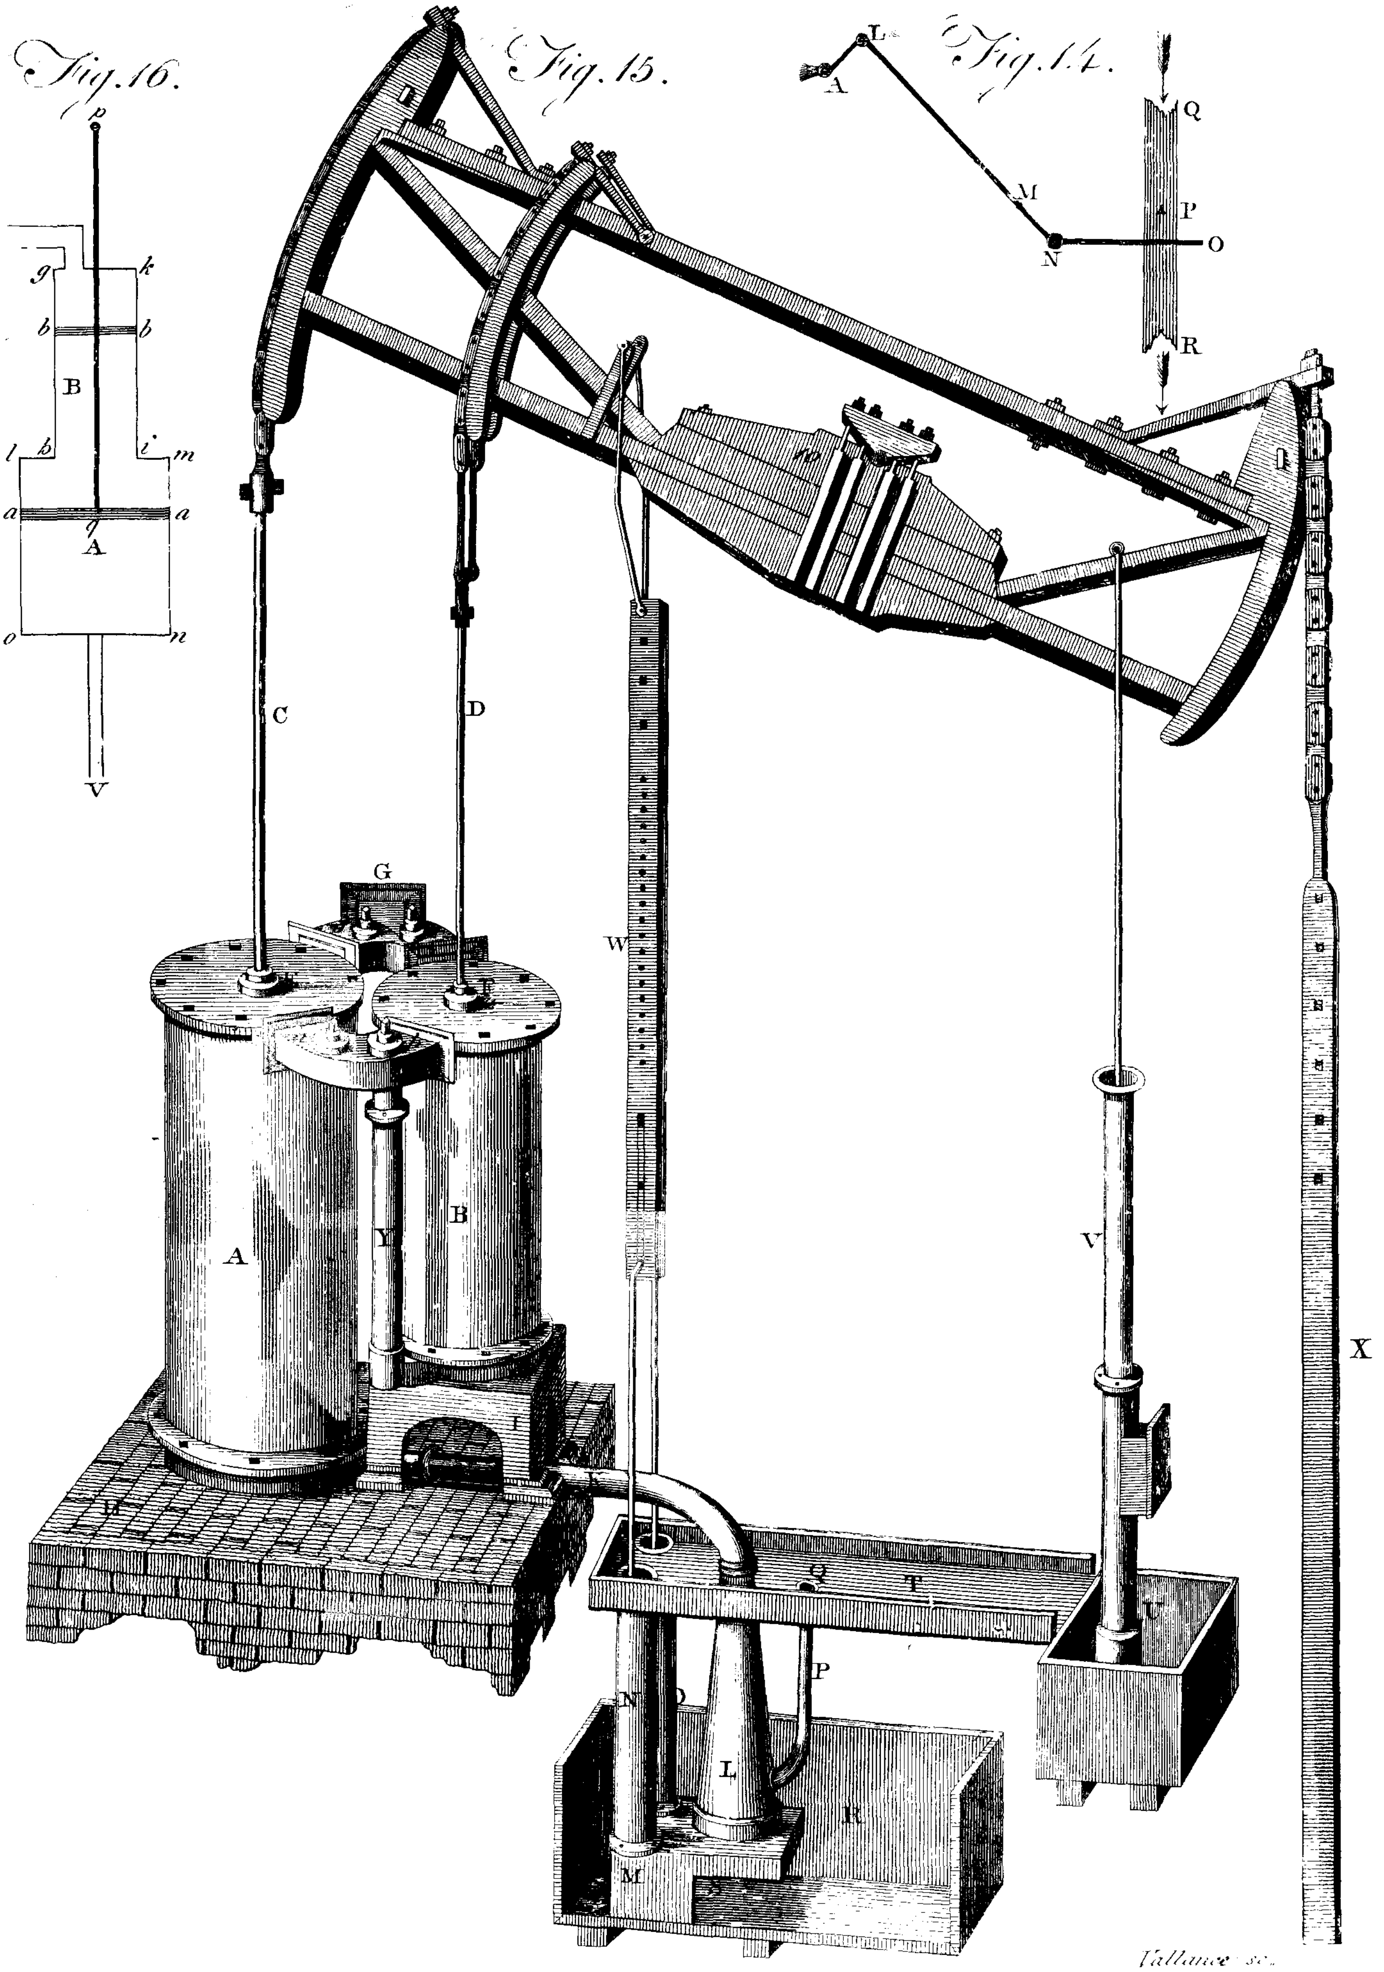
We ſhall conclude our account of this noble engine with obſerving, that Mr Watt's form ſuggeſts the conſtruction of an excellent air-pump. A large veſſel may be made to communicate with a boiler at one ſide, and with the pump-receiver on the other, and alſo with a condenſer. Suppoſe this veſſel of ten times the capacity of the receiver: fill it with ſteam from the boiler, and drive out the air from it; then open its communication with the receiver and the condenſer. This will rarefy the air of the receiver 10 times. Repeating the operation will rarefy it 100 times; the third operation will rarefy it 1000 times; the fourth 10,000 times, &c. All this may be done in half a minute.

Steam-*Kitchen.* Ever ſince Dr Papin contrived his digeſter (about the year 1690), ſchemes have been propoſed for dreſſing victuals by the ſteam of boiling water. A philoſophical club uſed to dine at Saltero's coffeehouſe, Chelſea, about 30 years ago, and had their victuals dreſſed by hanging them in the boiler of the ſteam-egine which raiſes water for the ſupply of Picadilly and its neighbourhood. They were completely dreſſed, and both expeditiouſly and with high flavour.

A patent

Hornblower's

STEAM ENGINE



Vallance sc.

Steam-Kitchen.

A patent was lately obtained for an apparatus for this purpofe by a tin-man in London; we think of the name of Tate. They are made on a much more effective plan by Gregory, an ingenious tradefman in Edinburgh, and are coming into very general ufe.

It is well known to the philofopher that the fteam of boiling water contains a prodigious quantity of heat, which it retains in a latent ftate ready to be faithfully accounted for, and communicated to any colder body. Every cook knows the great fcalding power of fteam, and is difpofed to think that it is much better than boiling water. This, however, is a miftake; for it will raife the thermometer no higher than the water from which it comes. But we can affure the cook, that if he make the fteam from the fpout of a tea-kettle pafs through a great body of cold water, it will be condenfed or changed into water; and when one pound of water has in this manner been boiled off, it will have heated the mafs of cold water as much as if we had thrown into it feven or eight hundred pounds of boiling hot water.

If, therefore, a boiler be properly fitted up in a furnace, and if the fteam of the water boiling in it be conveyed by a pipe into a pan containing victuals to be dreffed, every thing can be cooked that requires no higher degree of heat than that of boiling water: And this will be done without any rifk of fcorching, or any kind of overheating, which frequently fpoils our difhes, and proceeds from the burning heat of air coming to thofe parts of the pot or pan which is not filled with liquor, and is covered only with a film, which quickly burns and taints the whole difh. Nor will the cook be fcorched by the great heat of the open fire that is neceffary for dreffing at once a number of difhes, nor have his perfon and clothes foiled by the fmoke and foot unavoidable in the cooking on an open fire. Indeed the whole procefs is fo neat, fo manageable, fo open to infpection, and fo cleanly, that it need neither fatigue nor offend the delicacy of the niceft lady.

We had great doubts, when we firft heard of this as a general mode of cookery, as to its economy; we had none as to its efficacy. We thought that the fteam, and confequently the fuel expended, muft be vaftly greater than by the immediate ufe of an open fire; but we have feen a large tavern dinner expeditioufly dreffed in this manner, feemingly with much lefs fuel than in the common method. The following fimple narration of facts will fhow the fuperiority. In a paper manufacture near Edinburgh, the vats containing the pulp into which the frames are dipped are about fix feet diameter, and contain above 200 gallons. This is brought to a proper heat by means of a fmall cockle or furnace in the middle of the liquor. This is heated by putting in about one hundred weight of coals about eight o'clock in the evening, and continuing this till four next working, renewing the fuel as it burns away. This method was lately changed for a fteam heater. A furnace, having a boiler of five or fix feet diameter and three feet deep, is heated about one o'clock in the morning with two hundred weight of coals, and the water kept in brifk ebullition. Pipes go off from this boiler to fix vats, fome of which are at 90 feet diftance. It is conveyed into a flat box or veffel in the midft of the pulp where it condenfes, imparting its heat to the fides of the box, and thus heats the furrounding pulp. Thefe fix vats are as completely heated in three hours, expending about three hundred weight of coals, as they were formerly in eight hours, expending near 18 hundred weight of coals. Mr Gregory, the inventor of this fteam-heater, has obtained (in company with Mr Scott plumber, Edinburgh) a patent for the invention; and we are perfuaded that it will come into very general ufe for many fimilar purpofes. The dyers, hatmakers, and many other manufacturers, have occafion for large vats kept in a continual heat; and there feems no way fo effectual.

Indeed when we reflect ferioufly on the fubject, we fee that this method has immenfe advantages confidered merely as a mode of applying heat. The fteam may be applied to the veffel containing the victuals in every part of its furface: it may either be made to enter the veffel, and apply itfelf immediately to the piece of meat that is to be dreffed, and this without any rifk of fcorching or overdoing.—And it will give out about $\frac{7}{8}\frac{2}{3}$ of the heat which it contains, and will do this only if it be wanted; fo that no heat whatever is wafted except what is required for heating the apparatus. Experience fhews that this is a mere trifle in comparifon of what was fuppofed neceffary. But with an open fire we only apply the flame and hot air to the bottom and part of the fides of our boiling veffels: and this application is hurried in the extreme; for to make a great heat, we muft have a great fire, which requires a prodigious and moft rapid current of air. This air touches our pans but for a moment, imparts to them but a fmall portion of its heat; and, we are perfuaded that three-fourths of the heat is carried up the chimney, and efcapes in pure wafte, while another great portion beams out into the kitchen to the great annoyance of the fcorched cook. We think, therefore, that a page or two of this work will not be thrown away in the defcription of a contrivance by which a faving may be made to the entertainer, and the providing the pleafures of his table prove a lefs fatiguing tafk to this valuable corps of practical chemifts.

Plate CCCCLXXIX. fig. 5.

Let A reprefent a kitchen-boiler, either properly fitted up in a furnace, with its proper fire-place, afh-pit, and flue, or fet on a tripod on the open fire, or built up in the general fire-place. The fteam-pipe BC rifes from the cover of this boiler, and then is led away with a gentle afcent in any convenient direction. C reprefents the fection of this conducting fteam-pipe. Branches are taken off from the fide at proper diftances. One of thefe is reprefented at CDE, furnifhed with a cock D, and having a taper nozzle E, fitted by grinding into a conical piece F, which communicates with an upright pipe GH, which is foldered to the fide of the ftewing veffel PQRS, communicating with it by the fhort pipe I. The veffel is fitted with a cover OT, having a ftaple handle V. The piece of meat M is laid on a tin plate grate KL, pierced with holes like a cullender, and ftanding on three fhort feet *n n n*.

The fteam from the boiler comes in by the pipe I, and is condenfed by the meat and by the fides of the veffel, communicating to them all its heat. What is not fo condenfed efcapes between the veffel and its cover. The condenfed water lies on the bottom of the veffel, mixed with a very fmall quantity of gravy and fatty matter from the victuals. Frequently, inftead of a cover, another ftew-veffel with a cullender bottom is fet on this one, the bottom of the one fitting the mouth of the other: and *it is observed*, that when this is done, the dish in the under vessel is more expeditiously and better dressed, and the upper dish is more slowly, but as completely stewed.

This description of one stewing vessel may serve to give a notion of the whole; only we must observe, that when broths, soups, and dishes with made sauces or containing liquids, are to be dressed, they must be put into a smaller vessel, which is set into the vessel PQRS, and is supported on three short feet, so that there may be a space all round it of about an inch or three quarters of an inch. It is observed, that dishes of this kind are not so expeditiously cooked as on an open fire, but as completely in the end, only requiring to be turned up now and then to mix the ingredients; because as the liquids in the inner vessel can never come into ebullition, unless the steam from the boiler be made of a dangerous heat, and every thing be close confined, there cannot be any of that tumbling motion that we observe in a boiling pot.

The performance of this apparatus is far beyond any expectation we had formed of it. In one which we examined, six pans were stewing together by means of a boiler $10\frac{1}{2}$ inches in diameter, standing on a brisk open fire. It boiled very briskly, and the steam puffed frequently through the chinks between the stew-pans and their covers. In one of them was a piece of meat considerably above 30 pounds weight. This required above four hours stewing, and was then very thoroughly and equally cooked; the outside being no more done than the heart, and it was near two pounds heavier than when put in, and greatly swelled. In the mean time, several dishes had been dressed in the other pans. As far as we could judge, this cooking did not consume one-third part of the fuel which an open fire would have required for the same effect.

When we consider this apparatus with a little more knowledge of the mode of operation of fire than falls to the share of the cooks (we speak with deference), and consider the very injudicious manner in which the steam is applied, we think that it may be improved so as to surpass any thing that the cook can have a notion of.

When the steam enters the stew-pan, it is condensed on the meat and on the vessel; but we do not want it to be condensed on the vessel. And the surface of the vessel is much greater than that of the meat, and continues much colder; for the meat grows hot, and continues so, while the vessel, made of metal which is a very perfect conductor of heat, is continually robbed of its heat by the air of the kitchen, and carried off by it. If the meat touch the side of the pan in any part, no steam can be applied to that part of the meat, while it is continually imparting heat to the air by the intermedium of the vessel. Nay, the meat can hardly be dressed unless there be a current of steam through it; and we think this confirmed by what is observed above, that when another stew-pan is set over the first, and thus gives occasion to a current of steam through its cullender bottom to be condensed by its sides and contents, the lower dish is more expeditiously dressed. We imagine, therefore, that not less than half of the steam is wasted on the sides of the different stew-pans. Our first attention is therefore called to this circumstance, and we wish to apply the steam more economically and effectually.

We would therefore construct the steam-kitchen in the following manner:

We would make a wooden chest (which we shall call the Stew-chest) A B C D. This should be made of deal, in very narrow slips, not exceeding an inch, that it may not shrink. This should be lined with very thin copper, lead, or even strong tinfoil. This will prevent it from becoming a conductor of heat by soaking with steam. For further security it might be set in another chest, with a space of an inch or two all round, and this space filled with a composition of powdered charcoal and clay. This should be made by first making a mixture of fine potter's clay and water about as thick as poor cream: then as much powdered charcoal must be beat up with this as can be made to stick together. When this is rammed in and dry, it may be hot enough on one side to melt glass, and will not discolour white paper on the other. Fig. 6.

This chest must have a cover L M N O, also of wood, having holes in it to receive the stew-pans P, Q, R. Between each pan is a wooden partition, covered on both sides with milled lead or tinfoil. The whole top must be covered with very spongy leather or felt, and made very flat. Each stew-pan must have a bearing or shoulder all round it, by which it is supported, resting on the felt, and lying so true and close that no steam can escape. Some of the pans should be simple, like the pan F, for dressing broths and other liquid dishes. Others should be like E and G, having in the bottom a pretty wide hole H, K, which has a pipe in its upper side, rising about an inch or an inch and half into the stew-pan. The meat is laid on a cullender plate, as in the common way; only there must be no holes in the cullender immediately above the pipe.—These stew-pans must be fitted with covers, or they may have others fitted to their mouths, for warming sauces or other dishes, or stewing greens, and many other subordinate purposes for which they may be fitted.

The main-pipe from the boiler must have branches, (each furnished with a cock), which admit the steam into these divisions. At its first entry some will be condensed on the bottom and sides; but we imagine that these will in two minutes be heated so as to condense no more, or almost nothing. The steam will also quickly condense on the stew-pan, and in half a minute make it boiling hot, so that it will condense no more; all the rest will now apply itself to the meat and to the cover. It may perhaps be advisable to allow the cover to condense steam, and even to waste it. This may be promoted by laying on it flannel soaked in water. Our view in this is to create a demand for steam, and thus produce a current through the stew-pan, which will be applied in its passage to the victuals. But we are not certain of the necessity of this. Steam is not like common air of the same temperature, which would glide along the surfaces of bodies, and impart to them a small portion of its heat, and escape with the rest. To produce this effect there *must* be a current; for air hot enough to melt lead, will not boil water, if it be kept stagnant round the vessel. But steam imparts the *whole* of its latent heat to any body colder than boiling water, and goes no farther till this body be made boiling hot.

It

It is a moſt faithful carrier of heat, and will deliver its whole charge to any body that can take it. Therefore, although there were no partitions in the ſtew-cheſt, and the ſteam were admitted at the end next the boiler, if the pan at the farther end be colder than the reſt, it will all go thither; and will, in ſhort, communicate to every thing impartially according to the demand. If any perſon has not the confidence in the ſteam which we expreſs, he may ſtill be certain that there muſt be a prodigious ſaving of heat by confining the whole in the ſtew cheſt; and he may make the pans with entire bottoms, and admit the ſteam into them in the common way, by pipes which come through the ſides of the cheſt and then go into the pan. There will be none loſt by condenſation on the ſides of the cheſt; and the pans will ſoon he heated up to the boiling temperature; and hardly any of their heat will be waſted, becauſe the air in the cheſt will be ſtagnant. The chief reaſon for recommending our method is the much greater eaſe with which the ſtew-pans can be ſhifted and cleaned. There will be little difference in the performance.

Nay, even the common ſteam-kitchen may be prodigiouſly improved by merely wrapping each pan in three or four folds of coarſe dry flannel, or making flannel bags of three or four folds fitted to their ſhape, which can be put on or removed in a minute. It will alſo greatly conduce to the good performance to wrap the main ſteam pipe in the ſame manner in flannel.

We ſaid that this main-pipe is conducted from the boiler with a gentle aſcent. The intention of this is, that the water produced by the unavoidable condenſation of the ſteam may run back into the boiler. But the rapid motion of the ſteam generally ſweeps it up hill, and it runs into the branch-pipes and deſcends into the ſtew-pans. Perhaps it would be as well to give the main-pipe a declivity the other way, and allow all the water to collect in the hot well at the farther end, by means of a deſcending pipe, having a loaded valve at the end. This may be ſo contrived as to be cloſe by the fire, where it would be ſo warm that it would not check the boiling if again poured into the boiler. But the utmoſt attention muſt be paid to cleanlineſs in the whole of this paſſage, becauſe this water is boiled again, and its ſteam paſſes through the heart of every diſh. The circumſtance forbids us to return into the boiler what is condenſed in the ſtew-pans. This would mix the taſtes and flavours of every diſh, and be very diſagreeable. All this muſt remain in the bottom of each ſtew-pan; for which reaſon we put in the pipe riſing up in the middle of the bottom. It might indeed be allowed to fall down into the ſtew-cheſt, and to be collected in a common receptacle, while the fat would float at top, and the clear gravy be obtained below, perhaps fit for many ſauces.

The completeſt method for getting rid of this condenſed ſteam would be to have a ſmall pipe running along the under ſide of the main conductor, and communicating with it at different places, in a manner ſimilar to the air diſcharger on the mains of water-pipes. In the paper manufacture mentioned above, each ſteam-box has a pipe in its bottom, with a float-cock, by which the water is diſcharged; and the main pipe being of great diameter, and laid with a proper acclivity, the water runs back into a boiler.

But theſe precautions are of little moment in a ſteam-kitchen even for a great table; and for the general uſe of private families, would hurt the apparatus, by making it complex and of nice management. For a ſmall family, the whole apparatus may be ſet on a table four feet long and two broad, which may be placed on caſters, ſo as to be wheeled out of the way when not in uſe. If the main conductor be made of wood, or properly caſed in flannel, it will condenſe ſo little ſteam that the cooking table may ſtand in the remoteſt corner of the kitchen without ſenſibly impairing its performance; and if the boiler be properly ſet up in a ſmall furnace, and the flue made ſo that the flame may be applied to a great part of its ſurface, we are perſuaded that three fourths of the fuel uſed in common cookery will be ſaved. Its only inconvenience ſeems to be the indiſpenſable neceſſity of the moſt anxious cleanlineſs in the whole apparatus. The moſt trifling neglect in this will deſtroy a whole dinner.

We had almoſt forgotten to obſerve, that the boiler muſt be furniſhed with a funnel for ſupplying it with water. This ſhould paſs through the top, and its pipe reach near to the bottom. It will be proper to have a cock on this funnel. There ſhould alſo be another pipe in the top of the boiler, having a valve on the top. If this be loaded with a pound on every ſquare inch, and the fire ſo regulated that ſteam may be obſerved to puff ſometimes from this valve, we may be certain that it is paſſing through our diſhes with ſufficient rapidity; and if we ſhut the cock on the funnel, and load the valve a little more, we ſhall cauſe the ſteam to blow at the covers of the ſtew-pans. If one of theſe be made very tight, and have a hole alſo furniſhed with a loaded valve, this pan becomes a digeſter, and will diſſolve bones, and do many things which are impracticable in the ordinary cookery.

Si quid noviſti rectius iſtis,
Candidus imperti; —ſi non, his utere noſtris.

STEATITES or *Soap earth*, a genus of the magneſian order of earths. Of this genus there are ſeveral ſpecies, for which ſee MINERALOGY. According to the analyſis of Bergman, 100 parts of ſteatites contain 80 of ſilex, 17 of mild magneſia, 2 of arigillaceous earth, and nearly 1 of iron in a ſemioxidated ſtate.

This ſubſtance may be formed into a paſte with water, ſufficiently ductile to be worked on the potter's wheel; and by expoſure to a great heat it is hardened ſo as to ſtrike fire with ſteel. It has alſo the property of *FULLER's Earth* in cleanſing cloths from greaſe: but it does not diffuſe in water ſo well as clays do; and when digeſted with vitriolic acid, it does not form alum, as clays do, but a ſalt ſimilar to Epſom ſalt. From its ſoftneſs and ductility it may be eaſily formed into pots for the kitchen; and hence it has got the mane of *lapis ollaris*.

STEATOMA, a kind of encyſted tumor, conſiſting of a matter like ſuet or lard, ſoft, without pain, and without diſcolouring the ſkin.

STEEL, iron united with carbone. See IRON.

Steel has properties diſtinct from thoſe of iron, which render it of ſuperior value. From its higher degree of hardneſs it admits a finer poliſh and aſſumes a brighter colour. When tempered, it poſſeſſes a higher degree of elaſticity, and is alſo more ſonorous. It is more weakly attracted by the load-ſtone, it receives more ſlowly the magnetic power, but it preſerves it longer. When expoſed to a moiſt air, it does not contract ruſt ſo eaſily as

Steel.

iron. It is alſo heavier, increaſing in weight, according to Chaptal, one hundred and ſeventieth part. M. Rinman has given as the reſult of ſeveral accurate experiments on different kinds of ſteel the following ſpecific gravity 7,795, while he makes ductile iron 7,700, and crude iron 7,251.

All iron is convertible into ſteel by expoſing it to a certain degree of heat for a certain time along with a quantity of charcoal. Chemiſts differ in opinion concerning the nature and effects of this proceſs. Some ſay that ſteel is produced by abſorbing a quantity of caloric or heat in a latent ſtate, as the older chemiſts had ſaid it was formed by abſorbing phlogiſton. Lavoiſier ſeems to have aſcribed the qualities of ſteel to a ſlight degree of oxidation, others to a combination with plumbago or black lead, and others to a union with carbone. In agreeing with thoſe who ſay the formation of ſteel is owing to carbone, we do not differ eſſentially from thoſe who attribute it to plumbago; for the art of chemiſtry has now found that theſe ſubſtances are very nearly allied. Plumbago is a true charcoal combined with a little iron. The brilliant charcoal of certain vegetable ſubſtances, more eſpecially when formed by diſtillation in cloſe veſſels, poſſeſſes all the characters of plumbago. The charcoal of animal ſubſtances poſſeſſes characters ſtill more peculiarly reſembling it. Like it they are difficult to incinerate, they leave the ſame impreſſion on the hands and upon paper; they likewiſe contain iron, and become converted into carbonic acid by combuſtion. When animal ſubſtances are diſtilled by a ſtrong fire, a very fine powder ſublimes, which attaches itſelf to the inner part of the neck of the retort, and this ſubſtance may be made into excellent black lead pencils.

Chaptal's Chemiſtry, vol. ii. p. 347.

There are two ways of making ſteel, namely, by fuſion and by cementation. The firſt way is uſed to convert iron into ſteel immediately from the ore, or from crude or caſt-iron. By the ſecond way, bar-iron is expoſed to a long continued heat ſurrounded by charcoal. Each of theſe ways has advantages peculiar to itſelf; but the ſame cauſes in fact predominate in both, for both kinds of ſteel are produced by heat and charcoal. The only difference between the two methods is this; in making ſteel by fuſion the charcoal is not ſo equally defended from the acceſs of air as in the other way.

Swedenborgius has given the following deſcription of the method uſed in Dalecarlia for making ſteel from caſt-iron. The ore from which the crude iron to be converted into ſteel is obtained is of a good kind. It is black, friable, and compoſed of many ſmall grains, and it produces very tough iron. The converſion into ſteel is made upon a forge-hearth, ſomething ſmaller than common. The ſides and bottom are made of caſt-iron. The tuyere is placed, with very little inclination, on one of the ſide-plates. The breadth of the fire-place is fourteen inches; its length is greater. The lower part of the tuyere is ſix inches and a half above the bottom. In the interior part of the fire-place there is an oblong opening for the flowing of the ſuperfluous ſcoriæ. The workmen firſt put ſcoriæ on the bottom, then charcoal and powder of charcoal, and upon theſe the caſt-iron run or cut into ſmall pieces. They cover the iron with more charcoal, and excite the fire. When the pieces of iron are of a red white, and before they begin to melt, they ſtop the bellows, and carry the maſs under a large hammer, where they break it into pieces of three or four pounds each. The pieces are again brought to the hearth, and laid within reach of the workman who plunges ſome of them into the fire, and covers them with coal. The bellows are made to blow ſlowly till the iron is liquefied. Then the fire is increaſed; and when the fuſion has been long enough continued, the ſcoriæ are allowed to flow out; and at that time the iron hardens. The workman adds more of the pieces of crude iron, which he treats in the ſame manner; and ſo on a third and a fourth time, till he obtains a maſs of ſteel of about a hundred pounds, which is generally done in about four hours. This maſs is raiſed and carried to the hammer, where it is forged, and cut into four pieces, which are farther beat into ſquare bars four or five feet long. When the ſteel is thus forged, it is thrown into water that it may be eaſily broken; for it is yet crude and coarſe-grained. The ſteel is then carried to another hearth ſimilar to the former, and there broken in pieces. Theſe pieces are laid regularly in the fire-place, firſt two parallel, upon which ſeven or eight others are placed acroſs; then a third row acroſs the ſecond, in ſuch a manner that there is ſpace left between thoſe of the ſame row. The whole is then covered with charcoal, and the fire is excited. In about half or three quarters of an hour the pieces are made hot enough, and are then taken from the fire, one by one, to the hammer, to be forged into little bars from half a foot to two feet long, and while hot are thrown into water to be hardened. Of theſe pieces ſixteen or twenty are put together ſo as to make a bundle, which is heated and welded, and afterwards forged into bars four inches thick, which are then broken into pieces of convenient length for uſe.

The method of converting iron into ſteel by cementation is a very ſimple proceſs. It conſiſts ſolely in expoſing it for a certain time to a ſtrong degree of heat, while cloſely covered with charcoal and defended from the external air. The furnaces employed for converting iron into ſteel (ſays a manufacturer of this metal) are of different ſizes; ſome capable of converting only three or four tons weight, while others are capacious enough to contain from ſeven to eight or ten tons. The outſides of theſe furnaces riſe up in form of a cone, or ſugar-loaf, to the height of a very conſiderable number of feet. In the inſide, oppoſite to each other, are placed two very long cheſts, made either of ſtone, or of bricks capable of bearing the ſtrongeſt fire; which is placed between the two cheſts. The bars of iron, after the bottom is furniſhed with a neceſſary quantity of charcoal duſt, are laid in *ſtratum ſuper ſtratum*, with intermediate beds of the charcoal duſt, to ſuch a height of the cheſts as only to admit of a good bed at top; which is then all covered over, to prevent the admiſſion of the common air; which, could it procure an entrance, would greatly injure the operation. The iron being thus ſituated, the fire is lighted; which is ſome time before it can be raiſed to a ſufficient degree of heat to produce any conſiderable effect. After which it is continued for ſo many days as the operator may judge proper; only now and then drawing out what they call a proof bar. This is done by openings fit for the purpoſe at the ends of the cheſt, which are eaſily and with expedition ſtopped up again, without occaſioning any injury to the contents left behind. When the operator

tor apprehends the conversion is sufficiently completed, the fire is suffered to go out, and the furnace, with its contents, is left gradually to cool. This may take up several days: after which the furnace is discharged, by taking out the bars of steel and the remainder of the charcoal dust.

There is a manufactory established in the parish of Cramond, about five miles from Edinburgh, in which this method is practised with great success. Great quantities of steel are made there, which we have reason to believe is of as excellent a quality as any that can be procured from other countries.

When the charcoal is taken out, it is found as black as before it was introduced into the furnace, unless by accident the external air has got admittance. The bars preserve their exterior form only; the surface frequently exhibits a great number of tumors or blisters, whence they are called *blistered steel.*

The hardness of steel is much increased by tempering. This consists in heating it to a red heat, and then plunging it suddenly into cold water. If it be allowed to cool slowly, it still preserves its ductility; or if it be heated again after being tempered, it loses its hardness, and again becomes ductile. In heating steel for tempering it, the most remarkable circumstance is, the different colours it assumes, according to the degree of heat it has received. As it is gradually heated, it becomes white, then yellow, orange, purple, violet, and at last of a deep blue colour.

According to Reaumur, the steel which is most heated in tempering is generally the hardest. Hence it is believed, that the more violent the heat to which steel is exposed, and the more suddenly it is plunged into cold water, the harder the steel will be. Rinman, again, has deduced a conclusion directly opposite, that the steel which is naturally hardest demands the least degree of heat to temper it. Different methods have been proposed to determine what degree of heat is most proper; but the easiest method is to take a bar of steel, so long, that while one end is exposed to a violent heat, the other may be kept cold. By examining the intermediate portions, it may be found what degree of heat has produced the greatest hardness.

By tempering, steel is said to increase both in bulk and in weight. Reaumur says, that a small bar six inches long, six lines broad, and half an inch thick, was increased at least a line in length after being tempered to a reddish white colour; that is, supposing the dilatation proportional in all dimensions increasing at the rate of 48 to 49. Iron also expands when heated; but when the heat passes off, it returns to its former dimensions. That the weight of steel is also augmented by tempering, has been found by experiment. Rinman having weighed exactly in an hydrostatic balance two kinds of fine steel made by cementation, and not tempered, found their density to be to that of water as 7,991 to 1; after being tempered, the density of the one was 7,553, and that of the other 7,708. M. de Morveau took three bars just of a size to enter a certain caliber 28 lines long, and each side two lines broad; one of the bars was soft iron, and the two others were taken from the same piece of fine steel. In order to communicate an equal degree of heat to each, in an earthen vessel in the midst of a wind furnace, the bar of soft iron and one of the bars of steel were thrown into cold water; the other bar of steel was cooled slowly over some pieces of charcoal at a distance from the furnace. The bar of iron and the one of steel that was allowed to cool slowly passed easily into the caliber again; but the bar of tempered steel was lengthened almost one-ninth of a line.

There is no doubt but tempering changes the grain; that is, the appearance of the texture of a piece of steel when broken. This is the mark which is usually observed in judging of the quality of steel, or of the tempering which suits it best. The tempered bar is broken in several places after having received different degrees of heat in different places. What proves completely the effect of heat upon the grain, at least in some kinds of steel, is, that a bar of steel exposed to all the intermediate degrees of heat, from the smallest sensible heat to a red heat, is found to increase in fineness of grain from the slightly heated to the strongly heated end. The celebrated Rinman has made many experiments on the qualities of steel exposed to different degrees of heat in tempering, but particularly to three kinds, viz. steel heated to an obscure red, to a bright red, and to red white. Hard brittle steel, made by cementation, and heated to an obscure red and tempered, exhibited a fine grain, somewhat shining, and was of a yellow white colour. When tempered at a bright red heat, the grain was coarser and more shining; when tempered at a red white heat, the grain was also coarse and shining.

With a view to determine how far steel might be improved in its grain by tempering it in different ways, M. de Morveau took a bar of blistered steel, and broke it into four parts nearly of the same weight. They were all heated to a red heat in the same furnace, and withdrawn from the fire at the same instant. One of the pieces was left at the side of the furnace to cool in the air, the second was plunged into cold water, the third into oil, and the fourth into mercury. The piece of steel that was cooled in the air resisted the hammer a long time before it was broken; it was necessary to notch it by the file, and even then it was broken with difficulty. It showed in its fracture a grain sensibly more fine and more shining than it was before. The second piece, which had been plunged into water, broke easily: its grain was rather finer than the first, and almost of the same white colour. The third piece, which was tempered in oil, appeared very hard when tried by the file; it was scarcely possible to break it. Its grain was as fine, but not quite so bright, as that which was tempered in water. The fourth piece, which was dipped into mercury, was evidently superior to all the rest in the fineness and colour of the grain. It broke into many fragments with the first stroke of the hammer, the fractures being generally transverse.

M. de Morveau was not altogether satisfied with these experiments, and therefore thought it necessary to repeat them with finer steel. He took a bar of steel two lines square, such as is used in Germany for tools by engravers and watchmakers; he divided it into four pieces, and treated them in the same way as he had done the blistered steel. The first piece, which was cooled in the air, it was very difficult to break: the fracture appeared in the midst of the grain very fine, but white and shining. The second, which was tempered in water, was broken into three fragments at the first

first blow; its grain was perfectly equal, of a grey ash-colour, and of remarkable fineness. One of its sides was polished, and a drop of the nitrous acid which was poured upon it left a black spot, but not deep. But when a drop of the same acid was poured on the middle of the fracture, after it had been equally polished, it left a black spot much deeper. The third piece, which was plunged in oil, bent as easily as the piece which was cooled in the air; the file made an impression on it with difficulty; it was necessary to break it with a vice: its grain was inferior in fineness to the second, but it was of a darker colour. The fourth, which was tempered in mercury, exhibited a grain of an intermediate fineness between the second and the third. From these experiments, it appears that steel may be hardened by tempering it, not only with water, but with any other liquid which is capable of accelerating its cooling.

Steel may be unmade, or reduced to the state of iron, by a management similar to that by which it is made, that is, by cementation. But the cement used for this purpose must be composed of substances entirely free from inflammable matter, and rather capable of absorbing it, as calcareous earth or quicklime. By a cementation with calcareous earth, continued during eight or ten hours, steel is reduced to the state of iron. After it has been tempered, it may be again untempered, and softened to any degree that we think proper; for which purpose we have only to heat it more or less, and to let it cool slowly. By this method we may soften the hardest-tempered steel.

Steel-Bow Tenants. See Tenure.

Salt of Steel. See Chemistry, n° 697.

Steel-Yard, is one of the most ancient presents which science has made to society; and though long in desuetude in this country, is in most nations of the world the only instrument for ascertaining the weight of bodies. What is translated *balance* in the Pentateuch, is in fact steelyard, being the word used by the Arabs to this day for their instrument, which is a steelyard. It is in common use in all the Asiatic nations. It was the *statera* of the Greeks and Romans, and seems to have been more confided in by them than the balance; for which reason it was used by the goldsmiths, while the balance was the instrument of the people.—*Non aurificis statera sed populari trutina examinare.* Cic. de Or. 238.

Plate CCCCLXXXI.

The steelyard is a lever of unequal arms, and, in its most perfect form, is constructed much like a common balance. It hangs in sheers E (fig. 1.) resting on the nail C, and the scale L for holding the goods hangs by a nail D on the short arm BC. The counter weight P hangs by a ring of tempered steel, made sharp in the inside, that it may bear by an edge on the long arm CA of the steelyard. The under edge of the centre nail C, and the upper edge of the nail D, are in the straight line formed by the upper edge of the long arm. Thus the three points of suspension are in one straight line. The needle or index of the steelyard is perpendicular to the line of the arms, and plays between the sheers. The short arm may be made so massive, that, together with the scale, it will balance the long arm unloaded. When no goods are in the scale, and the counter weight with its hook are removed, the steelyard acquires a horizontal position, in consequence of its centre of gravity being below the axis of suspension. The rules for its accurate construction are the same as for a common balance.

The instrument indicates different weights in the following manner: The distance CD of the two nails is considered as an unit, and the long arm is divided into a number of parts equal to it; and these are subdivided as low as is thought proper: or in general, the long arm is made a scale of equal parts, commencing at the edge of the nail C; and the short arm contains some determined number of those equal parts. Suppose, then, that a weight A of 10 pounds is put into the scale L. The counterpoise P must be of such a weight, that, when hanging at the division 10, it shall balance this weight A. Now let any unknown weight W be put into the scale. Slide the hook of the counterpoise along the long arm till it balances this weight. Suppose it then hanging at the division 38. We conclude that there is 38 pounds in the scale. This we do on the authority of the fundamental property of the lever, that forces acting on it, and balancing each other, are in the inverse proportion of the distances from the fulcrum to their lines of direction. Whatever weight the counterpoise is, it is to A as CD to 10, and it is to the weight W as CD to 38; therefore A is to the weight W as 10 to 38, and W is 38 pounds: and thus the weight in the scale will always be indicated by the division at which it is balanced by the counterpoise.

Our well informed readers know that this fundamental property of the lever was discovered by the renowned Archimedes, or at least first demonstrated by him; and that his demonstration, besides the defect of being applicable only to commensurable lengths of the arms, has been thought by metaphysicians of the first note to proceed on a postulate which seems equally to need a demonstration. It has accordingly employed the utmost refinement of the first mathematicians of Europe to furnish a demonstration free from objection. Mr D'Alembert has given two, remarkable for their ingenuity and subtlety; Foncenex has done the same; and Professor Hamilton of Trinity-college, Dublin, has given one which is thought the least exceptionable. But critics have even objected to this, as depending on a postulate which should have been demonstrated.

Since we published the volume containing the article Mechanics, there has appeared (Phil. Trans. 1794) a demonstration by Mr Vince, which we think unexceptionable, and of such simplicity that it is astonishing that it has not occured to any person who thinks on the subject. Our readers will not be displeased with an account of it.

Let AE (fig. 2.) be a mathematical lever, or inflexible straight line, resting on the prop A, and supported at E by a force acting upwards. Let two equal weights b and d be hung on at B and D, equidistant from A and E. Pressures are now exerted at A and E; and because every circumstance of weight and distance is the same, the pressure at E, arising from the action of the weight b on the point B, must be the same with the pressure at A, arising from the action of the weight d on the point D; and the pressure at E, occasioned by the weight d, must be the same with the pressure at A, occasioned by the weight b. This must be the case wherever the weights are hung, provided that the distance AB and DE are equal. Moreover, the

the sum of the pressures at A and E is unquestionably equal to the sum of the weights, because the weights are supported solely at A and E. Let the two weights be hung on at C the middle point; the pressure at E is still the same. Therefore, in general, the pressure excited at the point E, by two equal weights hanging at any points B and D, is the same as if they were hung on at the middle point between them: but the pressure excited at E is a just measure of the effort or energy of the weights *b* and *d* to urge the lever round the point A. It is, at least, a measure of the opposite force which must be applied at E to sustain or balance this pressure. A very fastidious metaphysician may still say, that the demonstration is limited to a point E, whose distance from A is twice AC, or $= AB + AD$. But it extends to any other point, on the authority of a postulate which cannot be refused, viz. that in whatever proportion the pressue at E is augmented or diminished, the pressure at this other point must augment or diminish in the same proportion. This being proved, the general theorem may be demonstrated in all proportions of distance, in the manner of Archimedes, at once the most simple, perspicuous, and elegant of all.

We cannot help observing, that all this difficulty (and it is a real one to the philosopher who aims at rendering mechanics a demonstrative science) has arisen from an improper search after simplicity. Had Archimedes taken a lever as it really exists in nature, and considered it as *material*, consisting of atoms united by cohesion; and had he traced the intermediate pressures by whose means the two external weights are put in opposition to each other, or rather to the support given to the fulcrum; all difficulty would have vanished. (See what is said on this subject in the article *Strength of Timber*, &c.)

The quantity of goods which may be weighed by this instrument depends on the weight of the counterpoise, and on the distance CD from the fulcrum at which the goods are suspended. A double counterpoise hanging at the same division will balance or indicate a double quantity of goods hanging at D; and any counterpoise will balance and indicate a double quantity of goods, if the distance CD be reduced to one-half. Many steelyards have two or more points of suspension D, to which the scale may occasionally be attached. Fig. 6. of Plate XCI. Vol. II. represents one of these. It is evident, that in this case the value or indication of the divisions of the long arm will be different, according to the point from which the scale is suspended. The same division which would indicate 20 pounds when CD is three inches, will indicate 30 pounds when it is two inches. As it would expose to chance of mistakes, and be otherwise troublesome to make this reduction, it is usual to make as many divided scales on the long arm as there are points of suspension D on the short arm; and each scale having its own numbers, all trouble and all chance of mistake is avoided.

But the range of this instrument is not altogether at the pleasure of the maker. Besides the inability of a slender beam to carry a great load, the divisions of the scale answering to pounds or half-pounds become very minute when the distance CD is very short; and the balance becomes less delicate, that is, less sensibly affected by small differences of weight. This is because in such cases the thickness which it is necessary to give the edges of the nails does then bear a sensible proportion to the distance CD between them; so that when the balance inclines to one side, that arm is sensibly shortened, and therefore the energy of the preponderating weight is lessened.

We have hitherto supposed the steelyard to be in equilibrio when not loaded. But this is not necessary, nor is it usual in those which are commonly made. The long arm commonly preponderates considerably. This makes no difference, except in the beginning of the scale. The preponderancy of the long arm is equivalent to some goods already in the scale, suppose four pounds. Therefore when there are really 10 pounds in the scale, the counterpoise will balance it when hanging at the division 6. This division is therefore reckoned 10, and the rest of the divisions are numbered accordingly.

A scientific examination of the steelyard will convince us that it is inferior to the balance of equal arms in point of sensibility: But it is extremely compendious and convenient; and when accurately made and attentively used, it is abundantly exact for most commercial purposes. We have seen one at Leipzig which has been in use since the year 1718, which is very sensible to a difference of one pound, when loaded with nearly three tons on the short arm; and we saw a waggon loaded with more than two tons weighed by it in about six minutes.

The steelyard in common use in the different countries of Europe is of a construction still simpler than what we have described. It consists of a batten of hard wood, having a heavy lump A (fig. 3.) at one end, and a swivel-hook B at the other. The goods to be weighed are suspended on the hook, and the whole is carried in a loop of whip-cord C, in which it is slid backward and forward, till the goods are balanced by the weight of the other end. The weight of the goods is estimated by the place of the loop on a scale of divisions in harmonic progression. They are marked (we presume) by trial with known weights.

The chief use that is now made of the steelyard in Great Britain is for the weighing of loaded waggons and carts. For this it is extremely convenient, and more than sufficiently exact for the purpose in view. We shall describe one or two of the most remarkable; and we shall begin with that at Leipzig already mentioned.

This steelyard is represented in fig. 4. as run out, and just about to be hooked for lifting up the load. The steelyard itself is OPQ, and is about 12 feet long. The short arm PQ has two points of suspension *c* and *b*; and the stirrup which carries the chains for holding the load is made with a double hook, instead of a double eye, that it may be easily removed from the one pin to the other. For this purpose the two hooks are connected above by an hasp or staple, which goes over the arm of the steelyard like an arch. This is represented in the little figure above the steelyard. The suspension is shifted when the steelyard is run in under cover, by hooking to this staple the running block of a small tackle which hangs in the door through which the steelyard is run out and in. This operation is easy, but

but neceffary, becaufe the ftirrup, chains, and the ftage on which the load is placed, weigh fome hundreds.

The outer pin *b* is 14 inches, and the inner one *c* is feven inches, diftant from the great nail which refts in the fheers. The other arm is about $10\frac{1}{4}$ feet long, formed with an obtufe edge above. On the inclined plane on each fide of the ridge is drawn the fcale of weights adapted to the inner pin *c*. The fcales correfponding to the outer pin *b* are drawn on the upright fides. The counterpoife flides along this arm, hanging from a faddle-piece made of brafs, that it may not contract ruft. The motion is made eafy by means of rollers. This is neceffary, becaufe the counterpoife is greatly above a hundred weight. This faddle-piece has like two laps on each fide, on which are engraved vernier fcales, which divide their refpective fcales on the arm to quarters of a pound. Above the faddle is an arch, from the fummit of which hangs a little plummet, which fhows the equilibrium of the fteelyard to the weigher, becaufe the fheers are four feet out of the houfe, and he cannot fee their coincidence with the needle of the fteelyard. Laftly, near the end of the long arm are two pins *d* and *e*, for fufpending occafionally two eke weghts for continuing the fcale. Thefe are kept hanging on adjoining hooks, ready to be lifted on by a little tackle, which is alfo hooked immediately above the pins *d* and *e*.

The fcales of weights are laid down on the arm as follows. Let the eke-weights appropriated to the pins *d* and *e* be called D and E, and call the counterpoife C. Although the ftirrup with its chains and ftage weigh fome hundreds, yet the length and fize of the arm QP gives it a preponderancy of 300 pounds. Here, then, the fcale of weights muft commence. The counterpoife weighs about 125 pounds. Therefore,

1. When the load hangs by the pin *b*, 14 inches from the centre, the diftance from one hundred to another on the fcale is about 11 inches, and the firft fcale (on the fide of the arm) reaches from 300 to 1200. In order to repeat or continue this, the eke-weight E is hung on the pin *e*, and the counterpoife C is brought back to the mark 300; and the two together balance 1100 pounds hanging at *b*. Therefore a fecond fcale is begun on the fide of the arm, and continued as far out as the firft, and therefore its extremity marks 2000; that is, the counterpoife C at 2000 and the eke-weight E at *e* balance 2000 hanging at *b*.

2. To continue the fcale beyond 2000, the load muft be hung on the inner pin *c*. The eke-weight E is taken off, and the eke-weight D is hung on its pin *d*. The general counterpoife being now brought clofe to the fheers, it, together with the weight D at *d*, balance 2000 pounds hanging at *c*. A fcale is therefore begun on one of the inclined planes a-top, and continued out to 4000, which falls very near to the pin *d*, each hundred pounds occupying about five inches on the arm. To complete the fcale, hang on the eke-weight E on its pin *e*, and bring back the counterpoife to the fheers, and the three together balance 3800 hanging at *c*. Therefore when the counterpoife is now flid out to 4000, it muft complete the balance with 5800 hanging at *c*.

It required a little confideration to find out what proportion of the three weights C, D, and E, would make the repetitions of the fcale extend as far as poffible, having very little of it expreffed twice, or upon two fcales, as is the cafe here. We fee that the fpace correfponding to a fingle pound is a very fenfible quantity on both fcales, being one-ninth of an inch on the firft two fcales, and one-twentieth on the laft two.

This very ponderous machine, with its maffy weights, cannot be eafily managed without fome affiftance from mechanics. It is extremely proper to have it fufceptible of motion out and in, that it may be protected from the weather, which would foon deftroy it by ruft. The contrivance here is very effectual, and abundantly fimple.

When the fteelyard is not in ufe, it is fupported at one end by the iron-rod F, into which the upper end of the fheers is hooked. The upper end of this rod has a ftrong hook E, and a little below at *a* it is pierced with a hole, in which is a very ftrong bolt or pin of tempered fteel, having a roller on each end clofe to the rod on each fide. Thefe rollers reft on two joifts, one of which is reprefented by MN, which traverfe the building, with juft room enough between them to allow the rod F to hang freely down. The other end O of the fteelyard refts in the bight of a large flat hook at the end of a chain W, which hangs down between the joifts, and is fupported on them by a frame with rollers H. This is connected with the rollers at G, which carry the fheers by means of two iron-rods, of which one only can be feen. Thefe connect the two fets of rollers in fuch a manner that they muft always move together, and keep their diftance invariable. This motion is produced by means of an endlefs rope HI ZLKVH paffing over the pulleys I and K, which turn between the joifts, and hanging down in a bight between them. It is evident that by pulling on the part LZ we pull the frame of rollers in the direction GH, and thus bring the whole into the houfe in the pofition marked by the dotted figure. It is alfo plain, that by pulling on the part L K we force the roller frame and the whole apparatus out again.

It remains to fhow how the load is raifed from the ground and weighed. When the fteelyard is run out for ufe, the upper hook E juft enters into the ring D, which hangs from the end of the great oaken lever BCA about 22 feet long, turning on gudgeons at C about 5 feet from this end. From the other end A defcends a long iron rod SR, which has one fide formed into a toothed rack that is acted on by a frame of wheel-work turned by an endlefs fcrew and winch Q. Therefore when the hook E is well engaged in the ring D, a man turns the winch, and thus brings down the end A of the great lever, and raifes the load two or three inches from the ground. Every thing is now at liberty, and the weigher now manages his weights on the arm of the fteelyard till he has made an equilibrium.

We need not defcribe the operation of letting down the load, difengaging the fteelyard from the great lever, and bringing it again under cover. The whole of this fervice is performed by two men, and may be done in fucceffion by one, and is over in five or fix minutes.

The moft compendious and economical machine of this kind that we have feen is one, firft ufed (we have heard) for weighing the riders of race-horfes, and afterwards

terwards applied to the more reputable service of weighing loaded carriages.

Fig. 5. is a plan of the machine. KLMN is the plan of a rectangular box, which has a platform lid or cover, of size sufficient for placing the wheels of a cart or waggon. The box is about a foot deep, and is sunk into the ground till the platform-cover is even with the surface. In the middle of the box is an iron lever supported on the fulcrum pin *i k*, formed like the nail of balance, which rests with its edge on arches of hardened steel firmly fastened to the bottom of the box. This lever goes through one side of the box, and is furnished at its extremity with a hard steel pin *l m*, also formed to an edge below. In the very middle of the box it is crossed by a third nail of hardened steel *g b*, also formed to an edge, but on the upper side. These three edges are in one horizontal plane, as in a well made balance.

In the four corners A, A′, E′, E, of the box are firmly fixed four blocks of tempered steel, having their upper surfaces formed into spherical cavities, well polished and hard tempered. ABCDE represents the upper edge of an iron bar of considerable strength, which rests on the cavities of the steel blocks in A and E, by means of two hard steel studs projecting from its under edge, and formed into obtuse angled points or cones. These points are in a straight line parallel to the side KN of the box. The middle part C of this crooked bar is faced with hard-tempered steel below, and is there formed into an edge parallel to AE and KN, by which it rests on the upper edge of the steel pin *g b* which is in the lever. In a line parallel to AE, and on the upper side of the crooked bar ACE, are fixed two studs or points of hardened steel B and D projecting upwards above half an inch. The platform-cover has four short feet like a stool, terminated by hard steel studs, which are shaped into spherical cavities and well polished. With these it rests on the four steel points B, B′, D′, D. The bar ACE is kneed in such a manner vertically, that the points A, B, D, E and the edge C are all in a horizontal plane. These particulars will be better understood by looking at the elevation in fig. 6. What has been said of the bar ACE must be understood as also said of the bar A′ C′ E′.

Draw through the centre of the box the line *a b c* perpendicular to the line AE, BD. It is evident that the bar ACE is equivalent to a lever *a b c*, having the fulcrum or axis AE resting with its extremity C on the pin *b g* and loaded at *b*. It is also evident that *a* C is to *a b* as the load on this lever to the pressure which it exerts on the pin *g b*, and that the same proportion subsists between the whole load on the platform and the pressure which it exerts on the pin *g b*. It will also appear, on an attentive consideration, that this proportion is nowise deranged in whatever manner the load is placed on the platform. If very unequally, the two ends of the pin *g b* may be unequally pressed, and the lever wrenched and strained a little; but the total pressure is not changed.

If there be now placed a balance or steelyard at the side LK, in such a manner that one end of it may be directly above the pin *l m* in the end of the lever EOF, they may be connected by a wire or slender rod, and a weight on the other arm of the balance or steelyard may be put in equilibrio with any load that can be laid on the platform. A small counterpoise being first hung on to balance the apparatus when unloaded, any additional weight will measure the load really laid on the platform. If *a b* be to *a c* as 1 to 8, and EO to EF also as 1 to 8, and if a common balance be used above, 64 pounds on the platform will be balanced by one pound in the scale, and every pound will be balanced by $\frac{1}{4}$th of an ounce. This would be a very convenient partition for most purposes, as it would enable us to use a common balance and common weights to complete the machine: Or it may be made with a balance of unequal arms, or with a steelyard.

Some have thought to improve this instrument by using edges like those of the nails of a balance, instead of points. But unless made with uncommon accuracy, they will render the balance very dull. The small deviation of the two edges A and E, or of B and D, from perfect parallelism to KN, is equivalent to a broad surface equal to the whole deviation. We imagine that, with no extraordinary care, the machine may be made to weigh within $\frac{1}{1000}$th of the truth, which is exact enough for any purpose in commerce.

It is necessary that the points be attached to the bars. Some have put the points at A and E in the blocks of steel fastened to the bottom, because the cavity there lodged water or dirt, which soon destroyed the instrument with rust. But this occasions a change of proportion in the first lever by any shifting of the crooked bars; and this will frequently happen when the wheels of a loaded cart are pushed on the platform. The cavity in the steel stud should have a little rim round it, and it should be kept full of oil. In a nice machine a quarter of an inch of quicksilver would effectually prevent all these inconveniences.

The simplest and most economical form of this machine is to have no balance or second steelyard; but to make the first steelyard EOF a lever of the first kind, viz. having the fulcrum between O and F, and allow it to project far beyond the box. The long or outward arm of this lever is then divided into a scale of weights, commencing at the side of the box. A counterpoise must be chosen, such as will, when at the beginning of the scale, balance the smallest load that will probably be examined. It will be convenient to carry on this scale by means of eke-weights hung on at the *extremity* of the lever, and to use but one moveable weight. By this method the divisions of the scale will have always one value. The best arrangement is as follows: Place the mark O at the beginning of the scale, and let it extend only to 100, if for pounds; or to 112, if for cwts; or to 10, if for stones; and let the eke-weights be numbered 1, 2, 3, &c. Let the lowest weight be marked on the beam. This is always to be added to the weight shown by the operation. Let the eke-weights stand at the end of the beam, and let the general counterpoise always hang at O. When the cart is put on the platform, the end of the beam tilts up. Hang on the heaviest eke-weight that is not sufficient to press it down. Now complete the balance by sliding out the counterpoise. Suppose the constant load to be 312lb. and that the counterpoise stands at 86, and that the eke-weight is 9; we have the load=986+312,=1298 lbs.

STEELE (Sir Richard), was born about the year 1676 in Dublin; in which kingdom one branch of the family was possessed of a considerable estate in the

Steele. county of Wexford. His father, a counsellor at law in Dublin, was private secretary to James duke of Ormond; but he was of English extraction: and his son, while very young, being carried to London, he put him to school at the Charter-house, whence he was removed to Merton College in Oxford. Our author left the university, which he did without taking any degree, in the full resolution to enter into the army. This step was highly displeasing to his friends; but the ardour of his passion for a military life rendered him deaf to any other proposal. Not being able to procure a better station, he entered as a private gentleman in the horse-guards, notwithstanding he thereby lost the succession to his Irish estate. However, as he had a flow of good-nature, a generous openness and frankness of spirit, and a sparkling vivacity of wit, these qualities rendered him the delight of the soldiery, and procured him an ensign's commission in the guards. In the mean time, as he had made choice of a profession which set him free from all the ordinary restraints in youth, he spared not to indulge his inclinations in the wildest excesses. Yet his gaieties and revels did not pass without some cool hours of reflection; it was in these that he drew up his little treatise intitled *The Christian Hero*, with a design, if we may believe himself, to be a check upon his passions. For this purpose it had lain some time by him, when he printed it in 1701, with a dedication to Lord Cutts, who had not only appointed him his private secretary, but procured for him a company in Lord Lucas's regiment of Fusileers.

The same year he brought out his comedy called *The Funeral or Grief à la mode.* This play procured him the regard of King William, who resolved to give him some essential marks of his favour; and though, upon that prince's death, his hopes were disappointed, yet, in the beginning of Queen Anne's reign, he was appointed to the profitable place of gazetteer. He owed this post to the friendship of lord Halifax and the earl of Sunderland, to whom he had been recommended by his school-fellow Mr Addison. That gentleman also lent him an helping hand in promoting the comedy called *The Tender Husband*, which was acted in 1704 with great success. But his next play, The Lying Lover, had a very different fate. Upon this rebuff from the stage, he turned the same humorous current into another channel; and early in the year 1709, he began to publish the Tatler: which admirable paper was undertaken in concert with Dr Swift. His reputation was perfectly established by this work; and, during the course of it, he was made a commissioner of the stamp-duties in 1710. Upon the change of the ministry the same year, he joined the duke of Marlborough, who had several years entertained a friendship for him; and upon his Grace's dismission from all employments in 1711, Mr Steele addressed a letter of thanks to him for the services which he had done to his country. However, as our author still continued to hold his place in the stamp office under the new administration, he forbore entering with his pen upon political subjects; but, adhering more closely to Mr Addison, he dropt the Tatler, and afterwards, by the assistance chiefly of that steady friend, he carried on the same plan much improved, under the title of *The Spectator.* The success of this paper was equal to that of the former; which encouraged him, before the close of it, to proceed upon the same design in the character of the *Guardian.* This was opened in the beginning of the year 1713, and was laid down in October the same year. But in the course of it his thoughts took a stronger turn to politics: he engaged with great warmth against the ministry; and being determined to prosecute his views that way by procuring a seat in the house of commons, he immediately removed all obstacles thereto. For that purpose he took care to prevent a forcible dismission from his post in the stamp office, by a timely resignation of it to the Earl of Oxford; and at the same time gave up a pension, which had been till this time paid him by the queen as a servant to the late prince George of Denmark. This done, he wrote the famous Guardian upon the demolition of Dunkirk, which was published Aug. 7. 1713; and the parliament being dissolved next day, the Guardian was soon followed by several other warm political tracts against the administration. Upon the meeting of the new parliament, Mr Steele having been returned a member for the borough of Stockbridge in Dorsetshire, took his seat accordingly in the house of commons; but was expelled thence in a few days after, for writing the close of the paper called the *Englishman*, and one of the political pieces intitled the *Crisis.* Presently after his expulsion, he published proposals for writing the history of the duke of Marlborough: at the same time he also wrote the *Spinster*; and, in opposition to the *Examiner*, he set up a paper called the *Reader*, and continued publishing several other things in the same spirit till the death of the queen. Immediately after which, as a reward for these services, he was taken into favour by her successor to the throne, king George I. He was appointed surveyor of the royal stables at Hampton-Court, governor of the royal company of comedians, put into the commission of the peace for the county of Middlesex, and in 1715 received the honour of knighthood. In the first parliament of that king, he was chosen member for Boroughbridge in Yorkshire; and, after the suppression of the rebellion in the north, was appointed one of the commissioners of the forfeited estates in Scotland. In 1718, he buried his second wife, who had brought him a handsome fortune and a good estate in Wales; but neither that, nor the ample additions lately made to his income, were sufficient to answer his demands. The thoughtless vivacity of his spirit often reduced him to little shifts of wit for its support; and the project of the Fish-pool this year owed its birth chiefly to the projector's necessities. This vessel was intended to carry fish alive, and without wasting, to any part of the kingdom: but notwithstanding all his towering hopes, the scheme proved very ruinous to him; for after he had been at an immense expence in contriving and building his vessel, besides the charge of the patent, which he had procured, it turned out upon trial to be a mere project. His plan was to bring salmon alive from the coast of Ireland; but these fish, though supplied by this contrivance with a continual stream of water while at sea, yet uneasy at their confinement, shattered themselves to pieces against the sides of the pool; so that when they were brought to market they were worth very little.

The following year he opposed the remarkable peerage bill in the house of commons; and, during the course

course of this opposition to the court, his licence for acting plays was revoked, and his patent rendered ineffectual, at the instance of the lord chamberlain. He did his utmost to prevent so great a loss; and finding every direct avenue of approach to his royal master effectually barred against him by his powerful adversary, he had recourse to the method of applying to the public, in hopes that his complaints would reach the ear of his sovereign, though in an indirect course, by that canal. In this spirit he formed the plan of a periodical paper, to be published twice a-week, under the title of the *Theatre;* the first number of which came out on the 2d of January 1719-20. In the mean time, the misfortune of being out of favour at court, like other misfortunes, drew after it a train of more. During the course of this paper, in which he had assumed the feigned name of *Sir John Edgar*, he was outrageously attacked by Mr Dennis, the noted critic, in a very abusive pamphlet, intitled *The Character and Conduct of Sir John Edgar.* To this insult our author made a proper reply in the Theatre.

While he was struggling with all his might to save himself from ruin, he found time to turn his pen against the mischievous South-Sea scheme, which had nearly brought the nation to ruin in 1720; and the next year he was restored to his office and authority in the playhouse in Drury-Lane. Of this it was not long before he made an additional advantage, by bringing his celebrated comedy called the *Conscious Lovers* upon that stage, where it was acted with prodigious success; so that the receipt there must have been very considerable, besides the profits accruing by the sale of the copy, and a purse of 500l. given to him by the king, to whom he dedicated it. Yet notwithstanding these ample supplies, about the year following, being reduced to the utmost extremity, he sold his share in the play-house; and soon after commenced a law-suit with the managers, which in 1726 was determined to his disadvantage. Having now again, for the last time, brought his fortune, by the most heedless profusion, into a desperate condition, he was rendered altogether incapable of retrieving the loss, by being seized with a paralytic disorder, which greatly impaired his understanding. In these unhappy circumstances, he retired to his seat at Languanor near Caermarthen in Wales, where he paid the last debt to nature on the 21st of September 1729, and was privately interred, according to his own desire, in the church of Caermarthen. Among his papers were found the manuscripts of two plays, one called *The Gentleman*, founded upon the eunuch of Terence, and the other intitled *The School of Action*, both nearly finished.

Sir Richard was a man of undissembled and extensive benevolence, a friend to the friendless, and, as far as his circumstances would permit, the father of every orphan. His works are chaste and manly. He was a stranger to the most distant appearance of envy or malevolence; never jealous of any man's growing reputation; and so far from arrogating any praise to himself from his conjunction with Mr Addison, that he was the first who desired him to distinguish his papers. His greatest error was want of economy: however, he was certainly the most agreeable, and (if we may be allowed the expression) the most innocent rake that ever trod the rounds of dissipation.

STEEPLE, an appendage erected generally on the western end of churches, to hold the bells. Steeples are denominated from their form, either spires or towers: the first are such as ascend continually diminishing either conically or pyramidally; the latter are mere parallelopipeds, and are covered a-top platform like.

STEERAGE, on board a ship, that part of the ship next below the quarter deck, before the bulk-head of the great cabin where the steersman stands, in most ships of war. See STEERING.

STEERING, in navigation, the art of directing the ship's way by the movements of the helm; or of applying its efforts to regulate her course when she advances.

The perfection of steering consists in a vigilant attention to the motion of the ship's head, so as to check every deviation from the line of her course in the first instant of its motion; and in applying as little of the power of the helm as possible. By this she will run more uniformly in a straight path, as declining less to the right and left; whereas, if a greater effort of the helm is employed, it will produce a greater declination from the course, and not only increase the difficulty of steering, but also make a crooked and irregular tract through the water. See HELM.—The helmsman should diligently watch the movements of the head by the land, clouds, moon, or stars; because, although the course is in general regulated by the compass, yet the vibrations of the needle are not so quickly perceived as the sallies of the ship's head to the right or left, which, if not immediately restrained, will acquire additional velocity in every instant of their motion, and demand a more powerful impulse of the helm to reduce them; the application of which will operate to turn her head as far on the contrary side of her course. —The phrases used in steering a ship vary according to the relation of the wind to her course. Thus, if the wind is fair or large, the phrases used by the pilot or officer who superintends the steerage are, *port, starboard*, and *steady*. The first is intended to direct the ship's course farther to the right; the second is to guide her farther to the left; and the last is designed to keep her exactly in the line whereon she advances, according to the course prescribed. The excess of the first and second movement is called *hard a-port*, and *hard a starboard;* the former of which gives her the greatest possible inclination to the right, and the latter an equal tendency to the left.—If, on the contrary, the wind is foul or scant, the phrases are *luff, thus*, and *no nearer:* the first of which is the order to keep her close to the wind; the second, to retain her in her present situation; and the third, to keep her sails full.

In a ship of war, the exercise of steering the ship is usually divided amongst a number of the most expert sailors, who attend the helm in their turns; and are accordingly called *timoneers*, from the French term *timonier*, which signifies "helmsman." The steerage is constantly supervised by the quarter-masters, who also attend the helm by rotation. In merchant-ships every seaman takes his turn in this service, being directed therein by the mate of the watch, or some other officer. —As the safety of a ship, and all contained therein, depends in a great measure on the steerage or effects of the helm, the apparatus by which it is managed should often be diligently examined by the proper officers. In-

deed,

deed, a negligence in this important duty appears almost unpardonable, when the fatal effects which may result from it are duly considered.

STEGANIUM. See SLATE.

STEGANOGRAPHY, the art of secret writing, or of writing in ciphers, known only to the persons corresponding. See CIPHER.

STELLARIA, STICHWORT, in botany: A genus of plants belonging to the class of *decandria*, and order of *trigynia*: and in the natural system arranged under the 22d order, *Caryophylleæ*. The calx is pentaphyllous and spreading. There are five petals, each divided into two segments. The capsule is oval, unilocular, and polyspermous. There are nine species, the nemorum, dichotoma, radians, holostea, graminea, cerastoides, undulata, biflora, and arenaria. Three of these are British plants. 1. *Nemorum*, broad-leaved stichwort. The stalks are about a foot or eighteen inches high, and branched in a panicle at the top. The leaves are heart-shaped, and of a paler green on the under than on the upper side; the lower ones being supported by foot-stalks which are hairy and channelled; the upper ones are sessile. The calyx is erect, somewhat hairy and white on the margins. The petals are bifid almost to the base. There is a small nectarium between the longer stamina and the calyx.—2. *Holostea*, greater stichwort. The stalks are about two feet long; the petals are nearly twice the length of the calyx, and divided half-way to the base. It is common in woods and hedges.—3. *Graminea*, less stichwort. The stem is near a foot high. The leaves are linear and entire, and the flowers grow in loose panicles. It is frequent in dry pastures. There is a variety of this species called *bog stichwort*, with smooth, oval, sessile leaves, and few leaves, which grows often in wet marshy places. The stalk is quadrangular; the petals scarcely longer than the calyx, and bifid to the base.

STELLATE, among botanists, expresses leaves which grow not less than six at a joint, and are arranged like the rays of a star.

STELLERA, GERMAN GROUNDSEL, in botany: A genus of plants belonging to the class of *octandria*, and order of *monogynia*; and in the natural system arranged under the 31st order, *Veprecula*. There is no calyx. The corolla is quadrifid. The stamina are very short. There is only one seed, which is black. The species are two in number, passerina and chamaejasme.

STELLIONATE, in the civil law, a kind of crime committed by a fraudulent bargain, where one of the parties sells a thing for what it is not; as if I sell an estate for my own which belongs to another, or convey a thing as free and clear which is already engaged to another, or put off copper for gold, &c.

STEM, in botany, that part of a plant arising out of the root, and which sustains the leaves, flowers, fruits, &c. By washing and rubbing the stems of trees, their annual increase is promoted; for the method of doing which, see the article TREE.

STEM of a Ship, a circular piece of timber into which the two sides of a ship are united at the fore-end: the lower end of it is scarfed to the keel, and the bowsprit rests upon its upper end. The stem is formed of one or two pieces, according to the size of the vessel; and as it terminates the ship forward, the ends of the wales and planks of the sides and bottom are let into a groove or channel, in the midst of its surface, from the top to the bottom; which operation is called *rabiting*. The outside of the stem is usually marked with a scale, or division of feet, according to its perpendicular height from the keel. The intention of this is to ascertain the draught of water at the forepart, when the ship is in preparation for a sea-voyage, &c. The stem at its lower end is of equal breadth and thickness with the keel, but it grows proportionally broader and thicker towards its upper extremity. See *SHIP-Building*.

STEMMATA, in the history of insects, are three smooth hemispheric dots, placed generally on the top of the head, as in most of the hymenoptera and other classes. The name was first introduced by Linnæus.

STEMODIA, in botany: A genus of plants belonging to the class of *didynamia*, and order of *angiospermia*; and in the natural system ranging under the 40th order, *Personatæ*. The calyx is quinquepartite; the corolla bilabiated; there are four stamina; each of the filaments are bifid, and have two antheræ. The capsule is bilocular. There is only one species, the maritima.

STEMPHYLA, a word used by the ancients to express the husks of grapes, or the remains of the pressings of wine. The same word is also used by some to express the remaining mass of the olives, after the oil is pressed out.

STEMPHYLITES, a name given by the ancients to a sort of wine pressed hard from the husks.

STEMPLES, in mining, cross bars of wood in the shafts which are sunk to mines.

In many places the way is to sink a perpendicular hole, or shaft, the sides of which they strengthen from top to bottom with wood-work, to prevent the earth from falling in: the transverse pieces of wood used to this purpose they call *stemples*, and by means of these the miners in some places descend, without using any rope, catching hold of these with their hands and feet.

STEMSON, in a ship, an arching piece of timber fixed within the apron, to reinforce the scarf thereof, in the same manner as the apron supports the scarf of the stern. In large ships it is usually formed of two pieces.

STENOGRAPHY (A).

CHAP. I.

THE art of ſtenography, or ſhort writing, was known and practiſed by moſt of the ancient civilized nations. The Egyptians, who were diſtinguiſhed for learning at an early period, at firſt expreſſed their words by a delineation of figures called *hieroglyphics*. A more conciſe mode of writing ſeems to have been afterwards introduced, in which only a part of the ſymbol or picture was drawn. This anſwered the purpoſe of ſhort-hand in ſome degree. After them the Hebrews, the Greeks, and the Romans*, adopted different methods of abbreviating their words and ſentences, ſuited to their reſpective languages. The initials, the finals, or radicals, often ſerved for whole words; and various combinations of theſe ſometimes formed a ſentence. Arbitrary marks were likewiſe employed to determine the meaning, and to aſſiſt legibility; and it ſeems probable that every writer, and every author of antiquity, had ſome peculiar method of abbreviation, calculated to facilitate the expreſſion of his own ſentiments, and intelligible only to himſelf.

*Vide Buxtorf, Diog. Laertius, Plutarch, &c.

It is alſo probable, that ſome might by theſe means take down the heads of a diſcourſe or oration; but few, very few, it is preſumed, could have followed a ſpeaker through all the meanders of rhetoric, and noted with preciſion every ſyllable, as it dropt from his mouth, in a manner legible even to themſelves.

To arrive at ſuch conſummate perfection in the art was reſerved for more modern times, and is ſtill an acquiſition by no means general.

In every language of Europe, till about the cloſe of the 16th century, the Roman plan of abbreviating (viz. ſubſtituting the initials or radicals, with the help of arbitraries, for words) appears to have been employed. Till then no regular alphabet had been invented expreſsly for ſtenography, when an Engliſh gentleman of the name of *Willis* invented and publiſhed one (B). His plan was ſoon altered and improved, or at leaſt pretended to be ſo. One alteration ſucceeded another; and at intervals, for a ſeries of years paſt, ſome men of ingenuity and application have compoſed and publiſhed ſyſtems of ſtenography, and doubtleſs have themſelves reaped all the advantages that attend it. But among the various methods that have been propoſed, and the different plans that have been adopted by individuals, none has yet appeared fortunate enough to gain general approbation; or proved ſufficiently ſimple, clear, and conciſe, to be univerſally ſtudied and practiſed.

Some ſyſtems are replete with unmeaning ſymbols, perplexing arbitraries, and ill-judged contractions: which render them ſo difficult to be attained by a common capacity, or ordinary application, that it is not to be wondered at if they have ſunk into neglect, and are now no longer known (C). Other ſyſtems, by being too prolix, by containing a multiplicity of characters, and thoſe characters not ſimply or eaſily remembered, become ineffectual to the purpoſe of expedition, and are only ſuperior in obſcurity to a common hand. Some, again, not only reject all arbitraries and contractions, but even prepoſitions and terminations; which laſt, if not too laviſhly employed and badly deviſed, highly contribute to promote both expedition and legibility; and though they reduce their characters to fewer than can poſſibly expreſs the various modifications of ſound, yet they make nearly one half of them complex. In the diſpoſition of the vowels, there is the greateſt perplexity in moſt ſyſtems. A dot is ſometimes ſubſtituted for all the vowels indiſcriminately, and the judgment is left to determine which letter out of ſix any dot is intended to expreſs; or a minute ſpace is alloted them; ſo that unleſs they be arranged with mathematical preciſion they cannot be diſtinguiſhed from one another; but ſuch a minute attention is inconſiſtent with the nature of ſhort-hand, which ſhould teach us to write down in a ſhort time, as well as in ſmall bounds, what we wiſh to preſerve of what we hear. Nor is the plan of lifting the pen and putting the next conſonant in the vowel's place, in the middle of words, leſs liable to objections; or that of repreſenting all the vowels by diſtinct characters, being obviouſly ill calculated for facility and diſpatch, and conſequently inadmiſſible into any uſeful ſyſtem.

It is to be confeſſed, that the perſon who firſt propoſed

(A) The value of ſtenography is not unknown to the learned; and the care and ſucceſs with which it has been lately cultivated in theſe kingdoms will, in all probability, ſoon render it an object of general attention. No one, however, appears to us to have ſimplified and improved the art ſo much as Dr Mavor, author of *Univerſal Stenography*, who has liberally permitted us to preſent our readers with a complete view of his ſcheme. To thoſe who wiſh to become proficients in SHORT-WRITING, we earneſtly recommend his entire publication (printed for Cadell and Davis, Strand, London), which in many ſchools of the firſt reputation now forms a deſerved claſs-book.

(B) Mr Locke ſays, a regular method of ſhort-writing ſeems to be known and practiſed only in Britain. This is not now the caſe; and indeed there is no reaſon to doubt whether characters may not be invented to expreſs the various ſounds, or letters, employed in any language, either ancient or modern.

(C) A liſt of writers on ſtenography. Mr Addy, Aldridge, Angell, Annet, Blandemore, Bloſſet, Botley, Bridges, Byrom, Coles, Croſs, Dix, Everardt, Ewen, Facey, Farthing, Gibbs, Græme, Gurney, Heath, Holdſworth, Hopkins, Jeake, Labourer, Lane, Lyle, Macauley, Maſon, Mavor, Metcalfe, Nicholas, Palmer, Rich, Ridpath, Shelton, Steele, Tanner, Taylor, Thickneſſe, Tiffen, Webſter, Weſton, Williamſon, Willis, B. D. and Willis, &c.

posed the omission of vowels in the middle of words (D), which it is obvious are not wanted, and invented letters, which could be connected as in a running hand without lifting the pen in the middle of the word, made a real improvement on the works of his predecessors. But, in fine, most systems, either in their plan or execution, labour under some capital defect, attended with circumstances highly discouraging to the learner, and which in a great measure defeat the end of their invention, by being too complicated to be learned with ease and remembered with accuracy, or to be practised with the expedition which is requisite; and so difficult to be deciphered, that a man can scarcely read what he has just written.

To obviate these defects; to provide against prolixity and conciseness, which might occasion obscurity; to exhibit a system founded on the simplest principles, which might be easily learned and read, and yet be capable of the utmost expedition—were the motives that gave rise to the present attempt.

This method will be found different from any yet published, and superior to all in the disposition of the vowels and the facility of arranging them; the confusion in placing which seems to detract from the merit of the best performances on the subject; and it may be affirmed, without ostentation, that characters simpler in their form, and more perfect in their union, have not been applied to the art of stenography.

As well as it could be determined, the simplest characters are appropriated to the letters most usually employed: indeed, as far as possible, those which are complex have been rejected; but as it was an object always kept in view that the writing should be on a line, a few are admitted into the alphabet for that reason.

The characters for the double and triple consonants are the easiest that could be invented, consistent with perspicuity (E); for care has been taken to provide against all obscurity which might arise by adopting letters too similar in their formation; and with respect to the prepositions and terminations, those which occur most frequently are expressed by the simplest characters, which will be found perfectly easy in their application.

The arbitraries are few in number (F), and the arbitrary abbreviations, as they are entirely from the letters of the alphabet, and chosen from some thousands of words in common use, will well repay the learner for an hour's trouble in committing them to memory.

The last chapter lays down a scheme of abbreviation, comprised in a few rules, perfectly easy to be understood and practised by proficients in this art, which we hope will answer the expectation of the author, and will be found free from the perplexity complained of in many systems where abbreviation is admitted. The principal rules are new, are so easy, so extensive in their use, and so consistent with expedition and legibility, if applied with judgment, that they alone might suffice. The learner is however advised by no means to adopt any of them, till experience has convinced him that they may be used without error or injury to legibility. All abbreviating rules are suited to those only who have made some progress in the stenographic art; for although they certainly promote expedition in a wonderful manner, and afford the greatest ease to a proficient, yet a learner, as expedition is not his first, though his ultimate view, should admit of nothing that in the least renders the reading difficult.

CHAP. II.

1 The general principles of stenography.

The English alphabet consists of twenty-six letters; six of which are vowels, *a*, *e*, *i*, *o*, *u*, and *y*; and the other twenty consonants, *b*, *c*, *d*, *f*, *g*, *h*, *j*, *k*, *l*, *m*, *n*, *p*, *q*, *r*, *s*, *t*, *v*, *w*, *x*, and *z*.

This alphabet, as is observed by the best grammarians that have written on the language, is both defective and redundant in expressing the various modifications of sound*.

Custom or prejudice has assigned some letters a place, when others would with much more propriety express the same sound: and to this may be added, that several letters, sometimes in one word, seem to be admitted for no other reason than to perplex a young beginner or a foreigner, as an obstruction to true pronunciation, and to add to the apparent length of the word, when they are entirely quiescent and useless. That this is the genius of the orthography of our language must be perceived by the most superficial observer; but no modern tongue is absolutely free from the same exceptions. In particular, the French has a great number of dormant letters, which, it is obvious, render the pronunciation more difficult and perplexing to learners (G).

* Lowth's Gram. Priestley's Gram. Sheridan's Lectures on Elocution.

But as it is neither our business nor our intention to propose a mode of spelling different from that in common use, when applied to printing or long-hand writing (since several innovators in orthography have fallen into contempt, and their plans have been only preserved as beacons to warn others of the folly of endeavouring to subvert established principles §); we shall only observe, that in stenography, where the most expeditious and concise method is the best, if consistent with perspicuity, the following simple rules are studiously to be regarded and practised.

§ Preface to Johnson's Dictionary.

Rule I. All quiescent consonants in words are to be

(D) Mr Byrom rejected vowels entirely in the middle of words, as others before him had only done partially. Without critically examining the executive part of his performance, which is very defective, it must be owned, that it is above the reach of human ingenuity to exceed his general plan; which for ever must be the basis of every future rational system.

(E) Those for *th* and *ch* may be either made upright or sloping to the right.

(F) These are not by any means proscribed; they may be employed or not according to the fancy of the learner.

(G) The Latin and Greek claim a just superiority over every modern tongue in this respect. In them no confusion or doubt can arise from the manner of spelling; and the reader can scarcely be wrong (unless in quantity) in sounding all the letters he sees.

2 Rules for the conſonants.

be dropped; and the orthography to be directed only by the pronunciation: which being known to all, will render this art attainable by thoſe who cannot ſpell with preciſion in long hand.

Rule II. When the abſence of conſonants, not entirely dormant, can be eaſily known, they may often be omitted without the leaſt obſcurity.

Rule III. Two or ſometimes more conſonants may, to promote greater expedition, be exchanged for a ſingle one of nearly ſimilar ſound; and no ambiguity as to the meaning enſue (h).

Rule IV. When two conſonants of the ſame kind or ſame ſound come together, without any vowel between them, only one is to be expreſſed; but if a vowel or vowels intervene, both are to be written: only obſerve, if they are perpendicular, horizontal, or oblique lines, they muſt only be drawn a ſize longer than uſual; and characters with loops muſt have the ſize of their heads doubled||.

|| Vide Plate ccccLXXXII.

3 Firſt rule exemplified.

Might is to be written *mit*, ſight *ſit*, machine *maſhin*, enough *enuf*, laugh *laf*, prophet *profet*, phyſics *fiſiks*, through *thro'*, foreign *foren*, ſovereign *ſoveren*, pſalm *ſam*, receipt *reſet*, write *rite*, wright *rit*, iſland *iland*, knavery *navery*, temptation *temtation*, knife *niſe*, ſtick *ſtik*, thigh *thi*, honour *onour*, indictment *inditement*, acquaint *aquaint*, chaos *kaos*, &c.

4 Second rule exemplified.

Strength *ſtrenth*, length *lenth*, friendſhip *frenſhip*, connect *conek*, commandment *comanment*, conjunct *conjunt*, humble *humle*, lumber *lumer*, ſlumber *ſlumer*, number *numer*, exemplary *exemlary*, &c.

5 Third rule exemplified.

Rocks *rox*, acts *aks* or *ax*, facts *faks* or *fax*, diſtricts *diſtriks* or *diſtrix*, affects *afeks* or *afex*, afflicts *afliks* or *aflix*, conquer *konkr*, &c.

6 Fourth rule exemplified.

Letter *leter*, little *litle*, command *comand*, error *eror*, terror *teror*, &c. But in *remember*, *moment*, *ſiſter*, and ſuch like words, where two conſonants of the ſame name have an intervening vowel, both of them muſt be written.

Theſe four rules with their examples, being carefully conſidered by the learner, will leave him in no doubt concerning the diſpoſition and management of the conſonants in this ſcheme of ſhort-writing; we ſhall therefore proceed to lay down rules for the application of the vowels with eaſe and expedition.

7 Rules for the vowels

Rule I. Vowels, being only ſimple articulate ſounds, though they are the connectives of conſonants, and employed in every word and every ſyllable, are not neceſſary to be inſerted in the middle of words; becauſe the conſonants, if fully pronounced, with the aſſiſtance of connection, will always diſcover the meaning of a word, and make the writing perfectly legible.

Rule II. If a vowel is not ſtrongly accented in the incipient ſyllable of a word, or if it is mute in the final, it is likewiſe to be omitted; becauſe the ſound of the incipient vowel is often implied in that of the firſt conſonant, which will conſequently ſupply its place.

Rule III. But if the vowel conſtitutes the firſt or laſt ſyllable of a word, or is ſtrongly accented at its beginning or end, that vowel is continually to be written.

Rule IV. If a word begins or ends with two or more vowels though ſeparated, or when there is a coalition of vowels, as in dipthongs and tripthongs; only one of them is to be expreſſed, which muſt be that which agrees beſt with the pronunciation.

Rule V. In monoſyllables, if they begin or end with a vowel, it is always to be inſerted, unleſs the vowel be *e* mute at the end of a word.

Such are the general principles of this art; in vindication and ſupport of which it will be needleſs to offer any arguments, when it is conſidered that brevity and expedition are the chief objects, if conſiſtent with legibility; and the ſubſequent ſpecimens in the orthography recommended will, we hope, be ſufficient to ſhow that there is no real deficiency in the laſt mentioned particular.

8 Specimen of the mode of ſpelling in ſtenography.

He who md us mſt be etrnl, grt, nd mnptnt. It is ur dty, as rſnl bngs, to ſrv, lv, nd oby hm.—A mn tht wd avd blm, ſhd be ſrkmſpk in al hs axns, nd ndvr wth al hs mt to pls evry bdy.—I wd nt frm any knxns wth a mn who hd no rgrd fr hmſlf; nthr wd I blv a mn who hd ons tld me a li.—Onr is of al thngs the mſt dfklt to prſrv ntrnſhd; nd whn ons mpchd, lk the chſty of a wmn, nvr ſhns wth its wntd lſtr.—Wth gd mnrs, kmplſns nd an eſy plt adrs, mny mk a fgr in the wrl, whs mntl ablts wd ſkrſly hv rsd thm abv the rnk of a ſtmn.—Idlns is the prnt of a thſnd mſfrtns, wch ar nvr flt by the ndſtrs: it is a pn nd a pnſhmnt of itslf, nd brngs wnt nd bgry in its trn.—Vrtu is the frſt thng tht ſhd be rgrdd; it is a rwrd of itslf; mks a mn rſpktbl hr, nd wl mk hm etrnly hpy hrftr.—Prd is a mſt prnſs pſn, wch yt ws plntd by hvn in ur ntr, to rs ur emlsn to imtt grt nd wrthy krktrs or axns, to xt in us a sl fr wht is rt nd gſt, nd a ldbl ndgnſn gnſt oprſrs nd wrkrs of any knd of nkty; in ſhrt, to mk us st a prpr vlu upn urſlvs, nd dſps a wrthls ſlo, hu evr xltd. Ths fr prd is a vrtu, nd my gſtly be kld a grtns of ſl. Bt prd, lk othr pſns, gnrly fxs upn rng obgks, or is apld in rng prprſns. Hu kmn is it to ſe a rtch whm evry vs hs rndrd mſrbl, nd evry ſly kntmtbl, vlng hmſlf on hs hi brth, nd bſtng ths ilſtrs nſſtrs, of whm he nhrts nthng bt the nm or ttl! nſſtrs who if thy nu hm, wd dſn thr dpndnt wth kntmt. But al prd of ths ſrt is ſly, nd evr to be avdd.

CHAP. III.

As the whole of this art depends upon a regular method and a ſimple alphabet, we have not only endeavoured to eſtabliſh the former on ſatisfactory principles, but have been careful to appropriate, according to the comparative frequency of their occurrence, ſuch characters for the letters as, after repeated trials and alterations, were conceived to be the beſt adapted for diſpatch.

9 Stenographic alphabet.

The ſtenographic alphabet conſiſts of 18 diſtinct characters (viz. two for the vowels and the reſt for the conſonants), taken from lines and ſemicircular curves; the formation and application of which we ſhall now explain, beginning with the vowels.

For the three firſt vowels, *a*, *e*, and *i*, a comma is appropriated

(h) By this rule likewiſe *q* and *v* in the middle of words, but never in the beginning, may be exchanged for *k* and *f*, when they admit of an eaſier connection with the following character, or will make the writing appear neater.

propriated in different positions; and for the other three, *o*, *u*, and *y*, a point. The comma and point, when applied to *a* and *o*, is to be placed, as in Plate CCCCLXXXII. at the top of the next character; when for *e* and *u*, opposite to the middle; and when for *i* and *y*, at the bottom.

This arrangement of the vowels is the most simple and distinct that can easily be imagined. Places at the top, the middle, and the bottom of characters, which make three different positions, are as easily distinguished from one another as any three separate characters could be; and a comma is made with the same facility as a point.

10 Lines. Simple lines may be drawn four different ways; perpendicular, horizontal, and with an angle of about 45 degrees to the right and left. An ascending oblique line to the right, which will be perfectly distinct from the rest when joined to any other character, may likewise be admitted. These characters being the simplest in nature, are assigned to those five consonants which most frequently occur, viz. *l*, *r*, *t*, *c* hard or *k*, and *c* soft or *s*.

11 Circles. Every circle may be divided with a perpendicular and horizontal line, so as to form likewise four distinct characters. These being the next to lines in the simplicity of their formation, we have appropriated them for *b*, *d*, *n*, and *m*.

12 Curves and lines. The characters expressing nine of the consonants are all perfectly distinct from one another; eight only remain which are needful, viz. *f*, *g* or *j*, *h*, *p*, *q*, *v*, *w*, and *x*. To find characters for which we must have recourse to mixed curves and lines. The characters which we have adopted are the simplest in nature after those already applied, admit of the easiest joining, and tend to preserve lineality and beauty in the writing.

It must be observed that we have no character for *c* when it has a hard sound, as in *castle*; or soft, as in *city*; for it naturally takes the sound of *k* or *s*, which in all cases will be sufficient to supply its place.

R likewise is represented by the same character as *l*; only with this difference, *r* is written with an ascending stroke (I), and *l* with a descending; which is always to be known from the manner of its union with the following character; but in a few monosyllables where *r* is the only consonant in the word, and consequently stands alone, it is to be made as is shown in the alphabet for distinction's sake.

Z, as it is a letter seldom employed in the English language, and only a coarser and harder expression of *s*, must be supplied by *s* whenever it occurs; as for *Zedekiah* write *Sedekiah*, &c.

CHAP. IV.

The prepositions and terminations in this scheme are so simple, that the greatest benefit may be reaped from them, and very little trouble required to attain them; as the incipient letter or the incipient consonant of all the prepositions and of several of the terminations is used to express the whole. But although in Plate CCCCLXXXII. sufficient specimens are given of the manner of their application, that the learner of less ingenuity or more slow perception may have every assistance, we have subjoined the following directions. 13 Rules for prepositions and terminations.

Rule I. The preposition is always to be written without joining, yet so near as plainly to show what word it belongs to; and the best way is to observe the same order as if the whole was to be connected.

Rule II. A preposition, though the same letters that constitute it may be met with in the middle or end of a word, is never to be used, because it would expose to obscurity.

Rule III. Observe that the proposition *omni* is expressed by the vowel *o* in its proper position; and for *anti*, *anta*, *ante*, by the vowel *a*, which the radical part of the word will easily distinguish from being only simple vowels.

The first rule for the prepositions is (allowing such exceptions as may be seen in the Plate) to be observed for the terminations; and also the second *mutatis mutandis*; except that whenever *sis*, *sus*, *sys*, *cious*, *tious*, and *ces* occur, they are to be expressed as directed in the fourth rule for the consonants, whether in the beginning, middle, or end of words (K).

Rule IV. The terminative character for *tion*, *sion*, *cion*, *cian*, *tian*, is to be expressed by a small circle joined to the nearest letter, and turned to the right; and the plurals *tions*, *sions*, *cions*, *cians*, *tians*, *tience*, by a dot on the same side.

Rule V. The terminative character for *ing*, is to be expressed likewise by a small circle, but drawn to the left hand; and its plural *ings* by a dot (L).

Rule VI. The plural sign *s* is to be added to the terminative characters when necessary.

Rule VII. The separated terminations are never to be used but in polysyllables or words of more syllables than one.

These rules duly observed will point out a method as concise and elegant as can be desired, for expressing the most frequent and longest prepositions and terminations in the English language. If it should be thought necessary to increase their number by the addition of others, it will be an easy matter for any one of the least discernment to do so, by proceeding on the principles before laid down.

CHAP. V.

Though a more concise method of writing, or more numerous abbreviations, may not be indispensably necessary, if the foregoing directions be practised for a considerable time, yet contractions will be found extremely 14 Rules for abbreviations.

(I) The character for *h*, when lineality requires it, may be made from the bottom and inverted (see Plate CCCCLXXXII.) And often *h* may be omitted entirely; or a vowel may be substituted in its stead, without any injury to legibility, it being rather a breathing than letter.

(K) But in a few words where three horizontal characters meet, it will be better to express the *sis*, &c. by the semielliptical character in Plate CCCCLXXXII. opposite *tious*.

(L) In horizontal characters, by the left hand is meant the top, and by the right the space below the letter (see *ing* joined, Plate CCCCLXXII.) In all other characters the right and left positions will naturally be known.

tremely useful and convenient to those who have attained a proper knowledge of the subject, and lead to a greater degree of expedition, at the same time that they diminish the labour of writing. It has been observed in the introduction, that abbreviations are only to be employed by proficients in this art; because expedition is not the first, though the ultimate, object in view: and that an easy legibility is of the utmost consequence to the learner; which, however, cannot be preserved, if he adopts too soon those very rules which in time will afford him the greatest ease when applied with judgement.

The following short and practical rules will be found, we hope, fully adequate to every purpose for which they were intended, and are far superior in the facility of their application to any which we have seen.

RULE I. The usual abbreviations in long-hand are always to be followed; as Mr for Master, M. D. for Doctor of Physic, and Abp. for Archbishop, &c.

RULE II. Substantives, adjectives, verbs, and participles, when the sense will direct to the meaning, are to be expressed by their initial consonant with the distinguishing marks exhibited in Plate CCCCXXXII. viz. a substantive must have the dot exactly over its initial consonant; an adjective must have a dot under it; a verb is to be expressed by a comma over its initial consonant; and a participle by a comma under (M). These being the four principal parts of speech will be sufficient; and an adept will never be at a loss to know when he can with safety apply this rule to them.

RULE III. To render the writing more legible, the last letter of the word may be joined to the first, and the proper mark applied.

RULE IV. The constituent or radical part of words, especially if they are long, will often serve for the whole, or sometimes the first syllable; as, we ought to moderate our *ex.* by our *circum.*; a man's *man.* commonly shape his *for.*

RULE V. All long words without exception may have their prepositions or terminations expressed by the incipient consonant of such preposition or termination.

RULE VI. When there is a great dependence between the parts of a sentence, the initial letter will often suffice; as *L.* is the capital of Great *B.*; the eldest *S.* of the king of Great *B.* is styled prince of *W.* Every one, it is presumed, will allow this to be perfectly legible in long-hand, then why may it not in stenography?

RULE VII. The terminations *ness* and *less* may be omitted; as *faithfulness* is only to be written *faithful*; *forwardness*, *forward*; *heedless*, *heed*; *stubbornness*, *stubborn*, &c.

RULE VIII. The second and third persons of verbs, ending in *eth* and *est* may be expressed by *s*; as, he *loves*, thou *teaches*; instead of he *loveth*, thou *teachest*: or even without *s*; as, he *love*, &c.

RULE IX. Words may often be entirely omitted, and yet no ambiguity ensue; as, *In beginning God created heaven and earth*, for In *the* beginning God created *the* heaven and *the* earth.

RULE X. When there is an immediate repetition of a sentence or word, a line is to be drawn under the sentence or word to be repeated; as, Amen, Amen, is to written <u>*Amen*</u>; but if any words intervene before a word or sentence is to be repeated, the line must be drawn as before, and a ∧ or mark of omission placed where the repetition should begin; as, <u>*Is it just the innocents should be*</u> condemned ∧ reviled?

THE CONTENTS of the STENOGRAPHIC PLATES.

Fabricius's Reply to Pyrrhus.

As to my poverty, you have indeed, Sir, been rightly informed. My whole estate consists in a house of but mean appearance, and a little spot of ground, from which by my own labour I draw my support. But if by any means you have been persuaded to think, that this poverty makes me less considered in my country, or in any degree unhappy, you are extremely deceived. I have no reason to complain of fortune, she supplies me with all that nature requires; and if I am without superfluities, I am also free from the desire of them. With these I confess I should be more able to succour the necessitous, the only advantage for which the wealthy are to be envied; but as small as my possessions are, I can still contribute something to the support of the state and the assistance of my friends. With regard to honours, my country places me, poor as I am, upon a level with the richest: for Rome knows no qualifications for great employments but virtue and ability. She appoints me to officiate in the most august ceremonies of religion; she entrusts me with the command of her armies; she confides to my care the most important negotiations. My poverty does not lessen the weight and influence of my counsels in the senate; the Roman people honour me for that very poverty which you consider as a disgrace; they know the many opportunities I have had in war to enrich myself without incurring censure; they are convinced of my disinterested zeal for their prosperity; and if I have any thing to complain of in the return they make, it is only the excess of their applause. What value then can I set upon your gold and silver! What king can add any thing to my fortune! Always attentive to discharge the duties incumbent on me, I have a mind free from self-reproach, and I have an honest fame. *Dodsley's Preceptor.* Plate CCCCLXXXIII.

Letter to a Friend against Waste of Time.

Converse often with yourself, and neither lavish your time, nor suffer others to rob you of it. Many of our hours are stolen from us, and others pass insensibly away; but of both these losses the most shameful is that which happens through our own neglect. If we take the trouble to observe, we shall find that one considerable part of our life is spent in doing evil, and the other in doing

(M) The dot or comma being placed thus will never occasion them to be mistaken for vowels, because they should always be on one side or other; whereas the mark for parts of speech must constantly be placed exactly over or under.

doing nothing, or in doing what we ſhould not do. We don't ſeem to know the value of time, nor how precious a day is; nor do we conſider that every moment brings us nearer our end. Reflect upon this, I entreat you, and keep a ſtrict account of time. Procraſtination is the moſt dangerous thing in life. Nothing is properly ours but the inſtant we breathe in, and all the reſt is nothing; it is the only good we poſſeſs; but then it is fleeting, and the firſt comer robs us of it. Men are ſo weak, that they think they oblige by giving of trifles, and yet reckon that time as nothing for which the moſt grateful perſon in the world can never make amends. Let us therefore conſider time as the moſt valuable of all things; and every moment ſpent, without ſome improvement in virtue or ſome advancement in goodneſs, as the greateſt ſublunary loſs.

St Paul's Speech before Agrippa and Feſtus.

I think myſelf happy, king Agrippa, that I ſhall anſwer for myſelf this day before thee, touching all things whereof I am accuſed of the Jews: eſpecially becauſe I know thee to be expert in all cuſtoms and queſtions which are among the Jews, wherefore I beſeech thee to hear me patiently. My manner of life from my youth, which was at firſt among mine own nation at Jeruſalem, know all the Jews, which knew me from the beginning (if they would teſtify), that, after the ſtraiteſt ſect of our religion I lived a Phariſee. And now I ſtand and am judged for the hope of the promiſe made by God unto our fathers: unto which promiſe our twelve tribes inſtantly ſerving God day and night hope to come; for which hope's ſake, king Agrippa, I am accuſed of the Jews. Why ſhould it be thought a thing incredible with you, that God ſhould raiſe the dead, when God himſelf has given aſſurance of it unto all men, in that he hath raiſed Chriſt from the dead? As for my own part, moſt noble Feſtus, I own I once verily thought that even I myſelf ought to do many things contrary to the name of Jeſus of Nazareth. Which thing I alſo did in Jeruſalem. I puniſhed the ſaints oft in every ſynagogue, and compelled them to blaſpheme; and being exceedingly mad againſt them, I perſecuted them even unto ſtrange cities. In purſuit of which, as I went to Damaſcus, with authority and commiſſion from the chief prieſts: At mid-day, O king, I ſaw in the way a light from heaven, above the brightneſs of the ſun, ſhining about me, and them which journeyed with me. And when we were all fallen to the earth, I heard a voice ſpeaking unto me, and ſaying in the Hebrew tongue, Saul, Saul, why perſecuteſt thou me? It is hard for thee to kick againſt the pricks. And I ſaid, Who art thou, Lord? And he ſaid, I am Jeſus whom thou perſecuteſt. But riſe, and ſtand upon thy feet: for I have appeared unto thee for this purpoſe to make thee a miniſter and a witneſs both of theſe things which thou haſt ſeen, and of thoſe things in which I will appear unto thee. Whereupon, O king Agrippa, I was not diſobedient to the heavenly viſion: but ſhewed firſt unto them of Damaſcus, and at Jeruſalem, and throughout all the coaſts of Judea, and then to the Gentiles, that they ſhould repent and turn to God. For theſe cauſes the Jews caught me in the temple, and went about to kill me. Having therefore obtained help of God, I continue unto this day, witneſſing both to ſmall and great, ſaying none other things than thoſe which the prophets and Moſes did ſay ſhould come: That Chriſt ſhould ſuffer, and that he ſhould be the firſt that ſhould riſe from the dead, and ſhould ſhow light unto the people, and to the Gentiles. This is the real truth: Believe me, I am no peſtilent fellow, nor mover of ſedition; but always endeavour all that lies in me to preſerve a conſcience void of offence towards God and towards man: nor can the Jews prove the things whereof they now accuſe me. Neither am I, Feſtus, beſide myſelf; but ſpeak thus freely before the king, becauſe he knows theſe things to be fact; yea, I am fully perſuaded the king knows them all to be fact; for they were not done in a corner. King Agrippa, believeſt thou the prophets? I know that thou believeſt. And would to God that not only thou but alſo all that hear me this day, were altogether ſuch as I am except theſe bonds. *Holmes's Rhetoric.*

Pope to Atterbury.

Once more I write to you as I promiſed, and this once I fear will be the laſt; the curtain will ſoon be drawn between my friend and me, and nothing left but to wiſh you a long good night; may you enjoy a ſtate of repoſe in this life not unlike that ſleep of the ſoul which ſome have believed is to ſucceed it, where we lie utterly forgetful of that world from which we are gone, and ripening for that to which we are to go. If you retain any memory of the paſt, let it only image to you what has pleaſed you beſt; ſometimes preſent a dream of an abſent friend, or bring you back an agreeable converſation. But, upon the whole, I hope you will think leſs of the time paſt than the future; as the former has been leſs kind to you than the latter infallibly will be. Do not envy the world your ſtudies: They will tend to the benefit of men, againſt whom you can have no complaint; I mean, of all poſterity: and, perhaps, at your time of life, nothing elſe is worth your care. What is every year of a wiſe man's life but a cenſure or critic on the paſt? Thoſe whoſe date is the ſhorteſt, live long enough to laugh at one half of it: The boy deſpiſes the infant, the man the boy, the philoſopher both, and the Chriſtian all. You may now begin to think your manhood was too much a puerility; and you will never ſuffer your age to be but a ſecond infancy. The toys and baubles of your childhood are hardly now more below you than thoſe toys of our riper and our declining years; the drums and rattles of ambition, and the dirt and bubbles of avarice. At this time, when you are cut off from a little ſociety, and made a citizen of the world at large, you ſhould bend your talents not to ſerve a party, or a few, but all mankind. Your genius ſhould mount above that miſt, in which its participation and neighbourhood with earth hath long involved it: To ſhine abroad, and to heaven, ought to be the buſineſs and the glory of your preſent ſituation. Remember it was at ſuch a time that the greateſt lights of antiquity dazzled and blazed the moſt; in their retreat, in their exile, or in their death. But why do I talk of dazzling or blazing? it was then that they did good, that they gave light, and that they became guides to mankind. Thoſe aims alone are worthy of ſpirits truly great, and ſuch I therefore hope will be yours. Reſentment indeed may remain, perhaps cannot be quite extinguiſhed, in the nobleſt minds; but revenge will never harbour there: Higher principles than

FABRICIUS' REPLY TO PYRRHUS.

LETTER &c.

St. PAUL'S SPEECH.

POPE TO ATTERBURY.

Vallance sc

than those of the first, and better principles than those of the latter, will infallibly influence men whose thoughts and whose hearts are enlarged, and cause them to prefer the whole to any part of mankind, especially to so small a part as one's single self. Believe me, my Lord, I look upon you as a spirit entered into another life, as one just upon the edge of immortality, where the passions and affections must be much more exalted, and where you ought to despise all little views and all mean retrospects. Nothing is worth your looking back; and therefore look forward, and make (as you can) the world look after you; but take care it be not with pity, but with esteem and admiration. I am, with the greatest sincerity and passion for your fame as well as happiness, your, &c.

The above most charming and most affectionate letter was written about a month before Atterbury bishop of Rochester was sent into banishment, and is universally admired.

STENTOROPHONIC TUBE, a speaking trumpet; thus called from Stentor, a person mentioned by Homer. See TRUMPET.

STEP, in a ship, a block of wood fixed on the decks or bottom of a ship, and having a hole in its upper side, fitted to receive the heel of a mast or capstern. The steps of the main and foremasts of every ship rest upon the kelson, to which they are firmly secured by knees, bolts, or spike-nails. The step of the mizen-mast usually rests upon the lower deck.

STEPHANIUM, in botany: A genus of the *monogynia* order, belonging to the *pentandria* class of plants; and in the natural method ranking under the 47th order, *Stellatæ*. The calyx is monophyllous, turbinated, and quinquepartite; the corolla is monopetalous, funnel-shaped, having its tubes curved and ventricose: the pericarpium is a bilocular berry containing two seeds, flattened on one side and round on the other. This genus is nearly allied to that of *Psychotria*. There is only one species, viz. *Guianense*, a native of the warmer parts of America.

STEPHANOPHORUS, in antiquity, the chief priest of Pallas, who presided over the rest. It was usual for every god to have a chief priest; that of Pallas was the Stephanophorus just mentioned, and that of Hercules was called Dadouchus.—Stephanophorus was also a priest that assisted the women in the celebration of the festival Thesmophoria.

STEPHANUS (Byzantinus), an able grammarian, who lived in the 5th or 6th century. He wrote a Dictionary, in which he made a great number of observations, borrowed from mythology and history, which showed the origin of cities and colonies, of which we have nothing remaining but a mean abridgment by Hermolaus the grammarian; but from that work the learned have received great light; and Sigonius, Casaubon, Scaliger, Salmasius, &c. have employed themselves in illustrating it.

STEPHEN, king of England. See ENGLAND, n° 108, &c.

STEPHEN, or *St Stephen's Day*, a festival of the Christian church, observed on the 26th of December, in memory of the first martyr St Stephen.

STEPHENS, a family of printers deservedly celebrated. They flourished at the revival of learning, and contributed a great deal towards dispelling the cloud of ignorance which had so long overshadowed Europe. Some of the classics before the 16th century were in a great measure lost, and all of them were exceedingly corrupted. By their abilities and indefatigable industry these defects were supplied, and the learned were furnished with beautiful and correct editions of the Greek and Roman authors. Thus the world was not only supplied with an inexhaustible fund of amusement and instruction in these ancient writings; but it is to the ardour which they inspired, and to the model of elegance which they displayed, that the present advanced state of literature is in a great measure owing.

HENRY STEPHENS, the first of these illustrious men, was born in France, soon after the discovery of printing, perhaps about the year 1465. He settled as a printer at Paris, and was probably patronized by Louis XII. A great proportion of the books which he published were Latin: They are printed in the Roman letter, and are not inelegant, though some of them abound rather too much in contractions. He died about the year 1520, and left behind him three sons, Francis, Robert, and Charles. His widow married Simon de Colines (*Colinæus* in Latin), who thus got possession of Henry's printing-house, and continued the profession till his death.

Of FRANCIS, the eldest son, little more is known than that he carried on business along with his father-in-law Colinæus, and that he died at Paris in 1550.

ROBERT STEPHENS, the second son, was born in 1503. In his youth he made great proficiency in the Roman, Greek, and Hebrew languages, and at the age of 19 had acquired so much knowledge, that his father-in-law entrusted him with the management of his press. An edition of the New Testament was published under his inspection, which gave great offence to the Paris divines, who accused him of heresy, and threatened to prevent the sale of the book. Soon after he began business himself, and married Perrete the daughter of Jodocus Badius, a printer and an author. She was a woman of learning, and understood Latin, which indeed was the necessary consequence of her situation. Her husband always entertained a number of learned men as correctors of the press: Being foreigners, and of different nations, they made use of no other language but Latin; which Perrete being accustomed to hear, was able in a short time not only to understand, but even to speak with tolerable ease.

In 1531 he published his Latin "Thesaurus;" a work of great importance, which he laboured at for two years. The mark which he put upon all his books was a tree branched, with a man looking upon it, and these words *noli altum sapere*, to which he sometimes added *sed time*. In 1539, Francis I. made him his printer, and ordered a new set of elegant types to be founded for him. His frequent editions of the New Testament gave great offence to the doctors of the Sorbonne, who accused accuse him of heresy for his annotations, and insisted upon the suppression of some of his books. Although Henry the French king in some measure protected him, the persecution of these divines rendered him so unhappy, not to mention the expence and loss of time which an almost constant attendance at court unavoidably occasioned, that in 1552 he abandoned his country and went to Geneva. Here he embraced the protestant religion, and thus justified in some measure the suspicions of his theological enemies. It has been affirmed by several writers that he carried along with him the royal types, and the moulds also in which they were cast; but it is certain that he never afterwards made use of those types. Besides, is it possible that the author of so daring a theft could have been not only protected in Geneva, but even courted and honoured by the most eminent men of the age? Is it credible that such a crime could have been concealed for 60 years; or that Henry, the son and heir of the perpetrator, would have enjoyed the favour of the French king, if Robert Stephens had acted such a shameful part? If he was burnt in effigy at Paris, it was not for theft, but for having changed his religion. After his arrival at Geneva, he published an account of the dispute between him and the Paris divines, which does as much honour to his abilities as his *Thesaurus* does to his learning. He died in 1559, after a life of the most extraordinary industry. The books of which he was the editor were not fewer than 360. Many of them were ancient classics in different languages. Several were accompanied with annotations which he collected, and all of them were corrected by collating manuscripts. He was so anxious to attain perfect accuracy, that he used to expose his proofs in public, and reward those who discovered a mistake. His books consequently were very correct. It is said that his New Testament, called *O Mirificam* (because the preface begins with these words), has not a single fault.

It was Robert Stephens who first divided the New Testament into verses during a journey between Paris and Lyons. The advantages of this improvement are fully counterbalanced by its defects. It has destroyed the unity of the books, and induced many commentators to consider every verse as a distinct and independent aphorism. To this in some measure is to be ascribed the many absurd interpretations and creeds that have been forced out of that book.

By his last will his estate was left exclusively to such of his children as should settle at Geneva. He left behind him three sons, Henry, Robert, and Francis.

Charles Stephens, the third son of Henry, was, like the rest of his family, familiarly acquainted with the learned languages. This recommended him to Lazarus de Baif, who made him tutor to his son, and in 1540 carried him along with him to Germany. He studied medicine, and practised it with success in France. He did not, however, forsake the profession of his family, but exercised it in Paris, where he became the editor of many books remarkable for neatness and elegance. He wrote above thirty treatises on different subjects, particularly on botany, anatomy, and history. He died in 1564.

Robert Stephens, the son of Robert the first of that name, did not accompany his father to Geneva, but continued to profess the Catholic religion, and to reside at Paris. His letter was remarkably beautiful.— He was made king's printer, and died about 1589.

His brother Francis was also a printer. He embraced the Protestant religion, and resided at Geneva.

Henry Stephens, the remaining son of Robert, was born at Paris in 1528. He became the most learned and most celebrated of all his family. From his very birth almost he gave proofs of uncommon abilities, and displayed an ardent passion for knowledge. The Medea of Euripides, which he saw acted while at school, first kindled his love for poetry, and inspired him with the desire of acquiring the language in which this tragedy is written. He intreated his father not to condemn him to study Latin, which he already understood from conversation, but to initiate him at once into the knowledge of Greek. His father willingly granted his request; and Henry applied with such vigour, that in a short time he could repeat the Medea by heart. He afterwards studied Greek under Peter Danesius, who was tutor to the Dauphin, and finally heard the lectures of Tusanus and Turnebus. He became eager at an early age to understand astrology, and accordingly attended a professor of that mysterious art; but he was not long in discovering its absurdity. At 19 he began his travels, which he undertook in order to examine foreign libraries, and to become acquainted with learned men. He spent two years in Italy, and returned into France completely master of Italian, and bringing along with him copies of several scarce authors, particularly a part of Anacreon, which before was thought lost.

He found his father publishing an edition of the New Testament, to which he prefixed some Greek verses.— Soon after, he visited England and the Netherlands, where he met with John Clement, an Englishman, to whom he was indebted for the remaining odes of Anacreon. During this journey he learned the Spanish language, which was very much spoken at that time in the Low Countries.

Whether Henry accompanied his father to Geneva or not is uncertain; at least he must have returned immediately to France, for we find him soon after established at Paris, and publishing the odes of Anacreon. In 1554 he went to Rome, and thence to Naples. This journey was undertaken at the request, and in the service, of the French government. He was discovered, and would have been arrested as a spy, had he not by his address and skill in the language of the country been able to pass himself for a native of Italy. On his return to France he assumed the title of printer to Ulric Fugger, a very rich and learned German nobleman, who allowed him a considerable pension.

In 1560 he married a relation, as is generally supposed, of Henry Scrimigeour, a Scotch nobleman, with whom he was intimately acquainted. She was a woman, as he himself informs us, endowed with the noblest spirit and the most amiable dispositions. Her death, which happened in 1566, brought on a disease that had twice attacked him before. It was a disgust at all those pursuits which had formerly charmed him, an aversion to reading and the sight of books. It was probably occasioned by too constant and severe an application to literary pursuits. In 1572 he published his *Thesaurus Linguæ Græcæ*, one of the greatest works, perhaps, that ever was executed by one man, if we consider

der the wretched materials which more ancient dictionaries could furniſh, if we conſider the ſize and perfection of the work, and the immenſe labour and learning which muſt have been employed in the compilation. This work had been carried on at a greater expence than he could well bear. He expected to be reimburſed by the ſale of the book, but he was unfortunately diſappointed. John Scapula, one of his own ſervants, extracted from it whatever he thought would be moſt ſerviceable to ſtudents, and publiſhed it beforehand in 4to. By this act of treachery Henry was reduced to poverty.

See Scapula.

About this time he was much beloved by Henry III. of France, who treated him ſo kindly, and made him ſuch flattering promiſes, that he reſided frequently at court. But theſe promiſes were never fulfilled, owing to the civil wars which ſoon after diſtracted France, and the unfortunate death of king Henry himſelf. During the remainder of his life his ſituation was very unſettled. We find him ſometimes at Paris, ſometimes in Geneva, in Germany, and even in Hungary. He died at Lyons in 1598, at the age of 70. He was fond of poetry from his very infancy. It was a cuſtom of his to compoſe verſes on horſeback, and even to write them, though he generally rode a very mettleſome ſteed. His *Theſaurus* was his great work, but he was alſo the author of ſeveral other treatiſes. His poems are numerous: His Apology for Herodotus is a witty ſatire on the Roman Catholics. His Concordance to the New Teſtament muſt have been a laborious work, and has deſervedly endeared him to every Chriſtian who wiſhes to acquire a rational and critical knowledge of the Scriptures. The number of books which he publiſhed, though fewer than his father, was great, and ſuperior in elegance to any thing which the world had then ſeen. A great proportion of them were Greek; he was the editor, however, of many Roman and even of ſome eaſtern writings. His Greek claſſics are remarkably correct; the principal of them are Homer, Anacreon, Æſchylus, Maximus Tyrius, Diodorus Siculus, Pindar, Xenophon, Thucydides, Herodotus, Sophocles, Diogenes Laertius, Plutarch, Plato, Apollonius Rhodius, Æſchynes, Lyſias, Callimachus, Theocritus, Herodian, Dionyſius Hallicarnaſſenſis, Dion Caſſius, Iſocrates, Appian, Xiphilin, &c. His temper in the latter part of his life is repreſented as haughty and ſevere, owing probably to his diſappointments. He left behind him a ſon and two daughters, one of whom was married to the learned Iſaac Caſaubon.

Paul Stephens, the ſon of Henry, continued his father's profeſſion at Geneva. He was a man of learning, and wrote tranſlations of ſeveral books, and publiſhed a conſiderable number of the ancient claſſics; but his editions poſſeſs little of his father's elegance. He died in 1627, at the age of 60, after ſelling his types to one Chouet a printer.—His ſon Antony, the laſt printer of the family, abandoned the proteſtant religion, and returned to France, the country of his anceſtors. He received letters of naturalization in 1612, and was made printer to the king; but managing his affairs ill, he was reduced to poverty, and obliged to retire into an hoſpital, where he died in 1674, miſerable and blind, at the age of 80.

Stephens's Medicine for the Stone. See Alkali, nº 17.

STERCORARIANS, or Stercoranistæ, formed from *ſtercus* "dung," a name which thoſe of the Romiſh church anciently gave to ſuch as held that the hoſt was liable to digeſtion, and all its conſequences, like other food.

STERCULIA, in botany: A genus of plants belonging to the claſs of *monœcia*, and order of *monodelphia*; and in the natural ſyſtem under the 38th order, *tricoccæ*. The male calyx is quinquepartite; there is no corolla, but there are 15 filaments. The female calyx is quinquepartite; there is no corolla; the germen is placed on a pillar, and the capſule is quinquelocular, and many-ſeeded. There are three ſpecies, the balanghas, fœtida, and platanifolium, all foreign plants.

STEREOGRAPHIC projection, is the projection of the circles of the ſphere on the plane of ſome one great circle, the eye being placed in the pole of that circle. See *Projection of the Sphere.*

STEREOMETRY, Στερεομετρια, formed of στερεος *ſolid*, and μετρον *meaſure*, that part of geometry which teaches how to meaſure ſolid bodies, *i. e.* to find the ſolidity or ſolid contents of bodies; as globes, cylinders, cubes, veſſels, ſhips, &c.

STEREOTOMY, formed from στερεος, and τομη, *ſection*, the art or act of cutting ſolids, or making ſections thereof; as walls and other membranes in the profiles of architecture.

STERILITY, barrenneſs, in oppoſition to fertility. It has been aſſerted by many authors, that all monſters produced by a mixture of different ſpecies of animals, ſuch as mules, are barren; but this does not hold univerſally, even with the mule, which is the inſtance moſt generally adduced. See Mule.

Sterility in women ſometimes happens from a miſcarriage, or violent labour injuring ſome of the genital parts; but one of the moſt frequent cauſes is the ſuppreſſion of the menſtrual flux.—There are other cauſes ariſing from various diſeaſes incident to thoſe parts; by which the uterus may be unfit to receive or retain the male ſeed;—from the tubæ fallopianæ being too ſhort, or having loſt their erective power; in either of which caſes no conception can take place;—from univerſal debility and relaxation; or a local debility of the genital ſyſtem; by which means, the parts having loſt their tone or contractile power, the ſemen is thrown off immediately *poſt coitum*;—from imperforation of the vagina, the uterus, or the *tubæ*, or from diſeaſed ovas, &c. Hence medical treatment can only avail in caſes ariſing from topical or univerſal debility; in correcting irregularities of the menſtrual flux, or in removing tumors, cicatrices, or conſtrictions of the paſſage, by the art of ſurgery.

STERIS, in botany: A genus of plants belonging to the claſs of *pentandria*, and order of *digynia*. The calyx is quinquepartite; the corolla wheel-ſhaped; the berry is unilocular, and many-ſeeded. There is only one ſpecies, the janava, a foreign plant.

STERLING, an epithet by which genuine Engliſh money is diſtinguiſhed. It is unneceſſary to mention the various conjectures of antiquaries about the origin and meaning of this appellation. The moſt probable opinion ſeems to be this, that ſome artiſts from Germany, who were called *Eſterlings*, from the ſituation of their country, had been employed in fabricating this money,

Henry's Hiſtory of Great Britain, vol. iii. p. 541.

money, which consisted chiefly of silver pennies; and that from them the penny was called an *esterling*, and the money *esterling* or *sterling* money.

STERN, the posterior face of a ship; or that part which is represented to the view of a spectator, placed on the continuation of the keel behind. The stern is terminated above by the taffarel, and below by the counters; it is limited on the sides by the quarter-pieces, and the intermediate space comprehends the galleries and windows of the different cabins. See *Quarter of a Ship*, Ship, and Ship-building.

Stern-Fast, a rope used to confine the stern of a ship or boat to any wharf or jetty-head, &c.

Stern-Most, in sea language, usually denotes that part of a fleet of ships which is in the rear, or farthest a-stern, as opposed to head-most.

Stern-Post, a long straight piece of timber erected on the extremity of the keel, to sustain the rudder and terminate the ship behind.

This piece, which is expressed by B in the pieces of the hull, Plate CCCCLIV. fig. 1. ought to be well secured and supported; because the ends of all the lower planks of the ship's bottom are fixed in a channel, cut on its surface; and the whole weight of the rudder is sustained by it.

Stern-Sheets, that part of a boat which is contained between the stern and the aftmost or hindmost seat of the rowers. It is generally furnished with benches to accommodate the passengers. See Boat.

STERNA, the Tern; a genus of birds arranged under the order of *palmipedes*. The marks of this genus are a straight, slender, pointed bill, linear nostrils, a slender and sharp tongue, very long wings, a small back toe, and a forked tail. There are 25 species, according to Dr Latham; the caspia, cayana, surinamensis, fuliginosa, africana, stolida, philippina, simplex, nilotica, boysii, striata, vittata, spadicea, piscata, hirundo, panaya, cinerea, alba, minuta, sinensis, australis, metopoleucos, fissipes, nigra, and obscura. Three of these only are found in Great Britain; the hirundo, minuta, and fissipes.

1. The *hirundo*, common tern, or great sea-swallow, weighs four ounces one-quarter; the length is 14 inches; the breadth 30; the bill and feet are of a fine crimson; the former tipt with black, straight, slender, and sharp-pointed; the crown, and hind part of the head, black; the throat, and whole underside of the body, white; the upper part, and the coverts of the wings, a fine pale grey. The tail consists of 12 feathers; the exterior edges of the three outmost are grey, the rest white; the exterior on each side is two inches longer than the others: in flying, the bird frequently closes them together, so as to make them appear one slender feather.

Latham's Synopsis, vol. vii.

This is a very common species; frequents the sea-coasts and banks of lakes and rivers during the summer, but most common in the neighbourhood of the sea. It is found also in various parts of Europe and Asia, according to the season; in the summer as far as Greenland and Spitzbergen, migrating in turn to the south of Austria and Greece. It lays three or four eggs about the month of June, of a dull olive colour, an inch and three quarters in length, marked with irregular black spots, intermixed with some others of a smaller size, and less bright; the little end is almost free from any markings. These are laid among the grass or moss. The young are hatched in July, and quit the nest very soon after. They are carefully fed by their parents, and fly in about six weeks. This bird appears to have all the actions on the water which the swallow has on land, skimming on the surface, and seizing on every insect which comes in its way; besides which, the moment it spies a fish in the water, it darts into that element, and seizing its prey arises as quickly to the place from which it dipped.

These birds are also found in America; come into New England in May, and go away in autumn, and are called there the mackarel gull. At Hudson's Bay they are known by the name of black-head. They are observed to lay their eggs in small hollows on the shore, sometimes lined with a few leaves. They are often found in great numbers on the islets in the middle of the rivers, and are thought good eating. The natives of Hudson's Bay call them *Kenouch ene ou keask*. They are bold, not fearing mankind, and in the time of incubation will attack any one, frequently darting down so as to touch a person's hat, without his giving the least offence.

2. The *minuta*, or smaller sea-swallow, (called by Linnæus *larus minuta*), weighs only two ounces five grains; the length 8 inches and a half; the breadth 19 and a half. The bill is yellow, tipt with black; the forehead and cheeks white; from the eyes to the bill is a black line; the top of the head and hind part black; the breast and under side of the body clothed with feathers so closely set together, and of such an exquisite rich gloss and so fine a white, that no sattin can be compared to it: the back and wings of a pale grey: the tail short, less forked than that of the former, and white: the legs yellow: the irides dusky.—These two species are very delicate, and seem unable to bear the inclemency of the weather on our shores during winter, for we observe that they quit their breeding places at the approach of it, and do not return till spring. The manners, haunts, and food of this species are the same with those of the former; but they are far less numerous.

3. The *fissipes*, or black tern, is of a middle size between the first and second species. The usual length is 10 inches; the breadth 24; the weight two ounces and a half. The head, neck, breast, and belly, as far as the vent, are black; beyond is white; the male has a white spot under its chin; the back and wings are of a deep ash colour: the tail is short and forked; the exterior feather on each side is white; the others ash-coloured: the legs and feet of a dusky red. Mr Ray calls this a *cloven-footed gull*, as the webs are depressed in the middle, and form a crescent. These birds frequent fresh waters, breed on their banks, and lay three small eggs of a deep olive colour, much spotted with black. They are found during spring and summer in vast numbers in the Fens of Lincolnshire, make an incessant noise, and feed on flies as well as water insects and small fish. Birds of this species are seen very remote from land. Kalm saw flocks of hundreds in the Atlantic Ocean, midway between England and America, and a later voyager saw one 240 leagues from the Lizard, in the same ocean.

STERNE (Laurence), an English writer of a very peculiar cast, was born at Clomwell, in the south of Ireland, on 24th November 1713. His father Roger Sterne was the grandson of Sterne archbishop of York, who has been supposed, we know not upon what grounds, to to have been the author of the excellent book intitled "The Whole Duty of Man" Laurence inherited nothing of his anceſtor's manner of writing, but rather reſembled Rabelais, whoſe wit he carried with him even into the pulpit.

In 1722 he was ſent to ſchool at Halifax in Yorkſhire, where he continued till 1732, when he was removed to Jeſus' College in Cambridge. How long he reſided in college, or what progreſs he made in literature or ſcience, is not known: his works diſplay rather native genius than profound erudition. Upon quitting the univerſity he went to York, and being in orders was preſented to the living of Sutton by the intereſt of his uncle Dr Sterne, a prebendary of the church. In 1741 he married, and was ſoon afterwards made a prebendary of York, by the intereſt alſo of his uncle, who was then upon very good terms with him; but "quickly quarrelled with him (he ſays), and became his bittereſt enemy, becauſe he would not be a party man, and write paragraphs in the newſpapers." By his wife's means he got the living of Stillington, but remained near 20 years at Sutton, doing duty at both places. He was then in very good health, which, however, ſoon after forſook him; and books, painting, fiddling, and ſhooting, were, as he tells us, his amuſements.

In 1760, he went to London to publiſh his two firſt volumes of "Triſtram Shandy;" and was that year preſented to the curacy of Coxwold. In 1762 he went to France, and two years after to Italy, for the recovery of his health; but his health never was recovered. He languiſhed under a conſumption of the lungs without the ſlighteſt depreſſion of ſpirits, till 1768, when death put a period to his terreſtrial exiſtence.

The works of Sterne are very generally read. They conſiſt of, 1. The Life and Opinions of Triſtram Shandy; 2. Sermons; 3. A Sentimental Journey; 4. Letters, publiſhed ſince his death. In every ſerious page, and in many of much levity, the author writes in praiſe of benevolence, and declares that no one who knew him could ſuppoſe him one of thoſe wretches who heap misfortune upon misfortune: But we have heard ancedotes of him extremely well authenticated, which proved that it was eaſier for him to praiſe this virtue than to practiſe it. His wit is univerſally allowed; but many readers have perſuaded themſelves that they found wit in his blank pages, while it is probable that he intended nothing but to amuſe himſelf with the idea of the ſage conjectures to which theſe pages would give occaſion. Even his originality is not ſuch as is generally ſuppoſed by thoſe fond admirers of the Shandean manner, who have preſumed to compare him with Swift, Arbuthnot, and Butler. He has borrowed both matter and manner from various authors, as every reader may be convinced by the learned, elegant, and candid comments on his works publiſhed by Dr Farrier, in the fourth volume of the Memoirs of the Literary and Philoſophical Society of Mancheſter.

STERNOCOSTALES, commonly called the *muſculi triangulares ſterni*, in anatomy, are five pairs of fleſhy planes, diſpoſed more or leſs obliquely on each ſide the ſternum, on the inſides of the cartilages of the ſecond, third, fourth, fifth, and ſixth true ribs.

STERNO-HYOIDÆUS, in anatomy. See *Table of the Muſcles*, under the article ANATOMY.

STERNOMANTIS, in antiquity, a deſignation given to the Delphian prieſteſs, more uſually called PYTHIA.—Sternomantis is alſo uſed for any one that had a propheſying demon within him.

STERNOMASTOIDÆUS, a muſcle. See *Table of the Muſcles*, under ANATOMY.

STERNOTHYROIDEUS, a muſcle. See *Table of the Muſcles*, under ANATOMY.

STERNUM. See ANATOMY, nº 37.

STERNUTATIVE, or STERNUTATORY, a medicine proper to produce ſneezing. See SNEEZING.

STETIN, or STETTIN, a ſeaport town of Germany, in the circle of Upper Saxony, and capital of Hither Pomerania, with the title of a duchy, and a caſtle. It had long a famous ſchool, which the wars of Germany never diſtubed. The ancient dukes of Pomerania reſided here; and it was taken by the elector of Brandenburg in 1676, but given to Sweden by the treaty of Nimeguen. In 1713 it ſubmitted to the allies; and then the ſaid elector was put in poſſeſſion again of this important place, which is a bulwark to the Marche of Brandenburg; and the fortifications have been greatly improved. It is now a flouriſhing place, and carries on a conſiderable trade. It is ſeated on the river Oder, 72 miles north of Francfort, and 70 north by eaſt of Berlin. E. Long. 14. 38. N. Lat. 53. 35. The duchy is 125 miles in length, and borders upon Mecklenburg, and partly upon Brandenburg. The breadth is from 17 to 25 miles, and it is divided by the river Oder into two parts.

STEW, a ſmall kind of fiſh-pond, the peculiar uſe of which is to maintain fiſh, and keep them in readineſs for the daily uſe of the family, &c.

STEWS (from the French *eſtuves*, i. e. *thermæ*, *balneum)*, thoſe places which were permitted in England to women of profeſſed incontinency, and that for hire would proſtitute their bodies to all comers; ſo called, becauſe diſſolute perſons are wont to prepare themſelves for venereous acts by bathing; and hot baths were by Homer reckoned among the effeminate ſort of pleaſures. Theſe ſtews were ſuppreſſed by King Hen. VIII. about the year 1546.

STEWARD (*ſeneſcallus*, compounded of the Saxon *ſteda*, i. e. "room;" or *ſtead* and *weard*, "a ward" or "keeper"), an officer appointed in another's ſtead or place, and always taken for a principal officer within his juriſdiction. Of theſe there are various kinds. The greateſt officer under the crown is the lord high-ſteward of England, an office that was anciently the inheritance of the earls of Leiceſter, till forfeited by Simon de Mountfort to King Henry III. But the power of this officer is ſo very great, that it has not been judged ſafe to truſt it any longer in the hands of a ſubject, excepting only *pro hac vice*, ocaſionally: as to officiate at a coronation, at the arraignment of a nobleman for high-treaſon, or the like. During his office, the ſteward bears a white ſtaff in his hand; and the trial, &c. ended, he breaks the ſtaff, and with it his commiſſion expires. There is likewiſe a lord-ſteward of the king's houſehold, who is the chief officer of the king's court, has the care of the king's houſe, and authority over all the officers and ſervants of the houſehold, except ſuch as belong to the chapel, chamber, and ſtable.

STEWARD, an officer in a ſhip of war, appointed by the purſer to diſtribute the different ſpecies of proviſions

Steward. ſions to the officers and crew; for which purpoſe he is furniſhed with a mate and proper aſſiſtants.

Court of the Lord High STEWARD *of Great Britain*, is a court inſtituted for the trial of peers indicted for treaſon or felony, or for miſpriſion of either. The office of this great magiſtrate is very ancient, and was formerly hereditary, or at leaſt held for life, or *dum bene ſe geſſerit*: but now it is uſually, and hath been for many centuries paſt, granted *pro hac vice* only; and it hath been the conſtant practice (and therefore ſeems now to have become neceſſary) to grant it to a lord of parliament, elſe he is incapable to try ſuch delinquent peer. When ſuch an indictment is therefore found by a grand jury of freeholders in the King's bench, or at the aſſizes before the juſtices of *oyer* and *terminer*, it is to be removed by a writ of *certiorari* into the court of the lord high-ſteward, which has the only power to determine it. A peer may plead a pardon before the court of King's-bench, and the judges have power to allow it, in order to prevent the trouble of appointing an high-ſteward merely for the purpoſe of receiving ſuch plea: but he may not plead in that inferior court any other plea, as guilty or not guilty of the indictment, but only in this court; becauſe, in conſequence of ſuch plea, it is poſſible that judgment of death might be awarded againſt him. The king, therefore, in caſe a peer be indicted of treaſon, felony, or miſpriſion, creates a lord high-ſteward *pro hac vice* by commiſſion under the great ſeal; which recites the indictment ſo found, and gives his Grace power to receive and try it *ſecundum legem et conſuetudinem Angliæ*. Then when the indictment is regularly removed by writ of *certiorari*, commanding the inferior court to certify it up to him, the lord high-ſteward directs a precept to a ſerjeant at arms, to ſummon the lords to attend and try the indicted peer. This precept was formerly iſſued to ſummon only 18 or 20 ſelected from the body of the peers; then the number came to be indefinite; and the cuſtom was for the lord-high-ſteward to ſummon as many as he thought proper (but of late years not leſs than 23); and that thoſe lords only ſhould ſit upon the trial; which threw a monſtrous weight of power into the hands of the crown, and this its great officer, of ſelecting only ſuch peers as the then predominant party ſhould moſt approve of. And accordingly, when the earl of Clarendon fell into diſgrace with Charles II. there was a deſign formed to prorogue the parliament, in order to try him by a ſelect number of peers; it being doubted whether the whole houſe could be induced to fall in with the views of the court. But now, by ſtatute 7 W. III. c. 3. upon all trials of peers for treaſon or miſpriſion, all the peers who have a right to ſit and vote in parliament ſhall be ſummoned at leaſt 20 days before ſuch trial, to appear and vote therein; and every lord appearing ſhall vote in the trial of ſuch peer, firſt taking the oaths of allegiance and ſupremacy, and ſubſcribing the declaration againſt popery.

Blackſt. Comment. vol. iv.

During the ſeſſion of parliament, the trial of an indicted peer is not properly in the court of the lord high-ſteward, but before the court laſt mentioned of our lord the king in parliament. It is true, a lord high-ſteward is always appointed in that caſe to regulate and add weight to the proceedings: but he is rather in the nature of a ſpeaker *pro tempore*, or chairman of the court, than the judge of it; for the collective body of the peers are therein the judges both of law and fact, and the high-ſteward has a vote with the reſt in right of his peerage. But in the court of the lord high-ſteward, which is held in the receſs of parliament, he is the ſole judge of matters of law, as the lords triors are in matters of fact; and as they may not interfere with him in regulating the proceedings of the court, ſo he has no right to intermix with them in giving any vote upon the trial. Therefore, upon the conviction and attainder of a peer for murder in full parliament, it hath been holden by the judges, that in caſe the day appointed in the judgment for execution ſhould lapſe before execution done, a new time of execution may be appointed by either the high court of parliament during its ſitting, though no high-ſteward be exiſting, or, in the receſs of parliament, by the court of King's-bench, the record being removed into that court. Steward.

It has been a point of ſome controverſy, whether the biſhops have now a right to ſit in the court of the lord-high-ſteward to try indictments of treaſon and miſpriſion. Some incline to imagine them included under the general words of the ſtatute of King William "all peers who have a right to ſit and vote in parliament;" but the expreſſion had been much clearer, if it had been "all lords," and not "all peers;" for though biſhops, on account of the baronies annexed to their biſhoprics, are clearly lords of parliament, yet their blood not being ennobled, they are not univerſally allowed to be peers with the temporal nobility: and perhaps this word might be inſerted purpoſely with a view to exclude them. However, there is no inſtance of their ſitting on trials for capital offences, even upon impeachments or indictments in full parliament, much leſs in the court we are now treating of; for indeed they uſually withdraw voluntarily, but enter a proteſt, declaring their right to ſtay. It is obſervable, that in the 11th chapter of the conſtitutions of Clarendon, made in parliament 11 Hen. II. they are expreſsly excuſed, rather than excluded, from ſitting and voting in trials, when they come to concern life or limb: *epiſcopi, ſicut cæteri barones, debent intereſſe judiciis cum baronibus, quouſque perveniatur ad diminutionem membrorum vel ad mortem.* And Becket's quarrel with the king hereupon was not on account of the exception (which was agreeable to the canon law), but of the general rule, that compelled the biſhops to attend at all. And the determination of the houſe of lords in the earl of Danby's caſe, which hath ever ſince been adhered to, is conſonant to theſe conſtitutions; "that the lords ſpiritual have a right to ſtay and ſit in court in capital caſes, till the court proceeds to the vote of guilty or not guilty." It muſt be noted, that this reſolution extends only to trials in full parliament; for to the court of the lord high-ſteward (in which no vote can be given, but merely that of guilty or not guilty), no biſhop, as ſuch, ever was or could be ſummoned: and though the ſtatute of King William regulates the proceedings in that court, as well as in the court of parliament, yet it never intended to new-model or alter its conſtitution; and conſequently does not give the lords ſpiritual any right, in caſes of blood, which they had not before. And what makes their excluſion more reaſonable is, that they have no right to be tried themſelves in the court of the lord high-ſteward, and therefore ſurely ought not to be judges there. For the privilege of being thus tried

depends

depends upon nobility of blood rather than a seat in the house, as appears from the trials of popish lords, of lords under age, and (since the union) of the Scotch nobility, though not in the number of the sixteen; and from the trials of females, such as the queen consort or dowager, and of all peeresses by birth; and peeresses by marriage also, unless they have, when dowagers, disparaged themselves by taking a commoner to their second husband.

Steward of the Chiltern Hundreds. See Chiltern *Hundreds.*

STEWART (Dr Matthew), was in 1717 born at Rothsay in the isle of Bute, of which parish his father was the minister. Being intended for the church, he went through the usual course of a grammar-school education, and was in 1734 received as a student into the university of Glasgow. There he had the happiness of having for his preceptors in moral science and in mathematics the celebrated professors Hutcheson and Simson; by the latter of whom he was instructed in what may not improperly be called the *arcana* of the ancient geometry.

Mr Stewart's views making it necessary for him to remove to Edinburgh, he was introduced by Dr Simson to Mr Maclaurin, that his mathematical studies might suffer no interruption; and he attended the lectures of that great master with such advantage as might be expected from eminent abilities, directed by the judgment of him who made the philosophy and geometry of Newton intelligible to ordinary capacities. Mr Stewart, however, had acquired, from his intimacy with Dr Simson, such a predilection for the ancient geometry, as the modern analysis, however powerfully recommended, could not lessen; and he kept up a regular correspondence with his old master, giving him an account of his progress and his discoveries in geometry, and receiving in return many curious communications respecting the *Loci Plani* and the porisms of Euclid. See Porism and Simson.

Account of Dr Stewart in the Edinburgh Philosophical Transactions, vol. i. by Mr Playfair.

While the second invention of porisms, to which more genius was perhaps required than to the first discovery of them, employed Dr Simson, Mr Stewart pursued the same subject in a different and new direction. In doing so, he was led to the discovery of those curious and interesting propositions which were published under the title of *General Theorems* in 1746. They were given without the demonstrations; but did not fail to place their discoverer at once among the geometers of the first rank. They are for the most part porisms, though Mr Stewart, careful not to anticipate the discoveries of his friend, gave them no other name than that of theorems.

Our author had before this period entered into the church; and obtained, through the patronage of the duke of Argyle and the earl of Bute, the living of Roseneath, a retired country parish in the west of Scotland: but in 1747 he was elected to the mathematical chair in the university of Edinburgh, which had become vacant the year before by the death of Mr Maclaurin. The duties of this office gave a turn somewhat different to his pursuits, and led him to think of the most simple and elegant means of explaining those difficult propositions which were hitherto only accessible to men deeply versed in the modern analysis. In doing this, he was pursuing the object which of all others he most ardently wished to attain, *viz.* the application of geometry to such problems as the algebraic calculus alone had been thought able to resolve. His solution of Kepler's problem was the first specimen of this kind which he gave to the world; and it was impossible to have produced one more to the credit of the method he followed, or of the abilities with which he applied it. On this problem the utmost resources of the integral calculus had been employed. But though many excellent solutions had been given, there was none of them at once direct in its method and simple in its principles. Mr Stewart was so happy as to attain both these objects; and his solution appeared in the second volume of the Essays of the Philosophical Society of Edinburgh for the year 1756. In the first volume of the same collection there are some other propositions of Mr Stewart's, which are an extension of a curious theorem in the fourth book of Pappus. They have a relation to the subject of porisms, and one of them forms the 91st of Dr Simson's Restoration. They are besides very beautiful propositions, and are demonstrated with all the elegance and simplicity of the ancient analysis.

The prosecution of the plan which he had formed of introducing into the higher parts of mixed mathematics the strict and simple form of ancient demonstration, produced the *Tracts Physical and Mathematical*, which were published in 1761, and the *Essay on the Sun's Distance*, which was published in 1763. In this last work it is acknowledged that he employed geometry on a task which geometry cannot perform; but while it is granted that his determination of the sun's distance is by no means free from error, it may safely be asserted that it contains a great deal which will always interest geometers, and will always be admired by them. Few errors in science are redeemed by the display of so much ingenuity, and what is more singular, of so much sound reasoning. The investigation is everywhere elegant, and will probably be long regarded as a specimen of the most arduous inquiry which has been attempted by mere geometry.

The *Sun's Distance* was the last work which Dr Stewart published; and though he lived to see several animadversions on it made public, he declined entering into any controversy. His disposition was far from polemical; and he knew the value of that quiet which a literary man should rarely suffer his antagonists to interrupt. He used to say, that the decision of the point in question was now before the public; that if his investigation was right it would never be overturned, and that if it was wrong it ought not to be defended. A few months before he published the essay just mentioned, he gave to the world another work, intitled *Propositiones Geometricæ More Veterum Demonstratæ*. This title, it is said, was given to it by Dr Simson, who rejoiced in the publication of a work so well calculated to promote the study of the ancient geometry. It consists of a series of geometrical theorems for the most part new; investigated first by an analysis, and afterwards synthetically demonstrated by the inversion of the same analysis.

Dr Stewart's constant use of the geometrical analysis had put him in possession of many valuable propositions which did not enter into the plan of any of the works that have been enumerated. Of these not a few

have

have found a place in the writings of Dr Simson, where they will for ever remain to mark the friendship of these two mathematicians, and to evince the esteem which Dr Simson entertained for the abilities of his pupil.

Soon after the publication of the *Sun's Distance*, Dr Stewart's health began to decline, and the duties of his office became burdensome to him. In the year 1772 he retired to the country, where he afterwards spent the greater part of his life, and never resumed his labours in the university. But though mathematics had now ceased to be his business, they continued to be his amusement till a very few years before his death, which happened on the 23d of January 1785, at the age of 68.

The habits of study, in a man of original genius, are objects of curiosity, and deserve to be remembered. Concerning those of Dr Stewart, his writings have made it unnecessary to remark, that from his youth he had been accustomed to the most intense and continued application. In consequence of this application, added to the natural vigour of his mind, he retained the memory of his discoveries in a manner that will hardly be believed. He rarely wrote down any of his investigations till it became necessary to do so for the purpose of publication. When he discovered any proposition, he would put down the enunciation with great accuracy, and on the same piece of paper would construct very neatly the figure to which it referred. To these he trusted for recalling to his mind at any future period the demonstration or the analysis, however complicated it might be. Experience had taught him, that he might place this confidence in himself without any danger of disappointment; and for this singular power he was probably more indebted to the activity of his invention than the mere tenaciousness of his memory. Tho' he was extremely studious, he read few books, and verified the observation of M. D'Alembert, that of all the men of letters, mathematicians read least of the writings of one another. His own investigations occupied him sufficiently; and indeed the world would have had reason to regret the misapplication of his talents, had he employed in the mere acquisition of knowledge that time which he could dedicate to works of invention.

Stewart, in Scots law. See Law, N° clviii. 5.

STEWARTIA, in botany: A genus of plants belonging to the class of *monodelphia*, and order of *polyandria;* and in the natural system ranging under the 37th order, *Columniferæ*. The calyx is simple; the style is simple, with a quinquefid stigma; the apple is without juice, quinquelobed, monospermous, bursting open with a spring five ways. There is only one species, the *malacodendron*, which is a foreign plant.

STIBADIUM, among the Romans, a low kind of table-couch or bed of a circular form, which succeeded to the triclinia, and was of different sizes, according to the number of guests they were designed for. They were called *hexaclina*, *octaclina*, or *enneaclina*, according as they held six, eight, or nine guests, and so of any other number.

STIBIUM, a name for Antimony.

STICHOS, a name given by the old writers to a pectoral confection, the principal ingredient of which was the herb *marrubium* or horehound.

STICKLEBACK, in ichthyology. See Gasterosteus.

Foot-STICKS, in printing, slips of wood that lie between the foot of the page and the chase, to which they are wedged fast by the quoins, to keep the form firm, in conjunction with the side-sticks, which are placed at the side of the page, and fixed in the same manner by means of quoins.

STIFFLE, or great muscle, in the manege, is the part of the hind leg of a horse which advances towards his belly. This is a most dangerous part to receive a blow upon.

STIGMA, a brand or impression with a hot iron; a mark of infamy. See Stigmatizing.

Stigma, in botany, the summit or top of the style, accounted by the sexualists the female organ of generation in plants, which receives the fecundating dust of the tops of the stamina, and transmits its vapour or effluvia through the style into the heart of the seed-bud, for the purpose of impregnating the seeds.

STIGMATA, in natural history, the apertures in different parts of the bodies of insects communicating with the tracheæ or air-vessels, and serving for the office of respiration.

Stigmata, in antiquity, certain marks impressed on the left shoulders of the soldiers when listed.

Stigmata, were also a kind of notes or abbreviations, consisting only of points, disposed various ways; as in triangles, squares, crosses, &c.

Stigmata, is also a term introduced by the Franciscans, to express the marks or prints of our Saviour's wounds, said to have been miraculously impressed by him on the body of their seraphic father St Francis.

STIGMATIZING, among the ancients, was inflicted upon slaves as a punishment, but more frequently as a mark to know them by: in which case, it was done by applying a red-hot iron marked with certain letters to their fore-heads, till a fair impression was made; and then pouring ink into their furrows, that the inscription might be the more conspicuous.

Soldiers were branded in the hand with the name or character of their general.

After the same manner, it was customary to stigmatize the worshippers and votaries of some of the gods. The marks used on these occasions were various; sometimes they contained the name of the god, sometimes his particular ensign, as the thunderbolt of Jupiter, the trident of Neptune, the ivy of Bacchus, &c. or they marked themselves with some mystical number, whereby the god's name was described. To these three ways of stigmatizing St John is supposed to refer (Rev. chap. xiii. ver 16, 17.) Theodoret is of opinion, that the Jews were forbidden to brand themselves with stigmata, because the idolaters, by that ceremony, used to consecrate themselves to their false gods.

Among some nations, stigmatizing was considered as a distinguishing mark of honour and nobility. In Thrace, as Herodotus tells us *, it was practised by none but persons of credit, nor omitted by any but persons of the meanest rank. The ancient Britons are also said to have imprinted on the bodies of their infants the figures of animals, and other marks, with hot irons.

* Lib. v.

STIL de grain, in the colour trade, the name of a composition used for painting in oil or water, and is made of a decoction of the lycium or Avignon berry, in alum-water, which is mixed with whiting into a paste, and formed into twisted sticks. It ought to be chosen

chosen of a fine gold yellow, very fine, tender, and friable, and free from dirt.

STILAGO, in botany; a genus of plants belonging to the class of *gynandria*, and order of *triandria*. There is one female. The calyx is monophyllous, and almost three-lobed. There is no corolla, and the berry is globular. There is only one species, the bunius.

STILBE, in botany; a genus of plants belonging to the class of *polygamia*, and order of *diœcia*. The exterior calyx of the hermaphrodite flower is triphyllous; the interior is quinquedentate and cartilaginous. The corolla is funnel-shaped and quinquefid. There are four stamina; and there is one seed in the interior calyx calyptrate. The female flower is similar, has no interior calyx nor fruit. There are three species, the pinastra, ericoides, and cornua, all foreign plants.

STILE. See STYLE.

STILL, the name of an apparatus used in chemistry and in the distillation of ardent spirits. See CHEMISTRY-*Index* at *Distillation* and *Still*.

STILL-Bottoms, in the distillery, a name given by the traders to what remains in the still after working the wash into low wines. These bottoms are procured in the greatest quantity from the malt-wash, and are of so much value to the distiller in the fattening of hogs, &c. that he often finds them one of the most valuable articles of the business.

STILLINGFLEET (Edward), bishop of Worcester, was the son of Samuel Stillingfleet gentleman, and was born at Cranborn in Dorsetshire in 1635. He was educated at St John's College, Cambridge; and having received holy orders, was, in 1657, presented to the rectory of Sutton in Nottinghamshire. By publishing his *Origines Sacræ*, one of the ablest defences of revealed religion that has ever been written, he soon acquired such reputation, that he was appointed preacher of the Rolls Chapel; and in January 1665 was presented to the rectory of St Andrew's, Holborn. He was afterwards chosen lecturer at the Temple, and appointed chaplain in ordinary to king Charles II. In 1668 he took the degree of doctor of divinity; and was soon after engaged in a dispute with those of the Romish religion, by publishing his discourse concerning the idolatry and fanaticism of the church of Rome, which he afterwards defended against several antagonists. In 1680 he preached at Guildhall chapel a sermon on Phil. iii. 26. which he published under the title of *The Mischief of Separation;* and this being immediately attacked by several writers, he in 1683 published his *Unreasonableness of Separation.* In 1685 appeared his *Origines Britannicæ*, or the Antiquities of the British church, in folio. During the reign of king James II. he wrote several tracts against popery, and was prolocutor of the convocation, as he had likewise been under Charles II. After the revolution he was advanced to the bishopric of Worcester, and was engaged in a dispute with the Socinians, and also with Mr Locke; in which last contest he is generally thought to have been unsuccessful. He died at Westminster in 1699, and was interred in the cathedral of Worcester, where a monument was erected to his memory by his son. Dr Stillingfleet wrote other works besides those here mentioned, which, with the above, have been reprinted in 6 vols. folio.

STILLINGFLEET (Benjamin), an ingenious naturalist, was grandson of the preceding. His father Edward was fellow of St John's College in Cambridge, F. R. S. M. D. and Gresham professor of physic: but marrying in 1692, he lost his lucrative offices and his father's favour; a misfortune that affected both himself and his posterity. However, going into orders, he obtained, by his father's means, the living of Newington-Butts, which he immediately exchanged for those of Wood-Norton and Swanton in Norfolk. He died in 1708.

Benjamin, his only son, was educated at Norwich school, which he left in 1720, with the character of an excellent scholar. He then went to Trinity-College in Cambridge, at the request of Dr Bentley, the master, who had been private tutor to his father, domestic chaplain to his grandfather, and much indebted to the family. Here he was a candidate for a fellowship, but was rejected by the master's influence. This was a severe and unexpected disappointment, and but little alleviated afterwards by the Doctor's apology, that it was a pity that a gentleman of Mr Stillingfleet's parts should be buried within the walls of a college.

Perhaps, however, this ingratitude of Dr Bentley was not of any real disservice to Mr Stillingfleet. By being thrown into the world he formed many honourable and valuable connections. He dedicated some translations of Linnæus to the late lord Lyttleton, partly, he says, from motives of private respect and honour. Lord Barrington gave him, in a very polite manner, the place of the master of the barracks at Kensington; a favour to which Mr Stillingfleet, in the dedication of his Calendar of Flora to that nobleman, alludes with equal politeness, as well as with the warmest gratitude. His Calendar of Flora was formed at Stratton in Norfolk in the year 1755, at the hospitable seat of his very worthy and ingenious friend Mr Marsham, who had made several observations of that kind, and had communicated to the public his curious observations on the growth of trees. But it was to Mr Wyndham of Felbrig in Norfolk that he appears to have had the greatest obligations: he travelled abroad with him, spent much of his time at his house, and was appointed one of his executors (Mr Garrick was another), with a considerable addition to an annuity which that gentleman had settled upon him in his lifetime.

Mr Stillingfleet's genius seems, if we may judge from his works, to have led him principally to the study of natural history; which he prosecuted as an ingenious philosopher, an useful citizen, and a good man. In this walk of learning he mentions, as his friends, Dr Watson, Mr (afterwards Dr) Solander, Mr Hudson, Mr Price of Foxley, and some others; to whom may be added the ingenious Mr Pennant. Nor can we omit the flattering mention which the late Mr Gray makes of him in one of his letters, dated from London in 1761: "I have lately made an acquaintance with this philosopher, who lives in a garret here in the winter, that he may support some near relations who depend upon him. He is always employed, consequently (according to my old maxim) always happy, always cheerful, and seems to me a very worthy honest man. His present scheme is to send some persons, properly qualified, to reside a year or two in Attica, to make themselves acquainted with the climate, productions,

and

and natural history of the country, that we may understand Aristotle, Theophrastus, &c. who have been heathen Greek to us for so many ages; and this he has got proposed to lord Bute, no unlikely person to put it in execution, as he is himself a botanist."

Mr Stillingfleet published a volume of miscellaneous tracts, which is in much esteem, and does great honour to his head and heart. They are chiefly translations of some essays in the *Amœnitates Academicæ*, published by Linnæus, interspersed with some observations and additions of his own. In this volume he shows also a taste for classical learning, and entertains us with some elegant poetical effusions of his own. But his Essay on Conversation, published in the first volume of Dodsley's Collection of Poems, entitles him to a distinguished rank among the English poets. This poem is addressed to Mr Wyndham, with all that warmth of friendship which distinguishes Mr Stillingfleet. As it is chiefly didactic, it does not admit of so many ornaments as some compositions of other kinds. However, in contains much good sense, shows a considerable knowledge of mankind, and has several passages that in point of harmony and easy versification would not disgrace the writings of the most admired poets. Here more than once Mr Stillingfleet shows himself still sore for Dr Bentley's cruel treatment of him; and towards the beautiful and moral close of it (where it is supposed he gives us a sketch of himself) seems to hint at a mortification of a more delicate nature, which he is said to have suffered from the other sex.

To these disappointments it was perhaps owing that Mr Stillingfleet neither married nor went into orders. His London residence was at a saddler's in Piccadilly; where he died in 1771, aged above 70, leaving several valuable papers behind him. He was buried in St James's church, without the slightest monument of his having existed.

STILLINGIA, in botany; a genus of plants belonging to the class of *monœcia*, and to the order of *monodelphia*. The male calyx is hemispherical and multiflorous. The corolla is tubulous, and erose or gnawed. The female calyx is unifloro us and inferior. The corolla is superior. The style is trifid, and the capsule three-grained. There is only one species, the sylvatica.

STILYARD. See *Steel-Yard*.

STILPO, a celebrated philosopher of Megara, flourished under the reign of Ptolemy Euergetes. In his youth he had been addicted to licentious pleasures, from which he religiously refrained from the moment that he ranked himself among philosophers. When Ptolemy Soter, at the taking of Megara, offered him a large sum of money, and requested that he would accompany him into Egypt, he accepted but a small part of the offer and retired to the island of Ægina, whence, on Ptolemy's departure, he returned to Megara. That city being again taken by Demetrius the son of Antigonus, and the philosopher required to give an account of any effects which he had lost during the hurry of the plunder, he replied, that he had lost nothing; for no one could take from him his learning and eloquence. So great was the fame of Stilpo, that the most eminent philosophers of Athens took pleasure in attending upon his discourses. His peculiar doctrines were, that species or universals have no real existence, and that one thing cannot be predicated of another. With respect to the former of these opinions, he seems to have taught the same doctrine with the sect afterwards known by the appellation of *Nominalists*. To prove that one thing cannot be predicated of another, he said, that *goodness* and *man*, for instance, are different things, which cannot be confounded by asserting the one to be the other: he argued farther, that goodness is an universal, and universals have no real existence; consequently, since nothing cannot be predicated of any thing, goodness cannot be predicated of man. Thus, whilst this subtle logician was, through his whole argument, predicating one thing of another, he denied that any one thing could be the accident or predicate of another. If Stilpo was serious in this reasoning; if he meant any thing more than to expose the sophistry of the schools, he must be confessed to have been an eminent master of the art of wrangling; and it was not wholly without reason that Glycera, a celebrated courtezan, when she was reproved by him as a corrupter of youth, replied, that the charge might be justly retorted upon himself, who spent his time in filling their heads with sophistical quibbles and useless subtleties. In ethics he seems to have been a Stoic, and in religion he had a public and a private doctrine, the former for the multitude, and the latter for his friends. He admitted the existence of a supreme divinity, but had no reverence for the Grecian superstitions.

Enfield's History of Philosophy, vol. i.

STILOBATUM, in architecture, denotes the body of the pedestal of any column.

STILTON, a town of England, in the county of Huntingdonshire, 75 miles from London, south-west of Yaxley, on the Roman highway from Castor to Huntingdon, called *Ermine-street* some parts of which, in this neighbourhood, appear still paved with stone. This place is famous for cheese which is called *English Parmesan*, and is brought to table full of mites or maggots. For making Stilton cheese, we have the following receipt in the first volume of the *Repository of Arts and Manufactures*:

"Take the night's cream, and put it to the morning's new milk, with the rennet; when the curd is come, it is not to be broken, as is done with other cheeses, but take it out with a soil-dish altogether, and place it in a sieve to drain gradually; and as it drains, keep gradually pressing it till it becomes firm and dry; then place it in a wooden hoop; afterwards to be kept dry on boards, turned frequently, with cloth binders round it, which are to be tightened as occasion requires, and changed every day until the cheese become firm enough to support itself; after the cloth is taken off, the cheese is rubbed every day all over, for two or three months, with a brush; and if the weather be damp or moist twice a-day; and even before the cloth is taken off, the top and bottom are well rubbed every day.

STIMULANTS, in medicine, substances which increase the action of certain parts of the body. In particular, they quicken the motion of blood, increase the action of the muscular fibres, and affect the nervous system.

STIMULI, in botany; a species of armature or offensive weapon, with which some plants, as nettle, cassada, acalypha, and tragia, are furnished. Their use, says Linnæus, is by their venomous punctures to keep

keep off naked animals that would approach to hurt them.

STING, an apparatus in the bodies of certain insects, in form of a little spear, serving them as a weapon of offence.

Sting-Ray, in ichthyology. See Raia.

Falconer's Marine Dictionary.

STINK-pot, an earthen jar or shell, charged with powder, grenadoes, and other materials of an offensive and suffocating smell. It is frequently used by privateers, in the western ocean, in the attack of an enemy whom they design to board; for which purpose it is furnished with a light fuse at the opening or touch-hole. See Boarding.

STINT, a species of the Tringa.

STIPA, Feather Grass, in botany: A genus of plants belonging to the class of *triandria*, and order of *digynia*: and in the natural system ranging under the 4th order, *Gramina*. The calyx is bivalved. The exterior valve of the corolla is terminated by an awn; the base is jointed.

There are nine species, the pennata, juncea, capillata, aristella, tenacissima, avenacea, membranacea, arguens, and spicata. Of these one only is British, the *pennata*, or common feather grass. The beards are feathered. The plant rises to the height of 10 inches, grows on mountains, and flowers in July or August.

STIPEND, among the Romans, signifies the same with tribute; and hence *stipendarii* were the same with *tributarii*.

Stipend, in Scots law. See Law, § clix. 12.

STIPULA, in botany, one of the fulcra or props of plants, defined by Linnæus to be a scale, or small leaf, stationed on each side the base of the footstalks of the flower and leaves, at their first appearance, for the purpose of support. Elmgren restricts it to the footstalks of the leaves only.

STIPULATION, in the civil law, the act of stipulating, that is, of treating and concluding terms and conditions to be inserted in a contract. Stipulations were anciently performed at Rome, with abundance of ceremonies; the first whereof was, that one party should interrogate, and the other answer, to give his consent, and oblige himself. By the ancient Roman law, nobody could stipulate but for himself; but as the Tabelliones were public servants, they were allowed to stipulate for their masters; and the notaries succeeding the Tabelliones have inherited the same privilege.

STIRIA, a province of Germany, in the circle of Austria, with the title of a duchy. It is bounded on the north by the archduchy of Austria, on the east by Hungary, on the south by Carniola, and on the west by Carinthia and the archbishopric of Saltsburg; being 125 miles in length and 77 in breadth. It is said to contain 22 cities, 95 towns, 338 castles, 15 convents, and 200,000 inhabitants. Though it is a mountainous country, yet there is a great deal of land fit for tillage, and the soil is so good, that the inhabitants never were in want of corn. It contains mines of very good iron; whence the arms made there are in great esteem. The women differ greatly from the Austrians, and are very plain and downright. They have all swellings on their throats, called *bronchoceles*. The men are also very simple, and are very zealous worshippers of the Virgin Mary. They delight to sit at home in the chimney-corner, never troubling their heads about foreign affairs. The chief town is Gratz.

STIRLING, a town of Scotland, situated on the river Forth, 35 miles north-west of Edinburgh, in W. Long. 3. 59. N. Lat. 56. 6. It is also called *Sterling* and *Striveling*; from the former of which Boethius falsely derives the name *Sterling money*; because, says he, Osbeit, a Saxon prince, after the overthrow of the Scots, established a mint there. The name of *Striveling* is said to have been derived from the frequency of strifes or conflicts in the neighbourhood. The town contains about 4000 inhabitants. It has a manufacture of tartans and shalloons, and employs about 30 looms in that of carpets. The great street is very broad. In it is the tolbooth, where is kept the standard for the wet measures of Scotland. The other streets are narrow and irregular.—Stirling is in miniature a resemblance of Edinburg; being built on a rock of the same form, with a fortress on the summit. The origin of the castle is unknown. The rock of Stirling was strongly fortified by the Picts, amongst whom architecture and several other useful arts had made a considerable progress. As it lay in the extremities of their kingdom, the possession of it was the occasion of frequent contests betwixt them and their neighbours the Scots and Northumbrians; each of whose dominions did, for some time, terminate near it.

When the Scots, under Kenneth II. overthrew the Pictish empire near the middle of the ninth century, they endeavoured to obliterate every memorial of that people. They not only gave new names to provinces and towns, but, with all the rage of barbarians, demolished many magnificent and useful edifices which had been reared up by them, and this fortress among the rest. It was, however, soon rebuilt, though upon an occasion not very honourable to the Scots.

Upon the death of Kenneth II. in 855, his brother Donald V. mounted the throne of Scotland. In the beginning of his reign the kingdom was invaded by Osbrecht and Ella, two Northumbrian princes, who, uniting their forces with the Cumbrian Britons, and a number of Picts, who upon their expulsion from their native country had taken refuge in England, advanced to Jedburgh, where Donald encountered them; and, after a fierce and bloody battle, obtained a complete victory: but, having taken up his station in Berwick, in supine security, the Northumbrians, informed of the careless posture in which the Scottish army lay, surprised them by a hasty march, dispersed them, and made a prisoner of the king. Pursuing the advantage they had gained, they marched northward, and subdued all before them to the Frith of Forth and the town of Stirling. But the forlorn situation of the Scots, without a king and without an army, obliging them to sue for peace, they obtained it, upon condition that they should pay a sum of money for the ransom of the king, and yield up all their dominions upon the south side of the Forth to the conquerors.

The Northumbrians taking possession of the territories ceded to them by this treaty, rebuilt the castle of Stirling, and planted it with a strong garrison, in order to preserve their new conquests, upon the frontiers of which it was situated. Our authorities also inform us, us, that they erected a stone-bridge over the Forth, upon the summit of which a cross was raised, with the following inscription in monkish rhyme.

Anglos a Scotis separat crux ista remotis;
Armis hic stant Bruti, Scoti stant hic, cruce tuti.

Which is thus translated by Bellenden.

I am a free marche, as passengeris may ken,
To Scottis, to Britonis, and to Inglismen.

None of the ancient English historians mention this conquest. The whole story, as well as the inscription wears much of a monkish garb; yet its authenticity is not a little confirmed by the arms of the town of Stirling, upon which is a bridge, with a cross, and the last line of the above Latin distich is the motto round it.

We must not, however, imagine, that in those times that fortress bore any resemblance to the present structure, which is adapted to the use of fire-arms. Its size and form probably resembled those castles which, under the feudal constitution, the English and Scottish barons used to erect upon their estates for dwelling-houses; and which, in those barbarous ages, they found necessary to fortify for their defence, not only against foreign invaders, but often against the attacks of their own neighbours. It is directly such a Gothic figure as this which represents the *Castrum Strivilense* upon the arms of Stirling.

This fortress, after it had continued in the possession of the Northumbrian Saxons about 20 years, was, together with the whole country upon the south side of the Forth, restored to the Scots, upon condition of their assisting the Saxons against their turbulent invaders the Danes. Upon the arms of Stirling are two branches of a tree, to represent the *Nemus Strivelense;* but the situation and boundaries of that forest, which was probably a wing of the Caledonian, cannot be ascertained. Upon the south of Stirling, vestiges of a forest are still discernible for several miles. Banks of natural timber still remain in the castle-park, at Murray's wood, and near Nether Bannockburn; and stumps of trees, with much brushwood, are to be seen in all the adjacent fields.

When Kenneth III. received intelligence of the Danes having invaded his dominions, he appointed the castle of Stirling to be the place of rendezvous for his army; and he marched from thence to the battle of Loncarty, where he obtained a victory over those rovers, in the end of the 10th century.

In the 12th century, this castle is spoken of as a place of great importance, and one of the strongest fortresses in the kingdom. In 1174, a calamity, not unusual amongst the Scottish monarchs, befel William, who at that time occupied the throne. He was taken prisoner in an unsuccessful expedition which he made into England; and, after having been detained 12 months in captivity, was released, upon stipulating to pay a large sum of money for his ransom; and, until payment thereof, delivering into the hands of the English the four principal fortresses in the kingdom, which in those days were Stirling, Edinburgh, Roxburgh, and Berwick. This was the first great ascendant that England obtained over Scotland; and indeed the most important transaction which had passed between these kingdoms from the Norman conquest.

Though the Scottish monarchs, in their frequent perambulations through the kingdom, often visited Stirling, and held their courts for some time in the castle; yet it did not become a royal residence till the family of Stuart mounted the throne, and it was from different princes of this family that it received its present form. It was the place of the nativity of James II.; and, when raised to the throne, he frequently kept his court in it. It is well known to have been the place where that prince perpetrated an atrocious deed, the murder of William earl of Douglas, whom he stabbed with his own hand. The royal apartments were at that time in the north-west corner of the castle, and are now the residence of the fort-major. The room where the murder was committed still goes by the name of *Douglas's room.* See SCOTLAND, n° 304, 305.

James III. contracting a fondness for the castle on account of its pleasant situation, made it the chief place of his residence, and added several embellishments to it. He built within it a magnificent hall, which in those days was deemed a noble structure, and is still entire. It now goes by the name of the *parliament-house*, having been designed for the accommodation of that supreme court. It was covered with an oaken roof of exquisite workmanship, which, though very little decayed, was a few years ago removed to make way for one of more modern structure. James also erected a college of secular priests in the castle, which he called the *chapel-royal,* and which proved one cause of his own ruin. As the expences necessary for maintaining the numerous officers of such an institution were considerable, he annexed to it the revenues of the rich priory of Coldingham in the Merse, which at that time happened to become vacant. This priory had for a long time been holden by persons connected with the family of Hume; and that family, considering it as belonging to them, strongly opposed the annexation. The dispute seems to have lasted several years; for one parliament had passed a vote, annexing the priory to the chapel-royal, and a subsequent one enacted a statute prohibiting every attempt that was contrary or prejudicial to that annexation.

James V. was crowned in the castle of Stirling; and the palace, which is the chief ornament of it, was the work of that prince. This is a stately and commodious structure, all of hewn stone, with much statuary work upon it. It is built in form of a square, with a small court in the middle, in which the king's lions are said to have been kept; and hence it still goes by the name of the *lions' den.* The palace contains many large and elegant apartments; the ground-story is now converted into barrack-rooms for the soldiers of the garrison; the upper affords a house for the governor, with lodgings for some of the subaltern officers.

Opposite to the palace, upon the north, stands an elegant chapel, which was built by James VI. for the baptism of his son prince Henry in 1594. In this chapel is preserved the hulk of a large boat, which that whimsical monarch caused to be built and placed upon carriages, in order to convey into the castle the provisions for that solemnity.

A strong battery, with a tier of guns pointing to the bridge over the Forth, was erected during the regency of Mary of Lorraine, mother to queen Mary. It is called the *French battery,* probably because constructed by engineers of that nation. The last addition was made to the fortifications in the reign of queen Anne. Formerly they reached no farther than the old gate, upon which the flag-staff now stands: but in that reign they were considerably enlarged upon the side towards the town; and barracks, which are bomb-proof, with several other conveniences for a siege, were erected.

Upon the south side of the castle lies a park inclosed with a stone-wall, called the *king's park*, and near to the foot of the rock on which the castle stands, lay the royal gardens; vestiges of the walks and parterres, with a few stumps of fruit-trees, are still visible; but by long neglect, and the natural wetness of the soil, the place is now little better than a marsh. In the gardens is a mount of earth in form of a table, with benches of earth around it, where, according to tradition, the court sometimes held *fetes-champetres*. In the castle-hill is an hollow, comprehending about an acre of ground, and having all the appearance of an artificial work, which was used for jousts, tournaments, and other feats of chivalry.

Northward of the castle lies the Govan, or perhaps more properly the *Gowling* hill (A); in the middle of which is a small mount called *Hurly Haaky*, upon which duke Murdoch and his two sons were executed for treasonable practices in the reign of James I.

The prospect from the castle is most delightful, as well as extensive, being greatly beautified, especially upon the east, by the windings of the Forth; which are so many, that though the distance by land from Stirling to Alloa is, in a straight line, not quite six miles, it is said to be 24 by water. As this river generally runs upon plain ground, it rolls its stream in so slow and silent a manner, that what Silius Italicus saith of the Ticinus is applicable to it, if, instead of *lucenti* in that poet, we should for once read *lutoso*; for the clay-banks, together with the tide, which flows above Stirling, render the Forth perpetually muddy:

Vix credas labi, ripis tam mitis opacis
Somniferam ducit lutoso gurgite lympham.

The lordship and castle of Stirling were a part of the usual dowry of the queens of Scotland, at least after the family of Stuart came to the throne, in which they were invested at their marriage.

Robert lord Erskine was appointed governor of the castle by king David II. and the office continued in that family till 1715.

This fortress hath been the scene of many transactions. Being by its situation considered as a key to the northern parts of the kingdom, the possession of it hath been always esteemed of great importance to those who sought to be masters of Scotland. It was undoubtedly a place of strength when the art of war by ordnance was in its infancy; but though it resisted the utmost efforts of the rebels in 1746, it could not now hold out three days if besieged, by an army of a few thousand men conducted by an engineer of knowledge and integrity.

STIRLINGSHIRE, a county of Scotland, of which Stirling is the capital. It extends 20 miles in length and 12 in breadth; being bounded on the west by part of Lennox and Clydesdale; on the east, by Clackmannanshire, the river Forth, and part of Lothian; on the south-east, by Lothian; and on the north, by Monteith. The face of the country is open and agreeable, diversified by hill and dale, well watered with streams and rivers; the principal of which is the Forth, rising in the neighbourhood of a high mountain called *Ben-Lomond*, and, running eastward, forms the frith of Edinburgh. The southern part is hilly, affording plenty of game, and pasturage for sheep, horses, and black cattle. The eastern part is fertile, producing plentiful harvests of corn, and great abundance of coal. Lead-ore is found in different parts of the shire; and the rivers abound with pike, trout, and salmon.

STIRRUP, in the manege a rest or support for the horseman's foot, for enabling him to mount and for keeping him firm in his seat.

Stirrups were unknown to the ancients. The want of them in getting upon horseback was supplied by agility or art. Some horses were taught to stoop to take their riders up; but the riders often leapt up by the help of their spears, or were assisted by their slaves, or made use of ladders for the purpose. Gracchus filled the highways with stones, which were intended to answer the same end. The same was also required of the surveyors of the roads in Greece as part of their duty.

Menage observes, that St Jerome is the first author who mentions them. But the passage alluded to is not to be found in his epistles; and if it were there, it would prove nothing, because St Jerome lived at a time when stirrups are supposed to have been invented, and after the use of saddles. Montfaucon denies the authenticity of this passage; and, in order to account for the ignorance of the ancients with regard to an instrument so useful and so easy of invention, he observes, that while cloths and housings only were laid upon the horses backs, on which the riders were to sit, stirrups could not have been used, because they could not have been fastened with the same security as upon a saddle. But it is more probable, that in this instance, as in many others, the progress of human genius and invention is uncertain and slow, depending frequently upon accidental causes.

Berenger's History and Art of Horsemanship, vol. i. p. 65.

STIRRUP *of a Ship*, a piece of timber put upon a ship's keel, when some of her keel happens to be beaten off, and they cannot come conveniently to put or fit in a new piece; then they patch in a piece of timber, and bind it on with an iron, which goes under the ship's keel, and comes up on each side of the ship, where it is nailed strongly with spikes; and this they call a stirrup.

STOBÆUS (John), a laborious Greek writer, who lived at the end of the fourth century, composed many works, of which there are only his Collections remaining, and even these are not as he composed them; many things being inserted by later authors. This work contains many important sentiments collected from the ancient writers, poets, and philosophers.

STOCK, in gardening, &c. the stem or trunk of a tree. What stock is most proper for each kind of fruit, ought as well to be considered and known, as what soil is

(A) So called from the wailings and lamentations (in Scotch *gowlings*) that were made for Duke Murdoch.

Stock, Stockholm.

is most suitable to trees; for on these two things the future vigour of trees, and the goodness of fruit, equally depend. The best way for those who intend to plant, is to raise their own stocks, by which they will be better assured of what they do; but if they should buy their trees of nurserymen, they should diligently inquire upon what stocks they were propagated. See GRAFTING.

STOCK, in trade. See *CAPITAL Stock*.

STOCK-Broker. See BROKER and STOCKS.

STOCK-Dove, in zoology. See COLUMBA.

STOCK-Jobbing, the art or mystery of trafficking in the public stocks or funds. See FUND and *Stock-JOBBING*.

STOCK Gilly-flower, in botany. See CHEIRANTHUS.

STOCKHOLM, the capital of Sweden, is situated in the province of Upland, in E. Long. 19. 30. and N. Lat. 59. 20. Its foundation is by the best Swedish writers generally attributed to Birger Jarl, regent of the kingdom about the middle of the 13th century during the minority of his son Waldemar, who had been raised to the throne by the states of the kingdom; but it was not before the last century that the royal residence was transferred from Upsala to this city.

This capital, which is very long and irregular, occupies, beside two peninsulas, seven small rocky islands, scattered in the Mæler, in the streams which issue from that lake, and in a bay of the gulf of Bothnia. A variety of contrasted and enchanting views are formed by numberless rocks of granite rising boldly from the surface of the water, partly bare and craggy, partly dotted with houses, or feathered with wood. The harbour is an inlet of the Baltic: the water is clear as crystal, and of such depth that ships of the largest burthen can approach the quay, which is of considerable breadth, and lined with spacious buildings and ware-houses. At the extremity of the harbour several streets rise one above another in the form of an amphitheatre; and the palace, a magnificent building, crowns the summit. Towards the sea, about two or three miles from the town, the harbour is contracted into a narrow strait, and, winding among high rocks, disappears from the sight; and the prospect is terminated by distant hills, overspread with forest. It is far beyond the power of words, or of the pencil, to delineate these singular views. The central island, from which the city derives its name, and the Ritterholm, are the handsomest parts of the town. Excepting in the suburbs, where the houses are of wood painted red, the generality of the buildings are of stone, or brick stuccoed white. The royal palace, which stands in the centre of Stockholm, and upon the highest spot of ground, was begun by Charles XI.: it is a large quadrangular stone edifice, and the style of architecture is both elegant and magnificent.

Coxe's Travels, vol. ii.

It is the habitation not only of the royal family, but also of the greater part of the officers belonging to the household. It likewise comprehends the national or supreme court of justice, the colleges of war, chancery, treasury, and commerce; a chapel, armoury, library, and office for the public records; but the greater number of inferior officers and servants belonging to the court, are, with the foot-guards, quartered on the burghers. The castle, and all the stately edifices in the kingdom, are covered with copper. The palace of the nobility, in which this order sits during the session of the diet, is an elegant building adorned on the outside with marble statues and columns, and on the inside with painting and sculpture. This and three other palaces stand on the banks of the lake, and are built on the same model, so as to compose an uniform piece of architecture. The bank, built at the expence of the city, is a noble edifice, and joins with many sumptuous houses belonging to the nobility in exhibiting a splendid appearance. The houses of the burghers are generally built of brick in the city; but in the suburbs they are commonly made up of timber, and therefore very subject to conflagrations. These houses are often framed in Finland, according to the plan and dimensions prescribed: whence they are transported in pieces to Stockholm by water, and there set up by the carpenters. These wooden habitations, if kept in proper repair, will last 30 or 40 years, and are deemed warmer, neater, and more healthy than those of brick or stone. To prevent the danger of conflagrations, the city is divided into 12 wards. In each of these there is a master and four assistants, who forthwith repair to the place where the fire breaks out; and all porters and labourers are obliged to range themselves under the master of the ward to which they belong. A fire-watch patroles the streets by night, to give warning or assistance as it may be wanted; and a centinel is maintained in the steeple of every church, to toll the bell on the first appearance of any such accident. The police of Stockholm is entirely subjected to the regulations of the grand governor, assisted by a deputy and bailiff of the castle. This city is the staple of Sweden, to which all the commodities of the kingdom are brought for exportation, and where almost all the imports from abroad are deposited. The port or haven formed by the lake Mæler is large enough to contain 1000 sail of shipping; and furnished with a key or wharf about an English mile in length, to which the vessels may lie with their broadsides. The greatest inconveniencies attending this situation are, the distance from the sea, which is not within less than 10 miles of the town; the want of tides; and the winding of the river which is remarkably crooked. It opens into the Baltic; and the entrance, which is dangerous and rocky, the Swedes have secured with two small forts: within, it is perfectly safe and commodious. The northern suburbs are remarkable for the king's gardens, and for the great number of artisans who have chosen their habitations in this quarter. In the southern suburbs the Muscovite commodities are sold; and here is a magnificent exchange where the merchants daily assemble.

Stockholm, Stocking.

STOCKING, that part of the clothing of the leg and foot which immediately covers and screens them from the rigour of the cold. Anciently, the only stockings in use were made of cloth, or of milled stuffs sewed together; but since the invention of knitting and weaving stockings of silk, wool, cotton, thread, &c. the use of cloth stockings is quite discontinued. Dr Howel, in his History of the World (vol. ii. p. 222.) relates, that queen Elizabeth, in 1501, was presented with a pair of black knit silk stockings by her silk-woman, and thenceforth she never wore cloth ones any more. The same author adds, that king Henry VIII. ordinarily wore cloth hose, except there came from Spain, by great chance, a pair of silk stockings. His son, king Edward VI. was presented with a pair of long Spanish silk stockings by Sir Thomas Gresham, and

and the present was then much taken notice of. Hence it should seem, that the invention of knit silk stockings originally came from Spain. Others relate, that one William Rider, an apprentice on London bridge, seeing at the house of an Italian merchant a pair of knit worsted stockings from Mantua, took the hint, and made a pair exactly like them, which he presented to William earl of Pembroke, and that they were the first of that kind worn in England, anno 1564.

The modern stockings, whether woven or knit, are formed of an infinite number of little knots, called *stitches*, *loops*, or *meshes*, intermingled in one another.

Knit stockings are wrought with needles made of polished iron, or brass wire, which interweave the threads and form the meshes the stocking consists of. At what time the art of knitting was invented it is perhaps impossible to determine, though it has been usually attributed to the Scots, as it is said that the first works of this kind came from Scotland. It is added, that it was on this account that the company of stocking-knitters, established at Paris 1527, took for their patron St Fiacre, who is said to have been the son of a king of Scotland. But it is most probable that the method of knitting stockings by wires or needles was first brought from Spain.

Woven stockings are generally very fine; they are manufactured on a frame or machine made of polished iron, the structure of which it is needless to describe, as it may be seen in almost every considerable town in this country. The invention of this machine is, by Mr Anderson, attributed to William Lee, M. A. of St John's College, Cambridge, at a period so early as 1589. Others have given the credit of this invention to a student of Oxford at a much later period, who, it is said by Aaron Hill*, was driven to it by dire necessity. This young man, falling in love with an inn-keeper's daughter, married her though she had not a penny, and he by his marriage lost a fellowship. They soon fell into extreme poverty; and their marriage producing the consequences naturally to be expected from it, the amorous pair became miserable, not so much on account of their sufferings, as from the melancholy dread of what would become of their yet unborn infant. Their only means of support were the knitting of stockings, at which the woman was very expert: "But sitting constantly together from morning to night, and the scholar often fixing his eyes, with stedfast observation, on the motion of his wife's finger's in the dexterous management of her needles, he took it into his imagination, that it was not impossible to contrive a little loom which might do the work with much more expedition. This thought he communicated to his wife, and joining his head to her hands, the endeavour succeeded to their wish. Thus the ingenious stocking-loom, which is so common now, was first inverted; by which he did not only make himself and his family happy, but has left his nation indebted to him for a benefit which enables us to export silk stockings in great quantities, and to a vast advantage, to those very countries from whence before we used to bring them at considerable loss in the balance of our traffic."

* See An Account of the Rise & Progress of the Beech Oil Invention, &c. 8vo. 1715.

STOCKS, *or* Public Funds *in England*. By the word *stock* was originally meant a particular sum of money contributed to the establishing of a fund to enable a company to carry on a certain trade, by means of which the person became a partner in that trade, and received a share of the profit made thereby, in proportion to the money employed. But this term has been extended farther, though improperly, to signify any sum of money which has been lent to the government, on condition of receiving a certain interest till the money is repaid, and which makes a part of the national debt. As the security both of the government and of the public companies is esteemed preferable to that of any private person, as the stocks are negotiable and may be sold at any time, and as the interest is always punctually paid when due; so they are thereby enabled to borrow money on a lower interest than what could be obtained from lending it to private persons, where there must be always some danger of losing both principal and interest.

But as every capital stock or fund of a company is raised for a particular purpose, and limited by parliament to a certain sum, it necessarily follows, that when that fund is completed, no stock can be bought of the company; though shares already purchased may be transferred from one person to another. This being the case, there is frequently a great disproportion between the original value of the shares and what is given for them when transferred: for if there are more buyers than sellers, a person who is indifferent about selling will not part with his share without a considerable profit to himself; and on the contrary, if many are disposed to sell, and few inclined to buy, the value of such shares will naturally fall in proportion to the impatience of those who want to turn their stock into specie.

A stock may likewise be affected by the court of chancery; for if that court should order the money, which is under their direction, to be laid out in any particular stock, that stock, by having more purchasers, will be raised to a higher price than any other of the like value.

By what has been said, the reader will perceive how much the credit and interest of the nation depends on the support of the public funds. While the annuities and interest for money advanced is there regularly paid, and the principal insured by both prince and people (a security not to be had in some nations), foreigners will lend them their property, and all Europe be interested in their welfare; the paper of the companies will be converted into money and merchandise, and Great Britain can never want cash to carry her schemes into execution. See the article Fund.

Stocks, a frame erected on the shore of a river or harbour, whereon to build shipping. It generally consists of a number of wooden blocks, ranged parallel to each other, at convenient distances, and with a gradual declivity towards the water.

Stocks, a wooden machine to put the legs of offenders in, for securing disorderly persons, and by way of punishment in divers cases.

STOCKTON upon Tees, a handsome town in the county of Durham, about 16 miles south of the city of Durham. It is now a port of considerable trade; though, at the Restoration, it was a despicable village, the best house in which could hardly boast of any thing better than clay-walls and a thatched roof. About

About 40 years ago it sent out in one year 75 vessels for the port of London; and the trade is much increased since.

STOEBE, BASTARD ÆTHIOPIAN, in botany: A genus of plants belonging to the class of *syngenesia*, and order of *polygamia segregata;* and in the natural system ranging under 49th order *compositæ*. The calycle is uniflorous; the corollets are tubular and hermaphrodite; the receptacle is naked, and the pappus is feathery. There are nine species, the æthiopica, ericoides, prostrata, gnaphaloides, gomphrenoides, scabra, reflexa, rhinocerotis, and disticha; all plants of foreign growth.

STOICS, the name given to a sect of Grecian philosophers, from Στοα, "the porch in Athens," which the founder of the sect chose for his school. For the peculiar tenets of this sect, see METAPHYSICS, Chap. IV. Part 3. MORAL PHILOSOPHY, n° 8. and ZENO.

STOLBERG, a small town of Germany, in the circle of Upper Saxony, and territory of Thuringia, of which it is the capital place. It is seated between two mountains, 58 miles north-west of Leipsic. E. Long. 11. 8. N. Lat. 51. 42.

STOLE, a sacerdotal ornament worn by the Romish parish-priests above their surplice, as a mark of superiority in their respective churches; and by other priests over the alb, at celebrating of mass, in which case it goes across the stomach; and by deacons, over the left-shoulder, scarf-wise: when the priest reads the gospel for any one, he lays the bottom of his stole on his head. The stole is a broad swath, or slip of stuff, hanging from the neck to the feet, with three crosses thereon.

Groom of the STOLE, in England, the eldest gentleman of his Majesty's bed-chamber, whose office it is to present and put on his majesty's first garment, or shirt, every morning, and to order the things in the chamber.

STOMACH, in anatomy. See ANATOMY, n° 91.

STOMACHIC, medicines that strengthen the stomach and promote digestion, &c.

Stomachic corroboratives are such as strengthen the tone of the stomach and intestines; among which are carminatives, as the roots of galangals, red gentian, zedoary, pimpinella, calamus aromaticus, and arum. Of barks and rinds, those of canella alba, sassafras, citrons, Seville and China oranges, &c. Of spices, pepper, ginger, cloves, cinnamon, cardamums, and mace.

STONE (Edmund), a distinguished self-taught mathematician, was born in Scotland; but neither the place nor time of his birth are well known; nor have we any memoirs of his life, except a letter from the Chevalier de Ramsay, author of the Travels of Cyrus, in a letter to father Castle, a Jesuit at Paris, and published in the Memoires de Trevoux, p. 109, as follows: "True genius overcomes all the disadvantages of birth, fortune, and education; of which Mr Stone is a rare example. Born a son of a gardener of the duke of Argyle, he arrived at eight years of age before he learnt to read.—By chance a servant having taught young Stone the letters of the alphabet, there needed nothing more to discover and expand his genius. He applied himself to study, and he arrived at the knowledge of the most sublime geometry and analysis, without a master, without a conductor, without any other guide but pure genius.

"At 18 years of age he had made these considerable advances without being known, and without knowing himself the prodigies of his acquisitions. The duke of Argyle, who joined to his military talents a general knowledge of every science that adorns the mind of a man of his rank, walking one day in his garden, saw lying on the grass a Latin copy of Sir Isaac Newton's celebrated *Principia*. He called some one to him to take and carry it back to his library. Our young gardener told him that the book belonged to him. 'To you?' replied the Duke. 'Do you understand geometry, Latin, Newton?' I know a little of them, replied the young man with an air of simplicity arising from a profound ignorance of his own knowledge and talents. The duke was surprised; and having a taste for the sciences, he entered into conversation with the young mathematician: he asked him several questions, and was astonished at the force, the accuracy, and the candour of his answers. 'But how, said the Duke, came you by the knowledge of all these things?' Stone replied, 'A servant taught me, ten years since, to read: does one need to know any thing more than the 24 letters in order to learn every thing else that one wishes?' The Duke's curiosity redoubled—he sat down upon a bank, and requested a detail of all his proceedings in becoming so learned.

"I first learned to read, said Stone: the masons were then at work upon your house: I went near them one day, and I saw that the architect used a rule, compasses, and that he made calculations. I inquired what might be the meaning and use of these things; and I was informed that there was a science called Arithmetic: I purchased a book of arithmetic, and I learned it.—I was told there was another science called Geometry: I bought the books, and I learnt geometry. By reading I found that there were good books in these two sciences in Latin: I bought a dictionary, and I learned Latin. I understood also that there were good books of the same kind in French: I bought a dictionary, and I learned French. And this, my lord, is what I have done: it seems to me that we may learn every thing when we know the 24 letters of the alphabet."

"This account charmed the Duke. He drew this wonderful genius out of his obscurity; and he provided him with an employment which left him plenty of time to apply himself to the sciences. He discovered in him also the same genius for music, for painting, for architecture, for all the sciences which depend on calculations and proportions."

"I have seen Mr Stone. He is a man of great simplicity. He is at present sensible of his own knowledge; but he is not puffed up with it. He is possessed with a pure and distinterested love for the mathematics, though he is not solicitous to pass for a mathematician; vanity having no part in the great labour he sustains to excel in that science. He despises fortune also; and he has solicited me twenty times to request the duke to give him less employment, which may not be worth the half of that he now has, in order to be more retired, and less taken off from his favourite studies. He discovers sometimes, by methods of his own,

own, truths which others have discovered before him. He is charmed to find on these occasions that he is not a first inventor, and that others have made a greater progress than he thought. Far from being a palgiary, he attributes ingenious solutions, which he gives to certain problems, to the hints he has found in others, although the connection is but very distant," &c.

Mr Stone was author and translator of several useful works; viz. 1. A New Mathematical Dictionary, in 1 vol. 8vo, first printed in 1726. 2. Fluxions, in 1 vol. 8vo, 1730. The Direct Method is a translation from the French, of Hospital's Analyse des Infiniments Petits; and the Inverse Method was supplied by Stone himself. 3. The elements of Euclid, in 2 vols. 8vo, 1731. A neat and useful edition of those Elements, with an account of the life and writings of Euclid, and a defence of his elements against modern objectors. Beside other smaller works. Stone was a fellow of the Royal Society, and had inserted in the Philosophical Transactions (vol. 41, p. 218) an "Account of two species of lines of the 3d order, not mentioned by Sir Isaac Newton or Mr Stirling."

Stone (Jerome), the son of a reputable seaman, was born in the parish of Scoonie, in the county of Fife, North Britain. His father died abroad when he was but three years of age, and his mother, with her young family, was left in very narrow circumstances. Jerome, like the rest of the children, having got the ordinary school education, reading English, writing, and arithmetic, betook himself to the business of a travelling chapman. But the dealing in buckles, garters, and such small articles, not suiting his superior genius, he soon converted his little stock into books, and for some years went through the country, and attended the fairs as an itinerant bookseller. There is great reason to believe that he engaged in this new species of traffic, more with a view to the improvement of his mind than for any pecuniary emolument. Formed by nature for literature, he possessed a peculiar talent for acquiring languages with amazing facility. Whether from a desire to understand the Scriptures in their original languages, or from being informed that these languages are the parents of many others, he began his philological pursuits with the study of the Hebrew and Greek tongues; and, by a wonderful effort of genius and application, made himself so far master of these, without any kind of assistance, as to be able to interpret the Hebrew Bible and Greek Testament into English *ad aperturam libri*. At this time he did not know one word of Latin. Sensible that he could make no great progress in learning, without the knowledge of at least the grammar of that language, he made application to the parish schoolmaster for his assistance. Some time afterwards, he was encouraged to prosecute his studies at the University of St Andrew's. An unexampled proficiency in every branch of literature recommended him to the esteem of the professors; and an uncommon fund of wit and pleasantry rendered him, at the same time, the favourite of all his fellow students, some of whom speak of him to this day with an enthusiastic degree of admiration and respect. About this period some very humorous poetical pieces of his composition were published in the Scots Magazine. Before he had finished his third session, or term, at St Andrew's, on an application to the College by the master of the school of Dunkeld for an usher, Mr Stone was recommended as the best qualified for that office; and about two or three years after, the master being removed to Perth, Mr Stone, by the favour of his Grace the Duke of Atholl, who had conceived a high opinion of his abilities, was appointed his successor.

When he first went to Dunkeld, he entertained but an unfavourable opinion of the Gaelic language, which he considered as nothing better than a barbarous inarticulate gibberish; but being bent on investigating the origin and descent of the ancient Scots, he suffered not his prejudices to make him neglect the study of their primitive tongue. Having, with his usual assiduity and success, mastered the grammatical difficulties which he encountered, he set himself to discover something of the true genius and character of the language. He collected a number of ancient poems, the production of Irish or Scottish bards, which, he said, were daring, innocent, passionate, and bold. Some of these poems were translated into English verse, which several persons now alive have seen in manuscript, before Mr Macpherson published any of his translations from Ossian.

He died while he was writing and preparing for the press a treatise, intitled, "An Inquiry into the Original of the Nation and Language of the ancient Scots, with Conjectures about the Primitive State of the Celtic and other European Nations;" an idea which could not have been conceived by an ordinary genius. In this treatise he proves that the Scots drew their original, as well as their language, from the ancient Gauls. Had Mr Stone lived to finish this work, which discovers great ingenuity, immense reading, and indefatigable industry, it would have thrown light upon the dark and early periods of the Scottish history, as he opens a new and plain path for leading us through the unexplored labyrinths of antiquity. But a fever put an end to his life, his labours, and his usefulness, in the year 1757, being then only in the 30th year of his age. He left, in manuscript, a much esteemed and well-known allegory, intitled "The Immortality of Authors," which has been published and often reprinted since his death, and will be a lasting monument of a lively fancy, sound judgement, and correct taste. It was no small ornament of this extraordinary character, that he paid a pious regard to his aged mother, who survived him two years, and received an annual pension from the Duchess of Atholl as a testimony of respect to the memory of her son.

STONEHIVE, or Stonehaven, a small town in the county of Kincardine, in Scotland, 15 miles south from Aberdeen. It was built in the time of Charles II. and stands at the foot of some high cliffs, in a small bay, with a rocky bottom, opening a little in one part, so that small vessels may find admittance, but only at high water. A pier laps over this harbour from the north side to secure them after their entrance. The town contains about 800 inhabitants. The manufactures are sail-cloths and Osnaburghs, knit worsted and thread stockings.

STONES, in natural history, bodies which are insipid, not ductile, nor inflammable, nor soluble in water. But as this is the definition given of earths by chemists and naturalists, we must refer the reader to the articles Earth, and Mineralogy, Part II. class 1. for a

view

view of the classification of stones. Here we will only make a few observations concerning their natural history.

As philosophers have perplexed themselves much about the origin and formation of the earth (a subject certainly far beyond the ken of the human intellect, at least if we believe that it was made by the almighty power of God), so they have also proposed theories to explain the origin of stones. When philosophers limit their inquiries within the boundaries of science, where they are led by the sober and safe conduct of observation and experiment, their conclusions may be solid and may be useful; but when, throwing experiment and observation aside, they rear a theory upon an airy nothing, or upon a single detached fact, their theories will vanish before the touch of true philosophy as a romantic palace before the rod of the enchanter. Sometimes from whim, or caprice, or vanity, they attempt to confound every thing: They wish to prove that the soul is mere matter, that plants are animals, and that fossils are plants, and thus would vanish two substances, spirit and dead matter, entirely from the world; as if the Author of Nature were actuated by sordid views of parsimony in the works of creation, though we evidently see that a generous profusion is one of the characteristic marks of these works. We leave the task of confounding the different classes of being to those philosophers whose minds are too contracted to comprehend a great variety of being at one view, or who prefer novelty to every thing else. We content ourselves with the old opinion, that the soul is a spiritual substance; that plants are plants, and that stones are stones.

We have been led into these remarks by finding that some philosophers say that stones are vegetables; that they grow and increase in size like a plant. This theory, we believe, was first offered to the world by M. Tournefort, in the year 1702, after returning from his travels in the east. It was founded on a curious fact. In surveying the labyrinth of Crete, he observed that the names which visitors had engraved upon the rock were not formed of hollow but of prominent letters like basso relievos. He supposes that these letters were at first hollowed out by knives; that the hollows have since been filled up by the growth of the stone; and hence he concludes that stones vegetate. We wish we were fully assured of the fact that the letters were at first hollowed, before we attempt to account for their prominency. But even allowing the supposition to be true that they were at first hollow, we reply it is only a single fact, and that it is altogether unphilosophical to deduce a general system from a single fact.

In the *second* place, this protuberancy of the characters is very improperly called vegetation, for it is not produced by a process in any respect like the vegetation of a plant. Vegetation supposes vessels containing fluids and growth by expansion; but who ever heard of vessels in a stone, of fluids moving in them, or of the different parts expanding and swelling like the branch or trunk of a tree? Even the fact which Tournefort mentions proves nothing. He does not pretend to say, that the rock itself is increasing, but only that a few small hollows are filled with new stony matter, which rises a little above the surrounding surface of the rock. This matter evidently has been once liquid, and at length has congealed in the channel into which it had run.—But is not this easily explained by a common process, the formation of stalactites? When water charged with calcareous matter is exposed to the action of air, the water evaporates, and leaves the calcareous earth behind, which hardens and becomes like a stone.

Having thus examined the principal fact upon which M. Tournefort founds his theory, it is unnecessary to follow him minutely through the rest of his subject.—He compares the accretion of matter in the labyrinth to the consolidation of a bone when broken, by a callus formed of the extravasated nutritious juice. This observation is thought to be confirmed, by finding that the projecting matter of the letters is whitish and the rock itself greyish. But it is easy to find comparisons. The difficulty, as Pope says, is to apply them. The resemblance between the filling up of the hollow of a stone, and the consolidation of a broken bone by a callus, we confess ourselves not philosophers enough to see. Were we writing poetry in bad taste, perhaps it might appear. The circumstance, that the prominent matter of the letters is whitish, while the rock is greyish, we flatter ourselves strengthens our supposition that it consists of a deposition of calcareous matter. Upon the whole, we conclude, we hope logically, that no such theory as this, that stones are vegetables, can be drawn from the supposed fact respecting the labyrinth. We have to regret, that the account which we have seen of the subject is so imperfect, that we have not sufficient materials for a proper investigation. Tournefort has not even told us of what kind of stone or earth the accretion consists; yet this single information would probably have decided the question (A).

Artificial

(A) To give a more distinct notion of Tournefort's theory, we shall subjoin his conclusions: From these observations (he says) it follows, that there are stones which grow in the quarries, and of consequence that are fed; that the same juice which nourishes them serves to rejoin their parts when broken; just as in the bones of animals, and the branches of trees, when kept up by bandages; and, in a word, that they vegetate. There is, then (he says), no room to doubt but that they are organized; or that they draw their nutritious juice from the earth. This juice must be first filtrated and prepared in their surface, which may be here esteemed as a kind of bark; and hence it must be conveyed to all the other parts. It is highly probable the juice which filled the cavities of the letters was brought thither from the bottom of the roots; nor is there any more difficulty in conceiving this than in comprehending how the sap should pass from the roots of our largest oaks to the very extremities of their highest branches. Some stones, then (he concludes), must be allowed to vegetate and grow like plants: but this is not all; (he adds), that probably they are generated in the same manner; at least, that there are abundance of stones whose generation is inconceivable, without supposing that they come from a kind of seeds, wherein the organical parts of the stones are wrapped up as those of the largest plants are in their seeds.

Stone.

Artificial STONE. See STUCCO.

Elastic STONE. See *Elastic* MARBLE.

Philosopher's STONE See PHILOSOPHER'S STONE.

Precious STONES. See GEM.

Rocking STONE, or *Logan*, a stone of a prodigious size, so exactly poised, that it would rock or shake with the smallest force. Of these stones the ancients give us some account. Pliny says, that at Harpasa, a town of Asia, there was a rock of such a wonderful nature, that if touched with the finger it would shake, but could not be moved from its place with the whole force of the body*. Ptolemy Hephestion mentions† a gygonian stone near the ocean, which was agitated when struck by the stalk of an asphodel, but could not be removed by a great exertion of force. The word *gygonius* seems to be Celtic; for *gwingog*, signifies *motitans* the rocking stone.

* Lib. ii. c. 69.
† Lib. iii. c. 3.

Many rocking stones are to be found in different parts of Britain; some natural, others artificial, or placed in their position by human art. In the parish of St Leven, Cornwall, there is a promontary called *Castle Treryn*. On the western side of the middle group, near the top, lies a very large stone, so evenly poised that any hand may move it from one side to another; yet it is so fixed on its base, that no lever nor any mechanical force can remove it from its present situation. Is is called the *Logan stone*, and is at such a height from the ground that no person can believe that it was raised to its present position by art. But there are other rocking stones, which are so shaped and so situated, that there can be no doubt but they were erected by human strength. Of this kind Borlase thinks the great *Quoit* or *Karn-lehau*, in the parish of Tywidnek, to be. It is 39 feet in circumference, and four feet thick at a medium, and stands on a single pedestal. There is also a remarkable stone of the same kind in the island of St Agnes in Scilly. The under rock A is 10 feet 6 inches high, 47 feet round the middle, and touches the ground with no more than half its base. The upper-rock C rests on one point only, and is so nicely balanced, that two or three men with a pole can move it. It is eight feet six inches high, and 47 in circumference. On the top there is a bason D hollowed out, three feet eleven inches in diameter at a medium, but wider at the brim, and three feet deep. From the globular shape of this upper stone, it is highly probable that it was rounded by human art, and perhaps even placed on its pedestal by human strength. In Sithney parish, near Helstone, in Cornwall, stood the famous logan, or rocking stone, commonly called *Men Amber*, q. d. *Men on Bar*, or the *top-stone*. In was eleven feet by six and four high, and so nicely poised on another stone that a little child could move it, and all travellers who came this way desired to see it. But Shrubsall, Cromwell's governor of Pendennis, with much ado caused it to be undermined, to the great grief of the country. There are some marks of the tool on it, and, by its quadrangular shape, it was probably dedicated to Mercury.

Plate CCCCLXXII. fig. 7.

Borlase, chap. iv. p. 181.

That the rocking stones are monuments erected by the Druids cannot be doubted; but tradition has not informed us for what purpose they were intended. Mr Toland thinks that the Druids made the people believe that they alone could move them; and that by a miracle; and that by this pretended miracle they condemned or acquitted the accused, and brought criminals to confess what could not otherwise be extorted from them. How far this conjecture is right we shall leave to those who are deeply versed in the knowledge of antiquities to determine.

Sonorous STONE, a kind of stone remarkable for emitting an agreeable sound when struck, and much used in China for making musical instruments which they call *king*.

The various kinds of sonorous stones known in China differ considerably from one another in beauty, and in the strength and duration of their tone; and what is very surprising, is, that this difference cannot be discovered either by the different degrees of their hardness, weight, or fineness of grain, or by any other qualities which might be supposed to determine it. Some stones are found remarkably hard, which are very sonorous; and others exceedingly soft, which have an excellent tone; some extremely heavy emit a very sweet sound; and there are others as light as pumice-stone which have also an agreeable sound.

The chemists and naturalists of Europe and America have never yet attempted to discover, whether some of our stones may not have the same properties as the sonorous stones of the extremities of Asia. It however appears, that the Romans were formerly acquainted with a sonorous stone of the class of *hiang-che*. Pliny (says the Abbé du Bos, in his Reflections on Poetry and Painting, when speaking of curious stones) observes that the stone called *chalcophonas*, or *brazen sound*, is black; and that, according to the etymology of its name, it sends forth a sound much resembling that of brass when it is struck. The passage of Pliny is as follows: *Chalcophonas nigra est; sed elisa æris tinnitum reddit.*

Some sonorous stones were at length sent into France, and the late Duke de Chaulnes examined them with particular attention. The following are some of his observations: "The Academy of Sciences, Mr Romé de Lisle, and several other learned mineralogists, when asked if they were acquainted with the black stone of which the Chinese king was made, for answer cited the passage of Pliny mentioned by Boethius de Bott, Linnæus, and in the Dictionary of Bomare, and added what Mr Anderson says in his Natural History of Iceland respecting a bluish kind of stone which is very sonorous. As the black stone of the Chinese becomes of a bluish colour when filed, it is probably of the same species. None of the rest who were consulted had ever seen it. The Chinese stone has a great resemblance at first sight to black marble, and like it is calcareous; but marble generally is not sonorous. It also externally resembles touchstone, which is a kind of basaltes, and the basaltes found near volcanos; but these two stones are vitrifications."

The duke next endeavoured to procure same information from the stone-cutters. They all replied, that blue coloured marble was very sonorous, and that they had seen large blocks of it which emitted a very strong sound; but the duke, having ordered a king to be constructed of this kind of stone, it was found that it did not possess that property. By trying the black marble of Flanders, a piece was at length found which emitted an agreeable found: it was cut into a king, which is almost as sonorous as those of China. All these observa-

Stone.

tions give us reaſon to believe that the ſtones of which the king are formed are nothing elſe but a black kind of marble, the conſtituent parts of which are the ſame as thoſe of the marble of Europe, but that ſome difference in their organization renders them more or leſs ſonorous.

Swine-Stone (*lapis ſuillus*) or *fetid ſtone*, ſo called from its exceſſively fetid ſmell, calcareous earth impregnated with petroleum. It is found, 1. Solid, with the particles ſcarcely viſible, of a black colour, as the marble found in Flanders, and in the province of Jutland in Sweden. 2. With viſible grains of a blackiſh brown colour, found likewiſe in ſome places of Sweden. 3. With coarſe ſcales, found alſo in Sweden. Great part of the limeſtones found in England belong to this claſs, and emit a very fetid ſmell when ſtruck violently, but it ſoon goes off in the fire.

Stone-Marrow. See Clay, ſpecies 4.

Stone-Ware, a ſpecies of pottery ſo called from its hardneſs. See *Delft-Ware*, Porcelain, and Pottery.

"Clay is a principal ingredient in pottery of all kinds which has the property of hardening in the fire, and of receiving and preſerving any form into which it is moulded. One kind of clay reſiſts the moſt violent action of the fire after being hardened to a certain degree, but is incapable of receiving a ſufficient degree of hardneſs and ſolidity. A ſecond kind aſſumes a hardneſs reſembling that of flint, and ſuch a compactneſs that veſſels made of it have a gloſſy appearance in their fracture reſembling porcelain. Theſe two ſpecies owe their peculiar properties of reſiſting heat without melting, to ſand, chalk, gypſum or ferruginous earth, which they contain. A third ſpecies of clay begins to harden with a moderate fire, and melts entirely with a ſtrong fire. It is of the ſecond ſpecies that ſtone-ware is made.

"The moſt famous manufactory of ſtone-ware, as well as of other kinds of pottery, is at Burſlem in Staffordſhire. This can be traced with certainty at leaſt two centuries back; but of its firſt introduction no tradition remains. In 1686, as we learn from Dr Plot's Natural Hiſtory of Staffordſhire publiſhed in that year, only the coarſe yellow, red, black, and mottled wares, were made in this country; and the only materials employed for them appear to have been the different coloured clays which are found in the neighbourhood, and which form ſome of the meaſures or ſtrata of the coal-mines. Theſe coarſe clays made the body of the ware, and the glaze was produced by powdered lead-ore, ſprinkled on the pieces before firing, with the addition of a little mangaueſe for ſome particular colours. The quantity of goods manufactured was at that time ſo inconſiderable, that the chief ſale of them, the Doctor ſays, was "to poor crate-men, who carried them on their backs all over the country."

Anderſon's Commerce, vol. iv.

"About the year 1690, two ingenious artiſans from Germany, of the name of Eller, ſettled near Burſlem, and carried on a ſmall work for a little time. They brought into this country the method of glazing ſtone-ware, by caſting ſalt into the kiln while it is hot, and ſome other improvements of leſs importance; but finding they could not keep their ſecrets to themſelves, they left the place rather in diſguſt. From this time various kinds of ſtone-ware, glazed by the fumes of ſalt in the manner abovementioned, were added to the wares before made. The white kind, which afterwards became, and for many ſucceeding years continued, the ſtaple branch of pottery, is ſaid to have owed its origin to the following accident. A potter, Mr Aſtbury, travelling to London, perceiving ſomething amiſs with one of his horſe's eyes, an hoſtler at Dunſtable ſaid he could ſoon cure him, and for that purpoſe put a common black flint ſtone into the fire. The potter obſerving it, when taken out, to be of a fine white, immediately conceived the idea of improving his ware by the addition of this material to the whiteſt clay he could procure: accordingly he ſent home a quantity of the flint ſtones of that country, where they are plentiful among the chalk, and by mixing them with tobacco-pipe clay, produced a white ſtone-ware much ſuperior to any that had been ſeen before.

"Some of the other potters ſoon diſcovered the ſource of this ſuperiority, and did not fail to follow his example. For a long time they pounded the flint ſtones in private rooms by manual labour in mortars; but many of the poor workmen ſuffered ſeverely from the duſt of the flint getting into their lungs, and producing dreadful coughs, conſumptions, and other pulmonary diſorders. Theſe diſaſters, and the increaſed demand for the flint powder, induced them to try to grind it by mills of various conſtructions; and this method being found both effectual and ſafe, has continued in practice ever ſince. With theſe improvements, in the beginning of the preſent century, various articles were produced for tea and coffee equipages. Soon after attempts were made to furniſh the dinner table alſo; and before the middle of the century, utenſils for the table were manufactured in quantity as well for exportation as home conſumption.

"But the ſalt glaze, the only one then in uſe for this purpoſe, is in its own nature ſo imperfect, and the potters, from an injudicious competition among themſelves for cheapneſs, rather than excellence, had been ſo inattentive to elegance of form and neatneſs of workmanſhip, that this ware was rejected from the tables of perſons of rank; and about the year 1760, a white ware, much more beautiful and better glazed than ours, began to be imported in conſiderable quantities from France.

"This inundation of a foreign manufacture, ſo much ſuperior to any of our own, muſt have had very bad effects upon the potteries of this kingdom, if a new one, ſtill more to the public taſte, had not appeared ſoon after. In the year 1763, Mr Joſiah Wedgwood, who had already introduced ſeveral improvements into this art, invented a ſpecies of earthen ware for the table quite new in its appearance, covered with a rich and brilliant glaze, bearing ſudden alternations of heat and cold, manufactured with eaſe and expedition, and conſequently cheap, and having every requiſite for the purpoſe intended. To this new manufacture the queen was pleaſed to give her name and patronage, commanding it to be called *Queen's ware*, and honouring the inventor by appointing him her majeſty's potter.

"The common clay of the country is uſed for the ordinary ſorts; the finer kinds are made of clay from Devonſhire and Dorſetſhire, chiefly from Biddeford; but the flints from the Thames are all brought rough by ſea, either to Liverpool or Hull, and ſo by Burton. There is no conjecture formed of the original rea-

ſon

ſon of fixing the manufacture in this ſpot, except for the convenience of plenty of coals, which abound under all the country.

"The flints firſt are ground in mills, and the clay prepared by breaking, waſhing, and ſifting, and then they are mixed in the requiſite proportions. The flints are bought firſt by the people about the country, and by them burnt and ground, and ſold to the manufacturers by the peck.

"The mixture is then laid in large quantities on kilns to evaporate the moiſture; but this is a nice work, as it muſt not be too dry; next it is beat with large wooden hammers, and then is in order for throwing, and is moulded into the forms in which it is to remain: this is the moſt difficult work in the whole manufacture. A boy turns a perpendicular wheel, which by means of thongs turns a ſmall horizontal one, juſt before the thrower, with ſuch velocity, that it twirls round the lump of clay he lays on it into any form he directs it with his fingers.

"There are 300 houſes which are calculated to employ, upon an average, twenty hands each, or 6000 in the whole; but of all the variety of people that work in what may be called the preparation for the employment of the immediate manufacturers, the total number cannot be much ſhort of 10,000, and it is increaſing every day. Large quantities are exported to Germany, Ireland, Holland, Ruſſia, Spain, the Eaſt Indies, and much to America; ſome of the fineſt ſorts to France."

Stone in the Bladder. See Medicine, n° 400. Surgery-*Index*: and Alkali, n° 17, 18, 19.

Stone, in merchandize, denotes a certain weight for weighing commodities. A ſtone of beef at London is the quantity of eight pounds: in Herefordſhire 12 pounds: in the North 16 pounds. A ſtone of glaſs is five pounds; of wax eight pounds. A ſtone of wool (according to the ſtatute of 11 Hen. VII.) is to weigh 14 pounds; yet in ſome places it is more, in others leſs; as in Glouceſterſhire 15 pounds; in Herefordſhire 12 pounds. Among horſe-courſers a ſtone is the weight of 14 pounds.

The reaſon of the name is evident. Weights at firſt were generally made of ſtone. See Deut. xxv. 13. where the word אבן tranſlated *weight*, properly ſignifies a *ſtone*.

Stone-Chatter, in ornithology. See Motacilla.

STONEHENGE, a celebrated monument of antiquity, ſtands in the middle of a flat area near the ſummit of a hill ſix miles diſtant from Saliſbury. It is incloſed by a circular double bank and ditch near 30 feet broad, after croſſing which we aſcend 30 yards before we reach the work. The whole fabric conſiſted of two circles and two ovals. The outer circle is about 108 feet diameter, conſiſting when entire of 60 ſtones, 30 uprights and 30 impoſts, of which remain only 24 uprights, 17 ſtanding and 7 down, $3\frac{1}{2}$ feet aſunder, and 8 impoſts. Eleven uprights have their 5 impoſts on them by the grand entrance. Theſe ſtones are from 13 to 20 feet high. The leſſer circle is ſomewhat more than 8 feet from the inſide of the outer one, and conſiſted of 40 leſſer ſtones (the higheſt 6 feet), of which only 19 remain, and only 11 ſtanding: the walk between theſe two circles is 300 feet in circumference. The Adytum or Cell is an oval formed of 10 ſtones (from 16 to 22 feet high), in pairs, with impoſts, which Dr Stukeley calls *trilithons*, and above 30 feet high, riſing in height as they go round, and each pair ſeparate, and not connected as the outer pair; the higheſt 8 feet. Within theſe are 19 more ſmaller ſingle ſtones, of which only 6 are ſtanding. At the upper end of the Adytum is the altar, a large ſlab of blue coarſe marble, 20 inches thick, 16 feet long, and 4 broad; preſſed down by the weight of the vaſt ſtones that have fallen upon it. The whole number of ſtones, uprights, impoſts, and altar, is exactly 140. The ſtones are far from being artificial, but were moſt probably brought from thoſe called the *Grey Weathers* on Marlborough Downs, 15 or 16 miles off; and if tried with a tool they appear of the ſame hardneſs, grain, and colour, generally reddiſh. The heads of oxen, deer, and other beaſts, have been found on digging in and about Stonehenge; and human bones in the circumjacent barrows. There are three entrances from the plain to this ſtructure, the moſt conſiderable of which is from the north-eaſt, and at each of them were raiſed on the outſide of the trench two huge ſtones with two ſmaller within parallel to them.

Gough's edition of Cambden's Britannia, vol. i. p. 107.

It has been long a diſpute among the learned, by what nation, and for what purpoſe, theſe enormous ſtones were collected and arranged. The firſt account of this ſtructure we meet with is in Geoffroy of Monmouth, who, in the reign of King Stephen, wrote the hiſtory of the Britons in Latin. He tells us, that it was erected by the counſel of Merlin the Britiſh enchanter, at the command of Aurelius Ambroſius the laſt Britiſh king, in memory of 460 Britons who were murdered by Hengiſt the Saxon. The next account is that of Polydore Virgil, who ſays that the Britons erected this as a ſepulchral monument of Aurelius Ambroſius. Others ſuppoſe it to have been a ſepulchral monument of Boadicea the famous Britiſh Queen. Inigo Jones is of opinion, that it was a Roman temple; from a ſtone 16 feet long, and four broad, placed in an exact poſition to the eaſtward, altar-faſhion Mr Charlton attributed it to the Danes, who were two years maſters of Wiltſhire; a tin tablet, on which were ſome unknown characters, ſuppoſed to be Punic, was digged up near it in the reign of Henry VIII. but is loſt; probably that might have given ſome information reſpecting its founders. Its common name, *Stonehenge* is Saxon, and ſignifies a "ſtone gallows," to which thoſe ſtones, having tranſverſe impoſts, bear ſome reſemblance. It is alſo called in Welch *choir gour*, or "the giant's dance."

Mr Groſe thinks that Dr Stukeley has completely proved this ſtructure to have been a Britiſh temple in which the Druids officiated. He ſuppoſes it to have been the metropolitan temple of Great Britain, and tranſlates the words *choir gour* "the great choir or temple." The learned Mr Bryant is of opinion that it was erected by a colony of Cuthites probably before the time of the Druids; becauſe it was uſual with them to place one vaſt ſtone upon another for a religious memorial; and theſe they often placed ſo equably, that even a breath of wind would ſometimes make them vibrate. Of ſuch ſtones one remains at this day in the pile of Stonehenge. The ancients diſtinguiſhed ſtones erected with a religious view, by the name of *ambr*; by which was ſignified any thing ſolar and divine. The Grecians called them πετραι αμβροσιαι, *petræ ambroſiæ*. Stonehenge, according

Groſe's Antiquities, vol. vi. p. 40.

cording to Mr Bryant, is composed of these amber stones: hence the next town is denominated *Ambresbury*; not from a Roman Ambrosius, for no such person ever existed, but from the *ambrosiæ petræ*, in whose vicinity it stood. Some of these were rocking stones; and there was a wonderful monument of this sort near Penzance in Cornwall, which still retains the name of *main-amber*, or the sacred stones. Such a one is mentioned by Apollonius Rhodius, supposed to have been raised in the time of the Argonautæ, in the island Tenos, as the monument of the two-winged sons of Boreas, slain by Hercules; and there are others in China and other countries.

STOOK, a term used in many parts of Britain for a shock of corn containing 12 sheaves.

STOOL, in medicine, an evacuation or discharge of the fæces by the anus.

Stool, in mining, is used when the miners leave off digging deeper, and work in the ends forward. The end before them is called the *stool*.

Stool, in ship-building, the name of the supporters of the poop and top lanterns.

STOOPING, in falconry, is when a hawk, being upon her wings at the height of her pitch, bends down violently to take the fowl.

STOPPERS, in a ship, certain short pieces of rope, which are usually knotted at one or both ends, according to the purpose for which they are designed. They are either used to suspend any heavy body, or to retain a cable, shroud, &c. in a fixed position. Thus, the anchors, when first hoisted up from the ground, are hung to the cat-head by a stopper attached to the latter, which passing through the anchor-ring, is afterwards fastened to the timber-head; and the same rope serves to fasten it on the bow at sea; or to suspend it by the ring which is to be sunk from the ship to the bottom. The stoppers of the cable have a large knot and a laniard at one end, and are fastened to a ring-bolt in the deck by the other. They are attached to the cable by the laniard, which is fastened securely round both by several turns passed behind the knot, or about the neck of the stopper; by which means the cable is restrained from running out of the ship when she rides at anchor.

The stoppers of the shroud have a knot and a laniard at each end. They are only used when the shrouds are cut asunder in battle, or disabled by tempestuous weather; at which time they are lashed, in the same manner as those of the cables, to the separated parts of the shroud, which are thereby reunited, so as to be fit for immediate service. This, however, is only a temporary expedient.

STOPS. See Punctuation; and Scripture, n° 136.

STORAX. See Styrax.

STORK, in ornithology. See Ardea.

STOVE for heating apartments, greenhouses, hot-houses, fruit-walls, &c.

When treating of the mechanical properties of air, we explained in sufficient detail the manner in which the expansion produced in a mass of air by heat produces that motion up our chimneys which is called the draught of the chimney; and, in the article Smoke, we considered the circumstances which tend to check, to promote, or to direct this current, so as to free us from the smoke and vitiated air which necessarily accompanies the consumption of the fuel. In Pneumatics we also attended to the manner in which our fires immediately operate in warming our apartments. At present, when about to describe a method of warming intrinsically different, we must pay some more attention to the distinguishing circumstance. Without pretending to explain the physical connection of heat and light, it may suffice to observe, that heat, as well as light, is communicated to distant bodies in an instant by radiation. A person passing hastily by the door of a glass-house feels the glow of heat in the very moment he sees the dazzling light of the furnace mouth, and it is interrupted by merely screening his face with his hand. In this way is an apartment partly warmed by an open fire; and we avoid the oppressive heat by sitting where the fire is not seen, or by interposing a screen. We are apt to connect this so strongly in the imagination with the light emitted by the fire, that we attribute the heat to the immediate action of the light. But this opinion is shown to be gratuitous by a curious experiment made before the Royal Society by Dr Hooke, and afterwards, with more care and accurate examination, by Mr Scheele. They found, that by bringing a plate of the most transparent glass briskly between the fire and one's face, the heat is immediately intercepted without any sensible diminution of the light. Scheele, by a very pretty investigation, discovered that the glass made the separation, and did it both in refraction and reflection; for he found, that when the light of the same fire was collected into a focus by means of a polished metal concave speculum, a thermometer placed there was *instantly* affected. But if we employ a glass speculum foiled in the usual manner with quicksilver, of the same diameter and focal distance, and of equally brilliant reflection, there is hardly any sensible heat produced in the focus, and the thermometer must remain there for a very long while before it is sensibly affected. When we repeated this curious experiment, we found, that after the glass has remained a long while in this position, whether transmitting or reflecting the light, it loses in a great measure its power of intercepting the heat. By varying this observation in many of its circumstances, we think ourselves entitled to conclude, that the glass absorbs the heat which it intercepts, and is very quickly heated by the absorption. While it rises in its own temperature, it intercepts the heat powerfully; but when it is, as it were, saturated, attracting no more than what it immediately imparts to the air in corporeal contact with it, the heat passes freely through along with the light. If the glass be held so near the fire that the surrounding air is very much heated, no sensible interruption of heat is perceived after the glass is thus saturated. We found the cheek more quickly sensible than the thermometer of this instantaneous radiation of the heat which accompanies the light, or is separated from it in this experiment. It is a very instructive experiment in the physiology of heat.

We cannot say how far this radiation of heat may extend, nor whether the accompanyment of light is absolutely necessary. The mathematician proceeds on the supposition that it extends as far as the radiation of light, and that, being also rectilineal, the density of the heat is proportional to that of the light. But these notions are somewhat gratuitous; and there are appearances,

appearances which render them doubtful. When with a lens of an inch in diameter we form a focus on a piece of black unpolished marble of an inch diameter, the mathematician must allow that no more rays fall on the marble than if the lens were away: therefore the marble should be equally warmed in either case. But it is by no means so, as we have repeatedly found by exposing it during equal times, and then dropping it into water. The water which is heated by the marble on which the focus has been formed will be found to have acquired from it much more heat than from the other. The tops of lofty mountains which are never shaded by clouds, but enjoy perpetual sunshine and serenity, instead of being warmer than the valleys below, are covered with never-melting snow; and we have some grounds to suspect that the genial influence of the sun requires the co-operation of the atmosphere, and to doubt whether there is any warmth at the moon, on which no atmosphere like ours can be observed. Perhaps the heat which cheers us, and fertilizes our earth, is chemically separated from our atmosphere by its elective attraction for the light of the sun. Our successors in the study of meteorology need not fear that the subject of their research will be soon deprived of scientific allurements. We know but little of it after all the progress we have made during this last century, and it still presents an ample field of discussion.

We said that the accompanyment of light is not demonstrably necessary. We are certain that heat may be imparted without any sensible light, in a manner which we can hardly suppose any thing but radiation. If a piece of very hot iron be placed a little without the principal focus of a metallic concave speculum, and a very sensible air-thermometer be placed in its conjugate focus, it will instantly show an elevation of temperature, altho' the iron is quite imperceptible to an eye which has even been a long while in the dark. No such rise of temperature is observed if the thermometer be placed a little to one side of the focus of the speculum; therefore the phenomenon is precisely similar to the radiation of light. We are obliged therefore to acknowledge that the heat is radiated in this experiment in the same way that light is in the common optical experiments.

Although this is the most usual way that we in this country employ fuel for warming our apartments, it is by no means the only way in which the heat diffused from this fuel may be imparted to distant bodies. It is not even the most effectual method; it is diffused also by immediate commmunication to bodies in contact. The air in immediate contact with the burning fuel is heated, and imparts some of its heat to the air lying beyond it, and this is partly shared with the air which is still farther off; and this diffusion, by communication *in contactu*, goes on till the remote air contiguous to the walls, the floor, the ceiling, the furniture, the company, all get a share of it in proportion to their attractions and their capacities. And as the air is thus continually supplied, and continually gives out heat, the walls, &c. become gradually warmer, and the room becomes comfortable and pleasant. But we apprehend that no great proportion of the heat actually acquired by the room is communicated in this way. This diffusion by contact is but slow, especially in air which is very dry; so slow indeed, that the air in the immediate neighbourhood of the fuel is hurried up the chimney before it has time to impart any of the heat received in contact. We know that the time employed in diffusing itself in this way through stagnant air to any moderate distance is very considerable. We imagine therefore that the heat communicated to our rooms by an open fire is chiefly by radiation, but in a way something different from what we mentioned before. We imagine, that as the piece of glass in Dr Hooke's experiment absorbs the heat, so the whole mass of air which fills the room intercepts the radiated heat in every part of the room where the fire is seen, and is as it were saturated with it throughout, and ready to impart it to every body immersed in it. We cannot otherwise account for the *equability* of the heat in the different parts of the room. Mere radiation on the solid bodies would warm them in the inverse duplicate ratio of their distances from the fire; and diffusion by contact, if compatible with the rapid current up the chimney, would heat the room still more unequably. Recollect how slowly, and with what rapid diminution of intensity, the colour of blue vitriol is communicated to water even to a very small distance. But because all parts of the air of the room absorb radiated heat, what is saturated at a higher temperature, being nearer to the fire, rises to the ceiling, spreads outwards along the ceiling, and has its place supplied by the air, which is thus pushed towards the fire from the places which are not directly illuminated.

Far different is the method of warming the room by a stove. Here the radiation, if any, is very feeble or scanty; and if a passage were allowed up the chimney for the warmed air, it would be quickly carried off. This is well known to the English who reside in the cold climates of St Petersburgh, Archangel, &c. They love the exhilarating flutter of an open fire, and often have one in their parlour; but this, so far from warming the room during the extreme cold weather, obliges them to heat their stoves more frequently, and even abstracts the heat from a whole suite of apartments. But all passages this way are shut up when we warm a room by stoves. The air immediately contiguous to the stove is heated by contact, and this heat is gradually, though slowly, diffused through the whole room. The diffusion would however be very slow indeed, were it not for the great expansibility of air by heat. But the air surrounding the stove quickly expands and rises to the ceiling, while the neighbouring air slides in to supply the place, nay is even pushed in by the air which goes outwards aloft. Thus the whole air is soon mixed, and the room acquires almost an equal temperature throughout.

The warming by stoves must therefore be managed upon very different principles from those adopted in the employment of open fires. The general principle is, 1*st*, To employ the fuel in the most effectual manner for heating the external part of the stove, which is immediately efficient in warming the contiguous air; and, 2*d*, To keep in the room the air already warmed, at least as much as is consistent with wholesomeness and cleanliness

The first purpose is accomplished by conducting the flue of the furnace round its external parts, or, in short, by making every part of the flue external. Of all forms, that of a long pipe, returned backwards and forwards, up and down (provided only that the place of its

its last discharge be considerably higher than its entry from the fire-place), would be the most effectual. We have seen a very small stove constructed in this way, the whole being inclosed in a handsome case of polished iron plate, pierced and cut into elegant foliage like the cock of a watch, so that the odd looking pipes were completely concealed. Though only three feet long, one foot thick, and six feet high, it warmed a very lofty room of 24 feet by 18, and consumed less than half the fuel of a stove of the more usual make, which did not so fully warm a smaller chamber.

It would occupy a volume to describe the immense variety of stoves which ingenuity or architectonic taste has constructed. We shall content ourselves with giving a specimen of the two chief classes into which they may be distinguished.

The air of a room may be equally warmed, either by applying it to the surface of a small stove made very hot, or to the surface of a much larger stove more moderately heated. The first kind is chiefly used in Holland, Flanders, and the milder climates of Germany and Poland. The last are universally used in the frozen climates of Russia and Sweden. The first are generally made of cast iron, and the last of brick-work covered with glazed tiles or stucco.

Plate CCCCLXXIV. Fig. 1. represents a small German stove fully sufficient for warming a room 24 feet by 18. The base is about three feet broad and 14 inches deep, that is, from back to front, and six or seven feet high. The decoration is in the fashion of that country; but the operative structure of it will admit of any style of ornament. A, is the fire-place, and the wood or charred coal is laid on the bottom, which has no bars. Bars would admit the air too freely among the fuel, and would both consume it too fast and raise too great a heat. That no heat may be uselessly expended, the sole of the fire-place and the whole bottom of the stove is raised an inch or two above the floor of the room, and the air is therefore warmed by it in succession, and rises upwards. For the same reason the back of the stove is not in contact with the wall of the room, or of the niche in which it is placed. The fire-place is shut up by a door which fits closely to its case, and has a small wicket at the bottom, whose aperture is regulated by a sliding plate, so as to admit no more air than what suffices for slowly consuming the fuel. The flame and heated air rise to the top of the fire-place three or four inches above the arch or mantle-piece, and get out laterally by two narrow passages B, B, immediately below the top plate of the base. The current bends downward on each side, passes at C, C, under the partition plates which divide the two side chambers, and then rises upwards through the outer division of each, and passes through narrow slits D, D, in the top plate, and from thence along the two hollow piers E, E. The two lateral currents unite at the top of the arch, and go through the single passage F into the larger hollow behind the escutcheon G. From this place it either goes straight upwards into the vent in the wall by a pipe on the top of the stove, or it goes into the wall behind by a pipe inserted in the back of the stove. The propriety of this construction is very obvious. The current of hot air is applied to exterior parts of the stove everywhere except in the two side chambers of the base, where the partition-plates form one side of the canal. Even this might be avoided by making each of these side-chambers a detached hollow pillar. But this would greatly increase the trouble of construction and joining together, and is by no means necessary. The arch H has a graceful appearance, and affords a very warm situation for any thing that requires it, such as a drink in a sick person's bed-chamber, &c. Persons of a certain class use this place for keeping a dish warm; nay, the lower part of the arch is frequently occupied by an inclosed chamber, where the heat rises high enough even for dressing victuals, as will be easily imagined when we reflect that the sole of it is the roof of the fire-place.

The stove now described is supplied with fuel and with air by the front door opening into the room. That there may be room for fuel, this middle part projects a few inches before the two side chambers. These last, with the whole upper part of the stove, are not more than ten inches deep. The passages, therefore, from the fire-place are towards the back of it; so that if we have a mind to see the fire (which is always cheerful), the door may be thrown open, and there is no danger of the smoke coming out after the current has once warmed the upper part of the stove. When the stove is of such dimensions that the base is about two feet and a half or three feet high, the fire-place may be furnished with a small grate in the British style. If the door is so hung that it can not only be thrown back, but lifted off its hinges, we have a stove grate of the completest kind, fully adequate, in our mild climate, to warm a handsome apartment, even with an open fire; and when we hang on the door, and shut up the fire-place, a stove of the dimensions already given is almost too much for a large drawing-room.

We have frequently remarked, that one side of these stoves grows much warmer than the other, and that it was difficult to prevent or remedy this; and we imagine that this is an unavoidable defect in all stoves with a double flue. It is scarcely possible to make the fire so equable in the fire-place, that one side shall not be a little warmer than the other, and a brisker current will then be produced in it. This must increase the consumption of the fuel on that side, which will increase the current, will heat this side still more, and thus go on continually till the fuel on this side is expended; after which the other side will obtain and increase the superiority. The flue is made double, that the fire-place may occupy the middle of the front; and it will be difficult to gain this point of symmetry with one flue. The inconvenience may, however, be corrected by damping valves placed in some part of the upright funnels E, E.

In the colder winters on the continent, it is thought necessary to increase the effect by making the fire-place open to the back of the stove. Its mouth or door communicates with or is joined to an opening of the same dimensions formed in the wall, and the door is on the other side in an antichamber or lobby. In Westphalia, and other places of Germany, the apartments are disposed round a spacious lobby, into which all their fire-places open, and are there supplied with fuel. By this construction it is plain that the air of the room, already warmed by the stove, is not carried off, and the room is more heated. But this method is very unfavourable to cheerfulness and health. The same air confined, and

repeatedly

repeatedly breathed and compounded with all the volatile emanations of the room, quickly loſes that refreſhing quality that is ſo deſirable, and even ſo neceſſary for health. It is never renewed except by very partial admixtures when the room doors are thrown open, and becomes diſagreeable to any perſon coming in from the open air; and in the houſes of the leſs opulent becomes really offenſive and nauſeous.

Something of this is unavoidable in all rooms heated by ſtoves. Even in our apartments in this country, perſons of delicate nerves are hurt by what they call the cloſe air of a room; and it is long before the ſmell of dinner is quite removed from a dining-room, notwithſtanding the copious current up the chimney. This muſt be incomparably more ſenſible in a room heated by a ſtove; and this inconvenience in peculiarly ſenſible with reſpect to the ſtove which we are conſidering at preſent, where we employ a ſmall ſurface heated to a great degree.

Such ſtoves are ſeldom made of any thing elſe than caſt-iron. This (in thoſe parts at leaſt which are in immediate contact with the fuel) is in a ſtate of continual calcination, and even throwing off ſcales. This indeed is not ſeen, becauſe it is the bottom or ſole of the fire place which is ſo heated: but the effect on the air of the room is the ſame. The calcination of the iron is occaſioned by the combination of pure vital air with the iron. This is abſtracted from the general maſs of atmoſpheric air in the room, of which it uſually conſtitutes about $\frac{2}{7}$ths. By this abſtraction the remainder becomes leſs fit for ſupporting animal life or flame, and may even become highly deleterious. In every degree the remainder becomes leſs refreſhing, and grows dull and oppreſſive. This is always accompanied by a peculiar ſmell, which, though not diſguſting, is unpleaſant. It reſembles the ſmell of burnt feathers, or more exactly the ſmell we feel if we rub violently for ſome time the palms of our hands together when perfectly dry.

For ſimilar reaſons theſe iron ſtoves occaſion a ſickly ſmell, by burning every particle of duſt which falls on the hot parts; and if they be wiped with a woollen cloth, or any cloth not perfectly free from every kind of greaſy or oily matter, a ſmell is produced for a day or days afterwards; ſo that without the moſt ſcrupulous attention we ſuffer by our very cleanlineſs.

For ſuch reaſons we think that the ſtoves of brick work covered with ſtucco or with glazed tiles are vaſtly preferable. Theſe are much uſed in the genteeler houſes in Flanders and Holland, where they are made in the moſt elegant forms, and decorated with beautiful ſculpture or enamel; but it is plain that they cannot be ſo effectual, nor equally warm a room with the ſame expence of fuel. Earthen ware, eſpecially when covered with porous ſtucco, is far inferior to metal in its power of conducting heat. If built of bricks, they muſt be vaſtly more bulky when the fire-place and flues are of the ſame dimenſions. The moſt perfect way of conſtructing them would certainly be to make them of pottery, in parts exactly fitted to each other, and joined by a proper cement. This mode of conſtructing would admit of every elegance of form or richneſs of ornament, and would not be ſo bulky as thoſe which are built of bricks. The great difficulty is to prevent their cracking by the heat. Different parts of the ſtone being of very different heats, they expand unequally, and there is no cement which can withſtand this, eſpecially when we recollect that the ſame heat which expands the baked earth cauſes the clay or cement, with which the parts of the ſtove are put together or covered, to contract. Accordingly thoſe earthen ware ſtoves ſeldom ſtand a winter or two without cracking in ſome place or other, even when ſtrengthened by iron hoops and cramps judiciouſly diſpoſed within them. Even hooping them externally, which would be very unſightly, will not prevent this; for nothing can reſiſt the expanſion and contraction by heat and cold. When a crack happens in a ſtove, it is not only unſightly, but highly dangerous; becauſe it may be ſo ſituated, that it will diſcharge into the room the air vitiated by the fire.

For theſe and other reaſons, we can ſcarcely hope to make ſtoves of brick-work or pottery which ſhall bear the neceſſary heat without cracking; and their uſe muſt therefore be confined to caſes where very moderate heat is ſufficient. We need not deſcribe their conſtruction. It is evident that it ſhould be more ſimple than that of iron ſtoves; and we imagine that in the very few caſes in which they are likely to be employed in this country, a ſingle fire-place and an arch over it, divided, if we pleaſe, by a partition or two of thin tile to lengthen the flue, will be quite enough. If the ſtove is made in whole or in part of potters ware, a baſe for the fire-place, with an urn, column, obeliſk, or pyramid above it, for increaſing the ſurface, will alſo be ſufficient. The failure commonly happens at the joinings, where the different pieces of a different heat, and perhaps of a different baking, are apt to expand unequally, and by working on each other one of them muſt give way. Therefore, inſtead of making the joints cloſe and uſing any cement, the upper piece ſhould ſtand in a groove formed in the undermoſt, having a little powdered chalk or clay ſprinkled over it, which will effectually prevent the paſſage of any air; and room being thus given for the unequal expanſion, the joint remains entire. This may be conſidered as a general direction for all furnace-work, where it is in vain to attempt to hinder the mutual working of the parts.

We have ſeen ſtoves in ſmall apartments at St Peterſburg, which were made internally of potters ware, in a great variety of forms, and then covered with a thick coat of ſtucco, finiſhed externally with the utmoſt elegance of ornament, and we were informed that they were very rarely ſubject to crack. They did not give much heat, on account of the very low conducting power of the porous ſtucco; but we imagine that they would be abundantly warm for a moderate room in this country.

When fitted up in theſe ſituations, and with theſe precautions, the brick or pottery ſtoves are incomparably more ſweet and pleaſant than the iron ones.

But in the intenſe colds of Ruſſia and Sweden, or even for very large rooms in this country, ſtoves of theſe ſmall dimenſions are not ſufficiently powerful, and we muſt follow the practice of thoſe countries where they are made of great ſize, and very moderately heated. It is needleſs to deſcribe their external form, which may be varied at pleaſure. Their internal ſtructure is the ſame in all, and is diſtinctly deſcribed in PNEUMATICS, n° 364. We ſhall only enlarge a little on the pecu-

peculiarities connected with the general principle of their construction.

The stove is intended as a sort of magazine, in which a great quantity of heat may be quickly accumulated, to be afterwards slowly communicated to the air of the room. The stove is therefore built extremely massive; and it is found that they are more powerful when coated with clay as wet as can be made to hang together. We imagine the reason of this to be, that very wet clay, and more particularly stucco, must be exceedingly porous when dry, and therefore a very slow conductor of heat. Instead of sticking on the glazed tiles with no more clay or stucco than is sufficient to attach them, each tile has at its back a sort of box baked in one piece about two or three inches deep. It is represented in fig. 2. This is filled with mortar, and then stuck on the brick-work of the stove, which has a great number of iron pins or hooks driven into the joints, which may sink into this clay and keep it firmly attached when dry. This coating, with the massive brick-work, forms a great mass of matter to be heated by the fuel. The lowest chamber, which is the fire-place, is somewhat wider, and considerably thicker than the stories above, which are merely flues. When the fire-place is finished and about to be arched over, a flat iron bar of small thickness is laid along the top of the side-wall on both sides, a set of finishing bricks being moulded on purpose with a notch to receive the iron bar. Cross bars are laid over these, one at each end and one or two between, having a bit turned down at the ends, which takes hold of the longitudinal bars, and keeps them from being thrust outwards either by the pressure of the arch or by the swelling in consequence of the heat. In fig. 3. A is the cross section of one of the long bars, and BC is part of one of the cross bars, and CD is the clench which confines the bar A. This precaution is chiefly necessary, because the contraction of the stove upwards obliges the walls of the other stories to bear a little on the arch of the fire-place. The building above is kept together in like manner by other courses of iron bars at every second return of the flue. The top of the stove is finished by a pretty thick covering of brick-work. The last passage for the air at H (see PNEUMATICS, fig. 62.) has a ring lining its upper extremity, and projecting an inch or two above it. The flat round it is covered with sand. When we would stop this passage, a cover shaped like a bason or cover for dishes at table, is whelmed over it. The rim of this, resting on the sand, effectually prevents all air from coming through and getting up the vent. Access is had to this damper by a door which can be shut tight enough to prevent the heated air of the room from wasting itself up the vent. When the room is too warm, it may be very rapidly cooled by opening this door. The warm air rushes up with great rapidity, and is replaced by cool air from without.

The management of the stove is as follows. About eight o'clock in the morning the *pietchnick*, or servant who has the charge of the stoves, takes off the cover, shuts the damper-door, and opens the fire-place door. He then puts in a handful of wood shavings or straw, and kindles it. This warms the stove and vent, and begins a current of air through it. He then lays a few chips on the sole of the fire-place, immediately within the door; and behind this he arranges the billets of birchwood, with their ends inwards. Then he lays on more wood in the front, till he thinks there is enough. He sets fire to the chips, shuts the door, and opens the small wicket at its bottom. The air blows the flame of the chips upon the billets behind them, and thus kindles them. They consume slowly, while the billets in front remain untouched by the fire. The servant, having made his first round of the rooms, returns to this stove, and opens the door above to admit air into the vent. This is to supply its draught, and thus to check the draught in the body of the stove, which is generally too strong at this time, and would consume the fuel too fast. By this time the billets in the front are burning, first at the bottom, and the rest in succession as they sink down on the embers, and come opposite to the wicket. The room does not yet feel any effect from the fire, the heat of which has not yet reached its external surface; but in about half an hour this grows warm. The upper door is shut again, that no heat may now be wasted. The pietchnik by and by spreads the embers and ashes over the whole bottom of the fire-place with a rake, by which the bottom is greatly heated, and heats the air contiguous to it externally (for it stands on little pillars) very powerfully. He takes care to bring up to the top of the ashes every bit of wood or coal that is not yet consumed, that all may be completely expended. He does this as briskly as possible, that the room may not lose much warmed air by keeping open the fire-place door. At his last visit, when he observes no more glowing embers, he shuts the fire-place door and wicket, and puts the damper on the passage above, and shuts its door.—All this is over in about an hour and a half after kindling the fire. All current of air is now at an end within the stove, and it is now a great mass of brick-work, heated to a great degree within, but only about blood-warm externally. The heat gradually spreads outwards, and the external surface of the stove acquires its greatest heat about three o'clock in the afternoon; after which it gradually cools till next morning.

This heat seldom is so great that one cannot bear to touch the stove with his cheek, and to keep it there. In consequence of this it can burn none of the dust which unavoidably falls on the stove, and we are never troubled with the sickening smells that are unavoidable when we employ the small cast iron stoves much heated. The great expence of heat in a room arises from the glass windows. The pane is so thin that the external air keeps it continually cold, and thus the windows are continually robbing the air of the room of its heat. This expence of heat is reduced to less than one third by double casements. The inner casement is about as much colder than the room as the outer casement is warmer than the air of the fields; and we have the singular advantage of having no ice formed on the glasses. But to ensure this last advantage, the seams of the inner casement must be pasted with paper, and those of the outer casement must be left unpasted. If we do the contrary, we shall certainly have ice on the outer casement; the reason of which is easily seen.

We have been thus particular in our description of the management, because the reasons of some particulars are not very obvious, and the practice would not readily occur to many people; so that a person who, on the

 faith

Stove.

faith of our recommendation, should prefer one of these stoves to the German stove, whose management is simple and obvious, might be greatly disappointed. But by following this method, we are confident that the Russian stove will be found much superior both in warmth and agreeable air. The spreading out of the embers, and waiting till all is reduced to ashes before the doors are shut, is also absolutely necessary, and a neglect of it would expose us to imminent danger of suffocation by fixed air; and this is the only inconvenience of the Russian stove, from which the other stove is free. The fixed air has no smell; and the first indication of its presence is a slight giddiness and lassitude, which disposes us to sit down and to sleep. This would be fatal; and we must immediately open the upper passage and the fire-place door, so as to produce a strong current to carry the vitiated air of the room up the chimney. Throwing up the sashes, or at least opening all the doors, is proper on such an occasion.

If we burn pit-coal, either raw or charred, this precaution is still more necessary; because the cinder is not so easily or so soon completely consumed. This fuel will require a little difference in the management from wood fuel, but which is easily seen by any person of reflection. The safe way would be to rake out all half-burnt coal before shutting up the doors.

If we use raw pit-coal, great care is necessary to prevent the accumulation of soot in the upper part of the stove. It is an inaccessible place for the chimney sweep; and if we attempt to burn it out, we run a great risk of splitting that part of the stove which is the most slightly constructed. It is advisable therefore to burn it away every day, by giving a brisk draught with an open door for five minutes. With wood or coak there is no danger.

It will not be improper in this place to give some instructions for the construction of stoves for warming several floors in a great manufactory, such as a cotton-mill, or a public library or museum.

In such situations we think cleanliness, wholesomeness, and sweetness of air, no less necessary than in the drawing room of a man of opulence. We therefore recommend the brick-stove in preference to the iron one; and though it would not be the best or most economical practice to heat it but once a-day, and we should rather prefer the German practice of constant feeding, we still think it highly proper to limit the heat to a very moderate degree, and employ a large surface.

If the disposition of the rooms allows us the conveniency of a thick party-wall, we would place the stove in the middle of this wall, in an arch which pierces through the wall. Immediately above this arch we would carry up a very wide chimney through the whole height. This chimney must have a passage opening into each floor on both sides, which may be very accurately shut up by a door. The stove being set up under the arch, it must have a pipe communicating with its flue, and rising up through this chimney. Could an earthen pipe be properly supported, and secured from splitting by hoops, we should prefer it for the reasons already given. But as this is perhaps expecting too much, we must admit the use of a cast iron pipe. This is the real chimney or flue of the stove, and must be of as great diameter as possible, that it may act, by an extensive surface, all the way up.

The stove stands under the arch in the wall; but the air that is warmed by its surface would escape on both sides, and would be expended in that single floor. To prevent this, the stove must be inclosed in a case: this may be of brick-work, at the distance of two or three inches from the stove all round. It must be well shut in above, and at the foundation must have a row of small holes to admit the air all around it. This air will then be warmed over the whole space between the stove and the case, pass up the chimney, and there receive additional heat from the flue pipe which is in the middle. Great care must be taken that the fire-place door have no communication with the space between the stove and its case, but be inclosed in a mouth-piece which comes through the case, and opens into the feeding room. Thus all the air which goes up to the rooms will be pure and wholesome, provided we take care that every thing be kept clean and sweet about the air holes below. Observe that those air-holes which are near the furnace door must be inclosed in a wooden trunk which takes in its air at some distance from this door; for since the current between the stove and case may be almost as great as the current within the stove (nay, when a puff of wind beats down the chimney, it may even exceed it), there is a risk of some vitiated air and smoke being drawn into the case.

If the stove cannot be placed in the arch of a party-wall, it may be set adjoining to a side or outer wall, and furnished with a case, a large chimney, and a flue-pipe, in the same manner. But in this case a great deal of heat is wasted on this outer wall, and carried off by the external air. In this situation we would recommend to line that part of the wall which is behind the stove (at two or three inches distance), and the whole of the chimney, with plaster on laths. These should be nailed on battens properly fastened on the wall, leaving a space of an inch between the laths and the wall. The plaster should be of the most spungy kind, having in it a quantity of clay in powder instead of the full proportion of sand. Horse-dung, washed with water and strained through coarse flannel, leaves a great portion of unassimilated vegetable fibre, which will mix very intimately in the plaster, and make it a substance very unfit for conducting heat. There is no danger of catching fire by this lining. We have seen a most tremendous fire rage for three hours, in contact with a partition of lath and plaster (on the plaster-side however), without discolouring the thin laths on the other side. We once saw a cottage chimney on fire, and burn till the soot was consumed. This chimney was nothing but a pipe of a foot wide, made of laths, and plastered on the inside and outside; and it passed through a thatched roof. We therefore recommend this in place of the brick-case for inclosing the stove. It would save heat; and as it might be made in pieces on detached frames, which could be joined by iron straps and hinges, any part of the stove could be laid open for repairs at pleasure.

We have no hesitation in saying that a stove constructed in this manner would be greatly superior in power to any we have seen, and would be free from many of their disgusting defects. We beg leave therefore to conclude this part of the subject by describing one which was to have been erected in one of the churches of the city of Edinburgh.

Fig. 4. is a sketch of the plan of the church contained

ed in the parallelogram AFED. P marks the place of the pulpit, and LMNO the front of the galleries. Theſe are carried back to the ſide walls AB and DC. But at the end oppoſite to the pulpit they do not reach ſo far, but leave a ſpace BFEC about 12 feet wide. Below the back of the galleries, on each ſide, there is a paſſage ABGH, KICD, ſeparated from the ſeated part of the church by partitions which reach from the floor to the galleries, ſo that the ſpace HGIK is completely ſhut in. The church is an ancient Gothic building, of a light and airy ſtructure, having two rows of large windows above the arcades, and a ſpacious window in the eaſt end above the pulpit. The congregation complain of a cold air, which they feel pouring down upon their heads. This is more particularly felt by thoſe ſitting in the fronts of the galleries. We imagine that this ariſes chiefly from the extenſive ſurface of the upper row of windows, and of the cold ſtone-walls above, which robs the air of its heat as it glides up along the ſides of the church. It becomes heavier by collapſing, and in this ſtate deſcends in the middle of the church.

The ſtove S is placed againſt the middle of the weſt wall at the diſtance of a few inches, and is completely incloſed in a caſe of lath and plaſter. The vent, which is to carry off the ſmoke and burnt air, is conveyed up or along the wall, and through the roof or ſide-wall, but without any communication with the caſe. In like manner the fire-place door is open to the paſſage, without communicating with the caſe; and care is taken that the holes which admit the air into the caſe are ſo diſpoſed that they ſhall run no riſk of drawing in any air from the fire-place door.

From the top of this caſe proceed two trunks Q, R, each of which is two feet broad and ſix inches deep, coated within and without with the moſt ſpungy plaſter that can be compoſed. For this purpoſe we ſhould recommend a compoſition of powdered charcoal and as much clay and quicklime as will give it a very ſlight coheſion. We know that a piece of this may be held in the hand, without inconvenience, within an inch of where it is of a glowing red heat.—Theſe trunks open into another trunk XVTYZ, which ranges along the partition immediately under the galleries, and may be formed externally into a corniche, a little maſſive indeed, but not unſightly in a building of this ſtyle. This trunk is coated in the ſame manner. It has ſeveral openings *a*, *a*, &c. which have ſliders that can be drawn aſide by means of handles acceſſible from the outer paſſage.—At the extremities X and Z of this trunk are two perpendicular trunks which come up through the galleries, and are continued to a conſiderable height. At their junction with their horizontal trunk are two doors large enough to admit a lamp. Each perpendicular trunk has alſo a valve by which it can be completely ſtopped.

The ſtove is managed as follows: Early in the morning the ſuperintendant ſhuts all the ſliders, and ſets a lamp (burning) in each of the trunks X and Z, and ſhuts the doors. He then puts on and kindles the fire in the ſtove, and manages it either in the Ruſſian or German method. Perhaps the latter is preferable, as being liable to feweſt accidents from miſtake or neglect.

The lamps ſet in the lower ends of the upright trunks preſently warm them, and produce a current of air upwards. This muſt be ſupplied by the horizontal trunk, which muſt take it from the caſe round the ſtove. Thus a current is begun in the direction we wiſh. By and by the air in the caſe acquires heat from the ſtove, and the current becomes extremely briſk. When the manager perceives this, he removes the lamps, ſhuts the valves, and opens the holes *a*, *a*, &c. beginning with the moſt remote, and proceeding ſlowly towards the ſtove from each extremity of the horizontal branches. The heated air now iſſues by theſe holes, glides along the ceiling below the galleries, and eſcapes, by riſing up along the fronts of the galleries, and will be ſenſibly felt by thoſe ſitting there, coming on their faces with a gentle warmth. It will then riſe (in great part) ſtraight up, while ſome of it will glide backwards, to the comfort of thoſe who ſit behind.

The propriety of ſhutting the valves of the upright trunks is evident. If they were left open, no air would come out by the holes *a*, *a*, &c.; but, on the contrary, the air would go in at theſe holes to ſupply the current, and the ſtove be rendered uſeleſs. The air delivered by theſe holes will keep cloſe to the ceiling, and will not, as we imagine, incommode thoſe who ſit below the galleries. But if it ſhould be found to render theſe parts too warm, holes may be pierced through the ceiling, by which it will riſe among the people above, and muſt be very comfortable. It will require the careful attention of ſome intelligent perſon to bring all this into a proper train at firſt, by finding the proper apertures of the different holes, ſo as to render the heat equable through the whole ſpace. But this being once aſcertained the difficulty is over.

The air trunks muſt be very capacious, but may be contracted towards the extremities as their lateral diſcharges diminiſh; and the row of holes which admit the air to the caſe round the ſtove muſt be fully able to ſupply them.

It muſt be obſerved, that in this conſtruction the aſcenſional force is but ſmall. It is only the height of a ſhort column of warm air from the ground to the galleries. At firſt indeed it is great, having the unlimited height of the perpendicular trunks at X and Z; but during the uſe of the ſtove it is reduced to nine or ten feet. It is neceſſary, therefore, that the ſtove be highly heated, perhaps conſiderably beyond the Ruſſian practice, but yet inferior to the heat of the German iron ſtoves. But ſtill we ſtrongly recommend the brick or pottery ſtoves, on account of the wholeſome ſweetneſs of the air which they furniſh; and we are certain that a ſtove of moderate dimenſions, eight feet long, for inſtance, by eight feet high, will be ſufficient for warming a church holding 1200 or 1500 people. If the ſtove could be placed lower, which in many ſituations is very practicable, its effect would be proportionally greater, becauſe all depends on the rapidity of the current. When we are limited in height, we muſt extend the ſtove ſo much the more in length, and make the air trunks more capacious. Theſe and many other circumſtances of local modification muſt be attended to by the erector of the ſtove; and without the judicious attention of an intelligent artiſt, we may expect nothing but diſappointment. It is hardly poſſible to give inſtructions ſuited to every ſituation; but a careful attention to the general principle which determines the aſcenſional force will free the artiſt from any great riſk of failure.

We

We may say the same thing of stoves for conservatories, hot houses, hot walls, &c. and can hardly add any thing of consequence to what we have already said on these heads in the article PNEUMATICS.

We must not, however, dismiss the subject without taking notice of the very specious projects which have been frequently offered for drying malt by stoves. Many of these are to be seen in the publications of the Academies of Stockholm, Upsal, Copenhagen, and some have been erected in Great Britain; but they have not been found to answer.

On Drying of Malt.

"We apprehend that they cannot answer. To dry malt, and make it fit for the ales and beers for which this island is so famous, it is by no means enough that we give it a proper and an equable supply of heat.—This alone would bake it and make it flinty, causing the moisture to penetrate the mealy particles of the grain; and, by completely dissolving the soluble parts, would render each kernel an uniform mass, which would dry into a flinty grain, breaking like a piece of glass.—A grain of malt is not an inert pulp. It is a SEED, in an active state, growing, and of an organised structure. We wish to stop it in this state, and kill it, not by heating it, but by abstracting its moisture. We thus leave it in its granulated or organized form, spungy, and fit for imbibing water in the mash tub, without running into a paste.

"To accomplish these purposes, the construction of our malt kilns seems very well adapted. The kiln is the only flue of the furnace, and a copious *current* of air is formed through among the grains, carrying off with it the water which is evaporated by the heat. But this evaporation, being chiefly in consequence of the vapour being immediately dissolved by the passing air, will stop as soon as the current of air stops. This current has to make its way through moist grain, laid in a pretty thick bed, and matted together. Some force, therefore, is necessary to drive it through. This is furnished by the draught of the kiln. Substituting a stove, immediately applied to the malt, will not have this effect. The only way in which we think this can be done different from the present, is to have a horizontal flue, as has been proposed in these projects, spread out at a small distance below the grate on which the malt is laid, and to cover the whole with a high dome, like a glass house dome. This being filled with a tall column of hot air, and having no passage into it but through the malt, would produce the current which we want. We are convinced that this will make much less fuel serve; but we are by no means certain that the sulphureous and carbonic acid which accompanies the air in our common kiln is not a necessary or a useful ingredient in the process. It is well known that different coaks, cinders, or charcoals, impart different qualities to the malts, and are preferred *each for its own purpose*. Were this a matter of indifference, we know a method of rapidly drying malt much more economical and expeditious than by either kiln or stove." But this has nothing to do with our present subject, of which we now take leave.

STOURBRIDGE, or STURBICH, the name of a field near Cambridge, noted for its famous fair kept annually on the 7th of September, and which continues for a fortnight. The commodities are, horses, hops, iron, wool, leather, cheese, &c. This place is also noted for an excellent species of clay capable of resisting an intense heat. It is used in making pots for glass-houses, fire-bricks, &c. and is sold at an high price.

STOW, the name of a market-town in Gloucestershire in England, situated in W. Long. 1. 50. N. Lat. 51. 54. It is also the name of a fine seat of the Marquis of Buckingham in Buckinghamshire. Here are the best gardens in England, adorned with busts, statues, obelisks, pavilions, and temples. It is two miles from the town of Buckingham.

STOW (John), the industrious historian, son of Thomas Stow merchant taylor of St Michael's, Cornhill, in London, was born about the year 1525. Of the early part of his life we know very little, except that he was bred to his father's business, which in the year 1560 he relinquished, devoting himself entirely to the study of our ancient historians, chronicles, annals, charters, registers, and records. Of these he made a considerable collection, travelling for that purpose to different parts of the kingdom, and transcribing such manuscripts as he could not purchase. But this profession of an antiquary being attended with no present emolument, he was obliged for subsistence to return to his trade.—It happened, however, that his talents and necessities were made known to Dr Parker archbishop of Canterbury; who being himself an antiquary, encouraged and enabled Mr Stow to prosecute his darling study. In those times of persecution, though Elizabeth was then upon the throne, honest John Stow did not escape danger. His collection of Popish records was deemed cause of suspicion. His younger brother Thomas preferred no less than 140 articles against him before the ecclesiastical commission; but the proof being insufficient, he was acquitted. In 1565 he first published his Summary of the Chronicles of England. About the year 1584 he began his Survey of London. In 1585 he was one of the two collectors for a great muster of Limestreet ward: in the same year he petitioned the corporation of London to bestow on him the benefit of two freemen, to enable him to publish his survey; and in 1589 he petitioned again for a pension. Whether he succeeded, is not known. He was principally concerned in the second edition of Holinshed's chronicle, published in 1587. He also corrected, and twice augmented, Chaucer's works, published in 1561 and in 1597. His survey of London was first published in 1598. To these laborious works he would have added his large Chronicle, or History of England; but he lived only to publish an abstract of it, under the title of *Flores Historiarum*. The folio volume, which was printed after his death, with the title of *Stow's Chronicle*, was taken from his papers by Edmund Howes. Having thus spent his life and fortune in these laborious pursuits, he was at last obliged to solicit the charitable and well disposed for relief. For this purpose, king James I. granted him, in 1603, a brief, which was renewed in 1604, authorising him to collect in churches the benefactions of his fellow-citizens. He died in April 1605, aged 80; and was buried in his parish church of St. Andrew's, Undershaft, where his widow erected a decent monument to his memory. John Stow was a most indefatigable antiquarian, a faithful historian, and an honest man.

STOWMARKET, a town of Suffolk, in England, situated in E. Long. 1. 6. N. Lat. 52. 16. It is a large handſome place, ſituated between the branches of the rivers Gypping and Orwell, and is remarkable for having the beſt cherries in England.

STOWAGE, the general diſpoſition of the ſeveral materials contained in a ſhip's hold, with regard to their figure, magnitude, or ſolidity.

In the ſtowage of different articles, as ballaſt, caſks, caſes, bales, and boxes, there are ſeveral general rules to be obſerved, according to the circumſtances or qualities of thoſe materials. The caſks which contain any liquid are, according to the ſea phraſe, to be *bung-up* and *bilge-free*, i. e. cloſely wedged up in an horizontal poſition, and reſting on their quarters: ſo that the bilges where they are thickeſt being entirely free all round, cannot rub againſt each other by the motion of the veſſel. Dry goods, or ſuch as may be damaged by the water, are to be carefully incloſed in caſks, bales, caſes, or wrappers; and wedged off from the bottom and ſides of the ſhip, as well as from the bow, maſts, and pump-well. Due attention muſt likewiſe be had to their diſpoſition with regard to each other, and to the trim and centre of gravity of the ſhip; ſo that the heavieſt may always be neareſt the keel, and the lighteſt gradually above them.

STRABISMUS, ſquinting. See MEDICINE-*Index*.

STRABO, a celebrated Greek geographer, philoſopher, and hiſtorian, was born at Amaſia, and was deſcended from a family ſettled at Gnoſſus in Crete. He was the diſciple of Xenarchus, a Peripatetic philoſopher, and at length attached himſelf to the Stoics. He contracted a ſtrict friendſhip with Cornelius Gallus, governor of Egypt, and travelled into ſeveral countries to obſerve the ſituation of places, and the cuſtoms of nations. He flouriſhed under Auguſtus, and died under Tiberius about the year 25, in a very advanced age.—He compoſed ſeveral works, all of which are loſt except his Geography in 17 books; which are juſtly eſteemed very precious remains of antiquity. The two firſt books are employed in ſhowing, that the ſtudy of geography is not only worthy of, but even neceſſary to, a philoſopher; the third deſcribes Spain; the fourth, Gaul and the Britannic iſles; the fifth and ſixth, Italy and the adjacent iſles; the ſeventh, which is imperfect at the end, Germany, the countries of the Getæ and Illyrii, Taurica Cherſoneſus, and Epirus; the eighth, ninth, and tenth, Greece with the neighbouring iſles; the four following, Aſia within Mount Taurus; the fifteenth and ſixteenth, Aſia without Taurus, India, Perſia, Syria, Arabia; and the ſeventeenth, Egypt, Æthiopia, Carthage, and other places of Africa. Strabo's work was publiſhed with a Latin verſion by Xylander, and Notes by Iſaac Caſaubon (or rather by Henry Scrimzeer, from whom Caſaubon chiefly ſtole them), at Paris, 1620 in folio. But the beſt edition is that of Amſterdam in 1707, in two volumes folio, by the learned Theodore Janſonius ab Almelooveen, with the entire notes of Xylander, Caſaubon, Meurſius, Cluver, Holſtenius, Salmaſius, Bochart, Ez. Spanheim, Cellarius, and others. To this edition is ſubjoined the *Chreſtomathiæ*, or epitome of Strabo; which according to Mr Dodwell, who has written a very elaborate and learned diſſertation about it, was made by ſome unknown perſon between the years of Chriſt 676 and 996. It has been found of ſome uſe, not only in helping to correct the original, but in ſupplying in ſome meaſure the defect in the ſeventh book. Mr Dodwell's diſſertation is prefixed to this edition.

STRADA (Famianus), a very ingenious and learned Jeſuit, was born at Rome the latter end of the 16th century, and taught rhetoric there, in a public manner, for fifteen years. He wrote ſeveral pieces upon the art of oratory, and publiſhed ſome orations with a view of illuſtrating by example what he had inculcated by precept. But his *Proluſiones Academicæ* and his *Hiſtoria de Bello Belgico* are the two works which raiſed his reputation, and have preſerved his memory. His hiſtory of the war of Flanders was publiſhed at Rome; the firſt decade in 1640, the ſecond in 1647; the whole extending from the death of Charles V. which happened in 1558, to the year 1590. It is written in good Latin, as all allow; but its merit in other reſpects has been variouſly determined. His *Proluſiones Academicæ* ſhow great ingenuity, and a maſterly ſkill in claſſical literature; that proluſion eſpecially in which he introduces Lucan, Lucretius, Claudian, Ovid, Statius, and Virgil, each of them verſifying according to his own ſtrain. They have been often printed. We know not the year of Strada's birth or of his death.

STRAHAN (William,) an eminent printer, was born at Edinburgh in the year 1715. His father, who had a ſmall appointment in the cuſtoms, gave his ſon the education which every one of decent rank then received in a country where the avenues to learning were eaſy, and open to men of the moſt moderate circumſtances. After having paſſed through the tuition of a grammar-ſchool, he was put apprentice to a printer; and when a very young man, removed to a wider ſphere in that line of buſineſs, and went to follow his trade in London. Sober, diligent, and attentive, while his emoluments were for ſome time very ſcanty, he contrived to live rather within than beyond his income; and though he married early, and without ſuch a proviſion as prudence might have looked for in the eſtabliſhment of a family, he continued to thrive, and to better his circumſtances. This he would often mention as an encouragement to early matrimony; and uſed to ſay, that he never had a child born that Providence did not ſend ſome increaſe of income to provide for the increaſe of his houſehold. With ſufficient vigour of mind, he had that happy flow of animal ſpirits that is not eaſily diſcouraged by unpromiſing appearances.

His abilities in his profeſſion, accompanied with perfect integrity and unabating diligence, enabled him, after the firſt difficulties were overcome, to advance with rapid ſucceſs. And he was one of the moſt flouriſhing men of the trade, when, in the year 1770, he purchaſed a ſhare of the patent for king's printer of Mr Eyre, with whom he maintained the moſt cordial intimacy during the reſt of his life. Beſide the emoluments ariſing from this appointment, as well as from a very extenſive private buſineſs, he now drew largely from a field which required ſome degree of ſpeculative ſagacity to cultivate on account of the great literary property which he acquired by purchaſing the copy-rights of the moſt celebrated authors of the time. In this his liberality kept equal pace with his prudence, and in ſome caſes went perhaps rather beyond it. Never had ſuch rewards been given to the labours of literary men as now were received from him and his aſſociates in thoſe purchaſes of copy-rights from authors.

Having now attained the first great object of business, wealth, Mr Strahan looked with a very allowable ambition on the stations of political rank and eminence. Politics had long occupied his active mind, which he had for many years pursued as his favourite amusement, by corresponding on that subject with some of the first characters of the age. Mr Strahan's queries to Dr Franklin in the year 1769, respecting the discontents of the Americans, published in the London Chronicle of 28th July 1778, show the conception he entertained of the important consequences of that dispute, and his anxiety as a good subject to investigate, at that early period, the proper means by which their grievances might be removed, and a permanent harmony restored between the two countries. In the year 1775 he was elected a member of parliament for the borough of Malmsburg in Wiltshire, with a very illustrious colleague, the Hon. C. J. Fox; and in the succeeding parliament, for Wootton Basset, in the same county. In this station, applying himself with that industry which was natural to him, he was a useful member, and attended the house with a scrupulous punctuality. His talents for business acquired the consideration to which they were intitled, and were not unnoticed by the minister.

In his political connections he was constant to the friends to whom he had first been attached. He was a steady supporter of that party who were turned out of administration in spring 1784, and lost his seat in the house of commons by the dissolution of parliament with which that change was followed: a situation which he did not show any desire to resume on the return of the new parliament; arising from a feeling of some decline in his health, which had rather suffered from the long sittings and late hours with which the political warfare in the preceding had been attended. Without any fixed disease, his strength visibly declined; and though his spirits survived his strength, yet the vigour and activity of his mind were also considerably impaired. Both continued gradually to decline till his death, which happened on the 9th of July 1785 in the 71st year of his age.

Endued with much natural sagacity, and an attentive observation of life, he owed his rise to that station of opulence and respect which he attained, rather to his own talents and exertion, than to any accidental occurrence of favourable or fortunate circumstances. His mind was not uninformed by letters; and from a habit of attention to style, he acquired a considerable portion of critical acuteness in the discernment of its beauties and defects. In one branch of writing he particularly excelled—the epistolary; in which he not only showed the precision and clearness of business, but possessed a neatness as well as a fluency of expression which few letter-writers have been known to surpass. Letter-writing was one of his favourite amusements; and among his correspondents were men of such eminence and talents as well repaid his endeavours to entertain them. Among these, as beforementioned, was the justly celebrated Dr Franklin, originally a printer like Mr Strahan, whose friendship and correspondence, notwithstanding the difference of their sentiments in political matters, he continued to enjoy till his death. One of the latest letters which he received from his illustrious and venerable friend, contained a humorous allegory of the state of politics in Britain, drawn from the profession of printing; of which, though the Doctor had quitted the exercise, he had not forgotten the terms.

The judicious disposition which Mr Strahan made of his property, affords an evident proof of his good sense and propriety. After providing munificently for his widow and children his principal study seems to have been to mitigate the affliction of those (and many there were) who would more immediately have felt his loss, by bequeathing them liberal annuities for their lives; and (recollecting that all of a profession are not equally provident) he left 1000l. to the Company of Stationers, the interest to be divided among infirm old printers.

As the virtuous connections of the life and the heart are always pleasing to trace—of Mr Strahan it may briefly be said, that his capacity, diligence, and probity, raised him to the head of his profession. The good humour and obliging disposition which he owed to nature, he cultivated with care, and confirmed by habit. His sympathetic heart beat time to the joy and sorrow of his friends. His advice was always ready to direct youth, and his purse open to relieve indigence. Living in times not the purest in the English annals, he escaped unsullied through the artifices of trade and the corruption of politics. In him a strong natural sagacity, improved by an extensive knowledge of the world, served only to render respectable his unaffected simplicity of manners, and to make his Christian philanthropy more discerning and useful. The uninterrupted health and happiness which accompanied him for half a century in the capital, proves honesty to be the best policy, temperance the greatest luxury, and the essential duties of life its most agreeable amusement. In his elevated fortune, none of his former acquaintance ever accused him of neglect. He attained prosperity without envy, enjoyed wealth without pride, and dispensed bounty without ostentation.

STRAIKS, in the military art, are strong plates of iron, six in number, fixed with large nails called *straik-nails*, on the circumference of a cannon-wheel, over the joints of the fellows; both to strengthen the wheel, and to save the fellows from wearing on hard ways or streets.

STRAIN, a pain occasioned by the violent extension of some membranous or tendinous part.

STRAIN, *Stress*, in mechanics, are terms indiscriminately used to express the force which is *excited* in any part of a machine or structure of any kind tending to break it in that part. Thus every part of a rope is *equally* strained by the weight which it suspends. Every part of a pillar is *equally* strained by the load which it supports. A mill axle is *equally* twisted and strained in every part which lies between the part of the wheel actuated by the moving power and the part which is resisted by the work to be performed. Every part of a lever or joist is *differently* strained by a force acting on a distant part.

It is evident that we cannot make the structure fit for its purpose, unless the strength in every part be at least equal to the stress laid on, or the strain excited in that part. It is no less plain, that if we are ignorant of the principles which determine this strain, both in intensity and direction, in relation to the magnitude and the situation of its remote cause, the only security we have for success is to give to every part of the assem-

blage

blage such solidity that we can leave no doubt of its sufficiency. But daily experience shows us that this vague security is in many cases uncertain, if we are thus ignorant. In all cases it is slovenly, unlike an artist, attended with useless expence, and in machines is attended with a loss of power which is wasted in changing the motions of a needless load of matter.

It must therefore greatly tend to the improvement of all professions occupied in the erection or employment of such structures to have a distinct notion of the strains to which their parts are exposed. Frequently, nay generally, these strains are not immediate, but arise from the action of forces on distant parts, by which the assemblage is strained, and there is a tendency to rupture in every part. This strain is *induced* on every part, and is there modified by fixed mechanical laws. These it is our business to learn; but our chief object in this investigation is to determine the strength of materials which it is necessary to oppose in every part to this strain; and how to oppose this strength in such a manner that it shall be exerted to the best advantage. The notions of strain and strength therefore hardly admit of separation; for it is even by means of the strength of the intermediate parts that the strain is propagated to, or excited in, the part under consideration. It is proper therefore to consider the whole together under the article STRENGTH *of Materials* in mechanics.

STRAINING, is the clarification of a liquor, by passing it through a sieve or filter. The word is derived from the French, *estreindre*; which is formed from *ex*, "out of," and *stringere*, "to press."

STRAIT, a narrow channel or arm of the sea, shut up between lands on either side, and affording a passage out of one great sea into another.

There are three kinds of straits. 1. Such as join one ocean to another. Of this kind are the straits of Magellan and Le Maire. 2. Those which join the ocean to a gulf: the straits of Gibraltar and Babelmandel are of this kind, the Mediterranean and Red Sea being only large gulfs. 3. Those which join one gulf to another; as the straits of Caffa, which join the Palus Mæotis to the Euxine or Black Sea. The passage of straits is commonly dangerous, on account of the rapidity and opposite motion of currents. The most celebrated strait in the world is that of Gibraltar, which is about from 24 to 36 miles long, and from 15 to 24 broad, joining the Mediterranean sea with the Atlantic ocean. The straits of Magellan, discovered in 1520 by F. Magellan, were used some time as a passage out of the North into the South Sea; but since the year 1616, that the strait of Le Maire has been discovered, the former has been disused; both because of its length, which is full three hundred miles, and because the navigation thereof is very dangerous, from the waves of the North and South Seas meeting in it and clashing. The strait at the entrance of the Baltic is called the *Sound*. That between England and France, *Le pas de Calais*, or the *Channel*. There are also the straits of Weigats, of Jesso, of Anian, of Davis, and Hudson, &c.

STRAKES, or STREAKS, in a ship, the uniform ranges of planks on the bottom and sides of a ship, or the continuation of planks joined to the ends of each other, and reaching from the stem to the stern-post and fashion-pieces; the lowest of these, which is called the *garboard-streak*, is let into the keel below, and into the stem and stern-post. They say also a ship *heels a strake*, that is, hangs or inclines to one side the quantity of a whole plank's breadth.

STRAKES, or *streks*, in mining, are frames of boards fixed on or in the ground, where they wash and dress the small ore in a little stream of water, hence called *straked ore*.

STRALSUND, a strong and rich sea-port town of Germany, in Hither Pomerania, and was formerly an important trading-place. In 1678 it was forced to surrender to the elector of Brandenburg, after 1800 houses had been burnt to ashes in one night's time. After this the Swedes defended it to the last extremity; and Charles XII. in 1714, came hither after his return out of Turkey. But the crown of Sweden not being able to hold out against five great powers, it was forced to submit in 1715. In 1720 it was rendered back to Sweden, but in a very poor condition. It is almost surrounded by the sea and the lake Francen, and has a harbour separated from the isle of Rugen by a narrow strait. It is 15 miles north-west of Grippswald, and 40 north-east of Gustrow. E. Long. 13. 28. N. Lat. 54. 17.

STRAMONIUM, in botany; a species of DATURA.

STRAND (*Saxon*), any shore or bank of a sea or great river. Hence the street in the west suburbs of London, which lay next the shore or bank of the Thames, was called the *Strand*. An immunity from custom, and all impositions upon goods or vessels by land or water, was usually expressed by *strand* or *stream*.

STRANDED (from the Saxon *strand*), is when a ship is by tempest, or by ill steerage, run on ground, and so perishes. Where a vessel is stranded, justices of the peace, &c. shall command constables near the sea-coasts to call assistance for the preservation of the ship; and officers of men of war are to be aiding and assisting thereto.

STRANGE (Sir Robert), "who carried the art of engraving to so great perfection in this country, was a man of such general merit, that a life of him, not merely estimating his character as an artist, but also pourtraying his private virtues and domestic habits, would be both useful and entertaining. Such a life, we have reason to believe, will be presented to the public. Modest as he was ingenious, he used indeed to say that the works of an artist should serve for a life and monument to him. His works no doubt will perpetuate his name whilst any taste for the fine arts remains. In the mean time, we cannot but here give a short sketch of his history, the accuracy of which may be depended on.

"Sir Robert Strange was born in the island of Pomona in Orkney, July the 14th 1721; and died at London July the 5th 1792. He was lineally descended from David Strange or Strang, a younger son of the family of the Stranges or Strangs (A) of Balcasky, in the county

(A) The name of *Strange* or *Strang* is indiscriminately used in the old charters and deeds of the Balcasky family, now in the possession of Sir Robert Anstruther of Balcasky, baronet.

Strange.

ty of Fife, who settled in Orkney at the time of the Reformation. But as there were no males remaining of the elder branch of the Stranges of Balcasky, Sir Robert became the male representative of it, and was found by a legal investigation to have a right to the armorial bearings and every other mark of honour belonging to that ancient family.

"He received his classical education at Kirkwall in Orkney under the care of a learned, worthy, and much respected gentleman, Mr Murdoch Mackenzie, still alive (1795), who has rendered infinite service to his country by the accurate surveys and charts he has given of the islands of Orkney and of the British and Irish coasts.

"Originally intended for the law, Mr Strange soon become tired of that profession, and perceived that his genius decisively led him to the arts of drawing and engraving. For this purpose he was introduced to the late Mr Richard Cooper at Edinburgh, the only person there who had then any taste in that line of the fine arts. He was bound with him as an apprentice for six years; during which time he made such progress in his new profession, that his friends entertained the highest expectation of his success; nor were they disappointed.

"In the year 1747 he married Isabella, only daughter of William Lumisden, son of Bishop Lumisden; and soon after his marriage he went to France, where with the most ardent application he prosecuted his studies, chiefly at Paris, under the direction of the celebrated Le Bas, who engraved many excellent prints from the Dutch painters. It was from Le Bas he had the first hint of the use of the instrument commonly called *the dry needle;* but which he afterwards greatly improved by his own genius, and which has added such superior beauties to his engravings.

"In the year 1751 Mr Strange removed with his family from Edinburgh and settled at London, where he engraved several fine historical prints, which justly acquired to him great reputation. At this period historical engraving had made little progress in Britain, and he may be properly considered as its father.

"The admiration he always had for the works of the great Italian painters made him long desire to visit Italy, the seat of the fine arts; and the farther he advanced in life, he became the more persuaded that a journey to that country was essential to an artist who had the laudable ambition to excel in his profession. He therefore undertook this journey in the year 1760. In Italy he made many admirable drawings, several of which he afterwards engraved. These drawings are now in the possession of Lord Dundas.

"Everywhere in Italy singular marks of attention were bestowed on Mr Strange; not only by great personages, but by the principal academies of the fine arts in that country. He was made a member of the academies of Rome, Florence, and Bologna, and professor in the royal academy at Parma.

"To show the estimation in which his talents were held at Rome, we cannot but record the following anecdote. The ceiling of the room of the Vatican library, in which the collection of engravings are kept, is elegantly painted by Signor Rotfanelli. It represents the progress of engraving; and the portraits of the most eminent artists in that line are there introduced, among which is that of our artist. Under his arm he holds a portfolio, on which his name is inscribed. He is the only British artist on whom this honour has been conferred.

"In France, where he resided many years at different periods, his talents likewise received every mark of attention that could be bestowed on a foreigner. He was made a member of the royal academy of painting at Paris.

"His majesty King George III. ever attentive to the progress of the fine arts in Britain, and sensible of the advantages of which engraving particularly has been to this country, even in a commercial light; and desirous to give a mark of his royal approbation of the merit of Mr Strange, whom he considered as at the head of his profession and the great improver of it—was graciously pleased to confer the honour of knighthood on him the 5th of January 1787.

"Such was Sir Robert Strange as an artist; nor was he less distinguished by his truly amiable moral qualities, which endeared him to all who had the happiness to know him.

"With regard to his works, he left fifty capital plates, still in good condition, which are carefully preserved in his family. They are engraved from pictures by the most celebrated painters of the Roman, Florentine, Lombard, Venetian, and other schools. They are historical, both sacred and profane, poetical, allegorical.

From his earliest establishment in life, Sir Robert carefully preserved about eighty copies of the finest and most choice impressions of each plate he engraved; which, from length of time, have acquired a beauty, mellowness, and brilliancy, easier seen than described. He did this with a view of presenting them to the public at a period when age should disable him from adding to their number. These he collected into as many volumes, and arranged them in the order in which they were engraved. To each volume he prefixed two portraits of himself, on the same plate, the one an etching, the other a finished proof, from a drawing by John Baptiste Greuse. This is the last plate he engraved; and which is a proof that neither his eyes nor hand were impaired by age. It likewise shows the use he made both of aquafortis and the graver. Each volume, besides a dedication to the king, contains an introduction on the progress of engraving, and critical remarks on the pictures from which his engravings are taken. These volumes were ready to be given to the public, when Sir Robert's death and consequent circumstances delayed this magnificent publication; a publication which does so much honour to the artist, and to the country which gave him birth (B)"

STRANGER,

(B) Solicitous to make all our biographical articles the vehicles of truth, we applied for information respecting Sir Robert Strange, to the person whom we considered as the most capable of furnishing it, and who we imagined would be gratified by our application. With some difficulty we obtained, as a favour to ourselves, the sketch of

STRANGER, in law, denotes a person who is not privy or party to an act. Thus a stranger to a judgement is he to whom a judgment does not belong; in which sense the word stands directly opposed to party or privy.

STRANGLES, in FARRIERY. See that article, § xiv.

STRANGURY, a suppression of urine. See MEDICINE, n° 119.

STRAP, among surgeons, a sort of band used to stretch out limbs in the setting of broken or disjointed bones.

STRAP, in a ship, the rope which is spliced about any block, and made with an eye to fasten it any where on occasion.

STRAPS, in the manege. The straps of a saddle are small leather straps, nailed to the bows of the saddle, with which we make the girths fast to the saddle.

STRAPADO, or STRAPPADO, a kind of military punishment, wherein the criminal's hands being tied behind him, he is hoisted up with a rope to the top of a long piece of wood, and let fall again almost to the ground; so that, by the weight of his body in the shock, his arms are dislocated. Sometimes he is to undergo three strapadoes or more.

STRASBURG, an ancient, large, handsome, populous, and strong city of France in Alsace. It contains about 200 streets, part of which are very narrow, and most of the houses are built after the ancient taste. However, there are a great number of handsome buildings, such as the hotel of the marshal of France, who is commander of the city; the hotel of the cardinal of Rouen, the bishop's palace, the Jesuits college, the royal hospital, the hotel of Hesse-Darmstadt, the arsenal, the town-house, and the cathedral. It has a wooden bridge over the Rhine, which is thought to be one of the finest in Europe; as is likewise the cathedral church, whose tower is the handsomest in Germany, and the clock is greatly admired by all travellers. Some look upon it as one of the wonders of the world, and the steeple is allowed to be the highest in Europe. The clock not only shews the hours of the day, but the motion of the sun, moon, and stars. Among other things there is an angel, which turns an hour-glass every hour; and the twelve apostles proclaim noon, by each of them striking a blow with a hammer on a bell. There is likewise a cock, which is a piece of clock-work, that crows every hour. There are 700 steps up to the tower or steeple, it being 500 feet high. It was a free and imperial city; but the king of France became master of it in 1681, and greatly augmented the fortifications, though before it had as many cannon as there are days in the year. The inhabitants were formerly Protestants, and carried on a great trade; but most of them have been obliged to embrace the Catholic religion, though there is still a sort of toleration. Such was Strasburg before the French revolution; what it is now we have not leisure to inquire. It is seated on the river Ill, 55 miles north of Basil, 112 south-west of Mentz, and 255 east of Paris. E. Long. 7. 51. N. Lat. 48. 35.

STRATA, in natural history, the several beds or layers of different matters whereof the earth is composed. See QUARRY.

The strata whereof the earth is composed are so very different in different countries, that it is impossible to say any thing concerning them that may be generally applicable: and indeed the depths to which we can penetrate are so small, that only a very few can be known to

---

of his life, which we have laid before our readers, upon the express condition that we should not alter *a single word of it*; as the composition, we were told, would do *honour to our work*. We have observed the condition, and therefore cannot claim this honour to any of the usual writers in the Encyclopædia Britannica. If Sir Robert's more intimate friends shall be pleased with the article, their gratitude will be due not to us, but to some of his nearest relations; and what may appear its defects to others (for the tastes of mankind are vere different), we trust will be supplied by the following authentic catalogue of his works: Plate 1. Two Heads of the author—one an etching, the other a finished proof, from a drawing by John Baptiste Greuse; 2. The Return from Market, by Wouvermans; 3. Cupid, by Vanloo; 4. Mary Magdalen, by Guido; 5. Cleopatra, by the same; 6. The Madonna, by the same; 7. The Angel Gabriel, by the same; 8. The Virgin, holding in her hand a book, and attended by angels, by Carlo Maratt; 9. The Virgin with the Child asleep, by the same; 10. Liberality and Modesty, by Guido; 11. Apollo rewarding Merit and punishing Arrogance, by Andrea Sacchi; 12. The Finding of Romulus and Remus, by Pietro da Cortona; 13. Cæsar repudiating Pompeia, by the same; 14. Three Children of King Charles I. by Vandyke; 15. Belisarius, by Salvator Rosa; 16. St Agnes, by Dominichino; 17. The Judgment of Hercules, by Nicolas Poussin; 18. Venus attired by the Graces, by Guido; 19. and 20. Justice and Meekness, by Raphael; 21. The Offspring of Love, by Guido; 22. Cupid sleeping, by the same; 23. Abraham giving up the Handmaid Hagar, by Guercino; 24. Esther a Suppliant before Ahasuerus, by the same; 25. Joseph and Potiphar's Wife, by Guido; 26. Venus blinding Cupid, by Titian; 27. Venus, by the same; 28. Danae, by the same; 29. Portrait of King Charles I. by Vandyke; 30 The Madonna, by Correggio; 31. St Cæcilia, by Raphael; 32. Mary Magdalen, by Guido; 33. Our Saviour appearing to his Mother after his Resurrection, by Guercino; 34. A Mother and Child, by Parmegiano; 35. Cupid meditating, by Schidoni; 36. Laomedon King of Troy detected by Neptune and Apollo, by Salvator Rosa; 37. The Death of Dido, by Guercino; 38. Venus and Adonis, by Titian; 39. Fortune, by Guido; 40. Cleopatra, by the same; 41. Two Children at School, by Schidoni; 42. Mary Magdalen, by Correggio; 43. Portrait of King Charles I. attended by the Marquis of Hamilton, by Vandyke; 44. Queen Henrietta, attended by the Prince of Wales, and holding in her Arms the Duke of York, by the same; 45. Apotheosis of the Royal Children, by West; 46. The Annunciation, by Guido; 47. Portrait of Raphael Sancio D'Urbino, by himself: 48. Sappho, by Carlo Dolci; 49. Our Saviour asleep, by Vandyke; 50. St John in the Desert, by Murillo.

Strata.

to us at any rate; those that lie near the centre, or even a great way from it, being for ever hid. One reason why we cannot penetrate to any great depth is, that as we go down the air becomes foul, loaded with pernicious vapours, inflammable air, fixed air, &c. which destroy the miners, and there is no possibility of going on. In many places, however, these vapours become pernicious much sooner than in others, particularly where sulphureous minerals abound, as in mines of metal, coal, &c.

But however great differences there may be among the under strata, the upper one is in some respects the same all over the globe, at least in this respect, that it is fit for the support of vegetables, which the others are not, without long exposure to the air. Properly speaking, indeed, the upper stratum of the earth all round, is composed of the pure vegetable mould, though in many places it is mixed with large quantities of other strata, as clay, sand, gravel, &c.; and hence proceed the differences of soil so well known to those who practice agriculture.

It has been supposed, by some naturalists, that the different strata of which the earth is composed were originally formed at the creation, and have continued in a manner immutable ever since: but this cannot possibly have been the case, since we find that many of the strata are strangely intermixed with each other; the bones of animals both marine and terrestrial are frequently found at great depths in the earth; beds of oyster-shells are found of immense extent in several countries; and concerning these and other shell fish it is remarkable, that they are generally found much farther from the surface than the bones or teeth either of marine or terrestrial animals. Neither are the shells or other remains of fish found in those countries adjoining to the seas where they grow naturally, but in the most distant regions. Mr Whitehurst, in his Inquiry into the Original State and Formation of the Earth, has given the following account of many different kinds of animals, whose shells and other remains or *exuviæ* are found in England; though at present the living animals are not to be found except in the East and West Indies.

A CATALOGUE *of* EXTRANEOUS FOSSILS, *shewing where they were dug up; also their native Climates. Mostly selected from the curious Cabinet of Mr* NEILSON, *in* King-street, Red-Lion Square.

Their names, and Places where found.	Native Climates.
CHAMBERED NAUTILUS. Sheppy Islands; Richmond in Surrey; Sherbone in Dorsetshire,	*Chinese Ocean, and other Parts of that great sea.*
TEETH OF SHARKS. Sheppy Island, Oxfordshire, Middlesex, Surrey, Northamptonshire,	*East and West Indies.*
SEA-TORTOISE, several kinds; the *Hawksbill, Loggerhead, and Green* species. Sheppy Island,	*West Indies.*
MANGROVE TREE OYSTERS. Sheppy Island,	*West Indies,*
COXCOMB TREE OYSTERS. Oxfordshire, Gloucestershire, Dorsetshire, and Hanover,	*Coast of Guinea.*
VERTEBRÆ *and* PALATES *of the* ORBES. Sheppy Islands, and many other parts of England,	*East and West Indies.*
CROCODILE. Germany, Derbyshire, Nottinghamshire, Oxfordshire, and Yorkshire,	
ALLIGATOR'S TEETH. Oxfordshire, Sheppy Island,	*East and West Indies.*
The BANDED BUCCINUM. Oxfordshire, and the Alps,	*West Indies.*
The DIPPING-SNAIL, and STAR-FISH. Sheppy Island,	*West Indies.*
TAIL BUCCINUM. Sheppy Island, Hordel Cliff, Hampshire,	*East Indies.*

Nothing has more perplexed those who undertake to form theories of the earth than these appearances. Some have at once boldly asserted, from these and other phenomena, that the world is eternal. Others have had recourse to the universal deluge. Some, among whom is the Count de Buffon, endeavour to prove that the ocean and dry land are perpetually changing places; that for many ages the highest mountains have been covered with water, in consequence of which the marine animals just mentioned were generated in such vast quantities, that the waters will again cover these mountains, the habitable part of the earth become sea, and the sea become dry land as before, &c. Others have imagined that they might be occasioned by volcanoes, earthquakes, &c. which confound the different strata, and often intermix the productions of the sea with those of the dry land.

These subjects have been discussed under the article EARTH, to which therefore we refer the reader; and shall conclude with some account of the strata in those places where they have been most particularly observed.

Under the article NATURAL HISTORY, Sect. I. it is observed, that the upper strata of the earth and mountains generally consist of rag-stone, the rest of slate, the third of marble filled with petrifactions, the fourth again of slate, and the next of free-stone. But we are far from considering this as a rule which holds universally. The strata differ exceedingly in a great number of places; some instances of which we shall give from Mr Whitehurst.—At Alfreton Common in Derbyshire, the strata are,

Inquiry into the Original State and Formation of the Earth, p. 211.

Mr Forster has given an account of some of the strata of the South-Sea islands, the substance of which may be seen in the following table.

SOUTH GEORGIA.

1. No soil, except in a few crevices of the rocks.
2. Ponderous slate, with some irony particles, in horizontal strata, perpendicularly intersected with veins of quartz.

Southern Isle of NEW ZEALAND.

1. Fine light black mould, in some places nine inches deep, but generally not so much.
2. An argillaceous substance, nearly related to the class of TALCONS, turned into earth by the action of the air.
3. The same substance farther indurated, in oblique strata, generally dipping to the south.

EASTER ISLAND.

1. Reddish-brown dusty mould, looking as if it had been burnt.
2. Burnt rocks, resembling slags or dross and other volcanic matters.

MARQUESAS.

1. Clay mixed with mould.
2. An earthy argillaceous substance mixed with tarras and puzzolana.

OTAHEITE.

The shores are coral rock, extending from the reef encircling these isles to the very high-water mark. There begins the sand, formed in some places from small shells and rubbed pieces of coral; but in others the shores are covered with blackish sand, consisting of the former sort mixed with black, sometimes glittering, particles of mica, and here and there some particles of the refractory iron ores called in England SKIM, the *ferrum micaceum* of Linnæus, and KALL the *molybdænum spuma lupi* of the same author. The plains from the shores to the foot of the hills are covered with a very fine thick stratum of black mould, mixed with the abovementioned sand, which the natives manure with shells. The first and lower range of hills are formed of a red ochreous earth, sometimes so intensely red, that the natives use it to paint their canoes and cloth. The higher hills consist of a hard compact, and stiff clayey substance, hardening into stone when out of the reach of the sun and air. At the top of the valleys, along the banks of the rivers, are large masses of coarse granite stones of various mixtures; in one place are pillars of a grey, solid basaltes; and, in several others, fragments of black basaltes.

FRIENDLY ISLANDS and NEW HEBRIDES.

The same with the above.

MALLICOLLO.

Yellowish clay mixed with common sand.

TANNA, *a Volcanic Island.*

The chief strata here are clay mixed with aluminous earth, interspersed with lumps of pure chalk. The strata of the clay are about six inches, deviating very little from the horizontal line.

NEW CALEDONIA and the *adjacent Isles.*

The shores consist of shell-sand, and particles of quartz; the soil in the plains a black mould mixed with this sand. The sides of the hills composed of a yellow ochreous clay, richly spangled with small particles of cat-silver, or a whitish kind of daze, the *mica argentea* of Linnæus. The higher parts of the hills consist of a stone called by the German miners *gestellstein*, composed of quartz and great lumps of the above cat-silver. The latter is sometimes of an intensely red or orange colour, by means of an iron ochre.

"From the above account," says Mr Forster, "it appears, I think, evidently, that all the high tropical isles of the South Sea have been subject to the action of volcanoes. Pyritical and sulphureous substances, together with a few iron-stones, and some vestiges of copper, are no doubt found in several of them: but the mountains of New Caledonia are the most likely to contain the richest metallic veins; and the same opinion, I suspect, may be formed of the mountains in New Zealand."

In the city of Modena in Italy, and for some miles round that place, there is the most singular arrangement of strata perhaps in the whole world. From the surface of the ground to the depth of 14 feet, they meet with nothing but the ruins of an ancient city. Being come to that depth, they find paved streets, artificers' shops, floors of houses, and several pieces of inlaid work. After these ruins they find a very solid earth, which one would think had never been removed; but a little lower they find it black and marshy, and full of briars. Signior Ramazzini in one place found a heap of wheat entire at the depth of 24 feet; in another, he found filbert-

filbert-trees with their nuts. At the depth of about 28 feet, they find a bed of chalk, about 11 feet deep, which cuts very easily; after this a bed of marshy earth of about two feet, mixed with rushes, leaves, and branches. After this bed comes another of chalk, nearly of the same thickness; and which ends at the depth of 42 feet. This is followed by another bed of marshy earth like the former; after which comes a new chalk-bed, but thinner, which also has a marshy bed underneath it. This ends at the depth of 63 feet; after which they find sand mingled with small gravel, and several marine shells. This stratum is usually about five feet deep, and underneath it is a vast reservoir of water. It is on account of this water that the soil is so frequently dug, and the strata so well known in this part of the world. After coming to the sandy bottom abovementioned, the workmen pierce the ground with a terebra or auger, when the water immediately springs up with great force, and fills the well to the brim. The flow is perpetual, and neither increases by rain, nor decreases by drought. Sometimes the auger meets with great trees, which give the workmen much trouble; they also sometimes see at the bottom of these wells great bones, coals, flints, and pieces of iron.

It has been asserted by some, that the specific gravity of the strata constantly increased with the depth from the surface. But Dr Leigh, in his Natural History of Lancashire, speaking of the coal-pits, denies the strata to lie according to the laws of gravitation; observing, that the strata there are first a bed of marle, then free-stone, next iron-stone, then coal, or channel mire, then some other strata, then coal again, &c. This determined Mr Derham to make a nicer inquiry into the matter: accordingly, in 1712, he caused divers places to be bored, laying the several strata by themselves; and afterwards determined very carefully their specific gravity. The result was, that in his yard the strata were gradually specifically heavier and heavier the lower and lower they went; but in another place in his fields, he could not perceive any difference in the specific gravities.

Acquainting the Royal Society therewith, their operator Mr Hauksbee was ordered to try the strata of a coal pit, which he did to the depth of 30 strata: the thickness and specific gravity of each whereof he gives
Vol. xxvii. p. 541. us in a table in the Philosophical Transactions; and from the whole makes this inference, that it evidently appears the gravities of the several strata are in no manner of order, but purely casual, as if mixed by chance.

STRATAGEM, in the art of war, any device for deceiving and surprising an enemy. The ancients dealt very much in stratagems; the moderns wage war more openly, and on the square. Frontinus has made a collection of the ancient stratagems of war.

STRATEGUS, στρατηγος, in antiquity, an officer among the Athenians, whereof there were two chosen yearly, to command the troops of the state.

Plutarch says, there was one chosen from out of each tribe; but Pollux seems to say they were chosen indifferently out of the people. The people themselves made the choice; and that on the last day of the year, in a place called *Pnyx*. The two *strategi* did not command together, but took their turns day by day; as we find from Herodotus and Cornelius Nepos. Sometimes indeed, as when a person was found of merit vastly superior, and exceedingly famed in war, the command was given to him alone: but it was ever a rule, not to put any person in the office but whose estate was in Attica, and who had children, that there might be some hostages and securities for his conduct and fidelity. Constantine the Great, besides many other privileges granted to the city of Athens, honoured its chief magistrate with the title of Μεγας Στρατηγος, *Magnus Dux*.

STRATH, in the Scottish language, signifies a long narrow valley, with a river running along the bottom.

STRATHEARN, a beautiful and extensive valley in Perthshire, bounded on the north by the lofty ridge of mountains called the *Grampians*, and on the south by the Ochils, which are rounded on the tops and covered with verdure. It is called *Strathearn* from the river Earn, which runs through the middle of it from west to east for about 30 miles. On each side of the banks of this beautiful stream are many villages and country-seats distinguished for romantic situations. Were we to single out any of the villages, we would mention Crieff, which stands on a fine sloping ground on the north side of the Earn, and has been much admired by travellers for its situation, and the variety, contrast, singularity, and beauty of the prospect which it affords.

STRATHNAVER, a subdivision or district of the county of Sutherland in Scotland; bounded on the north by the ocean, on the east by Caithness, on the south by Sutherland properly so called, and on the west partly by Ross and partly by the ocean.

STRATIOTES, Water-soldier, in botany: A genus of plants belonging to the class of *polyandria*, and to the order of *hexagynia*; and in the natural system ranking under the first order, *palmæ*. The spatha is diphyllous: the perianthium is trifid. There are three petals, and the berry is six celled and inferior. There are three species, the aloides, the acoroides, and alismoides. The *aloides* alone is of British extraction, which is also called the *water aloe*, or *fresh-water soldier*. The root consists of long fibres tufted at the ends. The leaves are thick, triangular, pointed, and prickly at the edges. The flowers are white and floating on the water, and blossom in June. This plant may be seen in slow rivers and fens.

STRATO, a philosopher of Lampsacus, disciple and successor in the school of Theophrastus, about 248 years before the Christian era. He applied himself with uncommon industry to the study of nature; and after the most mature investigations, he supported that nature was inanimate, and that there was no god but nature. (See *Plastic Nature*). He was appointed preceptor to Ptolemy Philadelphus, who not only revered his abilities and learning, but also rewarded his labours with unbounded liberality. He wrote different treatises, all now lost.

STRAWBERRY, in botany. See Fragaria.

Strawberry-Tree. See Arbutus.

END OF THE SEVENTEENTH VOLUME.

E R R A T A.

Vol. III. p. 258. col. 1. l. 20. For "in the 50th," read "in the 75th."

Vol. X. p. 7. col. 2. l. 22. from bottom. For "isosceles rectangle," read "isosceles triangle."
p. 471. col. 2. l. 27. from bottom. For "prevents," read "perverts."

Vol. XIII. p. 204. col. 2. l. 17. For "after the 364th. in the year 440," read "in the year 312, or, as Cedrenus says, in the year 393."

Vol. XIV. p. 67. col. 2. l. 27. from bottom. For "St Claget," read "Dr Claget."

Vol. XVI. p. 196. col. 2. l. 23. Instead of the sentence beginning with "In the mean time," read "On the 9th June Admiral Montague fell in with the French fleet returning to port, amounting to 19 sail of the line."
p. 682. col. 1. l. 37. For "Milan," read "Misnaw."
p. 696. col. 2. l. 3. For "σκηπτικος," read "σκεπτικος."

Vol. XVII. p. 180. col. 2. l. 16 from bottom. For "covers them," read "they cover."
p. 524. col. 2. l. 12. For "where," read "when."
p. 533. col. 2. l. 30. After the word "likewise," add "possible."
p. 556. col. 2. l. 18. from bottom. Erase the sentence beginning with the word "Candidates."
